# Accuracy Enhancement of Prediction Method using SMOTE for Early Prediction Student's Graduation in XYZ University

Ainul Yaqin*, Majid Rahardi, Ferian Fauzi Abdulloh

Computer Science Faculty, University of AMIKOM Yogyakarta, Yogyakarta, Indonesia

*Abstract*—According to the Minister of Education and Culture of the Republic of Indonesia's regulations from 2014, one of the essential elements in implementing higher education is the student's study duration. Higher education institutions will use early graduation prediction as a guide when developing policy. According to XYZ University data, the student study period is Grade Point Average (GPA), Gender, and Age are all aspects to consider. Using a dataset of 8491 data, the Prediction of Early Graduation of Students based on XYZ University data was examined by this study, particularly in the information systems and informatics study program. The aim is to find significant features and compare three prediction models: Artificial Neural Networks (ANN), K-Nearest Neighbor (K-NN) method, and Support Vector Machines (SVM). The Challenge in the development of a prediction model is imbalanced data. The Synthetic Minority Oversampling Technique (SMOTE) handles the class imbalance problem. Next, the machine learning models are trained and then compared. Prediction results increase. The best test accuracy value is on ANN with a data Imbalance of 62.5% to 70.5% after using SMOTE, compared to the accuracy test on the K-NN method with SMOTE 69.3%, while the SVM method increased to 69.8%. The most significant increase in recall value to 71.3% occurred in the ANN.

*Keywords—Prediction study period; SMOTE; neural network; k-nearest neighbors; support vector machine*

## I. INTRODUCTION

### A. Background

One of the criteria that can be used to determine a student's performance in higher education is the student's study duration. The information about the study session is recorded in the academic database in this case, and management can utilize it to assess decision-making. The Informatics and Information Systems Study Program at XYZ University is an example of a study program with the maximum number of active students and continues to increase every year. Management can identify early prevention strategies connected to Drop Out (DO) instances by using the prediction model for the student study period, which will have a domino effect on accreditation.

Undergraduate students must take at least 144-semester credits with a study period of four years or less to meet learning outcomes, as expressly stated in the Regulation of the Minister of Education and Culture of the Republic of Indonesia in 2014, a section on graduate competency standards article 17 [1]. Consequently, the study program

manager is required to keep track of student progress to reduce the number of dropouts. The development of prediction models for students' study periods using machine learning models has been done using several parameters Gender[2], GPA [3][4], Number of semester credit units (credits), parents' job, high school major, high school city[2][5]. In this study, a prediction model for the study period was constructed utilizing semester 1 to 4 GPA values based on XYZ University's educational program, which highlights concentration selection in semester four lectures, ages, and Gender.

The K-Nearest Neighbor technique (K-NN), Artificial Neural Networks (ANN), and Support Vector Machines are some examples of popular machine learning methods for Prediction (SVM) [6]. The Challenge in the development of a prediction model is imbalanced data. This situation prompted us to use the Synthetic Minority Oversampling Technique (SMOTE) to improve prediction utilizing balance data [7] to handle the class imbalance problem. University XYZ datasets are used in an experimental study to validate the suggested approach, including selecting a prediction model and performance indicators. In the following areas, this study adds to the existing body of knowledge:

*1)* ANN, K-NN, and SVM were used to create an effective model.

*2)* To analyze the relevant features extracted from the dataset that has an impact on the machine learning algorithm's performance.

*3)* Performance of ANN, K-NN, and SVM models using Imbalance data is compared using SMOTE.

Thirty percent of machine learning methods used in predicting student performance are artificial neural networks and vector machines at 6,20%. Other methods used are decision tree, nave Bayes, and k-Nearest Neighbor 17% each [6].

### B. Related Work

Agustin [8] used class year, GPA, and grades from nine courses as parameters with the Naive Bayes Classification Technique, K-Nearest Neighbor, and Neural Network to predict student study period. His research divided predictions into three classes: fast, precise, and slow. And using the most influential attribute selection, namely, GPA, using the classifier attribute.

---

*Corresponding Author.

Prediction of students' graduation time using the K-Nearest Neighbor Algorithm with the parameter GPA of students during the seventh semester will be used as training data. Data of students who pass are used as sample data. K-Nearest Neighbor works according to the given data sample. The highest level of Accuracy can be achieved when k = 3 [9].

The fundamental purpose of SVM is to separate the data set into classifications to find the most negligible Hyperplane. The gamma value used varies from 0 to 1, but a good default gamma value is 0.1 and can be achieved Accuracy of 73% [10].

The rest of the paper is organized as follows: Section II outlines the proposed approach, the dataset, preprocessing, and data visualization to uncover the dataset's hidden pattern. It also explains the various algorithms employed in this study. The discussion and analysis of the results, performance metrics, and experimental study design are all described in Section III. In Section IV, the findings are discussed. Section V concludes with a discussion of future work.

## II. RESEARCH METHODOLOGY

This research will use a method divided into three stages: preprocessing, predictive Process, and evaluation. The research flow is shown in Fig. 1.

Fig. 1. Research Methodology.

### A. Synthetic Minority Oversampling Technique (SMOTE)

Several approaches to dealing with data imbalances include *undersampling*, *oversampling*, and *hybrid* methods [11]. Oversampling technique is often adopted to overcome the problem by generating new synthetic sample data [12][7][13]. In comparison, the *Undersampling technique* has an approach of removing data from the majority class to balance the class distribution [14].

### B. Artificial Neural Networks (ANN)

A Neural Network (ANN) is a group of small processing units based on a human neural network in general [15]. The learning system is a never-ending process of adding to the NN's knowledge (continuity). When used to recognize an object, the inside will be fully utilized. The anatomy of neural networks [16] is shown in Fig. 2.

The following data is provided by the ANN Structure shown in Fig. 2. The "Input Layer" is made up of input nodes that transmit data from the outside world to the network. A "hidden layer" is formed when a group of hidden nodes is combined [17]. The hidden layer nodes of the ANN have an activation function that allows for a curvilinear fit between the input and output units (layers). The activation function you choose has a big impact on how well your network works. [18].

Fig. 2. Arsitektur ANN.

### C. K-Nearest Neighbor method (K-NN)

K-NN is a statistical classification technique that uses the closest training samples in Feature Space to classify objects. It's a lazy learning algorithm in which the K-NN function is approximated locally and all calculations are postponed until classification is completed [19]. The K-NN algorithm generally uses the Euclidean distance formula, such as the formula 1:

$$D_{xy}\sqrt{\sum_{i=1}^{n} \quad (X_i - y_i)^2} \tag{1}$$

The transition from distances to weights should follow some kernel functions. Typical examples of this function include rectangular kernel, triangular kernel, cosine kernel, Gauss kernel, and inversion kernel [20].

### D. Support Vector Machines (SVM)

Support Vector Machines (SVM) is a supervised learning algorithm that uses a learning algorithm that analyzes data related to classification and regression analysis [21]. In SVM modeling, there are several different kernels, including Radial Base (RBF), linear (LIN), sigmoid (SIG), and polynomial (POLM melakrefrefPOL) [22]. SVM reformats non-linear into linear by generating a Hyperplane and converting it to a straightforward form that can be processed [23].

The support vector is the closest training point to the Hyperplane, so maximizing the margin is considered a rule by minimizing the value of *w* [22]. The Decision Function Formula of SVM as in formula 2 and the SVM Scheme is shown in Fig. 3.

$$f(x) = sign\ (w.x + b) \tag{2}$$

### E. Evaluation

At this stage, an Evaluation or Model Evaluation is carried out on each model based on the accuracy score using the *Confusion Matrix* to determine the Accuracy of Prediction, *recall, precision,* and *F-Measure* [24].

Fig. 3. Skema SVM.

## III. EXPERIMENTAL STUDY

To test the proposed technique, this experiment chooses a diverse range of prediction algorithms, datasets, and performance metrics. Data sources, classification methods, performance measurements, and experimental design are all discussed in this subsection.

### A. Data Source

The data was obtained by using query study data for students of the informatics and information systems study program in the class of 2004 to 2015 from the XYZ University database with a total data of 10,274. The dataset obtained consists of NIM, Gender, SMA, Date of Birth, Date of graduation, and GPA 1 to GPA 4. Summary dataset is shown in Table I.

TABLE I.     SUMMARY DATASET

| COLUMN | TYPE | DATA NULL/ISNA() |
|---|---|---|
| NIM | object | 0 |
| GENDER | object | 0 |
| Senior High School | object | 569 |
| Birth Date | datetime64[ns] | 38 |
| Graduation Date | datetime64[ns] | 458 |
| GPA 1 | float64 | 8 |
| GPA 2 | float64 | 258 |
| GPA 3 | float64 | 406 |
| GPA 4 | float64 | 766 |

### B. Prediction Model

This section discusses the algorithms used in this study. The prediction Model use ANN, K-NN, and SVM algorithm. The feature selection phase used the ONE-HOT algorithm, and an enhanced version of SMOTE was used in the rebalancing phase.

The first architectural model will be built with the ANN Algorithm in this study uses 1 hidden layer [25] with 1 to 100 neurons and a learning rate of 0.1 to 0.5, and a maximum iteration of 1000. The second model uses the K-NN algorithm by comparing and testing various K values from 2 to 1000. The third model uses SVM Algorithm by choosing the kernel between RBF and Linear [26].

### C. Performance Measures (Evaluation)

Accuracy, true positive rate (Recall), true negative rate, precision, G-Mean, F-measure, and computation time are all popularly used performance indicators in classification. The following are the definitions for these metrics.

*1)* True Positive (TP): TP is the number of instances that are correctly positive.

*2)* True Negative (TN): TN stands for the number of instances that are correctly negative.

*3)* False Positive (FP): The number of positive events that have been misclassified as negative.

*4)* False Negative (FN): the number of negative instances that have been misclassified as positive.

*5)* TP rate (TPR) is also called sensitivity measure or Recall like formula 3.

$$sensitivity = TP/(TP + FN) \tag{3}$$

*6)* TN rate is called specificity measure like the formula 4.

$$specificity = TN/(TN + FP) \tag{4}$$

*7)* FP rate is called Type-I error like the formula 5.

$$Type-I\ error = FP/(FP + TN) \tag{5}$$

*8)* Type-II error is another term for the FN rate. Like the formula 6

$$Type-II\ error = FN/(FN + TP) \tag{6}$$

*9)* Overall Accuracy: The percentage of accurately anticipated instances, such as formula 7, is referred to as accuracy.

$$Accuracy = (TN + TP)/(TP + FP + TN + FN) \tag{7}$$

*10)* Precision: This is the Number of fault-prone modules that are fault-prone modules like formula 8.

$$Precision = TP/(FP + TP) \tag{8}$$

*11)* G-Mean: it is the geometric mean of sensitivity and precision like the formula 9.

$$G\ Mean = \sqrt{sensitivity * Precision} \tag{9}$$

*12)* The harmonic mean of precision and recall is known as the F-Measure. The F-measure, like the formula 10, has been frequently utilized in information retrieval.

$$F\ Measure = (2 * Precision * TPR)/(Precision + TPR) \tag{10}$$

### D. Experimental Design

The following procedure was used to carry out the experiment:

**Input**: Dataset University XYZ
**Tool:** Jupyter - Python Base
**Step 1**: Pre-Processing Data
In this Phase, several processes are carried out, namely:
1. The Process of cleaning null data from 10,274 data to 8491 data
2. The filtering process is carried out by:
   a. The value of the study period is obtained through the difference between the year of study and the date of graduation by labeling the study period on time if the study period is <=48 months with a label 1 and late study with a label 0 if the study period > 48 months
   b. Get the student's age (years) during semester 4 by calculating the difference between the start date of college and the date of birth plus 2 years.
3. The transformation process is carried out by:
   a. Categorize data from school and age
   b. Combining age group data with Gender

4. The scaling process is carried out on Semester 1 GPA data into Semester 4 GPA data using MinMax Scaler(MMS)[27] like formula 11 [28]:

$$MMS = (X - X_{min})/(X_{min} - X_{max}) \quad (11)$$

**Step 2**: Correlation Analysis

Correlation analysis was used to determine the degree of relationship between GPA 1, GPA 2, GPA 3, GPA 4, Age, Gender, Year of Class, and Senior High School during the study period.

**Step 3**: Features Selection

In this stage, feature determination is carried out, which will be used in the prediction model

**Step 4**: Split Data Train and Testing and Balancing using SMOTE

In this Step, Data distribution is divided into 80% training data and 20% testing data. Then, the training data is balanced with SMOTE and then stored in other variables

**Step 5**: Training Prediction Model

In this Phase, the prediction model was built with ANN, K-NN, and SVM trained using the Imbalanced training data and SMOTE training data. So it produces six models.

**Step 6**: Evaluation

In this Phase, evaluate the results of testing data as much as 20% of the dataset on six models (in the model training phase) such as Accuracy, recall, precision, G-Means, and F-Measure.

## IV. RESULTS

### A. Dataset

The results of the preprocessing of the dataset are shown in Table II.

### B. Correlation Analysis

Fig. 4 shows that the GPA 1 to 4 has a correlation value of >0.3 with the Study Period. Then the Gender-Age value data with Study Period also indicates a negative relationship with a correlation value of -0.13

### C. Features Selection

At this stage, the features are determined by setting a GPA 1 to 4, and Gender-Age is the feature and the Study Period is the target. Then Categorical Features Encoding is carried out for Gender-Age data. So that the resulting features selection data includes as many as 12 features. The result of feature selection is shown in Table III.

### D. Split Data

In this Phase, the data was obtained from 6792 training data and 1699 testing data. The summary of training data is shown in Fig. 5. Training Balance data is shown in Fig. 6.

*E. Results of Artificial Neural Network Training Model*

Network modeling is done by finding the best model with the GridSerachCV function in sklearn. Modeling is based on several parameters of the activation function, namely, tanh, relu, and logistics, with the Number of neurons in the hidden layer ranging from 1 to 100 neurons, a learning rate of 0.1 to 0.5, and a maximum iteration of 1000. The best model of ANN obtained activation function = "tanh", learning rate = 0.1 , alpha = 0.1 and neuron = 99 in the hidden layer. The result of the ANN Training Model is shown in Table IV.

*F. Results of K-Nearest Neighbors (K-NN) Training Model*

K-NN modeling is carried out with uniform and distance and testing various K values from 2 to 1000. The Result of the Highest Accuracy is shown in Fig. 8 and Table V.

*G. Results of Support Vector Machine (SVM) Training Model*

SVM modeling is done by choosing a kernel between RBF and linear, with the results shown in Fig. 9.

TABLE IV. RESULT OF ANN TRAINING MODEL

| Training Data | Study Period (Target) | | ANN training accuracy | ANN testing accuracy |
|---|---|---|---|---|
| | 0 | 1 | | |
| Imbalance | 3792 | 3000 | 0.7005 | 0.6250 |
| SMOTE | 3792 | 3792 | 0.6969 | 0.7080 |

## H. Evaluation

The evaluation phase, this study uses data testing as much as 1699 data on six models that have been trained. The results can be seen in Table VII.

Based on Table VII, the results of conformity testing are performed using a confusion matrix, and the test results are displayed in graphical form as follows in Fig. 11.

Fig. 11. Confusion Matrix Test Result.

## V. CONCLUSION

Based on the results, this study can be formulated as follows. SMOTE can increase the recall value and test the accuracy of ANN, K-NN, and SVM models with relevant features extracted, namely GPA 1 to 4, and Encoding of Gender-Age based on correlation values. Prediction results have the best increase in the value of accuracy testing on ANN with a data Imbalance of 62.5% to 70.5% after using SMOTE, compared to the accuracy test on the K-NN method with SMOTE 69.3%. In comparison, the SVM method increased to 69.8%. The most significant increase in recall value to 71.3% occurred in the ANN.

*Abstract*—The methods of natural language text classification have the characteristic of diversification, and the text characteristics are the basis of the method effectiveness; this paper takes the car service complaint data as an example to study the classification modeling for the texts with subjectivity characteristic. The effective handling of car service complaints is important for improving user experience and maintaining brand reputation; manual classification commonly has the disadvantages of experience dependence, prone to error, heavy workload and so on; corresponding automatic classification modeling research is of great practical significance. The core links of the research method in this study include word segmentation, text vectorization, feature selection and dimensionality reduction based on correlation, classification modeling based on progressive method and random forest, and model reliability analysis; the research results show that the car service complaint texts could be effectively classified based on the method in this study, which could provide a reference for related further research and application.

*Keywords—Car service complaint; text classification; machine learning; natural language texts*

## I. INTRODUCTION

Car service complaints widely exist in the use of cars of different types, brands, and use times. Effective classification of service complaint texts is an important part of the basis for the efficient and reasonable handling of corresponding complaints. The classification of service complaints could be done by users or receiving staff, if this work is handed over to the users, on one hand, it might increase the user's irritability and dissatisfaction, and on the other hand, the users possibly make mistakes because they might don't know much about the professional field; if the complaint receiving staff conducts manual classification, there are also problems such as heavy workload, experience dependence, and error-prone; therefore, it is of great practical value to carry out the automatic classification modeling and realize automatic classification of service complaint.

Machine learning methods are widely used in data processing such as classification and regression, and they are also quite widely used in automatic classification of natural language texts [1-4]. The text classification modeling methods based on machine learning have the characteristics of

diversification and different applicability. In recent years, related researchers have carried out a lot of studies on different types of texts, which provides a well foundation for follow-up text classification modeling research. In general, it has the necessary theoretical basis and important practical significance to carry out automatic classification modeling for car service complaint texts so as to realize automatic classification of the complaints, through reasonably using machine learning methods based on the characteristics of the complaint texts.

Chinese text classification modeling based on machine learning commonly involves data preprocessing, text vectorization, classification modeling, and model reliability analysis, among which, text vectorization and classification modeling are commonly the core links. In related research, the methods used in text vectorization mainly involve three categories, including word frequency-based methods such as TF-IDF and Bag-of-words [5-7], distributed static word vector-based methods such as Word2vec [8-11], distributed dynamic word vector-based methods such as BERT [12-13]. Different types of methods commonly have different characteristics and applicable scenarios; the methods based on word frequency is relatively simple in principle and convenient to implement, but text vectorization based on this kind of methods would lose context information; the distributed static word vector methods and the distributed dynamic word vector methods both understand and represent words based on context, and could effectively retain context information in the process of text vectorization; the main difference between the static word vector methods and the dynamic word vector methods is the polysemy distinction of a word, the static word vector methods couldn't distinguish the different interpretations of a word in different contexts, while the dynamic word vector methods have the ability to distinguish. In text classification modeling, after the texts are converted to vectors, it is commonly necessary to further process classification information so as to obtain text classification prediction results; in related researches, the basic methods used in classification information processing mainly involve two categories, including classical machine learning methods [14], such as Naive Bayes and random forests, and various neural network methods [15-19]. The neural network methods used in text classification have the characteristic of diversification, including basic neural network methods such as CNN, RNN,

LSTM, BILSTM, and various improved neural network methods suitable for different application scenarios. At the same time, the neural network method has the characteristic of flexible superposition, different kinds of neural networks could be stacked up for use. Applying the methods based on different types of neural networks stacking to the classification information processing, the effect of multi-layer classification information processing could be achieved, which commonly could improve the quality of classification information extraction and the classification accuracy of the model. In addition, ensemble learning methods are gradually being used in natural language text classification research in recent years [20]. Ensemble learning methods could comprehensively use a variety of basic methods, which could firstly build multiple individual models based on different kinds of basic methods, and then perform horizontal integration of basic models through certain strategies, obtaining prediction results through two-stage process processing. In general, the natural language text classification modeling based on machine learning has the characteristics of multi-link research process and diversified research methods; different types of basic methods commonly have different characteristics and applicability differences; in text classification modeling, technical routes and technical methods could be designed and selected based on actual text characteristics.

The basic characteristics of car service complaint texts include quite rich emotional expressions and professional vocabularies. After data preprocessing and basic analysis, based on the characteristics of the service complaint texts, this study uses the Jieba word segmentation tool for word segmentation, word frequency-based method for text vectorization, and correlation method for feature selection; the classification model is trained based on progressive training method and random forest, and the feature dimension is adjusted through the modeling feedback; model reliability is assessed based on the effect of data amount on the modeling and the effect of text length on the probability distribution of classification predictions. It is expected that this study could provide effective reference for subsequent related research and application.

## II. TECHNICAL ROUTE

The technical route of this study includes data sorting, data characteristic analysis, splitting words, feature extraction, classification modeling, model reliability analysis, conclusion and outlook. In feature extraction, the method based on word frequency and correlation analysis is used; in classification modeling, random forest and progressive method are used to construct classification model.

The technical route is shown as Fig. 1.

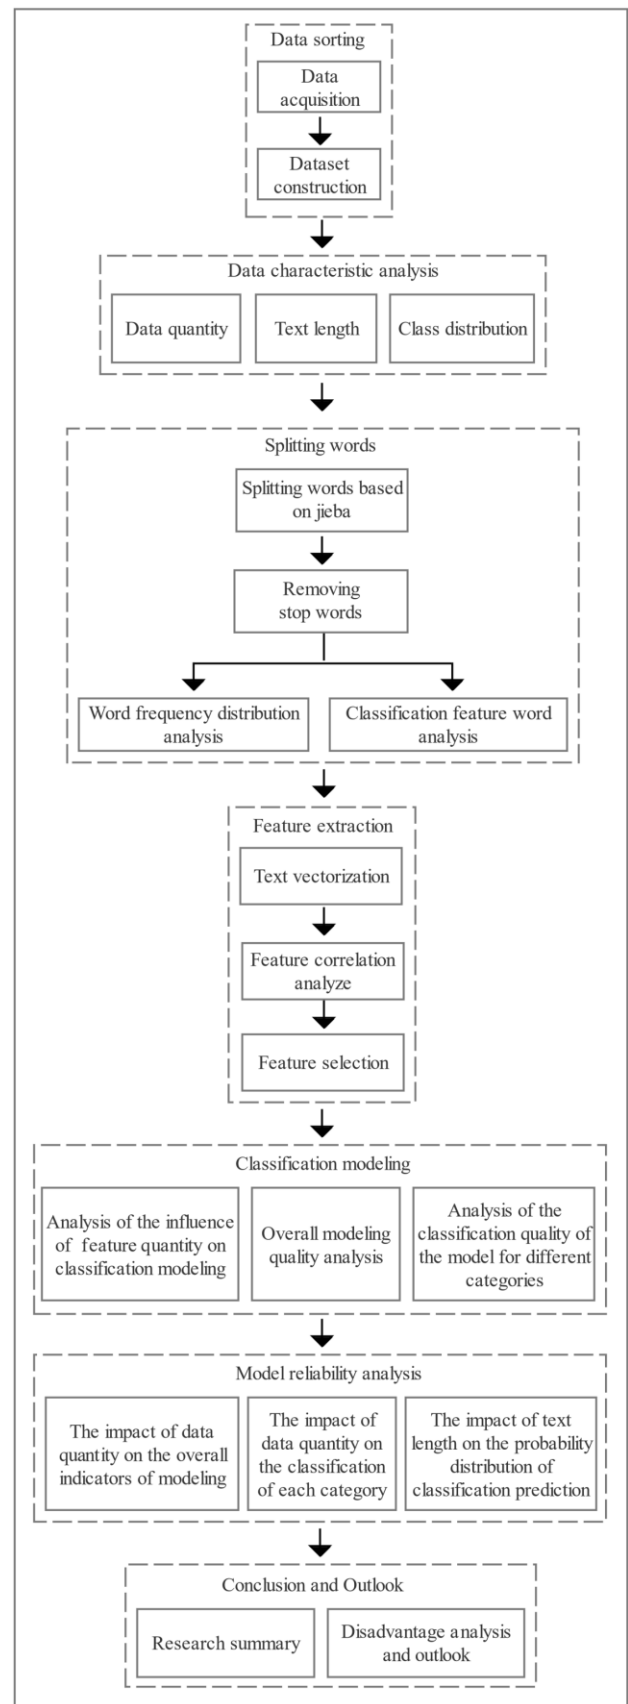

Fig. 1. Technical Route Figure.

## III. DATA

The research data of this study is from the Beijing Car Quality Net Information Technology Limited Company. The dataset used includes seven classes of car service complaint text data, which includes service attitude, personnel technology, service charge, not keeping promise, sale fraud, accessory dispute, service process is not perfect. The total data amount of the dataset is 2100, and the data amount of each class is 300.

The characteristics of data amount and text length of the dataset are shown in Table I.

The data distribution of the dataset in terms of car type, purchase and use time, and brand is shown in Fig. 2. The coverage of the dataset in terms of car type, purchase and use time, and brand is relatively comprehensive, and the overall distribution uniformity is quite well.

TABLE I. DATA DESCRIPTION

| No. | Class | Data amount | Average length of text | Maximum length of text | Minimum length of text | Text length standard deviation |
|-----|-------|-------------|------------------------|------------------------|------------------------|--------------------------------|
| 1 | Service attitude | 300 | 18.5033 | 24 | 15 | 1.8352 |
| 2 | Personnel technology | 300 | 19.1167 | 26 | 15 | 1.9806 |
| 3 | Service charge | 300 | 18.6133 | 24 | 14 | 1.9156 |
| 4 | Not keeping promise | 300 | 18.5500 | 24 | 13 | 1.8670 |
| 5 | Sale fraud | 300 | 18.7100 | 29 | 14 | 2.2065 |
| 6 | Accessory dispute | 300 | 18.5267 | 30 | 15 | 1.9618 |
| 7 | Service process is not perfect | 300 | 18.7033 | 26 | 14 | 2.2193 |
| 8 | All | 2100 | 18.6748 | 30 | 13 | 2.0098 |

Fig. 2. Data Distribution Characteristics.

## IV. Word Segmentation

Chinese text classification commonly needs to separate the texts into words, in this study, Jieba tool is used for word segmentation, which is widely used in Chinese text segmentation. After word segmentation, the data process of removing stop words is conducted to remove the feature words with low classification relevance. After removing stop words, the word segmentation result is shown in Table II. In the different classes, the highest word amount is 2865 and the lowest amount is 2611; the highest unique word amount is 743 and the lowest amount is 516; the highest value of repetition rate is 0.8129 and the lowest value is 0.7154.

The distribution differences of the global high frequency words in different classes could reflect the applicability of the data processing method based on word frequency in the classification modeling for the corresponding text data to a large extent. The analyze result for the word frequency distribution of the global high frequency words of the dataset in the different classed is shown in Fig. 3. Overall, the higher the global word frequency value, the higher the difference of the word frequency distribution of the feature words in the different classes; the distribution of the global high frequency feature words of the dataset in different classes shows a high degree of discrimination as a whole, which shows that the data processing method based on word frequency is suitable for the classification modeling scene targeted in this study. The class high frequency feature words are shown in Table III.

TABLE II. Word Segmentation Results

| No. | Class | Number of characters | Number of separated words | Number of unique words | Repetition rate |
|-----|-------|----------------------|---------------------------|------------------------|-----------------|
| 1 | Service attitude | 5551 | 2611 | 743 | 0.7154 |
| 2 | Personnel technology | 5735 | 2788 | 719 | 0.7421 |
| 3 | Service charge | 5584 | 2682 | 618 | 0.7696 |
| 4 | Not keeping promise | 5565 | 2758 | 516 | 0.8129 |
| 5 | Sale fraud | 5613 | 2865 | 558 | 0.8052 |
| 6 | Accessory dispute | 5558 | 2802 | 620 | 0.7787 |
| 7 | Service process is not perfect | 5611 | 2731 | 544 | 0.8008 |
| 8 | All | 39217 | 19237 | 2092 | 0.8913 |

## V. FEATURE EXTRACTION AND CLASSIFICATION MODELING

Based on basic analysis for the data characteristics, this study adopts the bag-of-words method based on word frequency for text vectorization, and operates feature word correlation analysis for the feature selection and word vector dimensionality reduction.

Based on correlation analysis, feature words with a degree of correlation higher than 0.95 are partly removed to reduce the dimension of the word vectors and improve the efficiency of model training, model classification. Through the feature selection, 257 features with high relevance are removed, and 1689 features are reserved. Fig. 4 shows the correlation matrix of part global high frequency features in the dataset.

In this study, the random forest combined with progressive model training method is used for the classification model training. In the model training, the features involved are gradually increased for obtaining the optimal amount of the modeling features by comparing the results of multiple rounds of training, in order to avoid too little features used do not contain enough classification information for supporting high quality classification modeling, or the model prediction accuracy, model classification efficiency are negatively affected due to too much features used. The research results show that in this study, the optimal modeling effect is obtained when using 1689 features.

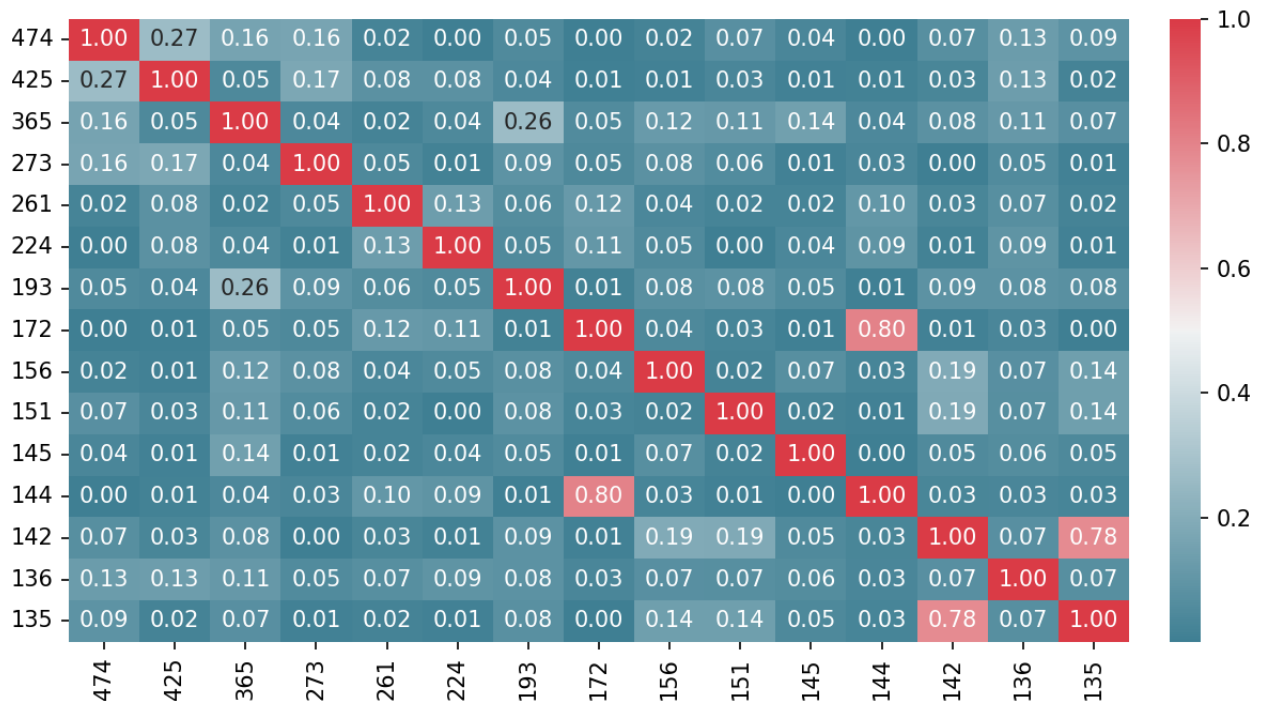
Table IV shows the comparison of the progressive multi-round training results from the aspects of feature selection ratio, feature amount, overall accuracy, overall precision, overall recall, overall f1-score, highest f1-score in the classes, and lowest f1-score in the classes.


Fig. 4. Correlation Matrix Heatmap.

TABLE IV. CLASSIFICATION MODEL TRAINING

## VI. MODEL RELIABILITY ANALYSIS

Model reliability analysis is of great significance to the classification modeling, since the modeling is commonly based on limited data, and the modeling indexes mainly reflect the overall quality of the model. The applicability of the model to new data and the reliability of the model classification under specific condition are commonly difficult to evaluate based on the overall modeling result indexes.

This study evaluates the reliability of the model from two aspects: the effect of data amount on the modeling and the effect of text length on the model prediction probability distribution. In term of the effect of data amount, Table V shows the comparison of the multi-round model training result parameters under the condition of increasing data amount. In term of the effect of text length, the first 8 and last 8 text data in the global text length rank are selected for model classification prediction probability distribution analysis. The model classification prediction probability distribution is shown in Table VI.

TABLE V.    THE EFFECT OF DATA AMOUNT ON MODEL TRAINING

| No. | Data use ratio | Data amount | Accuracy | Precision | Recall | F1-score | Highest f1-score in the classes | Lowest f1-score in the classes |
|---|---|---|---|---|---|---|---|---|

## VII. CONCLUSION AND OUTLOOK

This study focus on the issue of car service complaint classification modeling, the dataset used involves 7 classed of service complaint texts, and the data amount of every class is all 300; the core links of the research process include word segmentation, text vectorization, the feature selection and dimensionality reduction based on correlation analysis, the classification modeling based on random forest and progressive method, and the model reliability analysis based on data amount and text length; the results show that based on the method of this study, the effective classification for the car service complaint texts could be realized. In this study, when the feature amount reaches 1689, the optimal modeling effect is obtained, the values of overall accuracy, overall precision, overall recall, overall f1-score, the highest f1-score in the classes, the lowest f1-score in the classes respectively reach 0.8476, 0.8550, 0.8476, 0.8495, 0.9123 and 0.7619; in the model reliability analysis, when the data use ratio reaches 85%, the modeling effect is generally stable; the analysis results of

the effect of text length on the model classification prediction probability distribution show that the distribution is overall high discriminative.

In summary, the car service complaint data could be effectively classified based on the method of this study, which could provide reference for the classification modeling of the natural language texts with subjectivity characteristic; at the same time, this study still belongs to theoretical research, and has not been applied to practice.

*Abstract*—**Electroencephalography (EEG), or brain waves, is a commonly utilized bio signal in emotion detection because it has been discovered that the data recorded from the brain seems to have a connection between motions and physiological effects. This paper is based on the feature selection strategy by using the data fusion technique from the same source of EEG Brainwave Dataset for Classification. The multi-layer Stacking Classifier with two different layers of machine learning techniques was introduced in this approach to concurrently learn the feature and distinguish the emotion of pure EEG signals states in positive, neutral and negative states. First layer of stacking includes the support vector classifier and Random Forest, and the second layer of stacking includes multilayer perceptron and Nu-support vector classifiers. Features are selected based on a Linear Regression based correlation coefficient (LR-CC) score with a different range like $n_1$, $n_2$, $n_3$, $n_4$ a, for $d_1$ used $n_1$ and $n_2$ dataset ,for $d_2$ dataset, combined dataset of $n_3$ and $n_4$ are used and developed a new dataset $d_3$ which is the combination of $d_1$ and $d_2$ by using the feature selection strategy which results in 997 features out of 2548 features of the EEG Brainwave dataset with a classification accuracy of emotion recognition 98.75%, which is comparable to many state-of-the-art techniques. It has been established some scientific groundwork for using data fusion strategy in emotion recognition.**

## I. INTRODUCTION

With the rapid advancement of computers and human contact technology, there is a significant demand in the area of human interaction for a more intelligent and humanized human-machine interface (HMI). A (BCI) brain-computer interface transforms a way of transforming brain processes that are connected directly to the brain of a living organism, such as a human or an animal. BCI serves as a bridge for communication between both the human brain and as a tool to detect different applications, such as emotion identification and different applications [1].

Human communication, daily life, and work all rely heavily on emotional expressiveness. It can be characterized as positive, neutral, or negative experiences arising from a variety of physiological activities, and it includes a wide range of emotions such as sadness, happiness, surprise, anger, and disgust [2][3][4].

Emotion recognition research has become more common among researchers with the development of sensor-based technology and processes and accessibility have improved. Emotion recognition can have important applications, whether professional, personal, or personal [5] such as in the fields of medicine [6], education, psychology, computer games, driving, security, entertainment [7], and workload evaluation, and many others [8].

Emotions can be detected in a variety of ways, including brain waves and facial expressions. Brain waves are a means of obtaining emotion that can be both intrusive and non-invasive. In wires and an intrusive Brain-computer-interface (BCI) are surgically implanted on the accessible brain surface. The non-invasive method is known as BCI, and it provides a simple, fast, and beneficial method for collecting the brainwaves, which comprises functional magnetic resonance imaging (fMRI), Magnetoencephalogram (MEG), Electroencephalogram (EEG), and numerous signaling have already been approved, recognized, and classified as non-physiological and physiological signals, respectively. In the practical application of emotion recognition, Gesture, Text, movement, speech, voice intonation, and facial expression, among other non-physiological signals, are indeed the original concept is a term that has been used a lot in the past. More studies have recently been conducted using physiological signals such as electrocardiogram (ECG) and electroencephalogram (EEG) [9].

This study proposes an electroencephalography (EEG) signal analysis technique for recognizing and classifying emotional states, as well as a correlation-based data reduction strategy coefficient score between features with a different range and developed a new dataset. Machine learning models are grouped into three types: supervised, unsupervised, and reinforcement learning, as well as a specific form termed ensembles learning, based on the methodology utilized [10].

An ensemble machine learning algorithm is often known as stacking. Stacking is the process of learning how to aggregate the prediction of participating ensemble components using a machine learning model and minimize the variation. In this paper extension of Stacking Classifier with two layers of learning models i.e., Multi-layer Stacking Classifier is developed.

In this research article there are four contributions: 1) Calculated the correlation coefficient score of features

based on linear regression model. 2) Prepared a different dataset with a particular range and applied a data fusion strategy. 3) Developed a method which has already been tested through a developed dataset. 4) Calculated the time complexity of each classifier.

This manuscript's structure is as follows: Section II describes the related work on emotion recognition, data reduction, and on machine learning techniques. Section III describes about possible approach for reducing data in an EEG analysis by generating restricted electrode correlations zones. Section IV explains the configuration for the classification procedure as well as the methods used to carry out the experiments. The results of executing the proposed solutions are discussed in Section V, and the work's conclusions are discussed in Section VI.

## II. RELATED WORK

A method for classifying emotional states using wavelet compression, EEG data, and sensor classification procedure, links electrodes in a 10/20 model to Brodmann n areas and reduces computational load. The emotions modelling is based on hold value of an adjusted space from the Russell Arousal Valence Space and the Geneva model, and the classification procedure was accomplished using an SVM Classification process, which achieved an 81.46%, classification performance for a multi-class problem [11].

Researchers used the zero-time window-based using the numerator group-delay to derive immediate frequency features function to correctly detect the periods in each emotional situation. Using QDC and RNN, as well as the DEAP database, separate class systems were constructed used to test them [12].

There are two types of network entropy metrics calculated: nodal degree entropy and clustering coefficient entropy. The effective characteristics are fed into the SVM classifier using the AUC method to accomplish emotion recognition across participants. The findings of the experiment revealed that the properties of 18 channels selected by AUC were significant (p 0.005) for the EEG signals of 62 channels [13].

The program collects features from EEG data and uses machine learning techniques to classify emotions, with different segments of a trial being utilized to train the proposed model and examine its impact on emotion detection outcomes. Second, using the classification performance and two emotion coefficients, namely, the correlations and entropy coefficients, a unique activation curve for emotions is created. The activation curve can not only define emotions, but it may also indicate the emotional activating mechanism to some extent. Next, the two factors are combined to provide a weight coefficient, which improves emotion recognition accuracy. Experiments on the DEAP and SEED datasets were conducted to validate the suggested technique [14]. Based on the SJTU emotion EEG datasets (SEED) and the ResNet50 and Adam

optimizer, the CNN model is being used to train the features and recognize the emotions of positive, negative and neutral states of real EEG signals in a single model [15]. This study presented a new model called the "hybrid model" that merged three ensemble models. For classification challenges, a set of features is retrieved from raw IoT datasets from various IoT domains utilizing linear discriminant analysis (LDA), Principal component analysis (PCA), and Isomap. The classifiers' accuracy, area under the curve (AUC), and F1 score are used to compare their performances [16].

A feature extraction subsystem and a classifier subsystem are created in this paper for an EEG-based emotion recognition system. 9 features extracted from the time and frequency domain from the EEG sign were used because the greater performance of the feature extraction module may result in higher recognition accuracy [17]. Authors have created a machine learning algorithm based on ensembles. The data was cleaned using a pre-processing technique, and feature selection was done using wrapper-based methods; additionally, a stacking-based ensemble learning model was used to identify the MDD participants in the final stage [18]. The proposed research makes a significant addition by presenting an enhanced version of the agent-based data reduction algorithm that incorporates the stacking generalization mechanism for data reduction. Enhancing the performance of the categorization results in the model discussed in [19]. Considering the aforementioned factors and applying the skills in this sector, it is inspired to write this research to address the following problem.

- How accuracy and prediction performance can be improved?
- How to overcome from overfitting problem?
- How precise can the EEG waves be classified?
- What are other essential features can derive using EEG data?

## III. DATASET DETAILS

Performed thorough analysis on the EEG Brainwave Dataset, which is publicly available, in each state: happy, neutral, and negative - data was collected for 3 minutes from two subjects (1 male, 1 female). To record the TP9, AF7, AF8, and TP10 EEG placements, the author employed a Muse EEG headgear with dry electrodes.

## IV. PROPOSED METHODOLOGY

In this section, discussed about a possible approach for reducing data in an EEG analysis by generating restricted electrode correlations zone and explains about the configuration for the classification procedure as well as the methods used to carry out the experiments.

### A. Data Preprocessing

In Machine Learning, data preprocessing relates to the procedure of organizing and managing basic information to make it appropriate for creating and training Machine Learning models. First libraries are required for data preprocessing, identifying missing values, so, the EEG

brainwave dataset has no missing values, and provides the label for each category like positive, negative, and neutral.

### B. Feature Selection

For features, correlation coefficient score is determined with a linear regression model. For each feature set, selected the subset of features based on the range and created a new dataset.

### C. Correlation Coefficient Score

To calculate the correlation coefficient, the linear regression model is used. The linear relationship between multiple Correlations is used to assess variables. Correlation is used to predict one variable from the other. Because the good variables are so closely related to the aim, using correlation to pick features stands to reason. Furthermore, variables should really be relevant to the goal yet unrelated to each other. It anticipates one from the other if the two variables are correlated. As a result, if features are correlated, the model only needs one among them because the other provides no additional information. The linear correlation coefficient is a mathematical expression that measures the degree and direction of a relationship between two variables:

$$r = \frac{\sum \frac{(x_i - \bar{x})}{s_x} \frac{(y_i - \bar{y})}{s_y}}{n - 1} \tag{1}$$

Where $\bar{x}$ and $s_x$ are represented, the sample mean and sample deviation of the x's. And $\bar{y}$ and $s_y$ are represented the mean and standard deviation of the y's.

A different method of calculating the correlation coefficient is as follows:

$$r = \frac{s_{xy}}{\sqrt{s_{xx} s_{yy}}} \tag{2}$$

Where,

$$s_{xx} = \sum x^2 - \frac{(\sum x)^2}{n}$$

$$s_{xy} = \sum xy - \frac{(\sum x)(\sum y)}{n}$$

$$s_{yy} = \sum y^2 - \frac{(\sum y)^2}{n}$$

The properties of "r" are as follows:

- It is always in the range of -1 to +1.

- Because it is a dimensionless quantity measure, "r" would have been the same that whether two variables were measured in pounds and inches or grams and centimeters.

- Favorable "r" levels are linked to positive connections.

- Bad "r" values are linked to negative relationships.

First, Linear Regression model is used to find the feature importance of each feature. Then correlation coefficient Scoreis determined for each feature. Following ranges are considered for each dataset.

$n_{1=}0.0\ to\ 0.3;$

$n_2 = 0.31\ to\ 0.5;$

$n_3 = 0.51\ to\ 0.75;$

$n_4 = 0.76\ to\ 1.0.$

Based on the Correlation Coefficient score value, it is found that 610 features importance score are within 0.0-0.3, 179 features are within 0.31-0.5, 136 features are within the range 0.51-0.75 and 77 features are within 0.76 to 1.0. After applying the data fusion technique for the EEG brainwave dataset, 997 features are selected. At this stage developed a four set of datasets with different feature values. Then selected all the unique features from $n_1$ and $n_2$ and generated the new dataset called $d_1$ which has 787 columns excluding the label. The same procedure has been applied on $n_3$ and $n_4$ and after combining the features and filtering the unique features, around 211 are considered, i.e., $d_2$. And finally, by considering $d_2$ and $d_3$ determined 997 unique features and that is final dataset to work on.

$d_1, d_2,$ and $d_3$ are the final combined dataset of $d_1$,

and $d_2$, which details as follows:

$n_1 = (2132\ trails \times 610\ features)$

$n_2 = (2132\ trails \times 179\ features)$

$d_1 = n_1 + n_2 = (2132\ trails \times 787\ features)$

$n_3 = (2132\ trails \times 136\ features)$

$n_4 = (2132\ trails \times 77\ features)$

$d_2 = n_3 + n_4 = (2132\ trails \times 210\ features)$

$d_3 = d_1 + d_2 = (2132\ trails \times 997\ features).$

### D. Machine Learning Classifiers

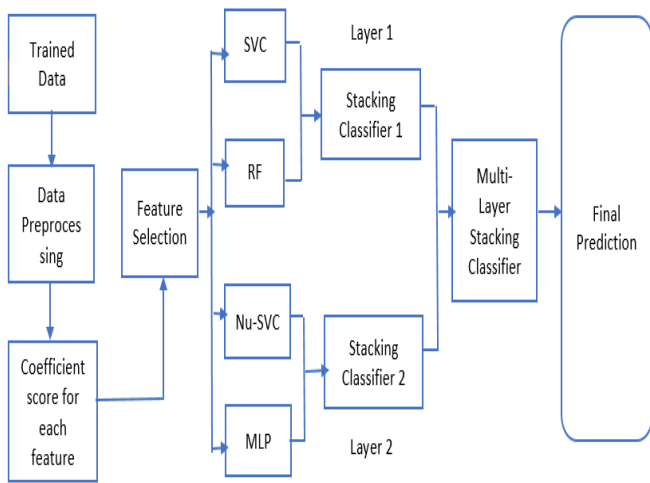
The method of feature selection, the LR-CC algorithm chooses the most essential features for predicting emotional states. The next step is to classify the emotions by using a dataset using a machine learning technique. Multilayer stacking Classifier is developed based on Stacking Classifier 1 and Stacking Classifier 2 method on Support vector classifier, Random Forest for a Stacking Classifier 1 (layer1), and Nu-Support vector classifier, r, and Multi-Layer Perceptron for Stacking Classifiers 2 (layer 2) as low-level base learners and Random Forest as meta learner algorithm. This section examines step-by step working of the suggested model and overall design. Fig. 1 establishes the framework. First, there are the EEG signals that have been pre-processed from the dataset based on correlation coefficient score; the feature selection stage selects the features based on the data fusion technique and makes a new dataset, i.e., $d_3$


Fig. 1.   Architecture Diagram of Multi-layer Stacking Model based on different Machine Learning Classifier Called as Learners and Meta Classifier.

Two layers of Classifiers are implemented separately first and created as a Stacking Classifiers 1 and 2 with a random forest as a meta learner, after implementation of these stacking 1 and 2, developed a multi-layer Stacking Classifier which is based on the predictions of Stacking Classifier 1, and Stacking Classifier 2 as an input and generate a final prediction. A feedforward artificial neural network is a multilayered perceptron in which the functions and structure of the ANN are like the brain's activities and structure [20]. Neurons are basic components that are connected and work in tandem. These neurons are linked by a vital link that contains the information to solve difficulties [21]. For regression and classification issues, a support vector machine (SVM) is a supervised machine learning technique. Each property is represented by a point in n-dimensional space (n = number of features). A hyperplane is created to do linear classification, which effectively separates the two classes. Kernel approaches such as Gaussian kernel, Laplace kernel, and Polynomial kernel are utilized for non-linear classification [22]. Random forest is a decision tree-based learning technique that combines numerous decision trees. It forecasts by aggregating decision tree forecasts [23]. The resilience of SVC and Nu-SVC isn't always the best option, and random forest is suitable in situations [24]. It is difficult to acquire using a Multilayer Perceptron to find the best parameters. Developed a multi-layer stacking ensemble model to address these concerns and increase forecast accuracy. Support Vector Classifier (SVC), Nu-Support Vector Classifier (NuSVC), Multi-layer Perceptron (MLP), and Random Forest classifier,layer 1, and layer 2 will be trained and tested individually. These four models will compensate for shortcomings and provide superior outcomes when stacking. The following shows the algorithm for multilayer stacking with 2 layers. SVC, RF classifier for Stacking 1 or layer 1 as $L_1$ Classifier and for Stacking 2 or layer 2 as $L_2$ has Nu-SVC and MLP. After implementation of these classifiers, developed a new model i.e., multi-layer stacking which is based on $L_1$ and $L_2$ and for meta classifier $M$ used Random Forest with cross validation K and generate a prediction $P$. Confusion matrix will be used to evaluate each classifier's performance. Finally, results are compared by stacking the predictions of different classifiers.

## V.   EXPERIMENTAL RESULTS

The main source of dataset consists of 2132 records and 2548 features, after data pre-processing, feature selection is made based on the Linear Regression-Correlation Coefficient (LR-CC) with a Correlation coefficient score of features, 997 features have been selected by applying the data fusion technique, The data fusion method focuses on a group of features that need to be improved, refined, or obtained. on the original dataset. Data fusion techniques are applied with feature level for selecting the features from the same source, i.e., the EEG Brainwave dataset to develop a single dataset.

The classification is divided into 3 parts, in the first part i.e., base learners are learned, and findings are predicted after selecting the features separately in the second part layer 1 and layer 2 are learned and findings are predicted separately, and in the third part, to solve the problems with the individual implements Stacking Classifiers 1 and 2 are developed and made a new prediction as input for the multilayer stacking classifier. In the multi-layer stacking, classifiers are trained layer 1(SVC+RF) and layer 2(Nu-svc+MLP) and the base learners predicted output to the multi-layer stacking as an input.

Developed different datasets and combined them into one dataset by using data fusion techniques. Proposed models are tested are tested on different datasets and accuracy of the algorithms are shown in Fig. 2. It is observed the accuracy of the existing algorithm and Proposed algorithm i.e., multi-layer stacking with $n_1$ dataset which has 610 features.

Represented the summary of Fig. 2 to Fig. 8 in the form of Table I, in this table, in which proposed model achieved highest accuracy with the unique combination of datasets.

### A. Performance Evaluation

To evaluate the developed models, confusion matrix is determined. A confusion matrix is a table that shows how well a classification model (or "classifier") performs on a set of test data for which the true values are known. This is a list of rates that are frequently generated using a binary classifier's confusion matrix:

- Accuracy: What percentage of the time does the classifier get it right?

$$\frac{TP+TN}{N} \tag{3}$$

- Precision: When it predicts yes, how often does it get it right?

$$\frac{TP}{TP+FP} \tag{4}$$

- Recall: The number of true positives divided by the total number of true positives and false negatives equals recall.

$$\frac{TP}{TP+FN} \tag{5}$$

- F1-score: The genuine general positive rate (recall) and precision are weighted averages.

### B. Confusion Matrix for Each Classifier

The confusion matrix, which includes metrics such as Sensitivity, Accuracy, Precision, Specificity, and measure, is used to evaluate the algorithm's efficiency after it has been implemented. Fig. 9 to 14 are the confusion matrix of SVC, MLP, Nu-SVC, RF, stacking 1, stacking 2 and Multi-Layer stacking are shown in Fig. 15. Similarly, ensembles models.

TABLE I.      ACCURACY OF CLASSIFIERS

| Dataset / Models | $n_1$ | $n_2$ | $n_3$ | $n_4$ | $d_1$ | $d_2$ | $d_3$ |
|---|---|---|---|---|---|---|---|
| SVC | 94.37 | 96.09 | 96.56 | 94.84 | 96.25 | 97.96 | 98.28 |
| RF | 95.93 | 94.53 | 96.40 | 94.37 | 96.87 | 97.03 | 95.23 |
| Nu-SVC | 94.06 | 94.21 | 95 | 92 | 94.53 | 95.78 | 96.25 |
| MLP | 95.93 | 95.93 | 97 | 94.21 | 97.03 | 96.81 | 97.65 |
| Stacking 1 | 95.96 | 96.25 | 97.03 | 96.09 | 97.05 | 97.05 | 98.43 |
| Stacking 2 | 94.84 | 95.15 | 96.25 | 94.65 | 95.78 | 97.81 | 95.31 |
| Multi-layer stacking | 96.4 | 96.25 | 98.24 | 96.25 | 97.81 | 98.43 | 98.75 |

Fig. 14. Confusion Matrix of Stacking 2 Model.

As a result of the increased focus on boosting prediction performance, multi-layer stacking ensembles model depicted to improved predictive performance in this investigation. Various classifications are used such as SVC, MLP, Nu-SVC, RF as a base learner and divided these into two layers stacking 1 and stacking 2, and Random Forest as a meta learner. Eventually, merged these four different models to trade-off various constraints and which provided higher performance. Fig. 8 is a summary of the findings. Evaluated the developed

multilayer stacking model to establish state strategies and discovered that suggested approach outperforms them by a wide margin. In contrast, tested proposed models on different datasets and found that proposed method works better compared to other state-of-the-art methods upon these datasets, it's helpful to improve forecast accuracy. Table II shows the comparison state of the art methods for the recognition of neutral, negative, and positive emotions. Accuracy comparison of this research method with other methods of data reduction strategies or feature selection is the recognition of neutral, negative, and positive emotions.

Fig. 15. Confusion Matrix for Multi-layer Stacking.

TABLE II. COMPARISON OF THE PROPOSED MODEL

| Study | Classifiers | Dataset | Feature Selection | Accuracy |
|---|---|---|---|---|
| Proposed method | Multi-Layer Stacking | EEG brainwave Data | 997 features selected based on LR-CC | 98.75 |
| [26] | Deep neural network | EEG brainwave dataset | 63 features with information gain | 94.89 |
| [17] | Random Forest | DEAP dataset | Features Selected from the time and frequency domains | 62.85 |
| [25] | KNN | EEG Brainwave dataset | PCA used for feature selection | 96.22 |
| [13] | SVM | DEAP Dataset | Select features based on network entropy measures | 68.44 |

TABLE III.        ACCURACIES OF EMOTIONS

| Emotions | accuracy | Emotional State (0,1,2) |
|----------|----------|-------------------------|
| Happy | 99.66 | Positive-2 |
| Fear | 68.00 | Positive-2 |
| Surprise | 77.00 | positive-2 |
| Sad | 98.00 | Negative-0 |
| Angry | 71.00 | Negative-0 |
| Disgust | 61.00 | Negative-0 |
| Neutral | 100 | Neutral-1 |

Table III represents the average accuracy of recognition of emotions in positive, negative, and neutral state using the multi-layer classification approach. Highest accuracy achieved in neutral state as compared to other emotional state.

### C. Time Complexity

The amount of time needed for an algorithm to run as a function of the length of the input is known as temporal complexity. It calculates how long each statement of code in an algorithm takes to execute. Calculated time for each and every model and proposed multi-layer stacking model which shown in Table IV.

TABLE IV.        TIME COMPLEXITY OF EACH MODEL

| Model | Time |
|-------|------|
| SVC | 0.76 sec |
| MLP | 1.83 sec |
| Nu-SVC | 1.27 sec |
| RF | 0.27 sec |
| Stacking 1 | 4.69 sec |
| Stacking 2 | 6.70 sec |
| Multi-Layer Stacking | 19.09 sec |

## VI. CONCLUSION

In this study, a multi-layer stacking model for boosting the prediction accuracy of emotion recognition using several machine learning techniques to solve a multi-classification problem even with a small dataset. In the first step, Linear Regression-Correlation Coefficient (LR-CC) method is applied for selecting features based on their content which assists in improving forecast accuracy. An original dataset has 2548 features after applying the data fusion technique final dataset of 997 features are selected. The data has been divided into two categories: training and Testing. The training data is used to train the multi-layer stacking, and the testing data is used to make the predictions. Multi-Layer stacking is implemented by two layers, in each layer two base learners or machine learning algorithms are considered like SVM, MLP, Nu-SVC, RF, and set meta learner as a Random Forest. Individual classifiers are also implemented to make comparisons. The 98.75% accuracy is obtained for Multi-Layer Stacking. As compared to the single base learners, the results indicate that the multi-layer stacking model improves the predictive performance. However, proposed method took much time during the training process. In Future, planning to work on these issues to improve the computational cost and focus on multimodal data fusion strategy with higher classification performance.

# The Implementation of a Solution for Low-Power Wide-Area Network using LoRaWAN

Nicoleta Cristina GAITAN[1], Floarea PITU[2]

Faculty of Electrical Engineering and Computer Science, Stefan cel Mare University of Suceava[1, 2]
Integrated Center for Research, Development and Innovation in Advanced Materials, Nanotechnologies
and Distributed Systems for Fabrication and Control (MANSiD), Stefan cel Mare University, Suceava, Romania[1]

*Abstract*—In recent years, there has been an increasing emphasis on low-power wide-area network also knowns as LPWAN (Low-Power Wide-Area Networks) technologies that allow efficient and fast data transfer, thus desiring a large-scale integration of various devices facilitating long-distance communications in various fields such as agriculture, logistics, or infrastructure. This category of technologies includes SigFox, LoRa, NB-IoT and others. One area where these low-power technologies can be used successfully is agriculture, in which monitoring the humidity and temperature are crucial. The social-economic context of 2022 highlights as one of the main priorities the security of the food and the raw materials provided by the agriculture field, so the desire is to obtain a large, efficient, and traceable production. Starting from this context, in this paper an architecture based on LoRa (Long-Range) technology and the LoRaWAN protocol it is proposed. We will place special emphasis on monitoring the extremely important parameters in agriculture, namely temperature, humidity and pressure. Although there are multiple works of research in this direction or in similar directions in other fields of activity, we should mention that each of them focuses on certain strictly geographical area and most of the times the results are purely theoretical. The gain that comes with this paper consists first in the fact that there is a practical support implementable and secondly the solution described can be adapted to different geographical regions. Moreover, at the end of this paper, we will focus on the comparison and analysis at the architectural level of two LPWAN technologies, namely SigFox vs. LoRa implemented in the same context in order to find the best results.*

*Keywords—LoRa; low-power; LoRaWAN protocol; SigFox; LPWAN*

## I. Introduction

In the current social and economic context, the field of agriculture is once again proving to be an area of great global importance. With the onset of the COVID 19 pandemic in 2020, agriculture returned to the table of global discussions and thus brought up the issue of crop efficiency and how agriculture is divided globally into different production sectors. The main problem that deepened in this sector started with the COVID 19 pandemic and was related to the food supply chain and the level of agricultural productivity in each country [1]. Another problem facing the agricultural sector today is related to the military conflict between Ukraine and Russia. Both countries have a critical role to play globally in producing cereals and vegetable oils. Thus, with the sanctions imposed by the West on Russia and the fact that Ukraine can no longer export and produce the usual quantities of agricultural products

[2], we can say that agriculture needs particular attention, and the need to research in this field is justified. Investments in research in this field usually have technologies such as the Internet of Things (IoT) as a starting point.

When we refer to the IoT, we refer to the billions of devices interconnected by certain communication technologies that ensure the collection and exchange of data between them remotely without the need for a person's direct presence or intervention. IoT includes the family of low-power wide-area networks (LPWAN), which consists of several technologies such as LoRa, SigFox, NB-IoT (Narrow Band - Internet of Things), LTE-M (Long Term Evolutions for Machines), and so on [3]. These LPWAN technologies aim to reduce or even cushion the disadvantages of traditionally used communications networks, such as Zig-Bee, WiFi, Bluetooth, or even LTE. The applications of LPWAN technologies cover a wide range of fields. Still, the main ones are agriculture, logistics applications, infrastructure monitoring, personal and commercial applications, medical, etc. LoRa is a complex technology composed of two main components. The LoRa alliance [19] specifications present these components as two distinct levels: the physical LoRa level and the MAC protocol level, namely LoRaWAN [4].

### A. LoRa Physical Layer

LoRa is based on a radio modulation technique developed and patented by Semtech [5], which operates in the unlicensed spectrum of frequency bands. This technique is used especially when the power consumption is low and extended coverage is needed. The name refers to the long-distance data links covered by this technology. LoRa is one of the best choices when communication requires a very high range. LoRa covers up to 5 km in urban areas and 15 km or more in rural areas.

A vital feature of this type of technology is that it does not require considerable power resources, so devices that are operated on batteries can be used. The energy needed to transmit a data packet is very low, and this is because the data packets are small and are not transmitted continuously but only a few times a day. Moreover, when the end devices are asleep, the power consumption is of the order of mW and thus allows the operation of the same battery even for several years. LoRa uses the proprietary of spread spectrum modulation technology derived from Chirp Spread Spectrum technology, providing a trade-off between sensitivity and data rate while operating in a 125 kHz fixed bandwidth channel. In addition, LoRa uses orthogonal spread factors. This technique allows the network to

preserve the battery life of connected end devices by making adaptive optimizations based on each node's power level and data transmission at the individual level. The higher the spreading factor, the higher the processing gain and the reception sensitivity, but the data transmission rate will undoubtedly be lower [4][5].

### B. LoRaWAN MAC Layer

LoRaWAN is standardized by the LoRa Alliance and defines a MAC protocol and a system architecture for networks based on the physical LoRa layer. LoRaWAN provides an environment access mechanism that allows multiple end devices to communicate with a LoRa modulation gateway.

LoRa communications networks operate under a star-like topology where communication between end-devices and a central network server is done through gateway nodes that transparently transmit messages. The final devices communicate data taken from sensors to gateways, and these gateways will connect to a server through a network connection other than LoRaWAN. Usually, this connection is made through the WiFi protocol. Communications are bidirectional under this protocol, and uplink messages have priority. The LoRaWAN protocol operates in the free frequency band, between 863MHz and 870 MHz in Europe and 433 MHz in the United States [4].

In Fig. 1, it is presented the main stack layers of the LoRa architecture that are related to each other and how the ISM bands are used based on the geographical area. The Application layer does not directly relate to the MAC layer and the physical layer, so it is realized at a higher level based on the data saved on the server.

This paper presents a study about LoRa architecture with practical implementation in agriculture. Section II reviews state of the art in this area, while Section III describes the architecture we proposed. In Section IV, we made a comparison about LoRa vs SigFox, and the conclusions are drawn in Section V.

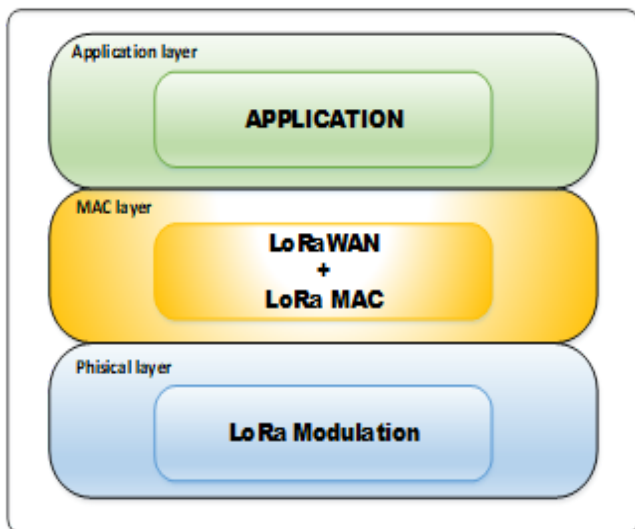

Fig. 1. The Main Stack Layers for LoRa Architecture.

## II. RELATED WORK

Integrating IoT technology into agriculture is not new; it has been introduced and implemented repeatedly but not on a vast scale but usually at the prototype level. The geographical areas with the greatest need for these technologies typically do not have people specialized in this direction or financial support. Interest in IoT technologies in agriculture has continued an upward trend in recent years, evidenced by outstanding research. One such work is [6], where the authors implemented a system based on a WSN architecture. In this paper, the researchers focus on real-time monitoring of temperature, light intensity, and humidity parameters. Once collected, this data is transmitted further through the LoRa-based gateway, and then visual processing and tracking are performed using a cloud tool. They concluded that the proposed architecture did not cover more than 600 meters following their research.

In [7], Klaina et al. propose a multi-scenario-focused approach to large-scale monitoring using multiple LPWAN technologies. This paper focuses on a network of sensors and various communications links. These sensors are mounted on both tractors and farmers. They came up with this proposal to evaluate and improve the equipment's performance and to monitor and manage them as efficiently as possible. At the level of this paper, different data links were tested to take into account the impact of soil, spatial distribution and infrastructure elements present. Their study showed that LPWAN networks provide better performance in the range covered. Still, better communication links were observed than in the traditional ZigBee network.

The study by Miles et al. [8] presents an evaluation of the performance of a LoRaWAN network using an NS-3 simulator. The authors propose and validate in this paper a mathematical model that focuses on estimating as accurately as possible the successful delivery of data packets on the network presented in a pilot farm starting from the transmission intervals and the number of nodes that make up the network. The conclusion they reached after conducting this study, consisting of a single network gateway and up to 1000 nodes, is that the proposed LoRaWAN architecture is suitable for various implementations in agriculture.

The performance and implementation of LoRa technology are not limited to agriculture, so there are many areas in which this technology has been successfully addressed. An example of such an implementation is made in [9], which proposes a street lighting monitoring system in a smart-city approach. Remote management and control of LED lights are done through LoRa technology. In another research paper [10], the authors propose a system for remote monitoring of forest fires in areas that are difficult to access through LoRa technology. The authors of this paper emphasize the importance of the distance covered by the system but also the reliability of the implementation.

Another proposal in which LoRa technology occupies a prominent place is the authors of Maftei et al. [11], in which a health application is implemented. In this paper, the authors designed a device to monitor the main health parameters such as heart rate, body temperature, blood oxygen saturation, and

the battery level that powers this system. This information is transmitted to a gateway via the LoRaWAN protocol, and then this information is processed and stored in a blockchain network. The achieved conclusion of this study shows that the LoRa protocol can be integrated well into the remote healthcare system but also in applications based on blockchain technologies.

In this section we have noticed that the LoRa technology and LoRaWAN protocol have multiples areas of application but although each study adds to the whole research ecosystem it should be noted that there are gaps. Some of these would be the fact of the distance covered; can this technology cover the expected distance in the agricultural sector as well? Or the values remain valid only for other types of applications in different fields, so this paper addresses and disseminates this fact. Another question that arises as a result of the research is how accurate is the data? Thus, even if the data obtained in the mentioned studies fall within reliable data, in the agricultural sector there is a danger that depending on the device used, the data will not correspond to reality, so in this study, we want to combat this phenomenon.

## III. System Description

To demonstrate the reliability of the LoRaWAN communications protocol in terms of implementation in agriculture, we propose a system architecture consisting of three main blocks: the final device or end node, the gateway, and the application server. The functionality of each component that composes our system will be described below.

### A. The End Node

In our paper the development board from STMicroelectronics, namely the NUCLEO-L973RZ board [12] represents the end node. This board is especially notable for its low-power MCU. This tool can also be used with other development boards such as Arduino or other similar devices. In our case, we used this board together with the expansion board I-NUCLEO-LRWAN1 [13]. This board contains the LoRaWAN USI WM-SG-SM-42 module and the ST HTS221 temperature and humidity sensor but also the ST LPS22HB pressure sensor as well as the sensor that incorporates both an accelerometer and an ST LSM303AGR gyroscope; however, in this paper, we focused only on the use of the temperature and humidity sensor as well as the pressure one.

In Fig. 2, we can see the end node device, which is in use in this application.

LPS22HB [14] is an ultra-compact piezo resistive sensor that works like a digital barometer. This device consists of a sensitive element that detects absolute pressure consisting of a suspended membrane. By certain specific STMicroelectronics methods, which are not open-sourced, it measures the desired values and then communicates them further to the main application via either I2C (Inter-Integrated Circuit) or SPI (Serial Peripheral Interface) interface. LPS22HB operates at -40 ° C to + 85 ° C and can measure pressure values between 260 hPa to 1260 hPa.

ST HTS221 [15] is an ultra-compact sensor for measuring relative temperature and humidity, and it consists of a sensitive

element such as a polymeric dielectric planar capacitor. The temperature detection range is between -40 ° C and +120 ° C, and a mixed-signal ASIC (application-specific integrated circuit) is used to transmit the measured information further to the main application via digital serial interfaces.

### B. The Gateway

The gateway includes two boards supplied by the same manufacturer, namely STMicroelectronics. The first board is the NUCLEO-F746ZG development board [16], which is the support on which the LoRa protocol-specific gateway expansion board will be attached, developed by Semtech.

### C. The Server

The server used in this implementation and to which data is transmitted through the gateway is from The Things Network (TTN) [17]. This IoT server is designed especially for the LoRaWAN protocol, being a free tool that promises maximum security, is used globally in over 151 countries and whose members exceed the number of 168 thousand.

### D. System Functionality

For the application to become functional, each of the three main components has to be configured, so the software utilities offered by STMicroelectronics were used for the development boards, namely, STM32CubeProgrammer and STM32CubeIDE.

For the gateway configuration, the devices used must be set in gateway mode, a setting done by programming the firmware. This operation is done as seen in Fig. 3.

Once the gateway firmware is programmed, it has to be configured in such a way that the parameters related to the frequency in which the device will work match the geographical area we are located. At this level, particular attention should be paid to the MAC address parameter of the device. The address is required later in establishing the connectivity with the server.

Fig. 4 presents the main parameters of the gateway as seen from a connection to the TeraTerm terminal. In this terminal, we have the opportunity to modify the main specifications, such as the MAC address or the frequency band.

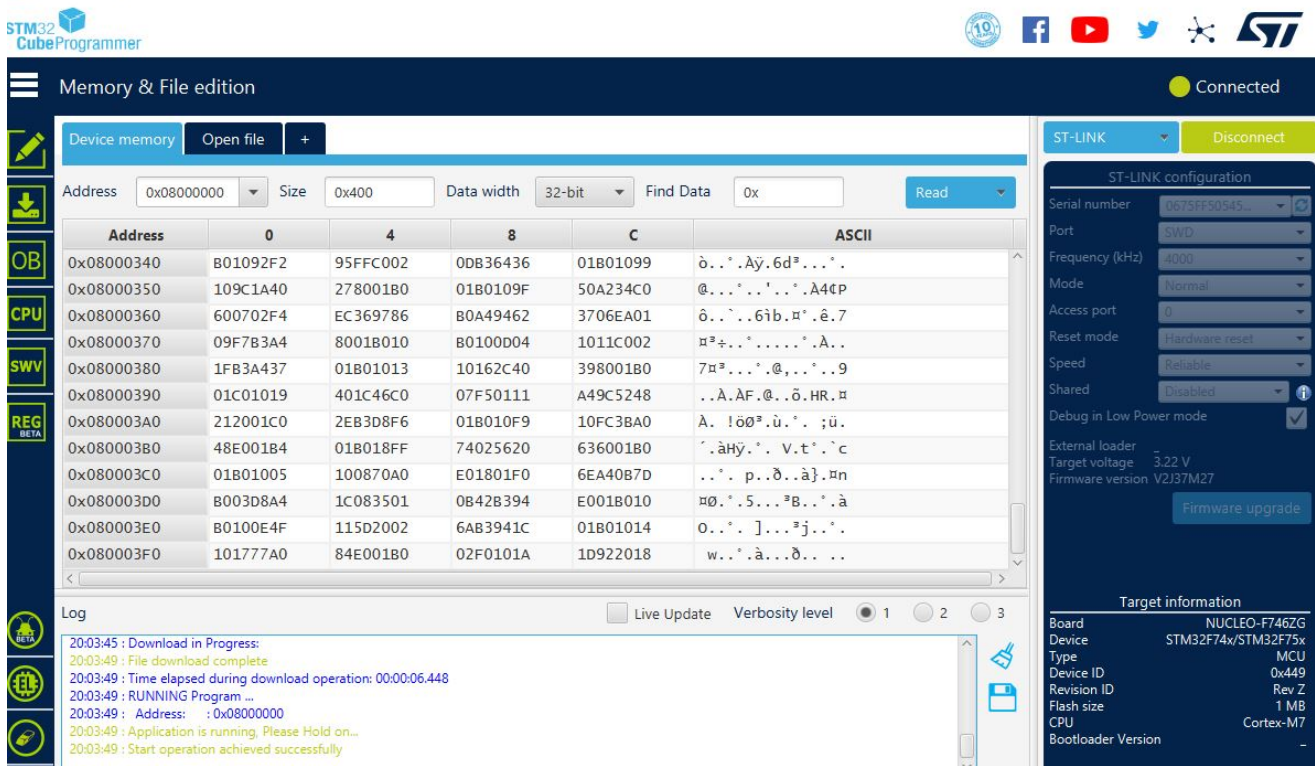
Fig. 2. The End Node Device used in this Application.


Fig. 3.    The Firmware Programming in STM32 Cube Programmer.

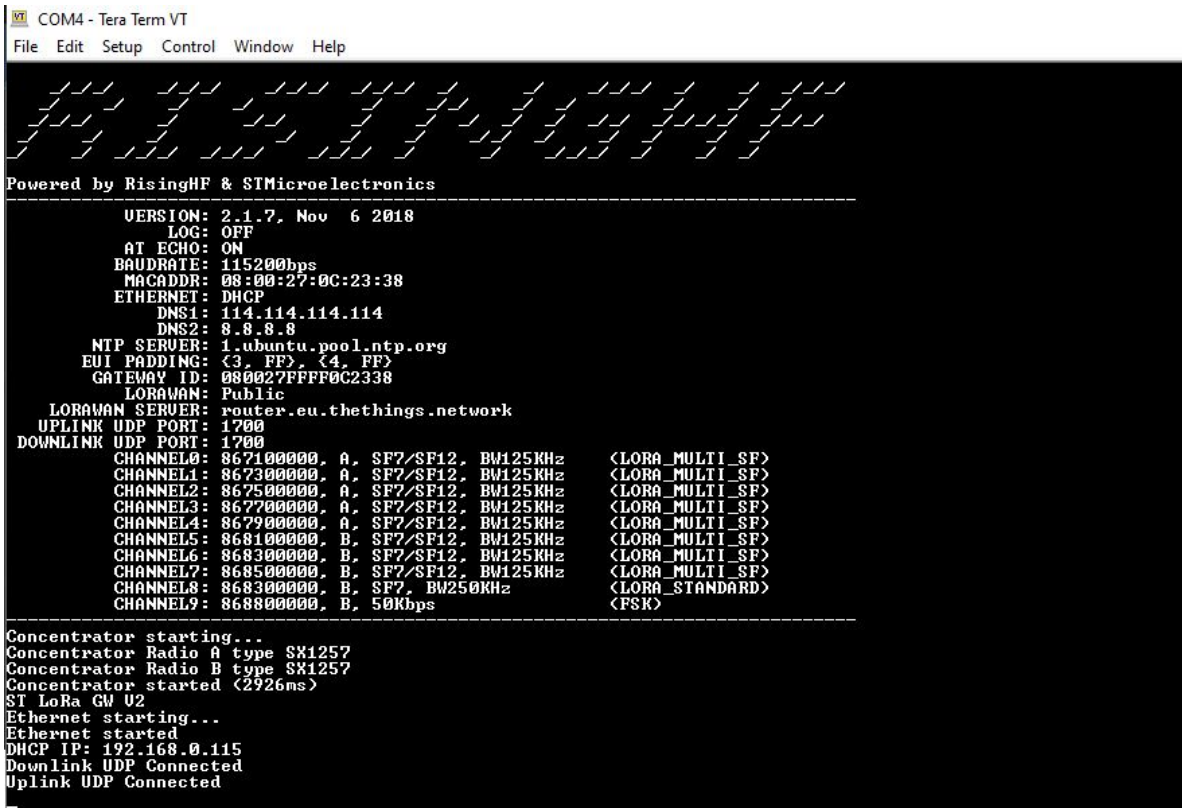

Fig. 4.    The Gateway Configuration Terminal in TeraTerm.
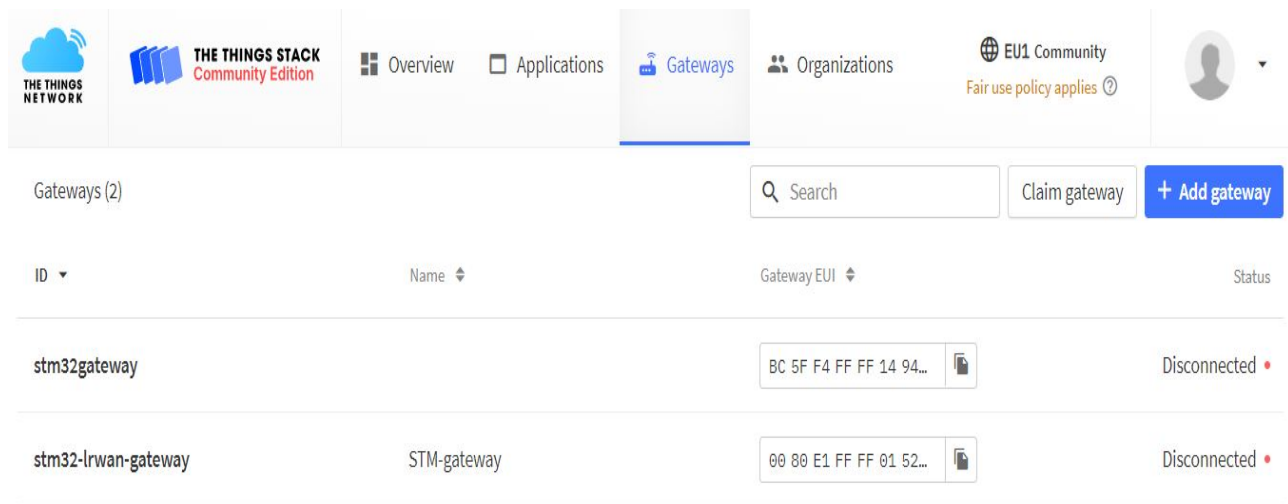

Fig. 5.   The Gateways Registered on TTN Server.

In order to be able to connect the application to the server, firstly, it is necessary to create an account on the server site and then add a device either as an end node or as a gateway. After completing these steps and verifying the connection functionality, the values received from the end node located in the remote area can be viewed and processed from the final application in TTN.

In Fig. 5, it can be seen the main interface of the gateways registered on the server. Here we can add another gateway or end device, and we can see the status at the time being. The gateways are displayed based on the MAC addresses enrolled initially.

## IV.  LoRa vs SigFox

Both the LoRaWAN protocol and SigFox are part of the same category of IoT technologies, namely LPWAN technologies, but the principle of operation differs. Our paper started from the premise of using such a system in agriculture. In this paper and in the previous one [18], both devices were integrated into the environment, but the particular emphasis was placed on how the data was transmitted and processed.

Thus, after making and completing all the necessary connections, we could see a significant advantage that the LoRaWAN protocol has compared to SigFox, namely, the coverage.

If in the previous paper, due to our geographical position, namely the northeastern region of Romania, we could not connect the system to a gateway and then to the actual SigFox server, this time using LoRa, we were able to configure our gateway. We also connected to a server that would allow the recording and processing of transmitted data. In addition to connecting to an already created server, the advantage of LoRa is that with the necessary hardware components, we can create our own server and integrate it into an application.

In this study, the emphasis was on creating a complete system for the agricultural sector for implicit monitoring of the main factors influencing the evolution of various crops, starting with the network node or end device and creating the final application as a result of data obtained from the server. This system was created to see how the LoRa infrastructure, which consists of the LoRa modulation technique and the LoRaWAN communication protocol [19][20], relates to the environment in which it is used and the additional benefits that this technology brings.

## V.  Conclusion

In the introduction of this paper, we started from the premise of comparing it with another work conducted in a different paper in the same field of agriculture but which is based on a different communication protocol, namely the LoRaWAN protocol compared to the SigFox protocol. The conclusion we have reached is that LoRa technology has a clear advantage ensuring a better connection. Once a gateway is configured, the data transmission does not depend strictly on the manufacturer's servers, as in the case of the SigFox protocol. Still, it can use open-source servers or even you can set up your own servers.

Another aspect that should be mentioned is that using the development boards mentioned in this paper, STMicroelectronics offers considerable support when it comes to configuring, programming and viewing the code used in different instances of the application.

Finally, we can conclude that as a LPWAN technology, LoRa, is a reliable solution in the field of agriculture and offers advantages from superior to traditional technologies. Also, an important thing to note is that this protocol allows users from everywhere to contribute to the development of its effectiveness.

*Abstract*—Most existing identification and tackling of chaos in swarm drone missions focus on single drone scenarios. There is a need to assess the status of a system with multiple drones, hence, this research presents an on-the-fly chaotic behavior detection model for large numbers of flying drones using machine learning techniques. A succession of three Artificial Intelligence knowledge discovery procedures, Logistic Regression (LR), Convolutional Neural Network (CNN), Gaussian Mixture Models (GMMs) and Expectation–Maximization (EM) were employed to reduce the dimension of the actual data of the swarm of drone's flight and classify it as non-chaotic and chaotic. A one-dimensional, multi-layer perceptive, deep neural network-based classification system was also used to collect the related characteristics and distinguish between chaotic and non-chaotic conditions. The Rössler system was then employed to deal with such chaotic conditions. Validation of the proposed chaotic detection and mitigation technique was performed using real-world flight test data, demonstrating its viability for real-time implementation. The results demonstrated that swarm mobility horizon-based monitoring is a viable solution for real-time monitoring of a system's chaos with a significantly reduced commotion effect. The proposed technique has been tested to improve the performance of fully autonomous drone swarm flights.

*Keywords—Chaos detection; swarm of drones; machine learning; autoencoder; Rössler system*

## I. INTRODUCTION

A swarm of drones is a group of two or more drones that exchange data and work as a single cooperative unit to accomplish a specific mission objective. Drone coordination has been extensively researched in the fields of surveillance systems, precision agriculture, transportation, disaster management, and entertainment [1] [2].

A swarm of small aircraft allows for a larger mission area, more flexible mission capabilities, greater resilience against single-point failure, and lower costs. Swarm drone research has covered a wide range of topics, including collision avoidance [3], [4], [5], [6], mission-level planning and control to enable high-level autonomy [7], [8], the human operator's communication with a swarm of drones [9], [10], ad hoc backbone network customized for a swarm operation, and the construction of small-scale airborne vehicles [11], [12]. Previously, technology-oriented research focused on how to improve performance and capacity [13], [14], [15], but more recent research has focused on making such swarm systems more safe, secure, and reliable to operate [7], [16], [17]. Studies in the development of new coordination algorithms that combine biological processes are based on self-regulation [18], [19], and environmental adaptability to allow a swarm of drones to work with greater sophistication, reliability, scalability, and flexibility [20].

A number of practical issues that might disrupt the successful completion of the swarm mission could arise during the operation of a swarm of drones. For example, the energy consumption limitation of drones, which limits drones in their ability to handle long-term flight, may cause one or more drones in the swarm to experience failure, necessitating the development of an intelligent, efficient power failure mechanism. Alternatives for aerial path loss should also be considered while maintaining drone security and safety. When considering a multi-drone environment, where a small or large group should operate together or act in the same aerial environment, various flight problems and obstacles, in addition to the aforementioned chaotic difficulties, may arise, such as weather conditions and signal loss. These chaotic issues, however, impose a number of constraints on the use of swarms of drones and must be addressed in real-time.

The ability to monitor or manage the disorder or instability of the drones in a swarm, and take predictive and critical steps as needed for the safe and dependable operation of swarm drones, is referred to as chaos handling. Many factors can have an impact on the system's health, such as issues with the drone system's actuators and sensors, communication connection flaws, and possibly hostile cyberattacks. Determining such causes requires a thorough understanding of the system, mission, and surroundings. Therefore, detecting chaos in swarm system behavior is the first step toward managing the system's health. This is crucial even when the source or type of chaos is unknown.

Despite extensive research into traditional model-based approaches for fault handling, identification, and isolation, particularly in aircraft safety systems, there are no known existing solutions for dealing with chaos among drones [21] [22]. Failure Detection, Identification, and Recovery (FDIR) has recently been extended to swarms of drone systems in terms of operations [23], and resistance against cyberattacks

[23], [24], [25], but there is still a need to address chaos among the swarm of drones, regardless of whether the causes of such chaos are known or unknown. In [26], evaluation of drones that use onboard sensor data for Failure Detection, Identification, and Recovery (FDIR) using a cooperative virtual sensor system for the design and experimental verification of techniques and procedures for handling chaos in swarm drone systems was done. Furthermore, compared to large aircraft, drone swarms are a new market entry; thus, failure mechanisms and chaos are not widely implemented or in use. Therefore, statistical methods which do not rely solely on the physical-based model of the drones may be a more viable option for detecting and mitigating chaos in the current swarm of drone systems. Thus, in this study, an attempt was made to develop a machine learning-based model for chaos detection in a swarm of drones; and a mitigation technique to deal with such chaotic conditions is also proposed.

The remaining sections of the paper are organized as follows: Section II discusses related works, while Section III describes the machine learning methods used in detecting and mitigating chaos in real-time swarm dataset. Section IV describes the chaos detection modeling process, while Section V presents the results of the model evaluations to demonstrate the effectiveness of the chaos detection and mitigation strategies for swarms of drones. Finally, the conclusion was presented in Section VI.

## II. RELATED WORK

Several significant studies have been conducted in order to apply data-driven machine-learning algorithms for detecting faults and anomalies in aerial vehicles. Some researchers combined chaotic dynamics with powerful swarm-based algorithms used in mobility models such as Ant Colony Optimization (ACO), Artificial Bee Colony (ABC), and Particle Swarm Optimization (PSO) [27], [28], [29]. The Lorenz and Rössler attractors are time-discretized, and the three-dimensional chaotic maps are addressed via a three-dimensional solvable chaos graph built from general chaos solutions.

A three-dimensional path planning for Unmanned Aerial Vehicles (UAVs) based on chaos particle swarm optimization, which addresses the shortcomings of particle swarm optimization (PSO) was proposed in [30]. However, the solution quickly falls into a local optimum and gradually converges with poor precision in a motion phase. The concept of the Chaos Optimization (CO) algorithm was incorporated into the PSO algorithm through in-depth analysis based on the conventional update operations on the velocity and location of the mobile nodes in the swarm. As a result, track preparation searches are eliminated and rapidity followed by convergence precision is enhanced.

In [31], a basic two-dimensional solvable chaos map was used to mathematically analyze chaotic modeling and simulation on a dynamic coordinate. Also in [32], a chaotic-based approach was used to maintain coordinated flight formation of swarm unmanned aerial vehicles at a low input cost. A study in [33] focuses on a discrete dynamic map (logistic map) to generate a chaotic sequence of bits [33]. The bits are then translated into locations that allow the robots to

construct a deterministic route plan. Meanwhile the R-UAVs are fractional three-dimensional when using the Qi system [34]. As a result, a three-dimensional chaotic dynamic solution should be used to model the mobility model of swarm UAVs.

The 3D chaotic-based-approach is used in ASIMUT to implement dynamic system mobility models for UAVs in an unpredictable regime. This mobility model is supplemented by a hybrid mobility model called Chaotic Ant Colony Optimization for Coverage (CACOC), which combines the ACO with the system's three ordinary differential equations. The mobility model is data-centric in a multi-level swarm perception networked on the multi-layer FANET architecture [35], [36]. Also, a collision avoidance technique was incorporated into a predictive mobility model, based on the assumption that all UAVs were flown at different altitudes to avoid collisions [37]. However, this may not be realistic in some UAV swarm applications.

For real-time detection and monitoring of aviation system abnormalities, a Multivariant Gaussian Mixture Model (MGMM) was proposed [38]. Also proposed was a Recurring Neural Network (RNN) method for events and trends which can reduce the security margins of a system using a dataset from a Flight Data Recorder (FDR) [39].

A K-nearest neighbor (KNN) methodology was introduced in [40] to identify the reasons and factors for drone failures and potential deteriorations in drone performance on the ground in order to assess the causes of failure and potential deterioration in drone performance during flight. An actual flight dataset was used in [41] to validate the developed Anomaly Detection (AD) model, which shows if there is any abnormality in the swarm drone flight. For the generation model, the AD model created a training model using a Deep Neural Network.

Most of the work done has focused only on the health management of a single drone; no methodological approach for the reliable detection of chaos in swarm flights has been proposed, with the goal of overcoming the aforementioned swarm drone behavior constraint. For example, an end to end fault analysis framework for a single micro aerial vehicle that only considers anomalies with obstacle detections [54]. Some studies used artificial neural network for sensor-based fault detection [55]. As a result, this current study proposes a machine learning-based, data-driven methodology for detecting chaotic anomalies in swarm flights. The proposed method aimed to address both the lack of marked recorded information in swarm flights and the disparity between non-chaotic and pathological data. This study investigates the use of moving average-based monitoring with a limited time frame to reduce noise in continuous monitoring while also allowing for responsive chaos detection.

In general, supervised learning approaches outperform unsupervised learning methods in classification problems. However, in the case of chaos detection, a relatively new type of self-supervised knowledge extraction that outperforms the fully supervised technique has been reported. As a result, this method can be used to detect chaos in in-flight data. A highly sophisticated self-supervised framework that outperforms all other unsupervised methods, and demonstrated that the

completely controlled approach ranks better and outperforms the other methods was developed in [42].

This paper backs up this claim by demonstrating that supervised learning is still a viable core framework when a significant amount of labeled data is available, and an adequate labeling process can be produced. This study makes three significant contributions: It (a) proposes a systematic process for data-driven chaos identification in swarm flights, (b) generates a real-time solution to such chaos, and (c) validates the method using real flight test data.

## III. METHODOLOGY

The following methods were used in this study to detect chaos in a swarm of drone flights: First, a set of unsupervised learning methods were employed: An Autoencoder (AE) was used to reconstruct and reduce the time series dimensionality of flight data, and then an Expectation–Maximization (EM) clustering by Gaussian Mixture Model (GMM) separated the flight data time series dimension into four categories: true chaos, unsure chaos, doubtful normal, and truly normal. Then, a Deep Neural Network was trained to extract features and detect chaos, which is a 1D-CNN concatenation of a single, multi-layer logistic regression perceptron neural network [43].

To properly identify chaos and handle it, three decisions must be made: (a) detecting chaos symptoms in the swarm, (b) identifying which drone is in chaos, and (c) providing a solution to such drones in a state of chaos. The chaotic detection technique makes these decisions by observing the kinematic characteristics of the drones, such as a drone's location and velocity. This chaos detection scheme is located at the ground station or controller, which monitors the health and the flying status of all swarm vehicles; thus, it transfers drone data to the ground station, where it is processed by the chaos detection scheme to show flight normality.

In this study, the swarm system employed a real-time Kinematic Velocity (KV) GPS-based precision navigation method as described by [44]. The dataset used as learning data for recognizing chaotic behavior during swarm mission execution was sourced from a series of swarm drone flight tests conducted by the Korean Aerospace Research Institute, in which up to 30 quadcopter drones were deployed [41].

A total of 50 tests were conducted, with individual and multiple groups of test drones. The output data from each drone trajectory consists of 248 parameters presented as time series, some of which include numerous observations of various parameters. As critical characteristics in detecting chaos in motion, three sites were chosen: the drone location and set point values, three-vehicle speed components, and vehicle status. The KV-GPS data, in which the accuracy was validated in [44] was used to calculate the location coordinates $(x_t, y_t, z_t)$ and velocity components in three dimensions for the drones. The following three parameters in Equation 1 are also considered chaotic, as they can be associated with errors between intended and actual behavior during drone movement coming from mission control.

$$x = x_t - x_s$$

$$y = y_t - y_s$$

$$z = z_t - z_s \qquad (1)$$

Also, inertial navigation system readings labeled GA from accelerometers and gyro sensors may also cause mechanical faults in drone systems because they can cause unexpected acceleration and angular rate behavior. Thus, the drone status indicator is used to verify the data consistency and calibration. Since this research aimed to develop a chaos detection and mitigation method that is independent of drone type and features, datasets are not tagged with drone identifiers as a result. Fig. 1 depicts an illustrative view of the swarm system configurations.

It should be noted that these topological indicators are not always the whole set of characteristics required to identify all potential chaos in swarm flights. These are, nevertheless, crucial indicators for sensing chaos produced by specific kinds of errors and failures. As a result, this research detects and identifies chaotic behavior using topological indicators and produces a solution to such a problem using a chaotic attractor. Also, the flight trajectory dataset is only partially labeled. Some of the incorrect events discovered during the flight test are classified as chaos. Table I lists the features of the indicators utilized in this paper.

Fig. 1. Configuration of the Swarm of Drone System.

TABLE I. PARAMETERS EXTRACTED FOR DRONE SWARM FLIGHT ANALYSIS

| Drone Parts | Parameter Description | Attribute |
|---|---|---|
| Drone state | Hovering Navigating | Discrete |
| Trajectory | Position $(x_t, y_t, z_t)$ | Continuous |
| GA | Gyro (Rate and integrals of drone body frame) Accelerometer (Axis (x,y,z) values and integrals of accelerometer) | Continuous |
| KV-GPS | Inertial Velocity Vectors and Positions | Continuous |

## A. Machine Learning Algorithms

This section discusses four machine learning methods that were used in this study to develop a data-driven chaos detection strategy. The first two are unsupervised learning algorithms that work with unlabeled data, whereas the last two are supervised classification algorithms that work with labeled data. The details are as follows:

*1) Autoencoder and Chaos Detection (AECD):* Autoencoder-based chaos detection (AECD) is a semi-supervised learning-based chaos identification technique. As part of this study, an autoencoder was used to compress the raw flight input data. Autoencoders (AE) are neural networks that are statistically based on a given probability distribution [45]. The autoencoder consists of two sub-models: encoder and decoder. The encoder compresses the input, while the decoder attempts to reconstruct the input from the encoder's compressed form. After training, the encoder model is saved, whereas the decoder is destroyed. For machine learning training, the encoder is then used as a data preparation tool, to extract features from raw data.

A single-layered neural network has an encoder and a decoder, as shown in Equations (2) and (3). This is the nonlinear transformation function of the autoencoder. Equation 2 depicts how an affine mapping uses nonlinearity to convert an input vector $d$ to a hidden vector $h$. In Equation 3, the decoder uses the same transformation as the encoder to rebuild the cached representation h back to the initial input space. As shown in Equation 4, the reconstruction error is defined as the difference between the original input vector $d$ and the reconstruction $z$. The reconstruction error is minimized via the autoencoder.

$$h = \sigma(W_{dh}d + b_{dh}) \qquad (2)$$

$$z = \sigma(W_{hd}d + b_{hd}) \qquad (3)$$

$$Reconstruction\ error\ =/\ d - z\ / \qquad (4)$$

where, $w$ and $b$ are the weights and biases of the neural network.

By adding noise to the original input vector d, the autoencoders use a noisy input vector $d'$ as the input vector. In other words, a noisy input d' was fed into the autoencoder in order to recreate the original input $d$. In this way, the autoencoder is protected from white noise in the data and collects only significant patterns in swarm flight data [46]. The reconstruction error is then calculated by measuring the difference between the final output and the noisy input reconstruction. The reconstruction error is then used to determine the chaos score.

Data points with a high degree of reconstruction are described as chaos. To train the autoencoder, only data with normal occurrences is utilized. The autoencoder will successfully reconstruct normal data after training but will fail to reconstruct chaotic data that the autoencoder has never seen. Algorithm 1 depicts the chaos detection technique based on autoencoder reconstruction errors.

$\quad\quad\quad\quad\quad\quad$ **end if**
**end for**

---

*2) Clustering using Gaussian Mixture Models (GMMs) and Expectation–Maximization (EM):* The flight data points were assumed to be distributed randomly in a Gaussian manner. Gaussian Mixture Models (GMMs) were used to simulate the data. Each flight data cluster's Gaussian parameters were determined using two parameters derived from an optimization technique called Expectation-Maximization (EM): the mean and standard deviation. Therefore, drone clusters can have any elliptical shape since the standard deviations in the x and y axes are obtained. As a result, each Gaussian distribution has exactly one cluster. The hidden variables were used to find the Maximum Likelihood Estimators (MLEs). Since the AECD model contains latent variables, maximum likelihood estimates of the model were sought using the EM method. As a result, the log-likelihood is as shown in Equation 5.

$$\log\big(P\ (D|\theta)\big) = \log(\textstyle\sum_z P((D,Z|\theta)) \qquad (5)$$

Where, $D$ represent the total number of observable variables

$Z$ represent the total number of latent variables, marginalized from the joint distribution.

Assuming datasets $D$ and $Z$, were selected at the same time, the entire dataset is referred to as {$D$, $Z$} and the incomplete dataset is referred to as D. From the original dataset, $Z$, is unknown, but the posterior $P(Z|D,\Theta)$ contains the information about $Z$. Therefore, the log-likelihood expectation was analyzed by using the M-step process to evaluate the posterior probabilities. The expectation of the entire data log-likelihood was maximized to get a new estimated parameter via the E-step process. The current value of the parameters $\theta^0$ was used in the E-step to obtain the posterior distribution of the latent variables, which is provided by $P\ (Z\ |D,\ \theta^0)$. This expectation, represented by $Q\ (\theta,\ \theta^0)$ is shown in Equation 6. The new parameter $\theta'$ is then determined in the M-step by maximizing $Q$ as shown in Equation 7.

$$Q(\theta, \theta^0) = E_{(Z|D,\theta^0)}[\log((D, Z|\theta))] =$$
$$P \sum_Z P(Z|D, \theta 0)\log(P(D, Z|\theta)) \quad\quad (6)$$

$$\theta' = argmax_\theta Q(\theta, \theta^0) \quad\quad (7)$$

where

$\theta = \mu_1, \cdots, \mu_k, \sigma_1, \cdots \sigma_k, \pi_1, \cdots, \pi_k$ are the unknown parameters used in deriving the MLE Gaussian Mixture Model. The relevant quantities for GMM are then derived to form the complete likelihood as shown in Equations 8 and 9.

$$\log(P(D, Z|\mu, \sigma, \pi)) = \sum_{i=1}^n \sum_{k=1}^m \quad )I(Z_i = k)(\log(\pi_k) + \log(N(D_i|\mu_k, \sigma_k)) \quad\quad (8)$$

$$E_{(Z|D)} \log(P(D, Z|\mu, \sigma, \pi)) = \sum_{i=1}^n \sum_{k=1}^m Y_Z(k)(\log \pi_k + \log(N(D_i|\mu_k, \sigma_k))) \quad\quad (9)$$

The posterior probabilities $\gamma Z_i(k)$ was evaluated from the current values of $\mu_k$ and $\sigma_{k..}$. Since $E_{Z/D}[I(Z_i=k)] = P(Z_i=k|D)$, marginal probability distribution can thus be replaced with the posterior probability $\gamma_{Zi}(k)$.

Hence, Expectation-Maximization is derived as follows: first, initial values were chosen for the parameters $\mu$ $\sigma$, and $\pi$, these parameters were employed in the E-step to evaluate the posterior probability $\gamma_{Zi}(k)$. With fixed $\gamma_{Zi}(k)$, the expected complete log-likelihood is maximized as shown in Equation 9 with respect to $\mu_k$, $\sigma_k$, and $\pi_k$.

*3) Convolutional Neural Network (CNN):* Convolutional Neural Network concept was used to extract features from drones' trajectories. It was noted that CNN has made great strides in handling two-dimensional image data and thus for one-dimensional time series data, locality/dispersion may also be used [43]. The CNN network structure employed in this study for cataloguing and classification comprises a stack of one-dimensional convolutional and max-pooling layers, including an additional global-pooling or flattening layer connected to the max-pooling layers. A Multi-layer Perceptron (MLP) is linked to the output layer of the one-dimensional CNN and then stochastic gradient descent is used to maximize the weights of both the MLP and CNN simultaneously [47]. A nonlinear activation function is used to transform a perception y into a linear combination that uses its weighted inputs to generate a single output which is dependent on many real-valued inputs (from the GMM and EM outputs). The perceptron is expressed in Equation 10.

$$y = \varphi(\sum_{i=1}^n \omega_i D_i + b) = \varphi(w^T x + b) \quad\quad (10)$$

*4) Logistic Regression (LR):* Logistic Regression (LR) was used for two-class classification in this study. LR is one of the easiest and most widely used methods of machine learning that can be used for two-class classification. It is a statistical method for predicting binary classes with intrinsically dichotomous values or target variables like one and zero. Equation 11 can be used to express the logistic regression hypothesis.

$$y = (1|1 + \exp(-(\beta_0 + \beta_1 D_1 + \beta_2 D_2 +, \cdots, \beta_m D_m) \quad\quad (11)$$

where, Dm denotes the explanatory features of the flight data and; βm denotes the related coefficients that will be optimized via a learning process.

Because y has a value between 0 and 1, the result can be interpreted as the likelihood of fitting to class 1. As shown in Equation 12, the most common loss function for optimizing coefficients is maximization of output probability.

$$loss(z, y) = -\sum_{i=1}^n (z_i \log y_i + (1 - z_i)\log(1 - y_i)) \quad\quad (12)$$

where, *n* represents the amount of data points and;

*z* represents the desired outcome.

Equation 12 illustrates how the loss function can also be viewed as the cross-entropy between z and y. Instead of using a neural network, this sigmoidal activation function is commonly used for categorization. In this scenario, the network is trained to minimize the cross-entropy loss.

*B. Rössler System (RS)*

The Rössler System (RS) was used to handle any drone's trajectory in the swarm that remains in a state of chaos. As shown in Equation 13, the numerical solution for a drone's three-dimensional trajectories is given as a fractional order of the Rössler System [34]. The data for the a drone's three coordinates in the (*x,y,z*) axis is given by a time step t.

$$\begin{cases} D_t x = y - z \\ D_t y = x + ay \\ D_t z = b + z(x - c) \end{cases} \quad\quad (13)$$

The RS is composed of three Ordinary Differential Equations (ODEs) with only one non-linear term, with constant values *a = 0.2, b = 0.2, and c = 9.0;* thus, each ODE can represent a dimension of a drone's flight trajectory [36], [48]. The synchronization of the RS with machine learning algorithm for trajectories in chaos was achieved after eliminating the leading drone's trajectory flight data observations. In order to remove the transient states, a numerical solution was constructed for this system using the fourth-order Runge-Kutta approach and record time points with each time step being *t = 0.1*.

## IV. CHAOS DETECTION AND MITIGATION MODEL DESCRIPTION

The details of the model description are as follows:

*A. Model Architecture*

Fig. 2 depicts the general architecture of the model for detecting and mitigating chaos in a swarm of drones. The flight test data used for this study were collected in advance but when swarm flight data is provided in real time, it is not automatically labeled. This is normal in chaos detection instances since the data can only be plainly labeled in the presence of a functioning chaos detector or if human investigators have thoroughly examined the data. As a result, the data was initially grouped and labeled into various relevant

groups using a clustering method. Four criteria are addressed in this study's labeling method because of the ambiguity in chaos judgments: Normal (N), chaos (C), tentative normal (Ñ), and tentative chaos (C̃). The last two categories were included because there are times when it's unclear whether the data provided is sufficient to determine whether a flight's behavior is chaotic or normal. After the labeled data has been secured, a binary classifier based on CNN was trained and validated on a set of training data to understand the critical characteristics in identifying chaos in swarm flight data. The trained model may then be utilized for both post-flight analysis and real-time chaos monitoring as a chaos detection technique. Meanwhile, as a chaos handling technique, the Rössler system was used to generate new flight paths for drones in the swarm that are in a chaotic state.

### B. Data Preparation

A total of 73,749-time series dataset were generated as a result of the data preprocessing analysis, which includes data cleaning, integration, and transformation.

*1) Data cleaning:* The data cleaning process includes the completion of missing values, the filtering of excessive noise, the elimination of outlines, and the resolution of solution discrepancies. The difference between the real and reference positions of the drones in the swarm, as well as the actual velocity, are used as input data. To correspond to the timestamps of the two distinct data sources, a linear interpolation approach was used. In order to get a different value to real data at the same time, a linear interpolation of reference data with low noise relative to actual signals was performed. Excessively high values, possibly due to the training dataset, remove noise aberrations.

*2) Data integration:* Data from multiple drones were combined to create a dataset containing drone identification numbers. The drone identification numbers are not explicitly used in the learning process, but they are necessary for evaluating the performance of the learned model. One label, a one-time stamp, and six kinematic variables are also included in the input data.

*3) Data normalization:* The goal of data normalization is to keep the array of values for the specified parameters within a certain range. The well-known standardizing approach was used in this study. As shown in Equation 14, the standardization approach normalized each data sequence by

computing the mean ($D_{mean}$) and standard deviation ($D_{std}$) values.

$$D_{normalized} = (D - D_{mean}/D_{std} \tag{14}$$

### C. Data Labelling and Clustering

Sensors mounted on drones produces multidimensional data which is characterized by a complex correlation, making it difficult to define the system's status. An autoencoder and chaos detection (AECD) algorithm was used to reduce the dimensionality of the data by identifying the primary correlation pattern between the variables. AECD is based on the assumption that the majority of system states can be adequately described by the characteristics of a few key components, and it has proven to be a successful feature extraction technique in a variety of situations [49]. The encoded kinematic information is represented by a six-dimensional AECD algorithm to produce the rate of cumulative dispersion to encode the component axes of a swarm of drones.

The clustering approach was used to facilitate labeling of unlabeled data in its raw form. Labeling data aids supervised learning processes in chaos classification by grouping data based on some kind of similarity or distance measure, making it easier for human specialists to classify the data.

This study employed clustering on the smaller space created by the AECD algorithm using Gaussian Mixture Models (GMMs) and Expectation-Maximization (EM). The time-series data for AECD was based on six variables for drone trajectories in the (x, y, z) axes and the velocity vectors (vx, vy, vz), with one drone label presented after AECD. Because the principal component axis was chosen to have a cumulative dispersion rate of 90% or higher, the number of dimensions reduced as a result of AECD may vary depending on the available flight data.

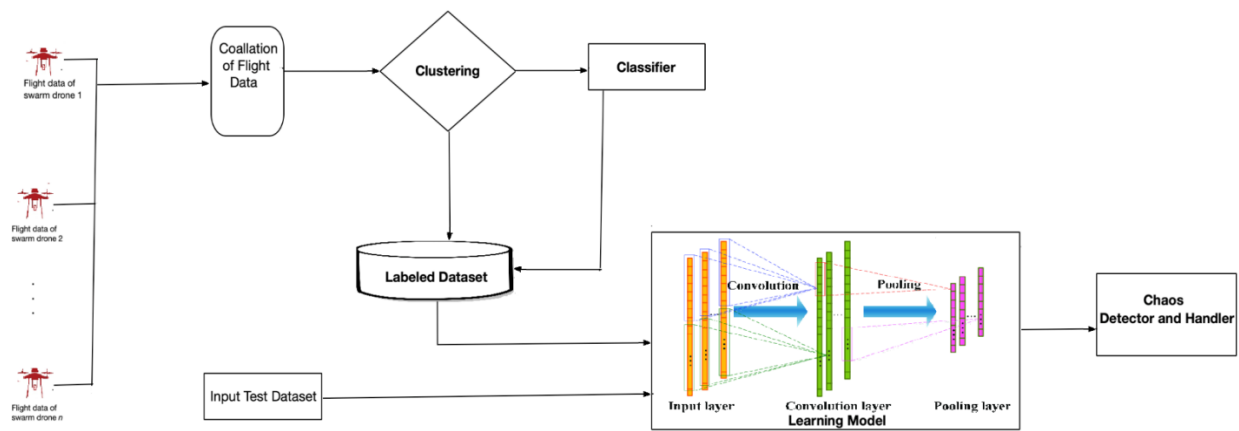
Specifically, clustering was performed on data that had been dimension-reduced, and the EM technique was used to maximize the number of clusters [50]. Based on the clustered findings, the state of each drone in the swarm was classified as Normal (N) or Chaos (C). The associated variables were obtained by categorizing them into two groups.


Fig. 2. Chaos Detection and Mitigation Model Architecture for Swarm of Drones.

It first examined the outcome of a swarm of drones in completing a specific scenario as a mission using KV–GPS data and trajectory location data. It finally checked the sensor signals to detect any chaos in the drone using the GA data. AECD, GMMs, and EM clustering are the three techniques that label unlabeled datasets into two categories: Normal (N) with a data sample of 23,501 and Chaotic (C) with a data sample of 20,266.

### D. Optimization and Classification of Data Sample

The data sample was classified and optimized in three stages. First, the data sample was standardized, then the data was classified using a CNN classifier, and finally, the classified data was optimized using Stochastic Gradient Descent with the AdaDelta optimization technique.

*1) Standardization of data samples:* After categorizing the normal and chaotic states, the drone-label information was deleted, leaving a total of six variables. To standardize the range of input variable values, a data standardization approach similar to pre-processing for clustering was used. In the labeled data, the Logistic regression technique was used for the binary categorized variables. The two-potential dependent-variable values of 0 and 1 represent the "normal" and "abnormal" results. Binary logistic models were used to assess the likelihood of a binary answer based on one or more predictor (or independent) functions.

*2) CNN Classifier:* To normalize the time sequence data of the kinematic variables specified in this study, the Gaussian Mixture Models and Expectation-Maximization technique were used. The data was first transferred through a one-dimensional Convolutional Neural Network (CNN) with six hidden layers, which was then linked to a dense multilevel perceptron with sigmoid activation at the output end. The sigmoid activation function result was compared to the target label value by reversing this error and its cross-entropy error (Equation 5), and was used to learn the overall neural network. A Stochastic Gradient Descent technique combined with minibatch was used for learning. Table II shows the details about the neural network layers and the parameters used to train the network, while Table III shows more details about

the design, it was created by first building a sufficiently large network and then controlling it with batch normalization [51].

*3) Stochastic and mini batch gradient descent in adadelta optimization:* Most neural network methods are designed to improve accuracy; they work best when each class studies the same (or comparable) amount of data. However, when the number of normal and chaotic drones is significantly different, a varied binary classification, such as in defect classification or chaotic detection, does not produce excellent results [52]. This method generates additional samples in order to achieve a one-to-one relationship between normal and abnormal data for batches in order to optimize AdaDelta to compensate for the imbalance used in the network's training [53].

The AdaDelta optimization method is a stochastic optimization methodology for Stochastic Gradient Descent with a per-dimension learning rate method. It aims to slow down the monotonously fast rate of learning. Rather than gathering all past squared gradients, AdaDelta limits the window of accumulated past gradients to a specific size. Only one example was analyzed at a time to perform a single step in Stochastic Gradient Descent (SGD). Using the SGD, the following steps were taken for each epoch:

*a)* Take the sample data,

*b)* Insert it to Convolutional Neural Network,

*c)* Find its gradient,

*d)* Use the computed gradient in step 3 for weight updates,

*e)* Repeat steps (a)–(d) for all of the items in the data sample.

Because only one example was considered at a time, the cost will fluctuate rather than decrease over the training examples. Considering, $mN$ and $mC$ denoting the number of data points labeled as normal (N) and chaotic (C), respectively. If the sampling required to produce a minibatch in the stores' gradient is carried out consistently, the predicted data quantity ratio for the two classes is $mN/mC$.

TABLE II. ONE-DIMENSIONAL CONVOLUTIONAL NEURAL NETWORK PARAMETER

| Layer | Input Variables (*n*, timestamp, 5) | Output (*n*, 160, 5) | Operation Standard |
|---|---|---|---|
| 1 | (n, 160, 5) | (*n*, 80, 10) | One-dimensional Convolutional, Rectified Liner Unit (ReLU), one-dimensional batch normalization |
| 2 | (n, 80, 10) | (*n*, 40, 20) | One-dimensional Convolutional, ReLU, one-dimensional batch normalization |

### E.  Handling Drones in Chaos

The optimized classified chaos based on the trajectories of the drones in the swarm were addressed in real time using the Poincare map from the Rössler system, with the data sample classified and labeled as chaos, mC. The Poincaré map was created by charting the function's value each time it crosses a specified plane in a specific direction.

Plotting the x, y, and z coordinates every time it passes through the x=0 plane, where x changes from negative to positive. As a result, the Poincare map converts the solutions of the three Ordinary Differential Equations of the Rössler system into the coordinates that best remove such drones from the chaotic state.

## V.  RESULT AND DISCUSSION

The detailed results are as follows:

### A.  Clustering and AECD

The flight data from a swarm of six drones was evaluated using the Autoencoder and Chaos Detection algorithms, as well as Gaussian Mixture Models and Expectation-Minimization for clustering. Fig. 3 and Fig. 4 depict the clustering results for a swarm of drones on a specific illustrative flight test day using

AECD and Gaussian Mixture Models. The first and second autoencoder components generated the distribution of data points in the reduced space; Fig. 3 is based on KV-GPS data, while Fig. 4 is based on GA data. The dimension was reduced to auto-decoded axes with a cumulative dispersion rate of at least 93% using the AECD process, and the clusters were discovered using Gaussian Mixture Models clustering with Expectation-Maximization. Fig. 4 depicts the distribution of data points in the reduced space formed by the autoencoder encoder and decoder components. A drone's data is disseminated in a very different way than data from other drones. As a result, it's reasonable to assume that data from the fourth drone in the swarm (Drn 4) will contain the chaotic time series. However, it is unclear how the clustering result is related to chaos, given that all data from a potentially problematic drone is unlikely to belong to a single cluster. The scatter plot for each cluster is shown in Fig. 5. This depicts the swarm's data point cluster. The plot aids in identifying the points of the root causes of chaos in a swarm, as well as the dependability of such points in relation to the rest of the swarm. Fig. 6 shows the percentage of data from each drone that belongs to a specific cluster. This depicts the effectiveness of such clusters of data points in relation to each drone in the swarm in order to identify the chaotic drone.

The majority of flight data from all drones falls into Clusters 4 and 9, but the distributions for the swarm's fourth drone (Drn 4) and the other drones differ. Drn 4 differs from the others in the ratio of data belonging to Clusters 4 and 9, with significantly more data belonging to Cluster 4 than Cluster 9 when compared to the other drones in the swarm. Another intriguing discovery is that data from Drn 4, a potentially chaotic drone, does not belong in Clusters 1, 2, 3, or 8. As a result, while the clustering does not indicate which drone may have exhibited chaotic behavior, the distribution of data among the clusters may indicate chaos in the flight data. Clusters 5, 6, and 7 may indicate chaos flight data, whereas Clusters 1, 2, 3, 8, and 9 indicate normal data. For the remainder of the clustering method, data from each drone in Clusters 4-6 was labeled "C," while data from Clusters 1-4, 8, and 9 was labeled "N." In cases of indistinct data, such as Cluster 3, and questionable data, such as the first drone (Drn 1) in Cluster 6, a human expert may examine the flight data to use as labeled data.

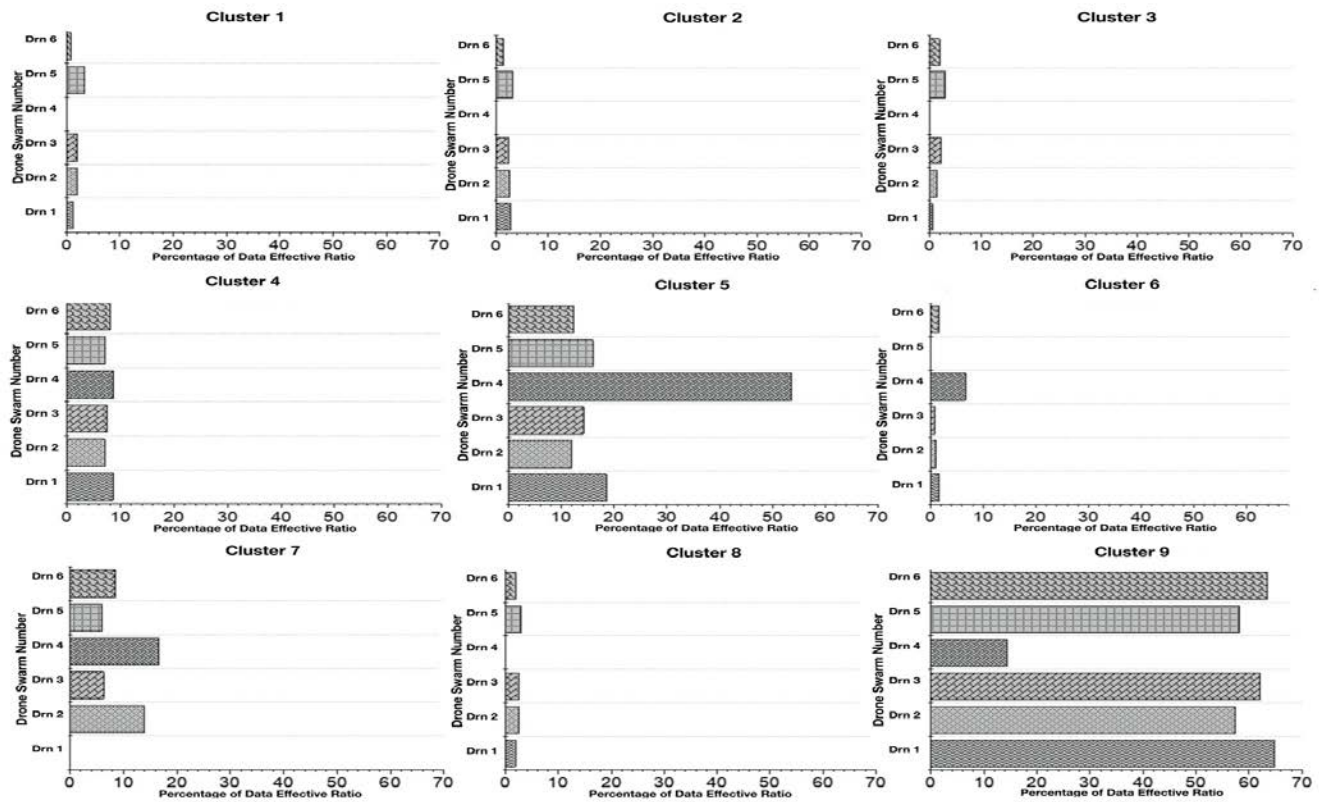

Fig. 6.    Clustering Results for Swarm Flight Data using Gaussian Mixture Models.

## B. Classification Results

The developed Convolutional Neural Network (CNN) classifier was trained until its cross-entropy and loss value converged on the learning parameters listed in Table II. The data from the test flight obtained from the swarm of drones was used as the training set of size 43,767; 70% of this dataset was used for training the neural network and 30% for model validation.

The dataset contains all of the drone's flight data, which was used to generate a test set with a size of 8,753. To validate the applicability of the sampling method, the test accuracy was equated with the variable rate of imbalance, resulting in the chaos data ratio versus the non-chaotic data in the initial dataset. If the recommended sampling is not used, chaotic swarm flight data is used in the learning process with the rate of imbalance relative to non-chaotic data. The chaos swarm flight dataset was replicated by the factor of the rate of inverse imbalance when samplings are used. The classification data accuracy was compared by the accurate classification out of all cases, which is dependent on the use of the sampling scheme to detect the differential imbalance of the original swarm flight data set. Fig. 7 compares the chaos findings of the case for the original rate of imbalance. This is the scenario when the swarm's sixth drone (Drn 6) exhibits chaotic flying behavior; only the sampling result clearly identifies chaos in the Drn 6

flight data. It is clear that the suggested sampling strategy significantly improves classification accuracy, achieving zero classification error. It should also be noted that when the sampling technique is not used, the classification accuracy is approximately 50%. One thing to keep in mind is that even with a higher imbalance rate of 0.5, there was no improvement as shown in Fig. 8.

Fig. 7.   Drone Imbalance Percentage (with Sampling).

Fig. 8.   Drone Imbalance Percentage (without Sampling).

### C. Discussion

The proposed chaos detection methods were tested to see if the trained neural network classifier was useful for time series entry using real flight test data. If the input time series did not belong to the training set, the results for a sample drone flight test data and probability were computed [43]. The swarm flight test data was used, with clustering findings shown in Fig. 5 and Fig. 6. When the time series of the entry was constantly fed into the network, the neural network's output value corresponds to the sixth drone (Drn 6). The first output comes in response to the Kinematic variables [44] in the first 16 seconds segment, as the Convolutional Neural Network (CNN) takes a length of 160 input at a data rate of 10 Hz. The neural network calculates the output in real-time in response to the most recent 160-times segment points. The possibility of being normal has been determined to fluctuate over time until it reaches zero. When the average was achieved over the entire duration of the swarm flight, the average probability value of the six drones flown in that swarm flight test was compared. There's a much higher chance that this troublesome drone will be in a state of chaos than usual. According to Drn 6, the time history of the film input variables revealed that the drone does not respond effectively to changes in the x- and z-direction in the 90s and 75s, respectively; thus, the chaos detection schema revealed that the system cannot be normal at 85 seconds from the

original data point, based on the behavior. Drn 6 crashed during the flight test, according to the original flight log. As a result of the application of the Rössler system's algorithm, the drone was sent on alternate routes assuming the chaos is in the trajectory flight data. This prevents drone 6 (Drn 6) from crashing in the test flight log. In terms of online chaos monitoring, the results showed that there were two extreme approaches to monitoring. Constant monitoring of the non-chaotic or chaotic probability allows for a high frequency assessment of system chaos. This method enables effective responsiveness in chaos detection because it constantly delivers updated information about the system's normalcy.

The output signal, on the other hand, was noticeably noisy during the transient period, as shown in Fig. 8. As shown, the average probability over the entire time duration provides a cooperative judgment on the system's chaos. Despite the fact that the decision frequency may be too low, this method may be the least noisy susceptible method. The non-chaotic/chaotic probabilities are averaged over a set period of time, and the dataset was then updated with new values.

The adjacent averaging window's time frame may overlap. The average non-chaotic probability was computed over 30 seconds and updated every 20 seconds, implying that one-third of the data is overlapped between time frames. The chaotic probability of 70 is around 40% in the first time segment window, increases to around 55% in the second time frame, and finally exceeds 90% in the third time window. This enables the chaos to be observed at a relatively high frequency while avoiding data noise.

## VI. Conclusion

This study proposed a machine learning-based chaos detection and a mitigation technique for the flight paths of a swarm of drones. The proposed techniques consist of three major steps: a labeling phase that uses lower-dimensional features to label unlabeled data, a binary/dual classification step that employs a 1-D CNN with a cross-entropy-based loss function, and a mitigation step that employs the Rössler system to generate new non-chaotic trajectories for drones in chaos. The deep neural network was trained using real flight test data. In this paper, Swarm mobility horizon-based monitoring was demonstrated to be a viable solution for real-time monitoring of a system's chaos with significantly reduced commotion effect. This technique can be used to mitigate the effects of drone crashes and failures in a fully autonomous swarm of drones.

A future focus will be the integration of network intrusion detection, monitoring, and mitigation into the overall health-management architecture of swarm drones. This could result in a more reliable fully autonomous swarm of drones by mitigating the effects of network intrusions, which can cause chaos and anomaly in a swarm of drones.

*Abstract*—Business Process Modelling (BPM) is a set of organised, structured, and related activities that boost the development and evolution of an organisation's success by understanding, improving, and automating existing business processes. Recently, the integration of Big Data Analytics (BDA) into BPM has widely gained more attention as a unique opportunity for organisations to enhance their efficiency, effectiveness, added value, and competitive advantage. However, some organisations still rely on old data-driven strategies and are late in integrating BDA into their BPM. This study aims to explore the possible contributions and challenges of integrating BDA into BPM. This study discovered that better decision making, embracing the organisation's performance, upgrading business process capabilities, and supporting supply chain management are the main contributions of BDA to BPM in organisations. However, poor data quality, shortage of BDA professionals, and data security and protection are the main challenges that hinder organisations from implementing BDA. This study provides valuable insights for organisations that intend to implement big data technologies in their business processes.

*Keywords—Big data analytics; business process modeling; BPM; organisation's performance*

## I. INTRODUCTION

Business Process Modelling (BPM) is a set of organised, structured, and related activities that operate together to accomplish an organisation's end goals. BPM is an essential factor in developing and evolving an organisation's success since it encourages understanding, improving, and automating existing business processes [1]. Additionally, Business process models must be efficiently modelled to generate a good functioning of the organisations [2].

BPM assures that the business processes are consistent and pushes business execution toward accomplishing the overall strategy and goals of the organisation. BPM enables the communication and documentation of an organisation's business processes [3]. It gives a united language and methodology for communicating procedures, information, and guidelines about the business processes within organisations. Also, BPM helps to ensure that business processes and rules are well-designed by formalising existing processes that may not be well-documented and adjusting them to be well-designed [4]. That leads to getting rid of the guesswork and confirming that these documented processes match the organisation's guidelines and legal regulations. BPM gives a clear understanding of the process's flow that influence

decision making process [5]. That helps managers figure out if there is a chance for further optimisation by improving the process's cycle time, utilising better resources, and allowing testing models before implementing them [6].

Big data provides excellent advantages for organisations as it gives accurate and consistent business insights, automated decisions for real-time processes, and the detection of fraud operations [7]. Besides that, big data helps organisations gain more leverage and return on investments and risk qualifications. Big data is currently a significant factor in the world of technology. Organisations use big data to increase revenues by targeting specific customers and retaining existing customers [8]. With the proper integration of big data, organisations can determine precisely what their customers are looking for, which gives them leverage to meet customers' needs. In addition, big data nowadays is used to target specific markets instead of spending tremendous money on advertising which reduces the costs for the organisations. Identifying risks and foreseeing potential opportunities are now possible by using big data [9]. Eventually, big data will be in almost every industry with significant advantages [10].

In recent years, using Big Data Analytics (BDA) to operate and manage business processes properly has widely gained more importance [11]. Therefore, integrating BDA into BPM represents a unique opportunity for organisations to enhance their efficiency and effectiveness along with the business to achieve added value and competitive advantage [12]. BDA can make a remarkable improvement in multiple aspects of BPM. One of the benefits BDA can bring to organisations is wastage management. According to previous studies, wastage consumes a massive chunk of an organisation's resources. BDA can help organisations develop efficient and effective waste management strategies [13]. As the measurement is at the centre of data analytics for waste management, it facilitates observing the business processes and, consequently, identifying the processes that generate the most waste. Based on that, the organisation can take actions to reduce wastage which leads to greater BMP. In addition, integrating BDA into BPM can develop powerful talent management for the organisations [14]. It can identify the problems in the production processes and propose solutions based on data analytics. Also, it can help the organisations in the process of recruitment and acquire talents that fit the business's needs and values. Besides that, it enables the organisations to foresee any turnover changes in process modelling.

Moreover, big data can generate patterns based on data to BPM to enhance customer management. When these generated patterns are integrated with business processes, they can evaluate the quality of customer services, bring up an accurate customer classification, acquire new customers and retain the current customers, predict customer behaviours, and improve customer value [15]. All these benefits will be significant advantages for the organisations.

However, the IT industry has significantly improved BDA's scope, while BPM societies haven't been really up to date with the massive jump in IT. BPM's societies keep relying on old modelling-based approaches, which are at a disadvantage [16]. In addition, a high percentage of companies feared the disruption of data-driven competitors, which led them to forge the adoption of embracing BDA. Besides that, many organisations believe that if they don't utilise the data appropriately and nimble, data analytics might compromise threats to them instead of being assets [17]. Additionally, some companies hesitate to change into data-driven companies due to the possibility of failure in changing business culture transformation. Hence, no accomplishments will be achieved with old BPM approaches to manage an organisation's processes because data is always limited.

Consequently, with the old BPM, the value of information is often insufficient for decision making, long time to analyse behaviours of products, services or customers, requires more cost for hardware, software and maintenance, and is always a step behind the other modernised organisations [18]. Moreover, as technology is constantly evolving, BPM faces the pressure of keeping up with the latest data and upgrades in terms of social media and unstructured data [19]. So, all of this must be put in perspective in pursuing a better rapport with the new technical world so that better decisions result in more outstanding outcomes.

BDA has raised the profit edges of businesses that have embraced it by enhancing efficiency and reducing costs. Indeed, the world is moving toward the Internet of Things (IoT) [20] and data analytics; organisations must integrate BDA into business process modelling before it's too late [21] [22]. Also, organisations should use BDA in BPM to enhance data-driven decisions which improve business-related outcomes [23]. That would come up with more new revenue opportunities, effective marketing strategies, customer's personalisation, and improved operational efficiency. Therefore, this study aims to explore (i) integration of BDA into BPM and (ii) related possible contributions and challenges.

## II. LITERATURE REVIEW

Various studies have been conducted, with the main focus being on why a diverse number of companies are not interested in embracing BDA to support BPM. In this section of the study, multiple arguments from different perspectives will be presented to demonstrate why some companies support adopting BDA in BPM and other companies do not support that.

Some companies believe the intense, increasing volume of data from new sources – mostly unstructured data – requires new approaches to process management [24]. Acquiring these approaches requires a new storage level, a higher level of computing power, and very skilled analytical expertise if companies want to reap valuable information and insights. For some companies, this is considered as a complexity that requires both talents and experience [25]. It can be a valid argument here if there was an abundant amount of data, and it would require much more work to filter the valuable data from the invaluable data.

In contrast, companies had the challenging mission to dig deep to explore the opportunities and the effect on the business of big data in managing business processes. Big data is evolving as a corporate criterion for business modelling. Big data is considered a tool that provides opportunities for creativity and innovation due to its high agility for the companies [26]. It can load a large amount of data, recognise links and understand patterns. Embracing big data to make digital transformation in organisations enables them to add digital content to the business processes [27]. This enhances the quality of decision-making based on real customers' relationship data. Furthermore, digital transformations will improve the management processes that allow the business to expand and gain more outstanding production and distribution.

On the other hand, moving to the digitisation of business modelling concerns companies worldwide [28]. Digitalisation has ruined the business management ways in several industries. For instance, in retail, companies such as Amazon strongly damaged the classic commerce like shopping malls. In some cases, business processes in companies require a tremendous amount of data to gain value rather than the size [28], [29]. Companies are allocating a lot of resources to collecting a massive amount of data that might not be as valuable as expected once they seek the correct data. Many barriers make organisations hesitate to chase big data related opportunities [30]. These barriers might include outdated IT infrastructure, complexity of processing big data, messiness and randomisation of big data, lack of data experiences and skills to coordinate with business processes, privacy concerns, and eventually, the organisation's cultures, which may not be conducive operationally for data-driven decision making.

According to previous research, businesses need quicker and more precise insights into growing volumes of transactional data [31]. BDA technology serves to achieve high efficiency in business processes and raises organisations' effectiveness to another level [32]. Digitalising organisations with BDA technology will add value to the organisations. To clarify, analysing big data in real-time supports the organisation to optimise the organisational vision by reviewing the past and foreseeing the future [33]. Besides that, acquiring BDA and coordinating it with BPM speeds up the processes like modelling, monitoring, measuring, redesigning, reengineering, process analysis, process enactment, enterprise application integration, and business intelligence [34]. Overall, these qualities possess great benefits for the organisations in various aspects.

Furthermore, the financial benefits of BDA in marketing and business increasingly rise year after year compared to the other organisations that are not implementing BDA technology

[35]. They also mentioned that the percentage of failure of embracing BDA is low, and it is caused by the lack of proper strategies to implement BDA. Thereupon, acquiring BDA technology requires companies to enhance their business process management.

Based on the conducted arguments, integrating BDA technology in an organisation is a risk that companies should take due to the intense pace of advanced technology. Accordingly, it might be a privilege and advantage if it is properly utilised, or it might be a loss of money if misused. BPM is a system that is based on data. Therefore, feeding up this system with more valuable and accurate data will strengthen the outcome of the system and produce supportive approaches that enhance business processes. In addition to that, based on the statistical studies, organisations that operate their business processes based on data analytics are exceptionally ahead of other organisations that don't use BDA until now.

## III. Contributions of BDA to BPM

### A. Better Decision Making

BDA can assist in better decision-making by collecting, storing, and analysing data across a collaborative network [36]. Integrating BDA in BPM enhances the user's experiences with a powerful realisation of what has happened in the past. It assesses what is happening currently and predicts the process's behaviours in the future [33]. Besides that, decision-making with BDA provides organisations with more accurate process models and better performance. BDA plays a prominent role in improving decision-making for organisations [37].

Four types of BDA enhance business processes to ensure efficiency in decision-making [38] [39] (Table I). BDA works majorly to provide a clearer insight to model the organisation's processes, which helps the organisations enhance their productivity and creativity. Modelling business processes based on clear visions and accurate patterns support the organisation's growth and stability [40].

TABLE I. Four Types of BDA to Enhance Business Processes

| Data Analytics Type | Description |
| --- | --- |
| Descriptive Analytics | Describe what happened and what went wrong, and at which stage? Based on the provided answers, organisations can detect obstacles and avoid mistakes during process modelling. |
| Diagnostic Analytics | Historical data can be measured against other data to answer why something happened. Comparing old data and recent data helps to give organisations a greater idea of their business's growth and stability. |
| Predictive Analytics | Predicting what is likely to happen in the future based on the data analysed. Creating patterns based on predictions gives the organisations a very supportive advantage to plan for improvement in every aspect of the business. Also, predicting what issues the organisations may face greatly benefits the organisations. |
| Prescriptive Analytics | Prescribing what action to be taken to eliminate a future problem. Make probabilities for each situation that might happen and create a backup plan to handle it. |

### B. Embracing BDA in BPM Shapes the Organisation's Performance

BDA significantly boosts customer deployment and superior organisational performance. BDA plays a vital role in shaping organisations' performance [41]. One of BDA's benefits is that it differentiates between high and low-performing organisations; therefore, those firms that apply BDA become proactive and future-oriented. In addition, big data can increase the likelihood of innovation performance, leading to the creation of patterns and behaviours in business processes [42]. Furthermore, BDA can build benefits for any organisation by improving its performance (process performance, financial performance, production performance, marketing performance, and partnership performance) and competitive advantage. Also, decisions in data-driven organisations are more likely to outcome positively and give more insights into business processes [43]. Hence, big data gives extra leverage for improving organisation performance. An organisation's performance is measured by various factors such as finance, quality, improvement, and value of the organisation in the market [44]. BDA is a major participant in each of these factors once it helps to enhance them in various ways [45]. Process modelling using BDA will strengthen the organisation's strategies, resulting in better revenue and financial stability.

Additionally, organised models in business enhance the quality and lead to improvement of the organisations [46]. Besides that, when the organisation is financially improving and its quality is enhanced, its value is raised in the market. Hence, the organisational performance is supported by using BDA.

### C. BDA Upgrades Business Process Capabilities

Big Data Analytics Capabilities (BDAC) is defined as the company's capabilities to influence technology and talented skills to take advantage of BD regarding the generation of perceptions essential to overperform competitors. To clarify, BDAC is the ability of organisations to come up with insights that support organisations using big data management [47].

Managing BDA is a challenging and complicated task for companies due to the variety of resources and types of data. Still, when the company is capable of managing that big data and utilising the outputs of BDA to enhance modelling business processes, then the organisations are taking greater advantages compared to others who can't manage BDA [48]. The ability to manage big data and extract value data differentiates successful firms from non-successful ones. Based on an organisation's financial welfare, big data is defined and evolved more technologically in organisations. In addition to that, BDA's capabilities assist in offering advantages such as optimising the data generation process, suggesting data integration from diverse sources, incorporating different types of findings into the business process, and data visualisation capability to facilitate the decision-making process [49].

Based on the expert's experience in using BDA techniques, organisations can precisely predict the market's needs and requirements and then develop their strategies and structures to accomplish the best insights about market needs and reveal future market objectives [50].

## D. BDA Supports Supply Chain Management (SCM) in Organisations

Embracing big data support supply chain management (SCM) in an organisation reflects significant advantages on business process models [51]. Applying big data improves existing business processes by focusing on current business needs and challenges, and data can be investigated to create saleable products and services as new value propositions. As the range of supply chains is global, the volume of data collected from its various processes and the rate at which it is being generated can be qualified as Big Data [52]. Also, marketing and sales are now counting on analysis of the unstructured and structured data to get more significant insights into customer needs and improve the cost aspects of supply chain processes [53]. The utilisation of BDA provides an incredible value in product development, market demand predictions, supply decisions, distribution optimisation, and customer feedback [54].

Moreover, big data can be applied in SCM for operational and development purposes, value discovery, value creation, and value capture [55]. There are several areas primary for applying big data for SCM. Fig. 1 illustrates the areas as the source, make, move, and sell [56].

**BDA and SCM in Organizations.**

| Source | Big data may be used to integrate with suppliers, evaluate sourcing channel options, and portion supplier negotiations. |
| Make | It involves reduction of capacity constraints, wherehousing optimisation, performance reporting, facility location\layout, and workforce analytics. |
| Move | The application of big data involves routing, scheduling, using transportation alternatives, optimising, and maintaining vehicles. |
| Sell | Big data enables micro segmentations of customers, the capture and prediction of customers demand and behaviours, as well as the price and the assortment optimisation. |

Fig. 1. Main Areas for BDA in SCM.

## IV. CHALLENGES OF INTEGRATION OF BD INTO BPM

Initially, organisations will need to gather vast amounts of data through mobile, social networks, digital videos, and sensors. Organisations then will need to integrate them into their business processes [57]. Therefore, they must be aware of the challenges of big data to have an intelligent and efficient BPM that aims to bring great value to process decision-makers and process modellers. Organisations have to manage many challenges and obstacles when they decide to integrate BDA into BPM, as explained in the following sections.

### A. Poor Data Quality

One of the most common challenges to embracing BDA in business organisations is poor data quality. When business organisations intend to be data-driven, data quality must be concerned cautiously because data quality directly impacts business outcomes [58]. Poor data quality leads to poor insights, which lead to poor decisions, and vital decisions based on low-quality data can have disastrous effects [59]. Poor data quality causes inefficiencies in business processes that rely on it. Instead of focusing on essential activities, these inefficiencies may result in very costly redo efforts validating and correcting data inaccuracies. Besides that, poor data quality leads to distrust [60]. Maintaining high-quality data might differ between complying with regulations and paying millions

in fines. Time, money, and reputations can be wasted if the data is incorrect, negatively impacting business organisations and eroding client confidence [61]. Therefore, it is critical to be aware of the importance of data quality because good data quality will enhance BPM, and poor data quality will lead to significant damage to BPM in any business organisation.

### B. Shortage of Professionals who Understand BDA

Business organisations that seek to integrate BDA into BPM will have to deal with large data sets that keep growing in size and variety. Incorporating data sets into an analytical platform becomes increasingly difficult because the volume and variety of data available today can overwhelm even the most experienced data engineers [62]. Therefore, the market has significantly demanded big data scientists and analysts. Because the position of a data scientist is multidisciplinary, businesses organisations must select someone with a diverse set of talents related to BDA. Another big issue that organisations confront is a shortage of professionals who are familiar with BDA [63]. Compared to the vast amount of data created, data scientists have a severe scarcity. For instance, when someone who is not an expert data engineer tries to merge unstructured and inconsistent data from several sources, mistakes occur and wrong insights are produced, resulting in missing data, inconsistent data, logic conflicts, duplicate data, and bad decisions [64]. Therefore, if there are no expert professionals to deal with this massive volume of big data efficiently and effectively, then integrating them with BPM is not helpful and it may bring wrong insights and false signals for business modelling, which will impact business organisations negatively as all the decisions will be based on inaccurate and useless insights.

### C. Data Security and Protection

Integrating BDA in BPM requires business organisations to seek massive data sets to develop enhanced business models and visions. More data brings more opportunities and potential threats simultaneously, especially when the data sets are less organised [65]. As businesses expand and add new tools to their software stacks and install new technologies to make sense of their data, the risk of security breaches increases. Therefore, business organisations that indiscriminately collect data from many sources may be gathering fraudulent (and so invalid and perhaps damaging) data [66]. Fake and inaccurate data will impact any analysis that a company can perform. Additionally, when businesses gather data without using precautions like encryption, access control, and firewalls, the data becomes subject to leaks, viruses, and data harvesting, which may be incredibly destructive to businesses and compromise customer privacy [67]. Thus, if the data are not well-protected and secured, the business will be damaged and lose its value in the market. As a result, data protection and security are important conditions to integrate BDA into BPM.

### D. Confusing a Variety of Big Data Technologies

Nowadays, there are many technologies specialised for BDA in the market. Acquiring the right technology for big data is a real challenge for organisations [68]. Each BDA technology has different processing, storing, cleaning, and reporting features. For instance, the speed of processing big data is essential for organisations. Therefore, some companies

will choose Spark technology to process because of its high speed, while others will be settled with Hadoop MapReduce's speed. Hence, if an organisation has less data and embraces Spark technology, it would lead to money wastage and vice versa [69]. Also, data storage makes a big difference in the organisation's big data processing. For instance, some organisations tend to go for Cassandra to store their data, while others would prefer to embrace Hbase to store their data. Therefore, the features of BDA technology may significantly impact organisations either positively or negatively, depending on selecting the right technology [70]. Choosing an appropriate technology for big data plays a significant role in enhancing the BPM. When the suitable technology is adopted, the business processes will be well strategised and organised, resulting in optimised business insights [71]. On the other hand, if the BDA technology is poorly chosen, the business processes will have unexpected outcomes and false foreseen.

### E. Managing Large Volume of Data

Managing large volumes of data is the first challenge for organisations to consider when integrating BDA into BPM [72]. These large volumes of data which are extracted from customer relationship management (CRM), enterprise resource planning (ERP), and other data sources, need to be consolidated and pulled into a unified manageable big data [73]. Besides that, the correct storage of these vast amounts of knowledge is one of the most critical concerns of big data. Data saved in data centers and company databases are continually growing [74]. Thus, it becomes difficult to manage large data sets as they increase rapidly over time. The majority of the data is unstructured and comes from various sources, including documents, movies, audio, text files, and other media. [75].

### V. CONCLUSION

This study discussed the possible contributions and challenges of integrating BDA into BPM. It illustrated the importance of BPM and how organisations pose the BPM as the backbone for their businesses to succeed. Also, how BPM participates in ensuring the business processes modelling is a consistent technique and pushes business execution toward accomplishing the overall strategy and goals of the organisation. Besides that, this study demonstrates the roles of BPM and how it organises and operates all the processes in an organisation to come out with the best possible performance. Another part of this study had closer attention to the value of BDA in today's technology world and how organisations embrace it to support their businesses. It explained how data is the core component of any organisation's success. More of BDA was illustrated in terms of the enhancement and encouragement BDA brings to any organisation. Multiple studies with different perspectives were argued in this study to demonstrate why some organisations strive to embrace BDA and others consider it a waste of time and effort. These studies concluded that embracing BDA strongly supports BPM and enhances the value of the organisations. Next, the study provides multiple contributions of BDA in BPM, such as how integrating BDA into BPM helps to understand the business and support decision-making efficiently and effectively. Another contribution was that the relationship between BDA

and business performance had been illustrated precisely. Furthermore, how BDA can support SCM and optimise its process lifecycle to enhance the operations in an organisation. It generally concentrates on implementing BDA with BPM to improve existing business processes by focusing on current business needs and challenges. In this way, data can be investigated to create saleable products and services as new value propositions. Then, BPM's capabilities with the existence of BDA were indicated to be at a very different level with BDA than without BDA. This study demonstrated that BDA's capabilities support BPM to provide advantages such as incorporating different types of findings into the business process, optimising the data generation process, data visualisation capability facilitating the decision-making process, and suggesting data integration from diverse sources. Additionally, the study explained the challenges of embracing BDA in organisations to support BPM. Three significant challenges were identified in this study to predict what organisations may need to manage if they decide to integrate BDA in BPM.

The first challenge is poor data quality, which generates false insights in modelling processes, resulting in wrong decisions. This challenge can be solved by fixing the data in the source system to correct data issues such as missing data and incomplete data. Therefore, data must be set and cleaned in the Extract, Transform and Load (ETL) phase before it is used to make any analytics and predictions [76]. Besides that, data analytics leaders must set data quality standards that can be applied across the organisation's business units. They must then establish a clear connection between business processes, organisational performance, and data assets [77]. Make a list of the organisation's current data quality challenges and how they affect the business. Then, data and analytics professionals may start creating a specific data quality improvement plan that is the "best fit" for the company [78].

The second challenge is the shortage of professionals who understand the BDA in BPM. This challenge can be solved by paying extra attention while interviewing BDA professionals to ensure these professionals understand the structures of the organisation's requirements and strategies in terms of business processing and data. In addition, automating data-related tasks is a new approach followed by companies to solve this challenge. Automated data management, data science, and analytics tools and platforms such as Alteryx and DataRobot have also come on to the scene. However, some experts have warned that inexperienced staff can pose a risk to data science automation [79]. Also, companies are looking into ways to democratise data science by upskilling and reskilling their staff to become less reliant on small teams of pricey experts to see a return on their data science investments [80].

The third challenge is data protection and security. It cannot be fully tackled, but organisations usually improve their safety to decrease the threat rate. Many companies take data discovery and classification as a new approach to protect their data. Data discovery and classification is a process that involves scanning data repositories for the types of data that organisations consider significant, sorting it into categories, and clearly labelling it with a digital signature indicating its classification [81]. Besides that, firewalls are very significant

tech to protect data in an organisation. To prevent unwanted traffic from entering the network, firewalls are used. Furthermore, organisations can only open particular ports, giving hackers less freedom to move to gain access to or download sensitive data [82].

In addition, there are other challenges, such as a variety of big data technologies in the market. This challenge can be avoided by understanding the needs and requirements of the organisations and then adopting a technology with specific features to meet the organisations' needs and requirements. Besides that, managing large volumes of data is considered a challenge in some organisations. This challenge can be avoided by targeting the correct data and focusing on the quality instead of the quantity of data. Eventually, the summary of this study supports the embracing of BDA in BPM to make organisations a better place in today's world. The efficiency and effectiveness that BDA brings to the organisations increase the value and enhance the performance of the organisations. Another finding in this study is that the fear and hesitation of embracing BDA by some organisations was because they think they may not be able to utilise the generated structured and unstructured data properly to support BPM. While in fact, the study proved how embracing BDA could strongly support BPM. Indeed, integrating BDA and BPM is a risk that should be taken due to its value to the organisations from different aspects. Furthermore, the study proved that BDA could increase productivity, encourage creativity, and enhance performance modelling. Additionally, the findings showed how integrating BDA and BPM assures understanding of the business processes and supports decision-making. To conclude, this paper recommends organisations take a step forward and embrace BDA to help positively organise process modelling and raise the business value.

Eventually, integrating BDA in BPM is an opportunity that every organisation should seek due to the valuable benefits it brings. BDA assists organisations in finding more efficient ways to organise businesses processes and increase their customer acquisitions and retention. Besides that, organisations will gain more opportunities to develop innovative new products to meet customers' changing needs with BDA. In addition, businesses use big data to plan their advertising by observing online activity, monitoring point-of-sale transactions, and assuring on-the-fly detection of dynamic changes in client behaviours. These are then utilised to determine the target group, the most crucial factor to consider while planning a campaign.

Moreover, reliance on BDA could manage an organisation's risk plan and create a clear vision to minimise potential risks. Also, businesses can achieve contextual intelligence across the supply chain by using BDA. Therefore, BDA will make a significant impact on BPM and these impacts will raise the quality of the organisation's performance.

The next phase of this technology development is a complete automation strategy. Researchers should conduct many studies to increase the automation of BDA within organisations. Automating BDA is an advanced strategy that can make a difference in the positive side of organisations. Some researchers have attempted to make theories about full automation for BDA in BPM. Still, they discovered that experts are not optimistic about this strategy because they believe that full automation in such an early stage may lead to many errors, negatively affecting BPM in organisations [83].

# K-Means Customers Clustering by their RFMT and Score Satisfaction Analysis

Doae Mensouri, Abdellah Azmani, Monir Azmani
Intelligent Automation Laboratory, FST of Tangier
Abdelmalek Essaadi University, Tetouan, Morocco

*Abstract*—**Businesses derive more revenue from building and maintaining long-term relationships with their customers. Therefore, it is essential to build refined strategies based on customer relationship management, with the purpose of increasing their turnover and profits while retaining their customers. In this context, customer segmentation, which is at the heart of marketing strategy, makes it possible to determine the answers to questions relating to the number of investments to be released, the marketing campaigns to be organized, and the development strategy to be implemented. This paper develops an extended RFMT (Recency, Frequency, Monetary, and Interpurchase Time) model, namely the RFMTS model, by introducing a new dimension as satisfaction 'S'. The aim of this model is to analyze online consumer satisfaction over time and discern changes to implement customer segmentation. This article proposes an approach to a segmentation, by client clustering along the unsupervised machine learning method k-means based on data generated using the proposed RFMTS model, in order to improve the customer relationship and develop more effective personalized marketing strategies. The study shows that including satisfaction to the existing RFM model for customer clustering has a major impact and helps identify customers who are satisfied and those who are not, unlike previous attempts to develop new RFM models. By ignoring the "satisfaction" indicator, what went well and what didn't went well cannot be understood. Consequently, the business loses its unsatisfied, loyal, and profitable customers and either fails or relies only on the satisfied ones to continue making profits for an indefinite period of time.**

*Keywords*—*Customer segmentation; customer satisfaction; RFMT model; machine learning; k-means*

## I. INTRODUCTION

As modern economies are primarily service-based, businesses increasingly derive revenue from building and maintaining long-term relationships with their customers. The key to a sustainable e-commerce business is understanding customer characteristics for personalized marketing strategies [1]. In such an environment, marketing aims to maximize customer value [2] and satisfaction, as well as the equity that characterizes the sum of these for all customers of the company.

This study focuses on customer segmentation based on behavioral data due to its availability and evaluation with time. RFM analysis is one of the most renowned techniques used to evaluate customers based on their buying behavior. After collecting and pretreating the data, a new model named RFMTS by adding a new dimension is proposed, which is

satisfaction, to the shopping behavior characteristics. Once the values of the new RFMTS model are calculated, k-means the most well-known and widely used clustering method [3], [4] is applied to variables to segment customers. Finally, the behavior of each cluster is analyzed to derive insights and help retailers make the right decisions for each cluster. Grouping customers into different groups on one hand helps to understand customers' needs [5]. On the other hand it allows a company to operate its subsequent segmentation in order to optimize its resources, as well as its sales and marketing efforts [6]. Furthermore, taking customer satisfaction into consideration helps to develop effective marketing strategies and reinforce customers loyalty. Customer satisfaction reflects the difference between the expected and perceived quality of a service [7]. In order to benefit from a large share of the market, companies try their best to reach higher levels of customer satisfaction, which is an important driving force for revenue growth [8], by improving their services [9]. The level of satisfaction determines whether a customer would like to order once again, and become loyal or leave the company [10]. Thus, the motivation for this study to include the satisfaction factor. The application of this approach is made on the e-commerce public dataset, which connects small businesses, but it can be applied to any set of data from which the five RFMTS variables can be extracted.

## II. RELATED WORK

### A. RFM (Recency, Frequency, Monetary)

RFM was first developed by A. M. Hughes [11] as a method of analyzing customer value. Over the past few decades this models have become a widespread paradigm for behavioral segmentation [12]–[14]. RFM makes it possible to distinguish, at a given moment, customers according to a value which is determined from their time interval since the recording of their last order, their frequency of purchases and the amount spent on their purchases.

- Recency (R): represents the value of the period between a customer's last purchase and current moment. A smaller value of recency implies that the customer purchase frequently. Similarly, a big value implies that the customer won't make a purchase shortly.

- Frequency (F): represents the number of purchases made by the customer. It is equal to the total number of purchases. A high value of frequency implies a high level of customer loyalty.

- Monetary value (M): represents the average value of a given customer's purchases. This is equal to the sum of all customer's purchases divided by the total number of purchases. A customer with a high monetary value, is a customer who provides high revenue to the company.

Several publications have attempted to develop new RFM models, taking into account additional variables, to test whether they perform better than the traditional RFM model. For example, Yeh et al. [14] extended the RFM model, namely RFMTC, by adding two parameters time since first purchase (T) and churn probability (C). In 2012, Alvandi et al. and Wei et al. [15] have developed LRFM model taking into account the duration (L) between the first and the last purchase of a customer. Based on the previous model, Peker et al. proposed a new one (LRFMP) by including the customer visit period (P) [16]. In 2017, Moghaddam et al. developed a new RFM model, namely RFMV, by adding a variable of variety of products (V) [17]. In 2018, Yoseph and Heikkila [18] introduced purchase rate of change (C) to show the quantity and sign of change in customer buying behavior. In 2021, a new parameter was introduced, the inter-purchase Time (T), defined as the time interval between two consecutive purchases by a customer in the same store or on the same website [1]. However, these expanded RFM models lack information revealing customer satisfaction ratings. In this regard, in this paper, RFMT model is extended as RFMTS model by taking satisfaction (S) into account.

### B. Customer Satisfaction

The existence of many service providers depends heavily on their competitive advantage in terms of customer satisfaction (CS) [19]. Existing studies [20], [21] have argued that modeling CS is an important research topic. Fornell defined CS as the overall evaluation of the quality of a product or service by a customer based on his purchase and consumption experience [22]. While R. L. Oliver [23] defined it as a judgment of the comfort level of a product/service feature or the product or service itself provides (or is providing) satisfaction related to consumption, including levels of underachievement or overachievement. Customer satisfaction has been examined extensively in past research, which includes the impacts of customer satisfaction [24], [25] and identify the determinants of CS [20], [26]. Customer satisfaction has not been introduced into the extant RFM model for customer segmentation. This article intended to introduce Satisfaction into the RFMT model to create a better performed model, namely RFMTS. Natural language processing is generally used to increase knowledge concerning customer satisfaction [27]. In this study S is equal to the sum of all customer's review score divided by the total number of reviews, since the review score is already defined in the database. Let $RS_0$ ... $RS_n$ be the review scores given by a customer c, thus the Sc value can be calculated as follows (Equation 1).

$$Sc = \frac{\sum_{i=0}^{n} RSi}{n+1} \qquad (1)$$

### C. Decision Making

RFMTS model can be used to segment customers in order to identify which customers are satisfied, unsatisfied, active, promising, lost, basic, low-value purchasers, loyal high spenders, at risk. Understanding segments can help retails better tailor their products, marketing strategies and investments. Several combinations of R, F, M, T, S are possible, some canceling out in front of the others. Table I shows the characteristics of the segments and the actions to take into account when dealing with some of them.

TABLE I. SEGMENTS CHARACTERISTICS

| Segment characteristics | Action |
|---|---|
| High R, High F, High M, Short T, High S | Loyal customers: improve their value by enticing them to place a few more orders. Increase their loyalty by offering exclusive perks that only the best customers can access. |
| High R, High F, High M, Short T, Low S | Loyal unsatisfied customers: solve their problems as fast as possible, can't lose them at any cost. |
| High R, Low F, Low M, Short T, High S | Promising customers: turn them into loyal customers by earning their trust, providing great service, and making them lives easier. |
| Weak R, Low F, Low M, Long T, Low S | Lost customers: identify their cause of dissatisfaction, learn from it and design campaigns to reactivate them |
| High R, Low F, High M, Moderate T, High S | Active customers: just like basic ones, keep them interested and active by personalizing their offers. |
| Weak R, Low F, Moderate M, Short T, Hight S | Basic customers: maximize their value by personalizing the offers intended for them. Take responsibility and offer a sincere apology if an error has occurred |

## III. IMPLEMENTATION

### A. Data Origin

The application of the approach presented in this article, is based on a dataset provided by Olist Store, the largest store in Brazilian markets that connects small businesses. Therefore, this dataset contains many purchases made between the periods 2016-2018 in different stores that used the Olist service. It is an open-source database, downloadable from the Kaggle site (https://www. kaggle.com), known as "Brazilian E-Commerce Public Dataset" and whose Fig. 1 illustrates its model with its different objects and their associations. In the application of the approach presented here, only the Payments, Customers, Orders and Reviews sub datasets (described by Tables II, III, IV and V) are used because they contain the variables necessary for the different variables' calculations.

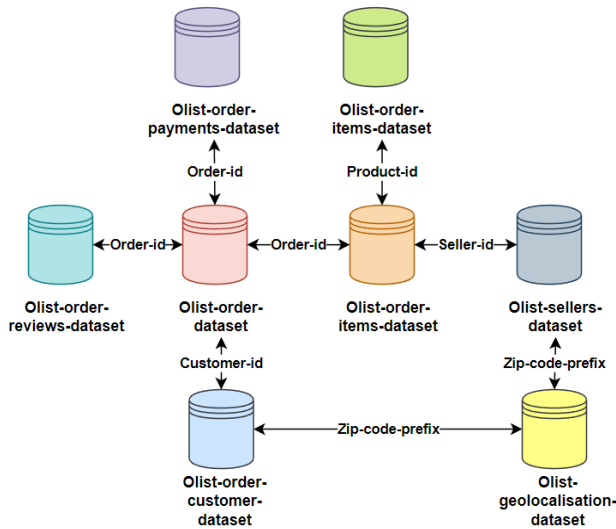
Initially the number of rows of the Customers, Orders, Payments, and Reviews sub datasets is 99.441, 99.478, 99.478 and 98.410 respectively. A first filter was performed to keep only the orders already concluded (order_status column) reducing their size to 96,478. For the customer data subset, after a first filtering only clients of the concluded orders were kept, its cardinality is no more than 93357. As for the payment, it had to be adapted to that of the orders with the same number of elements.


Fig. 1. The Dataset.

TABLE II. PAYMENTS DATASET

| Column | Description |
|---|---|
| Order_id | Order id |
| Payment_sequential | Sequences of the payments made in case of EMI |
| Payment_type | Mode of payment |
| Payment_installments | Number of installments in case of EMI purchase |
| Payment_value | Total amount paid for the purchase order |

TABLE III. CUSTOMERS DATASET

| Column | Description |
|---|---|
| Customer_id | Customer id |
| Customer_unique_id | Unique id of the Customer |
| Customer_zip_code_prefix | Zip code of customer's location |
| Customer_city | Customer's City |
| Customer_state | Customer's State |

TABLE IV. ORDERS DATASET

| Column | Description |
|---|---|
| Order_id | Order id |
| Customer_id | Customer id |
| Order_status | Order status.i.e shipped, delivered |
| Order_purchase_timeslamp | Timeslamp of the purchase |
| Order_approved_at | Timeslamp of the order approval |

TABLE V. REVIEWS DATASET

| Column | Description |
|---|---|
| review_id | Id of the review given on the product ordered by the order id. |
| order_id | A unique id of order made by the consumers. |
| review_score | review score given by the customer for each order on the scale of 1–5. |
| review_comment_title | Title of the review |
| review_comment_message | Review comments posted by the consumer for each order. |

## B. Data Preparation

Once the three sub datasets have been filtered and prepared, the next step is to merge them by their respective primary keys (customer_id, order_id) into a single dataset (Table VI) that will be used to generate other data including the CLV of each customer. However, the generation of CLVs which is done from the models of the Lifetimes library requires, as mentioned above, the application of the RFMTS model with the determination, for each of the 93357client its five variables: recency R, frequency F, monetary value M, regularity of purchase T (Time) and satisfaction S.

## C. Generation of Customer Data by Application of the RFMTS Model

At this level, the set of data constituted above (Table VI) will be enriched by the generation for each customer of the five aforementioned factors: Recency, Frequency, Monetary, and Regularity of purchase and Satisfaction value.

To be able to carry out certain calculations, it is necessary to specify the date during which this calculation must be carried out to simulate an immediate study of the transactions of the company. To be consistent with the initial dataset, August 29, 2018, is chosen as the last purchase made. As explained before, recency of each customer is equal to the period between the last purchase and August 29, 2018. Frequency is equal to the total number of purchases made by a customer. Monetary value is equal to the sum of all customer's purchases divided by the total number of purchases. Inter-purchase Time is equal to the period between the last and the first purchase divided by the frequency. The fifth variable, Satisfaction (S), measures the average customer's satisfaction S, it is equal to the sum of all review score divided by the total number of reviews given by a customer.

Table VII presents the new configuration of the study dataset after the generation of R, F, M, T and S for each customer.

## D. Clustering Customers based on RFMTS Model

After calculating the variables, Recency, Frequency, Monetary value, Inter-purchase time and satisfaction (Table VII), the next step is grouping the consumers based on the RFMTS model. For this an unsupervised Machine Learning method K-Means is using here.

TABLE VI. INITIAL DATASET

| Customer ID | Order ID | Order Purchase Time | Payment Value | Review Score |
|---|---|---|---|---|
| 0a0a…a872 | e481f…d6af7 | 10/2/2017 10:56 | 10.11 | 4 |

TABLE VII.    DATA AFTER CALCULATION F,R,M,T AND S

| Customer ID | R | F | M | T | S |
|---|---|---|---|---|---|
| 0a0a…a872 | 411.96 | 2 | 46.31 | 121.66 | 4.34 |
| c846…84a1 | 140.34 | 2.17 | 83.06 | 121.66 | 4.77 |
| 763c…2b93 | 210.55 | 2.30 | 220.76 | 91.25 | 3.17 |
| … | … | … | … | … | … |
| 9b7f…77d6 | 210.54 | 1.87 | 5675.43 | 170 | 4.05 |
| 455c…ba1b | 1350.29 | 2.15 | 130.89 | 320.27 | 1.24 |

*1) About K-means:* As shown in Fig. 2, the k-means algorithm procedure is a simple and easy way to classify a data set through a specified number K of clusters a priori [28], [29]. Each cluster is characterized by its center of gravity, that is, its central point whose coordinates are obtained by calculating the average of each of the coordinates of the sample points assigned to the clusters.

*2) K-means customers clustering:* Before using it, it was necessary to normalize the variables, because since it is a model that works with the distances of the data, the dimensions and magnitudes play a very important role in its implementation. As an example. Table VIII presents the array of normalized data.

In the case of this study, the "elbow method" was used to indicate the number of clusters which reduces the inertia (proximity of points to their centroid) to a relevant point [30].

**Initialization**
Choosing the starting points that are used as initial estimates of cluster centroids. They are taken as initial starting values.
**Loop:**
- **Build k clusters**: examine each point of the data set and assign it to the cluster whose centroid is closest.
- **The new centroids are calculated**: when each point in the data set is assigned to a cluster, it is necessary to recalculate the new centroids k.
**Until**
- No point changes its cluster assignment or until the centroids no longer move.

Fig. 2.    K-means Clustering Algorithm.

TABLE VIII.    ARRAY OF NORMALIZED DATA

array ([[-0.82886279, -0.84339079, -0.19094101, -0.10203975, -2.29586173],

TABLE IX.    NUMBER OF CUSTOMERS PER CLUSTER

| Cluster | Customer |
|---|---|
| 0 | 14203 |
| 1 | 41730 |
| 2 | 30313 |
| 3 | 5167 |
| 4 | 1994 |

Fig. 3.    Elbow Method.

Fig. 3 shows that the number five is the most appropriate for the segmentation. With this number of clusters, the model was trained with the scaled database and attaches the created labels to the initial Table VII.

At first glance, it can be seen from Table IX that the "0" cluster clearly refers to the group with the highest shopping users. A better visualization, of these new segments, can have place by using PCA to reduce the variables into two and be able to translate them into a scatter plot.

K-Means model did a good job of clustering the customers, but from the result of the graph (Fig. 4) and the number of customers per cluster (Table IX), it can be noticed that the order of the clusters does not really represent the importance of the customer versus profitability. This mini theory can be corroborated by looking at the R, F, M, T, S of each cluster (Table X).

Fig. 4.    PCA Dataset Visualization.

TABLE X.    AVERAGE RFMTS OF EACH CLUSTER

| Cluster | R | F | M | T | S |
|---|---|---|---|---|---|
| 0 | 212.91 | 2.25 | 204.84 | 273.75 | 3.15 |
| 1 | 152.08 | 2.19 | 70 | 30.41 | 4.65 |
| 2 | 395.41 | 2 | 28.33 | 10.34 | 4.51 |
| 3 | 1216.66 | 2.05 | 100.85 | 395.41 | 1.51 |
| 4 | 212.91 | 1.50 | 281.91 | 152.08 | 4.08 |

*3) Visualisation and analysis of the result:* Each cluster represents a segmentation of the market. To make the right decisions and develop efficient marketing strategies, it's necessary to analyze and understand the characteristics of each cluster. The RFMTS characteristics of each cluster are analyzed in this section. Table X lists the average RFMTS values of each cluster. Fig. 5, to Fig. 9 represent the distribution of the five clusters according to the respective distributions R, F, M, T, and S. The x axis of these figures represents the different clusters of customers, while the y axis represents the respective RFMTS values. The height of each rectangle is the range of y value variation, while the y value that lines up exactly with the line inside the rectangle represents the average value. The dataset used in this study contains 93357 customers. Fig. 10 shows the number of customers included in each one of the five clusters (C0, C1, C2, C3, and C4). Among the five clusters, cluster 0 (C0) has the highest percentage of the customers, equal to 44.7%, while cluster 4 (C4) has the lowest percentage of the customers, equal to 2.1%.

Cluster 0: contained 15.2% of the total customers (Fig. 10). It's characterized by a high R (7.95 months), low F (2.25), high M ($204,84), moderate T (9.46 months) and moderate S (3.15). Most customers in this cluster spend around $204.84. The last shopping date was around 9,46 months ago. The average satisfaction rating is around 3,15. Therefore, this cluster can be labeled as an active satisfied group.

Fig. 5. Distribution of the Five Clusters According to R.

Fig. 6. Distribution of the Five Clusters According to F.

Fig. 7. Distribution of the Five Clusters According to M.

Fig. 8. Distribution of the Five Clusters According to T.

Fig. 9. Distribution of the Five Clusters According to S.

Fig. 10. Clusters Size.

Cluster 1: as the largest sized group, Closter 0 represents 44,7% of all customers (Fig. 10). It's characterized by a high R (5.17 months), low F (2.19), low M ($70), short T (1.17 months) and a high S (4.65). The last purchase date was about 5.17 months ago. Even if M is low, the satisfaction is high, and T is short. Therefore, cluster 0 can be considered as a promising satisfied group.

Cluster 2: represents 32.5% of the total customers (Fig. 10). This cluster is characterized by a low R (13.05 months), low F (2), low M ($28.33), short T (0.34 months) and a high S (4.51). Customers in this cluster spent an average of $28.33, shopped twice in a short time, and their last purchase was around a year ago, and gave high ratings. Therefore, cluster 2 can be considered as the basic group.

Cluster 3: contained 5.5% of the total customers (Fig. 10). It is characterized by a weak R (40.03 months), a low F (2.05), a moderate M ($100.85), a long T (13.05 month) and a low S (1.51). It is the only cluster that simultaneously had low R, F, and S. Even if the average expense is around $100,85, the last purchase in this cluster was about 40,03 months ago, and the satisfaction is really low. Therefore, Cluster 3 can be considered as lost unsatisfied group.

Cluster 4: as the smallest sized group, cluster 4 represents 2,1% of all customers (Fig. 10). This cluster is characterized by a high R (7.56 months), low F (1.50), high M ($281.91), moderate T (5.66) and a high S (4.08). The most recent shopping date was about 7.56 months ago, the average spend is around $281.91, and the ratings are high. For these reasons, this cluster can be labeled as a gold profitable group.

Table XI represent the final table after assigning the corresponding cluster label to each customer.

TABLE XI.    FINAL DATASET

| Customer ID | R | F | M | T | S | Cluster |
|---|---|---|---|---|---|---|
| 0a0a…a872 | 411.96 | 2 | 46.31 | 121.66 | 4.34 | Basic |
| c846…84a1 | 140.34 | 2.17 | 83.06 | 121.66 | 4.77 | Promising satisfied |
| 763c…2b93 | 210.55 | 2.30 | 220.76 | 91.25 | 3.17 | Active satisfied |
| … | … | … | … | … | … | … |
| 9b7f…77d6 | 210.54 | 1.87 | 5675.43 | 170 | 4.05 | Gold profitable |
| 455c…ba1b | 1350.29 | 2.15 | 130.89 | 320.27 | 1.24 | Lost unsatisfied |

## IV. DISCUSSION AND RECOMMENDATIONS

This study is a sort of monograph on the importance of customer satisfaction. Its purpose is to segment customers, the heart of marketing strategy [31]. After pretreating the e-commerce dataset, RFMTS values were calculated for each customer. K-means was then used to segment the customers into five clusters. Finally, a cluster analysis was conducted to identify the characteristics of each customer's cluster. Cluster 0 is regarded as the active satisfied group. C1 is the promising group. While C2 contains basic customers, C3 is thought to be

a lost unsatisfied group. C4 is the gold-loyal group. Every company is trying its best to make their customers happy in a business environment that's highly competitive [32], [33]. Compared to previous work based on the RFMT model [1], the clusters obtained (lost group, promising, profitable, active profitable, and loyal) value the profitability of customers but neglect their satisfaction, which is a key factor for any successful and sustainable business. In turbulent markets, a company's reputation largely depends on customer satisfaction [34]. Failing to take customer satisfaction into account can lead to a marketing strategy that is not in line with the interests of customers and therefore have a negative effect on the business. Even if, in the case of this study, the satisfaction rate is high, the company should not rest on its laurels because everything can change, since trade is an area in perpetual transformation (competition, influence, exchange rate).

Finding new customers for the enterprise is essential, but retaining existing customers [35] can be even more important and profitable. Therefore, the company should develop marketing strategies to retain its customers.

- Increate the trust: trust is the belief that the other party of the exchange will not take advantage of opportunistic behavior and will act in a good manner [36]. It has been proven that trust has an important impact on customer purchase intention [37] and that it's a critical factor for online enterprises' success. Keeping the promises made to customers is essential to increasing customer trust and loyalty.

- Increase the net benefits: net benefit of online shopping includes both utilitarian and hedonic value [38]. It's the global benefits received from customers while shopping online. It includes enjoyment, monetary gain, delivery time and after sales service.

- Improve system quality: System quality has a significant impact on online customer satisfaction and decision-making [39], [40]. System quality includes the elements that evaluate the performance of a website, website design, page loading speed, website crashing, interruption, flexibility, and ease of navigation between pages.

- Increase customer reacquisition: customer defection is the decision to end a contract with a specific company [5], [41], [42]. Customer reacquisition provides companies with high economic benefits. An average business has a 60-70% chance of successfully reselling to active buyers, 20-40% to lost customers, and only a 5-20% chance of successfully sale to new prospects [43].

## V. CONCLUSION AND OUTLOOK

Segmentation helps to identify potential customers and understand their needs, which increases business revenue. Based on the existent RFMT (i.e., Recency, Frequency, Monetary, and Time) model, satisfaction (S) value was added to create a new model called RFMTS for better customer segmentation. The new model created can be applied to any

dataset from which the 5 variables (recency, frequency, monetary, time, and satisfaction) can be extracted. This study started with a typical relational database of an e-commerce site and ended with a segmentation of each of its customers according to their purchasing behaviors and satisfaction. After the customers' clusters are defined, business strategies can be generated to improve customer relationships.

Grouping customers into different groups based of the proposed RFMTS model helps decision makers identify market segments more clearly and thus develop more effective marketing and sales strategies to build customer loyalty [44]. This study opens the door to many outlooks, for example: Reinforced learning can be based on the results obtained in order to identify the cluster target of each type of offers. Being able to identify the best target for a specific offer allow the company to win at several levels, whether it be at the investment level, that the level of customer satisfaction, knowing that they prefer to receive that the adequate offers to their preferences.

*Abstract*—**Global Positioning System (GPS) has been developed in outdoor environments in recent years. GPS offers a wide range of applications in outdoor areas, including military, weather forecasting, vehicle tracking, mapping, farming, and many more. In an outdoor environment, an exact location, velocity, and time can be determined by using GPS. Rather than emitting satellite signals, GPS receivers passively receive them. However, due to No Line-of-Sight (NLoS), low signal strength, and low accuracy, GPS is not suitable to be used indoors. As consequence, the indoor environment necessitates a different Indoor Positioning System (IPS) approach that is capable to locate the position within a structure. IPS systems provide a variety of location-based indoor tracking solutions, such as Real-Time Location Systems (RTLS), indoor navigation, inventory management, and first-responder location systems. Different technologies, algorithms, and techniques have been proposed in IPS to determine the position and accuracy of the system. This paper introduces a review article on indoor positioning technologies, algorithms, and techniques. This review paper is expected to deliver a better understanding to the reader and compared the better solutions for IPS by choosing the suitable technologies, algorithms, and techniques that need to be implemented according to their situation.**

*Keywords—Global positioning system (GPS); indoor positioning system (IPS); real-time location system (RTLS)*

## I. INTRODUCTION

The positioning system is a method to determine the position of the object in space. In today's economy, many positioning systems are employed in all areas. In general, the positioning system can be divided into three types which are Global Positioning System (GPS), Local Positioning System (LPS), and Hybrid Positioning System (HPS) which have been highly useful in a wide variety of outdoor and indoor environments [1]. GPS is one of many satellites orbiting around the universe. GPS has several uses in a variety of fields in outdoor environments such as military, weather forecasting, vehicle tracking, mapping, farming, etc. [2]. An exact location, velocity, and time can be determined by using GPS. Rather than emitting satellite signals, GPS receivers passively receive them. The object's precision ranges from 2 to 6 meters. However, GPS is not suitable to determine the location indoors because there is

No Line-of-Sight (NLoS), low signal strength, and low accuracy.

LPS is one of the positioning technologies included in electronic performance and tracking systems, as it determines the position of an object in the Cartesian coordinate system [3]. It usually allows users to collect data to keep track of external load needs. Zone (up to 20 meters) and precise placement (from 0.1 to 3 meters) are types of LPS. The use of optimal LPS in an indoor environment becomes necessary with good accuracy, precision, cost, power consumption, and coverage. Wireless Fidelity (Wi-Fi), Bluetooth Low Energy (BLE), Radio Frequency Identification (RFID), and Ultrawideband (UWB) are an example of common wireless communication that is involved in LPS. However, LPS is more complex and expensive compared to GPS due to the deployment of infrastructure and hardware.

Meanwhile, HBS is a combination of GPS with LPS to track items in both outdoor and indoor environments. These systems were created to address the limitations of GPS, which is extremely accurate in open spaces but fails to perform well indoors or between tall buildings. Better position estimations can be determined by hybridizing the positioning information from different technologies. This way, the combination can enhance the system's accuracy and availability in diverse locations [4]. The solution is highly optimized, with opportunistic fingerprint selection and floor change detection minimizing time-consuming processing and a battery-saving subsystem reducing power consumption by turning off unnecessary technologies.

Through all of the positioning systems available, it can be divided into outdoor positioning and indoor positioning. For outdoor positioning, the GPS can always support with high accuracy, but Indoor Positioning Systems (IPS) face more challenges than outdoor positioning due to pervasive hindrances and interaction interference [5], multi-path effect, fading, reflecting, deep shadowing effect, and delay deterioration.

IPS refers to the technology that helps to locate the position of people or objects inside the buildings. The location data is sent into some sort of application software to make the data useful. The design of IPS depends on what type of indoor positioning technologies, indoor positioning algorithms, and

indoor positioning techniques are used in the system. IPS technologies provide a variety of location-based indoor tracking solutions [6], such as Real-Time Location Systems (RTLS), navigation, inventory management, and first-responder location systems.

IPS also can be divided into self-positioning and remote-positioning systems. A self-positioning happened when a system the positioning was measured by the node (device) itself. The node will act as a receiver and the transmitter will be the anchor node surrounding. By using this system, it guarantees privacy, but in another way, it burdens the node with the computational service to measure its location or position. The example of this system should have a reference sensor node also known as an anchor node with a known position and a target such as a node, object or people to be located (device). The reference sensor node sends a range request to the target's compatible mobile device such as a smartphone. Smartphones receive the signals and respond to the reference sensor node with a response. Sensors will calculate the traveling time between sensors and smartphones. The computed time sent by the sensors will then be received by the calculating center. A computation center is often a Personal Computer (PC) or a Base Station (BS). The calculating center, which had a strong computational capability, used a positioning algorithm to process the provided data and obtain the target's location result.

While, for the remote-positioning, the receiver will be placed at the anchor node surrounding while the node (device) will be reacted as the transmitter. The computational system will be a burden on the infrastructure (the server) while the node (device) can have lower power consumption. In this positioning system, the node (device) uses signals, transmitted by the anchor node to calculate its position.

IPS can be divided into two phases which is signal measurement is the first phase. The physical position of the target node will be calculated in the second phase using the signal characteristics collected in the first phase. The most frequent approach is ranging, which involves obtaining distance or angle estimations. Geometric techniques will be used to determine the target node's position as the intersection of position lines derived from position-related parameters at reference nodes. The two most popular geometric approaches are Trilateration and Triangulation. To filter the measurement noise and improve the accuracy, optimization-based statistical techniques are often used. The communication entity associated with individuals is represented in the first phase by certain signals transmitted between the target node and sensor nodes, as well as the number of reference nodes represented by the sensor nodes. At this moment, receivers will be gathering information about the signal's characteristics such as arrival time, signal intensity, and direction.

## II. LITERATURE REVIEW

Recently, Wi-Fi technologies in indoor positioning system have been topic of interest among researchers. The subsections that follow present some existing works for indoor positioning that implemented RSSI algorithm and Trilateration technique. RSSI algorithm are the most popular range-based. The primary concept is to use the power of the received signal, knowledge of the broadcast power, and the route loss model to estimate the distance between a transmitter and the receiver [7]. Trilateration technique is used to determine an object position using simultaneous range measurements from at least three reference APs at known locations.

The BLE with RSSI algorithm were proposed in [7]. Positioning algorithm were implemented in Java using Android SDK and been tested in Huawei B199 smartphone. Four Beacon devices were placed in one room and mobile device were placed in four different positions. The distance between mobile devices with Beacon devices were calculated by using RSSI and filtered by using Kalman Filter. Triangulation was used to calculated the current location of mobile devices. The average accuracy achieved in this system was 0.2 – 0.4m.

Researchers in [8] presented a Beacon Bluetooth device to overcome the limitation of other technologies. The distance estimation of the beacons, the number of signals collected by Android devices, and the internet connection from the Android smartphone all impact the accuracy of the user position. The Trilateration technique was employed in this study, along with a measuring methodology based on RSSI value. The result shows that accuracy achieved is 84%. According to the findings of the test, objects with thickness and density have a significant impact on the RSSI of the Beacon devices. Calibration on Beacons is important for fine-tuning RSSI values at a distance of 1 meter in order to improve the accuracy of the estimated distance between the beacon and the device. Disadvantages of using Bluetooth beacon is, to get high accuracy, more beacon devices need to be installed and resulting high in cost.

Therefore, after reviewing the limitations of other projects, this review suggests an implementation of existing Wi-Fi infrastructure with received signal strength values. In addition, the integration of RSSI algorithm and Trilateration technique with been suggested to determine the improvement of accuracy in the system.

## III. INDOOR POSITIONING TECHNOLOGIES

There are many different types of technologies that can be implemented in IPS. It is important to use the correct technology based on the type of positioning that needs to be developed. Satellite-Based, Magnetic-Based, Inertial Sensor-Based, Sound-Based (Audible Sound, Ultrasonic Sound, Acoustic Sound), Optical-Based, Radio Frequency-Based (Wi-Fi, BLE, RFID, and UWB), and Vision-Based [9] are examples of technologies as shown in Fig. 1.

### A. Satellite-based

The most popular system for outdoor systems is the Satellite-Based. It is based on a global network of satellites that transmit radio signals in medium-earth orbit. The basic GPS service provides users with an approximately average User Range Error (URE) of less than 7.8 meters 95 percent of the time, anywhere on or near the surface of the earth [10]. Satellite control systems take little effort and cost to set up, but their operation necessitates the installation of monitoring systems and dispatching software.
Fig. 1.   Types of Indoor Positioning Technologies.

Despite all of the benefits, GPS only works in open areas where satellite signals are consistently received. The scope of the global system is limited to transport and in some cases, mobile personnel [11]. However, due to technological limits of signal re-reflection in the premises, even with wide windows, satellite technologies will not be useful for premises, manufacturing, or deep mining.

### B. Magnetic-based

To determine the locations which relate to magnetic indoor positioning, the use of geomagnetic fields has been distorted [12]. Magnetic fields can be used in IPS in two methods [13]. The first method is when one makes use of anomalies induced by disruptions in the earth's magnetic field to perform positioning. Another method is using artificially generated magnetic fields in which coils of current-carrying wire are installed in strategic areas throughout the structure. On receiving node, each coil's magnetic field strength is measured.

To build an efficient magnetic field map, a map-building system for magnetic fields is needed. The magnetic field system consists of sensors such as an array, odometry, and a data alignment system. The position of the system is estimated by using odometry when the system is moving in a test area. At the same time, magnetic field data is measured. Finally, a magnetic field map is built when the data are aligned with the position. Earth's geomagnetic-based positioning system which is based on Earth does not require any additional hardware because it enables a smartphone compass to locate the position in an indoor environment [14]. It also has a stable signal [15]. The robustness can be obtained when using magnetic fields as fingerprinting in indoor environments [16]. When constructing indoor positioning systems, resilience is important since it may significantly minimize the number of measurements and time required to create a large fingerprint database.

External factors such as device diversity and user diversity need to be aware. Magnetic sensors may be made using a variety of sensing technologies and materials. As a result, multiple magnetic sensors at the same position may produce different results. Magnetic reading might be slightly different when using different sensors [17]. In addition, the different user has different step lengths; hence they generate different magnetic fingerprints.

### C. Inertial Sensor-based

Sensors based on inertia and associated measurement principles are known as inertial sensors. Accelerometers and gyroscopes are an example of inertial sensors. It does not require any external references [18] and installation since it does not depend on the environment.

The orientation inaccuracy will develop with time owing to sensor drift and recursive computation. Because accurate orientation information is a requirement for personal tracking/positioning and movement monitoring, incorrect orientation will impair the calculated accuracy of position. Magnetic field sensors are fused with inertial sensors using a Kalman filter to offer a long-term stable orientation solution.

In addition, the Inertial Navigation System (INS) is another localization navigation technology that is capable of calculating the location by a self-contained navigation technique that uses the existence of computers, motion sensors, and rotation sensors to be as the reference point. INS is normally used for a wide range of applications such as navigation of aircraft, tactical and strategic missiles, and submarines.

### D. Sound-based

Another technology used for localization systems is Sound-Based which is normally used in underwater monitoring and tracking. This technology can be classified into three categories which are Audible Sound, Ultrasonic, and Acoustic Sound. Sound waves travel at a slower rate than electromagnetic waves leading to the major problem which is to make time synchronization easier.

*1) Audible sound*: Due to its intrinsic qualities, Audible Sound has recently been studied as an emergent technique. Audible Sound can be used to store the data for location systems [19]. It has similar qualities to ultrasound but is less expensive and more acceptable for use in everyday life because of the availability of off-the-shelf equipment with broader coverage, such as loudspeakers and mobile phones, which may be utilized with just modest modifications. Audible Sound was assumed that it would disrupt the acoustic environment unfavorably [20], so it was not tackled.

*2) Ultrasound*: Ultrasonic systems employ sound frequencies above the hearing range (above 20 kHz) to establish the user's location by measuring the time an

ultrasonic signal takes to travel from a transmitter to a receiver.

"Active" and "Passive" are types of ultrasonic systems. The ultrasonic positioning system can be implemented in various applications such as healthcare, hotel business, offices, and other indoor building. The Time-of-Flight (ToF) approach, which involves measuring the signal propagation time from the sensor to the receiver, is the basis for ultrasonic positioning. Special tags use to transmit ultrasound impulses are applied to measure the distance. The receiver network analyses these signals and delivers data to the central system, which calculates the position with a 3 cm precision using multilateration.

The advantage of ultrasonic is it can work in real-time. The frequency of the signal varies can be up to 3 seconds. It also can carry out the system's operational deployment with fine-tuning. Apart from that, the accuracy of ultrasound can be identified within several centimeters.

However, an ultrasound signal is only slightly influenced by its surroundings and has very little penetration through walls [21], which might help it be more useful in the suggested ultrasonic indoor locating system.

*3) Acoustic sound*: Due to its unique benefits, audio-based indoor positioning technology, which functions by producing and receiving acoustic signals between nodes and the placement target, has recently gotten a lot of attention. An Angle of Arrival (AoA), Time of Arrival (ToA), Time Difference of Arrival (TDoA), and Frequency Difference of Arrival (FDoA) are measurements that depend on acoustic signal measurement. The measurements have been implemented in audio-based indoor positioning.

*E. Optical based*

Optical-Based positioning used for localization is normally in the form of an Electro-Magnetic (EM) spectrum since the techniques and challenges are quite different. This system is a flexible navigation system for deep space operations. Optical positioning can be characterized into two, which are Infrared (IR) and Visible Light Communications (VLC).

*1) Infrared (IR)*: An IR communication technology is extensively used, low-cost, and widely available [22]. Infrared signals are employed in a variety of applications, from consumer remote controls to data transmission. In [22], the researcher proposed a low-range IR signal with AoA estimation. The proposed concept is applied to overcome the localization problem that prevents NLoS issues. It has been applied to navigate a grocery cart in a difficult environment. The results of the tests range from centimeter-level accuracy in a static 1 Dimension (1D) environment to 1 m mean localization error in a 2 Dimension (2D) setup for a mobile cart moving at 140 cm/s. These findings suggest that utilizing easily accessible IR technology and low-cost hardware components, suitable localization precision, and real-time navigation support may be accomplished in the supermarket.

Other than that, [23] stated that IR Light Emitting Diode (LED) with a wide emitting angle is less complex than a laser-based. However, to have a sufficiently high Signal-to-Noise Ratio (SNR) for effective demodulation, a complex sensor design is required.

*2) Visible light communications (VLC)*: VLC has been deemed an appealing alternative for indoor location systems. Triangulation is one of the algorithms that has been applied in the VLC positioning system due to its low cost and accuracy. The location can be estimated using the geometric properties of the triangle, where the light-emitting diodes (LEDs) serve as anchors and the receivers serve as agents in VLC systems, by measuring the distances between multiple reference anchors. In harsh environments, however, the triangulation positioning algorithm may fail.

The advantages of VLC are illuminance that can be dimmed [24], intrinsic security, and a spectrum that is generally available. Furthermore, because VLC-based systems are less susceptible to multipath propagation and disturbance from other wireless devices, they should give superior location accuracy to radio-wave alternatives. VLC does not produce electromagnetic interference and it can be implemented in restricted buildings such as hospitals [25].

*F. Radiofrequency*

Radiofrequency (RF) technology was commonly used in IPS. It is a mixes narrow-band with spread-spectrum transmissions and is based on signal strength technologies [26], which are especially useful for wireless communication devices.

Wi-Fi, BLE, RFID, and UWB are among the common wireless communication technologies involved in RF. While RF-based systems offer various advantages for positioning, they have a severe flaw in the indoor environment. Accuracy, cost of implementation, and power consumptions are the important parameters that need to evaluate to choose the best and most affordable technologies.

*1) Wireless fidelity (Wi-Fi)*: Now-a-days, Wi-Fi, which is based on the IEEE 802.11 standard, is well-known and widely used in radio technology. When there are enough Wi-Fi access points and no dedicated infrastructure is required, Wi-Fi-based procedures are employed in interior scenarios; alternatively, existing building infrastructure may be utilized because most current buildings are equipped with Wi-Fi access points. Wi-Fi-based indoor navigation systems commonly used RSS Fingerprinting, Triangulation, or Trilateration techniques [27] for location estimation.

Access points are commonly utilized in a building's planned or current Wi-Fi wireless networking capacity whose position has been optimized for data connection. It calculates the distances between three or more Wi-Fi access points using the Wi-Fi receiver in a smartphone.

The accuracy of Wi-Fi for interior locating is normally 5-15 meters. The precision of this measurement is determined by the amount of shielding provided by walls, ceilings, and people, as well as the number of entry points. The inclusion of smartphone

sensors can enhance the findings, and the floor level can also be determined. The implementation of Wi-Fi might be low due to the existing Wi-Fi structure in each building; however, power consumption for a Wi-Fi-based positioning system is high.

*2) Bluetooth low energy (BLE)*: BLE is a kind of wireless communication optimized for short-range communication. It is virtually as accurate as Wi-Fi-based systems, and they employ RF signal sources to monitor users' whereabouts via proximity sensing or RSSI fingerprinting.

Smartphones are now often utilized as receivers for both Bluetooth and Wi-Fi signals, following recent advancements. Beacons are small devices for BLE that be mounted on the walls [28]. Beacons device use battery power supply, as for that, it requires battery placement.

For BLE, complex signal processing is needed to reach good accuracy. The implementation cost for BLE is low as it is one of the most popular and easily used in indoor positioning. The power consumption for BLE can be high due to high data throughput.

*3) Radiofrequency identification (RFID)*: RFID is a traditional method of automated identification that is based on RF wireless communication technology. A typical RFID system contains tags such as transponders, smart tags, a reader, and a host computer and software/ infrastructure. A wired or wireless connection connects the reader to the host computer. For tracking reasons, on electromagnetic transfer between RFID readers and RFID tags [29]. It mixes narrow-band with spread-spectrum transmissions and is based on signal strength technologies, which are especially useful for wireless communication devices. The electromagnetic field of sources or equipment produces radio waves.

The accuracy of RFID can be determined in a short range of 0.5 to 1m and does not suitable for high-range scale location usage. The batteries of RFID tags also have to be replaced if it needs to do a large coverage. The complexity is getting high due to the implementation of complex algorithms such as the Kalman filter, K-Nearest Neighbor (KNN), and Radio map. RFID has low power consumption.

*4) Ultra-wideband (UWB)*: UWB is a radio technique that uses a wide section of the radio spectrum to distribute high-bandwidth communications. It allows UWB to transmit large amounts of data with consuming minimal energy for short-range communication [30]. UWB pulses have a low frequency that allows them to travel through walls, equipment, and other impediments. It also will not interact with current Radio Frequency (RF) systems if it were properly constructed. Since reflected signals do not overlay directly with received signals, UWB's brief transmission pulses make it easy to differentiate between direct and reflected signals. As a result, multipath interference is not a problem with UWB. Fixed-location sensors receivers and tags are used in UWB.

The accuracy of UWB can be achieved by 0.1 to 0.3 meters which is much better than Wi-Fi and BLE. However, this technology is a unique solution that necessitates the use of certain components that it is best suited to industrial applications. Compared to other positioning technology systems, UWB utilizes less power, allowing for greater power efficiency and longer device battery life. The implementation of UWB is quite complex because it requires signal acquisition, synchronization, and tracking with high precision.

*G. Vision-based*

This method is based on video data processing and assessment. In general, there are two ways [31] to conduct video-based localization which are fixed camera systems and mobile camera systems.

*1) Fixed camera system*: Fixed camera systems are used when they can be mounted in fixed locations. For example, the moving objects have been captured using one or more cameras. The tracking target's characteristics must be utilized. If the target's prominent characteristics show in the camera's field of vision, the target's location may be determined by the camera's fixed position. The target's location is determined by its location inside the recorded picture and the spatial distribution of its conspicuous characteristics.

*2) Mobile camera system*: The camera in the mobile camera system is already equipped to perform the localization with the known position in several landmarks. There are two stages in localization to determine the mobile camera's location and orientation; the offline stage and the online stage. mages of the environment are captured at predefined locations and each image is processed to extract its unique features that are stored in a database in the offline stage. During the online stage, the camera captures a picture, which is then extracted and matched to previously recorded attributes to determine the camera's position.

## IV. Indoor Positioning Technologies Discussion

Each one of the technologies has its specialty. From the table below, we can conclude that GPS is not suitable to use in an indoor environment. Magnetic-based is suitable to determine the accuracy of position; however, it is complex and high in cost. In addition, inertial-based also can be used to determine the high accuracy and can be developed in a wide range of applications. However, fused with magnetic-based to get a long-term stabilization, it makes the system complex. Due to the high cost and its complexity, sound-based is the least suitable for indoor positioning systems. Optical-based and visual-based are low in cost system; however, it is complex and less accurate compared to other technologies.

Recently, the RF communication technologies such as Wi-Fi, BLE, RFID, and UWB are widely used in indoor positioning to develop location estimation. Their characteristic such as power consumption, accuracy, and cost are the factors that have been evaluated due to the benefits of an indoor positioning system as shown in Table I.

TABLE I.    SUMMARY OF TECHNOLOGIES IN IPS

| Technologies | Advantages | Disadvantages |
|---|---|---|
| Satellite-Based | • GPS easy to navigate<br>• Low-cost implementation | • Cannot be implemented in an indoor environment<br>• Less accurate |
| Magnetic-Based | •         High accuracy | • High-cost implementation<br>• Complex |
| Intertial-Based | •         High accuracy<br>•         Wide range application<br>•         Does not require hardware installation<br>•         High accuracy | • Fused with magnetic to get long-term stabilization<br>• Complex |
| Sound-Based | | |
| Audible Sound | • Less expensive<br>• Easy to implement | • High-cost implementation |
| Ultrasonic | • Close range distance measurement | • High-cost implementation |
| Acoustic sound | • Low-cost implementation<br>• Easy to implement | • Complex |
| Optical-Based | • Low-cost implementation | • Complex<br>• Low accuracy |
| Radio Frequency (RF)-Based | | |
| Wi-Fi | • Low-cost implementation | • High power consumption |
| BLE | • Low power consumption<br>• High accuracy | • Complex<br>• High-cost implementation |
| RFID | • Small size<br>• High accuracy<br>• Low power consumption | • High-cost implementation<br>• Complex |

| Vision-Based | • Low-cost implementation | • Low accuracy<br>• Complex |

## V.    INDOOR POSITIONING ALGORITHMS

Signal characteristics with geometrical parameters made up of metrics like angle, distance, and the signal may be used to compute the position of an object or user. The algorithms for indoor positioning as displayed in Fig. 2 are divided into two which are directly based and distance-based. The Angle of Arrival (AoA) and Angle Difference of Arrival (ADoA) can be categorized as direction-based. In addition, distance-based [32] are Phase of Arrival (PoA), Phase Difference of Arrival (PDoA), Reference Signal Received Power (RSRP), Received Signal Strength Indicator (RSSI), Channel State Information (CSI), ToA, TDoA, and Round-Trip Time (RTT).

### A. Direction-based

*1) Angle of arrival (AoA)/ angle difference of arrival (ADoa)*: The word 'Angle of Arrival' (AoA) is used in a simplified technique for 2D operation, calculating angles in a single plane [33]. Using multiple AoAs with known receiver absolute position, any multilateration approach may be used to determine the sender's absolute coordinate. An equipment

upgrades at receiver AoA [34] and error in non-linear dependent are primary difficulties.

The localization of AoA is determined by using directional antennas or antenna arrays as shown in Fig. 3. An antenna array may be used to determine the angle at which the broadcast signal impacts directly on the receiver by leveraging and measuring the difference in time of arrival at selected antennae array members. The position of the source is restricted along a line along the predicted line of bearing by a single AoA measurement. A triangulation technique may be implemented to produce position estimation when numerous AoA measurements are collected concurrently according to the environment.

To determine mobile node location, at least two reference nodes are required to perform the AoA algorithm. An equation for AoA is as follows [35]:

$$x = d_i cos(\emptyset_i) + x_i,$$

$$y = d_i cos(\emptyset_i) + y_i, \ i = 1, 2, 3 \tag{1}$$

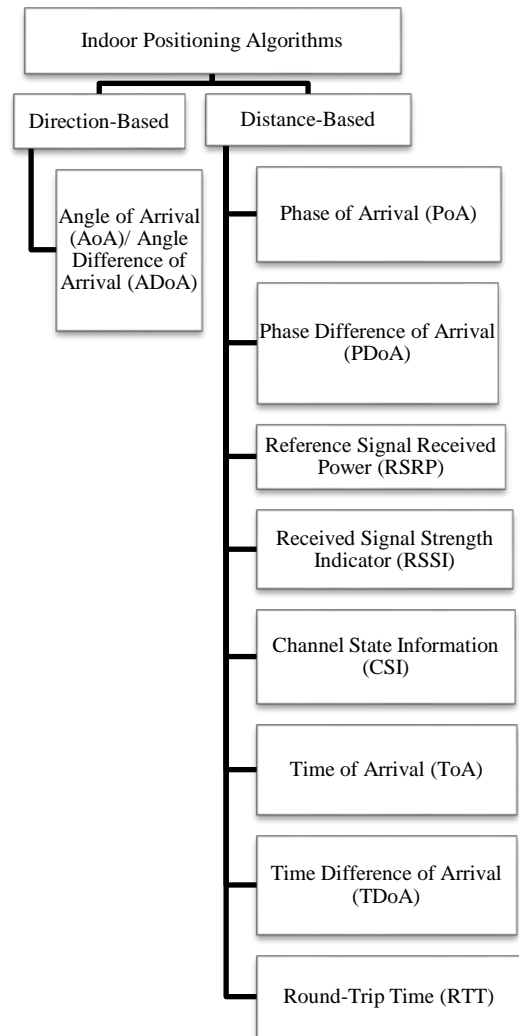

Fig. 2.   Types of Indoor Positioning Algorithms.
Fig. 3.   AoA based Localization.

## B.  Distance-based

*1) Phase of arrival (PoA)*: The phase of the carrier signal is used to calculate the distance in PoA ranging methods [36]. In a passive RFID 2D localization system, the PoA positioning approach was applied to improve the accuracy [37] and reduce the disruptions caused by multipath propagation.

To improve their effectiveness, PoA techniques can be used with other techniques like ToF, TDoA, and RSSI. However, for great accuracy, PoA positioning techniques may require LoS.

*2) Phase difference of arrival (PDoA)*: PDoA methods, which employ the delta between phases of the receiver to determine the angle between receivers and transmitters, were originally used in radar systems [38]. PDoA only requires two antennas. It does not need time to synchronize among base stations compared to TDoA positioning.

*3) Reference signal received power (RSRP)*: RSRP variables are physical layer data from a 4G cellular system that are used to anticipate a user's position with absolute precision [39]. RSSI algorithm is used to determine RSRP. It uses cell-specific reference signals to compute the mean achievable strength. As a result, compared to regular RSSI, it may provide more signal strength information linked with varied locations.

*4) Received signal strength indicator (RSSI)*: The Received Signal Strength (RSS), also known as the Received Signal Strength Indicator (RSSI), is a measurement of the strength of a radio signal that has been received. [40]. RSSI is also known as a measurement to show the condition of received power in the anchor nodes and it is used in most wireless communication methods [41]. RSSI-based localization has the advantage of simplicity [42]. RSS-based target localization is a popular issue in wireless sensor networks, with several applications [43]. This method is based on video data processing and assessment.

The traditional approach to RSS-based localization is to use RSS data to derive distance information between the sensor and the target. Unfortunately, when the number of sensors is insufficient, the traditional RSS-based localization approach fails to attain adequate accuracy due to the deteriorating effects of fading, shadowing, and reflections of the radio signal.

Furthermore, many targets are active at the same time in multiple target localization settings, and target signals overlap at each sensor. The traditional approach is no longer practicable since it is difficult for a sensor to directly extract distance information from every target. As a result, developing an effective RSS-based localization technique for various targets is quite important.

Hardware modifications such as the smartphone's form factor, receiver module due to a number, internal circuitry architecture, and antenna design such as built-in signal processing and data loss can all affect RSSI readings [44]. RSS readings may be acquired with little effort and without additional circuitry, resulting in significant cost and energy savings for sensors. With the estimation, position information can be acquired. Fig. 4 shows an overview of how signal strength affects distance. The user node is to be estimated. $RN_1$, $RN_2$, and $RN_3$ as reference nodes. There are three processes to determine the user position [45]. First, collect and measure RSSI. The second process is determining the RSSI distance using the path-loss equation. Lastly, position estimation uses the Trilateration method.

The distance between Mobile Node (MN) and each APs can be determined using RSSI from the Distance Power Law equation [46]:

$$P_r(d_i) = P_r(d_0) - 10nlog(\frac{d_i}{d_0}) + (-T) \times WAF \quad (dBm) \quad (2)$$

$P_r(d_0)$ represent the initial value, $d_0$ is received power at a close-in reference distance of one meter, $d_i$ is the distance between transmitter and receiver, $n$ is the path loss exponent between 0 to 5, $T$ is several walls between transmitter and receiver, $WAF$ is Wall Attenuation Factor. Based on the equation above, the distance $d_i$ can be calculated as follows:

$$d = e^{(\frac{P_r(d_0) - P_r(d_i) - T*WAF}{10})} \quad (3)$$

*5) Channel state information (CSI)*: In Wi-Fi indoor positioning, Channel State Information (CSI) is commonly been applied. It is because of the features based on the physical layer and descriptions of amplitude and phase information; CSI can represent fine-grained channel information. As a result, most researchers are interested in CSI-based positioning [47]. Signals are propagated in a Wi-Fi network using Orthogonal Frequency Division Multiplexing (OFDM) modulation. The signal is received by the terminal after being broadcast across the multipath channel by OFDM, which divides the communication channel into orthogonal sub-channels of various frequencies [48]. The properties of the communication link between the transmitter and the receiver are represented by CSI. CSI can be expressed as [48]:

$$Y = HX + N \quad (4)$$

Y represents the received signal vector. H is the channel information matrix, X is the transmitted signal vector, and N is additive white Gaussian noise. CSI also can be expressed as:

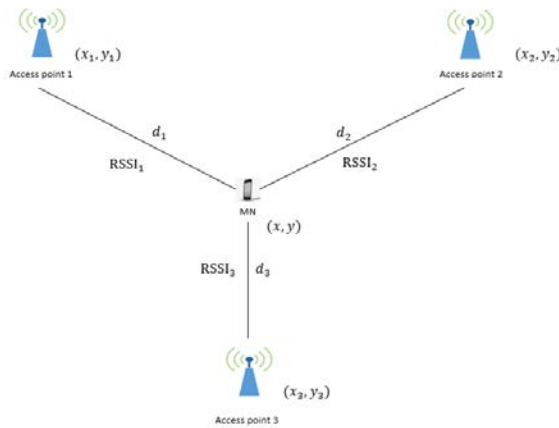
$$\widehat{H} = \frac{Y}{X} \quad (5)$$


Fig. 4. RSSI-based Localization.

Ĥ represents the Channel Frequency Response (CFR) for each subchannel. Researchers in [49] proposed deep learning-based indoor fingerprinting using CSI named as DeepFi. The system architecture is divided into offline and online training. Deep learning is used to train all the weights in offline training. Moreover, to decrease complexity, a greedy learning technique is employed to train all the weights layer by layer. During online training, the researcher used the probabilistic method to obtain the location. The result shows that DeepFi successfully minimizes location error when compared to three current approaches.

The extreme multipath and shadow fading effects, as well as the sensitivity to the dynamic environment, are two major obstacles to a functional CSI-based indoor positioning system. Short and long-term interference will cause the signal unavailable:

*6) Time of arrival (ToA)*: The absolute time when a radio signal from a transmitter reaches a distant receiver is known as the Time of Arrival (ToA) [50]. The simplest and most popular ranging approach is a ToA, which is most famously utilized in the GPS [51]. This algorithm is based on determining the time when the signal was sent to the target, the time when the signal arrives at the target, and the speed at which the signal travels. When all of these are known, the distance can be calculated by using [51]:

$$d = c * (t_{arrival} - t_{sent}) \tag{6}$$

C is the speed of light. The set of probable target locations may be identified using this distance. Many radiolocation systems employ ToA readings to accomplish true-range multilateration geo-positioning. When signals move at a constant velocity, the real range or distance may be determined directly from the ToA. The measured ToA depicts a circle with its center at the receiver in two-dimensional (2D) space, and the source must be on the circumference. In 2D, an equation is as follows [51]:

$$d = \sqrt{(x_{ref} - x)^2 + (y_{ref} - y)^2} \tag{7}$$

$(x_{ref}, y_{ref})$ is a known position of reference point. At least 3 or more reference points are needed to determine the target

position by finding the intersection. Fig. 5 states that 2D location estimation required a minimum of three sensors where A, B, and C are the distances between transmitter and receiver. An intersection can be required if there are at least three sensors. Meanwhile, for 3-Dimensional (3D) position estimation, it required at least four sensors [52] as shown in Fig. 5.

The clocks of the tag and the reader must be synchronized to get a perfect measurement of elapsed time. However, the cost for implementation is high and it is more complex.

*7) Time difference of arrival (TDoA)*: TDoA is a common approach for identifying targets using a set of sensor nodes with known positions. [53]. It is the second most used range technique, and it is more versatile than ToA in some ways. The time signal was received and the speed at which it traveled is all that is required for this technique. It is not the time when the signal was transmitted from the destination. Unlike previous geolocation methods, TDoA delivers accurate geolocation even for signals with power levels below the noise floor.

To achieve high-accuracy TDoA, precise synchronization between receivers is required. Anchors must be precisely synced, which necessitates the usage of synchronization beacons. Fig. 6 shows the working principle of TDoA.

Fig. 5. ToA-based Localization.

Fig. 6. TDoA-based Localization.

At a specific moment of timestamp at reception, $T_0$, the tag will blink and four access points receive the message at various times $(T_1 \ldots T_4)$. The difference time of arrival has to be computed to estimate the position of the tag using this equation [51]:

$$\triangle d = c * (\triangle t) \tag{8}$$

where c is the speed of light, $\Delta t$ is the difference in arrival times at each reference point. Meanwhile, for 2D, the equation is as follows [54]:

$$\triangle d = \sqrt{(x_2 - x)^2} - (y_2 - y)^2 - \sqrt{(x_1 - x)^2} - (y_1 - y)^2 \tag{9}$$

where $(x_1, y_1)$ and $(x_2, y_1)$ is a known position. This equation may be changed to the form of a hyperbola via nonlinear regression. After calculating a sufficient number of hyperbolas, the intersection may be used to determine the target's location.

*8) Round-trip time (RTT)*: Indoor positioning systems based on distance estimates were given Wi-Fi Round-Trip Timing (RTT). Unlike the Wi-Fi fingerprint approach, which necessitates the creation of a massive database known as a radio map, this protocol may be readily implemented in an indoor positioning system using only the AP's installation coordinates. In addition, Wi-Fi RTT is determined by Fine Timing Measurement (FTM).

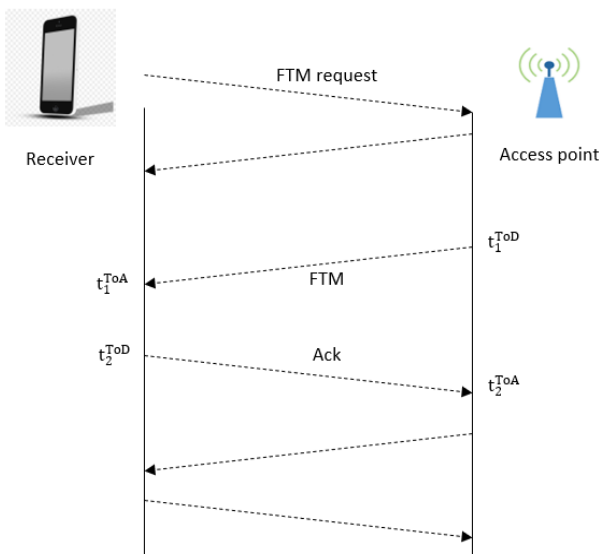
Fig. 7 shows the FTM is a ping-pong technique that measures the signals of RTT. Firstly, a smartphone needs to transmit the request to RTT AP [55]. The AP and smartphone then begin sending the FTM message and recording the transmission timestamp, as well as waiting for the acknowledgment packet and recording the receipt timestamp. As a result, ToA and Time of Departure (ToD) may be acquired and used to determine the ToF of the signal from transmitter to receiver. The distance between the AP and the smartphone is calculated using ToF.


Fig. 7. RTT-based Localization.

An Android system has RTT Application Programming Interface (API). It is used to obtain ToF using [55]:

$$ToF = \frac{(t_2{}^{ToA} - t_2{}^{ToD}) + (t_1{}^{ToA} - t_1{}^{ToD})}{2} \tag{10}$$

where $t_i{}^{ToA}(i = 1, 2, 3, ..)$ and $t_i{}^{ToD}(i = 1, 2, 3, ..)$ is ToA and ToD measurements. The distance between transmitter and smartphone then been calculated using the equation as follows:

$$d_{rtt} = ToF * c \tag{11}$$

c is representing the speed of light. Meanwhile, $d_{rtt}$ is the distance between transmitter and smartphone.

## VI. Indoor Positioning Algorithms Discussion

In summary, the signal-based is critical in determining position since it is used in the computation and estimation of a location. The algorithms that are commonly involved are AoA, ToA, TDoA, and RSSI positioning-based. However, due to complexity, high cost, and required additional hardware for AoA, ToA, and TDoA compared to RSSI. Therefore, the RSSI algorithm is the best solution for determining the user/ object position. The comparison of the indoor positioning algorithm is shown in Table II.

TABLE II.        SUMMARY OF ALGORITHMS IN IPS

| Algorithms | Advantages | Disadvantages |
|---|---|---|
| AoA | • Easy to implement<br>• Required at least two APs for localization | • Low accuracy in a large area<br>• Specialized antenna<br>• High-cost implementation<br>• Complex |
| ADoA | • No need for an angle phase | • Required additional sensor |
| PoA | • Signal change is easy to obtain | • Require LoS for high accuracy |
| PDoA | • High accuracy<br>• Reduce multipath effects | • Accuracy is depending on the multipath effect |
| RSRP | • Provide more signal strength | • Station interference and thermal noise have an influence |
| RSSI | • Low-cost implementation<br>• Easy to implement | • Low accuracy in a large area |
| CSI | • Good stability<br>• High accuracy | • High-cost implementation<br>• Complex |
| ToA | • Easy to implement<br>• Time measurement required for TDMA/ CDMA network | • Need a synchronized network<br>• High-cost of implementation<br>• Complex |
| TDoA | • The receiver does not need the time of transmission<br>• Time measurement required for TDMA/ CDMA network | • Need a synchronized network<br>• Complex |
| RTT | • High range measurement<br>• No need a synchronize between nodes | • Multipath effects<br>• Complex |

## VII. INDOOR POSITIONING TECHNIQUES

The current position or location of the target item was calculated using positioning techniques [56]. The algorithm and the output of the position are processed by the positioning technique. Triangulation, Trilateration, Proximity, Scene Analysis, Fingerprinting, and Pedestrian Dead Reckoning are the main technique for indoor positioning as shown in Fig. 8.
Fig. 8.   Types of Indoor Positioning Technique.

### A. Triangulation

Triangulation is a method of calculating a position based on the predetermined distance between three measuring devices and the measured angles from those three locations of an object [57]. Triangulation provides high accuracy if AoA has good precision. By increasing the number of access points, high precision may be obtained. However, a small error in angle calculation may affect the location accuracy.

This technique is particularly well suited to line-of-sight communication [58]. Calculating the angles and distance between reference points, as well as determining the position of a transmitter, are used to determine the position of an object. Triangulation can be divided into two categories: a) Lateration and b) Angulation. The basic localization for triangulation is shown in Fig. 9. From three access points, an angle measurement was made by the lines from distant points intersecting with the baseline.

These angles are then utilized to calculate unknown distances and, as a result, distance place was found [59]. The equation is as follows [60]:

$$x = d_1 sin(\theta_1) + x_1$$
$$y = d_1 cos(\theta_1) + y_1$$
$$x = -d_2 sin(\theta_2) + x_2 \qquad (12)$$
$$y = d_2 cos(\theta_2) + y_2$$
Fig. 9.   Triangulation Technique Localization.

### B. Trilateration

Trilateration is a more widely used technology that GPS also employs [59]. Trilateration is a method to determine an object's position using simultaneous range measurements from at least three reference nodes at known locations [61]. Measurements of angle do not involve trilateration [62]. Fig. 10 shows the three access points used in the trilateration technique in an indoor positioning system.

In practice, the edge-to-edge intersection of all reference circles is difficult to obtain due to the continuously changing in an indoor environment. The dependence of all three or more circles on edge-to-edge intersection reduces the estimation accuracy [63] of the trilateration technique.

The distance can be estimated using this equation [60]. It can be solved by using the matrix method:

$$d_1{}^2 = (x - x_1)^2 + (y - y_1)^2$$
$$d_2{}^2 = (x - x_2)^2 + (y - y_2)^2 \qquad (13)$$
$$d_3{}^2 = (x - x_3)^2 + (y - y_3)^2$$

### C. Proximity

Localization based on proximity is a type of range-free localization. Proximity is the simplest method for localization [64]. It also might be the primary option if the user doesn't know the specific Mobile Devices (MD) radio settings or the architecture of the surroundings. Many researchers have utilized proximity-based localization to locate objects in ad hoc and wireless sensor networks.
Fig. 10.  Trilateration Technique Localization.

Fig. 11 shows the proximity method for indoor positioning. In proximity methods, the MD's position is determined relative to the AN position instead of explicit distances to the ANs. The precision needed for proximity detection in interior contexts is less than one meter, while it is roughly 5-10 meters for GPS [65]. This is because 5-10 meters precision is possible for street-level navigation, and the substantial localization/ proximity mistake such as meter-wide library isle cannot be tolerated.

In contrast to triangulation and trilateration, proximity offers location information, not an absolute or relative position prediction. A grid of antennas with known positions is used to identify the location. When a mobile device detects mobility, the closest antenna is used to compute the position. If a mobile device detects more than one antenna, the location is calculated using the strongest signal. To calculate the access distance between mobile devices and determine mobile location, RSSI is used.

Apart from that, proximity is used in various systems that use Wi-Fi, Bluetooth, RFID, and UWB and requires minimal calibration. Larger spread readers are required to produce a dependable and wider coverage area. With huge spread readers, there is a risk of increased complexity.

### D. Scene Analysis

Scene analysis is one of the most popular approaches, as it is based on the observation of space features, is independent of direct sight, and produces good results even in contexts with many impediments [66].

Most of the scene analysis that has been proposed is based on the IEEE 802.11 standard due to its broad application. The scene analysis technique has several benefits over previous techniques, including increased resistance to the multi-path fading problem and the fact that it is not dependent on spatial-temporal variables like propagation time and signal reception angle. When there is NLoS between the radios in the network [67], these properties are extremely vulnerable to mistakes.

However, memory requirements for data storage and the human effort necessary [66] to execute the training step in the operational environment are the technique's key flaws.

### E. Fingerprinting

Environmental surveys are frequently required for scene analysis-based localization approaches to acquire fingerprints or properties of the environment where the localization system will be employed. One of the most often recommended ways for indoor positioning is the location fingerprinting approach. The potential of location fingerprinting is to reduce multipath and NLoS propagation difficulties [68]. Fingerprinting also has high accuracy compared to other methods [69]. Furthermore, because Wi-Fi access points (APs) are already installed indoors, and the RSSI data are easily available from mobile devices, Application Programming Interface (API), requires no new infrastructure gear.

Fingerprinting technique includes offline (training) and online (positioning) stages [70]. It's necessary to develop a reliable fingerprinting database. Fig. 12 shows an illustration of fingerprinting in the offline and online stages. At an offline stage, each AP was collected at the Reference Point (RP) and

extracted to generate fingerprints, which are then entered into a fingerprinting database. It is designed to learn the RSSI at each reference point.

During the online stage, the RSS of the test point is measured in real-time and compared to the offline fingerprints to establish location. The set is then orthogonalized to fulfill the essential criteria for the compressive sensing technique. The RSSD between APs is used to determine the processed set. The distance between offline and online values can be determined using [69]:

$$D_j = \sum_{i=1}^{m} \sqrt{\left(RSSI_{i(online)} - RSSI_{i(offline)}\right)^2} \qquad (14)$$

where, $i$ is the number of beacons ranging from 1 to the total number around tags, $m$. To compare the measured value to the database, determine the most similar fingerprint, and achieve localization, the RSSD value is utilized as the new fingerprint. Finally, precise localization is achieved using the compressive sensing theory.

### F. Pedestrian Dead Reckoning (PDR)

The PDR positioning technique is a self-contained positioning system. Its main premise is to use an accelerometer, gyroscope, and geomagnetic meter to acquire real-time motion direction and step information to determine the location information of the moving target. PDR positioning achieves excellent positioning accuracy in a short amount of time; however, it can only produce relative positioning findings, and cumulative mistakes exist [71]. If the heading inaccuracy in PDR can be corrected, it is dependable for consistently precise positioning.

Fig. 11. Proximity Technique Localization.

Fig. 12. Illustration of Fingerprinting Technique.

Researchers in [72] proposed to enhance PDR with RSSI. Erroneous headings will be corrected based on linear regression of locations computed using RSSI data derived from Wi-Fi signals to assure PDR's high dependability for extended duration placement. The outcomes of the experiment proved that the proposed strategy is practicable.

The user's position is calculated by combining the user's step length, several steps, and heading angle [73]. The step of the walking pedestrian can be expressed in [74]:

$$\begin{bmatrix} \widehat{x_k} \\ \widehat{y_k} \end{bmatrix} = \begin{bmatrix} x_0 \\ y_0 \end{bmatrix} + \sum_{i=1}^{k} \widehat{L_\iota} \bullet \begin{bmatrix} sin\ (\widehat{\theta_\iota}) \\ cos(\widehat{\theta_\iota}) \end{bmatrix} \tag{15}$$

Where $\begin{bmatrix} \widehat{x_k} \\ \widehat{y_k} \end{bmatrix}$ represent the estimated position of the step, $\begin{bmatrix} x_0 \\ y_0 \end{bmatrix}$ represent an initial position, $\widehat{L_\iota}$ is estimated step length, and $\widehat{\theta_\iota}$ is estimated heading angle.

## VIII. Indoor Positioning Techniques Discussion

According to the discussion above, the signal property used in a positioning technique has a big impact on how effective the positioning approach is. As a result, it is critical to comprehend positioning algorithms and techniques to employ the most relevant attribute. The comparison of the indoor positioning technique is shown in Table III. The table stated that triangulation, proximity, scene analysis, and PDR techniques are complex.

In addition, fingerprinting technique is complex because it involved offline (training) and online (positioning). Therefore, in this review, the Trilateration technique is suggested due to its low cost, ease of implementation, and high accuracy.

TABLE III. Summary of Techniques in IPS

| Technologies | Advantages | Disadvantages |
|---|---|---|
| Triangulation | • Low-cost implementation<br>• High accuracy within room level | • Low accuracy in a large area<br>• Complex<br>• Required angle measurement |
| Trilateration | • Simple<br>• Low-cost implementation<br>• High accuracy | • Accuracy may occur due to environmental changes |
| Proximity | • High accuracy | • High-cost implementation<br>• Complex |
| Scene Analysis | • High performance | • High-cost implementation<br>• Complex<br>• Medium accuracy |
| Fingerprinting | • No infrastructure needed | • Accuracy is depending on fingerprinting data resolution<br>• Complex |
| PDR | • Accuracy within a short amount of time | • Complex |

## IX. Conclusion

The overview of the positioning system and indoor positioning system was introduced. This review aims to provide a full understanding of indoor positioning technologies, algorithms, and techniques involved in an indoor environment. RF communication technologies such as Wi-Fi, BLE, RFID, and UWB are widely used in indoor positioning recently to develop location estimation. RSSI algorithm is the best algorithm to determine the user location estimation compared to AoA, ToA, and TDOA which required additional hardware, high cost, and are complex. Trilateration technique is suggested due to its low cost, ease of implementation, and high accuracy However, the use of technology, algorithm, and technique of indoor positioning are depending on many factors such as cost, available resources, type of environment, and the level of accuracy.

# A Lightweight ECC-based Three-Factor Mutual Authentication and Key Agreement Protocol for WSNs in IoT

Meriam Fariss, Hassan El Gafif, Ahmed Toumanari

Laboratory of Applied Mathematics and Intelligent Systems Engineering (MAISI)
National School of Applied Sciences (ENSA)
Agadir, Morocco

*Abstract*—The Internet of Things (IoT) represents a giant ecosystem where many objects are connected. They collect and exchange large amounts of data at a very high speed. One of the main parts of IoT is the Wireless Sensor Network (WSN), which is deployed in various critical applications such as military surveillance and healthcare that require high levels of security and efficiency. Authentication is a primary security factor that ensures the legitimacy of data requests and responses in WSN. Moreover, sensor nodes are characterized by their limited resources, which raise the need for lightweight authentication schemes applicable in IoT environments. This paper presents an informal analysis of the security of X. Li et al.'s protocol, which is claimed to be efficient and resistant to various attacks. The analysis results show that the reviewed protocol does not provide user anonymity and it is vulnerable to session key disclosure attack, many-time pad attack, and insider attack. To address all these requirements, a new three-factor authentication protocol is presented, which guarantees higher security using Physically Unclonable Function (PUF) and Elliptic Curve Cryptography (ECC). This protocol does not only withstand the security weaknesses in X. Li et al.'s scheme but also provides smart card revocation and is resistant to cloning attack. In terms of both computational and communicational costs, results demonstrate that the proposed scheme provides higher efficiency in comparison with other related protocols, which makes it notably suitable for IoT environments.

*Keywords—Mutual authentication; elliptic-curve cryptography; Physically Unclonable Function; wireless sensor networks; key-agreement; internet of things*

## I. INTRODUCTION

It is widely believed that the Internet of Things (IoT) [1, 2] is the upcoming promising technology that will bring many revolutionary changes in different life sides. The IoT architecture connects a set of heterogeneous things belonging to our daily life use and enables them to exchange a huge amount of data, which are also processed and stored. One of the principal application domains of IoT is Wireless Sensor Networks (WSN)[3]. WSNs are generally deployed in unattended areas and consist of widely distributed autonomous sensing devices, gateway nodes (GWNs), and remote users communicating over the public channel. The GWN represents a bridge of communication between sensors and users. Sensors play an important role in WSN by monitoring environmental and physical conditions and providing real-time data, which are

directly accessed by users as and when demanded. Therefore, a secure mutual authentication process represents a primary concern in WSNs allowing only legitimate users to access the sensed data. Moreover, WSN consists of many resource-constrained sensor nodes having limited power, low bandwidth and battery, small storage space, and limited computational abilities. These two main issues related to security concerns and performance limitations in WSN deployment represent an important challenge that must be taken into consideration in every proposed protocol. ECC represents an important security solution in WSN [4] by offering the same security level compared to other cryptography mechanisms (e.g. RSA) with much smaller key size and less computational power requirements, which makes it suitable for resource-constrained environments.

*Contribution.* Many authentication protocols are designed to ensure higher and efficient security in WSNs. However, some security and performance challenges are still not solved which makes these protocols vulnerable to several security attacks and not applicable in resource-constrained environments such as WSN. In this paper, an efficient three-factor mutual authentication and key agreement protocol is proposed that overcomes critical security concerns found in the studied protocols such as impersonation attacks, cloning attacks, and insider attacks. In addition, it guarantees user and sensor anonymity and untraceability. In contrast with the existing protocols, no secure channel assumption is required by this protocol. It is also more efficient than all the studied schemes in terms of communications cost. It is also computationally more efficient than most of the studied protocols. As a result, it is more suitable for WSN than the studied schemes. Additionally, this protocol provides smart card revocation (in case of lost/stolen smart card) and identity and password update feature. Another interesting feature provided by this protocol, that does not exist in the studied protocols, is that the GWN cannot decrypt the communicated messages between the user and the sensor since it does not possess the session key.

*Organization of the paper.* The remainder of this paper is organized as follows: Section II presents the related work. In Section III, an overview of the main preliminaries of the present paper is provided. Section IV, describes the principal weaknesses of X. Li et al.'s scheme [5]. The proposed protocol is described in detail in Section V. The security analysis of this

protocol and its performance analysis are described in Sections VI and VII respectively. Finally, some concluding remarks are given in Section VIII.

## II. RELATED WORK

In the literature, there are various mutual authentication protocols designed to address the security and performance challenges in WSNs. In 2009, Das [6] proposed a hash-based two-factor user authentication protocol for WSN using the smart card. Subsequently, many authentication protocols have been proposed to improve the security of Das' scheme [7–9]. He et al. (2010) [10] proposed an enhancement of [6] that overcomes insider and impersonation attacks. However, Kumar and Lee (2011) [11] have identified that He et al.'s protocol [10] lacks many security features such as no user anonymity and it does not establish a session key between the user and the sensor. In 2011, Yeh et al. [8] proposed an ECC-based authentication protocol for WSN to improve security with higher efficiency. Unfortunately, this protocol cannot provide mutual authentication and key agreement. To overcome the weaknesses detected in [8], Shi et al. (2013)[12] proposed a user authentication protocol based on ECC which improves security features, communicational, and computational costs. Nonetheless, [12] contains other weaknesses. Choi et al. (2014) [13] presented a review of [12] and have found that it is not secure since it cannot withstand session key attack and smart card attack. In the same year, Jiang et al. [14] proposed a two-factor authentication scheme for WSN. In 2015, Wu et al. [15] pointed out some weaknesses in [13] and [14] such as being vulnerable to off-line guessing attack and user forgery attack. Wu et al. presented an enhanced protocol based on ECC that addresses the security weaknesses detected and provides higher security. Nam et al. (2014) [16] proposed an authentication scheme for WSN using ECC that provides user anonymity and perfect forward secrecy. In 2015, Jiang et al. [17] designed an ECC-based two-factor authentication protocol. After reviewing He et al.'s scheme (2015) [18] and presenting its main security weaknesses such as stolen smart card attack and tracking attack, Jiang et al. proved that their proposed scheme achieves mutual authentication and key agreement between the user and the sensor, it also guarantees user anonymity and untraceability. In 2016, Lu et al. [19] proposed a two-factor mutual authentication and key agreement protocol using a smart card. They claimed that their proposition is resistant to insider attack due to the use of the hashed value of the password. It is also claimed to be resistant to many attacks such as known session-specific temporary information attack and a denial-of-service attack. In 2022, Chander et al. [20] proposed an improved two-factor authentication scheme for WSN using ECC.

To improve the security of two-factor authentication protocols, three-factor authentication has drawn researchers' attention and many three-factor authentication protocols are proposed [5, 21–25]. Moreover, biometric recognition [26] presents many advantages that guarantee a higher security level in WSNs compared with passwords. For this reason, many biometric-based authentication protocols have been proposed [27, 28]. In 2016, Park et al. [22] proposed a three-factor ECC-based authentication protocol using biometric information to overcome security weaknesses detected in Chang et al.'s

scheme (2015) [23] such as incorrectness of password change and off-line guessing attack. Later on, Jung et al. (2017) [24] pointed out that [23] is vulnerable to password guessing attack and user impersonation. They also demonstrated that this protocol does not provide session key verification. To overcome these security weaknesses, Jung et al. proposed an improved authentication and key agreement protocol using the user's biometric information. In the same year, S.Challa et al. [25] proposed a signature-based authentication and key agreement protocol in IoT using ECC. They claimed that their protocol is secure against several attacks such as privileged insider attack and stolen smart card attack. In 2018, X. Li et al.[5] proposed a fingerprint-based mutual authentication protocol for WSN, which they claimed provides user and sensor anonymity and untraceability and many other security features.

As you can notice from the aforementioned literature, important research work has been done to detect and overcome security weaknesses in WSN environments for secure communication between different entities. Moreover, security issues are not the only factor that should be taken into consideration. Each security protocol should be efficient enough to be applied and suitable for IoT applications due to the resource-constrained feature of different devices used. To address the security and efficiency issues raised in the previous work, this paper proposes a three-factor mutual authentication and key agreement protocol for WSN based on ECC.

## III. PRELIMINARIES

This section gives an overview of the main preliminary concepts used in the present paper.

### A. Physical Unclonable Function (PUF)

A PUF [29–31] is a low-cost technology that extracts entropy from uncontrollable manufacturing variations in the physical structure of identically produced devices. Typically, it is physically impossible to recreate the same conditions in another device even if the same manufacturing process is performed again, and it is mathematically impossible to accurately predict the PUF's behavior as well. PUF uses this entropy to generate a unique sequence of bits (response) for each device given an input (challenge) acting as the device's fingerprint that does not need to be stored in the device's memory. To measure the performance of a given PUF, researchers use two main metrics:

- Uniqueness ($\mu_{inter}$): the average fraction of dissimilar bits between responses of different PUFs to a given challenge. The ideal value of $\mu_{inter}$ is 0.5 (random).

- Reliability ($\mu_{intra}$): the average fraction of dissimilar bits between responses of a fixed PUF to a given challenge. This metric measure the average error resulted in PUF's output due to the undesirable noise. The ideal value of $\mu_{intra}$ is 0 (no error).

In our protocol, we use a recently proposed PUF scheme. HBN-PUF [32] is a strong, chaos-enhanced, and asynchronous PUF. According to [33], the creators of HBN-PUF aim to move quickly to commercialize this technology.

### B. Fuzzy Commitment Scheme

The fuzzy commitment scheme was introduced by Juels and Wattenberg in 1999[34]. This technique is commonly used in biometric authentication schemes and it combines error-correcting code techniques and cryptography. For an error-correcting code over a message space $M = \{0,1\}^k$, we consider a set of codewords $C \subset \{0,1\}^n$ where $n > k$ to achieve redundancy. Before transmission, each message $m \in M$ is mapped to a codeword $c \in C$. We define the translation function $g: M \to C$, and the decoding function $f: \{0,1\}^n \to C \cup \{\varnothing\}$ that maps arbitrary an $n$-bit string to the nearest codeword, else it outputs $\varnothing$. Biometric-based applications use a reference template generated firstly at the registration phase. At the authentication phase, a new biometric sample is provided and compared to the reference template which needs to be securely and secretly stored. Due to many reasons, the provided biometric sample is not the same as the reference template.

Let's consider the secure one-way hash function $h:\{0,1\}^n \to \{0,1\}^l$. The fuzzy commitment scheme is defined as follows: $F: \{0,1\}^n, \{0,1\}^n \to \{0,1\}^l, \{0,1\}^n$. $F$ commits a random codeword $c \in C$ to the biometric template $b$ provided at the registration phase to the server. The server computes then $F(c,b) = (\alpha, \delta)$, where $\alpha = h(c)$ and $\delta = c \oplus b$. The server stores $(\alpha, \delta)$ in its database. At the authentication phase, a noisy biometric data $b'$ is input by the user. To open the commitment $F$ using $b'$, the server computes $c' = f(b' \oplus \delta)$, using the decoding function $f$. Then, it compares $h(c')$ with the stored value of $\alpha$. If $h(c') = \alpha$, the commitment is opened successfully and the user is authenticated.

### IV. WEAKNESSES OF X. LI ET AL.'S SCHEME [5]

This section describes the functional and security flaws of X.Li et al.'s three-factor anonymous authentication scheme [5]. It involves three main types of entities: the user $U_i$, the trusted gateway node *GWN*, and the sensor node $S_j$.

### A. GWN Master Key Update

In the reviewed protocol, the *GWN* has its private key $x$ and the master key $K_{GWN}$. When the *GWN* updates $K_{GWN}$, it must recalculate $B_i = h(ID_i \| K_{GWN}) \oplus h(RPW_i \| c_i)$ for each $U_i$ and $K_{GWN-S} = h(SID_j \| K_{GWN})$ for each $S_j$. Moreover, when the *GWN* updates its private key $x$ it must recalculate its public key $X$ and send it to all users to be updated on their smart cards. Hence, the *GWN* master key update is a very expensive process.

### B. No Smart Card Revocation

When a user's smart card is lost/stolen, he/she should be able to send a revocation request to the *GWN*. However, X. Li et al.'s protocol does not provide this feature.

### C. No user Identity Change

In real life, the user needs to change his identity but X. Li et al.'s scheme does not provide this feature.

### D. Insider Attack

The protocol of X. Li et al. is exposed to an insider attack by a legitimate user, who can start by performing successfully a usual login phase by inputting his valid biometric information, $ID_i$ and $PW_i$. Then the login request message $\{M_2, M_4, M_5, M_6, M_7\}$ is sent to the *GWN*, which calculates $M_8 = ID_i \oplus K_{GWN-S}$ and sends it explicitly over the public channel to $S_j$. Since the $U_i$ knows his own $ID_i$, he can compute the secret key $K_{GWN-S} = M_8 \oplus ID_i$. By knowing this secret information, the adversary can perform many other attacks that we detail in the following paragraphs.

### E. Many-time Pad Attack

In X. Li et al.'s scheme, the same sensor node $S_j$ uses the One-Time Pad $K_{GWN-S}$ for all the users with whom it communicates: for user $U_1$ we have $M_8^1 = ID_1 \oplus K_{GWN-S}$, for user $U_2$ we have $M_8^2 = ID_2 \oplus K_{GWN-S}$, etc. If an attacker intercepts the message $M_8$ corresponding to at least two different users $U_1$ and $U_2$, he can perform the Many-Time Pad attack ($M_8^1 \oplus M_8^2 = ID_1 \oplus ID_2$). Generally, the $ID_i$ chosen by users is a low entropy information, hence the attacker can perform a dictionary attack to recover $ID_1$ (or $ID_2$) and can then calculate $K_{GWN-S} = M_8^1 \oplus ID_1$.

### F. User Anonymity

X. Li et al. presumed that the user's real identity $ID_i$ is shielded in their protocol; however, we proved in the aforementioned attack that user anonymity is not guaranteed. The adversary who has the secret key $K_{GWN-S}$ (from previous attacks) can easily reveal each user's identity by catching the exchanged message $\{M_8, M_9, M_{10}, M_{11}\}$ between the legitimate user and the *GWN* and computing $ID_i = M_8 \oplus K_{GWN-S}$.

### G. Session Key Disclosure Attack

From the insider attack, the adversary, who also knows $SID_j$, gets the sensor node secret key $K_{GWN-S}$ that allows him to calculate the session key as follows: the adversary obtains $ID_i$ from the user anonymity flaw, and calculates the *GWN* random number $r_g = M_9 \oplus h(ID_i \| K_{GWN-S})$ from the message $\{M_8, M_9, M_{10}, M_{11}\}$ sent by the *GWN*. The legal sensor $S_j$ generates its private random number $r_j$ and calculates $M_{12} = r_j \oplus K_{GWN-S}$ that it sends explicitly over the public channel to the *GWN*. The adversary can retrieve $r_j = M_{12} \oplus K_{GWN-S}$ from $M_{12}$ and $r_i = r_g \oplus M_{10}$ from $M_{10}$. Hence, the attacker can easily calculate the session key $SK = h(ID_i \| SID_j \| r_i \| r_j \| r_g)$.

### H. Sensor Impersonation Attack

X. Li et al. presumed that $S_j$ cannot be impersonated since the $S_j$'s secret key $K_{GWN-S} = h(SID_j \| K_{GWN})$ is unknown. Through the previous attacks, we have shown that $K_{GWN-S}$ can be calculated, thus an attacker can impersonate $S_j$.

### I. Sensor Node Untraceability

Any adversary can trace different sessions between a particular user $U_i$ and a sensor node $S_j$ since the exchanged message $M_8 = ID_i \oplus K_{GWN-S}$ stays the same in all sessions.

### V. PROPOSED PROTOCOL

To overcome the functional and security flaws described in the previous section, the current paper proposes this improved protocol that involves three main entities: the Gateway Node (*GWN*) as a trusted entity, the Sensor Node ($S_j$), and the User ($U_i$). It consists of six phases: initialization phase, user and sensor registration, login and mutual authentication, user's identity update, user's password update, and smart card revocation. Table I summarizes the notations used throughout this section.

| Parameter | Description |
|---|---|
| $U_i$ | User |
| $S_j$ | Sensor node |
| GWN | Gateway node |
| $F_p$ | Finite field of order $p$ |
| $E(F_p)$ | Elliptic Curve |
| $P$ | Generator Point |
| $n$ | Order of $P$ |
| $h()$ | Hash function |
| $C$ | Set of codewords |
| $pn_i$ | $U_i$'s phone number |
| $PUF()$ | Physical Unclonable Function |
| $x_{GWN}$ | GWN's private key (master key) |
| $X_{GWN} = x_{GWN}P$ | GWN's public key |
| $y_i$ | $U_i$'s private key |
| $Y_i = y_iP$ | $U_i$'s public key |
| $E_{AES}()_S$ | AES Encryption using the key $S$ |
| $D_{AES}()_S$ | AES Decryption using the key $S$ |
| $TS$ | Timestamp |
| $status_i$ | The status of the user (active or inactive) |
| $ID_i$ | $U_i$'s identity (64 bits) |
| $SID_J$ | Sensor identity (64 bits) |
| $SC$ | Smart Card |
| $DB$ | Database |

## A. Initialization Phase

Before the execution of the protocol, the initialization phase must be performed by the *GWN*. It selects an additive group $G$ and its generator point $P$ of order $n$ (a large prime number) on an elliptic curve $E(F_p)$ where $F_p$ is a finite field. *GWN* chooses randomly its private key $x_{GWN} \in Z_n^*$ and computes the corresponding public key $X_{GWN} = x_{GWN}.P$. At last, *GWN* stores its private key and publishes the system parameters $\{E(F_p), G, P, h(), X_{GWN}\}$ where $h()$ is a 128-bit hash function.

## B. Registration Phase

Unlike the reviewed scheme, the registration phase in this protocol does not require a secure channel to exchange data with the *GWN* neither for the user nor for the sensor.

*1) User registration:* In the user registration phase, it is assumed that $U_i$ already possesses a private key $y_i$ and published its corresponding public key $Y_i = y_i.P$. This key pair is needed to encrypt/decrypt the parameters $ID_i$, $b_i$, and $pn_i$. This phase involves $U_i$ and GWN. At the end of this phase, $U_i$ becomes a legitimate user. The details of this phase are shown in Fig. 1.

*2) Sensor registration:* This phase involves *GWN* and $S_j$. *GWN* should store some data in each $S_j$'s memory before deploying the sensors in the WSN. First, *GWN* selects $SID_j$ for each $S_j$, generates a random number $u_j$, and stores $SID_j$ and $u_j$ in $S_j$'s memory. Moreover, each $S_j$ has its own pre-implemented $PUF_j()$.*GWN* calculates $K_{GWN-S} = PUF_j(u_j)$ and stores $\{SID_j, K_{GWN-S}\}$ in its DB.

## C. Login and Mutual Authentication

To remotely access the sensed data of $S_j$, $U_i$ should perform a successful login. Moreover $U_i$, $S_j$, and *GWN* must be mutually authenticated to exchange data. This phase is performed over a public channel as shown in Fig. 2.

## D. User's Password Update

The password update phase allows a legitimate user $U_i$ to change his/her old password $PW_i^{old}$ to a new one $PW_i^{new}$. The steps of this phase are shown in Fig. 3.

Fig. 1.   User Registration Phase.

Fig. 3. User's Identity Update Phase.
Fig. 4. User's Password Update Phase.

### E. User's Identity Update

In addition to password update, this scheme allows each legitimate user $U_i$ to change his/her $ID_i$ whenever he/she wants, following the steps shown in Fig. 4.

### F. Smart Card Revocation and Re-registration

A legal user $U_i$ can revoke his/her lost or stolen SC through a secure process. Once $U_i$ realizes the loss of his/her *SC*, he/she informs *GWN* to obtain a new one. SC revocation and re-registration phase steps are described below:

- Revocation request: it is performed remotely over the public channel. The main purpose of this step is to deactivate the stolen/lost SC immediately when the Ui sends a revocation request to the GWN. Therefore, the re-registration step can be performed later on. First, the revocation request is sent by Ui to GWN which verifies the user's identity through a one-time password mechanism using Ui's phone number pni which was already stored in the GWN's database at the user's registration phase. Then, GWN checks if statusi=active. If it holds, GWN updates Ti=Null and statusi=inactive in its DB. Else, the revocation request is terminated. From then on, the lost/stolen SC is no more valid.

- Re-registration: this step aims to securely authenticate Ui who wants to re-register in the system after the revocation of his/her old SC. At the end of this step, a new active SC is delivered to the legitimate user by the GWN. First, Ui presents in person his/her Personal Identification Card to GWN for verification. Then the authenticated user inputs his IDi, chooses PWinew, and calculates HPWinew=h(PWinew ∥ uinew) (uinew is generated randomly). Then, Ui imprints binew. The GWN checks if IDi exists in its DB and statusi=inactive. If this is true, GWN chooses a codeword cinew∈C, calculates F(cinew, binew)=(αnew,

δnew) where αnew=h(cinew) and δnew= cinew⊕ binew. Then GWN computes Ainew=h(IDi∥HPWinew∥ cinew), Binew=h(HPWinew∥cinew), and Tinew=PUFinew(Binew).P. After performing these operations, GWN updates Tinew and sets statusi=active in its DB. Then GWN stores the parameters {αnew,δnew,Ainew,PUFinew(),f()} in the new SC. Finally, GWN delivers the new SC to Ui. When receiving the SC, Ui stores the random number uinew in his/her new SC. From then on, Ui can use his new active SC securely over the public channel.

## VI. SECURITY ANALYSIS OF THE PROPOSED PROTOCOL

### A. Informal Security Analysis

This section informally discusses the security features of the current protocol. This scheme provides important security features and resists many security attacks in WSN. Remember that all communications in this protocol are performed over the public channel and no secure channel assumption is required. Moreover, Table II presents the security features comparison between the proposed protocol and the following schemes: X.Li et al. [5], Choi et al. [13], Zhang et al. [35], and S.Challa et al. [25]. The first 12 evaluation criteria are proposed in [36]. In addition, proposed three new criteria are provided:

- C13. SN Anonymity: the sensor's identity is protected and its activity cannot be traced.

- C14. Freely Identity Change: the identity is memorable, and can be chosen freely and changed by the user.

- C15. Suitable for IoT: no direct communication between the users and sensors, the communication should be through a gateway.

Table II shows that all the studied schemes satisfies *C1*, *C2*, and *C3* except [35] that does not satisfies *C2* since it does not support password update feature. Except for [35] that does not

support smart cards, all the studied protocols are resistant to SC loss attack (*C4*). For instance, in the current protocol, when an adversary steals a legitimate user's smart card, he needs $B_i$ to calculate $t_i=PUF(B_i)$. However, $B_i=h(h(PW_i\|u_i)\|c_i)$ is not stored in SC, so the attacker has to compute it. This is not possible, because he needs to know the password $PW_i$ and the codeword $c_i$. Moreover, when $U_i$'s SC is stolen, the *GWN* changes the parameter *status$_i$* to *inactive* after performing a SC revocation, as explained previously, making it no more valid.

TABLE II. COMPARISON OF SECURITY FEATURES OF THE STUDIED PROTOCOLS

| Evaluation Criteria | [5] | [13] | [35] | [25] | Our protocol |
|---|---|---|---|---|---|
| C1. No password verifier-table | Yes | Yes | Yes | Yes | Yes |
| C2. Password friendly | Yes | Yes | No | Yes | Yes |
| C3. No password exposure | Yes | Yes | Yes | Yes | Yes |
| C4. No smart card loss attack | Yes | Yes | - | Yes | Yes |
| C5. Resistance to known attacks | | | | | |
|   - Replay Attack | Yes | Yes | Yes | Yes | Yes |
|   - Offline Password Guess | Yes | Yes | Yes | Yes | Yes |
|   - User Impersonation attack | Yes | No | Yes | Yes | Yes |
|   - SN Impersonation attack | No | Yes | Yes | Yes | Yes |
|   - GWN Impersonation attack | Yes | Yes | Yes | Yes | Yes |
|   - Cloning Attack | No | No | No | No | Yes |
|   - Insider Attack | No | Yes | Yes | Yes | Yes |
| C6. Sound repairability | No | No | - | Yes | Yes |
| C7. Provision of key agreement | Yes | Yes | Yes | Yes | Yes |
| C8. No clock synchronization | Yes | No | No | No | No |
| C9. Timely typo detection | Yes | Yes | No | Yes | Yes |
| C10. Mutual authentication | Yes | Yes | Yes | Yes | Yes |
| C11. User anonymity | No | No | No | Yes | Yes |
| C12. Forward secrecy | Yes | Yes | Yes | Yes | Yes |
| C13. SN anonymity | No | No | No | Yes | Yes |
| C14. Freely identity change | No | No | No | No | Yes |
| C15. Suitable for IoT | Yes | No | Yes | No | Yes |

The *C5* criteria consist of the following attacks:

- Replay attack: as shown in Table II, all the studied schemes are resistant to replay attack. In this protocol, timestamps are used to prevent this attack.

- Offline password guess: Table II shows that all the studied protocols are resistant to the offline password guess. In this protocol, if an attacker has Ui's SC, this means that he has access to four elements: $\alpha=h(ci)$, $\delta=ci\oplus bi$, $Ai=h(IDi\|h(PWi\|ui)\|ci)$, and ui. The goal of the attacker in this attack is to get PWi (we suppose that he already knows the IDi of SC owner). To guess PWi by performing a password dictionary attack on Ai, the attacker needs to know ci first. However, according to Juels and Wattenberg [34], it's impossible to retrieve ci from α and δ. In addition, the attacker cannot guess ci from Ai using a dictionary attack because ci is a random number with high entropy. As a result, the current protocol resists the offline password attack.

- User, GWN, and SN impersonation attack: this protocol is resistant to user, GWN, and SN impersonation attacks since the attacker cannot compute z1=h(IDi\|SIDi\|TSi\|Ea\|x2), z2=h(Ea\|TSG2\|x2), SG=h(Ea\|TSG1\|KGWN-Sj), or SSN=h(Ea\|TSj\|KGWN-Sj). That is because he is not able to get KGWN-Sj or to compute x2 as long as he does not have access to Ui's private key ti or GWN's master key xGWN. In contrast, [5] is vulnerable to the SN impersonation attack as showed in the "Weaknesses of X.Li et al.'s scheme" section above and [13] suffers from user impersonation attack.

- Cloning attack: In contrast with the other studied schemes, this protocol is resistant to cloning attack. To protect SC from the cloning attack, PUF is used to compute Ui's private key ti. Suppose that an attacker somehow succeeded to get the PWi and ci and cloned Ui's SC, then the attacker will try to compute ti'=PUFicloned(h(h(PWi\|ui)\|ci)). However, the computed ti' will be different from Ui's private key ti because the cloned PUFicloned is different from the original PUFi as explained previously in the preliminaries. Moreover, the current protocol is resistant to sensor cloning attack since if an attacker clones the sensor he will get uj and will try to compute K'GWN-S=PUFjcloned(uj). However, the computed K'GWN-S will be different from the original KGWN-S because the cloned PUFjcloned is different from the original PUFj.

- Insider attack: This attack is performed by a legitimate user Ua to gain additional privileges. The author in [5] is the only scheme that suffers from insider attack as we described in the "Weaknesses of X.Li et al.'s scheme" section above. In the following, a proof that this scheme is resistant to the insider attack is given. In this analysis, the goal is to prove that an insider attacker has no advantage compared with an outsider attacker. That is, all the insider attacker's additional information, that an outsider attacker does not possess, does not give him any additional power as an attacker. First, all the data that an insider attacker Ua possesses and outsider attackers do not have are specified as follows: IDa, PWa, ba,αa=h(ca),δa=ca⊕ba,ua,Aa=h(IDa\|h(PWa\|ua)\|ca),ta=PUFa(h(h(PWa\|ua)\|ca)), and in each session he has: ea and SIDj of the targeted sensor Sj. Notice that these data, except SIDj, are unique to Ua and do not consist of any information that is used by other users, sensor nodes, or GWN. Thus, these data give Ua no advantage to attack other users, sensor nodes, or GWN compared to an outsider attacker. Next, it is important to make sure that these data do not help Ua to extract some useful information from the messages exchanged in his sessions. In the following, the messages exchanged in each session of Ua are cited (excluding the messages generated by Ua): SG=h(Ei\|TSG1\|KGWN-S),Ei,TSG1,SSN=h(Ej\|TSj\|KGWN-S),Ej,TSj, z2=h(Ej\|TSG2\|x2), TSG2. Obviously, the public elements Ei, TSG1, Ej, TSj, and TSG2 can be retrieved by any attacker not only an insider attacker; thus, they represent no advantage of an insider attacker

over the outsider attackers. Besides, since the messages SG, SSN, and z2 are unique to each session, the insider attacker cannot use them to attack other sessions. Additionally, assuming that the used hash function is secure, the insider attacker cannot extract KGWN-S or x2 from SG, SSN, or z2. As a result, you can conclude that an insider attacker does not possess and cannot extract any additional useful information as an attacker compared to an outsider attacker. Thus, insider and outsider attackers have the same capabilities.

According to [36], sound repairability (*C6*) means that the scheme provides SC revocation without requiring the user to change her identity. As you can see in the smart card revocation and re-registration sub-section, this protocol perfectly fits to this criteria and does not require any identity update after SC revocation. The authors in [5] and [13] do not support the SC revocation feature at all and [35] does not support smart cards. Table II also shows that all the studied schemes guarantee mutual authentication (*C10*) and provision of a key agreement (*C7*). In [5], the generated session key consists of a hash of the user ID, the sensor SID, and three fresh nonces that are new for each session. As a result, if an attacker disclosed one or more session keys, he would not be able to guess the other session keys as long as the hash function is secure. Thus, [5] satisfies the forward secrecy criteria (*C12*). The rest of studied protocols, including our protocol, satisfy *C12* as well since the generated session key depend on a fresh ECDH shared key and by knowing some session keys the attacker will not be able to affect the other sessions except if he can resolve the ECDH problem which is cryptographically hard.

Only [5] satisfies the "No clock synchronization" (*C8*) criteria since all the other protocols employ timestamps to prevent replay attacks. Timely typo detection criteria (*C9*) require that the user will be timely notified if she inputs wrong credentials by mistake when login. This is satisfied by all the studied schemes except [35] which do not employ any checking locally in the login phase. The credentials in [35] are checked afterward by the gateway node. The current protocol and [25] meet the user and sensor node anonymity criteria (*C11* and *C13*). In this protocol, The user and sensor anonymity is guaranteed by the fact that $ID_i$ and $SID_j$ are not sent clearly over the public channel, and they are encrypted $Enc_i = E_{AES}(ID_i \| SID_j)_{h(x1)}$. Thus, no adversary can reveal the user's or sensor's real identity from the exchanged messages. The untraceability of the user and the sensor node is provided in this scheme through the fact that all exchanged data vary from one session to another. This is because $E_i$ and $E_j$ are generated in each session randomly, thus $Enc_i$, $z_1$, $S_G$, $S_{SN}$, and $z_2$ vary from a session to another since they are computed based on $E_i$ or $ID_j$. In contrast, [5] does not fulfill this criteria as showed in the "Weaknesses of X.Li et al.'s scheme" section above. The authors in [13] and [35] do not guarantee this criteria either since they communicate the user's ID and sensor's SID in clear during the authentication phase.

In addition to the abovementioned features, the current protocol is the only protocol that supports freely identity change (*C14*). Besides, it is suitable for IoT (*C15*) since there

is no direct data exchange between the user and the sensor node, unlike [13] and [25], where the sensor node contacts the user directly.

### B. Formal Security Analysis using AVISPA Tool

This section formally analyzes the security and authentication logic of the current protocol using the widely used AVISPA Tool. The implementation of this protocol in the HLPSL is provided. The analysis results will show that this protocol is safe. In this HLPSL specification, three basic roles representing the protocol's principals are defined: user, gateway, and sensor. In addition, there are two composed roles, session and environment, and a goals section where the security goals are specified. Table III contains the notations used in the specification and their corresponding notations in the protocol's login and authentication phase provided in Fig. 2.

TABLE III. HLPSL SPECIFICATION'S NOTATIONS AND THEIR CORRESPONDING PROTOCOL NOTATIONS

Fig. 5. User Role's HLPSL Specification.

Fig. 5 describes the user role specification. The gateway role's specification is provided in Fig. 6. The sensor role's specification is described in Fig. 7. In Fig. 8, the HLPSL specification of the session and environment roles is provided. Fig. 9 shows the analysis results obtained using the OFMC and CL-AtSe backends. Currently, AVISPA Tool provides four backends: OFMC, CL-AtSe, SATMC, and TA4SP. However, SATMC, and TA4SP do not support operations like xor() and exp(). Both OFMC and CL-AtSe analysis results show that this protocol is safe against active and passive attacks.

## VII. PERFORMANCE COMPARISON

This section presents the computational and communicational costs of this proposed protocol in comparison with other related schemes [5, 13, 25, 35]. To calculate the communication costs of the current protocol in comparison with the other related schemes, assume that the length of each element is as follows: user identity (64 bits), sensor identity (64 bits), hash (128 bits), timestamp (64 bits), ECC point (320 bits), AES (128 bits). From Table IV, you can obviously see that this protocol communication cost is the best compared to the other protocols. In terms of computation costs, the following notations are used: $T_{EPM}$ denotes the time cost of one point multiplication computation on ECC, $T_h$ denotes the time cost of one hash function computation and $T_{AES}$ denotes the time cost of one AES encryption/decryption operation [37]. Note that $T_{AES}$ requires much less time compared to $T_{EPM}$ [38]. Note also that compared to hash functions, PUFs require much less hardware overhead to implement [39], thus the negligible execution time of PUF will not be included in the comparison. Table IV provides a summary of the computation costs comparison. The computation cost of this protocol is considerably higher than the computation cost of X.Li et al.'s scheme [5]. This is explained by the fact that the reviewed protocol does not use ECC point multiplication operations in all steps of the mutual authentication phase, which makes it vulnerable to many attacks as previously discussed in Section IV. This protocol requires slightly more computational costs than Choi et al.'s scheme [13], but it is more secure as

shown previously in Table IV. In addition, note that at the sensor side, which is a resource-constrained device, the current protocol generates less computation cost compared to Choi et al.'s scheme. Compared to the protocols proposed by S.Challa et al. [25] and Zhang et al. [35], this protocol achieves a better efficiency level since it only requires the execution of 8 ECC point-scalar multiplications in total, while the former protocols require the execution of 14 ECC point-scalar multiplications.

## VIII. CONCLUSION

After reviewing X.Li et al.'s protocol and finding it to be vulnerable to many serious attacks such as insider attack, many time pad attack, lack of anonymity, and impersonation attacks, this paper presented a new mutual authentication and key agreement scheme that strengthens its security using three factors: password, smart card, and biometrics. The informal security analysis proved that this protocol resists all the attacks found in the studied protocol including X.Li et al.'s protocol. Additionally, a formal security analysis was given using AVISPA tool, which shows that the protocol is safe. In contrast with the studied protocols, this protocol also provides a freely identity change feature in addition to the password update.

TABLE IV.    COMPARISON OF COMPUTATION AND COMMUNICATION COSTS OF THE STUDIED PROTOCOLS

|  | [5] | [13] | [35] | [25] | Our protocol |
|---|---|---|---|---|---|
| Computation time of $U_i$ | $2T_{EPM}+8T_h$ | $3T_{EPM}+9T_h$ | $5T_{EPM}+4T_h$ | $5T_{EPM}+5T_h$ | $4T_{EPM}+8T_h+T_{AES}$ |
| Computation time of $GWN$ | $T_{EPM}+9T_h$ | $T_{EPM}+5T_h$ | $5T_{EPM}+5T_h$ | $5T_{EPM}+4T_h$ | $2T_{EPM}+5T_h+T_{AES}$ |
| Computation time of $S_j$ | $4T_h$ | $2T_{EPM}+6T_h$ | $4T_{EPM}+4T_h$ | $4T_{EPM}+3T_h$ | $2T_{EPM}+2T_h$ |
| Total of computation costs | $3T_{EPM}+21T_h$ | $6T_{EPM}+20T_h$ | $14T_{EPM}+13T_h$ | $14T_{EPM}+12T_h$ | $8T_{EPM}+15T_h+2T_{AES}$ |
| Communication costs (bits) | 2368 | 3072 | 3168 | 2464 | 2176 |

On the other side, the proposed protocol achieved better results in terms of communication compared to the studied protocols. Computationally, X.Li et al.'s protocol is the most efficient. However, this efficiency advantage comes at the expense of security as shown previously. In terms of security-efficiency ratio, the current protocol can be considered better than all the studied schemes. In the future, it will be interesting to improve this protocol to be suitable for mobile IoT applications where objects can jump from a gateway node zone to another in the same session without repeating the authentication process.

*Abstract*—**Aiming at the low efficiency of magnetic column surface defect detection, the vulnerability to human influence, and the insufficient anti-noise performance of existing 2D-OTSU threshold segmentation algorithm, an improved artificial fish swarm algorithm combined with 2D-OTSU algorithm was proposed to improve the accuracy and real-time of magnetic column surface defect detection. Firstly, the weight coefficient was added on the basis of the original 2D-OTSU algorithm, and the distance function was set to optimize the weight coefficient. The objective function was established by combining the inter-class discrete matrix and the intra-class discrete matrix, and the optimal threshold was obtained. Secondly, logistic model was used to optimize the perceptual range and moving step size of the artificial fish swarm algorithm, so as to balance the local and global search ability of the algorithm and improve the convergence speed of the algorithm. Finally, the optimal segmentation threshold is used to segment the image, and compared with other algorithms on four benchmark functions. Experimental results show that the improved algorithm can effectively reduce the time complexity of threshold segmentation and improve the efficiency of the algorithm. At the same time, the segmentation accuracy of the improved algorithm for magnetic column defects reaches 93%, which has good practicability.**

*Keywords*—*Defect detecting; threshold segmentation; artificial fish swarm algorithm; improved 2D-OTSU algorithm*

## I. Introduction

In the process of magnetic column production, the surface of magnetic column will produce scarring, edge drop, black film and crack. At present, magnetic column surface defects are mainly detected and classified by inspection ,which may result in missed detection and error detection in the detection process, affecting the economic benefits of enterprises [1-2].

In recent years, image processing technology has developed vigorously, and defect detection using image processing technology has the advantages of security, reliability and strong adaptability. How to rapidly and accurately segment images by using image processing technology has become a hot topic [3]. Otsu [4] proposed the dynamic threshold method, also known as Otsu segmentation algorithm, to determine the threshold value of image segmentation by the maximum variance between the target region and background region. Zhang et al. [5] used Canny edge detection and Otsu to segment the filtered image, effectively removing the noise of abnormal points. Bo et al. [6] and Wang et al. [7]proposed to use the maximum entropy method to select segmentation

threshold, when the image background is more complex, image segmentation is easy to cause partial information loss in the image and requires a large amount of calculation. The traditional Otsu algorithm only calculates the gray level of a single pixel without using the surrounding pixels, so there is a large error in the image threshold segmentation. On the basis of one-dimensional Otsu algorithm, 2D-OTSU algorithm is proposed to establish two-dimensional histogram based on the original image and the surrounding pixel smoothing information, which reduces the error in image segmentation and improves the accuracy of the algorithm.

In this paper, a threshold segmentation method of 2D-OTSU magnetic column image based on DLAFSA is proposed. By adding weight coefficient, the performance of 2D-OTSU algorithm is improved. The artificial fish swarm intelligence algorithm was introduced to improve its sensing range and moving step size, and the effectiveness of the improved artificial fish swarm intelligence algorithm was verified through performance test experiments.

## II. Related Work

Liu et al. [8] proposed 2D-OTSU algorithm, which extended Otsu method to the case of two-dimensional histogram. The optimal segmentation threshold was obtained by taking the maximum straight of two-dimensional measure criterion. As the one-dimensional space changed to two-dimensional space, the amount of computation increased and the calculation speed slowed down. He et al. [9] established the one-dimensional straight-line intercept histogram and the corresponding threshold selection criterion, which improved the anti-noise performance of the algorithm, but could not distinguish the low-light position information well. Xiao et al. [10] reduced the search space of threshold by mapping the pixel set of two-dimensional histogram to the trapezoidal region, thus improving the computing efficiency. However, some information was lost when the threshold space was compressed, which reduced the segmentation accuracy. Zeng et al. [11] combined the directional fuzzy reciprocal with the straight intercept histogram, replaced the gray information of the neighborhood with the fuzzy reciprocal, strengthened the details of the weak light position, and improved the segmentation accuracy of the model. Yang et al. [12] added local variance into 2D-OTSU, which not only took into account the degree of data dispersion between each pixel point and the central pixel point, but also improved the segmentation

*Corresponding Author.

accuracy while reducing noise interference, but its operation speed was still slow.

In order to solve such problems, many studies [13-15] use swarm intelligence to improve the traditional algorithm. For example, Ma [16] proposed the swarm intelligence whale algorithm, which uses swarm intelligence to conduct local search for threshold mechanism and then further search for global extreme value, thus improving the operation speed of the algorithm. Liu et al. [17] proposed to use the improved firefly algorithm to optimize the two-dimensional Otsu algorithm. In order to enable each firefly to find its own optimal position in the global, the mobile strategy was improved and global information was introduced in the iteration to enable firefly to have global search ability, avoid falling into local extremum and improve the operation efficiency.

### III. THRESHOLD SEGMENTATION

Threshold segmentation model has three parts, including establishing segmentation model, determining threshold criterion and solving threshold. As shown in Fig. 1(a) is the image of magnetic column surface defect to be segmented, and Fig. 1(b) is the result of segmentation of magnetic column surface image by selecting an appropriate threshold value. When the threshold value of image segmentation is an appropriate value, the target area of image defect is obvious, and the defect is completely separated from the background. When the segmentation threshold is too small, the defect region of magnetic column cannot be completely segmented, and the defect target region of magnetic column surface defect image is smaller than the actual defect area, as shown in Fig. 1(c). When the segmentation threshold is too large, the magnetic column surface defect image is over-segmented, and part of the background region of the magnetic column image is segmented into the defect region, as shown in Fig. 1(d). Therefore, determining the appropriate threshold algorithm is the key to image threshold segmentation.
(a)Image1  (b)Image2  (c)Image3  (d)Image4.

Fig. 1.   Segmentation Results of different Thresholds.

#### A.  Improved 2D-OTSU Algorithm

In order to get the best threshold value, threshold segmentation method is very important. OTSU method is the maximum inter-class variance method, which is the criterion to determine the threshold of image segmentation [18]. However, the noise resistance of this method is weak, and the magnetic column image with low contrast is easily affected by noise, so the image segmentation effect is not obvious. In view of this,

one-dimensional OTSU (1D-OTSU) method has no significant effect. Compared with 1D-OTSU, 2D-OTSU has lower sensitivity to noise and is more significant for defect image segmentation on magnetic column surface [19]. In order to eliminate the influence of isolated noise, weight coefficient is introduced, 2D-OTSU algorithm is improved to optimize the image segmentation effect.

Digital image $f(x, y)$ , its field smooths the image for $g(x, y)$ , $f(x, y)$ is the abscissa in a two-dimensional histogram, $g(x, y)$ is the ordinate, two-dimensional element $(i, j)$ is composed of pixel gray value i and field gray value j, The probability is $p_{ij} = \frac{f_{ij}}{N}$ . $f_{ij}$ is the number of $(i, j)$ 's, therefore.

$$\sum_{i=0}^{L-1}\sum_{j=0}^{L-1} f_{ij} = N, \sum_{i=0}^{L-1}\sum_{j=0}^{L-1} p_{ij} = 1 \tag{1}$$

If two-dimensional element is selected as the threshold value in the two-dimensional histogram, the two-dimensional histogram can be divided into four types of regions. Region 1 and region 3 are target and background region respectively, and region 2 and region 4 are noise and edge region, respectively. The two-dimensional histogram is shown in Fig. 2.

Fig. 2.   Two-dimensional Histogram.

Set the probability of target and background area as $\omega_0$ and $\omega_1$ , then

$$\omega_0 = \sum_{i=0}^{u-1}\sum_{j=0}^{v-1} p_{ij}, \omega_1 = \sum_{i=u}^{L-1}\sum_{j=v}^{L-1} p_{ij} \tag{2}$$

The corresponding mean values $\eta_0$ and $\eta_1$ are

$$\eta_0 = (\eta_{0i}, \eta_{0j})^T = \left[ \sum_{i=0}^{u-1}\sum_{j=0}^{v-1} i p_{ij}, \sum_{i=0}^{u-1}\sum_{j=0}^{v-1} j p_{ij} \right]^T \tag{3}$$

$$\eta_1 = (\eta_{1i}, \eta_{1j})^T = \left[ \sum_{i=u}^{L-1}\sum_{j=v}^{L-1} i p_{ij}, \sum_{i=u}^{L-1}\sum_{j=v}^{L-1} j p_{ij} \right]^T \tag{4}$$

The mean value of the total gray scale is

$$\bar{\eta} = \left(\overline{\eta_i}, \overline{\eta_j}\right)^T = \left[\sum_{i=0}^{L-1}\sum_{j=0}^{L-1} ip_{ij}, \sum_{i=0}^{L-1}\sum_{j=0}^{L-1} jp_{ij}\right]^T \tag{5}$$

The various internal discrete matrices is

$$S_k = \sum_{h=0}^{L-1} \omega_k \left[(h-\eta_k)(h-\eta_k)^T\right] \quad k = 0,1 \tag{6}$$

The discrete matrix between classes is

$$S = \sum_{k=0}^{1} \omega_k \left[(\eta_k - \bar{\eta})(\eta_k - \bar{\eta})^T\right] \tag{7}$$

The distance function between $\omega_0$ and $\omega_1$ is

$$r_{tr}(S) = \frac{\sum_{k=0}^{1} \omega_k \left[(\eta_{ki} - \overline{\eta_i})(\eta_{kj} - \overline{\eta_j})^2\right]}{\omega_0(1-\omega_0)} \tag{8}$$

When $r_{tr}(S)$ is the maximum of $(i,j)$, two-dimensional element $(u,v)$ is selected as the optimal threshold. However, isolated noise still exists. In order to eliminate the influence of isolated noise, this paper introduces weight coefficient $\beta$ on the basis of 2D-OTSU algorithm to determine the final comprehensive objective function and obtain the optimal threshold. The objective function is determined by studying the inter-class discrete matrix and the intra-class discrete matrix:

$$r_{tr}(S) = r_{tr}(S)_{max} - \beta r_{tr}(S_k)_{min} \tag{9}$$

$r_{tr}(S)$ is the maximum value of $r_{tr}(S)$ between classes, $r_{tr}(S_k)_{min}$ is the minimum value of $r_{tr}(S_k)$ within classes, and $\beta$ is the weight coefficient, which is related to the grayscale characteristics of the image and can be described by $\omega_k$. The calculation formula of weight coefficient $\beta$ is as follows:

$$\beta = 1 + \frac{1 - \exp(a - b\omega_k)}{1 + \exp(a - b\omega_k)} \tag{10}$$

Through 200 experiments, when a=0.6, b=0.045, the best weight coefficient $\beta$ is obtained, and the weight coefficient $\beta$ is added into the 2D-OTSU algorithm to eliminate the influence of isolated noise.

## B. 2D-OTSU Image Threshold Segmentation Method based on DLAFSA

Artificial fish swarm algorithm has strong ability to solve the optimal solution, high precision and fast convergence speed[20]. However, due to the characteristics of magnetic column defects, the traditional artificial fish swarm algorithm cannot completely meet the threshold segmentation of magnetic column surface defect image. In this paper, the artificial fish swarm algorithm is improved to improve the

accuracy of threshold segmentation algorithm of magnetic column surface defect image.

*1) Adjustment of perception range:* The size of visual represents the size of the search area of the individual fish. When the perceptual range of visual is larger, the search range of individual fish will be larger, which is conducive to the global search. When the perceptual range is small, the local range search is more accurate.

Carry on dynamic adjustment to visual, use dynamic change form to change visual original determination way. At the beginning of the algorithm, the whole magnetic column surface image is searched globally, and the range of Visual should be enlarged to improve the convergence of the algorithm. In the later stage of the algorithm, the local search is carried out in the magnetic column surface image, and the range variation of Visual should be reduced to improve the search speed of the algorithm. The Logistic model with dynamic transformation is used to dynamically adjust Visual, set the maximum and minimum value of visual change range as $visual_{max}$ and $visual_{min}$, visual dynamic adjustment formula is:

$$\begin{cases} \dfrac{dvisual}{dt} = \alpha(1 - \dfrac{visual}{visual_{min}})visual \\ visual(0) = visual_{max} \end{cases} \tag{11}$$

According to the logistic model, formula (11) is simplified as

$$visual(t) = \frac{vidual_{min}}{1 + (\dfrac{visual_{min}}{visual_{max}} - 1)e^{-\alpha t}} \tag{12}$$

Where, $\alpha$ is the initial decay rate, and $t$ is the number of iterations of the algorithm. The initial decay rate $\alpha$ is used to adjust the speed of visual descent. When $\alpha$ is larger, it indicates that visual attenuation speed is faster, when $\alpha$ is smaller, it indicates that visual attenuation speed is slow.

According to (11), when the number of iterations is zero, the value of Visual is the maximum $visual_{max}$. After t iterations, Visual approaches from the maximum value $visual_{max}$ to the minimum value $visual_{min}$. With the increasing number of iterations, Visual slowly converges from the maximum value $visual_{max}$ to the minimum value $visual_{min}$. Thus realized the algorithm from the beginning to the end of the visual value by the larger value dynamic conversion to the smaller value function.

*2) Move step size adjustment:* In the process of algorithm iteration, the larger step is, the faster the search speed is in the same visual. The smaller step is, the slower the search speed is and the more iterations are. At the beginning of the algorithm, visual range is larger, at this time, take a larger value of step, reduce the workload of searching the best position state, improve the convergence speed of the algorithm; In the later stage of the algorithm, the local area of the best position state has been determined, visual is a smaller search range, a

smaller step is needed to carry out a more detailed local search, improve the accuracy of the algorithm.

The adjustment requirements of parameter step are the same as those of Visual, in that a larger value is required at the beginning and a smaller value is required later. The parameters change dynamically during the algorithm, from large to small. Logistic model is also used to dynamically adjust parameter step, and the formula is as follows:

$$\begin{cases} \dfrac{dstep}{dt} = \alpha(1 - \dfrac{step}{step_{min}})step \\ step(0) = step_{max} \end{cases} \tag{13}$$

According to the Logistic model, formula (13) is simplified as:

$$step(t) = \frac{step_{min}}{1 + (\dfrac{step_{min}}{step_{max}} - 1)e^{-\alpha t}} \tag{14}$$

Where, $step_{max}$ is the maximum value of step and $step_{min}$ is the minimum value of step.

According to the experiment, $visual_{max} = 10$, $visual_{min} = 1$, $step_{max} = 8$, $step_{min} = 0.5$, $\alpha = 0.1$, that is, the transformation range of Visual is [1,10], and the change range of step is [0.5,8]. The dynamic transformation curve of Visual and STEP is shown in Fig. 3.

Fig. 3.    Dynamic Transformation Curve of Visual and Step.

In an iterative cycle of 50, when 10 generations, visual and step convergence to the minimum, that is to say, in the first ten generations for global search, the rest of the iteration cycle for local search, this artificial fish algorithm can quickly locate the optimal solution is not at the early stage of the iteration into local optimal solution, and can improve the accuracy of solution in the late iterations.

In the 2D-OTSU algorithm, an optimal threshold $(u, v)$ should be found for image segmentation, and the optimal threshold $(u, v)$ should be found through the distance measure function in the maximum inter-class variance method to achieve the purpose of image segmentation of magnetic column surface defects. In this paper, 2D-OTSU algorithm is improved by adding DLAFSA algorithm to improve the accuracy and anti-noise of 2D-OTSU algorithm. The objective function of 2D-OTSU algorithm was used as DLAFSA algorithm to obtain the optimal threshold of fish food concentration $f(X)$ , so as to carry out the threshold segmentation of magnetic column surface defect image.

The specific steps of 2D-OTSU image threshold segmentation based on DLAFSA are as follows:

- Initialize the algorithm parameters.

- Take the objective function of 2D-OTSU algorithm as the food concentration of DLAFSA algorithm to find the maximum distance function.

- Update the searcher position in the bulletin board to find the best position.

- Judge whether the optimal position or the condition of maximum iteration value of the algorithm is reached, and output the result; otherwise, continue to perform the previous step.

- Image threshold segmentation of magnetic column surface defects is carried out according to the optimal threshold value.

The 2D-OTSU image threshold segmentation flow chart based on DLAFSA is shown in the Fig. 4.

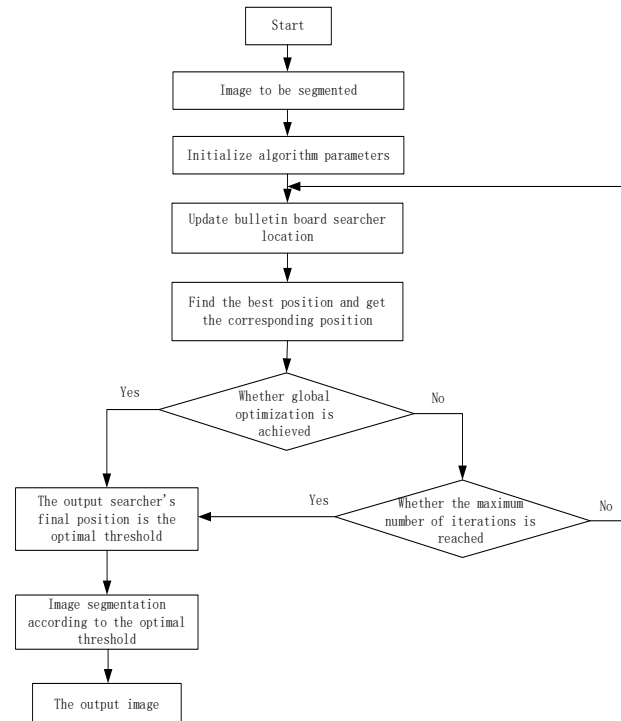

Fig. 4.    2D-OTSU Image Threshold Segmentation Flow Chart based on DLAFSA.

## IV. ALGORITHM PERFORMANCE TEST

In order to verify the effectiveness of the improved artificial fish swarm algorithm, the improved adaptive artificial

fish swarm algorithm DLAFSA and the standard artificial fish swarm algorithm AFSA are compared and tested by Benchmark function [19]. In DLAFSA algorithm, set parameters, $n = 20$, $visual_{max}$ =10, $visual_{min}$ =1, $step_{max}$ =8, $step_{min}$ =0.5, $\lambda$ =2. In the AFSA algorithm, visual=2, step=2, and other parameter settings are the same as those in the DLAFSA algorithm. The four selected test benchmark functions are shown in Table I.

TABLE I.  SELECTED FOUR TEST BENCHMARK FUNCTIONS

| The function name | Test functions | Variable scope | The optimal value |
|---|---|---|---|
| Rastrigin | $f_1(x) = \sum_{i=1}^{n} [x_i^2 - 10\cos(2\pi x_i) + 10]$ | [-5.12,5.12] | 0 |
| Ackley | $f_2(x) = -20e^{-0.2\sqrt{\frac{1}{n}\sum_{i=1}^{n} x_i^2}} - e^{\frac{1}{n}\sum_{i=1}^{n}\cos(2\pi x_i)} + 20 + e$ | [-50,50] | 0 |
| Rosenbrock | $f_3(x) = \sum_{i=1}^{n-1} [100(x_{i+1} - x_i^2)^2 + (x_i - 1)^2]$ | [-32,32] | 0 |
| Schaffer | $f_4(x) = 0.5 + \frac{\sin^2 \sqrt{x^2 + y^2} - 0.5}{[1 + 0.001(x^2 + y^2)]^2}$ | [-10,10] | 0 |

The parameters of DLAFSA algorithm and AFSA algorithm are set. During the performance comparison test, both algorithms are executed for 30 times. The performance of DLAFSA algorithm is verified by comparing the mean and variance of solutions obtained by DLAFSA algorithm and AFSA algorithm after the test of four selected benchmark functions, as well as the number of successful iterations of algorithm on the benchmark function and the average number of iterations required after successful iteration.

In the four classical benchmark functions, DLAFSA and AFSA algorithms set the number of iterations to 2000. $f_1(x)$ is a unimodal function $f_2(x)$, $f_3(x)$, and $f_4(x)$ are multimodal functions. Test results of DLAFSA and AFSA on the benchmark function are shown in Table II.

As can be seen from the data results in Table II, the mean values of solutions obtained from four different benchmark functions are smaller than those obtained from AFSA algorithm. Compared with AFSA algorithm, the variance of solutions obtained by DLAFSA algorithm in four different benchmark functions is smaller. From the comparison of mean and variance, DLAFSA algorithm has higher accuracy, and DLAFSA algorithm is better than AFSA algorithm.

TABLE II.  TEST RESULTS OF DLAFSA AND AFSA ON THE BENCHMARK FUNCTION

| Benchmark functions | DLAFSA | | AFSA | |
|---|---|---|---|---|
| | The mean | The variance | The mean | The variance |
| $f_1$ | 1.4203 | 0.2912 | 12.6237 | 2.7212 |
| $f_2$ | 5.6e-16 | 8.1e-16 | 2.8e-10 | 1.9e-12 |
| $f_3$ | 1.7e-28 | 2.7e-72 | 0.00681 | 0.0143 |
| $f_4$ | 3.5231 | 2.7873 | 6.6372 | 3.8221 |

TABLE III.  SUCCESSFUL ITERATION RESULTS OF DLAFSA AND AFSA

| Benchmark functions | DLAFSA | | AFSA | |
|---|---|---|---|---|
| | Number of successful | Average number of iterations | Number of successful | Average number of iterations |
| $f_1$ | 21 | 1074 | 15 | 1829 |
| $f_2$ | 16 | 1527 | 9 | 1672 |
| $f_3$ | 23 | 982 | 23 | 1082 |
| $f_4$ | 28 | 609 | 19 | 695 |

Table III shows the average iteration times required by DLAFSA algorithm and AFSA algorithm for successful iteration on benchmark functions when the test results and algorithm convergence are successful. It can be seen from the table that the successful iteration times of DLAFSA algorithm on four benchmark functions are more than the successful iteration times of AFSA algorithm on four benchmark functions. The average iteration times of DLAFSA algorithm on the successful iteration of the four benchmark functions are also less than that of AFSA algorithm on the successful iteration of the four benchmark functions. The performance of DLAFSA algorithm is better than that of AFSA algorithm.

## V. EXPERIMENTAL RESULTS AND ANALYSIS

In order to verify the effect and accuracy of the improved 2D-OTSU image threshold segmentation method on magnetic column surface defect image threshold segmentation, the 2D-OTSU image threshold segmentation method based on DLAFSA was compared with the traditional 2D-OTSU method and the improved firefly algorithm in literature [21]. The image segmentation of four magnetic column surface defects, namely, magnetic column scar, black slice, edge drop and crack, was analyzed by comparative experiment. The image threshold segmentation and comparison effect of magnetic column surface defects is shown in Fig. 5.

As can be seen from the comparison figure, magnetic column surface defects are complex and have many kinds of defects. For scarring and black spot defects, the traditional 2D-OTSU algorithm will produce many noise points. Although the algorithm in [21] effectively reduces noise points, the edge segmentation effect of magnetic column is poor. For side drop defects, the 2D-OTSU algorithm has more noise points, and both the algorithm in [21] and the algorithm in this paper can be well segmented. However, for crack defects with low contrast, the traditional 2D-OTSU image segmentation algorithm and the algorithm in [21] are still affected by isolated noise and cannot effectively extract magnetic column surface defects. However, the algorithm in this paper can effectively eliminate isolated noise and extract magnetic column surface defects. Table IV shows the comparison of optimal thresholds and time for processing magnetic columns with different defects using three threshold segmentation algorithms. It can be seen that the running time of 2D-OTSU using firefly algorithm is 32.2% of that of traditional 2D-OTSU. Although it can effectively reduce the running time, the running speed is still relatively slow. The proposed algorithm reduces the running time of the traditional 2D-OTSU algorithm by 82.45%，and ensures the accuracy of the algorithm while reducing the running time.

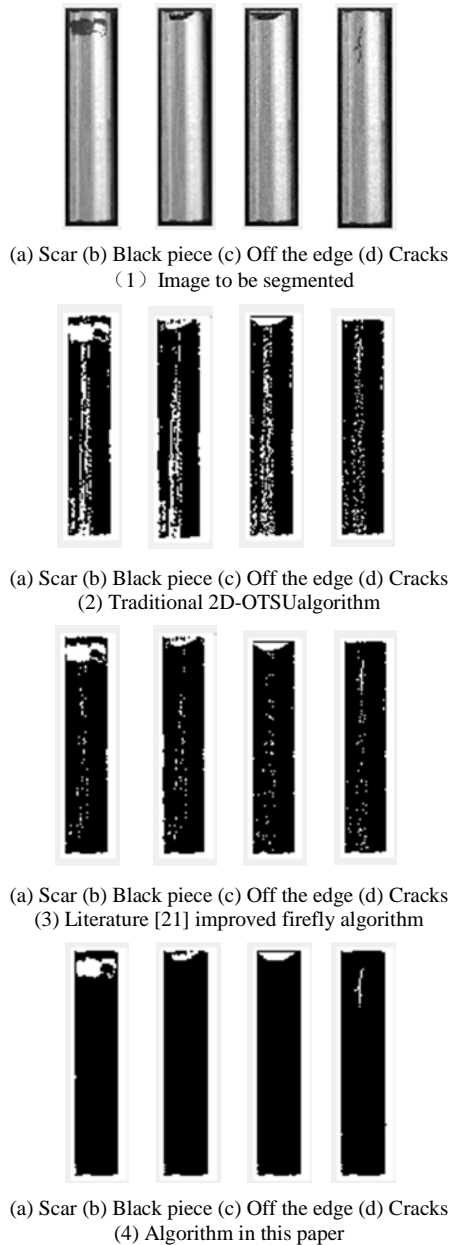

Fig. 5.    Threshold Segmentation Effect of different Methods.

TABLE IV.    THE OPTIMAL THRESHOLD AND SEGMENTATION TIME OF DIFFERENT ALGORITHMS ARE COMPARED

| Algorithm | Scar | Black piece | Off the edge | Cracks | Mean Spent time/ms |
|---|---|---|---|---|---|
| 2D-OTSU | (96,109) | (102,123) | (94,115) | (103,117) | 508.43 |
| Firefly algorithm + 2D-OTSU | (103,112) | (109,120) | (106,112) | (102,115) | 163.59 |
| Ours | (103,108) | (113,119) | (108,112) | (107,111) | 89.23 |

The threshold segmentation of 500 magnetic column images with defects is carried out by the method in this paper, and the images obtained are used as classification recognition samples after feature extraction. 300 of them are selected as

KNN classifier training sample set, and the remaining 200 as KNN classifier test sample set. The test samples are classified by the KNN classifier successfully trained. The classification recognition results are statistically analyzed, and the classification results are shown in Table IV.

TABLE V.    CLASSIFICATION RESULTS

|  | Scar | Black piece | Off the edge | Cracks | total |
|---|---|---|---|---|---|
| Actual sample size | 45 | 55 | 48 | 52 | 200 |
| Correct identification number | 41 | 52 | 44 | 49 | 186 |
| Leaving out the number | 0 | 0 | 0 | 0 | 0 |
| Mistakenly identified several | 2 | 2 | 1 | 1 | 6 |
| Recognition accuracy% | 91.1 | 94.5 | 91.7 | 94.2 | 93 |

Table V shows that the classification accuracy of four types of magnetic column surface defects reaches 93%, including 94.5% for black piece defects, the accuracy of cracks defect classification was 94.2%. Due to the difficulty in distinguishing edge defect from scar defect, the classification accuracy is lower than the other two defect types, but the recognition accuracy can reach more than 90%. The recognition accuracy of scar is 91.1%, the recognition accuracy of off the edge is 91.7%. In particular, the missing rate is 0, and all defects can be detected, which can meet the requirements of magnetic column surface defect detection.

## VI.    CONCLUSION

Aiming at the problems of low segmentation efficiency and weak anti-noise ability of traditional 2D-OTSU algorithm, this paper proposes a 2D-OTSU image threshold segmentation algorithm based on DLAFSA. In this paper, a weight coefficient is added to 2D-OTSU algorithm to eliminate isolated noise and distinguish background and target effectively. The artificial fish swarm algorithm is improved to improve the convergence and search speed of the algorithm and effectively reduce the time complexity of threshold segmentation by adjusting the perceived range and moving step size of fish swarm. By comparing the performance of adaptive artificial fish swarm algorithm DLAFSA with the standard artificial fish swarm algorithm AFSA using the benchmark function, it is concluded that the improved algorithm has higher accuracy, shorter convergence time and stronger overall performance than the original algorithm. Finally, the proposed algorithm is compared with the traditional 2D-OTSU method and the improved firefly algorithm in terms of segmentation accuracy and running time. Experimental results show that the proposed algorithm can better segment magnetic column edge, effectively eliminate isolated noise, improve the running speed of the algorithm, and ensure the segmentation accuracy.

*Abstract*—**Accurate diagnosis of lung cancer has been critical, and image segmentation and deep learning (DL) techniques have made it easier for medical people. Yet, the concept's effectiveness is extremely limited due to a scarcity of skilled radiologists. Although emerging DL-based methods frequently necessitate accordance with the regulation, such as labelled feature map, to train such networks, which is difficult to terminate on a big scale. This study proposed a swarm intelligence based modified DL model called MSCOA-DSCN to classify and forecast various Lung Diseases through anterior X-rays. Image enhancement with a modified median filter and edge enhancement with statistical range applied for better image production. The disparity between min and max pixels focused on the Statistical range from each 3×3 input image cluster. Utilized Enriched Auto-Seed Fuzzy Means Morphological Clustering for segmentation (EASFMC); they could function together to identify edges in X-Ray imaging. Used A deep separable convolution network (DSCN) was in the created system to predict the class of lung cancer, and Modified Butterfly Optimization Algorithm (MBOA) applied for the feature selection procedure. This present study compared with various state-of-the-art classification algorithms using the NIH Chest-Xray-14 database.**

## I. INTRODUCTION

In recent times, Lung cancer (LC) is the main leading causes of mortality among the most dangerous tumours that can harm a person's health. It has the highest mortality rate, including all tumours, and is the prominent basis of cancer death in human [1]. LC accounts for roughly 1.8 million people infected each year, or 13% of all cancer cases, and 1.6 million fatalities globally, or 19.4% of all cancer-related deaths. In 2020, the expected mortality of cancer patients in developing countries [2] was 679,421 men and 712,758 females, particularly in India. Around one in 68 men suffers this form of LC; about one in 29 women suffer breast cancer, therefore around one in nine Indians suffering cancer between the decades of 0 and 74.Increasing the risk of LC, the discovery in the early stages will improve survival rates significantly. Still, it is also impossible to discern the early-stage prediction of LC due to fewer symptoms [3].

Computer-based technology has significantly grown in importance around the globe. As of early January 2019,

COVID-19 causes causing substantial respiratory problems and severe health issues, leading to the possibility of the COVID-19 pathogenic virus and other such bacterial or viral infections [4]. As a result, the accurate intervention of lung disorders is rather critical than ever. Machine learning (ML) and DL can be beneficial throughout this case. The recognition of medical images in ML-based detection approaches necessitates a specific stage to isolate malignancies, automatic localization, and identification in internal organs, as well as particular processing, which is highly useful [5]. "DL approaches" that perform well in cancer categorization advance current trends.

Various studies have focused on how DL schemes might be used [6,7] with both the expansion of computer programming for medicine and social research initiatives, this approach has the potential to lower medical expenditures. The NIH chest X-ray image database is obtained mainly from the Kaggle repository [8] for use in development. A number of research works have been carried out on the diagnosis of chest diseases using artificial intelligence methodologies. In [9], multilayer, probabilistic, learning vector quantization, and generalized regression neural networks have been used for diagnosis chest diseases. The diagnosis of chronic obstructive pulmonary and pneumonia diseases was implemented using neural networks and artificial immune system [10]. In [11], the detection of lung diseases such as TB, pneumonia, and lung cancer using chest radiographs is considered. The histogram equalization in image segmentation was applied for image preprocessing, and feed forward neural network is used for classification purpose. The above research works have been efficiently used in classifying medical diseases; however, their performance was not as efficient as the deep networks in terms of accuracy, computation time, and minimum square error achieved. Deep learning-based systems have been applied to increase the accuracy of image classification [12]. These deep networks showed superhuman accuracies in performing such tasks. This success motivated the researchers to apply these networks to medical images for diseases classification tasks, and the results showed that deep networks can efficiently extract useful features that distinguish different classes of images [13]. Most commonly used deep learning architecture is the convolutional neural network (CNN). CNN has been applied to various medical images classification due to its power of extracting different level features from images

[14] [15]. This work presents a novel hybrid method for classifying lung illness in the aforementioned dataset. The research's significant contribution is the invention of a different hybrid DL system appropriate for detecting lung illness from X-ray pictures.

The study discusses the architectures of DSCN further with MBOA to help determine whether use individuals to diagnose LC in this research would work. The NIH chest X-ray image database is initially pre-processed images after that trained using the suggested DSCN-MBOA model to assess the percentage of lungs directly impacted by cancer and network image preparedness for LC. The networks in this translucent classification structure have achieved equivalent performance, latency (time), recall, f-measure, precision, and accuracy metrics. The following is the work's main contribution:

- The input x-ray images are first pre-processed with a modified median filter for noise reduction and statistical range edge detection.

- Enriched Auto-Seed Fuzzy Means Morphological Clustering is used for segmentation (EASFMC).

- By using DSCN and the MBOA for feature selection, the created method identifies a certain kind of lung illness.

The following is a conceivable structure for the manuscript: The second section discusses relevant research on lung classification and nodule identification and classification. Section 3 discusses the methodology of this study and a complete examination of the implemented dataset. Section 4 describes the findings and experimental discussion with their appropriate outcome results, while Section 5 finishes the research work with recommendations for further research.

## II. RELATED WORK

A complete examination of numerous LC detection approaches for forecasting cancer is an uncontrolled development in the lung region, notably in lung X-ray images described in this literature review. Liu et al. [16] developed a Convolutional Neural Network (CNN)-based cascade technique for lesion classification. To get the localization of the focal liver lesions, initially utilize the transfer learning (TL) method to learn the automatic recognition network on the experimental dataset. Peng et al., [17] utilized a parallel genetic algorithm (GA) to detect LC in chest X-ray images. The approach combines pattern matching and localized search strategies, and experiments have shown promising outcomes.

The 121-layer CNN (DenseNet121) and the TL algorithm being investigated by Ausawalaithong et al., [18] are mechanisms for diagnosing LC via chest X-ray data. This classifier trained on the sample until moving on to the LC image database to overcome the difficulty of a short dataset. Yan et al. [19] suggested a weakly supervised DL architecture

comprising squeeze-and-excitation blocks, multi-map transfer, and max-min pooling for grouping similar respiratory diseases, including identifying anomalous lesion locations on Chest X-ray14 dataset for diagnosing major lumbar spinal disorders. The extensive simulation shows that the proposed model has high effectiveness than the existing methods.

Yan et al. [20] described a new weakly-supervised learning model for classifying pulmonary diseases based on the analysis of given chest X-rays and localizing disease patches on X-rays at pixel-level refinement. The suggested network's benefits come from the acquisition of disease-specific characteristics during multi-map transfer layers and the cross-channel feature realignment provided by squeeze-and-excitation blocks somewhere between dense partitions. Heat maps, which are the raw material for producing the network's range of processes, are another way to display it.

The above X-ray scans are massive, containing 110,120 images and weighing almost 44 GB. Including the Chest X-ray-based LC expert systems, in [21] performed a thorough statistical study of different DL network models. The main objective is to obtain a performance evaluation for each DL network structure. It includes aspects of measurement, including accuracy performance, examination of training and validation time, memory utilization analysis, CPU and memory observation, graphics processing energy consumption, and some enhancement ideas.

In [22] suggested a Modified AlexNet (MAN) DL architecture to assess the lung abnormalities, where a threshold filter to reduce artifacts from Lung CT images is applied. Besides combining in-depth features with handcrafted features, this study introduces a new Ensemble-Feature-Technique (EFT). However, serial fusion and Principal Component Analysis (PCA)-based design to identify the significant feature set used. Compared to the other existing framework methods, experimental data show that MAN outperforms them. Bharati et al. [22] created new hybrid DL architecture (By merging data augmentation, VGG, and spatial transformer network (STN) into CNN) and denoted as VDSNet. Table I show the proposed methods' advantages and disadvantages in this literature review.

Here the Inference from the existing works is considered as conventional DL algorithms are robust, they underachieve when images are slanted, flipped or otherwise abnormally oriented. Again, hybrid approaches to evaluate the accuracy while reducing the learning rate are applied. The presented hybrid technique named DSCN- MSCOA may detect suspicious problematic regions using chest X-ray images that are highly effective and enhance diagnosis when compared to standard methods. In a way, it can improve the therapy's effectiveness for the affected individual in terms of accuracy, precision, etc.

TABLE I.        EXISTING PROPOSED METHODS WITH THEIR ADVANTAGES AND DISADVANTAGES

| Author | Dataset | Method | Advantages | Disadvantages | Performance metrics |
|---|---|---|---|---|---|
| Liu et al., [9] | 2594 chest x-rays and JSRT dataset | Cascaded CNN | Reduce the number of actions required to detect the condition and increase the learning duration. | The issue with using CNN to diagnose LC is that it is highly effective when the sample size is too small. | JSRT dataset: Precision of 0.885 and recall of 0.858. Chest x-ray: Precision of 0.985 and recall 0.958 |
| Peng et al., [10] | 154 pieces of medical images | GA | This results in more accurate learning without having to spend more time on it. | The reality that all tumor spots on chest X-rays were genetic conditions is overlooked because GA will not handle various diseases sequentially. | optimal solutions 100% execution time 14814s |
| Ausawalaithong et al., [11] | JSRT Dataset and ChestX-ray14 Dataset | CNN with TL | This suggested scheme is capable of resolving the issue of a small dataset. | Owing to the unavailability of features which include genetic factors and tobacco consumption rate in learning, as well as images, accuracy is reduced. | mean accuracy: 74.43±6.01%, mean specificity: 74.96±9.85%, and mean sensitivity: 74.68±15.33% |
| Yan et al., [13] | ChestX-ray14 dataset | weakly-supervised DL framework | As more of a result, using minimal samples can yield high accuracy. | Using the minimal number of bounding boxes, re-investigate an effective representation of lesion regions. | Average AUC 0.8302 |
| Wibisono et al., [13] | 110,120 images | five different CNN models | In terms of execution rate and accuracy, this might be the most efficient DL conceptual model. | The availability of sufficient labeling by a medical expert is a key barrier to applying DL models to serious health concerns. | AUROC scores 0.80 - 0.82, CPU utilization 527% - 940% memory usage 23.39 GB - 38 GB and execution time 2.91 hours - 7.6 hours. |
| Bhandary et al., [14] | chest X-Ray images and LIDC-IDRI | modified AlexNet | It is essential because it could be viewed as a program that helps physicians in doing further diagnostic procedures. | Though the recognition rate was improved by 0.05 on the ROC-AUC scoring system, there was always scope for change. | classification accuracy 97.27% |
| Bharati et al., [15] | NIH chest X-ray | VDSNet | It takes a lot less time to train, but the accuracy rate is significantly worse. | Unfortunately, this should result in a lengthy period of training. | validation accuracy of 73% |

## III. PROPOSED METHOD

An optimized DL-based technique opts to classify and extract LC regions on X-ray images. The proposed framework is composed of various successive components shown in Fig. 1. After pre-processing X-ray images using a modified median filter, the undesired LC components are masked using Enriched Auto-Seed Fuzzy Means Morphological Clustering (EASFMC) based segmentation and removal. After that, the features are extracted from the final fully-connected layers for the DSCN architecture, which are then optimized using MBOA. The optimized feature set input for DSCN for LC classification. Pre-processing is required because this technique requires an X-Ray image representation that could have noise, inappropriate blurring, or being out of perspective.

### A. Dataset Description

The dataset [8] file comprises a random sample of 5% of the whole dataset, with 5606 photos with a resolution of 1024 x 1024 pixels each. To build a .csv (comma-separated values) file with patient data in addition class labels for the entire dataset. The following is a description of the class. There are 15 "No findings" classes, as well as 14 diseases such as Edema type images (118), Emphysema type images (127), Cardiomegaly type images (141), Fibrosis type images (84), Pneumothorax type images (271), Consolidation type images (226), Pleural Thickening type images (176), Mass type images (284), Effusion type images (644), Infiltration type images (967) and Nodule type images (313). Also, technique classifies "No finds" for 3044 images.

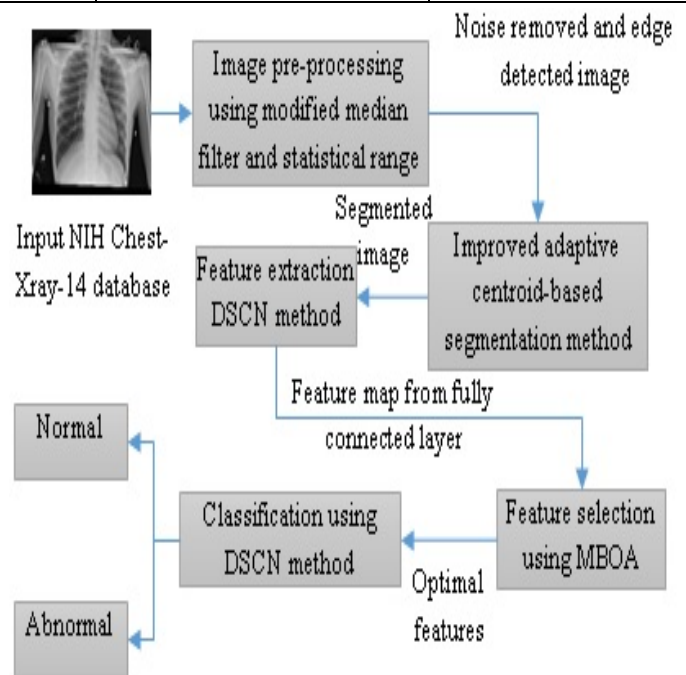

Fig. 1.    General Framework Diagram.

### B. Image pre-processing and Edge Detection

Modified Median Filter for noise Removal: The median filter [23] is the most widely utilized image-enhancing filter. It blurs and distorts images by modifying noisy, denoted as

corrupted pixels, and noiseless, indicated as uncorrupted pixels. The modified median filters incorporate a switching mechanism to replace several pixels when it is determined to be contaminated. These results of pixels in an image are computed by Algorithm 1. A three × three window across the image stretches by starting in the upper left corner. Its function is associated with the maximum and minimum image pixels within the window to determine whether a pixel remains uncorrupted or corrupted. When a pixel's value is between the top and minimum, it is uncorrupted. A refined pixel is left alone within a specified filtering window, whereas corrupted pixels swap by the median image pixel or an effectively understood immediate adjacent pixel; is done for each pixel value. Determine the absolute value $\vartheta$ by the difference between both the window's centre pixel as well as its neighboring pixels with n=8, which is expressed as in Eq. (1-2):

$$\vartheta = \frac{\sum_{i=1}^{n}|\varphi(i,j)|}{n} \text{ where } i,j = 1,2,\dots,n \tag{1}$$

$$thershold = \mu\left[\frac{avg}{avg+var}\right] \tag{2}$$

where the $threshold$ is the ideal threshold in the proposed algorithm and is the mean of (i,j). In the filtering window, the mean avg, as well as variance var of n neighbor pixels nearest to the center pixel, as well as variance var of n neighbor points adjacent to the center pixel is determined. It can be explained simply:

$$var = \sqrt{\frac{(\sum_{i=1}^{n} x(i,j)-ave)^2}{n}} \text{ and } avg = \frac{\sum_{i=1}^{n} x(i,j)}{n} \tag{3}$$

---

**Algorithm 1. The modified median filtering algorithm**

---

**Input:** Corrupted Input chest X-ray Image by noise

**Output:** Noise removed Image, using a $M \times N$ window

1. The $M \times N$ window is skimmed in excess of the entire image.
2. Category the pixels, denoted by $S_{ij}$ inside the window in ascending order.
3. Find minimum $S_{min}$, maximum $S_{max}$ and median $S_{med}$ of the pixel values
4. If ($S_{min} < S_{epicenter} < S_{max}$)
5. denote the medium pixel as uncorrupted such that no filtering required
6. Else
7. denote the medium pixel as corrupted
8. If ($S_{epicenter}$ is not an noise which is margin significance)
9. Substitute $S_{epicenter}$ through $S_{med}$
10. Else
11. Substitute $S_{epicenter}$ through $S_{i-1,j}$
12. End If
13. End If
14. Recurrence step 2 to 9 for the complete image and obtain noise removed image.

---

Statistical Range for Edge detection: The measures of dispersion between every maximum and minimum value of a specified collected data, matrix, or linear data in massive volumes of data, the variety can be used to detect edges. Every pixel is supplanted with a variety of grey values from the surrounding area. The variety also gives meaning to the mean, median, as well as mode, it can gain a piece of deeper knowledge through a variety of facts. In this study, the statistical range (SR) from each of the $3 \times 3$ matrix partitions from the lung input image was examined. The equation for determining SR is as follows:

$$SR = S_{med} - S_{min} \tag{4}$$

### C. EASFMC for Segmentation

The lung segmentation technique is a prerequisite in classifying lung images and yet is essential for effective cancer diagnoses. Earlier, used Otsu's approach [24] to determine a global specified threshold, then image edge detection was employed to extract the bounding box of the image's centre, i.e., the malignancy location on an image. The region is segmented using regions of interest with an EASFMC clustering methodology, a density-based technique for detecting spontaneously generated clusters in more extensive coverage of large databases with imperfection. EASFMC additionally clusters sites only in high-density areas, whereas endpoints in specific areas are considered outliers or interference. So the amount of segments is determined dynamically.

Based on EASFMC, the study proposes a method for extracting the characteristic features of cancer areas. The fuzzy concept, commonly employed in the classification process, is being used here for segmentation—the given image segments into several clusters due to specific fuzzified data clusters by keeping their geometric placements—the measure of similarity of each pixel to the precedent cluster's centre value using the membership degree. The method has indeed been designed in this study to determine its initial centroids reference value on its own, making the segmentation procedure automatic. The EASFMC Segmentation steps are explained in detail as follows.

Step 1: The ROI I(x,y) was obtained initially, which comprises the cancer area and the ordinary location, two reference cluster numbers must be specified for this. Those two main clusters $c$ were generated sequentially in an attempt to implement this segmentation quickly and easily.

$$c_1 = \frac{\sum\left(\sum_{m=1}^{i} \max(I(m,:))\right)}{N}$$

$$c_2 = \frac{\sum\left(\sum_{n=1}^{j} \max(I(m,:))\right)}{N}$$

Where $m = 1,2,\dots,i$ and $n = 1,2,\dots,j$. (5)

Where $i$ is the amount of rows, $j$ is the amount of columns in image $I(m,n)$ and N is the complete number of non-zero pixels.

Step 2: The differentiation between each pixel as well as clusters was computed, therefore two distance matrices, $dist_1$ and $dist_2$, respectively built for both $c_1$ and $c_2$ using the formulae below.

$$dist_1 = [c_1 - I(m,n)]^2 \text{ and }$$

$$dist_2 = [c_2 - I(m,n)]^2 \tag{6}$$

Step 3: The distance matrices acquired in the initial state were smooth fuzzified using the following equations, and even the coefficients were therefore normalised as well as fuzzified using a constant variable $\mathbb{r} > 1$ as then their summation was $1$, as well as the resultant smooth fuzzified output was preserved in $F_1$ and $F_2$.

$$F_1 = \frac{1}{(dist_1)^{\frac{2}{\mathbb{r}-1}}} \text{ and}$$

$$F_2 = \frac{1}{(dist_2)^{\frac{2}{\mathbb{r}-1}}} \tag{7}$$

This seems to be comparable to simply normalising the coefficients to achieve their summation 1 for $\mathbb{r} = 2$.

Step 4: Around an image $F(m,n)$, fuzzy rule-based assignment was conducted prior to $F_1$ and $F_2$, as well as the segmented images $seg_1$ (the segmented image with respect to initial cluster $c_1$) and $seg_2$ (another segmented image with respect to cluster $c_2$)were generated as follows:

$$seg_1(i,j) = I(m,n), if \ F_2(i,j) < F_1(m,n) \text{and}$$

$$seg_2(i,j) = I(m,n), if \ F_2(m,n) > F_1(m,n) \tag{8}$$

Step 5: The$seg_1$ and$seg_2$ were refined through updating the cluster value $c_1$ and $c_2$ consuming the subsequent equations.

$$c_{1update} = \frac{\sum(seg_1(i,j) \neq 0)}{N_1} \text{ and}$$

$$c_{2update} = \frac{\sum(seg_2(i,j) \neq 0)}{N_2} \tag{9}$$

Where $N_1$ and $N_2$ are the complete amount of non-zero pixels in $seg_1$ and $seg_2$correspondingly.

Step 6: Step 1 to 5 were repetitive once more with the new cluster centre values such as$c_{1update}$ and $c_{2update}$ up to the difference between two sequential restructured clusters were minimum.

Step 7: Mathematical morphology is used for the binary image, and the cancer regions are improved in the processed binary image. Formerly, DSCNN is applied for feature extraction yields the final results of feature extraction then also classification after X-ray image segmentation.

### D. Feature Extraction and Classification using DSCNN

In DSCNN, image features are extracted from the fully connected (FC) layers and then optimized utilizing the MSCOA method. The system gave a 2-dimensional feature map containing the retrieved image features as input. Provide N filters to every convolutional network layer to identify cancer region abnormalities across data points. Every neural inference produced a probability function in maintaining the likelihood of every output class. Fig. 3 depicts the DSCNN classifier's architectural framework. The network's initial layer was a normal convolutional layer throughout all situations. Another batch-normalization layer including activation function (rectified linear unit (ReLU) [25]) followed the convolutional layer.

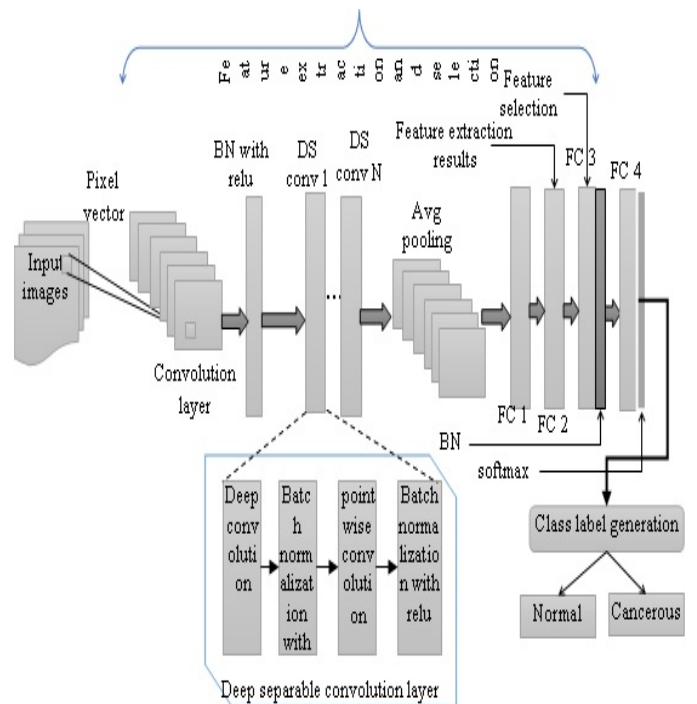

Fig. 2. General Architecture of the DSCNN for LC Detection.

Sophisticated features are represented efficiently by DSCNNs. Meanwhile, the number of convolution layers (Conv) and its type, pooling function, kernel size and activation function, and fully connected layers model. The primary goal is to acquire outstanding raw pixel information to identify the detection efficiency of the overall architecture. Following the DSCNN process of learning, MSCOA is used to isolate the optimal feature selection, just the most essential attributes that maximize classification performance. The DSCNNs fundamental aim of sharing weights over multiple layers is to reduce the curse of dimensionality. Can summarize entire network as (Conv1: $1 \times 3@64$) $\rightarrow$ (DSConv2: $1 \times 3@64$) $\rightarrow$ (FC1: 128) $\rightarrow$ (FC2: 128) $\rightarrow$ (FC3: 64) $\rightarrow$ (BN: 64) $\rightarrow$ (FC4: 64) and Fig. 2 shows the suggested DSCNN architecture into four layers: (1) Conv (2) Deep Separable Convolution layer (DS Conv), (3) Pooling layers, and (4) FC.

Conv: This is the first conv, with 64 filters, a kernel of dimension 3, as well as a stride of value 1, and it employs the ReLU as a non-linear function, followed by dropout regularization with a rate of 0.5 and then a size two max-pooling operations.

DS Conv: This is the second DS Conv, similar to Conv1, except that instead of max-pooling, this uses an adaptive average pooling layer.

FC: FC1, FC2, and FC3 are feature extraction and feature selection layers that output learned features from raw input, with 128, 128, and 64 neurons.

BN and FC4: FC4 is the final FC layer to produce the classification predictions, and BN (batch normalization) operation.

BN was used to speed up the training process while also reducing the risk of overloading due to regularization. After BN and ReLU activations, the input image array to the first conv layer. each of the DS conv layers 1 to N starts with a deep convolution, then BN and ReLU, before moving on to a pointwise conv, BN, and ReLU activation again. The application determines average pooling and FC layer containing soft max activations after the conv layers. Great learning rates can be employed when the activation patterns since the strength of the biases of each layer are much more equivalent, resulting in rapid system divergence.

The small number of features in the mini-batch creates a regularization effect since the activations of a single image file are not normalized by the mean and variance of each image file but rather by the mean and variance of the mini-batch wherein it occurs. Following the BN layer, a series of DS convs consisted of a deep wavelet convolution (DW conv) and a pointwise convolution (PW conv). A BN followed each one with ReLU activation. After that, an average pooling layer decreases the number of activations by introducing an averaging window to every input cable network's complete time-frequency feature map. Finally, the probabilities for every class label using an FC layer with softmax activations.

### E. Feature Selection using MBOA

The food gathering behavior of butterflies [26] inspired the Butterfly Optimization Algorithm (BOA) used to find and identify the best solution in a multi-dimensional domain. To reach a local and global optimum solution, certain unique places are allocated to butterflies in the ecosystem, including some input values. The calibration period starts after this, and the method runs like a virtual environment, optimizing the location of the features (butterflies) by tweaking its parameter. The primary three variables of the butterfly algorithm are used to move features (butterflies) from its random position to the optimal solution whereas butterflies use their keen sense of smell and scent to detect the presence of other butterflies.

Each scent in BOA has its unique distinct, enticing aroma and unique touch. This is one of the guiding features that set BOA apart from other meta-heuristics. To understand how fragrance is regulated in BOA [26], first understand how a technology such as music, lighting, or warmth is computed. The entire concept of identifying and managing the method is based on three key terms: stimulus intensity ($\mathcal{I}$), power exponent ($\mathcal{E}$) and sensory modality ($\mathcal{M}$). Sensation implies measuring the variety of energy and processing it by comparing methods in sensory modality technique, while methodology implies the basic information used by the sensors.

Currently, numerous modalities include lighting, music, and warmth. In BOA, while sI is the strength of the physical stimulus, when a butterfly emits a more visible smell, other butterflies in the area can sense be drawn towards it. The power of the butterfly or rational response represents an improvement in intensity, where pE is the parameter that considers regular expression, which accounts for fluctuating levels of absorption. This part conducted several stimuli estimating experiments on bugs, critters, and individuals, and they have hypothesized that as the number increases, insects become less sensitive to changes in the environment. Using these ideas, the fragrance $\mathfrak{FR}_i$ (fragrance is smell by $i$ th butterfly) in BOA is computed as [27]:

$$\mathfrak{FR} = \mathcal{M} * \mathcal{I}^{\mathcal{E}} \tag{10}$$

The global and the local search stage are utilized to assert that fragrance levels rise in a well-liked situation. A butterflies B would produce a smell that may be sensed from every location in the region in this manner. The butterfly finds the fitness values $\mathcal{F}$, which can be depicted as in the global search stage.

$$x_i^{iter+1} = x_i^{iter} + (\mathcal{R}^2 \times \mathcal{F} - x_i^{iter}) \times \mathfrak{FR}_i \tag{11}$$

where $x_i^{iter}$ is the way out vector $x_i$ for ith butterfly in iteration number $iter$. Fragrance of $i$th butterfly is represented by $frag_i$ and $\mathcal{R}$ is a random number which would be in between 0 and 1, also here $\mathcal{R} < P$, where $\mathcal{P}$ is the switching probability. Neighborhood or local search stage can be represented as

$$x_i^{iter+1} = x_i^{iter} + (\mathcal{R}^2 \times x_j^{iter} - x_k^{iter}) \times \mathfrak{FR}_i \tag{12}$$

where $x_j^{iter}$ and $x_k^{iter}$ are $j$th and $k$th butterflies from the search space. On the off chance that $x_k^{iter}$ has a place with a similar swarm and $x_i^{iter+1}$ turns into a neighborhood random walk. Scan for nourishment and mating accomplice by butterflies can happen at both neighborhood and global level and thus $\mathcal{P}$ is utilized as a part of BOA to switch between normal globe searches to concentrate local search.

By researching the scent and separating it from the poor one, the DSCNN-based feature findings contribute in the examination of fragrance in the movement of numerous butterflies and the transmittance of smell to interact to each other and go beyond the optimal butterfly. A butterfly with a little more fragrance and a higher fitness value can attract more butterflies in that region, and a butterfly with plenty of fragrance and sometimes a based on the fitness value can attract more butterflies in that area. Particles in the region can compress their replies by using the parameter $\mathcal{E}$. The $\mathfrak{FR}$ and $\mathcal{I}$ are the main issues to get the variance of $\mathcal{I}$ and formulation of $\mathfrak{FR}$. The values of $\mathcal{I}$ which are encoded with objective function and $\mathfrak{FR}$ is relative which is calculated as

$$\mathfrak{FR} = \mathcal{M} * \mathcal{I}^{\mathcal{E}} \left(1 - \frac{N_{tf} - N_{fs}}{N_{tf}}\right) \tag{13}$$

The accuracy of the DSCNN classifier has been employed as an efficiency analyzer in the creation of objective functions with a large number of features. Where ($N_{tf}$) denotes the overall quantity of features ($tf$), ($N_{fs}$) denotes the dimension of the feature subset ($fs$). The BOA's Sensory Modality $\mathcal{M}$ parameter instructs the butterflies to sense the fragrance

generated from other butterflies within the search region and direct their search to those providing the most scent [23]. Like the value of the $\mathcal{M}$, the parameter is increased, and the algorithm's performance improves throughout execution. As the number of iterations increases, the algorithm's performance improves for the period of the iterative search process. A significant impact on the efficiency of BOA and the performance will be enhanced considerably in comparison to the conventional BOA with Eq. (14), it is analyzed that the new values of $\mathcal{M}$ will have.

$$\mathcal{M}^{iter} = \mathcal{M}^{iter-1} * \frac{\left(10.0 - \frac{5}{0.9}\right)^2}{MaxGen} \tag{14}$$

where $iter$ is the current iteration number and MaxGen is the maximum number of iteration in the algorithm. In this suggested work, the adaptive mechanism of M is designed and used in the algorithm, which adds useful elements to the algorithm's performance and aids in acquiring alternative discoveries in the search space, enabling the BOA approach to achieve better results. The flowchart of MBOA is given in Fig. 3 and the pseudo code of MBOA is clarified in Algorithm 1.

## IV. EXPERIMENTAL RESULTS AND DISCUSSION

The proposed work DSCNN-MBOA classifies the collected features into two class labels: normal and cancerous. The lung X-ray images are generally contained the noise, so, the first step of the work is applying pre-processing techniques to remove unwanted and noisy information for further analysis. After that, these images will be passed via an operation of segmentation in which the cancer region is extracted. Then the segmented image will be the given input of the proposed DSCNN-MBOA for detection of the LC, MBOA used for feature selection and various parameters are then utilized to assess the performance of the proposal such as accuracy, precision, F1-score, execution time, specificity and sensitivity and compare with exiting methods such as VDSNet [22], modified AlexNet [21] and CNN with TL [20].

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} * 100 \tag{15}$$

$$Precision = \frac{TP}{TP+FP} * 100 \tag{16}$$

$$F1\ score = \frac{2*Precision*Recall}{Precision+Recall} \tag{17}$$

$$Specificity = \frac{TN}{TN+FP} * 100 \tag{18}$$

$$Sensitivity = \frac{TP}{TP+FN} * 100 \tag{19}$$

Here, FP described as False Positive, which is the total number of lung images that are presently negative and classified as positive. Where TP described as True Positive, which is the total number of lung images that are currently positive and classified as cancerous, FN described as False Negative, which is the total number of lung images that are presently positive and classified to be harmful as normal. TN described as True Negative, which is the total number of lung images that are currently negative and classified to be negative.

## A. Accuracy Comparison Results

Fig. 4 gives the accuracy of proposed and existing models for the number of features in a shared database. The proposed DSCNN-MBOA increases the accuracy with a value of 98.45%. The reason for this is that the threshold is primarily used to alter the size of the sub training dataset, but it is also utilized for other purposes. The lower the value, the more likely the raw dataset samples are dispersed among the sub training datasets. The incorporation of the MBOA mechanism in the proposed model improves accuracy performance because it increases the convergence speed of DSCNN.

## B. Precision Comparison Results

Fig. 5 indicates the precision of proposed and existing models for the number of features in a given database. As increasing the number of features, the precision is also maximized. E.g., the DSCNN-MBOA attains a precision of 98.5% compared to the VDSNet, modified AlexNet and CNN with TL. Because the DSCNN-MBOA combines feature extraction and classification into a single DSCNN-MBOA structure, it decreases the time necessary to compute the derived factors, resulting in a higher precision rate. DSCNN-MBOA performs best with high-speed converges, which is likely due to a lack of data on the features of the huge images, speeding up convergence time over the entire dataset.

Fig. 4. Accuracy Performance Comparison.

Fig. 5. Precision Performance Comparison.

*1) F1-sore comparison results:* From Fig. 6, it indicates the F1-sore of proposed and existing models for the number of features in given databases. E.g., the DSCNN-MBOA provides an f-measure of 98.85% compared to all other models such as VDSNet, modified AlexNet and CNN with TL. The reason is that the MBOA is effectively optimizing the features with high convergence speed, and thus DSCNN-MBOA has good validation results with a high F1-sore rate. The combined power of CNN, modified AlexNet and attention mechanism prove advantageous in LC detection.

*2) Execution time comparison results:* From Fig. 7, it indicates the execution time of proposed and existing models for the number of features in a given database. As increasing the number of features, the execution time is also maximized. E.g., the DSCNN-MBOA attains a recall of 527.15s compared to the VDSNet, modified AlexNet and CNN with TL. Because the proposed model can reduce more bias in all datasets and reduce minor variance and thus the model is simple to process the LC.

*3) Specificity comparison results:* From Fig. 8, it indicates the recall of proposed and existing models for the number of features in a given database. As increasing the number of features, the recall is also maximized. E.g., the DSCNN-MBOA attains a recall of 89.65% compared to the VDSNet, modified AlexNet and CNN with TL. Because existing methods are simple models that are ineffective for high-dimensional datasets, they are under fitting. EASFMC has the advantage of good segmentation of cancer regions, thus increasing the classification rate of the proposed DSCNN-MBOA. Existing techniques generally perform not well when images are rotated, tilted, or otherwise strangely oriented. As a result, hybrid approaches have improved accuracy while decreasing training time. The study's findings imply that DL models can be utilized to strengthen diagnosis when compared to standard methods.
Fig. 6.    F1-score Performance Comparison.

Fig. 7.    Execution Time Performance Comparison.

Fig. 8.    Specificity Performance Comparison.

*4) Sensitivity comparison results:* From Fig. 9, it gives the accuracy of proposed and existing models for the number of features in a shared database. The DSCNN-MBOA increases the accuracy and attains the sensitivity 95% when compared to VDSNet, modified AlexNet and CNN with TL. Thus the

proposed algorithm is more significant than the existing algorithms for better good validation results for predicting cancer. The proposed DSCNN-MBOA model was utterly independent of the abrupt feature changes. Thus, it could be helpful for LC n X-ray images. As can be seen from the results, the average max pooling is beneficial for the DSCNN model. Better performance can be achieved can reduce the influence of class imbalance on the training process and making the model pay more attention to classes that are difficult to recognize.

Fig. 9.    Sensitivity Performance Comparison.

## V.    CONCLUSION AND FUTURE WORK

On the basis of chest X-ray images, this study presents a hybrid DL (DSCNN-MBOA) based approach for LC identification. In order to improve cancer detection performance, the phases of background segmentation, feature set extraction, feature optimization, and DSCNN-based LC classification are used. The proposed method achieves a precision of 98.45% and a time complexity of 527.15s while maintaining a tradeoff with network performance. In chest X-ray images, the proposed hybrid technique may effectively detect the cancer zone. When working with a large dataset, this research project faces a number of problems. As a result, while small datasets can generate great accuracy, they are impractical for real-world applications. Besides applying improved DL or other innovative TL algorithms for the sample, then combining GoogLeNet, AlexNet, and ResNet-152 architecture to create a hybrid algorithm in the future, this study will combine GoogLeNet, AlexNet, and ResNet-152 architecture to create a hybrid algorithm. The use of image data augmentation techniques such as color space augmentations, feature space augmentations, hyper parameter optimization, and other methods to improve the accuracy of automated chest X-ray diagnosis systems will be explored. In future research, even though the dual dataset method is successful, a more advanced deep learning method will be proposed for lung disease detection. In the first study, more datasets will be collected to increase efficacy. As is common knowledge, deep learning success is strongly influenced by the quantity of labeled data available. So this research will combine hybrid deep neural networks. A study is also planned to develop novel robust optimization based hybrid CNN-based lung segmentation with multiple datasets.

*Abstract*—Face recognition technology is used in biometric security systems to identify a person digitally before granting the access to the system or the data in it. There are many kidnappings or abduction cases happen around us, however, the kidnap suspects will be set free if there is lack of evidence or when the victims are not able to testify in court because they suffer from post-traumatic stress disorder (PTSD). The objectives of this study are, to develop a device that will capture the image of a kidnapper as evidence for future reference and send the captured image to the family of the victim through email, to design a face recognition system to be used in searching kidnap suspects and to determine the best training parameters for the convolution neural network (CNN) layers used by the proposed face recognition system. The accuracy of the proposed system is tested with three different datasets, namely the AT&T database, face database from [23] and a custom face dataset. The results are 87.50%, 92.19% and 95.93% respectively. The overall face recognition accuracy of the proposed system is 98.48%. The best training parameters for the proposed CNN model are kernel size of 5x5, 32 and 64 filters for first and second convolutional layers and learning rate of 0.001.

*Keywords*—*Face recognition system; biometric identification; face detection; image processing; convolutional neural networks*

## I. INTRODUCTION

There are many kidnappings or abduction cases happen around us. The fate of the victim remains unknown until the suspect is found and arrested. In the cases of victims being rescued in time by the authorities, it is likely that the victims who suffer from post-traumatic stress disorder (PTSD) could not recognise or remember the face of the kidnapper during their testimony in court. Therefore, the purpose of this work is to develop a device to capture the image of a kidnapper and reduce the time taken for the authorities to find the suspect.

One of the most widely used technologies in the world today is the facial recognition technology. With the use of facial recognition, a biometric system can identify a person digitally before granting the access to it or the data in it. Complicated and unrealistic biometric security systems are often portrayed by computer graphics in many futuristic movies; however, Apple had taken one step forward and release a face unlock feature for its iPhone X in 2017. This breakthrough uses a sensor to scan the face of the user and saves it as the face ID. The phone can be unlocked when the face of the person unlocking the phone matched with the face ID. The release of this new authentication method has made a big impact in the smartphone industry and all the latest smartphones have started to implement the same face unlock feature in their systems. Facial recognition technology is also used in other systems, for instance, it is used in airport security, law enforcement, attendance systems and to search for a person. This system uses neural network in the development and implementation of face recognition system. Neural network can be trained to process and analyse data, recognise patterns, and make prediction about specific operations. Generally, the programmer needs to provide numerous examples to train neural network, in order for it to learn the patterns [1].

We proposed an idea which combines both hardware and software, where the hardware will capture image of the suspect and the software will perform facial recognition. Our approach allows the hardware to not only capture the image of the suspect but also send the captured image to notify the victim's family that the victim is in danger so that the family can report to the authorities and rescue the victim in a shorter period. The image is then be used as an input to the face recognition system to identify the suspect. The accuracy of the proposed system is 87.50% when tested with the AT&T database, 92.19% with face database from [23] and 95.93% with custom face database. The potential users of the proposed system could be women and children as they are often the target of abduction.

---

*Corresponding Author.

The device can be attached to the users' belongings and the users can press the button to activate the device when they are in danger and their family will be notified in no time. In addition to all this, the best training parameters for the convolutional neural network layers used by the proposed face recognition system will be determined.

The remain of this paper has been organized as follows: Section 2 discusses the related works. The background of the study is described in Section 3. Section 4 described the results and discussion and finally, the conclusion is described in Section 5.

## II. RELATED WORK

In [2], the factors that might affect the accuracy of face recognition systems are classified into two main categories, intrinsic and extrinsic factors. Physical conditions of the human faces are considered as intrinsic factors, for example, aging and facial expressions. Extrinsic factors are made up of partial occlusion, pose variance and illumination. The authors in [3] stated that a useful face recognition system must fulfill the following characteristics: firstly, it must be able to work well with both images and videos, secondly, it must be capable to process in real time, thirdly, it must be robust in illumination variation, fourthly it needs to perform its task without being affected by hair, ethnicity or gender of a person and lastly, it must be able to work with faces detected from all angles. They also stated that a robust face recognition system is made up of three basic steps: face detection, feature extraction and face recognition. There are various techniques that can be used for face recognition, such as Eigenface, Neural Network, Hidden Markov Model (HMM) and Support Vector Machine (SVM).

The Eigenface technique is used in [4] for building face recognition software and the average accuracy for their face recognition software is 85%. Next, a hybrid approach which consists of the Haar Cascades and Eigenface methods that can detect multiple faces in a single detection process is proposed in [5]. The accuracy of this proposed solution was reported to be 91.67%.

Another technique that can be used to develop a face recognition system is called the neural networks. This technique was used in [6] and the average accuracy of the proposed system was 96.84%. The authors in [7] proposed to improve the backpropagation artificial neural network (BP-ANN) for a better performance of the face recognition system. The proposed system yielded a success ratio of 82%. In [8], the researchers used a hybrid approach which includes Elman Neural Network, Curvelet transform and HSI colour space. The resulting accuracy obtained by the authors was 94%. In addition, the authors of [9] proposed an effective method for face recognition that uses Principal Component Analysis (PCA) and models trained with Feed Forward Back Propagation Learning (FFBPL) and Elman Neural Network. The results of FFBPL were 98.33% and 98.80% while the results of Elman Neural Networks were 98.33% and 95.14%.

Next, convolutional neural networks are widely used in research these days, in [10], a real-time face recognition system is built using CNN. The maximum accuracies of the proposed system are 98.75% for standard datasets and 98.00% for real-time inputs. An algorithm for face detection and recognition based on the same concept in [11][12] gives the accuracy of 97.9%. Besides, to develop a face recognition with small dataset, the authors proposed a method that uses a modified deep learning neural network in [13][14]. The accuracy of the proposed system achieved 99.6%. A deep convolutional neural network-based face recognition system that uses transfer learning approach is proposed in [15][16]. The accuracy of the proposed algorithm was 99.06%. In [17], an attendance system with face recognition based on deep learning technique. The overall accuracy obtained by the proposed system in a real-time environment was 95.02%. Similarly, an intelligent face recognizing attendance system that can identify several people simultaneously that is built based on CNN is proposed in [18]. The proposed system was tested with frontal view, side view and downwards view. The accuracies obtained for these three conditions were 81.25%, 75.00% and 43.75% respectively. A multi-face recognition system is proposed by the researchers in [19][20] to detect the prisoners in jail and the accuracy was 87%. Next, the researchers proposed a face recognition using a CNN model in [21][22]. The highest accuracy achieved by the proposed system was 98.3%. The authors in [23] proposed a deep CNN based face recognition system that can identify an individual in all possible conditions that might affect the accuracy of the face recognition system. The accuracies of the proposed system were 99.7% and 94.02% respectively. The authors of [24] proposed a home security system that uses face recognition technology developed by CNN. The Raspberry Pi was used as a microcontroller so that when the face of the homeowner was detected, the door will be unlocked automatically. The proposed system was able to achieve 97.5% accuracy.

A combination of 2D Hidden Markov Model (2DHMM) and Expectation-Maximalization (EM) algorithm is used in the face recognition system in [25] and its recognition rate was 99%. Besides that, in [26], two-dimensional Hidden Markov Models was used for face recognition. The recognition rates for 2D images were 93% and 95%. Next, the recognition rates for 3D images achieved 94% for both UMB-DB and FRGC databases. Lastly, the recognition rate for 2D+3D images was 96% for both databases.

By using wavelet Gabor filter and SVM, the authors in [27] have successfully built a 3D facial recognition system. The highest accuracy that the proposed system achieved was 97.3%. The authors in [28] proposed a face recognition that uses SVM with implementation of kernel as the classification method to identify lookalike faces. Two types of kernels were used in the proposed system, namely, the Radial Basis Function kernel and the polynomial kernel. The accuracy for both kernels is 94%.

## III. BACKGROUND OF THE STUDY

This system two uses publicly available face databases, namely AT&T database and a database provided by the author of [29]. Besides, a hardware device is used to capture the image of the kidnapper, the image will be used as input to the face recognition system, therefore a custom face dataset needs to be created to test the accuracy of the proposed system. The components used for the hardware are the ESP32-CAM, FTDI

adapter and push button. The block diagram of the ESP32-CAM is shown in Fig. 1. The hardware is programmed using Arduino IDE while the face recognition system is built in MATLAB.

Fig. 1.   ESP32-CAM Block Diagram.

The proposed system is developed according to the flowcharts shown in Fig. 2 to Fig. 4. Fig. 2 shows the flowchart of creating a custom face dataset. A custom face dataset is created because an ESP32-cam will be used to capture images of people, it is certain that during the testing process, the face captured by the device is not in the pre-curated face databases, such as the AT&T Database that contains a total of 400 images of 40 individuals. Hence, in order to yield higher accuracy, other than using the publicly available face dataset, we decided to create a custom face dataset for the system. After creating a face dataset, the face recognition system can be trained. The images in the face dataset created manually will be separated into two folders, one for testing purpose and another for training purpose. The same image cannot exist in both folders, in other words, all images of each individual in both folders must be different in terms of postures, lighting condition, facial expressions. The proposed system will be trained and tested with the images available before testing with the image captured directly from the ESP32-CAM.

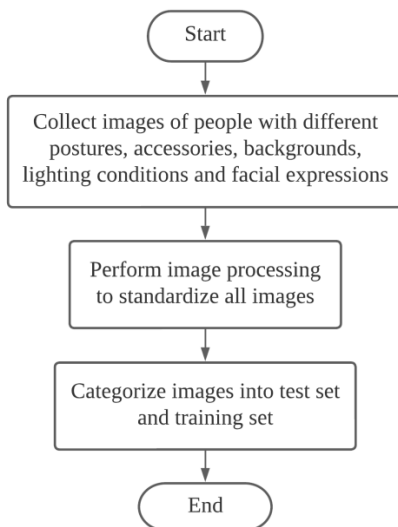

Fig. 2.   Flowchart of Creating a Custom Face Dataset.

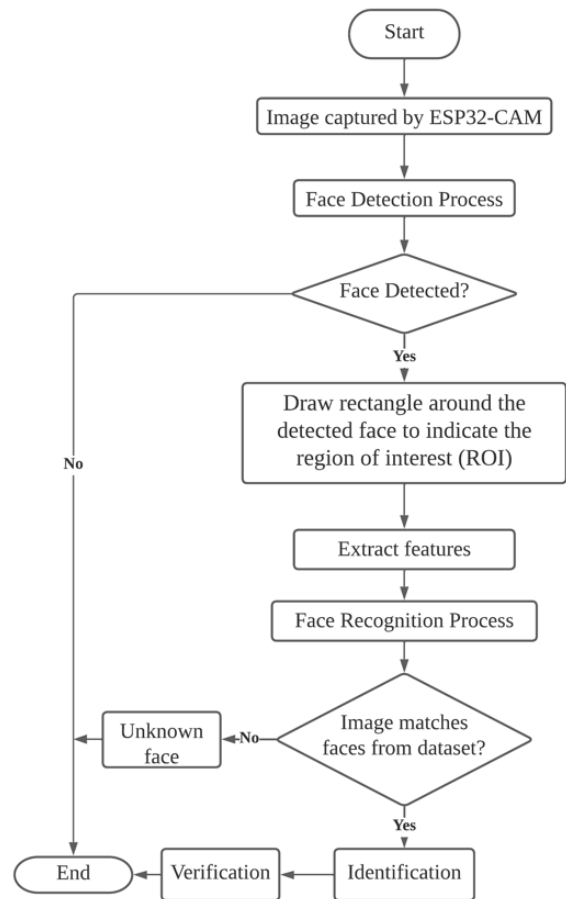

Fig. 3.   Face Recognition System Programming Flowchart.

Fig. 3 shows the programming flowchart of the ESP32-CAM using Arduino IDE. The initialization process includes assigning the SSID and password to the device so that it can connect to the Wi-Fi or mobile hotspot and setting up the email account that will be receiving the captured image. Initially, the device will be in deep sleep mode and when it is triggered by a button, it will wake from the deep sleep mode to perform its function, which is capturing images. After an image is captured, the image will be sent to the assigned email account through SMTP server. After sending the email successfully, the device will go back to deep sleep mode again.

Fig. 4 shows the programming flowchart of the proposed face recognition system. Firstly, the image captured by the ESP32-CAM must be downloaded from the email account before it can go through the face detection process. In face detection process, if the program detected a face, it would draw a rectangle around the face to mark it as a region of interest (ROI) so that the program can omit other unwanted parts to focus on features extraction. After extracting the facial features, the program will perform the face recognition process which uses the Neural Network as foundation. When the captured image matches the faces from dataset, the system will identify and verify the identity of the person being captured in the image. If the image does not match any of the faces from the dataset, it is an unknown face to the system and the program will terminate.

Fig. 4.   ESP32-CAM Programming Flowchart.

Fig. 5 shows the circuit connection between ESP32-CAM, FTDI Adapter and an external push button. A jumper wire is connected from GPIO 0 to GND for programming purpose and can be removed once the programming is finished. The push button is used to wake the ESP32-CAM from deep sleep mode and it is connected to the GPIO 13 pin. The TX pin of ESP32-CAM is connected to the RX pin of the FTDI Programmer and the RX pin of ESP32-CAM is connected to the TX pin of the FTDI Programmer so that data can be exchanged between these two devices in serial communication.

Fig. 5.   Circuit Design.

## IV.  RESULTS AND DISCUSSION

A good face recognition system must fulfill several criteria; the most important is the accuracy of the result. Face recognition systems are widely used in law enforcement, a slightly inaccurate result might cause an innocent person being wanted and wrongly accused of crime that he or she did not commit. To test the functionality of a face recognition system, face datasets are used. There are many different face datasets available publicly such as LFW, Yale and AT&T databases. This system uses AT&T databases and a custom face dataset. This section explains the development of a face recognition system and the combination of the system with some hardware that will be discussed in the following section.

### A.  Hardware Implementation

The hardware device is configured so that when the external button is pressed, the ESP32-CAM will take a picture, connect to the internet and send the picture to an assigned email address. Fig. 6 shows the image taken by the ESP32-CAM being sent to the assigned email address.

Fig. 6.   Image Taken by the ESP32-CAM Sent to an Assigned Email Address.

### B.  Training Parameters for the Proposed System

The researcher carried out an experiment to find out the values of the parameters that will give the CNN model the best accuracy in face recognition. The parameters chosen are the kernel size, the number of filters for convolutional layers and the learning rate.

Fig. 7 shows the validation accuracy and average elapsed training time of the CNN model. For easier understanding, the four values of the x-axis from the graph will be referred as set

A, B, C and D in the following discussion. From the graph, it can be concluded that in general, the validation accuracy for learning rate of 0.03 is the lowest compared to other learning rates, except for set B because the learning rate that gives the lowest validation accuracy for set B is 0.001. Thus, learning rate of 0.03 is the first to be eliminated.

Next, the total time elapsed for training range between 4 minutes and 9 minutes. The CNN model that uses the shortest average training time is set A while the longest is set D. Set C has the second shortest average training time, and compared to set A, the validation accuracy of set C is higher in overall. The aim is to find the value that will give the highest accuracy without compromising the training speed, set C meets the requirements, and from all the learning rates in set C, 0.001 gives the highest accuracy, 90.48%. Therefore, the parameters that will be used for training the CNN model are, kernel size of 5x5, 32 filters on the first convolutional layer and 64 filters on the second convolutional layer and learning rate of 0.001.

Fig. 7.   Validation Accuracy and Average Training Time of the CNN Model with different Training Parameters.

TABLE I.        LAYERS OF THE PROPOSED CNN MODEL

| Layer | Type | Activations | Learnable |
|---|---|---|---|
| 1 | Input | 112 x 92 x 1 | - |
| 2 | Convolution | 112 x 92 x 32 | Weights 5 x 5 x 1 x 32<br>Bias 1 x 1 x 32 |
| 3 | Batch Normalization | 112 x 92 x 32 | Offset 1 x 1 x 32<br>Scale 1 x 1 x 32 |
| 4 | ReLU | 112 x 92 x 32 | - |
| 5 | Max Pooling | 56 x 46 x32 | - |
| 6 | Convolution | 56 x 46 x 64 | Weights 5 x 5 x 32 x64<br>Bias 1 x 1 x 64 |
| 7 | Batch Normalization | 56 x 46 x 64 | Offset 1 x 1 x 64<br>Scale 1 x 1 x 64 |
| 8 | ReLU | 56 x 46 x 64 | - |
| 9 | Max Pooling | 28 x 23 x 64 | - |
| 10 | Fully Connected | 1 x 1 x 57 | Weights 57 x 41216<br>Bias 57 x 1 |
| 11 | Softmax | 1 x 1 x 57 | - |
| 12 | Classification Output | 1 x 1 x 57 | - |

Table I shows the CNN structure made up of 12 layers, which are the input layers, two convolutional layers, two batch normalization layers, two ReLU layers, two pooling layers, a fully connected layer, a Softmax layer and an output layer.

*C. Software Implementation*

Face detection is the first task to be done by a face recognition system after getting the input image. The proposed system uses the built-in cascade object detector for face detection. This detector uses Viola-Jones algorithm and it can be called by the vision.CascadeObjectDetector function. By default, the classification model of this function detects upright face that is facing forward, the classifiers used in this model are the weak classifiers based on classification and regression tree analysis (CART). There is another classification model that detects the same object but with classifiers which use local binary patterns (LBP) for facial features encoding. The difference between CART and LBP based classifiers is, the classification model that uses CART has the ability to model higher-order dependencies between facial features while the classification model that uses LBP is more robust to variation in illumination. There are others classification models to detect upper body, eyes, mouth and nose. Since the proposed system focuses on the face area, therefore the default classification model is used.

Next, to test the accuracy of the proposed face recognition system, folders of testing images which are not seen by the trained model were created. Fig. 8 shows some of the face recognition outcomes of the proposed system. The results obtained for testing the proposed system with three different face databases are recorded in Table II to Table IV while the comparison of the results is shown in Table V.

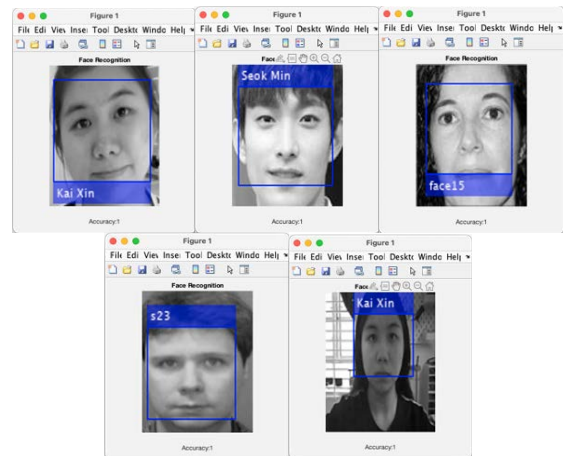

Fig. 8.   Face Recognition Outcomes of the Proposed System.

The results of the proposed system are classified into three groups, the true positive (TP), false negative (FN) and false positive (FP). The result is a TP when the predicted identity matches the actual identity. FP happens when the system predicted person A but the actual identity is person B, or in other words, the input image is the face of person B but the output result returns person A. Lastly, the FN result is caused by failure in detecting and recognising faces that are known by the system, that is, when the input image is person A which is known by the system, the proposed system failed to detect and

recognise the face of the person and return the face recognition result as "Unknown".

The face recognition accuracy is calculated by the following formula.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{1}$$

There are two classes in the custom face dataset, Class 1 is made up of images of celebrity while Class 2 is made up of the images of one of the authors. From Table II, Class 1 is tested by 20 images and the accuracy is 100%. On the other hand, the proposed system is able to recognise 239 out of 250 testing images correctly from Class 2, the accuracy is 95.60%. There are four FN results, and these might be caused by the low image resolution as the images are taken by a 2-megapixel ESP32-CAM. The average accuracy of the proposed system when tested with custom face dataset is 95.93%.

The proposed software system is also tested with two different pre-curated face databases that are publicly available. Table III shows the face recognition result when the system is tested with the dataset from reference [23]. The dataset is made up of 16 classes and the proposed system is tested by four images of each class. There are 59 TP and 5 FN results, yielding an average accuracy of 92.19%. Lastly, Table IV shows the face recognition result of AT&T database with total of 40 classes. The proposed system was tested with two images of each class and successfully recognized 70 out of 80 images. The average accuracy is 87.50%.

TABLE II.        FACE RECOGNITION RESULT OF CUSTOM FACE DATASET

| Class | Testing Images | TP | FN | FP | Accuracy |
|---|---|---|---|---|---|
| 1 | 20 | 20 | 0 | 0 | 100.00% |

| Total | | 70 | 10 | 0 | - |
| Average Accuracy | | | | | 87.50% |

TABLE V. COMPARISON BETWEEN THE FACE RECOGNITION ACCURACY OF DIFFERENT FACE DATABASES

| Face Database | Total Training Images | Total Testing Images | Accuracy |
|---|---|---|---|
| AT&T | 320 | 80 | 87.50% |
| Dataset from reference [23] | 244 | 64 | 92.19% |
| Custom face dataset | 1250 | 250 | 95.93% |

From Table V, the face recognition result for the images from the custom dataset is the highest, with the accuracy of 95.93%, while face recognition result using AT&T database is the lowest, with 87.50%. The accuracy of the face recognition for the custom face dataset is the highest because the two other face databases were trained with less than 20 images for a subject while the custom face dataset created by the researcher has 90 training images for the first class and 1160 for the second class. This is to ensure the result for images taken by the ESP32-CAM to have a higher accuracy. Therefore, with the face recognition result, it can be concluded that the goal is achieved. In short, the overall accuracy of the proposed system is 98.48%.

Furthermore, an experiment is carried out to find out the maximum distance between the camera and the face so that the face can be detected and recognised by the proposed system. The ESP32-CAM is placed at a certain distance from the face and five images are taken for each distance. The effect of distance between face and the ESP32-CAM on face detection rate and face recognition accuracy is recorded in Table VI. The results show that when the distance is beyond 200 cm, the face cannot be detected by the proposed system and the face recognition process cannot be carried out. This limitation could be overcome in future research by using a higher resolution camera module.

Table VII shows the accuracies of different face recognition systems that use custom face dataset. The proposed system is made up of hardware to capture the image of a kidnap suspect and software to identify the kidnap suspect, therefore a custom face dataset is created to test the functionality of the whole system. The accuracy of the proposed system is higher than the previous studies shown in Table VII.

TABLE VI. EFFECT OF DISTANCE BETWEEN THE FACE AND THE ESP32-CAM ON FACE DETECTION RATE AND FACE RECOGNITION ACCURACY

| Distance (cm) | Testing Images | Images with detected face | Face detection success rate | Face recognition Accuracy |
|---|---|---|---|---|
| 30 | 5 | 5 | 100.00% | 100.00% |
| 40 | 5 | 5 | 100.00% | 100.00% |
| 50 | 5 | 5 | 100.00% | 100.00% |
| 60 | 5 | 5 | 100.00% | 100.00% |
| 70 | 5 | 5 | 100.00% | 100.00% |
| 80 | 5 | 5 | 100.00% | 100.00% |
| 90 | 5 | 5 | 100.00% | 100.00% |
| 100 | 5 | 5 | 100.00% | 100.00% |
| 110 | 5 | 5 | 100.00% | 100.00% |
| 200 | 5 | 5 | 100.00% | 100.00% |
| 300 | 5 | 0 | 0% | 0% |

TABLE VII. ACCURACY OF FACE RECOGNITION SYSTEMS WITH CUSTOM FACE DATASET

| Method | Accuracy |
|---|---|
| Eigenface [3] | 85.00% |
| BPANN [6] | 82.00% |
| ENN, Curvelet transform, HSI Colour Space [7] | 94.00% |
| Deep learning [13] | 95.02% |
| Deep CNN [14] | 81.25% (Frontal view) 75.00% (Side view) 43.75% (Downwards) view |
| CNN [15] | 87.00% |
| Proposed method | 95.93% |

## V. CONCLUSION

This article presents the development and implementation of face recognition system using neural networks. The proposed system is made up of a hardware that can capture a picture and send it to an assigned email; and a software built in MATLAB for face recognition process. The findings of this research suggested that the best training parameters for the proposed system are kernel size of 5x5, number of filters of 32 for first convolutional layer, number of filters of 64 for second convolutional layer and initial learning rate of 0.001. The proposed system is robust as its overall face recognition accuracy is 98.48%. The limitation of the system is when the distance between face and ESP32-CAM is beyond 200 cm, face detection and recognition process cannot be carried out. The recommendations for future research include, using a higher resolution camera module, larger custom face dataset and hybrid approach of face recognition techniques that can increase the face recognition accuracy of the system.

*Abstract*—Medical Resonance Imaging (MRI) is non-radioactive-based medical imaging that provides a super-resolution of tissues. However, because of its complex nature using existing Deep Learning-based noise removal (i.e., Denoising) techniques, the reconstruction quality is poor and time-consuming. An extensive study shows very limited work has been done on Brain Multiple Sclerosis (MS) Lesions MRI. Designing an efficient noise removal technique will aid in improving MRI quality; thereby will aid in achieving better segmentation classification performance. In reducing computing time and enhancing image quality (i.e. reduce noise) this paper presents the Sparse Feature Aware Noise Removal (SFANR) technique for Brain MRI using Convolution Neural Network (CNN) architecture. A sparse-aware feature is incorporated into the patch-wise morphology learning model for removing noise in large-scale MRI MS lesion datasets. Experimental results demonstrated that our model SFANR outperforms all other state-of-art noise removal techniques in terms of Peak-Signal-Noise-Ratio (PSNR), Structural Similarity Index Metric (SSIM) with less running time.

## I. INTRODUCTION

With the advancement in sensor and computer technologies, medical imaging such as MRI, Positron Emission Tomography (PET), and Computed Tomography (CT) plays a very significant part in diverse diagnostic applications such as treating a serious ailment, radiosurgery, clinical diagnosis [1]. This MRI is used to obtain detailed information on soft tissues, and CT is used to obtain information on implants and bones. This work focuses on Multiple Sclerosis (MS) Lesion brain MRI data. Generally, the multi-contrast MRI provides the radiologists with additional information for studying different pathologies. In [1] demonstrated that for reducing time and redundancy, multi-echo saturation recovery MRI sequences are obtained at different inversion times and echo times to reconstruct a single MRI sequence [1]. Further, different parameter-map (PM) and parameter weighted (PW) contrasts can altogether be reconstructed. The state-of-art reconstruction methodologies employ pixel-wise least-square fitting of motion of macroscopic nuclear magnetization equation for obtaining relaxation parameter (i.e., by summing up all nuclear magnetic moment). Later, the PW contrasts are reconstructed through

PMs. However, due to patient motion, over-simplified models, non-linear fitting operations, flow, and partial volume significantly impact the quality of MS lesion brain MRI reconstruction [2]. In particular, the T2-FLAIR (T2-weighted fluid-attenuated inversion recovery) MS lesion brain MRI, low SNR (Signal-to-Noise-Ratio), chemical shift artifacts, and edge-enhancement are seen [3].

The CNNs-based model has attained very good results in medical imaging, especially for CT and MRI. In improving the quality of the image cross-modality between MR/PET [4], [5] and MR/CT [6] has been emphasized. Further, CNN is applied for MRI contrast enchantment. In [7], [8] contrast of T2-weighted MRI is improved using T2-weighted MRI, similarly, in [9] using T1-weighted and T2-weighted the FLAIR MRI is generated, and in [10] using 3T inputs construct 7T high-resolution MRI. All the above-mentioned methods use an encoder-decoder framework using Deep learning Techniques such as ResNets [11] and U-net [12].

In [13] for representing neighborhood features introduced localized network. In [14] the author enhances the texture of the image employed generative adversarial network (GAN). Further, in increasing the sharpness the author in [8] introduced an edge similarity loss function into the generative adversarial network. In [15] reduced the scanning time by combining contrast and under-sampling reconstruction. Additionally, [16] introduce feature structure to resolve unknown contrast problem during image reconstruction [17]. In [18] presented a new noise removal technique through multi-task deep GAN; However, poor correlation among different layers impacts the quality of the feature constructed. In addressing [1] designed an ensemble convolution neural network [19] to obtain high-quality feature sets [20], [21]. However, weights of a convolutional network [22] are updated individually for the entire MRI information; thus, the final reconstructed image exhibit higher noise, poor contrast, and limited sparse feature representation. In [23] addressed the above issues by employing morphology-based [24] feature construction using CNN. The model is efficient in eliminating noise with very good reconstruction quality; however, there exist optimization constraints in obtaining good quality sparse features.

In addressing the research problem, this paper presents sparse feature-aware noise removal technique for MS lesion MRI data. The patch-wise CNN framework can extract features in a parallel manner aiding in reducing training overheads.

Further, the SFANR model can remove different types of noise such as Rician, Gaussian, and Speckle more efficiently through the adoption of the morphological-based feature construction mechanism adopted in SFANR. The proposed noise removal technique helps in reducing redundant features and computation overheads; thus, significantly SFANR improves PSNR and SSIM.

The significance of SFANR is described below:

- The work presented a CNN-based noise removal technique using sparsity-aware morphological features.

- No prior work has considered denoising the brain MS lesions MRI.

- The SFANR achieves much higher PSNR and SSIM in comparison with existing denoising methodologies.

- The model achieves very less running time in comparison with other noise removal methodologies.

The rest of the manuscript is arranged as described. In Section II, the literature survey is discussed. In Section III, the proposed sparse feature aware noise removal technique for MS lesion Brain MRI is presented. In Section IV, the outcome i.e., MS lesion brain MRI reconstruction quality achieved using proposed SFANR and existing noise removal models is studied. In Section V, the significance of SFANR is concluded and future enhancement of the SFANR model is given.

## II. LITERATURE SURVEY

This section presents a survey of various noise removal techniques presented in recent times for brain MS lesions MRI. In [1], the author presented a fully-connected CNN-based denoising method by optimizing the loss layer. The three-dimensional CNN and residual network are merged for extracting multi-dimensional features. Finally, ensemble feature extraction along two models constructed by varying noise levels. The model is efficient in eliminating Gaussian-like noise.

In [17], the author designed a deep learning model through multi-task learning for extracting association among spatial and relaxation features. The model utilizes association mapping among different T2-weighted MRI with varying contrast for enhancing the reconstruction quality such as low SNR (Signal-to-Noise-Ratio), chemical shift artifacts, and edge-enhancement are seen [3] as shown in Fig. 1. Similarly, [18] designed a denoising model using GAN by extracting features from Multi-Contrast MRI.

In [20], the author designed a denoising method using end-to-end residual CNN. The image is reconstructed using a loss function employing mean square error to optimize the feature extraction process. In [21] an autonomous CNN-based model has been employed for removing noise in Diffusion tensor MRI data. The model denoising accuracies are not dependent on high SNR MRI input. Similarly, [22] presented a new noise removal technique that works with a single-subject dataset encompassing with low-noise of voxel-by-voxel Diffusion tensor MRI sequence by employing one-dimensional CNN and deep learning models.

Fig. 1. Low-quality Reconstruction Outcome Obtained using Standard Noise Removal Technique (a): T1-FLAIR (b): T2-FLAIR (c): T1-weighted [1].

In [23] a denoising model is presented to remove Rician noise from MRI using a sparse dictionary learning mechanism. The dictionary is constructed leveraging Maximum posterior combined using noisy MRI. Similarly, [24] used morphological features to address the impact of noise due to non-uniform illumination. Further, employed principal component analysis retains detailed features such as textures, smooth edges, etc. during RGB to grey conversion. The extracted features are trained using CNN. However, poor feature correlation during training significantly impacts noise removal accuracies.

An extensive survey shows exploiting sparse features and morphology construction, and CNN aided in improving noise removal performance; however, existing models are not efficient in adaptively removing different noises such as speckle, Rician, and Gaussian. In addressing the limitation in the next section, a novel methodology namely the sparse feature aware noise removal technique has been presented.

## III. PROPOSED METHODOLOGY

The proposed methodology for efficiently removing noise from brain MS lesions MRI is given. The proposed methodology employs a convolution neural network for eliminating noise in brain MS lesions MRI. A sparse feature-aware noise removal technique using CNNs improve the quality of MS lesion MRI data. The proposed methodology is composed of three stages morphology construction stage, aggregating sparsity-aware features into the patch-wise morphology stage, and validating the quality of image reconstructed image. First, in the morphological construction stage, a different sparsity feature-aware layer is created by sub-dividing the input MRI (i.e., each MRI is segmented into multiple patches; then, those patches are given as input to the SFANR-CNN model). The outcome i.e., sparse feature weight variance among different layers is used during the training process for the construction of morphology structure. In the subsequent stage, the sparsity-aware feature is used for the creation of morphology, and the information is trained with CNN and later used during the testing stage for removing noise

from MS lesion MRI data; thus, aiding in improving the quality of reconstructed MS lesion MRI images. In our work, the quality of noise removal technique is validated using Peak-Signal-to-Noise-Ratio (PSNR) and Structural Similarity Index Metric (SSIM). A significant amount of work has been done for removing noise in MRI datasets. Nonetheless, the standard noise removal methodologies exhibit poor performance due to issues like large dataset size, time consumption, high slew rate, large power absorption, and temporal dimension. The aforementioned issues are addressed through the construction of sparsity feature-aware CNN architecture using patch-wise morphological learning for designing an effective noise removal model with good processing efficiency.

### A. Convolution Neural Network

The CNN is widely used for removing noise from MRI and CT [19], [20]. The CNN-based noise removal techniques [21], [22], provide an effective way of eliminating a different kind of noise [23] from MRI and improving its reconstruction quality [24], [25], and enhancing segmentation [26], [27] and classification outcomes as well [28], [29]. The CNN employs a hierarchical learning mechanism where a feed-forward network is used for the extraction of different features and a hidden layer is used to optimize the feature learning weights. However, in this work sparsity-aware feature using CNN is modeled as shown in Fig. 2 shows removing noise from brain MS lesion MRI data. The proposed SFANR-CNN adopts a patch-wise morphological learning mechanism using prior information; thus, is very fast and efficient in removing a different kind of noise present in brain MS lesion MRI.

### B. Noise Removal Framework

This section presents a framework for removing noise from brain MS lesion MRI as shown in Fig. 2. Initially, the brain MS lesion MRIs are segmented into different patches. Later, the segmented brain MS lesion MRI is given as input to SFANR-CNN for extraction of sparsity-aware features. The sparsity-aware feature weights are optimized during the training process for the construction of morphology. Later, during the testing process, the constructed morphology is used for removing noise from brain MS lesion MRI. The quality of reconstructed brain MS lesion MRI using SFANR-CNN is measured in terms of PSNR and SSIM.

### C. Patch-wise Learning Model

Patch-wise morphological learning technique is presented for eliminating noise from MS lesion MRI data. Let noise $k$ be aggregated to the input brain MS lesion MRI patch signal $i$,

$$\mathbb{Y} = i + k, \tag{1}$$

where the value of parameter $k$ is generally set in the range of 8 and 12. Here, the patch-wise noise removal method is established considering the patch size of $m \times m$. The noise in MS lesion MRI data is individually removed from all the patches, and later MRI is reconstructed through the integration of entire patches within a frame; later, using the averaging function, the overlapped patches are optimized. In this work, the size of Morphology $\mathbb{D}$ is set to $m^2 \times n$ where $n$ is greater than $m^2$.

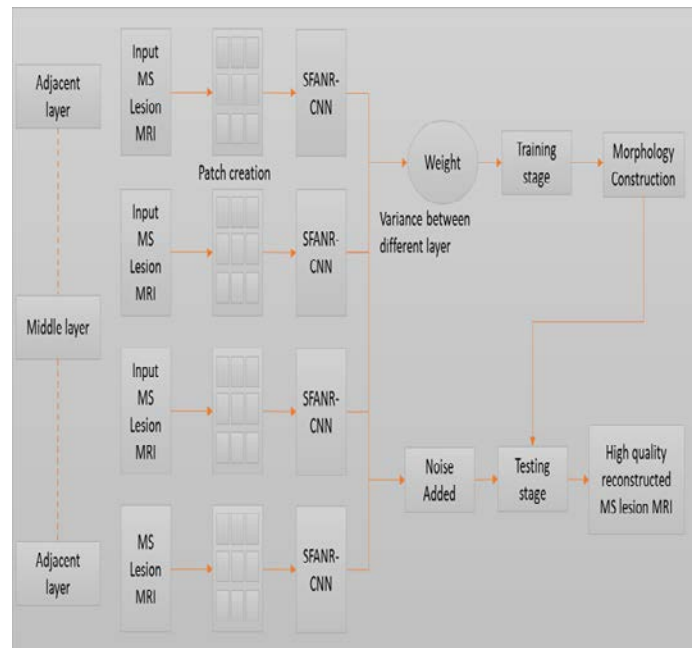

Fig. 2. Architecture of Sparse Feature aware Noise Removal (SFANR) Technique.

### D. Sparse Feature Aware Patch-wise Learning Model

In a patch-wise morphology construction-based noise removal mechanism the atomic element [28] is used as the basis function. A sparsity-aware linear noise removal mechanism is used to remove the noise within entire patches constructed from brain MS lesion MRI data. The additive white Gaussian noise error is minimized through the following mathematical representation.

$$\min\|\alpha\|_0 \; s.t. \|\mathbb{D}_\alpha - \mathbb{Y}\|_2 \leq \in, \tag{2}$$

where $\mathbb{Y}$ represents brain MS lesion MRI patch with the presence of noise, $l_0$ defines a pseudo normalization parameter that is used for estimating $\|\cdot\|$, and $\in$ defines pre-defined. Using $l_0$ the sparsity-aware feature can be optimized at the cost of convex normalization problem. The parameter $\in$ is optimized for approximating the normalization error $\|\mathbb{D}_\alpha - \mathbb{Y}\|_2$ through its variance. Then, using a sliding window the quality of denoised brain MS lesion MRI can be enhanced; similarly, the optimization of overlapping patches is done by employing averaging function as defined.

$$\mathbb{D} \leftarrow \eta \triangle \frac{\triangle \|i - \mathbb{D}_\alpha\|_2}{\triangle \mathbb{D}}, \tag{3}$$

where $\eta$ defines a parameter of the sliding window. Using the below equation the minimization of overlapping patches is done.

$$\min\|i - \mathbb{D}_\alpha\|_2 \; s.t. -1 \leq \alpha \leq 1, \tag{4}$$

Here, we evaluate the pixel mean of different patch sizes of $m \times k$, where $m$ and $k$ are hyper-parameters and $\bar{i}$ denotes local mean estimates for an image.

$$\bar{i} = \mathbb{F}\{i\} = \mathbb{F}\{\mathbb{Y} - k\} = \mathbb{F}\{\mathbb{Y}\} - \mathbb{F}\{k\} = \mathbb{F}\{\mathbb{Y}\} = \overline{\mathbb{Y}}, \tag{5}$$

where $\mathbb{F}$ is function to obtain pixel mean $\overline{\mathbb{Y}}_{,}$. We estimate that the actual input image is corrupted using Rician, Speckle, and Additive White Gaussian noise and which can be described using equation (6).

$$\log q(\mathbb{Y}|i) = \frac{1}{2\sigma^2}\sum_{r,n}(\mathbb{Y}_{r,n} - i_{r,n})^2, \qquad (6)$$

Here, the indexes $r$ and $n$ represent all positions of an MS lesion MRI data.

$$\min_\beta \mathcal{P} = \mathbb{F}\left\{\left(i - \bar{i} - \beta(\mathbb{Y} - \bar{i})\right)\right\}, \qquad (7)$$

where $\beta$ is a decision factor that defines if $\beta$ is close to 1 then the MS lesion MRI data will be noisy type $\mathbb{Y}$ and if $\beta$ is near to 0 then it is the de-noised image $\bar{i}$. Equation (7) demonstrates the minimization of squared error.

Patch-wise morphology learning is constructed encompassing distinctive sparse-aware features for both noiseless and noisy brain MS lesion MRI datasets. The patch-wise morphology learning methodology is very efficient in solving the complexity of optimization of sparsity feature construction; thus, improving brain MS lesion MRI reconstruction outcomes. The morphology construction is extremely fast which takes about 20% time and reaming time it takes for training the model for removing noise from brain MS lesion MRI. No heuristic knowledge is required for the construction of morphology; thus, one can learn sparse feature-based morphologies more adaptively. The constructed morphology is later used during the testing process to obtain a very good denoised brain MS lesion MRI.

### E. Training Patch-wise Learning Model for Removing Noise in MRI

Designing an efficient training model aid in detecting a different kind of noise and improves the brain MS lesion MRI reconstruction quality. However, the brain MS lesion MRI is extremely large and complex; thus, is time-consuming for performing the training process. In this work, the training time is reduced by adopting parallel execution of patch-wise morphology construction. The parameter selection for training is set as a random process where parameter estimation is carried out considering different patches and noise types. The small normalization vectors can be optimized easily where the regularization parameter is optimized using pre-training. Using CNN variance among different layers to optimize weight and morphology is constructed. The training efficiency for removing noise from brain MS lesion MRI is measured using PSNR and SSIM.

### F. The Testing Patch-wise Learning Model for Removing Noise in MRI

In the testing for removing noise from brain MS lesion MRI in this work the noise is detected patch-wise. Further, in avoiding the over-fitting problem the patch-wide weight variance is minimized. The morphology constructed during the training stage is used during the testing process for reducing noise in brain MS lesion MRI.

$$\hat{i} = \bar{i} + \frac{(\mathbb{F}\{(\mathbb{Y}-\mathbb{Y})^2\}-\sigma^2)(\mathbb{Y}-\bar{i})}{\mathbb{F}\{(\mathbb{Y}-\overline{\mathbb{Y}})^2\}}, \qquad (8)$$

where $\sigma$ defines the level of noise present in brain MS lesion MRI and the Eq. (8) defines noise removed MS lesion dataset mathematical representation. The testing process encompasses the estimation of $\bar{i}$ and $\mathbb{F}\left\{(\mathbb{Y}-\overline{\mathbb{Y}})^2\right\}$. The effectiveness of estimation of $\bar{i}$ is enhanced through reduction of noise from brain MS lesion MRI using patch-wise morphology information with a patch size of $m \times k$. The model aids in minimizing sparse error and overhead reduction. The improved probability distribution function using logarithm for removing noise in brain MS lesion MRI is given as.

$$i^{(t+1)} = i^{(t)} + \eta\left[\sum_{r=1}^{K} N_r^- * \psi_r\left(N_r * i^{(t)}\right) + \frac{\lambda}{\sigma^2}\left(\mathbb{Y} - i^{(t)}\right)\right] \quad (9)$$

where $\eta$ defines step size estimation, convolution is defined by $*$ sign, and $N_r^-$ describes the central pixel. To bring trade-off among likelihood and prior $\lambda$ is used. The outcome of $\lambda$ depends according to the presence of noise level $\sigma$. The experiment conducted in the next section shows the proposed SFANR-CNN is effective in removing a different kind of noise and enhancing the quality of brain MS lesion MRI in terms of PSNR and SSIM.

## IV. SIMULATION ANALYSIS AND RESULTS

This section studies the performance efficiency of the proposed SFANR technique and existing noise removal techniques [1], [17]. This work uses brain MS lesion MRI data used in [30] which is very similar to brain MRI used [1], [17]. In this work noise such as Speckle, Gaussian, and Rician is added to the brain MS lesion MRI. The performance of different noise removal techniques is measured in terms of PSNR and SSIM. The PSNR and SSIM are computed using the equation defined in [1]. The experiment is conducted on Windows 10 operating system running an I-5 quad-core processor with 16 GB RAM equipped with a dedicated 4GB CUDA GPU. Fig. 3 shows the input, MRI with noise, and reconstructed MS lesion brain MRI using the SFANR technique.

The graphical representation of PSNR is shown in Fig. 4. The graphical representation of SSIM is shown in Fig. 5. A higher value indicates better performance; thus, the SFANR achieves much better outcomes than existing methods, namely, a U-NET [1], Multi-Task Deep Learning (MTDL) [1], Deep Parallel Ensemble Denoising (DPED) [17]. Thus, are very efficient in removing Gaussian, Speckle, and Rician noise from MS lesion MRI.

The Table I shows the computation outcome achieved using proposed SFANR over existing noise removal methods such as DPED [1], Morphology learning CNN (ML-CNN) [24], and noise removal using dictionary learning (NRDL) [1]. The SFANR achieves much lesser running time than other existing methodologies; thus, are very efficient.

The Table II shows the SSIM and PSNR performance achieved using SFANR considering different noise. No prior work has considered such evaluation.

Original MS lesion MRI    Noise added MS Lesion MRI    Noise Removed MS lesion MRI
Fig. 3. The Outcome was achieved using the SFANR-CNN Model.

Fig. 4. PSNR achieved using SFANR-CNN and other Noise Removal Technique.

TABLE I. COMPUTATION TIME STUDY

| Methodology | Running time (seconds) |
|---|---|
| NRDL [23], 2019 | 143.97 |
| DPED [1] 2021 | 3.11 |
| ML-CNN [24], 2022 | 11.3 |
| SFANR | 2.98 |

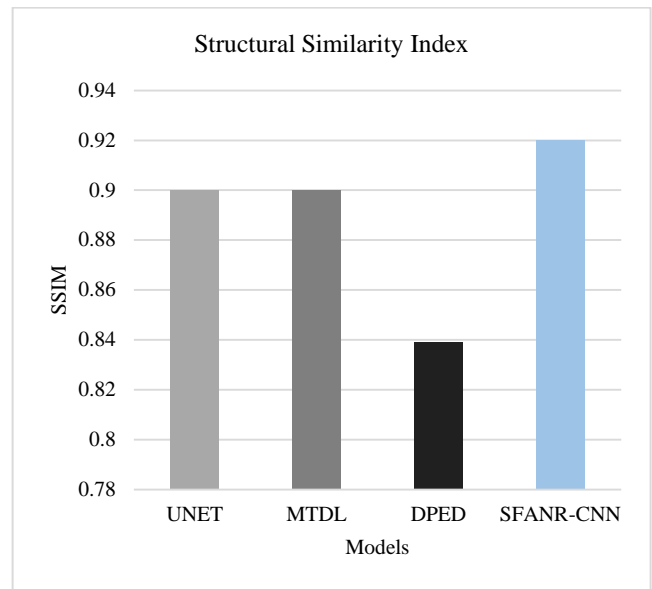

Fig. 5. SSIM achieved using SFANR-CNN and other Noise Removal Technique.

TABLE II. NOISE STUDY OF SFANR

| Methodology | PSNR (dB) | SSIM |
|---|---|---|
| Speckle | 37.34 | 0.901 |
| Gaussian | 39.63 | 0.925 |
| Rician | 38.54 | 0.903 |

The Table III shows comparative study of proposed SFANR with other methodologies. The table shows no prior work have worked on detecting and removing noise for brain MS lesion MRI. Then, each method is modeled to remove only one particular noise; however, SFANR are trained with multiple noise type such as Rician, Speckle, and Gaussian; thus, are adaptive to remove different noise.

TABLE III. COMPARATIVE ANALYSIS

| Methodology | Method | Noise Type | Metrics | MS Lesion MRI |
|---|---|---|---|---|
| Jian et al., [23], 2019 | Dictionary learning | Rician | SSIM, PSNR, & time | No |
| Aetesam et al., [1], 2021 | Parallel Ensemble Denoising | Gaussian-Impulse | SSIM, PSNR, &running time | No |
| Wang et al., [17], 2020 | Multi-task deep learning model | Gaussian | HFEN, SSIM, & PSNR | No |
| Bhutto et al., [24], 2022 | Morphology learning and CNN | Background noise | SNR & time | No |
| SFANR | Sparse-morphology using CNN | Rician, Speckle, and Gaussian | SSIM, PSNR, running time | Yes |

## V. CONCLUSION

MRI is a widely used detection technique; however, image detection is a complex and time-consuming procedure as data is not clear because of its noisy nature. Therefore, we have implemented a sparsity-based noise removal technique using CNN architecture for the high-quality reconstruction of thermal and ultrasound images with improved time efficiency. In our model SFANR-CNN, we implemented a patch-wise morphology learning algorithm by producing morphology while training for efficient denoising for various types of noises. We have used various parameters to define the high quality of our reconstructed MS lesion MRI namely PSNR and SSIM. Experimental outcomes show that our model SFANR-CNN outperforms all other state-of-art-algorithms in terms of PSNR and SSIM. Our model produces high PSNR results of 39.63 dB which is much higher than any other algorithm. Similarly, SSIM outcomes are 0.92 using our model SFANR-CNN. Alongside, a running time of 2.98 seconds is attained for removing noise. These results demonstrate the superiority of our model SFANR-CNN.

Future work would consider evaluating performance by introducing a different kind of noise. Designing a better noise removal technique will aid in detecting and segmenting MS lesions more efficiently which in the future will be considered.

# Sentiment Analysis of Covid-19 Vaccination using Support Vector Machine in Indonesia

Majid Rahardi[1]*, Afrig Aminuddin[2], Ferian Fauzi Abdulloh[3], Rizky Adhi Nugroho[4]

Faculty of Computer Science, Universitas Amikom Yogyakarta, Yogyakarta, Indonesia

*Abstract*—Along with the development of the Covid-19 pandemic, many responses and news were shared through social media. The new Covid-19 vaccination promoted by the government has raised pros and cons from the public. Public resistance to covid-19 vaccination will lead to a higher fatality rate. This study carried out sentiment analysis about the Covid-19 vaccine using the Support Vector Machine (SVM). This research aims to study the public response to the acceptance of the vaccination program. The research result can be used to determine the direction of government policy. Data collection was taken via Twitter in the year 2021. The data then undergoes the preprocessing methods. Afterward, the data is processed using SVM classification. Finally, the result is evaluated by a confusion matrix. The experimental result shows that SVM produces 56.80% positive, 33.75% neutral, and 9.45% negative. The highest model accuracy was obtained by RBF kernel of 92%, linear and polynomial kernels obtained 90% accuracy, and sigmoid kernel obtained 89% accuracy.

*Keywords*—*Covid-19; vaccination; support vector machine; twitter*

## I. INTRODUCTION

World Health Organization (WHO) announced that the Covid-19 virus has spread to countries since 2019. WHO officially set Covid-19 as a global pandemic on March 11, 2020 [1][2]. Various steps were taken to overcome this pandemic. One of them is the manufacture of vaccines. In Indonesia, President Joko Widodo inaugurated Perpres Nomor 99 Tahun 2020 About Vaccine Procurement and Vaccination Implementation In the Context of Combating the Corona Virus Pandemic Disease 2019 (Covid-19) [3].

The pros and cons of vaccination have attracted various groups to express opinions. Social media is a medium that is easy and fast to access. So, it is not uncommon for people to express their views on social media. According to APJII, around 51.5% of internet users in Indonesia use social media daily [4]. One of the social media that is often used in Indonesia is Twitter. Twitter has 152 million registered users worldwide and more than 500 million unregistered users per month[5].

The number of opinions and the ease of accessing social media allow researchers to research cyberspace. One of these studies is sentiment analysis. Sentiment analysis is a classification process to classify the text in the document into positive, negative, and neutral classes [6][7]. The results from sentiment analysis can be used for various purposes [8].

Based on that problem, this research will compare the sentiment analysis results regarding the Indonesian people's point of view towards Covid-19 vaccination activities from Twitter. First, the data are taken from Twitter in Bahasa. Afterward, the data is preprocessed. Then, sentiment analysis is carried out using the Support Vector Machine.

## II. LITERATURE REVIEW

### A. Sentiment Analysis

The opinion is a point of view or attitude of humans to a situation, entity, and others. The statement of each individual has a subjective nature. So that it can provide different points of view [9]–[12]. Differences of opinion can then be investigated, giving rise to a generalization of the field of study in the form of sentiment analysis. Sentiment analysis is an area of study that studies opinions, sentiments, evaluations, judgments, attitudes, and emotions towards an entity such as an organization, event, person, and goods [13].

### B. Preprocessing

Preprocessing is an activity that is carried out before further analysis of the data. In this process, entities and unnecessary information are removed. Preprocessing is done through several stages: cleaning, case folding, tokenizing, normalization, stopwords, and stemming[14]. Preprocessing aims to convert raw data into more structured data to be recognizable to the machine[15], [16].

### C. TF-IDF

TF-IDF consists of two interrelated matrices, namely TF and IDF. TF or Term-Frequency is a matrix that counts the number of times a word appears in a document [17]. IDF or Inverse Document Frequency is a matrix that counts the frequency of a word that appears throughout the document [17]. The purpose of TF-IDF is to calculate the importance level of words in a document [18][19]. The equation in TF-IDF can be seen in (1).

$$TFIDF(t,d) = T(t,d) \ X \ IDF(t) \tag{1}$$

t = the number of a term or word in the document.

d = the number of document.

### D. Synthetic Minority Oversampling Technique

The total of each dataset class determines the level of validity and accuracy of a model. The quality of a good dataset can be obtained with consistency and good trustworthiness. The imbalanced class dataset can be overcome by using SMOTE [20]. This technique utilizes the concept of K-Nearest Neighbor, which then SMOTE plays a role in making synthetic data from minority classes [21]. A new minority sample is

*Corresponding Author.

created using this method by linear interpolation between two minority samples [22].

### E. Support Vector Machine

Support Vector Machine is a method of machine learning used for data classification. This method is included in supervised learning. Therefore, labeling is required in the data [23][24]. Support Vector Machine works to separate data by finding the best hyperplane and margin maximum [25]. The hyperplane is a plane separator or differentiator between two classes, while the margin is the distance between the outermost samples of the class or which is called the Support Vector. The equation of Support Vector Machine can be seen in (2) [24].

$$w.x - b = 0 \tag{2}$$

where *w* represents the weight vector, *x* denotes the input vector, and *b* indicates the bias.

### F. Performance Evaluation Measure

Performance Evaluation Measure is a process for evaluating the performance or capability of a classification system or model [26]. Evaluations are displayed in a table with several entities called the confusion matrix. These entities include accuracy, precision, recall, and F1-Score.

Precision is the match value between the answers system and the user's information. The recall is the value of the accuracy of the unit of data with a previously called up team of information. Accuracy results from a comparison between correct information by the whole information. F1-Score is the value obtained from the weighted average between precision and recall. The equation of performance evaluation measure can be seen in (3), (4), (5), and (6) [27]–[29].

$$Precision = \frac{TP}{TP+FP} \tag{3}$$

$$Recall = \frac{TP}{TP+FN} \tag{4}$$

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{5}$$

$$F1\ Score = \frac{2(Precision)(Recall)}{(Precision+Recall)} \tag{6}$$

The table is known as the Confusion Matrix used to describe PEM. This table contains the results of the dataset test with the model that has been made in the prediction class and actual class. The table of Confusion Matrix can be seen in Table I [30].

True Positive indicates that the model previously predicted true proved true. True Negative suggests that the previous model was predicted wrong and proved wrong. False Positive shows that the previously predicted model true is proven false. False Negative indicates that the previously predicted model was proven wrong correct [27]–[29].

TABLE I.        CONFUSION MATRIX

|  | Actual True | Actual False |
|---|---|---|
| **True Predicted** | True Positive (TP) | False Positive (FP) |
| **False Predicted** | False Negative (FN) | True Negative (TN) |

### III. METHODS

#### A. System Overview

The system takes data through Twitter in Bahasa Indonesia with a total of 2000 tweets and the timeline between October 19, 2021, and October 22, 2021. After that, the data is manually labeled after cleaning the tweet. Then, do the preprocessing to clean up data noise and simplify the classification process. After that, word weighting was done using the TF-IDF method and sentiment dataset class balancing using the SMOTE method. Then, divide the dataset into data training and data testing. Next, classification sentiment is done using the Support Vector Machine and Evaluating the value indicated through Confusion Matrix. The system of this sentiment analysis process can be seen in Fig. 1.

#### B. Data Collection and Cleaning

Data collection is done through Twitter using the Twitter API. Twitter API consists of Access Token, Access Token Secret, API Key, and API Key Secret. This process is written in Python using Tweepy library. Researchers use the keywords "vaksin" and "vaksinasi" as a reference for searching and used in a CSV file or Comma Separated Values. Results of the Crawling Tweets process can be seen in Table II.

The next process that needs to be done is cleaning to simplify the labeling process. Also, removes URLs, punctuation, and numeric, including in the cleaning process. In addition, eliminating mentions of users by @ and deleting duplicate tweets are included in the cleaning process. The results of the cleaning process can be seen in Table III.

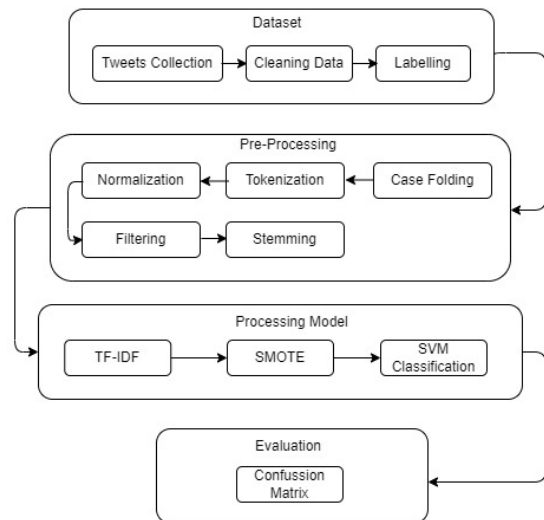

Fig. 1.   System Overview of Sentiment Analysis.

TABLE II.        RESULTS OF THE CRAWLING TWEETS

| Date and Time | User | Tweet |
|---|---|---|
| 2021-10-19 22:58:43 | COVID PASTI BERLALU | Para pelajar menyampaikan rasa terima kasih atas program vaksinasi yang terus dilakukan oleh pemerintah. #AyoVaksin #KaltaraSuksesVaksinasi #VaksinasiPulihkanRI #IndonesiaSehat #IndonesiaHebat https://t.co/h5x41UO3tF |

### C. Data Labelling

The labeling process needs to be done before the sentiment analysis process. This process is done manually conducted by researchers with several parameters. The parameter used is the positive sentiment with the number two symbol, a neutral sentiment with the number symbol one, and negative sentiment with zero. Results of the labeling process can be seen in Table IV.

TABLE IV. RESULTS OF THE LABELLING PROCESS

| Tweet after Cleaning | Label |
|---|---|
| Para pelajar menyampaikan rasa terima kasih atas program vaksinasi massal yang terus dilakukan oleh pemerintah | 2 |

### D. Data Preprocessing

This stage is one of the most important carried out in sentiment analysis. At this stage, data is cleaned of noise to form the data according to the standard. This process makes it easier for the system to recognize and analyze a word.

*1) Case Folding:* This process is changing each letter in the sentence to lowercase. The result of Case Folding process can be seen in Table V.

TABLE V. RESULTS OF CASE FOLDING PROCESS

| Tweet before Case Folding | Tweet after Case Folding |
|---|---|
| Para pelajar menyampaikan rasa terima kasih atas program vaksinasi massal yang terus dilakukan oleh pemerintah | para pelajar menyampaikan rasa terima kasih atas program vaksinasi massal yang terus dilakukan oleh pemerintah |

*2) Tokenizing:* This process is splitting sentences into a piece of the word called tokens. The result of the Tokenizing process can be seen in Table VI.

*3) Normalization:* This step is converting each word or token into a common phrase. The standard used in this case is the standard Indonesian word. This method was based on research published in the journal by Salsabila et al. [31]. The results of the Normalization process can be seen in Table VII.

*4) Stopwords or filtering:* This process removes words or tokens that are unnecessary and unrelated for further analysis. The result of the Stopwords process can be seen in Table VIII.

TABLE VI. RESULTS OF THE TOKENIZING PROCESS

| Tweet before Tokenizing | Tweet after Tokenizing |
|---|---|
| para pelajar menyampaikan rasa terima kasih atas program vaksinasi massal yang terus dilakukan oleh pemerintah | ['para','pelajar','menyampaikan','rasa','terima','kasih','atas','program','vaksinasi','massal','yang','terus','dilakukan','oleh','pemerintah'] |

TABLE VII. RESULTS OF THE NORMALIZATION PROCESS

| Tweet Tokens | Normalization |
|---|---|
| ['betul','vaksinasi','itu','penting','sbg','benteng','pertahanan','diri','dr','dalam'] | ['betul','vaksinasi','itu','penting','sebagai','benteng','pertahanan','diri','dari','dalam'] |

TABLE VIII. RESULTS OF THE STOPWORDS PROCESS

| Normalization | Stopwords |
|---|---|
| ['para','pelajar','menyampaikan','rasa','terima','kasih','atas','program','vaksinasi','massal','yang','terus','dilakukan','oleh','pemerintah'] | ['pelajar','menyampaikan','rasa','terima','kasih','atas','program','vaksinasi','massal','terus','dilakukan'] |

*5) Stemming:* This process changes words or tokens into a word form base. The results of the stemming process can be seen in Table IX.

TABLE IX. RESULTS OF THE STEMMING PROCESS

| Stopwords | Stemming |
|---|---|
| ['pelajar','menyampaikan','rasa','terima','kasih','atas','program','vaksinasi','massal','terus','dilakukan'] | ['ajar','sampai','rasa','terima','kasih','atas','program','vaksinasi','massal','terus','laku'] |

### E. Feature Extraction

Feature extraction or TF-IDF will calculate each word by the value against the number of documents used at this stage. This process aims to carry out the classification process easily and recognize words in the form of numbers. The results of the implementation of TF-IDF are as follows:

- Document 1: Ayo dukung program vaksinasi masal capai target herd immunity nasional untuk Indonesia sehat.

- Document 2: Mau sehat Ayo vaksinasi Indonesia bangkit.

The calculation of TF-IDF can be seen in Table X.

TABLE X. RESULTS OF TF-IDF PROCESS

| Word | TF | | IDF | TF-IDF Score | |
|---|---|---|---|---|---|
| | D1 | D2 | | D1 | D2 |
| Ayo | $\frac{1}{13}$ | $\frac{1}{13}$ | $\log\left(\frac{2}{2+1}\right) = 0.18$ | 0.013 | 0.013 |
| Dukung | $\frac{1}{13}$ | 0 | $\log\left(\frac{2}{1+1}\right) = 0$ | 0 | 0 |
| Program | $\frac{1}{13}$ | 0 | $\log\left(\frac{2}{1+1}\right) = 0$ | 0 | 0 |
| Vaksinasi | $\frac{1}{13}$ | $\frac{1}{13}$ | $\log\left(\frac{2}{2+1}\right) = 0.18$ | 0.013 | 0.013 |

| Indonesia | $\dfrac{1}{13}$ | $\dfrac{1}{13}$ | $\log\left(\dfrac{2}{2+1}\right)$ $= 0.18$ | 0.013 | 0.013 |
| Sehat | $\dfrac{1}{13}$ | $\dfrac{1}{13}$ | $\log\left(\dfrac{2}{2+1}\right)$ $= 0.18$ | 0.013 | 0.013 |
| Mau | 0 | $\dfrac{1}{13}$ | $\log\left(\dfrac{2}{1+1}\right) = 0$ | 0 | 0 |
| Bangkit | 0 | $\dfrac{1}{13}$ | $\log\left(\dfrac{2}{1+1}\right) = 0$ | 0 | 0 |

*F. Synthetic Minority Oversampling Technique*

SMOTE will balance the dataset by taking advantage of the TF-IDF value. Balancing dataset class is a must because there is a gap in data between positive, neutral, and negative classes. SMOTE will create class neutral and negative belonging to the minority class synthetic data to match the majority class, positive class. Before and after the implementation of SMOTE can be seen in Fig. 2 and 3.

Fig. 2. Before Implementation of SMOTE.

Fig. 3. After Implementation of SMOTE.

*G. Support Vector Machine*

This research tested the model using four Support Vector Machine kernels, i.e., linear, polynomial, RBF, and sigmoid. Various kernels are utilized to change the level of data dimensions to be different depending on the kernel used. The equation of each Support Vector Machine kernel can be seen in Table XI [32].

TABLE XI. SUPPORT VECTOR MACHINE KERNEL EQUATION

| Kernel | Equation | |
|---|---|---|
| Linear | $K(x_i, x) = x_i^T x$ | |
| Polynomial | $K(x_i, x) = (\gamma.x_i^T x + r)^p$ | $p$ = degree $r$ = coef() |
| RBF | $K(x_i, x) = exp(-\gamma|x_i^T x|^2)$ | $\gamma$ = gamma |
| Sigmoid | $K(x_i, x) = tanh(\gamma.x_i^T x + r)$ | $r$ = coef() |

## IV. RESULT

*A. Sentiment Analysis*

Researchers analyze sentiment by manually labeling each tweet. The labeled sentiment is done after the cleaning process. As a result, there are 1136 tweets (56.80%) with positive sentiment, 675 tweets (33.75%) with the neutral sentiment, and 189 (9.45%) tweets with negative sentiment. In the case of the imbalanced dataset, researchers implement SMOTE to balance the minority class and majority class.

*B. Performance Evaluation Measure*

The evaluation of the model in this research is presented in a confusion matrix table which consists of prediction class and actual class. The comparison of each kernel also becomes an evaluation parameter in this research.

*1) Linear kernel:* Parameters used in the test of the linear kernel, i.e., the complexity and maximum iterations. Increased complexity causes accuracy to decrease, and increasing the maximum iteration value tends to give a constant value with low volatility. The best accuracy result is 90% with C = 1 and max iteration = "default". The confusion matrix table of the linear kernel can be seen in Table XII, and the performance evaluation measure can be seen in Table XIII.

*2) RBF Kernel:* Parameters used in the test of RBF kernel, i.e., complexity and gamma. Testing the complexity value of more than five tends to produce high accuracy values constant, and increases in the value of gamma cause accuracy to decrease. The best accuracy result is 92% with C = 1 and gamma = 1. The confusion matrix table of the RBF kernel can be seen in Table XIV, and the performance evaluation measure can be seen in Table XV.

TABLE XII. CONFUSION MATRIX OF LINEAR KERNEL

| Actual | Predicted | | |
|---|---|---|---|
| | Negative | Neutral | Positive |
| Negative | 88 | 0 | 0 |
| Neutral | 4 | 117 | 13 |
| Positive | 3 | 15 | 101 |

TABLE XIII. PERFORMANCE EVALUATION MEASURE OF LINEAR KERNEL

| Sentiment | Precision | Recall | F1-Score |
|---|---|---|---|
| Negative | 0.93 | 1.00 | 0.96 |
| Neutral | 0.86 | 0.87 | 0.88 |
| Positive | 0.89 | 0.85 | 0.87 |

TABLE XIV. CONFUSION MATRIX OF RBF KERNEL

| Actual | Predicted | | |
|---|---|---|---|
| | Negative | Neutral | Positive |
| Negative | 88 | 0 | 0 |
| Neutral | 2 | 115 | 17 |
| Positive | 1 | 8 | 110 |

TABLE XV.    PERFORMANCE EVALUATION MEASURE OF RBF KERNEL

| Sentiment | Precision | Recall | F1-Score |
|---|---|---|---|
| **Negative** | 0.97 | 1.00 | 0.98 |
| **Neutral** | 0.93 | 0.86 | 0.89 |
| **Positive** | 0.87 | 0.92 | 0.89 |

*3) Polynomial Kernel:* Parameters used in the test of Polynomial kernel, i.e., complexity, gamma, and degree. Testing on three parameters causes a decrease in accuracy as the value increases. The best accuracy result is 90% with C = 1, gamma = "scale", and degree = 1. The confusion matrix table of the Polynomial kernel can be seen in Table XVI, and the performance evaluation measure can be seen in Table XVII.

TABLE XVI.    CONFUSION MATRIX OF POLYNOMIAL KERNEL

| Actual | Predicted | | |
|---|---|---|---|
| | Negative | Neutral | Positive |
| **Negative** | 88 | 0 | 0 |
| **Neutral** | 4 | 118 | 12 |
| **Positive** | 3 | 16 | 100 |

TABLE XVII.    PERFORMANCE EVALUATION MEASURE OF POLYNOMIAL KERNEL

| Sentiment | Precision | Recall | F1-Score |
|---|---|---|---|
| **Negative** | 0.93 | 1.00 | 0.96 |
| **Neutral** | 0.88 | 0.88 | 0.88 |
| **Positive** | 0.89 | 0.84 | 0.87 |

*4) Sigmoid Kernel:* Parameters used in the test of the sigmoid kernel, i.e., complexity and gamma. Increasing the value of complexity and gamma produces an accuracy value that tends to decrease. The best accuracy result is 89%, with C = 1 and gamma = "scale". The confusion matrix table of the sigmoid kernel can be seen in Table XVIII, and the performance evaluation measure can be seen in Table XIX.

TABLE XVIII. CONFUSION MATRIX OF SIGMOID KERNEL

| Actual | Predicted | | |
|---|---|---|---|
| | Negative | Neutral | Positive |
| **Negative** | 88 | 0 | 0 |
| **Neutral** | 7 | 114 | 13 |
| **Positive** | 5 | 13 | 101 |

TABLE XIX.    PERFORMANCE EVALUATION MEASURE OF SIGMOID KERNEL

| Sentiment | Precision | Recall | F1-Score |
|---|---|---|---|
| **Negative** | 0.88 | 1.00 | 0.94 |
| **Neutral** | 0.90 | 0.85 | 0.87 |
| **Positive** | 0.89 | 0.85 | 0.87 |

## V.    CONCLUSION

Sentiment class classification generates positive sentiment 1136 tweets (56.80%), neutral sentiment 675 tweets (33.75%), and negative sentiment 189 tweets (9.45%). The dataset class number gap is balanced through the SMOTE method, which generates 1136 tweets in all class sentiments. The classification results using the Support Vector Machine have the best accuracy result obtained on the RBF kernel by 92%, followed by Linear kernel and Polynomial kernel by 90%; lastly, the Sigmoid kernel by 89%.

# Application of Optimized SVM in Sample Classification

Xuemei Yao

School of Data Science and Information Engineering, Guizhou Minzu University, China

*Abstract*—Support vector machines (SVM) have unique advantages in solving problems with small samples, nonlinearity and high dimension. It has a relatively complete theory and has been widely used in various fields. The classification accuracy and generalization ability of SVMs are determined by the selected parameters, for which there is no solid theoretical guidance. To address this parameter optimization problem, we applied random selection, genetic algorithms (GA), particle swarm optimization (PSO) and K-fold cross validation (k-CV) method to optimize the parameters of SVMs. Taking the classification accuracy, mean squared error and squared correlation coefficient as the goal, the K-fold cross validation method is chosen as the best way to optimize SVM parameters. In order to further verify the best performance of the SVM whose parameters are optimized by the K-fold cross validation method, the back propagation neural network and decision tree are used as the contrast models. The experimental results show that the SVM-cross validation method has the highest classification accuracy in SVM parameter selection, which lead to SVM classifiers that outperform both BP neural networks and decision tree method.

*Keywords*—*Support vector machine; parameter optimization; K-fold cross validation; sample classification*

## I. INTRODUCTION

Support Vector Machine (SVM) is a theory that studies the rule of machine learning in the case of limited sample based on the statistical learning theory including Vapnik-Chervonenkis Dimension (VCD) and Structural Risk Minimization (SRM). SVM has many unique advantages in solving the problem of high-dimensional pattern recognition. It can use the limited sample information to compromise the complexity and learning ability of the model, and avoid the problems caused by over-learning and under-learning as much as possible, so that the system has a better ability to extend. SVM has attracted the attention and research interests of experts and scholars in various fields, and made a lot of research results in practical application, which has promoted the development of various fields [1-3].

Although SVM has been widely used in text classification [4], image recognition[5], prediction[6] and so on, its performance is mainly dependent on the selection of penalty factor and kernel parameter. So far, SVM parameter selection still does not have a complete set of theory and standards, but in practical application, the choice of parameter directly determines the classification accuracy and generalization ability of SVM [7-8]. The common methods of optimizing parameters are as follows, experimental method, grid search and numerical method. The first way means that you need to

select different parameters for multiple experiments, and then select a pair of parameters for the best results, which is not only time consuming and too random; the second method is feasible in the case of small samples, but the efficiency and feasibility is lower when the data is large; the third method is more sensitive to the selection of the initial value. With the development of artificial intelligence, some groups of intelligent optimization algorithm such as ant colony optimization algorithm (ACO), genetic algorithm (GA), particle swarm algorithm (PSO) and so on are used to optimize the parameters of SVM.

Rajeshwari et al [9] proposed a new Weighted-SVM kernel by applying a suitably transformed weight vector derived from particle swarm optimized neural networks. Yang et al [10] envisaged the analysis of the dissolved oxygen fault of the water quality monitoring system using the GA-SVM and the result exhibited a good accuracy. Faris et al [11] proposed a robust approach based on a recent nature-inspired metaheuristic called multi-verse optimizer for selecting optimal features and optimizing the parameters of SVM simultaneously and it can effectively reduce the number of features while maintaining a high prediction accuracy. John et al [12] proposed a detection technique using SVM with Grid search algorithm and recognized the disorder with an accuracy rate of 89%.

In the above research, it is for a specific field to select a suitable way to optimize the parameters of SVM, but it does not compare these parameter optimization algorithms in the same application to select the best way. To address this issue, based on the identification of Italian wine, random selection, GA, PSO and cross validation (CV) are used to optimize the parameters of SVM, and the best way was selected. In order to verify that the SVM which is optimized by the best way has a good classification accuracy, the neural network and decision tree are used as contrast model for analysis.

## II. METHODOLOGY

### A. Introduction of SVM

SVM is a statistical learning method proposed by Vapnik in 1992 based on VCD theory and SRM principle [13]. SVM maps the input space into a high dimensional kernel space by introducing the kernel function. In order to classify the sample, the optimal classification hyperplane with lower VCD is obtained in the high dimensional kernel space, so that one class is located on the side of the hyperplane and the other side of the hyperplane is another class. Take the Two-Dimensional (2D) space as an example showed in Fig. 1. There are many samples, some with five-pointed star and some with a circle.

Classification by SVM is to find a hyperplane (the red line in Fig. 1), according to the classification requirements, the sample will be divided into class 1 with five-pointed star and class 2 with circle. The point falling on the classification boundary is called support vector

Fig. 1.    Schematic Diagram of SVM in 2D Space.

The main idea of SVM is to establish a classification hyperplane $f(x) = 0$ as a decision surface for a multidimensional space to be classified, for any positive case x satisfying $f(x) > 0$, and the counter example is satisfied with $f(x) < 0$. The purpose of SVM is to find the appropriate $f(x)$ to maximize the isolation edge (Gap) and minimize the training error between the positive and negative examples. Through the decision-making surface to achieve the classification of the sample, the decision-making function can be written as:

$$f(x) = sign(\sum_{x_i \in S_V}^{n} a_i y_i k(x_i, x) + b) \qquad (1)$$

where $a_i$: Lagrange multiplier, s.t. $0 < a_i < c$

$S_V$: Support vector.

$K(x_i, x)$: Kernel function.

$x_i$: The positive examples.

$y_i$: The negative examples.

b: Threshold.

n: The number of samples.

In practical application, SVM has a complete theoretical basis, but it needs to choose different parameters and kernel functions for different conditions in order to obtain the desired results. Different support vector classifiers can be generated by using different kernel functions. Commonly used kernel functions are linear kernel function, radial basis function (RBF), polynomial kernel function and so on. Since it is only necessary to determine a parameter in RBF, which is beneficial to parameter optimization, RBF is chosen as the kernel function of SVM in this article. The expression can now be written as:

$$K(x_i, x) = exp(\frac{1}{2g^2}||x_i - x||^2) \qquad (2)$$

Where $g$ is the nuclear parameter to be determined. The penalty factor $c$ is an important parameter in SVM. It is used to control the weight of the loss and sorting interval. The bigger the value of $c$, the higher the fit degree of the model, but its generalization ability is reduced. According to SVM regression theory, $c$ and $g$ have a great influence on the classification results. Therefore, it is necessary to choose the best $c$ and $g$ to obtain the superior performance of SVM.

Definition 1

The mathematical model of SVM parameter will be written as: $P= \{bestc, bestg\}$.

Definition 2

The objective function of SVM parameter optimization is the accuracy of prediction model.

In this paper, the problem of SVM parameter optimization can be described mathematically:

For $\forall p=\{c,g\}$, satisfied $P=max(Accuracy)$

$$s.t.\begin{cases} P \subset p \\ c > 0 \\ g > 0 \end{cases} \qquad (3)$$

SVM solves the practical puzzles such as small sample, nonlinearity and high dimension. It has strong versatility, robustness and effectiveness and it is widely used in classification and regression. The SVM is originally designed for two classification problems. When dealing with multiple classification, it is necessary to combine multiple two classifiers to construct the appropriate multi-classifier. In this paper, the tool used in constructing the forecasting model is the LibSVM software package developed by Chih-Jen Lin of Taiwan University.

### B. SVM Parameter Optimiztion Method

*1) Random selection:* Random selection belongs to the experimental method. According to the theory of SVM, we randomly select different parameters to test and analyze the samples, and then choose a set of parameters with the highest classification accuracy. The method is too random and lacks of authoritative theoretical guidance.

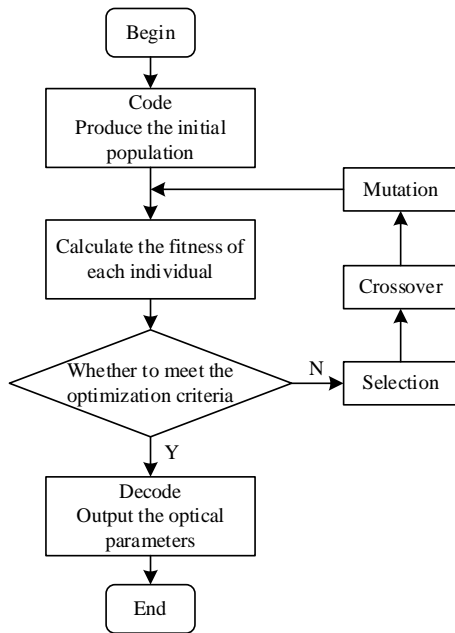
*2) Genetic Algorithm (GA):* GA is proposed by Professor J. Holland of the United States in 1975. Its main feature is the direct operation of the structure of the object; there is no limit of derivation and continuity of the function; it has better global optimization ability [14]. GA is a computational model for simulating the natural selection and genetic mechanism of Darwin's theory of biological evolution. It is a method for searching the optimal solution by simulating natural evolutionary processes [15]. It introduces the principle of "survival of the fittest" in the process of coding of parameter optimization. According to the selected fitness function, the individuals are selected by the selection, crossover and mutation of the genetic process, so that the individuals with good fitness value are retained, the remaining are eliminated. The new group not only inherited the previous generation of information, but also better than it. It is repeatedly until the conditions are satisfied. Genetic algorithm has been widely used in combinatorial optimization, machine learning, adaptive control and other fields. The process of GA shows in Fig. 2.


Fig. 2. Flow Chart of GA.

*3) Particle Swarm Optimization (PSO):* PSO is an optimization algorithm based on population intelligence in computing intelligence [16]. It is first proposed by Kennedy and Eberhart in 1995 and its basic concept comes from the study of predatory behavior of birds. PSO initializes a group of particles in the solvable space first. Each particle represents a potential optimal solution of the search space and the characteristics of particle are displayed by three indexes of position, velocity and fitness value. The particle moves in the solution space [17]. By tracking the trajectories of the particle, it updates the position and speed of individual constantly to follow the optimal output. The process of PSO algorithm shows in Fig. 3.

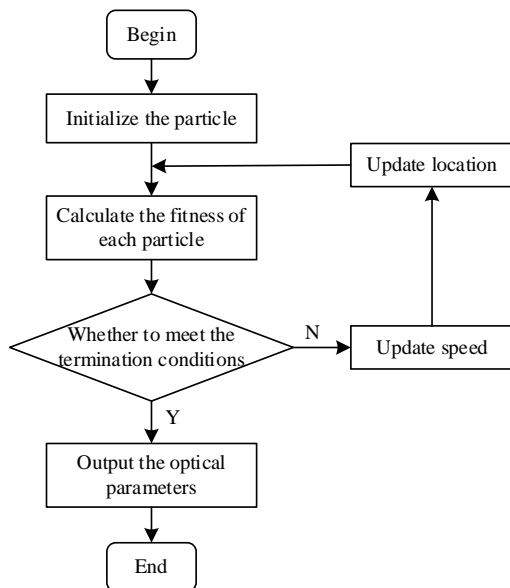

Fig. 3. Flow Chart of PSO.

*4) Cross-Validation (CV):* CV is a statistical analysis method used to verify the performance of a classifier. The basic idea is to divide the original data into two parts in a certain sense, one is the training set and the other is validation set [18-19]. Firstly, the training set is used to train the classifier, then the validation set is used to test the model to obtain the classification accuracy as the performance index of the classifier. The optimal parameters obtained by CV can effectively avoid the occurrence of over learning and less learning, and finally get the ideal prediction accuracy for the testing set. The Hold-out method, *K*-fold CV, Leave-one-out CV are commonly used methods. The second method is adopted in the article that is *K*-CV. Its basic idea is to divide the original data into *K* disjoint subsets, then it selects one of them as the validation set and the other *K*-1 subsets as the training set. The *K* models can be obtained in this way, and the average of the final classification accuracy of the *K* models as the performance index of the *K*-CV classifier. Generally speaking, *K* is greater than or equal to 2. But in practice, *K* is taken from 3. *K* will try to take 2 only when the original data is very small.

## C. Classification Forecasting Model Based on SVM

*1) Data preprocessing:* Raw data usually has a different order of magnitude, which directly affects the results of the data analysis. In order to eliminate the influence, data standardization is required to address the comparability between data indicators. The data is in the same order of magnitude after processing and it is suitable for comprehensive evaluation. Two commonly used normalized methods are as follows.

*a) Normalized between [0,1]:* The normalized mapping used in this method is as follows.

$$f: x \rightarrow y = \frac{x - x_{min}}{x_{max} - x_{min}} \tag{4}$$

where $x, y \in R^*$; $x_{min} = \min(x)$; $x_{max} = \max(x)$. The result of the normalization is that the raw data is scaled to [0,1].

*b) Normalized between [-1,1]:* The normalized mapping used in this method is as follows.

$$f: x \rightarrow y = 2 * \frac{x - x_{min}}{x_{max} - x_{min}} - 1 \tag{5}$$

where $x, y \in R^*$; $x_{min} = \min(x)$; $x_{max} = \max(x)$. The result of the normalization is that the raw data is scaled to [-1, 1].

*2) Classification forecasting model :* The classification prediction model based on SVM is divided into two stages: parameter optimization and prediction classification. The first stage is parameter optimization. The training set and testing set are separated from the original data, then the normalized preprocessing method makes the data samples in the same order of magnitude with the same dimension. The parameters of SVM are optimized by random selection, GA, PSO and *K*-fold CV method. The optimal parameters are selected from

three angles: accuracy, MSE and $r^2$. The second stage is prediction classification. The *K*-CV-SVM model is established with the best parameters to find he support vector of the training sample and determine the optimal classification hyperplane, and then forecast the testing set. In order to further verify the superior performance of *K*-CV-SVM model, neural network and decision tree are designed as contrast model. The overall structure of the paper is shown in Fig. 4.

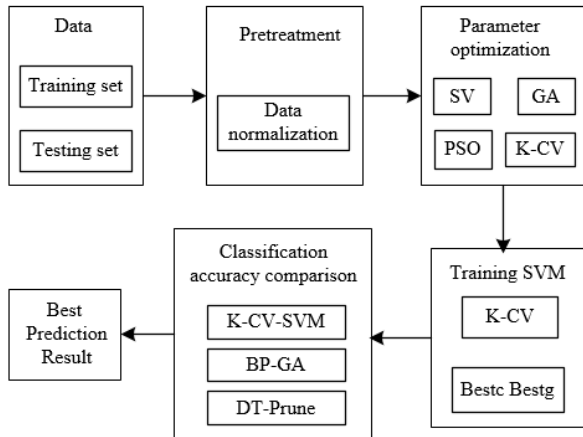

Fig. 4.   Diagram of SVM Classification.

## III. EXPERIMENTAL DISCUSSION

### A. *Experimental Data Description*

In order to verify the validity of the method proposed in this paper, we use the wine data to carry out the experimental. Wine data is from the UCI dataset and it can be download from the link: http://archive.ics.uci.edu/ml/datasets/Wine. These data are the results of a chemical analysis of wines grown in the same region in Italy but derived from three different cultivars. The analysis determines the composition of each wine. The data contains 178 samples and each contains 13 attributes and 1 label. The attributes which are the main chemical composition of wine donated by Riccardo Leardi are: 1) Alcohol; 2) Malic acid; 3) Ash; 4) Alcalinity of ash; 5) Magnesium; 6) Total phenols; 7) Flavanoids; 8) Nonflavanoid phenols; 9) Proanthocyanins; 10) Color intensity; 11) Hue; 12) OD280/OD315 of diluted wines; 13) Proline. Wine data is divided into two parts on average, one as a training set, and one as a testing set. The classification model is obtained by training the SVM, and then the model is used to predict the label of testing set. It is necessary to note that the selection of training set and testing set is fixed at the time of parameter optimization, but it is random selected when the classification prediction accuracy of SVM, BP and DT is analyzed.

### B. *Parameter Optimization of SVM*

In order to test the effectiveness of different methods for SVM parameter optimization, four kinds of prediction models are designed to compare and analyze, such as classification model of random selection parameters of support vector machine (RS-SVM), classification model of genetic algorithm optimization parameters of support vector machine (GA-SVM), classification model of particle swarm algorithm

optimization parameters of support vector machine (PSO-SVM), classification model of *K*-fold cross validation algorithm optimization parameters of support vector machine (*K*-CV-SVM).

*1) RS-SVM:* Random selection parameter refers to the absence of any restrictions, without any theoretical support, completely by the operator according to their own wishes to randomly specify the value of the parameter. If you do not manually set the parameters, SVM will use the default value to perform. In this paper, *c* is 13 and *g* is 17 by manual setting. The prediction accuracy of the model is 74.1573%, as shown in Table I. The classification prediction error of the model is shown in Fig. 9(a), and the classification chart is shown in Fig. 10(a).

*2) GA-SVM:* GA is a search heuristic algorithm used in solving the optimization problem in the field of artificial intelligence. The GA-SVM uses GA to find the best parameters for SVM. The parameters of GA are set as follows.

The number of iterations: 200.

The size of population: 20.

The probability of crossover: 0.4.

The probability of mutation: 0.2.

The result of model is that bestc is 3.2703, bestg is 3.6738, and classification accuracy is 97.7528%. They are showed in Table I. The best fitness curve is showed in Fig. 5. In the GA with the number of iterations of 200, it can be seen that the speed of parameter optimization converges faster. It is obvious that the average fitness of the population is stable between 85% and 93% after 10 generations of evolution, and tends to be stable. In this way, the classification prediction error of the model is shown in Fig. 9(b), and the classification chart is shown in Fig. 10(b).

Fig. 5.   Fitness Curve of GA-SVM.

*3) PSO-SVM:* PSO is an optimization algorithm based on group intelligence. Compared with GA, PSO has no selection, crossover and mutation operation, but it searches the result

through the particles in the solution space to follow the optimal way. The PSO-SVM uses PSO to find the best parameters for SVM. The parameters of PSO are set as follows.

The number of iterations: 200.

The size of population: 20.

The result of model is that bestc is 32.7842, bestg is 4.4621, and classification accuracy is 97.7528%. They are showed in Table I. The best fitness curve is showed in Fig. 6. Obviously, the stability of model fitness is poor and the variation range is large. The average fitness of the population fluctuates greatly between 50% and 80% after the population begins to evolve. It can be seen that there is still no steady trend with the number of iterations of 200. In this way, the classification prediction error of the model is shown in Fig. 9(c), and the classification chart is shown in Fig. 10(c).

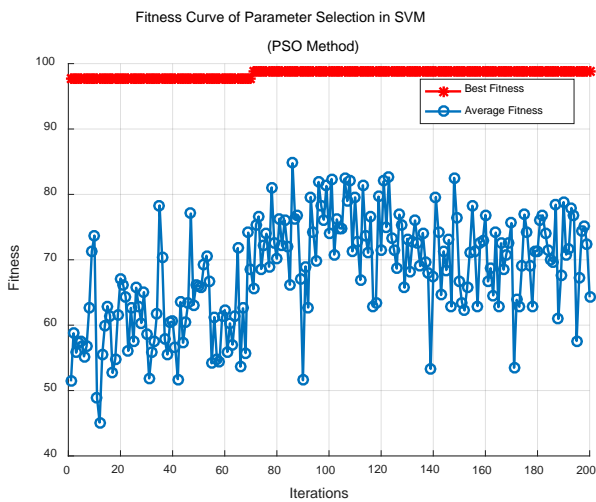

Fig. 6.    Fitness Curve of PSO-SVM.

*4) K-CV-SVM:* The model is designed using the *K*-CV method to obtain the best parameters of SVM and divides into two phases. The first stage is a rough choice. Let us set the value of *c* and *g* in a certain range ($2^{-10} < c < 2^{10}$ and $2^{-10} < g < 2^{10}$). When the value of *c* and *g* is selected, the training set is taken as the original data and the classification accuracy is obtained by the *K*-CV method. Finally, a pair of *c* and *g* with the highest classification accuracy are selected as the optimal parameter. If there are multiple sets of *c* and *g* corresponding to the highest classification accuracy, then select the combination with the smallest *c* as the optimal parameters; if the corresponding *c* has multiple *g*, then select the first group of *c* and *g* as the best parameter. The reason is that the larger *c* will lead to the occurrence of the over learning, that is, the classification accuracy of training set is high, but the testing set is very low. So in all combinations that can achieve the highest classification accuracy, the smaller *c* is considered a better choice for the object. The rough selection of the parameters gives the contour map as shown in Fig. 7.

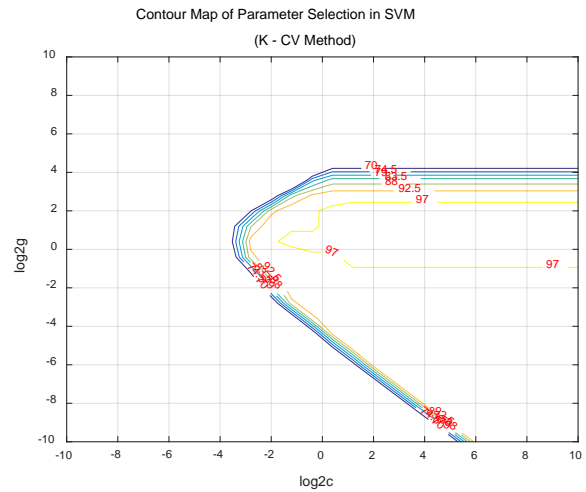

Fig. 7.    Contour Map of Parameter Selected Roughly.

In the Fig. 7, the *x*-axis represents the value of *c*, which is the logarithm of 2, and the *y*-axis represents the value of *g*, which is the logarithm of 2, and the contour line indicates the classification accuracy with corresponding *c* and *g* which are gained by *K*-CV method. As can be seen from the Fig. 7, the range of *c* can be reduced to $2^{-2}$~$2^4$, the range of *g* can be reduced to $2^{-2}$~$2^4$, so that the fine selection can be made on the basis of rough selection. The fine selection of the parameters gives the contour map as shown in Fig. 8.

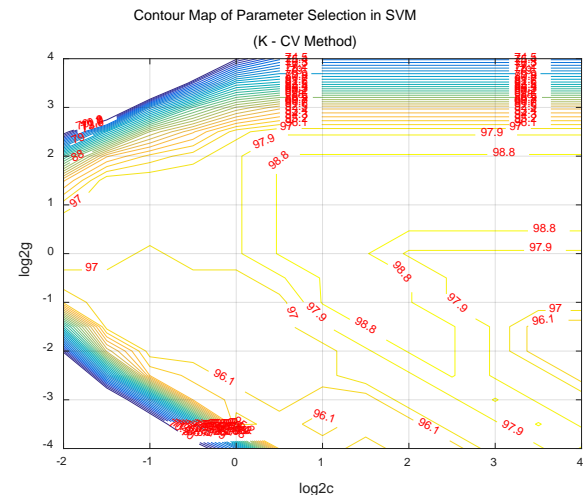

Fig. 8.    Contour Map of Parameter Selected Finely.

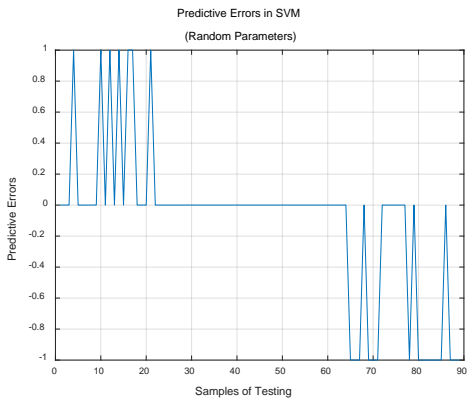
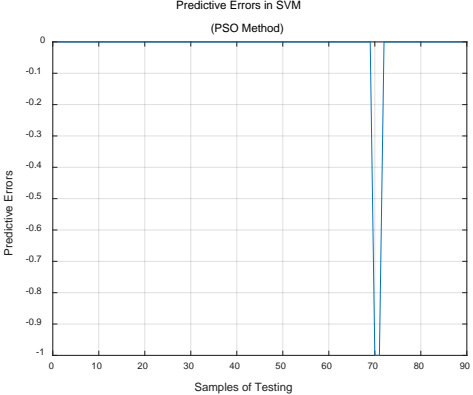
The result of fine selection of parameters is that *c* is 1.4142 and *g* is 1. In this way, the classification accuracy of model is 98.8764 showed in Table I, the classification prediction error of the model is shown in Fig. 9(d), and the classification chart is shown in Fig. 10(d).

The prediction error curve showed in the Fig. 9 indicates that the prediction error of RS-SVM is the largest, while the prediction error of k-CV-SVM is the smallest. The prediction error of GA-SVM and PSO-SVM are equal. The classification accuracy showed in Table I also illustrates it.


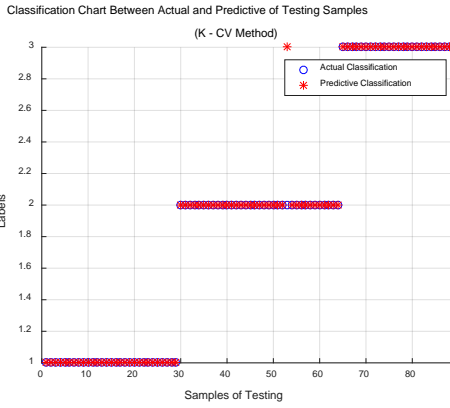
(a) Random Selected.


(b) GA Method.
(c) PSO Method.

(d) K-CV Method.

Fig. 9.   Predictive Error Curve of Different Parameter Optimization Methods.

(a) Random Selected
(b) GA Method

(c) PSO Method


(d) K-CV Method

Fig. 10.  Predictive and Practical Classification of different Parameter Optimization Methods.

Fig. 10 shows that the number of right classification is 66 and the number of wrong classification is 23 in the RS-SVM model. The number of misclassifications is the highest among the four models, that is, the prediction error of the model is the largest, which is consistent with Fig. 9(a). In the GA-SVM model, the number of right classification is 87 and the number of wrong classification is 2. The classification result of PSO-SVM model is equivalent to GA-SVM and the prediction error is similar, which is consistent with Fig. 9(b) and (c). In the K-CV-SVM model, the number of right classification is 88 and the number of wrong classification is 1. The number of misclassifications is the least among the four models, that is, the prediction error of the model is the least, which is consistent with Fig. 9(d). Overall, the K-CV-SVM model has the highest number of correct classification and the highest classification accuracy.

The other two parameters can also be obtained while the model is running. One is mean squared error (MSE), the other is squared correlation coefficient ($r^2$). Generally speaking, the accuracy is considered in the problem of classification and the MSE and $r^2$ are considered in regression issues. MSE is an indicator of the distance between the estimated and true values of the parameter. The smaller the value of MSE, the closer the results of the prediction model are to the real state and the model will have a better accuracy. $r^2$ is a statistical indicator used to describe the correlation and closeness between the variables. The larger the value of $r^2$, the closer is the relationship between the variables. The model optimizes the parameters of SVM with four different methods and carries out the prediction of classification. Table I shows that K-CV-SVM has the highest classification accuracy in four models. On the other hand, K-CV-SVM has the smallest MSE and maximum $r^2$, indicating that the prediction results of K-CV-SVM model are the closest to the real state. At the same time, compared with GA-SVM and PSO-SVM, the K-CV-SVM model consumes the least time when the classification accuracy is similar. Therefore, K-CV method is the best way to optimize the parameters of SVM, whether it is classification or regression.

## C. The Application of Optimized SVM in Classification

In order to further verify the best effect of SVM by the K-CV method to optimize the parameter, the back propagation neural network (BP) and decision tree (DT) are used as contrast model based on the same data set. In order to eliminate the influence of the random probability on model, the BP and DT model are run 50 times, and the best and the worst state are selected to increase the contrast effect. The results of prediction are showed in Table II.

It can be seen from Table II that the highest classification accuracy is 100% and the worst case is only 75.28% in the BP prediction model, and the number of wrong samples reached 22 which reflects the natural defect that the BP is easy to fall into the local optimum. In order to overcome the defect, the GA is used to optimize the initial weights and thresholds of the BP (GA-BP), and then the training and prediction are carried out. The classification accuracy of the GA-BP is improved to 93.62%. Similarly, the performance of the DT is also uneven, the best accuracy of the classification is 97.75% and the worst is only 78.65% and the number of wrong samples is 19. The reason is that the original DT is flourishing, which contains a lot of noise and boundary nodes, which is prone to over-fitting. In general, pruning is performed on the DT to improve the classification accuracy. The result in Table II shows that the classification accuracy of the DT after pruning (DT-Prune) is improved to 96.63%, which further confirmed the effect of pruning. Compared with K-CV-SVM, GA-BP and DT-Prune found that the classification accuracy of K-CV-SVM model is 98.88%, and only one sample is wrong. The K-CV-SVM model has the best performance in three models.

TABLE I. PARAMETER OPTIMIZATION RESULT CONTRAST

|  | Random | GA | PSO | K-CV |
|---|---|---|---|---|
| c | 13 | 3.2708 | 32.7842 | 1.4142 |
| g | 17 | 3.6738 | 4.4621 | 1 |
| Accuracy (%) | 74.1573 | 97.7528 | 97.7528 | 98.8764 |
| MSE | 0.2584 | 0.0225 | 0.0225 | 0.0112 |
| $r^2$ | 0.5907 | 0.9637 | 0.9637 | 0.9820 |
| Time(s) | 0.9340 | 12.6566 | 16.7837 | 5.2956 |

TABLE II. COMPARISON WITH OVERALL PERFORMANCE OF THREE PREDICTION METHOD

|  | SVM |  | BP |  |  | DT |  |  |
|---|---|---|---|---|---|---|---|---|
|  | K-CV | Best | Worst | GA-BP | Best | Worst | DT-Prune |
| Right Number | 88 | 89 | 67 | 83 | 87 | 70 | 86 |
| Wrong Number | 1 | 0 | 22 | 6 | 2 | 19 | 3 |
| Accuracy (%) | 98.88 | 100 | 75.28 | 93.26 | 97.75 | 78.65 | 96.63 |
| Time(s) | 5.36 | 1.22 | 2.76 | 0.96 | 1.56 | 1.55 | 2.65 |

## IV. CONCLUSION

SVM classification prediction model solves the problem of nonlinear and small sample, but the effect of classification has a great relationship with the parameter setting. According to the theory of SVM, the penalty factor (c) and the kernel parameter (g) have the greatest influence on the classification result. Therefore, the paper analyzes the efficiency of the four methods to optimize the parameters of SVM. Experiments show that the optimal parameters of SVM can be obtained by K-CV and the classification accuracy is highest. In order to further illustrate the conclusion, the BP and DT are designed as the contrast model. The final results show that K-CV-SVM model has a good overall performance both in classification and regression, and it is an effective method for classification and prediction.

Parameter optimization is of great significance to ensure the accuracy of the prediction model. At the same time, the convergence speed of the algorithm and the running time of the program are also a factor that cannot be ignored, especially in the case of huge samples. The results in Table II show that the K-CV-SVM model has the highest classification accuracy, but the running time of system is also the most. Therefore, the next step is to study how to ensure the accuracy rate at the same time to speed up the convergence rate and reduce the time consumption.

*Abstract*—The internet of things (IoT) is a collection of common physical things which can communicate and synthesize data utilizing network infrastructure by connecting to the internet. IoT networks are increasingly vulnerable to security breaches as their popularity grows. Cyber security attacks are among the most popular severe dangers to IoT security. Many academics are increasingly interested in enhancing the security of IoT systems. Machine learning (ML) approaches were employed to function as intrusion detection systems (IDSs) to provide better security capabilities. This work proposed a novel distributed detection system based on machine ML approaches to detect attacks in IoT and mitigate malicious occurrences. Furthermore, NSL-KDD or KDD-CUP99 datasets are used in the great majority of current studies. These datasets are not updated with new attacks. As a consequence, the ToN-IoT dataset was used for training and testing. It was created from a large-scale, diverse IoT network. The ToN-IoT dataset reflects data from each layer of the IoT system, such as cloud, fog, and edge layer. Various ML methods were tested in each specific partition of the ToN-IoT dataset. The proposed model is the first suggested model based on the collected data from the same IoT system from all layers. The Chi2 technique was used to pick features in a network dataset. It reduced the number of features to 20. Another feature selection tool employed in the windows dataset was the correlation matrix, which was used to extract the most relevant features from the whole dataset. To balance the classes, the SMOTE method was used. This paper tests numerous ML approaches in both binary and multi-class classification problems. According to the findings, the XGBoost approach is superior to other ML algorithms for each node in the suggested model.

*Keywords*—*Intrusion detection system (IDS); internet of things (IoT); ToN-IoT dataset; machine learning (ML)*

## I. INTRODUCTION

The internet of things (IoT) is a network of everyday physical objects which can communicate and synthesize data utilizing the current network infrastructure by connecting to the internet. These things are networked digital appliances or sensors that can collect data and transmit it across the internet. New applications and services are created as a result of the interplay between sensors, connectivity, people, and processes. In the IoT, these digital sensors or devices are known as "things" [1].

As IoT networks become more prevalent, they become more prone to security breaches. Cyber security attacks are one of the most common serious threats to IoT security. These attacks take several forms and target various resources on a wide range of IoT devices. These cyberattacks frequently target a large number of devices in an IoT network, which may then be utilized as a "resource" or "platform" for attacks such as distributed-denial-of-service (DDoS) and fraudulent operations such as ransomware and password attacks. As a result, securing IoT devices and building malicious (intrusion) detection models for IoT systems is becoming increasingly vital for protecting sensitive data[2].

Because the security of broad IoT is vital, it is critical for identifying IoT risks and defining current prevention methods. This work outline and categorize IoT security threats categories and common defense methods to give the reader the security foundation they need to understand the work[2]. The following are some of the reasons why IoT security procedures vary from those used in traditional security systems:

- IoT systems' computational power, memory capacity, battery life, and network bandwidth are all restricted. As a result, existing standard security solutions, which are often expensive in terms of resources, cannot be installed.

- IoT systems are widely scattered and heterogeneous. As a result, traditional centralized solutions may be ineffective. Furthermore, the distributed nature of IoT introduces new obstacles and restrictions to its security.

- IoT solutions are employed in an ever-changing physical context. Physical attacks, as a result, have been added to the list of typical security issues.

One of the IoT security protection solutions is IDS. An IDS [3] is software and/or hardware that monitors a network or system for hostile activity and issues quick alarms. Since 1970 IDSs have been used. They are divided into two categories: i) deployment and ii) detecting methods. There are two types of IDS deployments: HIDS and NIDS. HIDS (Host-based Intrusion Detection System) is an intrusion detection system installed on a host machine (i.e., a device or a Thing). They keep track of and evaluate system application files and the operating system. Insider intrusion detection and prevention are best accomplished through HIDS. NIDS (Network-based

Intrusion Detection System) captures and analyzes network packet traffic. To put it another way, they are sniffing packets. NIDSs are effective against external intrusion attacks. After the intrusion has occurred, the following situation will explore. An exemplary detection system is one that rapidly recognizes the compromised condition and minimizes the loss (s). IDSs come in many different forms. all categories of IDSs are presented in [4].

Signature detection(knowledge-based)[5], Anomaly detection (behavior-based) [6], and Hybrid detection are the different detection types of IDSs.

An intrusion prevention system (IPS) [7] is used to keep off intruders. An IPS reacts quickly and prevents harmful traffic from passing through by deleting sessions, restarting sessions, blocking packets, or proxying traffic. On the other hand, an IDS replied once an attack has been detected. Inline detection, layer seven switches, deceptive systems, application firewalls, and hybrid switches are all examples of IPS.

During the study experimentation, the following stages will be followed:

*1)* Choosing ToN-IoT as a new dataset [8]. The dataset was thoroughly analyzed by removing the flow identification attributes to eliminate bias and overfitting and preprocessing the data.

*2)* The ToN-IoT dataset also has many issues, including class imbalance, categorical attributes, and missing values. For challenges using the ToN-IoT dataset, a hybrid approach was provided.

*3)* The ToN-IoT dataset was utilized to test several machine learning (ML), which are: naïve bias (NB), logistic regression (LR), decision tree (DT), k-Nearest Neighbor (KNN), support vector machine (SVM), random forest (RF), XGBoost, Adaboost.

The subsequent are the research's major contributions:

*1)* Propose a distributed machine learning IDS for IoT with comparison to another research.

*2)* Most existing detection algorithms are evaluated using the NSL-KDD, KDD-CUP99, and UNSW-NB15 datasets. These databases are out of date and do not cover current IoT threats. However, the effectiveness of the proposed model is evaluated using an actual ToN-IoT dataset. As assessment measures, accuracy, precision, recall, F1-Score, and false-positive rate (FPR) are utilized.

*3)* Resolving issues with the ToN-IoT dataset, such as class imbalance, missing values, and irrelevant attributes that impact the IDS model's performance.

*4)* The Chi$^2$ and correlation matrix were used to select the most important attributes.

*5)* The class imbalance problem was solved using the SMOTE approach.

The paper organization is as follows: The sections below provide a short overview of IDS for IoT. The ToN-IoT dataset is briefly described in Section III. In Section IV is described the experimental techniques. In Section 5, the findings of the experiments are discussed. Finally, in Section VI, the conclusion is offered.

## II. RELATED WORK

Previously, many machine learning methods were used to malicious datasets in malicious intrusion detection research. IoT devices, as previously stated, are lightweight and low-powered devices with limited computing ability to run traditional antimalware solutions [9]. As a result, research is undertaken to address these issues.

Alhanahnah et al [10] set out to solve this problem by developing IoT malware detection technologies that could operate effectively on any platform while being lightweight despite resource limits. Lightweight signatures were created from high-level code to create the suggested solution. The investigation proved that the signature generating mechanism is effective. The proposed method was found to have an 85.2 % detection rate with zero false positives using analytical approaches.

Ngo and Nguyen [11] also investigated the increase of malware targeting IoT sensors and enhanced the efficacy of current malicious software detection techniques. The research looked at several prior studies on IoT security. The pros and cons of various malware detection technologies were examined and contrasted. The study discovered that the ELF-header approach had a low false detection rate of 0.2 % using tabular comparisons. Furthermore, employing the coding scheme to combine malware samples enhanced detection accuracy to over 98 %, according to the data.

Su et al. [12] suggested a lightweight technique to detect and classify DDoS malware and normal IoT applications. The research used a convolutional neural network to conduct experiments, allowing resource-constrained IoT devices to function normally. The correctness of the suggested design was tested using a five-fold validation technique. With an average accuracy of 94 %, the recommended design predicted malware.

Nguyen et al. [13] also assessed the efficacy of three deep learning-based techniques in identifying IoT malicious software. The models were developed using attributes 1) fixed-size-byte series, 2) fixed-size-color image, and 3) variable sized-sequence data. The fixed-size byte sequence strategy was less accurate than the variable-sized and fixed-size color picture approaches, with an accuracy of 90.58 %. However, the study was regarded as initial, and the authors recommended that further tests be conducted to increase the accuracy.

Alasmary et al. [14] used multiple datasets to see the relationships and variations between malicious software on various systems. A method was constructed and utilized for categorizing android malware, IoT malware, and non-threatening samples using control flow graphs. A 10-fold validation procedure was used to assess the performance of these models. The convolutional neural network (CNN) model was shown to have a 99.66 % accuracy in detecting IoT malware from normal samples in the study.

Hasan et al. [15] used artificial neural networks (ANN), SVM, and LR as machine learning algorithms to identify attacks and abnormalities in IoT sensors at IoT sites. With a

99.4 % accuracy, the experiment suggests that CNN is the preferable approach to apply in IoT for intrusion detection systems.

Authors [16] suggested a revolutionary real-time, distributed, and lightweight IDS, efficiently combining edge, fog, and cloud computing. It enables sophisticated data processing at the intermediaries' level, decreasing the amount of data sent to the cloud. As a result, processing occurs at hubs, routers, or gateways. The IDS's AIS architecture is made up of three parts:

A training engine: trains detectors using data from an initial learning dataset. Because it necessitates complicated and powerful processing units, this stage is handled on the cloud layer.

An analyzer examines abnormalities provided by detectors in order to warn and reject false positive signals. To increase precision, the authors apply memory cell detectors and genetic algorithms. The analyzer engine is installed at the fog layer since this stage necessitates a greater connection between the infected edge nodes and the main engine.

Detector sensors: Each node in the network is equipped with detecting logic. Various detectors might recognize each form of attack in the suggested IDS, which is intelligent and distributed. When a threshold is exceeded, the anomaly is transmitted to the analyzer engine, resulting in an intrusion warning.

The essential work strengths are as follows: a) Combination of innovative analysis in the cloud with lightweight analysis in the fog-layer; b) botnet attacks are detected using a smart strategy, and c) detection of zero-day attacks and unknown attacks based on an online self-training method. The lightweight IDS efficiency was evaluated using two datasets: SSH Brute Force dataset, and KDD-Cup99. According to testing data, the three-layered suggested approach achieves a 3.51 % false-positive rate (FPR) with 98.35% and 97.83% precision.

A real-time combination of specification-based and anomaly-based IoT IDS was proposed by Bostani and Sheikhan [17]. It may be used to identify sinkholes and selective-forwarding attacks in 6LowPAN networks. This IDS operates in two stages: router-level specification detection and root-level anomaly detection. First, the routers examine aspects of the traffic of a network and host nodes on a local level. The first phase's findings are forwarded to the root node for the second step and then deleted from routers to save memory and CPU resources. At the root node, the second phase is global intrusion detection, which involves performing anomaly-based analysis on entering data packets. To demonstrate appropriate real-time detection, they use three main experimental tests, each with ten simulations: the first contracts with assessment values, the second with network scale (small and medium-size) to confirm independent scale-network IDS, and the third with the option to extend detected attacks such as wormhole. According to the results of simulated situational experiments, the proposed hybrid technique may reach a true positive rate of 76.19 % and a FPR of 5.92 %.

Moustafa et al. [9] introduced an ensemble NIDS based on existing statistical characteristics to reduce harmful events, including botnet cyberattacks against HTTP, MQTT, and DNS protocols in IoT systems. The model has three phases: a) Using a thorough study of the TCP/IP model, a collection of attributes is derived from the network traffic protocols. The authors used the Bro-IDS tool for the basic characteristics and created a new extractor module (that collaborates with Bro-IDS) to derive further statistical aspects of transactional processes. b) The correlation coefficient is applied to the result attributes in this step-in order to obtain the essential ones. This phase allows NIDS's computational cost to be reduced. An ensemble technique using the AdaBoost (Adaptive Boosting) algorithm disperses the network data. Then, to identify attacks, Decision Tree (DT), NB, and ANN ML algorithms are used. When compared to individual ML algorithms, the AdaBoost technique improves detection performance. It is capable of dealing with any situation through the computation of an error function, the minor differences of the feature vectors are used to learn and select which learners can correctly categorize each instance of the input data, and the error function is assigned to each occurrence. They used the UNSW-NB15 and NIMS botnet datasets. The ensemble approach achieved between 95.25 % and 99.86 % of DR and 0.01% to 0.72 % of FPR.

Nguyen et al. [18] presented a self-learning anomaly-based IDS (DoT) that was autonomous. Their solution consists of Security Gateways that monitor system devices, as well as an IoT security service (which might be a service provider) that detects abnormalities in a device-type-specific mode. Network devices are automatically grouped based on their manufacturer's hardware and software specifications. Then, for each device type, anomaly models will be created. According to the authors, the used algorithm is Gated Recurrent Units (GRU), which is a recurrent neural network (RNN) that can train efficiently with little training data. As a result, final GRU models result from a collective learning process involving multiple Security Gateways while maintaining privacy. This IDS approach appears to be communication-efficient and ideal for distributed systems such as the internet of things. In order to identify the Mirai virus, the authors test their approach in a real-world smart home deployment. They have a DR with 95.6 % and no false alarms in 257 ms.

Illy et al. [19] presented a fog-to-things IDS architecture. The detecting method is implemented on two levels: the fog and cloud layers of the system. On the one hand, this design enables the authors to deal with their computationally demanding ML detection induced by ensemble learning (a combination of ML algorithms). On the other side, owing to fog detection provides for low latency detection and, consequently, quick reaction. As a result, anomaly detection is conducted first in the fog layer; if the traffic is detected as an attack, an alert is delivered to the security administrator. Additional analysis is performed in the cloud to categorize the kind of attack and provide it to him. They used a multi-expert mode and a multi-stage technique to evaluate alternative ML combinations. On the NSL-KDD dataset, they achieved 85.81 % overall accuracy for binary classification and 84.25 % overall accuracy for attack classification, respectively.

TABLE I.    A SUMMARY OF APPROACHES FOR IOT MALICIOUS DETECTION

| Authors | Study purpose | ML-methods | Data used for Evaluation |
|---|---|---|---|
| Alhanahnah [10] | Developing IoT malware detection technologies that could operate effectively on any platform while being lightweight despite resource limits. | Statistical technique | IoT malware dataset |
| Su [12] | Detecting and classifying DDoS | CNN | IoT DDoS malware dataset |
| Nguyen [13] | Identifying IoT malware. | Deep learning | They prepare their own data |
| Alasmary [14] | Detection of IoT network attacks. | KNN- ID3- Random Forest- AdaBoost-Multi-layer perceptron (MLP)-Naïve Bayes (NB) | Bot-IoT |
| Hasan [15] | Identifying attacks and anomalies | Neural Networks (NN), SVM, and logistic regression | Data collected from Kaggle |
| Hosseinpour [16] | Distributed IDS | Artificial Immune System (AIS) | KDD99 and SSH Brute Force from ISCX |
| Bostani [17] | A mixture of specification-based and Anomaly-based IDS | Unsupervised-Optimum Path Forest | NSL-KDD |
| Moustafa[9] | An ensemble NIDS | Decision Tree (DT), NB, and ANN | UNSW-NB15 |
| Nguyen [18] | A self-learning anomaly-based IDS | a recurrent neural network | Real-world smart home |
| Illy [19] | A fog-to-things IDS | ensemble learning | NSL-KDD |
| Gonzalo et al. [20] | Detecting IoT attacks | CNN, LSTM | KDD99, NSL-KDD, CISC2010 |
| Shafiq [21] | A new-feature selection algorithm. | Decision Tree (C4.5)-SVM-RF-NB | BoT-IoT |

Gonzalo et al. [20] demonstrated an embedded IoT micro-security that uses a CNN prototype to identify URL-based cyberattacks on a client's IoT devices. For botnet detection, the add-on works in concert with an RNN-LSTM model housed on the back end servers. With an accuracy of 94.30 % and an F-1 score of 93.58 %, CNN can detect phishing attacks. Botnet attacks are detected using LSTM with a 94.80% accuracy when all malicious in the dataset are utilized.

Shafiq et al. [21] demonstrated a malicious intrusion model for IoT. this study developed a new feature selection technique and tested the newly developed technique on several machine learning techniques such as s, C4.5 decision tree, and Random Forest classifiers; they got more than 95% accuracy. A summary of algorithms that are used to construct IDS for IoT is presented in Table I.

## III. STATE-OF-THE-ART DATASETS

KDD99 and NSL-KDD are the most extensively used NIDS/HIDS datasets. For assessment and testing, public attack datasets such as CAIDA [22], DEFCON [23], ADFA IDS[24] , KYOTO [25], and ISCX 2012 [26] are accessible. The most recent are either unlabeled data or unavailable data from certain nations, or data exclusive to a domain.

KDD99 [27] is a dataset used for constructing the robust NIDS for detecting "dangerous" connections from "great" ones. The dataset is a feature-extracted edition of the DARPA dataset. KDD99 comprises data from a military network with inserted attacks that are divided into four categories: i) DoS; ii) remote to user; iii) user to root; iv) probing. Using the Bro-IDS tool, KDD99 is based on 41 attributes for each sample+, as well as the class label. The attributes are divided into four categories [27]:

- 1–9: the fundamental attributes of each TCP connection.
- 10-22: attributes suggested by domain knowledge.
- 23-31: a two-second time frame was used to calculate traffic attributes.
- 32-42: host capabilities are intended to evaluate cyberattacks lasting longer than two seconds.

KDD99 is common and widely used for experimental analysis by security researchers. Various efforts [28, 29] were created to minimize the number of characteristics by picking the most important ones from the initial 41. However, numerous studies, such as [30, 31], have found KDD99 to have drawbacks, a few of the most notable ones:

The probability distributions of the testing and training sets diverge. To put it another way, KDD99 has imbalanced categorization.

- The data set is no longer current (1999).
- New attacks are not available.
- The data collected are not from an IoT system.

NSL-KDD [32] is an improved version of KDD99 that addresses its shortcomings. First, duplicate entries are deleted from the whole dataset. Second, a range of samples from the original KDD99 was chosen to acquire accurate findings from classifier systems. Third, the issue of an uneven probability distribution is no longer an issue. The lack of current low-footprint attack scenarios is a fundamental flaw in this collection.

UNSW-NB15 [33] was built by the Australian Centre for Cyber Security in 2015. Its purpose is to create a mixture of modern real-world activities and synthetic modern attacks behaviors. There are around two million and 540,044 records in four CSV files. Those records were created from 100GB of raw data recorded using the tcpdump utility (in pcap files).

The IoT dataset by Sivanathan et al. [34, 35]. Deals with categorization for IoT sensors based on network traffic characteristics. The authors provide a brilliant ecosystem for 28 IoT sensors, including cameras, lighting, plugs, motion sensors, appliances, and health-monitoring devices. They use statistical analysis to provide essential insights into network traffic patterns utilizing attributes such as port numbers, activity cycles, signaling patterns, and encryption suites. They also synthesized network traffic traces from their infrastructure for six months and provided them to the scholarly community.

The CICIDS database [36] is a recent Intrusion dataset provided by the Canadian Institute for Cyber-security, to represent the most recent attacks similar to real-world data. It was created using HTTP, HTTPS, FTP, SSH, and e-mail protocols to model the abstract behavior of 25 users. CIC-FlowMeter examines the data, including labeled data based on timestamps, starting, and ending IP addresses, ports, protocols,

and attacks. The authors developed the B-Profile technique to describe the behavior of FTP, SSH, HTTP, HTTPS, and e-mail protocols in order to simulate realistic traffic. While capturing the data, the authors used Brute Force FTP, SSH Heartbleed, and DDoS attacks. Unlike current standard IDS datasets, the assessment system [37] identified eleven critical attributes required to develop a valid benchmark dataset.

The CSE-CIC-IDS 2018 [38] dataset is a one-of-a-kind IDS dataset that has emerged to replace poor datasets that restrict IDS/NIDS experimental assessments. CSE-CIC-IDS2018 is an anomaly-based dataset containing intrusions in the network to overcome the usage of signature datasets: a) dos; b) Heartbleed; c) botnet; d) brute-force; e) DDoS; f) and web attacks were among the seven attack scenarios mentioned by the authors. The attack architecture consists of 50 nodes, whereas the target organization is divided into five departments, each with 30 servers and 420 hosts. CICFlowMeter-V3 was used to extract 80 characteristics from network traffic and system logs.

BoT-IoT [39] The ACCS Cyber Range Lab created a network environment based on IoT that includes both regular and botnet traffic. The Ostinato and Node-red tools were used to create IoT and non-IoT network traffic, respectively. The Argus program was used for extracting the dataset's original 42 attributes from a total of 69.3GB of pcap files. The collection comprises 477 normal flows (0.01 %) and 3,668,045 assault flows (99.99 %), totaling 3,668,522 flows. The dataset contains traffic from DDoS, DoS, OS, Data exfiltration, Keylogging attacks, and further DDoS and DoS operations put up on the protocol utilized. The main lack in this dataset is that it comprises over 99 % botnet traffic but just about 1% regular traffic.

TABLE II. AVAILABLE DATASETS

| Dataset | Dataset Advantages | Dataset Disadvantages |
|---|---|---|
| KDD99 | KDD99 is the most widely deployed dataset.<br>• Data that has been labeled and has 41 attributes for each connection and the class description.<br>• DOS, remote-to-user, user-to-root, and probing attacks are all used.<br>• (PCAP) network traffic is provided. | • The dataset is out of date, and KDD99 has imbalanced classes.<br>• Not for the internet of things (IoT) systems. |
| NSL-KDD | • It is an upgraded version of KDD99 that addresses the limitations of KDD99.<br>• no duplicated records in the training and test sets. | •There are not enough current low-footprint attack scenarios.<br>• Not for the internet of things (IoT). |
| UNSWNB15 | It offers real-world modern regular activities and synthetic modern attack behaviors.<br>• Network traffic (PCAP) and CSV files are available. | Because recent attacks and typical network traffic behave similarly, it is more complicated than the KDD99 dataset. |
| Sivanathan Dataset | • This IoT network traffic dataset is based on a real-world IoT network.<br>• CSV and PCAP files are available. | • Data that has not been tagged.<br>• No attack data is required for the IoT device proliferation and traffic characterization. |
| CICIDS | •labeled network flows used for building IDS based on machine learning.<br>• PCAP and CSV files are available.<br>• Brute Force, DoS, Heartbleed, Web-Attack, Botnet, and DDoS cyberattacks. | • Not public.<br>• Not for the internet of things (IoT). |
| CSE-CICIDS2018 | • PCAP, CSV, and log files are available.<br>• Brute-force, Botnet, DoS, DDoS, and Web attacks are all implemented.<br>• It is a dynamically produced dataset that may be modified, extended, and replicated. | • Not public.<br>• Not for the internet of things (IoT). |
| BoT-IoT | • IoT network traffic dataset.<br>• PCAP and CSV files are available. | • The main lack in this dataset is that it comprises over 99 % botnet traffic but just about 1% regular traffic. |

KDD99 is the most often used network dataset, as indicated in Table II. Since 1999, it has been in use. It is, unfortunately, out of date. NSL-KDD was built to overcome the limitations of KDD99. There are no duplicate records, and the data is balanced. UNSW-NB15 was proposed as a replacement for NSL-KDD, which lacks contemporary attacks. It is a well-known dataset that has been subjected to recent attacks. Meanwhile, when it comes to similarities between new attacks and normal activities, it is more complicated than KDD99. The Sivanathan et al. dataset, CSE-CIC-IDS 2018, and CICIDS are examples of more recent network datasets. Compared to the other datasets offered, Sivanathan's work is the only one that includes IoT network traffic. It is, however, intended for the proliferation of IoT devices rather than intrusion detection. CICIDS and CSE-CIC-IDS 2018 have labeled records but do not target IoT system security despite having an up-to-date attack list.

## IV. ToN-IoT Dataset

The ToN-IoT dataset was used in this investigation. The ToN-IoT includes telemetry data from linked devices, Linux operating system data, Windows operating system logs, and IoT network traffic, among other data sources acquired from the entire IoT system. A medium-scale IoT network provides diverse data. ToN-IoT was designed by the UNSW Canberra IoT Labs and the Cyber Range. The ToN-IoT repository contains the ToN-IoT dataset [40]. Furthermore, the ToN-IoT was represented in CSV format with a labeled column indicating attack or normal and a sub-category attack-type. Various types of cyberattacks, such as ransomware, password attack, scanning, denial of service (DoS), distributed denial of service (DDoS), data injection, backdoor, Cross-site Scripting (XSS), and Man-In-The-Middle (MITM) were represented. Various IoT and IIoT sensors were targeted in these attacks, launched, and gathered across the IIoT network. The dataset's details may be found in [40].

*1) ToN-IoT network dataset:* The network ToN-IoT dataset contains 44 attributes and a label classified as normal or attack for each data point. Fig. 1 shows the statistics for network data samples in the train-test ToN-IoT dataset.

*2) ToN-IoT Linux dataset:* Linux datasets are partitioned into three categories disk, memory, and process CSV files. The first CSV file contains attributes for disk usage in normal behavior and attack. The second CSV file is related to memory activity, containing ten attributes, a label column labeled as normal or attack, and an attack-type containing attack type (DoS, DDoS). The last file belongs to processes in Linux operating system. The Linux process ToN-IoT contains 14 attributes and an attack type for each data point. Fig. 1 shows the statistics for all Linux data records in ToN-IoT.

*3) ToN-IoT Windows dataset:* Windows datasets are contained records for windows 7 & 10. Windows 7 CSV file contains 133 attributes, labeled as normal or attack, and attack-type containing attack type (DoS, DDoS). Windows 10 CSV file contains 125 attributes, labeled as normal or attack and attack-type, which contain attack type (DoS, DDoS). The statistics for all Windows data in the ToN-IoT were presented in Fig. 1.

The network ToN-IoT dataset statistics records.

The windwos 7 ToN-IoT dataset statistics records.

The Linux ToN-IoT dataset statistics records.

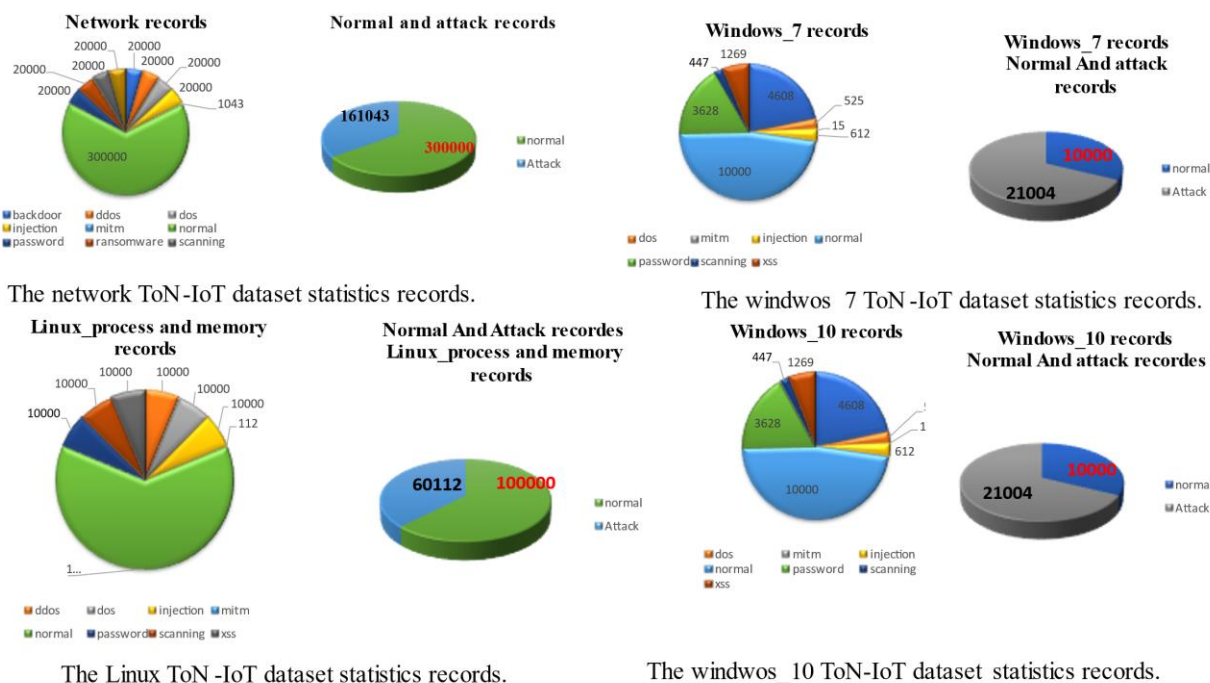
The windwos_10 ToN-IoT dataset statistics records.


Fig. 1. ToN-IoT Statistics.

## V. Distributed IDS

This part of work discusses the architecture of the proposed model, system components of the proposed detection model, and the various detection nodes in proposed model.

### A. Model Architecture

The primary purpose of the suggested detection system for IoT networks is to make on-demand security services more convenient while also preventing attacks. The proposed detection system employs a machine learning for detecting attacks in the network traffic within the IoT network and in all other nodes in IoT systems. As shown in Fig. 2, the proposed detection system functions primarily in various stages/phases - cloud phase, fog-network-detection phase, and a fog-host detection phase.

### B. Machine Learning Methods

The ToN-IoT dataset has been used to evaluate various machine learning (ML) approaches. The chosen algorithms are utilized for training, and testing ML approaches with various parameters in the preprocessing phase of data for intrusion detection. The accuracy, precision, recall, F1-Score, false-positive rate (FPR), and confusion matrix were used to evaluate the different classifiers. The methodologies utilized have demonstrated great performance in the production of IDSs and have proven to be successful in various industries. This study look at the logistic regression (LR), naïve bias (NB), support vector machine (SVM), decision tree (DT), random forest (RF), k-Nearest Neighbor (KNN), Adaboost, and XGBoost techniques, among others [41], [42].

### C. Model Nodes

In this section each node in the proposed model will discussed.

*1) Malicious network detection node (Cloud layer):* The framework for malicious/intrusion detection comprises the default procedure in machine learning:

    *a)* Data preprocessing and feature engineering.

    *b)* Training machine learning models.

    *c)* Evaluate the selected model.

The deployed IDS in the cloud was established using various feature-engineering techniques discussed in the next section.

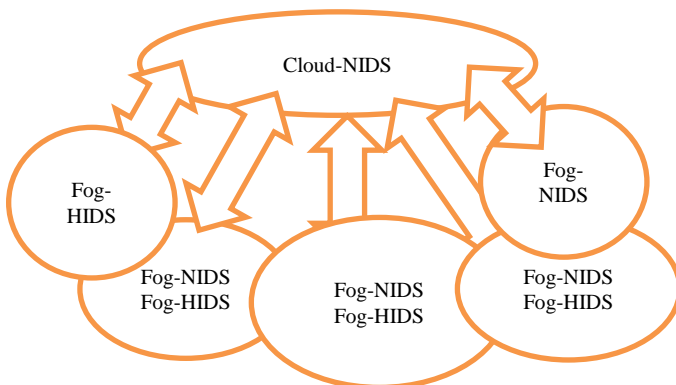

Fig. 2. The Proposed Detection System.

ToN-IoT preprocessing: Filtering and preparing are the most critical steps before supplying data into machine learning in order to achieve high performance. The used dataset has numerous obstacles, including missing values, categorical characteristics, and class imbalance. Unnecessary attributes may impact the performance of the chosen ML algorithms. Using permutations of multiple preprocessing and normalizing strategies, this work tested the selected ML algorithms using several preprocessing techniques.

- Missing value imputation: Missing values are common in the ToN-IoT. These missing values must be addressed appropriately. In the proposed model, the imputation of missing values is substituted with the most frequent value in each feature containing missing data. A second an approach was imputed numerical features using mean value.

- Converting categorical attributes to numerical: There are various categorical attributes in the ToN-IoT dataset. Numerical values must be assigned to the category characteristics. One-hot encoding was used to achieve this goal.

- Class-imbalance: The SMOTE technique was utilized to balance the classes in the used dataset. The ToN-IoT dataset is plagued with class imbalance distributions. Solutions to the imbalanced problem, oversampling, under-sampling, and hybrid techniques were proposed. Oversampling is the practice of duplicating the minority class points. Several researchers utilized it. However, this approach has the drawback of overfitting these spots. Others employ under-sampling, which reduces the dominating class's score. The problem with this method is that some of the elements that have been removed may be necessary for accurately portraying the class. A hybrid strategy was used; it duplicates minority class points while removing certain majority class points. Synthetic Minority Oversampling Technique (SMOTE) [43], [44] enhances basic random oversampling by providing synthetic minority class samples, addressing the overfitting problem that can occur with simple random oversampling. SMOTE creates new data points instead of replicating old ones. A linear combination of two comparable minority samples is used to generate extra minority data points.

- Several attributes such as timestamp, IP-address, source-port, and destination_port were removed from the dataset since they may cause overfitting.

The two key steps used during feature-engineering development are preprocessing based on the mentioned dataset challenges and data normalization. For high performance, ML approaches are evaluated using a variety of feature-engineering techniques:

Feature selection: Various aspects must be checked for intrusion detection, some of features will be valuable while others will be useless. The feature selection procedure is assigning a score to each potential feature and picking the best (k) attributes. A function of both is obtained by counting the frequency of a feature in training for each positive and negative

class occurrence separately. Non-essential attributes are removed, increasing accuracy, decreasing computation time, and reducing the overfitting problem, resulting in better performance. The used feature selection technique was Chi$^2$, which is a filter method.[31], [45].

$$X^2 = \sum_{i=1}^{m} \sum_{j=1}^{n} \frac{(O_i - E_i)^2}{E_i} \qquad (1)$$

where m indicates the no of attributes, n indicates the no of classes, $O_i$ is the observed frequency, and $E_i$ is the expected frequency.

- Data normalization: The ToN-IoT contains attributes with varying values, and some attributes have larger values than others. Because a technique may be slanted toward characteristics with larger values, differing values out of range might lead to inaccurate results. As a result, data normalization is critical in preventing outweighing attributes with greater values over attributes with smaller values by scaling the feature vector. Min-Max is used to scale data between [0:1] as presented in Eq. (2).

$$Z = \frac{x - x_{min}}{x_{max} - x_{min}} \qquad (2)$$

where x reflects the feature-value, Z reflects the feature-value after normalization, the maximum and minimum values of the feature are $x_{max}$ and $x_{min}$.

The training process: All ToN-IoT datasets are in CSV extension; initially, the ToN-IoT dataset was divided into two sets. The first set comprises training with 70% of the dataset. The second set contains unseen data for evaluating the performance of the selected ML algorithms. Before employing any preprocessing to the ToN-IoT, the splitting step was completed to avoid data leaking. The effectiveness of the chosen machine learning algorithms is evaluated using a variety of assessment measures, which will be provided in the next section. The previous steps associated with evaluating the performance of various ML algorithms utilizing ToN-IoT datasets are summarized in Fig. 3 and 4.

Classifier performance evaluation: Based on the ToN-IoT dataset, numerous metrics were utilized to assess the efficacy of various machine learning approaches. The chosen assessment techniques were chosen because they provide a detailed explanation of the outcomes for machine learning-based malicious detection [46].

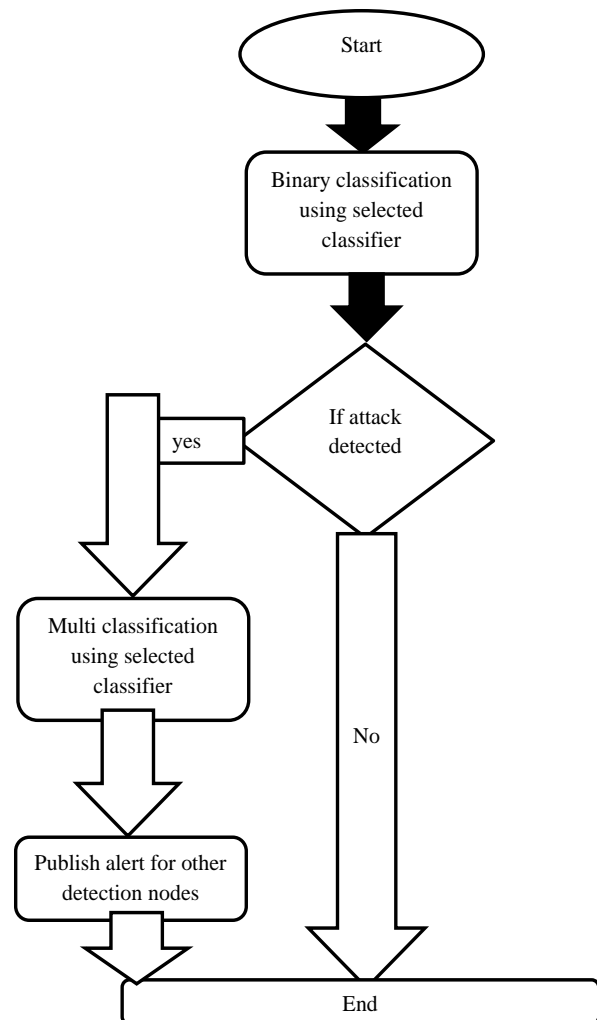
Fig. 3. The Procedure to Evaluate Network Dataset [41].


Fig. 4. The Overall Process for Malicious Detection.

The first metric is accuracy, which measures a technique's overall efficiency as a proportion of instances accurately identified as normal or attacks. The precision metric, which shows the proportion of accurately recognized attacks out of all

detected attacks, is the second metric. The third metric is recall, which represents the proportion of properly recognized attacks in the test dataset as a fraction of all attacks. The fourth metric is the F1-score. The final metric was the false-positive rate (FPR) [46]. These carefully chosen metrics are defined as follows:

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \qquad (3)$$

$$\text{Precision} = \frac{TP}{TP+FP} \qquad (4)$$

$$\text{Recall} = \frac{TP}{TP+FN} \qquad (5)$$

$$F1-score = 2 \times \frac{(precison * recall)}{(precision + recall)} \qquad (6)$$

$$\text{FPR} = \frac{FP}{FP+TN} \qquad (7)$$

Where true positive (TP) is the total number of actual attack records that are correctly identified as attacks. True Negative (TN) refers to the total number of real records that are correctly classified as normal records. False Negative (FN) refers to the total number of real attack samples that are incorrectly detected as normal. False Positive (FP) refers to the total number of normal samples that are incorrectly identified as attacks.

*2) Malicious network detection node (Fog layer):* In the fog computing layer, this work offer an IDS in the proposed architecture. Devices in this tier have more effective attributes than those on the IoT edge layer. It is feasible to use intrusion\ malicious detection to monitor the IoT system without sending the data to the cloud, eliminating the latency issue that has plagued several studies advocating cloud layer analysis. The fog layer has processing nodes nearest to the physical IoT system, processing instruments, and edge storage to identify threats more quickly. A binary classification approach and a multi-class classification method are used in the architecture to detect intrusions.

The process is shown in Fig. 5.

*1)* The fog node connects each terminal device to the network using various protocols and collects data created by each terminal sensor in real-time[47].

*2)* The original data is preprocessed and trained by the cloud server: The entire training dataset is collected on the cloud server, and the entire training procedure is completed there, including the generation, and saving of a training model.

*3)* The fog node transmits a detection command: After establishing a communication link with the terminal device, the fog node gathers a considerable quantity of network data and sends a detection instruction to the cloud server.

*4)* The cloud server provides the training phase: The cloud server sends the data preprocessing pipeline and the trained classification prototype to the fog node after receiving the detection instruction.

*5)* Fog-node detection: The fog-node receives the model and utilizes it for data preprocessing and detection, producing detection results.

*6)* Malicious response: The discovered anomalous data are forwarded to the malicious response module, which performs the necessary processing [47].

In the fog layer, the same malicious network IDS model was used, it was trained in the cloud layer.

*3) The host malicious detection node (fog layer):* The fog layer contains the operating system (OS) devices in the IoT system. a malicious detection model was deployed for each device in the fog layer in the IoT system. The deployed model is called a host intrusion detection system. A host IDS is considered to run on a single machine and protect it from interruptions or malicious attacks that could harm the device – or data. A HIDS uses the measurements in the host environment. These supplies are sent into the HIDSs as input.

Based on the selected ToN_IoT dataset, two operating systems (Linux and Windows 10&7) were included in the dataset. Based on these data, an intrusion model was designed for each partition of data to detect included attacks.

*a) Windows dataset (preprocessing):* The correlation study significantly influences the applicability of attributes in defining security events using machine learning models. We built a correlation coefficient function [43] for ranking the attributes powers into a range of [-1, 1] in order to estimate the correlation coefficient between the attributes without the label characteristics on the Windows 7 and 10 datasets. The direction of the link is indicated by the sign of the correlation coefficient, while the magnitude (i.e., how near it is to -1 or +1) reflects the strength of the relationships between the characteristics [43]. The correlation matrix was tweaked to find the most associated attributes with a cut-off value of 0.85 % or above. Table III shows the top ten most associated traits in each dataset. As presented in Table III illustrate the most linked attributes of the Windows 7 and 10 datasets, respectively. Machine/deep learning algorithms would.

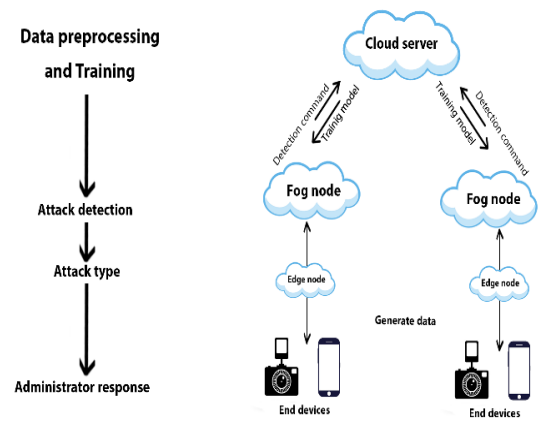

Fig. 5.    Cloud-Fog Intrusion Detection Scheme.

TABLE III. THE TOP TEN ATTRIBUTES

| Attributes ( win_7 ) | Attributes ( win_10 ) |
|---|---|
| Process _Total _IO Other _Bytes_sec | Network_I.Intel_R.._82574_L_GNC_ Current_Bandwidth |

*b) Preprocessing of Linux dataset:* Linux datasets are partitioned into three categories: disk, memory, and process. Timestamp and CMD attributes were eliminated from the dataset for obtaining high performance and far away from overfitting. The Correlation-matrices of the most critical attributes in the Win_7 dataset and Win_10 are extracted from another paper [48].

## VI. DATASET EVALUATION

In this part, the architecture of the suggested model was evaluated; the evaluation is based on binary classification and multi-class classification.

The presented results in this section are based on the best outcomes from the experimentations, other outcomes for classifiers such LR, NB, Adaboost, and SVM are neglected since these classifiers have poor results.

Malicious detection for network dataset evaluation (cloud layer):

Based on the newly available ToN-IoT dataset, the efficiency of the deployed machine learning approaches were investigated for malicious identification. The best parameters stated in the literature were selected [49], [50]. The experiments for this work were carried out in Python 3.8. All trials were run on a Windows 10 computer with a Core i7 processor and 16 GB of RAM. An experimental methodology was utilized to evaluate the effectiveness of the selected ML algorithms using the ToN-IoT network.

- Binary classification [41]: The results for the network dataset are introduced in this section. In addition to the confusion matrix, the accuracy, precision, recall, F1-score, and FPR are offered to evaluate the chosen ML algorithms. In general, the XGBoost produces considerable results for binary classification depending on multiple feature engineering strategies applied to the dataset.

Using all attributes, for XGBoost, the training accuracy is 0.992 %, the testing accuracy is 0.991 %, the recall is 0.984 %, the precision is 0.991 %, and the F1-score is 0.987 %, according to the results. With a significance of 0.007, k-Nearest Neighbor (KNN) exhibits relevance in the scenario of false-positive rate (FPR). The findings for the best ML techniques are shown in Table IV. The kNN, on the other hand, was the second-best technique. The training accuracy is 0.989 %, the testing accuracy is 0.988 %, the recall is 0.986 %, the precision is 0.979 %, and the F1-score is 0.983 %, according to the kNN findings. Naive bias is the poorest technique (NB). The heterogeneity of data in ToN-IoT datasets might explain the ML technique's performance variances. The findings of RF and DT are practically identical.

As a feature selection strategy, the $Chi^2$ was used. After using $Chi^2$ to evaluate ML algorithms based on a variety of criteria, because the optimum assessment measure is obtained with only 20 features, the best 20 attributes were selected from the total 108 attributes. After $Chi^2$, XGBoost provides considerable results, almost identical to testing with all characteristics. The training accuracy is 0.984 %, the testing accuracy is 0.983 %, the recall is 0.984 %, the precision is 0.967 %, the F1-score is 0.975 %, and the FPR is 0.008 %, according to the findings. The KNN approach was the second-best technique. Naive bias is the poorest technique (NB). ). The findings for the ML techniques are shown in Table IV.

Because ToN-IoT has an issue with class imbalance, another testing approach based on SMOTE was used; XGBoost and KNN also have the same best outcome with 0.990 % accuracies. Recall is 0.976 %, accuracy is 0.997 %, F1-score is 0.986 %, and FPR is 0.013 % for XGBoost in terms of other assessment criteria. KNN has a recall of 0.981 %, accuracy of 0.990 %, F1-score of 0.985 %, and FPR has the highest score of 0.001 % to other ML algorithms. XGBoost is superior to KNN since it requires less training and testing time.

Finally, the selected ML algorithms were assessed using $Chi^2$ and SMOTE for binary classification. With $Chi^2$ and SMOTE, KNN produces considerable results. The findings for the ML techniques are shown in Table IV.

- Multi-class classification: The dataset contains an attribute type that displays the attack sub-class for multi-class classification tasks, as stated before. There are ten sub-classes in ToN-IoT. In this part, candidates' ML methods will be analyzed for evaluating multi-classification tasks. When assessing prospective ML methods for a multi-class classification task, several factors must be considered. To begin, LR is most commonly employed to solve binary classification task and cannot be immediately used for multi-class classifications. As a result, to construct LR for multi-class classification, the one-vs-rest (OvR) approach is applied. Accuracy, precision, recall, F-score, and confusion matrix are the assessment measures used to compare all models. The multi-classification findings are summarized in Table V. When comparing all ML algorithms, XGBoost achieves decent results. The training accuracy for XGBoost is 0.986 percent, the testing accuracy is 0.983 %, the recall is 0.953 %, the

F1-score is 0.949 percent, and the FPR is 0.008 %. KNN comes in second with scores of 0.981 % for training accuracy and 0.979 % for testing accuracy, and the AdaBoost classifier has the worst metrics of all tested ML methods. SVM is the most time-consuming in terms of training and testing.

The Chi$^2$ feature selection methodology after was used evaluating all of the specified ML algorithms over the whole dataset. Chi$^2$ will assess all ML algorithms with the best 20 attributes from all 108 attributes. XGBoost achieves considerable results in binary classification, for example. The training accuracy is 0.985 percent, the testing accuracy is 0.982 %, the recall is 0.950 %, the precision is 0.943 %, the F1-score is 0.946%, and the FPR is 0.008 %. Table V. displays the results of all ML techniques applied with the Chi2 approach.

KNN was the second-best approach, AdaBoost is the poorest model.

Another approach based on the SMOTE technique was used. As seen in Table V, XGBoost outperforms other commonly used ML algorithms. Finally, the selected ML algorithms were assessed using the Chi$^2$ and SMOTE methodologies on the basis of the multi-class classification issue. With the Chi$^2$ and SMOTE methods, XGBoost achieves considerable results. The training accuracy of XGBoost is 0.980 %, while the FPR is 0.019 %. Table V. displays the outcomes of chosen ML approaches using the Chi$^2$ and SMOTE techniques.

In the cloud layer, the network intrusion detection was suggested to be deployed in the cloud for binary and multi-class classification problems, as shown in Fig. 6.

TABLE IV.    THE RESULTS OF THE BINARY CLASSIFICATION (NETWORK_DATA)

| Data | Models | Train Acc | Acc | Precision | Recall | F1-score | FPR | Confusion Matrix |

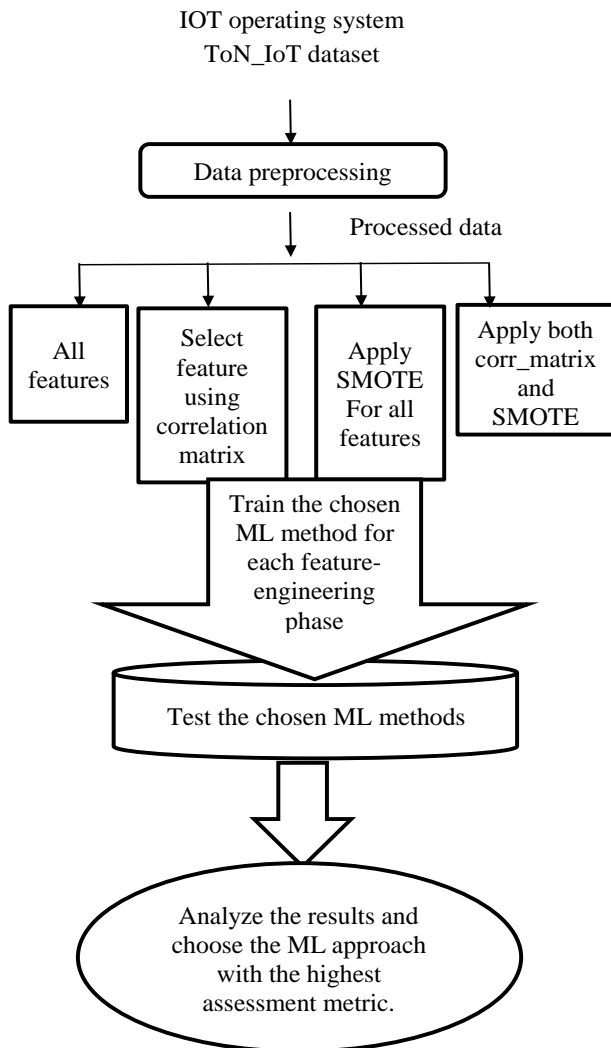

Fig. 6. The Process for Evaluating ML Methods on the OS ToN-IoT Dataset.

After applying various feature engineering techniques for the network ToN_IoT dataset, the XGBoost classifiers obtains optimal results using chi2 and SMOTE techniques that were used for class balancing and feature selection.

- Malicious detection for Linux dataset evaluation (fog layer): The same intrusion model was deployed in the fog layer with the same specification as discussed in earlier sections.

- Linux dataset evaluation (fog layer): This section focuses on the effectiveness of the used ML techniques for host malicious detection using the newly released Linux ToN-IoT dataset. Linux dataset was partitioned into three categories process, disk, and memory.

- Process_Linux (Binary classification): This section showed the findings for the Linux ToN-IoT dataset. In general, XGBoost is useful for binary classification. This experiment begin by impute missing values and then use the Min-Max normalization approach. Training accuracy is 0.994 %, testing accuracy is 0.993

%, recall is 0.990 %, precision is 0.991 %, and F1-score is 0.991 %, according to the findings. In terms of false-positive rate (FPR), XGBoost is significant at 0.005%. Table VI displays the results of all ML techniques applied without the SMOTE approach. The KNN approach, on the other hand, was the second-best methodology.

Because ToN-IoT has a class imbalance issue, another testing methodology based on SMOTE approach was used; RF and DT had the same better outcome with 0.992 % accuracies. In terms of other assessment measures, F1-score is 0.989 % for DT and RF, and FPR is 0.007 % for DT, which is superior to RF. Table VI displays the outcomes for several ML algorithms.

Multi-class classification (Process_Linux): For multi-class classification tasks, the Linux ToN-IoT dataset includes a feature type that displays the attack sub-category. When assessing prospective ML algorithms for a multi-class classification issue, several factors must be taken into account. The multi-classification findings are summarized in Table VII.

When compared to other ML algorithms, XGBoost achieves decent results. The training accuracy for XGBoost is 0.962 %, the testing accuracy is 0.954 %, the recall is 0.870 %, the precision is 0.909 %, the F1-score is 0.889 %, and the FPR is 0.004 %. DT and RF come in second with scores of 0.981 % for training accuracy and 0.979 % for testing accuracy, and the AdaBoost classifier has the worst statistics of all tested ML methods.

Another procedure was used based on the SMOTE method. As stated in Table VII. DT has the greatest outcomes compared to other used ML techniques.

- Memory_Linux (Binary classification): In this section, the results for memory-based Linux ToN-IoT dataset were presented. In general, RF is significant for binary classification. To begin with, the results reveal that the training accuracy is 0.999 %, the testing accuracy is 0.997 %, the recall is 0.993 %, the precision is 0.997 %, the F1- score is 0.995 %, and the FPR is 0.001 percent, with XGBoost achieving the best second result. Table VIII displays the results of all ML techniques applied without the SMOTE approach. NB is the worst approach.

Because ToN-IoT has a class imbalance problem, another approach based on SMOTE was used; RF produced the best result with 0.997 % accuracy.

- Multi-class classification (Memory_Linux): For multi-class classification tasks, the Linux memory ToN-IoT dataset includes a feature type that displays the attack sub-class. The multi-classification findings are summarized in Table IX.

When compared to other ML algorithms, XGBoost achieves decent results. The training accuracy for XGBoost is 0.986 %, the testing accuracy is 0.982 %, the recall is 0.922 %, the precision is 0.965 %, the F1-score is 0.943 %, and the FPR is 0.001 %. RF comes in second with scores of 0.988 % for training accuracy and 0.982 % for testing accuracy.

TABLE VI.        THE OUTCOMES OF THE BINARY CLASSIFICATION (LINUX_PROCESS_DATA)

Another approach was used based on the SMOTE method. As stated in Table IX, DT has the top outcomes compared to other employed ML methods.

- Malicious detection for windows dataset evaluation (fog layer): This work focuses on the efficiency of the chosen ML methods for malicious detection using the newly released Windows ToN-IoT dataset. The Windows dataset was partitioned into two categories, Win_10 and Win_7.

- Win_10 dataset (Binary classification): In this part, the outcomes for the Windows ToN-IoT were presented.

In general, XGBoost shows significance. Training accuracy is 1.0%, testing accuracy is 1.0%, and F1-score is 1.0%, according to the results. In the case of false-positive rate (FPR), XGBoost shows significance with 0.0. Table X. shows the results for the selected ML methods. Since ToN-IoT suffers from a class imbalance problem, another testing methodology was done based on SMOTE technique, XGBoost has the best result. Table X. shows the results for all used ML methods using SMOTE technique.

Another testing technique was based on the best selected attributes that were selected from a correlation matrix. XGBoost obtains the best result with and without SMOTE. Tables X shows the outcomes for all selected ML methods.

- Multi-class classification (Win_10): For multi-class classification issues, the ToN-IoT dataset includes a feature type that displays the attack sub-category. The multi-classification findings are summarized in Table XI.

When compared to other ML algorithms, XGBoost achieves decent results. XGBoost training accuracy is 1.0, its testing accuracy, recall, precision, and F1-score are all 1.0%, and its FPR is 0.00 %. Another testing approach based on the SMOTE technique was used. As seen in Table XI. XGBoost outperforms other commonly used ML algorithms.

- Win_7 dataset (Binary classification (Win_7): In general, for binary classification, XGBoost shows significant results for windows 7 dataset. Table XII displays the outcomes for the selected ML method.

ToN-IoT has a class imbalance problem, another testing methodology was done based on SMOTE technique, XGBoost has the best result.

XGBoost obtains the best result with and without SMOTE for multi-class classification. XGBoost shows significant outcomes. Table XIII displays the outcomes for the selected ML method.

## VII. CONCLUSION

Based on the ToN-IoT dataset, this study proposed a unique malicious detection technique for IoT. The ToN-IoT dataset was employed for training and testing, and the suggested model incorporates several essential aspects. There is a problem with a class imbalance in the ToN-IoT dataset, as well as missing values. this work which deal with ToN-IoT can cover more attacks than prior work with obsolete datasets like KDD-CUP99, NSL-KDD, and UNSW-NB15.The ToN-IoT contains nine types of attacks (Scanning, Cross-Site Scripting (XSS), Denial of Service (DoS), Distributed Denial of Service (DDoS), Backdoor, Injection Attack, Password Cracking Attack, Man-In-The-Middle (MITM), Ransomware.

Exploring, preprocessing, feature selection, class imbalance solution, training ML methods, and testing ML methods are the various system blocks. In a network dataset, the $Chi^2$ approach was utilized to select attributes. It lowered the number of attributes to 20, resulting in a quicker training time, lower model complexity, and the highest performance over the whole dataset. Another feature selection methodology was the correlation matrix which was used in the windows dataset to obtain the most relevant attributes from the whole dataset. The SMOTE approach was utilized to balance the classes. It improved performance by reducing dominant class bias, reducing overfitting, and improving the overall performance. A good evaluation metric was achieved by using Chi2, SMOTE, and correlation matrix as preprocessing approaches. For evaluating the performance of the deployed ML algorithms, many evaluation metrics (accuracy, precision, recall, F1-score, FPR, and confusion matrix) were used. The results determined that XGBoost outperforms all other ML approaches in binary classification and multi-class classification tasks after assessing the selected ML methods. The main contributions of this work are that it uses a new benchmark dataset that is updated with new attacks and gathered from a real IoT system. The gathered dataset reflects data from each layer of the IoT system, such as (the cloud, fog, and edge layers). The proposed model is a distributed malicious model based on a multi-layer for IoT system. Various ML methods were tested in each specific parathion of the ToN-IoT dataset. The prosed model is the first suggested model that is based on the collected data from the same IoT system from all layers and devices (sensors).

In the future, Deep learning methods such as (recurrent neural network, auto-encoder, and convolution neural network) will be used in the ToN-IoT dataset. More work might be done in the future to enhance the performance of the baseline techniques on the datasets. Advanced parameter optimization approaches (for example, Bayesian optimization and the genetic algorithm) can be used to optimize the model's hyperparameters and get superior outcomes.

*Abstract*—The COVID-19 infection was sparked by the severe acute respiratory syndrome SARS-CoV-2, as mentioned by the World Health Organization, and originated in Wuhan, Republic of China, eventually extending to every nation worldwide in 2020. This research aims to establish an efficient Medical Diagnosis Support System (MDSS) for recognizing COVID-19 in chest radiography with X-ray data. To build an ever more efficient classifier, this MDSS employs the concatenation mechanism to merge pretrained convolutional neural networks (CNNs) predicated on Transfer Learning (TL) classifiers. In the feature extraction phase, this proposed classifier employs a parallel deep feature extraction approach based on Deep Learning (DL). As a result, this approach increases the accuracy of our proposed model, thus identifying COVID-19 cases with higher accuracy. The suggested concatenation classifier was trained and validated using a Chest Radiography image database with four categories: COVID-19, Normal, Pneumonia, and Tuberculosis during this research. Furthermore, we integrated four separate public X-Ray imaging datasets to construct this dataset. In contrast, our mentioned concatenation classifier achieved 99.66% accuracy and 99.48% sensitivity respectively.

*Keywords—COVID-19; deep learning; transfer learning; feature extraction; concatenation technique*

## I. INTRODUCTION

A group of viruses named Coronaviruses, which includes MERS-CoV, SARS-CoV, and finally SARS-CoV-2, are likely reasons for mild to severe respiratory illnesses [1]. As reported in the report from the World Health Organization, the COVID-19 infection was espoused by the severe acute respiratory syndrome SARS-CoV-2 and originated in Wuhan, Republic of China, before spreading to every country and territory throughout the world in 2020 [2]–[4]. Furthermore, in the preliminary days of SARS-CoV-2, various respiratory symptoms including hyperthermia, cough, shortness of breath, exhaustion, and finally pneumonia are frequent [5], [6]. COVID-19 influences the cardiovascular and respiratory systems, and in extreme situations, it might result in multiple organ dysfunction syndrome or acute respiratory distress.

As a necessary consequence, COVID-19 diseases have become a major health concern that has spread globally. As a result, emerging innovations are important in preventing the outbreak of the epidemic. For these reasons, researchers throughout the world collaborate and work on strategies to overcome the virus's obstacles. In particular, new Artificial Intelligence (AI)-based methods can eliminate interpersonal physical-contact [7]–[11]. Drones, for instance, might be used

to sterilize public areas and thermal cameras could be used to detect rising temperatures.

In reality, the two subsets of AI are employed to health data analysis: the first subset is Machine Learning (ML) and the second is Deep Learning (DL) approaches, including radiography images or computed tomography scans, have been shown to be useful on detection of illness and monitoring [12]–[14], [15]–[17]. As a result, various types of human maladies, like as Parkinson's disease [18]–[21], brain tumor segmentation [22], [23], breast cancer [24], diabetes [25], medical image segmentation [26], and heart disease prediction [27]–[30], atherosclerosis diseases [31], could be identified using such techniques. AI advancements have also contributed in the development of a wide range of other scientific fields [32]–[34], [35]–[39].

This research focuses to establish a consistent MDSS [40] for monitoring COVID-19 in Chest Radiography data from a variety of virus diseases and pulmonary infections [41]–[44]. The essential innovation of this MDSS is the employment of the concatenation mechanism to merge pretrained convolutional neural networks (CNNs) predicated on Transfer Learning (TL) techniques to generate an efficient classifier. As a result, we integrated four separate X-Ray image databases in this work to introduce a further dataset, containing four categories: COVID-19, Viral Pneumonia, Normal, and finally Tuberculosis. Our suggested classifier was trained and validated using this novel dataset.

The remainder of this paper is organized as follows: The materials and methods are presented in Section II. The experimental results and discussion are presented in Section III. Finally, in Section IV, we conclude our work with some future research prospects.

## II. MATERIALS AND METHODS

### A. Schematic of the Planned COVID-19 Monitoring MDSS

We present, in this research, an automated method for classifying COVID-19 cases predicated on different TL classifiers (Fig. 1). This automated approach proposed is founded on the concatenation mechanism among two pretrained classifiers of the TL approach. This approach integrates the information taken from both Base-Models to construct the final classification result, which improves performance. To begin, we use the Keras library to choose two pre-trained classifiers (VGG16 and VGG19). The training and testing datasets of chest X-Ray images were produced using

four main public databases. COVID-19, Normal, Pneumonia, and Tuberculosis cases are included in this dataset. The pictures in the produced database are subjected to a series of preprocessing operations. By using the default channel of the network's input structure, all the Chest Radiography images were standardized to similarly input sizes (224×224×3).

In this architecture, the X-Ray training dataset is used to train our proposed concatenation classifier. We employ a cross-validation approach to validate the training phase after we have constructed the classifier to prevent the over-fitting problem. Our proposed classifiers' classification results were then evaluated using the testing dataset. Finally, the suggested concatenation classifier's performance was assessed using confusion matrices and a variety of score measures.

### B. Dataset Description

This subsection gives a summary of the datasets used during this research. This work was focused on the gathering and analysis of four public databases separated into four classifications: "COVID-19", "Tuberculosis", "Normal", and finally "Viral Pneumonia". The final dataset employed is mentioned in Table I. We exhibit different exemplary instances of the obtained dataset in Fig. 2.

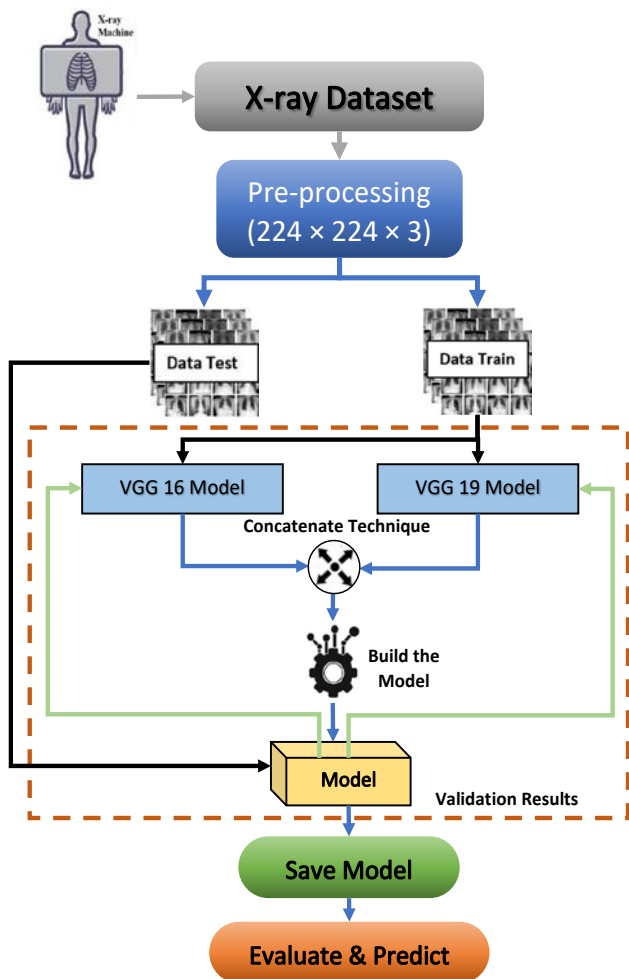

Fig. 1.    Schematic Depicting the Planned Classification MDSS Design.

### C. Background on TL Algorithms

Instead of developing and learning a CNN from scratch, the TF technique can be used. This technique is a paradigm of machine learning and as such, it is concerned with the knowledge and expertise gained while performing a task. In deep learning, this strategy is applied where the beginning points are saved as pretrained classifiers. This makes it easier for training and accurate efficiency. VGG16 and VGG19 are two pre-trained CNN classifiers that are shareable, and available. They had already been trained on a number of databases, including ImageNet. On a vast scale, it's a massive hierarchical image database. The technical structure of the TL classifiers is depicted in Fig. 3.

Fig. 3.    The Detailed Structure of the TL Classifiers: (a) VGG16 Classifier; (b) VGG19 Classifier.

### D. Planned Concatenation Classifier Depending on TL Technique

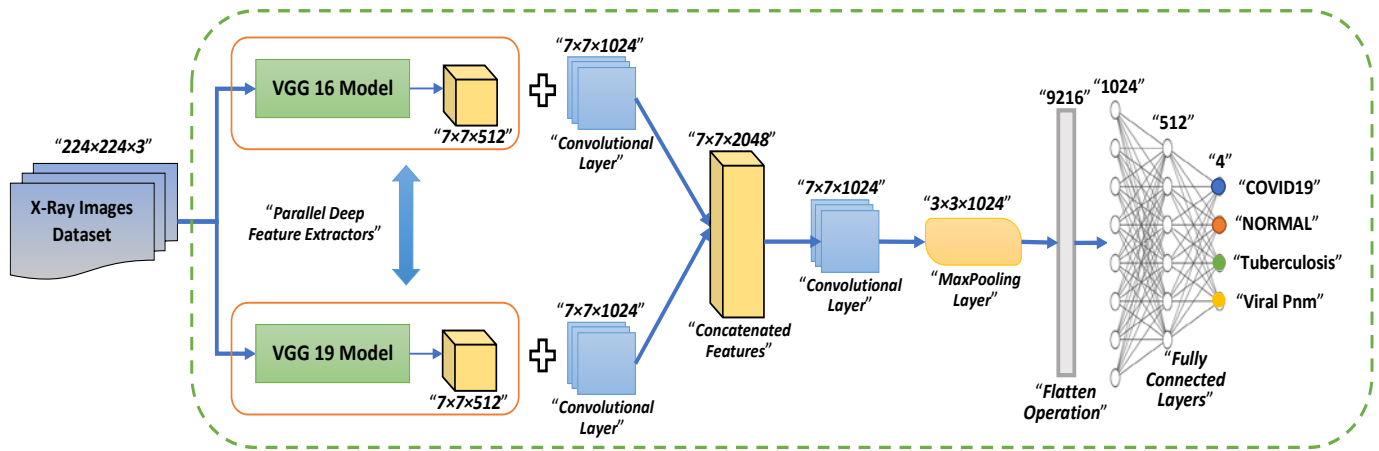
This subsection explains the technical structure of our classifier, which is shown in Fig. 1. In fact, we used two modified pre-trained TL classifiers, VGG16 and VGG19, both having an identical configuration input dimension, to build our recommended classifier with an initial input size of 3 channels, and 224×224 dimension (224×224×3). The entire flowchart of this classifier is shown in Fig. 4.


Fig. 4.    The Suggested Concatenated Classifier's Design.

## III. RESULTS AND DISCUSSION

### A. Classifier Performance Evaluation

*1) Confusion matrix and evaluation metrics:* The confusion matrix gives additional feedback about the performance of a classification algorithm, including properly predicted classes, incorrect classes, and the types of errors made. This will help to gather four critical factors for calculating the accuracy of the proposed classifier. TP (True Positive), TN (True Negative), FP (False Positive), and finally FN (False Negative) are the four elements. Expressions below give the confusion factors for the "COVID-19" class as depicted in Table II.

The five indicators employed in this work to evaluate our proposed classifier: Precision, Specificity, Sensitivity, Negative Predictive Value (NPV), and the last indicator is Accuracy.

*2) Cross-validation technique:* In the ML challenge, the Cross-Validation (CV) technique employs the K-Fold CV method. In fact, we begin by separating the data into training and testing sets. Folds have been generated from our training set, which have been divided into K subsets. Thereafter, we repeatedly fit the model K times, training the data on folds K-1 and assessing fold K each time. At the completion of the training, we average the performance on each of the folds to determine the classifier's final validation metrics. Fig. 5 provides a CV method implementation example.

TABLE II.    DEFINITION OF CONFUSION MATRIX FACTORS

| Confusion Factors | Definition |
|---|---|
| TP | The number of Chest Radiography images that are forecast exactly as COVID-19. |
| TN | The number of Chest Radiography images that are forecast exactly as not COVID-19. |
| FN | The number of Chest Radiography images that are forecast erroneously as not COVID-19. |
| FP | The number of Chest Radiography images that are forecast erroneously as COVID-19. |

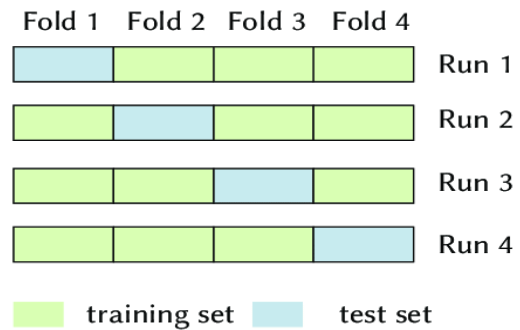

Fig. 5.    Example of the Cross-validation Method Implementation with a K-Fold Equal to 4.

### B. Experimental Results

*1) Results of the planned classifier training:* The planned concatenation classifier was built on the Google Collab platform, in this work. It's an AI virtualization technology (Cloud Computer Service) for AI research. An Intel Xeon Processor with 2 cores running at 2.20 GHz, 13GB of RAM, and finally a Tesla K80 GPU with 12GB of GDDR5 VRAM were used in this workstation. To validate this work, we used 4-fold cross-validation to build our planned concatenation classifier over 25 epochs to assure similar results. The charts for our Chest Radiography image datasets training and validation for fold 4 are described in Fig. 6.

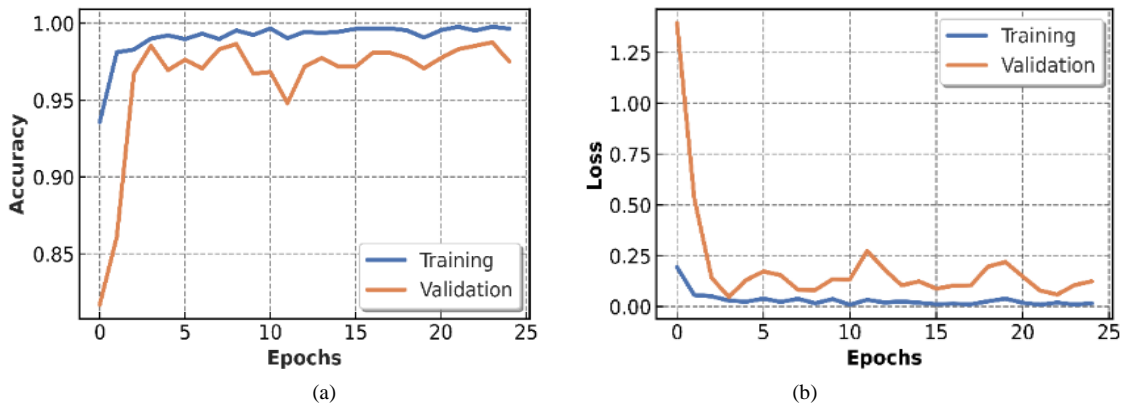
*2) Results of the planned classifier testing:* We may infer that our suggested classifier gives a robust classification of the four classes based on the results of our research. For all classification k-fold classifiers, the TP value for all categories, is higher than either the FP and FN numbers. In all k-fold classifiers, the COVID-19 class of FP and FN values is lower than the other classes. This indicates that our concatenation classifier has a low risk of confusing COVID-19 infected instances. The confusion matrix of the concatenated classifier for all folds is shown in Fig. 7.


Fig. 6.    Curves Produced in Fold 4: (a) Accuracy; (b) Loss.

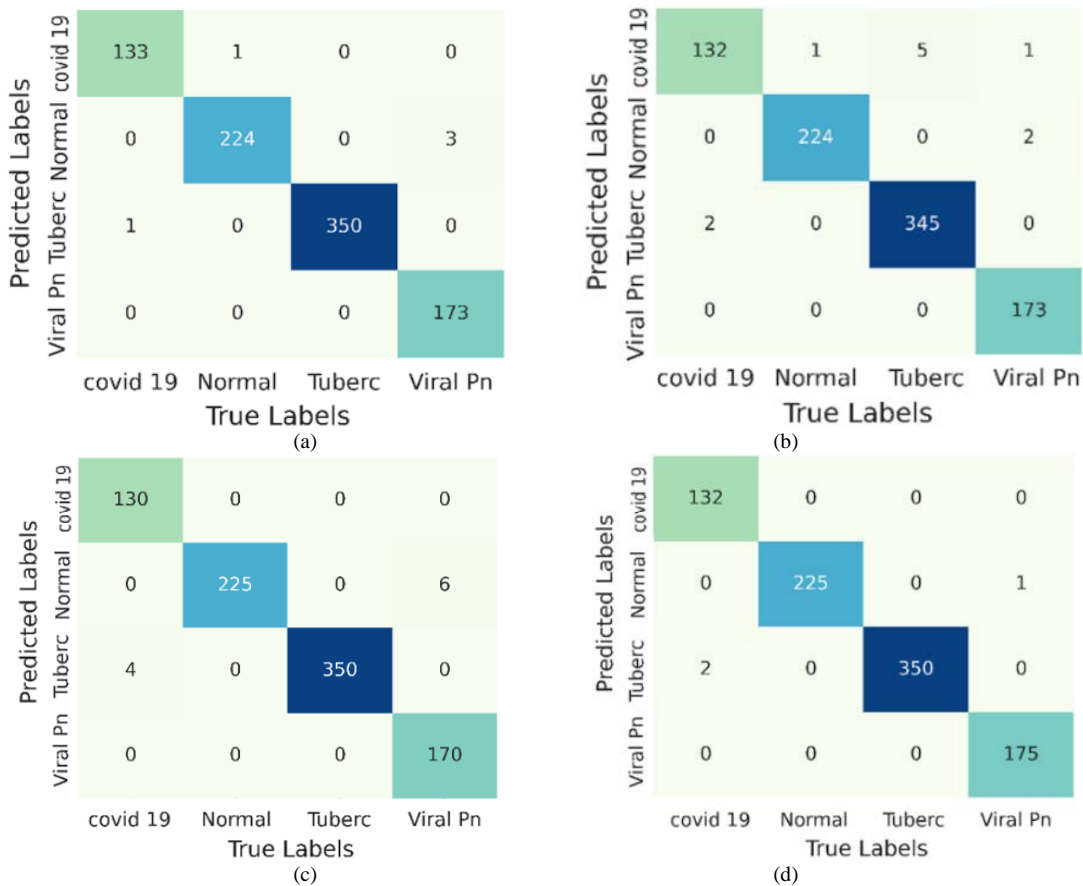

Fig. 7.    The Confusion Matrix of the Concatenated Classifier: (a) 1-Fold CM, (b) 2-Fold CM, (c) 3-Fold CM and (d) 4-Fold CM.

A ROC curve could be used to examine these results. This diagnostic test depicts the ratio of False Positive Rate against True Positive Rate as represented by this curve. A ROC curve, in general, helps to compare several classifiers based on the AUC variable's value. The ROC curve for our concatenation classifier in fold four is shown in Fig. 8.

Table III presents the performance evaluation scores of our proposed concatenation classifier for each fold to help elucidate these results.

### C. Discussion

In this paper, we developed an innovative COVID-19 diagnostic classifier based on a concatenation mechanism and two pre-trained TL classifiers. The goal of this proposed classifier is to provide the best algorithm possible for the detection of COVID-19 cases. This classifier was built and tested applying a dataset of produced Chest Radiography images from four different databases. Tuberculosis, Pneumonia, Normal and COVID-19 are the four classes in this dataset. In fact, we noticed in the experimental results section that our proposed classifier had a 99% accuracy for all folds. Furthermore, this classifier has a loss value of less than 3%.
Fig. 8. ROC Curves Findings for the Concatenated Classifier in Fold 4.

Many specialists from around the world have written and published articles on the coronavirus that causes COVID-19 disease in the previous two years. In recently published findings, AI Algorithms have been utilized to examine X-Ray images and assist in the diagnosis of infected cases. DL algorithms are the most frequent in image categorization because they produce better results than classical ML methods. In this subsection, we will examine the research published that applies DL approaches to detect COVID-19 by employing innovative methodologies.

COVIDetection-Net is a classifier used in the categorization of Chest Radiography images proposed by the authors in [45]. To extract the features, this classifier uses ShuffleNet and SqueezeNet networks, as well as Multiclass SVM to classify them. The suggested classifier had a 99.44% accuracy using a multi-class database (COVID-19, normal, Bacterial pneumonia, and Viral pneumonia).

Another paper published in [46], proposed a classifier called SARS-Net, by combining Graph CNN and CNN. X-Ray pictures from five different datasets were used to create this classifier, which had a classification accuracy of 97.6%.

A concatenation classifier was suggested in the scientific paper [47], to merge features retrieved employing the CNN with two pretrained models based on TL approaches like as ResNet-18 and GoogleNet. The two datasets used in this study: X-Ray images, and CT scans, contained binary classes: COVID-19, and non-COVID-19 for each dataset. The proposed classifier archived an accuracy of 98.9% and 99.3% for CT and X-Ray images.

The authors published a comparison analysis depending on TL approaches in [48]. This study proposes two modified models: MobileNetV3, and ResNet18. These models were developed using a database that included five categories: "COVID-19", "Tuberculosis", "Normal", "Bacterial Pneumonia", and finally "Viral Pneumonia". The accuracy of the proposed models was 99.3% and 99.6% for ResNet18 and MobileNetV3, respectively.

The mentioned works in this section show an improved recognition models by focusing on the analysis of the dataset used, the optimization of hyper-parameters, or the combination of the performance of several models based on various algorithms. However, feature engineering is an intriguing phase in recognition system development. Indeed, using extracted characteristics improves the performance of a recognition system. Indeed, the success of the categorization system is directly reliant on the recovered primitives. In Table IV, we summarized the performances finding of concatenation-based classifiers in comparison to our proposed classifier.

TABLE III. PERFORMANCE OF THE PROPOSED CONCATENATED CLASSIFIER ON EACH FOLD

| Folds | Loss | Accuracy | Precision | Sensitivity | Specificity | NPV |
|-------|------|----------|-----------|-------------|-------------|-----|
| F1 | 0.027 | 99.43% | 99.41% | 99.28% | 99.81% | 99.82% |
| F2 | 0.030 | 98.75% | 98.38% | 98.73% | 99.60% | 99.56% |
| F3 | 0.051 | 98.87% | 99.07% | 98.40% | 99.59% | 99.66% |
| F4 | 0.015 | 99.66% | 99.75% | 99.48% | 99.87% | 99.90% |

TABLE IV. COMPARATIVE RESULTS FOR THE PROPOSED CLASSIFIER WITH RELATED STUDIES

| Studies | Classifiers used | Accuracy | Precision | Sensitivity |
|---------|------------------|----------|-----------|-------------|
| [45] | COVIDetection-Net | 99.44% | 94.42% | 94.45% |
| [46] | SARS-Net | 97.6% | N/A | 92.9% |
| [47] | Concatenation CNN_ResNet18_GoogleNet | 99.3% | 99.79% | 98.8% |
| [48] | ResNet18 | 99.3% | 99.23% | 99.36% |
| | MobileNetV3 | 99.6% | 99.5% | 99.5% |
| Proposed classifier | **Concatenation VGG16_VGG19** | **99.66%** | **99.75%** | **99.48%** |

## IV. CONCLUSION

In conclusion, using the X-Ray images dataset, we provide a COVID-19 detection mechanism. The proposed concatenation classifier was built and tested utilizing a dataset of Chest Radiography images divided into four categories: COVID-19, Viral Pneumonia, Normal, and Tuberculosis. We integrated four separate online X-Ray picture collections to create this dataset. Concerning the novelty of this work, we use in the feature extraction phase a parallel deep feature extraction approach based on the TL models. This feature extraction approach increases the accuracy of our proposed models, thus identifying COVID-19 cases with higher accuracy. The proposed concatenation classifier achieved 99.6% accuracy and 99.48% sensitivity, respectively.

In future studies, we hope to use the proposed design to classify other illnesses, such as Parkinson's disease, heart disease, and cancer. Nonetheless, we want to use Artificial Intelligence of Things (AIoT) to enhance the resilience and accuracy of our MDSS for monitoring pandemics and tumors. This field is referred to as AIoT, and it integrates IoT infrastructure with artificial intelligence (AI) technology.

*Abstract*—Today, web content such as images, text, speeches, and videos are user-generated, and social networks have become increasingly popular as a means for people to share their ideas and opinions. One of the most popular social media for expressing their feelings towards events that occur is Twitter. The main objective of this study is to classify and analyze the content of the affiliates of the Pension and Funds Administration (AFP) published on Twitter. This study incorporates machine learning techniques for data mining, cleaning, tokenization, exploratory analysis, classification, and sentiment analysis. To apply the study and examine the data, Twitter was used with the hashtag #afp, followed by descriptive and exploratory analysis, including metrics of the tweets. Finally, a content analysis was carried out, including word frequency calculation, lemmatization, and classification of words by sentiment, emotions, and word cloud. The study uses tweets published in the month of May 2022. Sentiment distribution was also performed in three polarity classes: positive, neutral, and negative, representing 22%, 4%, and 74% respectively. Supported by the unsupervised learning method and the K-Means algorithm, we were able to determine the number of clusters using the elbow method. Finally, the sentiment analysis and the clusters formed indicate that there is a very pronounced dispersion, the distances are not very similar, even though the data standardization work was carried out.

*Keywords—Techniques; machine learning; classification; twitter*

## I. INTRODUCTION

The analysis of data derived from social media is of growing importance from various points of view, including academic and economic ones. Currently, there are 4.2 billion users on social networks worldwide, equivalent to 53.6% of the total population [1]. In Peru, there are 26.41 million social network users, equivalent to 81.4% of the population [2].

On Twitter, an average user makes six comments on all types of tweets, follows one user, and shares two tweets on average in 30 days; the number of likes and comments on social media tweets influences users' self-presentation [3]. Social networks are new spaces where groups of users with specific characteristics are centered, allowing them to share expressions, and opinions, these are considered the new means of communication and exchange of web content [4], [5], and the amount of data provided by users and feedback is

enormous, however, there is no predefined method or tool to sort and classify the comments, since knowing the opinions of users is of utmost importance to generate knowledge and make better decisions in the different areas [6],[5],[7].

The AFPs are private institutions whose sole purpose is to manage pension funds in the form of personal accounts that provide retirement, disability, and survivor's pensions and funeral expenses [8]. The objective of the AFP is to protect the older population from the risk of poverty and allow citizens to save for their retirement. This study aims to classify and analyze the sentiments of Twitter users (affiliates) using machine learning models, for this case we will work with the hashtag #afp.

Comments are composed of positive opinions that create a contagion effect, while criticism or negative comments also influence users' decisions [9], by which, it is important to classify and analyze users' sentiments to know their reactions to a certain topic or tweet. Supported by association rule learning and machine learning algorithms, it is possible to discover the relationships between words that associate sentiments [10],[11].

The article is organized as follows. Section II describes the main works related to sentiment analysis. Section III presents the method and case implementation. Section IV describes and discusses the results and discussions. Finally, Section V presents the conclusions.

## II. RELATED WORK

Currently, the Internet and social networks are environments in which large amounts of user data are collected [12]. Comments can negatively affect the reputation of a person or company and be harmed socially and/or economically, it is for this reason, that [13] argues that to generate social capital, it is necessary to work on the feedback generated by users on social networks.

The authors in [14],[15],[16] implemented an analysis model using machine learning classifiers, to measure and predict user profile credibility, the implemented model was evaluated on two different datasets with term frequency and three inverse document frequency variables. Similarly, in [17],[18],[19] identified features that can be useful for predicting whether a tweet or comment is a rumor or

information, using a rule-based approach involving regular expressions to categorize sentences.

In addition, [20] analyzed the existence of malicious users spreading malware or phishing in tweet comments, for which six classifiers were used: random tree, random forest, Naïve Bayes, Kstar, decision table, and decision stump. Likewise, [21] proposed an approach to extract from Twitter the image content, classify it and verify the authenticity of digital images and discover manipulation. Also [22] recommended a topic analysis and sentiment polarity classification with machine learning techniques for emergency management, finding that the most suitable classification model is random forests.

Likewise, [23] developed a system that employs sentiment analysis for product reviews (e.g., the company shares a photo of a new product in a tweet and it receives a thousand new product comments), the system classifies the comments as positive or negative.

Machine learning employs two types of techniques: supervised learning, which trains a model on known input and output data so that it can predict future results. Unsupervised learning finds hidden patterns or intrinsic structures in the input data. In the same context, in [24],[25],[26] the authors used natural language processing methods to detect fake news in social media posts, and also created a semi-supervised learning model for early detection.

In addition, in [27],[28] a supervised learning model for rumor verification using contextual features based on contextual word embeddings, speech acts, and the writing style was presented. In [29] the authors collected unstructured data from social networks, using an application implementing different supervised and unsupervised learning classification algorithms. Similarly, in [30] a novel method for generating opinion summaries in social networks was proposed, using the unsupervised learning technique, in [31] content analysis of textual Twitter data was performed using a set of supervised and unsupervised machine learning methods to appropriately cluster and classify traffic-related events.

Although previous studies considered many aspects of sentiment analysis in social networks, according to the review conducted, there is a gap to be investigated in the use of clustering rules to classify and analyze user sentiments, considering that these results would be of great use to stakeholders, as it would allow them to make better decisions supported with ML.

## III. METHOD AND IMPLEMENTATION OF THE CASE

This section presents the construction of the machine learning terminology, the method, and the detailed implementation of the proposed case study that seeks to predict members' sentiments regarding AFP of Peru.

Machine learning (ML) is a discipline of artificial intelligence that, through algorithms, teaches computers to build models from experience [32]. ML is divided into three types: supervised learning, unsupervised learning, and reinforcement learning, and these in turn are classified into different learning models, as shown in Fig. 1. The study uses

unsupervised learning, and the k-means algorithm, for which we will address only this category.

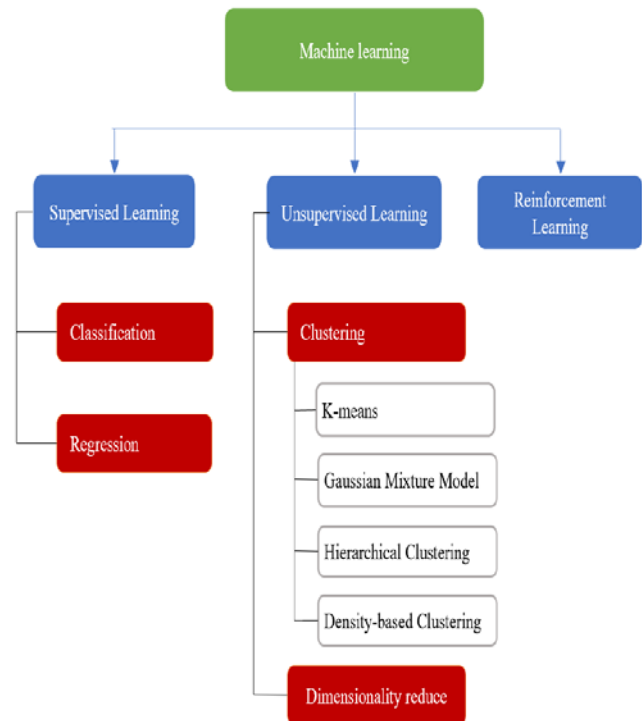

Fig. 1.   Types of Learning.

Unsupervised Learning: It does not require labeled data and can be processed by clustering methods. Clustering is a typical example of unsupervised learning that finds visual classifications that match the hypothesis [14]. The goal of clustering is to find similarities, regardless of the kind of data. Therefore, a clustering algorithm needs to know how to calculate similarity, and then start running.

K-Means: It is a clustering algorithm that combines the "n" observations into "k" clusters that are aggregated together according to specific similarities [33], as shown in Fig. 2.

Fig. 2.   Grouping of K-Means.

The K-Means algorithm follows the following steps:

- Initiation: The location of the centroids of the k clusters is chosen randomly.

- Assignment: Each datum is assigned to the nearest centroid.
- Updating: The centroid position is updated to the arithmetic mean of the data positions assigned to the cluster.

Steps 2 and 3 are followed iteratively until there are no more changes in the location of the centroids, or they move below a threshold distance from each step. The K-means algorithm seeks to solve an optimization problem, the function to be optimized being the sum of the quadratic distances from each object to the centroid of its cluster. The objects are represented by $d$ dimensional real vectors $(x_1, x_2, ..., x_n)$ and the algorithm constructs $k$ clusters where the sum of the distance of the objects, within each object s= $\{s_1, s_2, ..., s_k\}$, to its centroid is minimized. The problem is formulated as follows:

$$\frac{min}{s} E(\mu_i) = \frac{min}{s} \sum_{i=1}^{k} \sum_{x_j \in s_i} ||x_j - \mu_i||^2 \qquad (1)$$

Where S is the data set whose elements are the objects represented by vectors, where each of its elements represents an attribute. We have k cluster with its corresponding centroid $\mu_i$. On each centroid update, from the mathematical point of view, we impose the necessary condition of extrema to the function $E(\mu_i)$ which, for the quadratic function (1) is.

$$\frac{\partial E}{\partial \mu_i} = 0 \implies \mu_i^{(t+1)} = \frac{1}{|S_i^{(t)}|} + \sum_{x_j \in S_i^{(t)}} x_i$$

The k-means algorithm is simple and fast, however, it is necessary to decide the value of K and the final result will depend on the initialization of the centroids.

The Cross-Industry Standard Process for Data Mining (CRISP-DM) methodology was chosen for the development of the case. It is a model that divides the process into six main phases: business understanding, data compression, data preparation, modeling phase, evaluation, and implementation. CRISP-DM has a structured approach, establishing a set of tasks and activities for each phase.

### A. Business Understanding

The AFP is a private institution in charge of managing people's provisional savings. Like any company, with the arrival of COVID-19, the economy of the region has been severely affected and, therefore, the annualized profitability of the AFP has not been favorable. This has led the Congress of the Republic to promote laws such as free disaffiliation, 100% of contributions for those over 55 years of age, among other authorizations for controlled withdrawals under the context of a pandemic for the years 2020 to 2022. Peruvians' perception of the AFP has never been positive, probably because retirement pensions do not meet expectations, among other factors. In this context, the sentiment analysis of the case study aims to analyze and classify the opinions of AFP members. This analysis can help the AFP to make better decisions in its offerings to the market. Fig. 3 shows the general process of sentiment analysis.

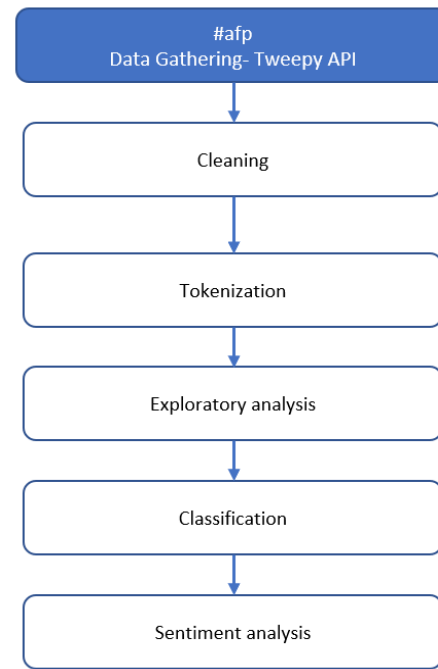

Fig. 3. General Sentiment Analysis Process.

Fig. 3 shows the general process of sentiment classification and analysis. It starts with extraction supported by libraries, then we move on to cleaning and tokenization, this process consists of removing from the text everything that does not provide information about the subject matter. For example, on Twitter, users can write in a way that they consider convenient, such as abbreviations, punctuation marks, web page URLs, single characters, numbers, etc.

Tokenization consists of dividing the text into its constituent units, in this case, words. Next, we perform the exploratory analysis, in this stage, we try to understand and study which words and how often they are used, as well as their meaning. In the Python or R language, one of the structures that facilitate the exploratory analysis is the DataFrame, which is where the information of the tweets is stored. The next step is to perform the classification, in this phase, to be able to apply classification algorithms to the text (tweets), a numerical representation of the text is created.

One of the most used ways is known as the Bag of words, this method consists of identifying the set formed by all the words (tokens) that arise in the corpus. Finally, we proceed with the sentiment analysis, for which it is necessary to have a dictionary in which a sentiment or sentiment level is associated with each word.

### B. Data Comprehension

The dataset for the case study has been collected on recent Tweets from May 2022, related to the hashtag #afp, with coordinates -12.062152, -77.0361328 corresponding to the city of lima. The dataset is composed of 18k tweets. The data we collected contains relevant information about most of the tweets such as their attributes (user_id, status_id, created_at, screen_name, text, source, display_text_width,

reply_to_status_id, favorite_count, replay_to_user_id, replay_to_screen_name, is_quote, retweet_count1, quote_count, media_url, media_t. co, media_expanded_url, etc.) which, in sum, are 90 attributes with 18k tweets to be processed, as shown in Fig. 4.

```
38  tweets_afp <- search_tweets(
39              q = "AFP",
40              geocode = "-12.062152,-77.0361328,20mi",
41              include_rts = FALSE,
42              n = 18000
43          )
```

Fig. 4. Tweet Search and Download Code.

*1) DataSet preparation:* This is an essential step before applying any machine learning model. The DataSet preparation phase starts with a crucial previous step, known as extraction, loading, and transformation, to load the extracted data to a source or data warehouse, in this case, it will be processed in a single computer with the necessary characteristics to support the processing of 18k tweets represented in a DataSet. The phases, as a whole, are described below:

*2) Extraction, loading, and transformation*: This process was implemented with the code illustrated in Fig. 4, the data were stored in a text file, then, supported with the *stringr* library, we performed the first preliminary cleaning, then the text file was converted to a csv file (write.csv ()), then we applied tokenization with the libraries tidyverse, tibble and a personal dictionary in Spanish loaded with the readxl library. And then we used lemmatization, that is, the root of a word that can be written in several forms and refer to the same thing. For example, if the words *pueblo, pueblito, pueblano* are found, the root of these three words is pueblo, thus avoiding redundancy in the analysis, this process is supported in a pre-trained model with the udpipe library, as shown in Table I.

In the next step, we performed an exploratory analysis of the data, using the bag-of-words(bow) model to obtain the most common words in the lexicon, obtaining a list of the most frequent words in the hashtag #afp. Fig. 5 shows a dense word cloud with some of the most used words in the generated corpus, also, it can be seen that several words are found in different positions.

TABLE I. LEMMATIZATION OF WORDS

| senten ce_id | sentence | token_ id | token | lemma |
|---|---|---|---|---|
| 1 | chabelitacongre | 1 | chabelitacongre | chabelitacongre |
| 1 | ayudas | 1 | ayudas | ayudas |
| 1 | pueblo | 1 | pueblo | pueblo |
| 1 | quitando | 1 | quitando | quitando |
| 1 | jubilación | 1 | jubilación | jubilación |
| 1 | problema | 1 | problema | problema |

Fig. 5. Most Popular Words Related to #afp from our Corpus.

Next, the syuzhet dictionary package is used, this package works with four sentiment dictionaries, such as: Bing, Afinn, Stanford, and NRC, in our case, we will work with NRC, since it is the only one available in several languages, including Spanish. This dictionary has 14182 words with categories of feelings, positive, negative, and the emotions of anger, anticipation, disgust, fear, joy, sadness, surprise, confidence, etc. This dictionary is used with the purpose of analyzing and grouping the words of the corpus and to know in which category the feelings are grouped. Fig. 6 shows that the negative sentiment of affiliates is most frequently repeated in the tweets, followed by positive sentiment, fear, confidence, anger, disgust, etc.

Fig. 6. Frequency of Terms in Sentiment Analysis.

Fig. 7 shows the words of the tweets grouped by sentiment, in it, we can analyze each of the words associated with a particular feeling. For example, the word money is the one that mostly generates the feeling of joy, followed by astonishment, confidence, anger, positive and premonition. In

574 | P a g e

the same line, the word congress is the one that mostly generates disgust, likewise, the word government is the one that mostly generates the feeling of fear.

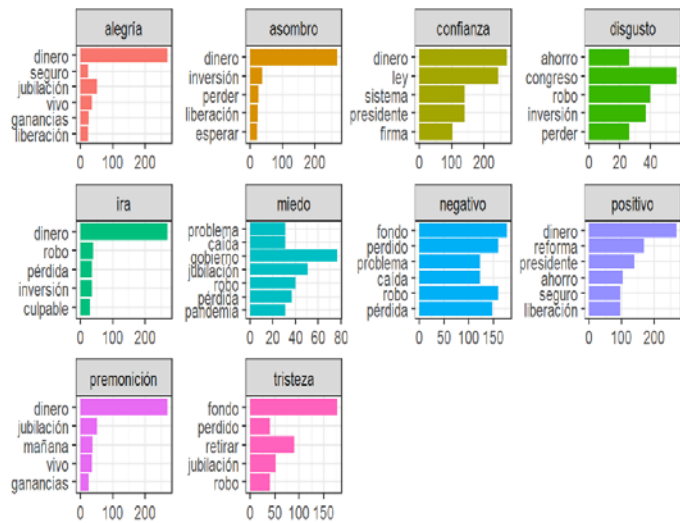

Fig. 7.    Words for Sentiment.

## C. Preparation and Clustering with K-means

At this stage, we have already extracted, cleaned the data and stored it in a text file. Next, we use the TM package, to call the functions VectorSource (), inspect () and removeSparseTerms (), the latter function to remove words that are not very frequent, and finally we convert the text into a word frequency matrix with the TermDocumentMatrix () function. The k-means clustering is a vector quantization method, which tends to find clusters of comparable spatial extent. Part of the code is shown in Fig. 8.

```
407  library(tm)
408  corpus <- Corpus(VectorSource(texto))
409  corpus
410  inspect(corpus)
411  # Printout of a corpus line
412
413  writeLines(as.character(corpus[[100]]))  # basic package
414  content(corpus[[100]])
415
416  d  <- tm_map(corpus, tolower)
417  inspect(d)
418  # Remove custom empty words
419  d <- tm_map(d, removeWords, sw.es)
420  inspect(d)
421
422  # Create Term Matrix with TermDocumentMatrix()
423  tdm <- TermDocumentMatrix(d)
424  tdm
```

Fig. 8.    Use of Libraries in R.

## D. Modeling Phase

In this context, it is very important to analyze the relationship between words with the findAssocs () function of the tm package. The calculation of the findAssocs () function is performed at the document level. Then, for each specific document containing the word in question, the other terms in those documents are associated, the other search terms are ignored. The function returns a list of all the other terms that meet or exceed the minimum threshold (findAssocs (tdm, "afp", 0.40)). The minimum correlation values are usually

relatively low due to the diversity of words. The tweets of the hashtag #afp have been cleaned and organized with tweets_tdm. For the case study, the function findAssocs () searches for the association of terms and manipulates the results with list_vect2df () from the qdap package and then creates the diagram with the ggplot2 library. Fig. 9 shows the strong association represented by the thickness of the lines between the words. The word afp is the root for the association of the other words, such as afp-money, afp-withdrawal, afp-funds, afp-system, afp-years, afp-law, afp-now, funds-withdrawal, withdrawal-law, afp-castle, etc. This association process allows us to know the words most associated and expressed by AFP members.

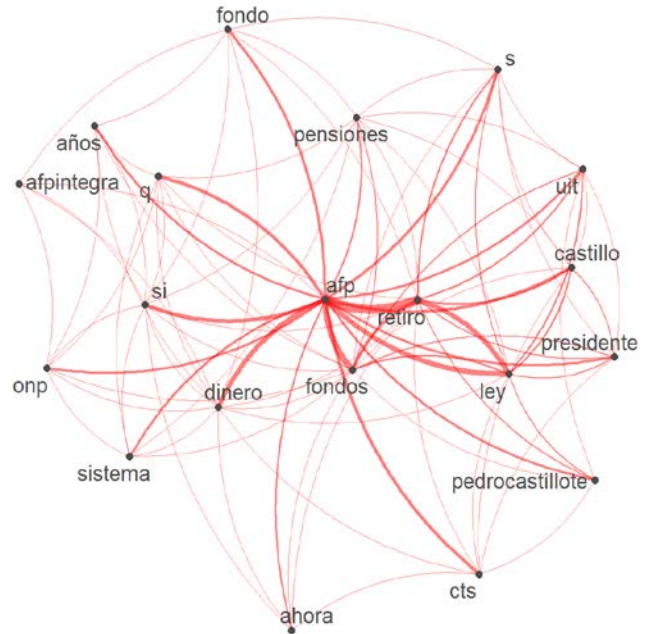

Fig. 9.    Frequency Represented in Line Thickness.

In Fig. 10, the sentiment classification is presented with the overall percentage of each positive, negative and neutral tweet found in the dataset. It can be seen that the sentiment classes are unequal, as a large part of the affiliates express themselves negatively or neutral concerning the hashtag #afp.

Fig. 10.  Sentiment Distribution of the Three Polarity Classes along with the Percentage of Tweets Referring to the #afp Hashtag.

## IV. RESULTS AND DISCUSSION

In this section, we present the performance of the k-means algorithm to obtain the best number of clusters and the results of the case study. In general, most clustering algorithms, including k-means, employ different numbers of clusters, and are evaluated by multiple validity measures to determine the most meritorious clustering results. To measure clustering performance, we use a precision index (IP), where $IP=\sum_{k=1}^{c} n(c_k)/n$, where $c_k$ is the number of data points that obtain the correct clustering for cluster k and n is the total number of data points.

The higher the accuracy index, the better the clustering performance. K-Means clustering is based on data partitioning, data that have the same features are grouped into one cluster, while data that have different features are grouped into other clusters. The steps of K-Means clustering are three: deciding the cluster number k, centroid initialization and assigning the data to the nearest cluster, the determination of the closeness of objects/data is determined based on the distance of objects/data, to calculate the distance of all data to each centroid point, the Euclidean distance theory is used, which is represented as follows.

$$D(i, j) = \sqrt{\left(x_{i1} - x_{J1}\right)^2 + \left(x_{i2} - x_{J2}\right)^2 + \cdots + \left(x_{ip} - x_{Jp}\right)^2}$$

Where:

D (i, j) = distance of the data to the cluster center j.

$X_{ik} = i^{th}$ in the $k^{th}$ date attribute.

$X_{ij} = j^{th}$ center point in the $k^{th}$ data attribute.

The centroid is the average of all data/objects within a particular cluster. Each data/object is reassigned using the new cluster centroid, the cluster does not change, then the clustering process is finished, otherwise, repeat the steps until there is no change for each cluster.

To determine the number of clusters in which the data are grouped, we use the elbow method, this method uses the mean of the observations to their centroid, i.e., it looks at the intra-cluster distances. The larger the number of clusters k, the intra-cluster variance tends to decrease. The smaller the intra-cluster distance the better.

The elbow method searches for the k value which satisfies that an increase of k does not substantially improve the mean intra-cluster distance. To find the number k, 15 clusters were assigned, in Fig. 11 it can be seen that the elbow(k) is formed at point 3, this means that the number of clusters that we will process will be k=3.

Once the number of clusters (k = 3) has been determined, we can start with the data processing. For this, the tweets had to be converted to numerical data, using one-hot encoding for the transformation, as shown in Table II.

It is advisable to scale values and not to introduce variables that are highly correlated or that are linear combinations of other variables, i.e., to avoid multicollinearity. The objective of scaling variables is to make them comparable, that is, to have a mean equal to zero and a standard deviation equal to one. The scaled method is achieved by using the following formula:

$$z(x) = \frac{x_i - centro(x)}{deviation(x)}$$

Where, center(x) is a measure of centrality with mean or median and variance (x) is a measure of dispersion such as standard deviation. The standardization of data is important as it makes the distances similar to that without scaling. Fig. 12 shows a representation by dimensions and the clusters formed. It is clearly observed that a cluster of comments or tweets are very homogeneous, with low values in cluster 1, we refer to the negative sentiment and high values in cluster 2, cluster 3 is presented in the central part with intermediate values in both cluster 1 and 2 corresponding to the positive and neutral sentiments.

Fig. 11. Elbow Method - Number of Clusters.

TABLE II. SUMMARY OF ONE HOT CODING

| Docs | afp | casa | hasta | los | que | seguro | son | tienes | todos | vida |
|------|-----|------|-------|-----|-----|--------|-----|--------|-------|------|
| 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 10 | 1 | 0 | 0 | 2 | 2 | 0 | 0 | 0 | 0 | 1 |
| 2 | 1 | 0 | 0 | 3 | 1 | 0 | 1 | 0 | 1 | 0 |

| 9 | 1 | 0 | 1 | 1 | 3 | 0 | 0 | 1 | 0 | 0 |
Fig. 12. Sentiment Analysis of #afp.

## V. CONCLUSION

In recent years, several approaches have been developed for sentiment analysis on social network data, specifically on Twitter. The process of sentiment analysis is often complex due to the huge amount of data and the need to achieve a high level of accuracy. This study presents the sentiment analysis of Twitter hashtag #afp data, for which the k-means algorithm was used. This algorithm is based on data partitioning, data having the same features that are grouped into a cluster. In this study, eight types of feelings (sadness, foreboding, positive, negative, fear, anger, disgust, confidence, amazement and joy) were used. After applying unsupervised learning with K-Means, it is seen that the negative feeling is the most recurrent, followed by positive feeling, fear, confidence, etc. As shown in Fig. 6 out of a total of 18000 tweets related to the hashtag #afp, tweets with sentiments, positive, neutral and negative represent 22%, 4% and 74% respectively. This means, that machine learning applying the K-Means algorithm proves to be efficient and practical, and can be easily applied for sentiment classification on related topics, where we do not have input and output tags.

This study provides theoretical and practical scopes. Regarding the theoretical scope, the study applies a machine learning approach, with the unsupervised learning method for sentiment analysis of AFP members, using Twitter data with the hashtag #afp. Also, sentiment analysis with machine learning can be applied in different industries such as marketing, services and academia, etc. In terms of practical scope, this study recommends machine learning with the unsupervised method to be applied in cases similar to the study, allowing it to be adapted and improved to achieve a better level of accuracy, especially in complex situations when performing textual analysis.

In this study, from the classification to the analysis of feelings, there was evidence of certain feelings that were most repeated, with negative feelings being the predominant one, with which we can conclude that the members do not feel represented or reject the actions of the AFP, followed by positive feelings, fear, trust, anger, sadness, disgust, premonition, joy and amazement, in that order. This study is not without limitations. Attribute mapping was applied to the initial data set; within this, there may be a diversity of factors, combinations that may affect the classification results. In future work, machine learning with the unsupervised method and the K-Means algorithm can be optimized to improve the accuracy of sentiment detection, classification and analysis.

# Registration Methods for Thermal Images of Diabetic Foot Monitoring: A Comparative Study

Doha Bouallal[1]*, Hassan Douzi[2], Rachid Harba[3]

IRF-SIC Laboratory, Ibn Zohr University, Agadir, Morocco[1, 2]
PRISME Laboratory, Orléans University, Orléans, France[1, 2, 3]

*Abstract*—**This paper presents a comparative study of image registration techniques for Diabetic Foot (DF) thermal images. Four registration methods (Intensity-based algorithm, Iterative closest point (ICP), subpixel registration algorithm, which is mainly based on Fast Fourier Transform (FFT), and the pyramid approach for subpixel registration) have been implemented and analyzed. The performances of the four algorithms were evaluated using several overlap and symmetry metrics such as the Dice similarity coefficient (DSC), Root Mean Square Error (RMSE) and peak signal to noise ratio (PSNR). The methods were analyzed in a first step on the images of contralateral feet (right and left) of the same subject, which is called in this paper "contralateral registration" and in a second step on a pair of images of the same subject but acquired in two different times T0 and T10 after applying a cold stress test, which is called "multi-temporal registration". Results showed that the intensity-based approach and the pyramid approach for subpixel registration algorithm give the best results in both types of registration (contralateral / multitemporal) and can be used efficiently for the registration of these types of images even under changing conditions.**

## I. INTRODUCTION

According to the World Health Organization (WHO) [1], by 2030 diabetes will be ranked the 7th leading cause of death worldwide. Type II diabetes (formerly known as non-insulin dependent diabetes or mature diabetes) results from a misuse of insulin by the body. It represents the majority of diabetes cases. It is largely the result of being overweight and not being physically active. A poorly controlled diabetes has a damaging impact on several organs of the body, namely the eyes (blindness), the kidneys (nephropathy) or renal failure, the heart (cardiac accident), the nervous system (neuropathy), the blood vessels (ischemia, stroke) and complications in the feet as ulcers that can lead to amputation of the lower limbs, known by the diabetic foot (DF) [2] which represents the core of our study. Diabetic foot ulcers are invariably preceded by inflammation, the presence of infection and pain. However, in the early stages of wound development, patients with diabetes may have difficulty experiencing pain due to neuropathic sensory loss [3]. On the other hand, inflammation can be identified by assessing the temperature of the affected foot. Thus, temperature assessment using a thermal camera appears to be a useful predictor of foot ulceration. Research shows that there is a significant relationship between increased temperature and diabetic foot complications [4][5].

Increased temperature can be detected up to a week before foot ulceration occurs. The most commonly used criterion is that if the point to point temperature difference $\Delta T$ of the corresponding area of the right and left foot is greater than 2.2C° [6], there is a high risk of infection or ulceration in diabetic feet. This is called hyperthermia (see Fig. 1) and this temperature difference map is calculated point-to-point between the left and right foot after the process of registration and overlap.

Thermography is a non-invasive technology and does not require any contact with the patient's skin. This allows using it to avoid any undesirable pressures that could affect the temperature measurement, as well as the transmission of pathological organisms. For all these reasons, it has been adopted as the main technology in our study.

In the literature, there are similar works for detecting hyperthermia areas in DF. Fraiwan et al. [7] , used intensity-based registration after segmenting the two plantar surfaces using Histogram shape thresholding, to align the two feet and detect the hyperthermia areas. In [8] they used ICP to register the two feet and calculate the point-to-point temperature difference.

Except that in these works the authors did not detail the performance of these methods or provide quantitative evaluations to assess the accuracy of the registration.

Kaabouch et al [9] separated the original image into two (left foot, right foot), identified the centroid and the farthest heel points of each foot, in order to calculate the angle of the feature line with respect to the vertical direction, finally they apply translation and rotation to adjust both feet in the center of the image and this technique is limited because it assumes that both feet are on the same plane in the image and have the same shape and size.

Fig. 1. Original Thermal Image, (b) Thermal difference Map $|\Delta T|$ for a Subject with an Ulcer.

*Corresponding Author.

In this paper, we analyze four different registration methods to obtain foot images aligned with high accuracy, in order to perform the thermal monitoring analysis, namely, the calculation of $|\Delta T|$ between the contralateral feet as shown in Fig. 1. This registration step requires high precision, because any deviation between the feet images will have a direct impact on the accuracy of detecting abnormal plantar temperature.

The rest of the paper is organized as follows. Section 2 called materials and methods describes the acquisition protocol of our data, the used equipment, and subjects who participated to our acquisition campaign. It presents also the existing thermal analysis for DF assessment, as well as the compared registration techniques. The third section is dedicated to the quantitative and qualitative results of the tested methods. Finally, the conclusion is presented in the last section.

## II. MATERIALS AND METHODS

### A. Image Acquisition

In this section, we first explain the choice of the smartphone thermal camera, then, we describe the acquisition protocol of our images and the recruitment of participants.

*1) The chosen camera:* is the FlirOne Pro camera, designed to be connected to a smartphone. This camera consists of two sensors. A thermal sensor that measures heat through infrared emission, and an RGB sensor designed to acquire visible images in parallel with the thermal core. The camera has a thermal image resolution of 160x120 pixels and a spectral range of 8-14 µm. FlirOne Pro can detect temperature differences of 0.1°C, which is sufficient to detect possible hyperthermia variations. It was used with a smartphone Samsung Galaxy S8.

*2) Acquisition protocol:* To collect our images, we adopted two acquisition protocols, the first one allows to obtain a single thermal image of the patient's feet, after letting him rest for 15 min (Fig. 2). The second one called Cold Stress test [10] is a protocol that consists in taking two acquisitions of the same patient in two different moments (Fig. 3).

As shown in Fig. 2, after the medical examination, Patients are requested to rest barefoot for a 15 minutes interval to allow the feet to regain their normal temperature. Finally, thermal and RGB images are acquired.

Fig. 2. Acquisition Protocol (Single Acquisition).

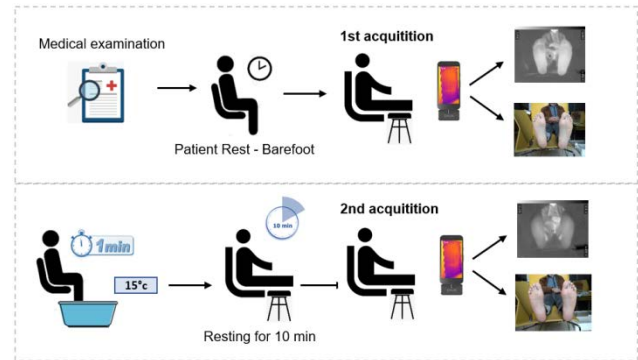

Fig. 3. Cold Stress Test Protocol (Multitemporal Acquisition).

Participants are asked to remove their shoes and socks. After a 15 minutes interval to allow the feet to recover their normal temperature, the person laid down on a stretcher or chair and placed his/her feet at the end of the stretcher, in a vertical position, and 10 cm apart. The baseline thermal image was taken freehandedly using a Samsung Galaxy S8 and a FLIR ONE Pro camera. After that, the patient is asked to immerse the feet, which are protected with thin plastic for 60 seconds in water at 15ºC. After 10 minutes, a new plantar thermal image is recorded. Fig. 3 illustrates the protocol step by step.

*3) Subjects:*

*a) Control group:* Composed of 82 healthy (non-diabetic) individuals who participated in two acquisition campaigns. The first one was conducted at the University of Orleans, France. Participants were members of Prisme staff. A total of 22 people participated in this first acquisition campaign. The second acquisition campaign was organized at the IBN Zohr University in Agadir, Morocco. In which volunteer students and members of the IRF-SIC laboratory without a history of diabetes participated. In this campaign, two acquisitions were carried out for 43 people in two different moments applying the protocol of the cold stress test described in Fig. 3. In addition to 17 people who participated in a single acquisition (Fig. 2). The criteria for recruiting individuals were simple: any adult volunteer who is non-diabetic and does not have a foot problem.

*b) Diabetic group:* 145 diabetic persons accepted to participate to our study within the diabetic Foot Service of the national hospital Dos De Mayo de Lima in Perou, and signed the informed consent form. For this campaign, we exclude patients with ulcers, partial or total amputations. All acquisitions and tests were carried out under the supervision of specialists and diabetologists, who performed a set of clinical examinations on the patients to monitor neuropathy and ischemia. Two images were captured for each patient at two different moments after applying the cold stress test (Fig. 3).

## B. DF Thermal Analysis Methods

The analyses of diabetic foot thermograms can be divided into three main categories, according to existing works in the literature. The first is the asymmetric analysis between the two feet of the patient. As several studies have shown [11][3][6], there is contralateral symmetry in the distribution of skin temperature in healthy individuals, and any asymmetry in this distribution may be indicative of an abnormality. Therefore, many scientific experiments are conducted on diabetic patients [4][8][12][13][14][10][15][16] in which they found that a temperature variation of 2.2°c or more between the two feet (right and left) was detected in diabetic patients who are at risk of developing ulcers in these hyperthermic areas (see Fig. 1). The second type of thermal analysis is temperature distribution analysis [17] . The advantage of this type of analysis is that the temperature difference between the contralateral feet is no longer used and each foot can be analyzed separately. In the majority of the works based on this type of analysis, they divide the feet into several regions called angiosomes [18] by which they classify the patient's foot as being at risk of ulceration [19] [20]. The last type of analysis is based on external stress; the purpose of this analysis is to observe the response of the body thermoregulation system after applying a specific stress. This stress can vary from immersing limb in hot or cold water [10] [21], or it can be a mechanical stress such as walking or running [22]. This evaluation was presented in [21] by the thermal recovery index (TRI) which is calculated between the feet of the same patient in two different moments before and after stress). As in the study [10], they evaluated the relationship between plantar foot temperature variation and cold stress test applied on diabetic patients, by calculating the difference in temperature of the same foot at two different times, which is called a multitemporal analysis.

These thermal analyses require a series of pre-processing steps of the foot thermograms, to prepare these zones of interest which are the plantar soles. The first task consists in segmenting the two feet and separating them from the rest of the background (Fig. 4), and in this study the images we are going to present are previously segmented using a neural architecture that is detailed in our previous work [23].

Once the feet have been segmented, a primordial step is to align the feet in order to calculate the temperature difference either by applying the contralateral analysis (asymmetry) or the analysis based on the external stress (mulitemporal). This step is the core of this work. Our objective is to find the most suitable registration method for our problem, which can be defined by two essential challenges;

- Variation in shape and position between the patient's feet, which complicates the registration.

- Dissimilarity between two images of the same patient foot taken at different times (in our case instant T0 before cold stress test and instant T10 after cold stress test), from different distances, or from different viewpoints.

Fig. 4. (a) Thermal Image, (b) Segmented Feet.

## C. Image Registration

*1) Registration types:* In this work we conducted two types of experiments. The first one is a contralateral registration, which consists of aligning the right and left feet of the same patient image. And the second is a mulitemporal registration applied on a pair of images of the same feet acquired in two different moments with the cold stress test.

*a) Contralateral registration:* the first dataset consists of thermal images of segmented feet as shown in Fig. 4(b). The image of the two feet is divided into two (left foot and right foot), the right foot is considered as the reference image (fixed) and the left foot (moving) is flipped horizontally to register it with the reference image, in order to calculate the temperature difference between the two feet after aligning them. The process is detailed in Fig. 5.

*b) Multitemporal registration:* this type consists of registering a pair of thermal images of the same patient taken at two different times. A first acquisition at time T0 captured before the application of the cold stress test [10] and a second acquisition at time T10 made 10 min after the application of the cold stress test.

This is a mulitemporal registration in which the goal is to align the two images of the same foot at two different times T0 and T10. The image of the right foot at time T10, which is considered as a target (moving image), is aligned with the image of the right foot at T0, which is considered as a reference image (fixed image), and the same for the left foot. The process is shown in Fig. 6.

*2) Registration techniques:* In our research, the objective is not to make the foot images identical. We are looking for the transformation that minimizes the distance between the information contained in one image and its correspondence on the other image. As well as studying the significant differences that will allow us to localize the region at risk of ulceration. In our case, the registration must not modify the size of potential anomalies, or make local deformations on the foot, since this could, for example, mask the detection of a hyperthermia area. Therefore, the registration methods chosen in this paper are linear, either rigid transformations (translation-rotation) such as the ICP [24] and the Sicairos et al. method [25], or affine transformations, namely intensity-based algorithm [26] and pyramid approach [27] . In the following, we will present the registration techniques that we have compared and evaluated on our database.
Fig. 5.    Contralateral Registration Process.

Fig. 6.    Multitemporal Registration (after Applying Cold Stress Test).

*a) Iterative Closest Point (ICP):* The Iterative Closest Point (ICP) algorithm is used to match two sets of data, most often in the form of point clouds or meshes corresponding to two partial views of the same object. Iteratively, the algorithm revises the transformation (combination of translation and rotation) needed to minimize an error metric, usually a distance between the source and target point clouds, such as the sum of squared differences between the coordinates of the matched pairs.

In this work, we used a maximum number of iterations of 300 and a minimum difference in the correspondence measure between two successive iterations of $1e^{-5}$. These values were chosen empirically, after a number of tests, as it was observed that no more than 300 iterations were required in any of the studied cases to converge to an optimal solution.

*b) Sicairos et al approach:* To perform a simple translation between two images, the usual technique for solving this problem is to compute an oversampled cross-correlation between the image to be registered and a reference image, using a Fast Fourier Transform (FFT), and locate its peak. The computational burden associated with this approach increases as the accuracy required for the registration increases, especially in terms of memory.

Therefore, as an alternative Guizar-Sicairos et al. [25] have developed different algorithms that significantly improve performance without sacrificing accuracy. These algorithms start with an initial estimation of the location of the cross-correlation peak obtained by the FFT method with an upsampling factor of $k_0$=2. This initial upsampling is used for the purpose of selecting an appropriate starting point for cross-

correlations that might have more than one peak of similar magnitude. This type of algorithm, as in the FFT upsampling approach, always uses all the information available in the images to compute the initial estimate and each point of the upsampled cross-correlation grid, which makes it very robust to noise. It has been demonstrated in [25] that these new registration refinement algorithms can achieve subpixel image registration with the same or better accuracy than traditional FFT oversampling but with significantly reduced computation time and memory requirements.

*c) Intensity-based registration:* The intensity-based registration method operates directly on the gray values of the images. The main goal of this technique is to find the right transformation that maximizes (or minimizes) the similarity metric between the corresponding voxels.

The most frequently used similarity measures are the sum of squared differences of pixel intensities, the regional correction or the mutual information.

As shown in the Fig. 7, the algorithm takes two images in input, the image to be registered (moving image) and the reference image (fixed image). It requires four other essential parameters, namely; a similarity metric, an optimizer and the type of transformation.

The process begins with the transformation type we specify and an internally determined transformation matrix. They jointly determine the specific image transformation which is applied to the moving image with a bilinear interpolation. Then the metric compares the transformed moving image to the fixed image and a metric value is returned.

Finally, the process stops when it has reached a point of decreasing efficiency or has reached the maximum number of iterations. If there is no stopping condition, the optimizer adjusts the transformation to start the next iteration.

In this experiment, we ran the intensity-based algorithm using One Plus One Evolutionary optimizer with an initial radius of $6,25\ e^{-3}/3,5$, growth factor of $1,05$ and a maximum iterations number of 300. The similarity metric used is a mattes mutual information metric. For the initial transformation type, we used affine transformation. These chosen parameters are the ones that gave the best results after several tests.

Fig. 7. Intensity-based Registration Algorithm [23].

*d) Pyramid Approach for subpixel registration:* Thévenaz et al. [27] proposed an automatic sub-pixel registration algorithm that minimizes the mean square intensity difference between a reference data set and a test data set, which can be images (two-dimensional) or even volumes (three-dimensional). This method uses an explicit spline representation of the images in conjunction with spline processing, and is based on a coarse-to-fine iterative strategy (pyramid approach).

The minimization is performed according to a new variation (ML*) of the Marquardt-Levenberg algorithm [28] for nonlinear least squares optimization. The geometric deformation model consists of a global three-dimensional (3D) affine transformation that can optionally be restricted to rigid body motion (rotation and translation), combined with isometric scaling. It also includes an optional adjustment of the contrast differences of the images.

According to [27] , this algorithm has shown excellent results for the registration of intramodal positron emission tomography (PET) and functional magnetic resonance imaging (fMRI) data.

## III. RESULTS

In order to assess the best approach for registering the thermal infrared images of the diabetic foot application, we have tested the four registration methods on our two types of acquisitions, the first "Contralateral" (Fig. 5) containing one image of the feet of each patient (left, right) and the second "Multitemporal" (Fig. 6) containing a pair of images of the same feet acquired at two different times. The purpose is to evaluate the robustness of these approaches in both cases of registration (contralateral/multitemporal) and under the changes that can occur in the position of the subject's feet, changes in the distance of acquisition or viewpoints, especially for the images captured at two different times.

### A. Evaluation Metrics

To quantitatively evaluate the performance of these algorithms, we adopted three evaluation metrics that are most commonly used in the field of registration evaluation. The first one is the Dice similarity Coefficient (DSC) [20], the second one is the RMSE (Root Mean square error) and the last one is PSNR (Peak Signal to Noise Ratio).

- Dice similarity coefficient (DSC): is a statistical indicator that measures the similarity of two samples.

- This score quantifies the overlap between the fixed foot and the registered one.

$$DSC = \frac{2*|X \cap Y|}{|X|+|Y|} \qquad (1)$$

X is the reference image and Y is the registered image.

- Root Mean Square error (RMSE): used to measure the difference per pixel between the moving image and reference image. The lower the value of RMSE, the better the registration performance.

$$RMSE(X,Y) = \sqrt{\frac{\sum_{i=1}^{n}(Xi-Yi)^2}{n}} \qquad (2)$$

where, X and Y are respectively the reference image and the registered image. n is the total number of pixels in the image.

- Peak Signal to noise ratio (PSNR) : is identified as a numerical measure for image registration quality based on the pixel differences between two images [29]. The Mathematical equation is provided as in equation 3 based on [29]. Where $MAX_I$ is the maximum possible pixel value of the image and MSE is mean square error between reference and target image. A higher PSNR value indicates a higher similarity between registered images. Contrarily, the smaller PSNR value indicates poor similarity between images.

$$PSNR = 10.\log_{10}\left(\frac{MAX_I^2}{MSE}\right) \qquad (3)$$

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(Xi - Yi)^2 \qquad (4)$$

### B. Comparative Results

From the results in Tables I and II, on one hand we deduce that the intensity-based method gives the best value for the Dice coefficient (0.97) followed by the pyramid method (0.96). (The best results are highlighted in bold). On the other hand, we notice that the four algorithms are more robust in the first type of registration (contralateral registration), which is reasonable, since in these acquisitions the two feet to be registered (right and left) are positioned at the same distance from the camera. So generally, in this case we are in front of geometrical transformations that can be considered as a combination of translation and rotation.

TABLE I.    COMPARATIVE RESULTS FOR CONTRALATERAL REGISTRATION BETWEEN RIGHT AND LEFT FEET

| Methods \\ Metrics | Intensity based registration | ICP | Sicairos et al | Pyramid approach |
|---|---|---|---|---|
| DSC | **0,97** | 0,95 | 0,93 | 0,96 |
| RMSE | 0,245 | 0,315 | 0,34 | **0,23** |
| PSNR | 25,85 | 23,62 | 22,90 | **26,41** |

TABLE II.    COMPARATIVE RESULTS FOR MULTITEMPORAL REGISTRATION

| Methods \\ Metrics | Intensity based registration | ICP | Sicairos et al | Pyramid approach |
|---|---|---|---|---|
| DSC | **0,968** | 0,905 | 0,89 | 0,94 |
| RMSE | 0,344 | 0,445 | 0,442 | **0,318** |
| PSNR | 22,24 | 19,85 | 19,85 | **23** |

Contrary to multi-temporal registration, in which we can clearly see that in some cases, the acquirer can change the distance and position of the camera between time T0 and T10 (ex: Fig. 12). With smartphone, freehandedly, the distance between the feet and the camera may slightly change. This generates a change of scale between the two feet, making the task of registration more complicated.

Based on the results of the two previous tables (Tables I and II) and the charts in the two Fig. 8, 9 and 10, we can see that the performance of the compared methods has decreased

between the contralateral and the multitemporal registration. For example, in Fig. 9 we have the ICP method with a DSC of 0.95 as a result of final overlap of the registered feet (right and left), this value decreased to 0.90 when applying ICP on the images of the same feet acquired at two different times, a difference of 5%.

And this is expected, since the transformation applied by ICP cannot perform perspective corrections. While in the images of the cold stress test the person making the acquisitions often changes the distance and position of the camera between the two instants. The only method that kept the same performance between the two types of registration is the intensity-based method. As shown in Fig. 9 dice values for multitemporal and contralateral registration are almost identical for this method, unlike the other algorithms.

Fig. 8.   Dice Coefficient, RMSE and PSNR Metrics for the Four Registration Methods Obtained with Images of Contralateral Feet (Registration between Right and Left Foot).

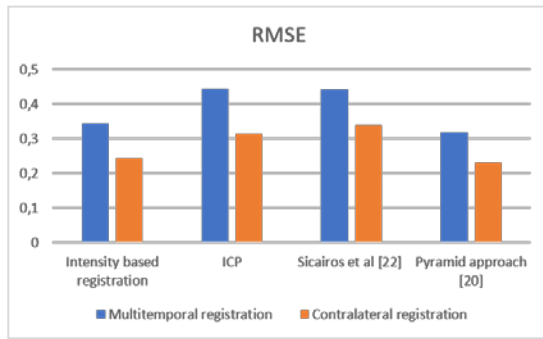
Fig. 9.   Dice Coefficient of the Four Registration Methods to Evaluate their Performance in Both Type of Registration (Contralateral and Multitemporal).


Fig. 10. RMSE of the Four Registration Methods to Evaluate their Performance in Both Type of Registration (Contralateral and Multitemporal).

The qualitative results are in total agreement with the results calculated above (Tables I and II), we see that in Fig. 11 All four registration methods obtain a visually correct overlap between the fixed thermal image and the registered foot when both feet of the subject are located at the same distance from the camera. And the two algorithms based on the intensity and the one of Thévenaz et al [27] (pyramid registration approach) give the best performances.

Fig. 11. Example of Contralateral Registration (Left Foot and Right Foot). in All Images, the Foot in Pink is the Fixed Foot (Right) and the Foot in Green is the Moving Foot (Left).

Fig. 12. Example of Multitemporal Registration (Right Foot at Time T0 and Right Foot at Time T10). in All Images, the Foot in Green is the Fixed Foot (Right Foot T0) and the Foot in Pink is the Moving Foot (Right Foot T10).

For multitemporal registration, as shown in Fig. 12 and 13, the added challenges to the algorithms are the change of the capturing view point and the difference distance from the camera between the acquisition at time T0 and the second acquisition at time T10. The methods that have proven their robustness in these cases are intensity based and pyramid approach. They align the images, where the feet don't have the same size and shape. Unlike the method of [9] which is limited and only works in the case where both feet are on the same plane in the image and have the same shape and size.

Fig. 13. Example of Multitemporal Registration (Left Foot at Time T0 and Left Foot at Time T10). in All Images, the Foot in Green is the Fixed Foot (Left Foot T0) and the Foot in Pink is the Moving Foot (Left Foot T10).

## IV. CONCLUSION

To diagnose the DF problem at an early stage and to detect the areas at risk of ulceration, it is necessary to have a fast and non-contact procedure with simple and low-cost devices. In order to achieve this goal, it is important to implement an approach with a high-level accuracy in diagnosis, ensuring that the acquisition and processing of data does not introduce systematic errors that can be avoided at the time of conception.

Medical diagnostic devices of DF supposed to perform these thermal analyses; such as the computation of temperature difference between contralateral feet or between feet after application of external stresses, require a correct alignment of the acquired images. Because any deviation between the images of the feet will have a direct impact on the accuracy of the subsequent abnormal temperature detection. Hence, the need to evaluate the performance of the registration techniques is used at the heart of this alignment.

In this work, a group of registration methods was implemented and evaluated to match thermal images for diabetic foot application. For the registration of contralateral feet, the methods compared in this paper gave satisfying results. However, when applying the multitemporal registration which consists in aligning the same foot captured in two different instants (T0 and T10), we notice that the performances of ICP and Sicairos et al method have decreased.

This can be explained by the complexity increased by changing the capturing view point and distance in two different moments.

While Intensity-based algorithm and pyramid approach have proved their stability and robustness in both types of registration, especially the intensity-based method, this is confirmed by the Dice coefficients obtained, which are 0.97 and 0.96 for intensity and pyramid respectively, in the case of contralateral registration. 0.968 and 0.94 in the case of multitemporal registration regardless of the distance between the subject and the camera.

This comparative study permitted to find the registration method that fits the most to our thermal images, with all their specificities and their complexity related to the adopted acquisition protocol. This "free hand " protocol is based mainly on a smartphone and the dedicated thermal camera. Even if on one hand it complicates the tasks of image processing such as segmentation and registration, on the other hand, it allows using the diagnosis system by patient in a convivial and simple way, without needing the intervention of a specialist.

In the future, we intend to develop thermal analysis approaches for the detection of hyperthermia areas. Subsequently we envisage combining and improving all these techniques, in order to integrate them into a complete system of diagnostic to help doctors and podiatrists to identify DF disorders in early stages. This will certainly decrease the risks of ulcerations and amputations.

*Abstract*—**Polycystic Ovary Syndrome is a common women's health problem caused by the imbalance in the reproductive hormones which causes problems in the ovaries. An appropriate machine learning (ML) algorithm can be applied to analyze the datasets and validate the performance of the algorithm in terms of accuracy. In this paper, a unique hybrid and optimized methodology are proposed which uses SVM linear kernel with Logistic Regression functionalities in a different way. The output of this model is passed on to the RMSprop optimizer. Optimization will train the model iteratively to get better output. For this research 1600 datasets were collected from the leading hospital in Bangalore Urban region. This optimized hybrid method is tested over PCOS datasets and it exhibited 89.03% accuracy. The results showed that the optimized-hybrid model works efficiently when compared to other existing ML Algorithms like SVM, Logistic regression, Decision tree, KNN, Random forest, and Adaboost. Also, the results of the optimized-hybrid SVLR model showed good results in terms of F-measure, precision, and recall statistical criteria. Overall this paper summarizes the working of the proposed optimized-SVLR hybrid model and prediction of PCOS.**

## I. INTRODUCTION

In the present world, there are very large innovations in the field of medicine which help clinical experts to predict any disease in a better and faster way. The research by Kirschner MA [2] shows that around 60-70% of the Indian young women population suffers from polycystic ovary syndrome (PCOS). PCOS is an endocrinopathy caused because of an imbalance of the reproductive hormones affecting women of reproductive age, which creates complications in the ovaries [1] [26]. The ovaries produce eggs which will be released every month in case of a healthy menstrual cycle. But ladies with PCOS will end up with irregular menstrual cycles as the egg may not develop as it should or it may not be released during ovulation [4]. Most women develop PCOS in their 20s and 30s but it can arise at any age after puberty [1]. Obesity is one of the root causes of PCOS and other infertility-related problems [5]. Women with PCOS have a number of obstacles to successful lifestyle improvement. For weight management,

the intrinsic factors range is changed in PCOS, which is indicated by recent research. This has an impact on how well PCOS-affected women can control their weight, although there is currently insufficient and conflicting evidence.

Computational model-based frameworks constructed with ML techniques are now widely regarded as valuable tools for predicting and analyzing a wide range of diseases. Around-the-clock ML approaches are sufficient to successfully and proficiently predict the disease [7]. ML models, in contrast to traditional techniques, do not require in-depth knowledge of data insights. SVM, Nave Bayes, Decision Tree, and Artificial Neural Network (ANN) is classifier models of ML approaches that are commonly used in medical services.

Due to the expensive computational tasks, and overfitting conditions, high dimensional data can have an impact on classifier accuracy in the majority of the existing research. The multiple characteristics are used by the previous research for classifying the PCOS problem, which affects the effectiveness of the classification results. To overcome these challenges, a novel Op-RMSprop algorithm has been proposed. The overfitting problem is reduced by selecting the most significant data by using the proposed model, and also it enhances the classification performance and processing time.

The proposed research's primary goal is to provide a unique and accurate prediction model which could predict the possibility of PCOS patients becoming infertile soon. Here a hybrid model is built combining the functionality of the two models Support Vector Machine and Logistic Regression Algorithms and the model is optimized using the RMSprop optimizer. One of the most important aspects of ML is optimization [6].The optimization model is created and the features of the optimization method from the input data are learned by the ML-based algorithms [8].The popularization and implementation of ML models are significantly influenced by the efficiency and effectiveness of quantitative optimization algorithms in the era of large databases [9]. For this research RMSProp Optimization model [33] has been used, which is one of the best optimization techniques available and provides optimal output, also this technique reduces the learning rate monotonically.

This paper summarizes various first-order optimization techniques in Section II, a Literature review on the application of ML in the healthcare domain in Section III, criteria for evaluation of ML algorithms in Section IV, the proposed framework in Section V, and Results of the proposed framework in Section VI and finally in Section VII Conclusion.

## II. Literature Review

In [16], Prof. Keshavaraj GK, and Prof.SuryaSukurmran explain about Data mining process where knowledge is extracted from huge datasets. Three main modules of Data mining are Clustering/ Classification, Association Rules, and Sequence Analysis. In classification/clustering data set is analyzed and a set of grouping rules is generated which is used to classify future data. In DM information is extracted from data sets and transformed into an understandable structure. It follows a computational methodology for discovering patterns in large data sets involving different approaches like AI, ML, statistics, and database systems. All DM tasks are either automatic or semi-automatic used for the examination of huge amounts of datasets. There are six common classes of tasks in DM they are: Anomaly detection, Regression, Classification, Clustering, Association rule learning, and Summarization. Classification is a prime methodology in data mining and is widely used to predict relationships for data instances. In this paper, a few basic classification techniques like DT induction, KNN classifier, and Bayesian networks are discussed. This paper aims to give an insight into various classification techniques in data mining.

In [17], the author summarizes the caused deaths due to heart disease which has become a major issue. With the rise in heart stroke rates at younger ages, there is a need to put in place an early-stage device to identify the signs of a heart attack and thereby avoid it. It is not possible for a common man to undergo ECG frequently and as a result, there must be an application to detect chances of heart stroke at an early stage. In this paper, the authors have proposed a model which can predict the chances of a heart stroke using basic attributes like BP, age, gender, pulse rate, etc. An Artificial Neural network algorithm has given the most accurate result.

In [18] the author gives insights into the constructive examination of different chronic diseases. ML algorithms provide a large impact on health care by giving an effective inspection of problems for accurate diagnosis. In this paper, the authors talk about the kidney problem which is associated with other numerous factors like hypertension, aging, and diabetes, and its effects on people in the age group 60 and above. The authors used ML techniques to analyze chronic kidney disease (CKD). Around 400 data sets were collected from the UCI repository and Apriori algorithm with 10-fold-cross validation. Six classification different algorithms like ZeroR, Naïve Bayes, J48, OneR, and IBK were applied to the datasets. Data were preprocessed and normalization of missing data was done before analyzing datasets. The results shown were 99% detection accuracy for CKD datasets using the Apriori algorithm [13]. This study examines different ML methods, especially classification and association techniques.

The paper also analyses the impacts of utilizing feature determination procedures in amalgamation with classification. This was carried out using the ANACONDA python tool. The outcomes were cross-checked with correctly classified instances, mean absolute value, and kappa statistic, with or without the feature_selection methodology. Datasets are processed with the Apriori_Association algorithm and the best results were achieved with IBk and Apriori associative algorithm with an accuracy of 99%.

Diabetes is considered to be the worst and perhaps most chronic illness that causes sugar levels to increase. If diabetes remains untreated and unidentified, a lot of problems can happen [24]. To address the common yet crucial problem, the ML concept was used. In this paper likelihood of diabetics was predicted using a high precision value obtained from the model built using ML techniques. Thus classification algorithms DT, SVM, and NB are used here, to detect diabetes at an early phase. Using Pima Indians Diabetes Database (PIDD) from the UCI system observation was done. The performance of all algorithms is measured on different parameters such as Precision, Accuracy, F-Measure2, and Recall. The values obtained from the experiments were verified using Working Characteristic Receiver (ROC) [24].

Breast cancer (BC) is the most often observed problem faced by women worldwide, causing cancer-related deaths [20]. To enhance the prediction and probability of survival considerably breast cancer must be detected at an early stage. Accurately classification of benign tumors can help patients avoid unwarranted treatments. In this paper, the author reviews ML techniques in breast cancer detection, and diagnosis. Artificial neural networks (ANNs), support vector machines (SVMs), decision trees (DTs), and k-nearest neighbors (k-NNs) were applied to the cancer datasets [20].

Daqqa, Khaled A. S. Abu et al [21], used data mining techniques for getting patterns and models which are undiscovered in datasets. Leukemia is a condition that affects blood status. Blood_Cell_Counter (CBC) is employed to determine Leukemia detection. Leukemia is determined by examining the blood cell relations, gender, age, and also current health condition of patients using ML techniques. Datasets of 4,000 patients were involved in this study. Three classification algorithms like SVM, k-NN, and DTs were used in this study. From the experimental results, while comparing the models 77.30% accuracy is achieved by the DT algorithm than the other methods.

The main research gap of the previous methods includes the lower performance results of the detection and diagnosis of the PCOS problem, high processing time, high overfitting problem, and high computational cost. The proposed model solves these problems, reduces the overfitting risk, and improves the classification performance and processing time of the model.

## III. Need for Optimization in Machine Learning

Building a model hypothesis, describing the objective function, and the model parameters are determined by solving the minimum and maximum of the objective function, these steps are important aspects of ML [10]. The first two steps of

these three crucial processes are ML modeling problems, and the desired model is solved by using the third step with optimization methods. The optimization problems are formulated in almost every ML algorithm. The optimization model is created and the features of the optimization method from the input data are learned by the ML based algorithms.

The most commonly used optimization technique is a first-order method. An extensive survey done on optimization methods by Sun et al [33] says that ML frequently employs first-order optimization algorithms. The commonly utilized first-order optimization algorithms that are used in the ML journey are summarized in Table I.

TABLE I.        SUMMARIZATION OF FIRST-ORDER OPTIMIZATION TECHNIQUES [33]

| Method | Properties | Advantages | Disadvantages |
|---|---|---|---|
| Gradient Descent | Here With every update, the model finds the target and gradually converges to the objective function's optimal values. | the objective function is convex | The cost of calculation is high since it operates by dynamically adjusting elements in the reverse direction of the objective function's gradient. |
| Stochastic Gradient Descent | Here, each iteration is based on a random sample that updates the gradient (theta) rather than directly calculating the gradient itself. | The cost of calculation is reduced since the time it takes to calculate each update is independent of the total number of training samples. | Determining the suitable learning rate is difficult. |
| Adagrad | Here the learning rate will be low if the high gradient, and vice versa | The approach can be used to solve problems with sparse gradients. Each parameter's learning rate is adaptively adjusted. | For addressing non-convex problems, it is not suitable. |
| RMSprop | It changes the way from total gradient accumulation to an exponential moving average. | It can be used to solve non-stationary and non-convex issues. Also, suitable for large and multidimensional space | The update procedure is rehashed around the local minimum within the late training period. |
| Adam | Combines the momentum method and adaptive methods | With large amounts of data and larger feature space, it is effective for solving most non-convex optimization problems | In some instances, the approach may fail to converge. |
| ADMM (alternating direction method of multipliers ) | The approach addresses optimization problems with linear constraints. | Divide and rule methodology | Difficult to calculate the penalty |

From Table I, we can infer that the RMSprop optimization technique is one of the best techniques which can be applied to medical datasets. It's one of the good and fast optimizers when compared to the existing optimizers. RMSProp is an algorithm that aims to find the global minima where the cost function reaches the smallest possible value. The technique relies on the concept of the Exponentially Weighted Average (EWA) of the gradients. The exponentially weighted average (EWA) is used to determine the moving average. It consists in keeping the previous values in a memory buffer. This is achieved by using this recursive formula:

$$V_t = \beta V_t\text{-}1 + (1\text{-} \beta)\, \theta_t \qquad (1)$$

Where $V_t$: Moving average value at 't' i.e. averaging $\theta_t$ over $1/1-\beta$ units (approx).

## IV.  BACKGROUND

PCOS is a famine problem faced mostly by young women between the ages of 19-35yrs. The risk of PCOS is higher if a woman is obese or if her mother, her sister, or her aunt had PCOS [2][27]. A few common signs of PCOS are as follows:

- Women undergoing PCOS may have an Irregular menstrual cycle i.e. they will fail to get periods or may have fewer periods (less than 8 times/ year) or they may have periods every 21 days or more frequently. Few ladies may even stop getting periods [11][25].

- Excessive hair on the facial hair or various body parts that men normally have. This phenomenon is named "Hirsutism", which affects about 70-80% of women having PCOS.

- Acne may be developed on the face, chest, or upper back.

- Hair thinning or loss of hair can happen on the scalp resulting in baldness.

- Increase in the weight or problem in losing weight

- Skin darkening in the neck region or other parts of the body.

- Skin tags are tiny flaps of excess skin in the neck section or armpits.

PCOS is caused because of two main reasons:

*1)* More production of androgens hormones, at times, is called "male hormones". Every woman contributes towards making a small number of androgens. Androgens are responsible for the overall development of male features such as male-pattern baldness in the female body [2][34]. Women having PCOS have higher androgens. Two major signs of androgens are it stops the egg from releasing during each menstrual cycle and extra growth of hair and acne [12][28].

*2)* An increase in insulin levels results in PCOS. Insulin is a hormone that is responsible for converting food into energy. Insulin resistance is a condition in which cells of the body fail to respond adequately to insulin, resulting in higher levels of insulin blood [3][35]. Most women with PCOS undergo insulin resistance when they are obese or overweight [14].

*3)* Multiple key factors include poor eating habits, less physical activity, and having a diabetes family background (usually type 2 diabetes). This can lead to type 2 diabetes over time. Fig. 1 shows the complex interaction with the underlying problem of PCOS. The figure describes the root cause of PCOS [29].

This section presents the results obtained through experimentation. It is important to find the best fitting classification algorithms [19] [22]. There are various criteria to measure the performance of the algorithms; they are listed as follows [23]:

- Classification accuracy: is the potential of the design to effectively foresee the class labels. It is given in the form of percentage.

- Speed: is the time taken to bring up the model.

- Robustness: to predict the system correctly with missing data and noisy observations.

- Scalability: A model can be precise and efficient when managing a growing quantity of data.

- Interpretability: the degree of interpretation that the algorithm provides.

- Rule Structure: Understanding the rule structure of the algorithm.

The second stage is to inspect performance criteria like measurements, the speed, and frequency of the working model, and intelligibility.

Fig. 1. Complex Interaction Underlying PCOS.

Accuracy (AC): is the percentage of correct predictions. It is calculated as per the confusion matrix.

$$AC = \frac{TN + TP}{TP + FP + FN + TN`} \qquad (2)$$

- TN --> true "-"

- TP --> true "+"

- FP --> false "+"

- FN--> false "-"

Precision (P): reflects the fraction of positive observations of "+" observations correctly predicted among the total "+" observations predicted.

$$P = \frac{TP}{TP+FP`} \qquad (3)$$

Recall (R): calculates the proportion of accurately projected positives in each class.

$$R = \frac{TP}{TP + FN} \qquad (4)$$

F-measure: The criteria for Recall and Precision are taken together than individually. Thus the F-Measure values that are obtained by the Harmonic Mean (HM) of both methods are considered. F-measure thus provides two levels of classification accuracy.

$$F-measure = \frac{2 \times P \times R}{P + R`} \qquad (5)$$

Where R is the recall and P is the precision.

ROC area: The curve shows how different classification algorithms perform in terms of prediction value. It is important for selection criterion for finding the correct methodology for classification. If the value approaches 1, it demonstrates that the classification was done properly.

RMSE: The RMSE is determined as the Mean Squared Error's square root. To calculate the dissimilarity between actual values and estimated values, RMSE is used. It shows the difference between expected and observed values' standard deviation. The RMSE value is desirable to a small.

$$RMSE = \sqrt{MSE} = \sqrt{\frac{\sum_{i=1}^{n} (yi - \hat{y}i)}{n}} \qquad (6)$$

## V. RESEARCH METHODOLOGY

The main purpose of this paper is to examine classification ML techniques based on the accuracy of prediction for PCOS detection. The paper explores different detection methodologies with different techniques using classification algorithms and analyses them for events that have been accurately described. These classification algorithms give early-stage PCOS analysis standards.

In the proposed methodology, a prediction model is built, and also the comparison of various classification algorithms is shown in Fig. 5. The main goal of this research is to propose the best classification technique using ML to predict PCOS. A comparative study of the proposed method is carried out using other cutting-edge techniques. Fig. 2 describes the different phases in brief:

*1) Dataset selection process:* The PCOS [30][32] is detected by selecting the dataset for analyzing data to extract necessary information. Datasets to implement the ML technique should be in large numbers to get accurate results. The dataset for this research is obtained from ESIC Hospital, Bangalore urban region. The data was collected from ladies within the age group of 19-40, working in different firms.

*2) Data Preprocessing and feature selection step:* The dataset retrieved from Survey had 20 attributes, out of which only 17 attributes are applicable for this research. The few missing records, invalid values, duplicate values, and unnecessary fields were removed. Based on the attribute-relation file format, the dataset is created using 17 attributes. It is then transformed into binomial form.

*3) Data:* A dataset stored in CSV format contained 1800 PCOS patient details containing 17 selected attributes. The final "class" attribute has the value "0/1", which shows that an individual with PCOS, like 1, and normal patients as "0". The PCOS dataset's standards, representations, and attributes are described in Table III. The dataset has 735 "non PCOS" and 1065 "PCOS" cases.

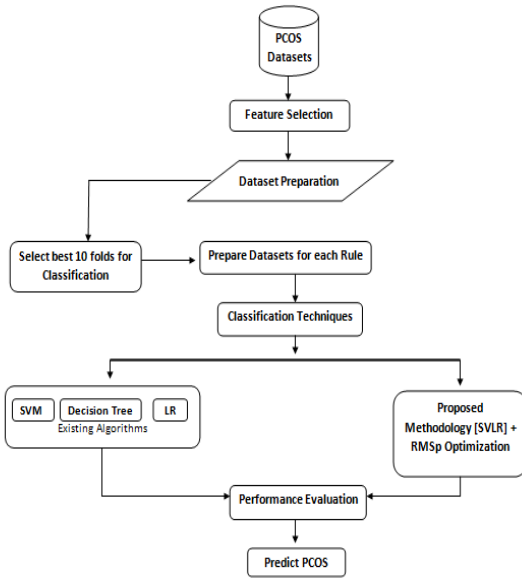

Fig. 2. Proposed Methodology.

### A. Proposed Optimized-Hybrid SVLR Classification Technique

This is a hybrid classifier combining the two classifiers i.e. Support vector machine and Logistic regression classifiers.

SVM can be used as a regression method by maintaining a few characteristics that characterize the algorithm. SVLR uses the same principles as the SVM for classification but with minor changes. This SVLR technique performs two stage classifications. The training and testing stages have a distinct window to extract the features from the datasets. The dataset after preprocessing is passed on to the SVLR machine model to analyze the dataset. The schematic diagram of the proposed method is given in Fig. 3.

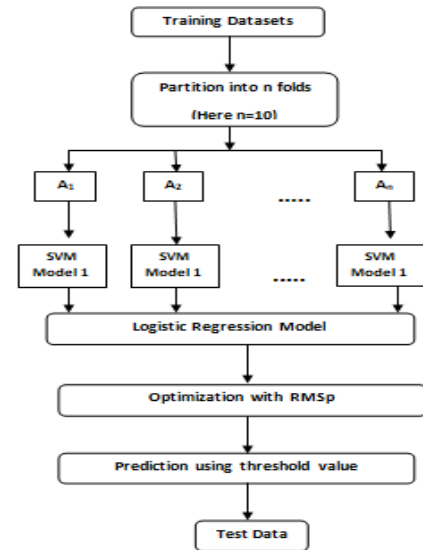

Fig. 3. Working on Proposed Optimized-SVLR Model.

### B. SVLR Algorithm

Let's represent the Dataset in the form $(A1, A_2, A_N)$ where N represents N- samples and where= 1, 2,..,10.

**Step** 1: There is an 'N' number of SVM Classifier models, represented as $SV_i$ running over 'N' sets of datasets. For every run, SVM Classifier will form a Hyperplane to say $h_i$ to $SV_i$.

**Step 2:** The distance $d_R$ to the hyperplane must be calculated for 'N' samples in the data set. Therefore the vector with 'n' dimension where $d=d_{k,1}...d_{k,n}$ is obtained.

**Step 3:** The 'd' vector is then prepared to be given to the Logistic Regression Model which will take all responses of the SVM model.

**Step 4:** After the evaluation with the LR model, the prediction is done and necessary parameters are evaluated using the threshold value. In the proposed method, the description of the attributes is given in Table II.

TABLE II.        DESCRIPTION OF ATTRIBUTES

| SL.No | Attributes | Description |
|---|---|---|
| 1 | Are your periods regular? (YES/NO) | two nominal values "yes" and "no" |
| 2 | Are you gaining weight Rapidly? (YES/NO) | two nominal values "yes" and "no" |
| 3 | Are you facing an excess of facial or Body Hair? (YES/NO) | two nominal values "yes" and "no" |
| 4 | Do you have patches of dark areas on your skin? (Yes/No) | two nominal values "yes" and "no" |
| 5 | Do You suffer from pimples? (YES/NO) | two nominal values "yes" and "no" |
| 6 | Do you face depression and anxiety? (YES/NO) | two nominal values "yes" and "no" |
| 7 | Do you have any family history of Hyper Tension? (YES/NO) | two nominal values "yes" and "no" |
| 8 | Are you finding any difficulty in maintaining your body weight? (YES/NO) | two nominal values "yes" and "no" |
| 9 | Do you have oily skin? (YES/NO) | two nominal values "yes" and "no" |
| 10 | Are you losing a lot of hair or has it become thinner in its strength? (YES/NO) | two nominal values "yes" and "no" |
| 11 | Do you exercise regularly? | two nominal values "yes" and "no" |
| 12 | Are you mentally stressed due to the following exercise? (Are you newly admitted to the hostel?) | two nominal values "yes" and "no" |
| 13 | Are you mentally stressed due to the following exercise? (Do you have personal problems?) | having two nominal values "yes" and "no" |
| 14 | Are you mentally stressed due to the following exercise? (Peer pressure?) | two nominal values "yes" and "no" |
| 15 | Are you mentally stressed due to the following exercise? (Change in dietary habits?) | two nominal values "yes" and "no" |
| 16 | How often do you eat fast food? | two nominal values "yes" and "no" |
| 17 | Any Family history of diabetes? | two nominal values "yes" and "no" |
| 18 | Class Label | PCOS suffering patient-Yes (1) else No(0) |

## C. RMSprop Optimization

Root Mean Squared Propagation is an extension to the gradient descent optimization algorithm [31] and is designed to speed up the optimization process, by decreasing the number of function evaluations that are needed to improvise the functionality of the optimization algorithm to obtain the best. RMSprop is similar to gradient descent with momentum in that it employs an exponentially weighted average of gradient, but the distinction is that it updates the parameters [15].

Implementation: The algorithm works better results by updating the model parameters such as the Weight (W) and bias (B).

Consider the parameters Wi and Wj which are used to update the parameters W and B. During the backward propagation:
Weight = W — learning rate * Wi

Bias = B — learning rate * Wj

The weighted averages of Wi and Wj's squares are exponentially weighted in the RMSprop algorithm.

$\Delta Wi = \beta * \Delta Wi + (1 — \beta) * Wi_2$

$\Delta Wj = \beta * \Delta Wj + (1 — \beta) * Wj_2$

Here, 'β' momentum is a separate hyperparameter that ranges from 0 to 1.

Then a new weighted average of observed and previous values must be calculated. After that the parameters are updated.

Weight = W — learning rate *Wi / sqrt($\Delta$Wi)

Bias = b — learning rate * Wj / sqrt($\Delta$Wj)

$\Delta$Wi is comparatively small so it is divided by Wi and $\Delta$Wj is comparatively large, so Wj is divided with a relatively larger number to slow down the changes on a vertical dimension.

## VI.   EXPERIMENTAL RESULTS

### A. Performance Evaluation of Existing ML Algorithms for PCOS Datasets

The PCOS datasets have been tested over different ML Algorithms. The performance measures of the paper have been summarized in Table III.

F-measure, Recall, Precision, ROC area, RMSE, and Accuracy value was calculated and compared.

The highest classification accuracy of 87.39 percent is obtained by Logistic Regression and SVM classifiers, as seen in the tables above. While comparing the RMSE values, also the SVM and LR classifiers achieve the reduced results of 0.35 then the other classifiers, and Decision Tree (DT) obtains the worst performance results with a value of 0.361.The LR algorithm has the largest ROC area, with a value of 0.87, therefore it has the best classification performance. SVM and LR are the best methods when precision and F-measure are considered. According to the recall criterion, the SVM and LR show a good value of 0.874. In terms of recall, precision, F-measure, and accuracy evaluation metrics, SVM and logistic regression are the best algorithms.

TABLE III.    EVALUATION OF ML ALGORITHMS

| Algorithm | F-measure | Recall | Precision | ROC area | RMSE | Accuracy (%) |
|---|---|---|---|---|---|---|
| KNeighbors Classifier | 0.827 | 0.84 | 0.827 | 0.883 | 0.32 | 84.032 |
| Support Vector Machine (SVM) Classifier | 0.871 | 0.874 | 0.869 | 0.788 | 0.355 | 87.395 |
| Decision Tree (DT) Classifier | 0.832 | 0.832 | 0.82 | 0.77 | 0.361 | 83.1 |
| Random Forest (RF) Classifier | 0.717 | 0.798 | 0.839 | 0.933 | 0.334 | 79.8319 |
| AdaBoost Classifier | 0.844 | 0.849 | 0.841 | 0.884 | 0.3291 | 84.87 |
| Gaussian Naïve base Classifier | 0.832 | 0.832 | 0.832 | 0.896 | 0.3365 | 83.1933 |
| Logistic Regression (LR) | 0.875 | 0.874 | 0.876 | 0.844 | 0.3572 | 87.395 |

### B. Performance Evaluation of Optimized RMSprop-SVLR Hybrid Algorithm for PCOS Datasets

The paper proposes a new optimized and hybrid ML Model which combines the features of both Support Vectors Machine as well as Logistic Regression Algorithms and performs optimization to enhance the output. The optimized-SVLR Model takes PCOS Datasets as input and checks for performance metrics.

The output value is accurately determined by the proposed method as per the results. Fig. 4(b) depicts the RMSE reduction curve of the gradient descent method during training and testing. The expected and observed outputs of the test signal are also shown in Fig. 4(a). The RMSE values can steadily decrease with iteration when relatively modest learning rates are utilized due to an effective network setup.

The average precision score and the recall trade-off were then shown. The Precision-Recall Curve depicts the distribution of values in detail. When there is a major deficiency in the dataset, the Precision-Recall Curve is performed and the PCOS problem is identified based on the performance of the curve because depending on a single metric is damaging and not a sufficient measure of selecting the algorithm

The Precision-Recall Curve and Average Precision Score are depicted in Fig. 5. Precision Score is the AP at the top of each graph. The AP for the Precision-Recall Curve is Average Precision Score is shown below in the figure.

Fig. 4.   Numerical Labels are used to calculate the RMSE in the Training Phase. Classification Results using the Provided (a) Over Modeled Labels as Output Labels and (b) RMSE Value based on Numerical Labels during the Training Process.

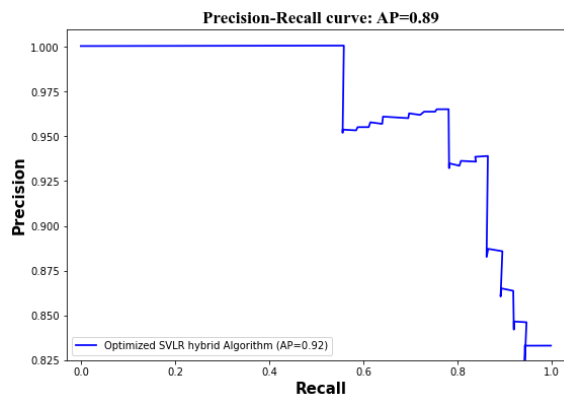

Fig. 5.   With Average Precision, the Precision-Recall Curve for Hybrid-SVLR Algorithm.

Table IV shows the performance of an optimized-SVLR algorithm. The optimized SVLR Algorithm is a hybrid algorithm that combines the features of Support Vector Machine and Logistic Regression. The model is optimized with RMSprop optimized algorithm. It is observed that Optimized-SVLR performed well for the given datasets for all the performance measures.

## C. Results and Discussion

The higher accuracy of 89% is achieved by the proposed Optimized-SVLR algorithm based on input images with feature extraction and PCOS diagnosis as per the results. The performance of each classifier is shown by the ROC curve for a better representation of this comparison. The true-positive and false-positive rates are compared by forming the curve. Based on this curve, the best classifier has the lowest false positive rates and highest true-positive rates. Fig. 6 illustrates the ROC curve.

As per the results, the developed SVLR model is the best classifier for PCOS diagnosis. Moreover, the Random Forest Classifier and the Gaussian Nave basis Classifier are the second and third high-performance classifiers, respectively.

The accuracy comparison of several existing classifiers with the proposed classifiers is given in Fig. 7. The optimized-hybrid SVLR model produces better accuracy than the prior classifiers; the SVLR model effectively diagnoses the PCOS problem.

TABLE IV. PERFORMANCE MEASURES OF OPTIMIZED SVLR HYBRID ALGORITHM

| Optimized SVLR Algorithm | Performance measures |
|---|---|
| Accuracy | 89 % |
| Recall | 0.92 |
| Precision | 0.89 |
| ROC area | 1.0 |
| RMSE | 0.29 |
| F-measure | 0.91 |

Fig. 6. The ROC Curve of the Classifiers for Diagnosis of PCOS.

Fig. 7. Accuracy Comparison Graph.

PCOS is a significant medical problem among women caused by the imbalance in the reproductive hormones which causes problems in the ovaries. An appropriate ML algorithm can be applied to analyze the datasets and validate the performance of the algorithm in terms of accuracy. A different hybrid and optimized methodology are proposed in this paper, which uses SVM linear kernel with Logistic Regression functionalities in a different way. The RMSprop optimizer receives the output of this model. The performance of the diagnosis is improved by training the model iteratively using optimization. 1600 datasets from the top hospital in Bangalore's urban area were gathered for this research.

## VII. CONCLUSION AND FUTURE REFERENCE

This paper addresses women's fertility problems caused because of polycystic ovary syndrome (PCOS). PCOS is a very common problem faced by women of the reproductive age. These risk factors causing this problem are unhealthy food habits, lack of exercise, hereditary, diabetes, prolonged medications, etc. The ML technique is applied to 1800 datasets that were collected from ESIC hospital, Bangalore. Various classification algorithms like, SVM, Decision Tree, Logistic Regression, Random forest, NB, Adaboost, and KNN were applied to the datasets collected. Accuracy, RMSE, ROC, Precision, Recall, and F-measure were calculated for the classification algorithm. Optimizing improves the performance of the algorithm and thus improves the overall performance. It is observed that the optimized hybrid SVLR performs well when compared with all other classification algorithms. The Optimized SVLR algorithms give an accuracy of 89.03, which is comparatively better than other classification algorithms. Also this new proposed optimized SVLR Algorithm could be applied to other healthcare domains to obtain better results in both medical as well as ML domains.

*Abstract*—The preservation and rational use of the grown harvest, obtaining the maximum product output from raw materials today is one of the most important state tasks. Automation of production processes is the main area in which production is currently advancing around the world. Everything that was previously performed by the person himself, his functions, not only physical but also intellectual, are gradually transferred to automation systems that perform technological cycles and exercise control over them. The purpose of the article is to analyze the effect of automation on the ability to store grain in elevators. The main research question is what factors should be considered when introducing an automation system into the grain storage process at elevators to improve the efficiency of process control at enterprises. To solve the question posed, a qualitative study was conducted using the method of an expert survey. The article reveals the factors that affect the quality of grain; the tasks implemented in the computerized process control system (CPCS) and management information and control system (MICS); the factors that hinder the grain elevator automation; the tasks solved by the automation of grain elevators in the framework of autonomous subsystems and integrated automatic control systems (ACS). It is concluded that the implementation of automation in the process of grain storage in elevators leads to an increase in grain quality, increased productivity, reduction or elimination of losses caused by theft and the peculiarities of grain storage, saving energy resources, minimizing the impact of the human factor, as well as the risks of accidents. At that, the inclusion of non-standard tools in the MICS and CPCS makes it easier to solve several current automation problems. Creating standard problem-oriented complexes of responsible decision-makers based on an integrated ACS, with the inclusion of certified object-oriented non-standard tools in their composition, is the most rational way to further improve the efficiency of the automated control system of the industry.

*Keywords—Grain elevator; automation; grain quality; grain storage; grain drying; grain losses*

## I. INTRODUCTION

Storage of grain products without losses is of great national importance and serves to solve several strategic tasks, such as guaranteeing the country's food security, providing raw materials for the processing industry, strengthening the feed base of animal agriculture, and creating appropriate conditions for effective export-import. Grain storage is one of the main factors of stabilization and increase of grain production not only in Russia. In the context of the global logistics crisis, it is necessary for grain to be able to be stored for as long as possible, without the deterioration of the consumer characteristics of grain quality. To do this, it is necessary that during its production, technological processes are carried out at the highest quality level, even if the enterprise does not have significant labor and financial resources.

In the broad sense of the term, storage means a system of technical and technological, regulatory, and economic-legal measures aimed at extending the shelf life of grain and seeds [1]. Technical and technological measures include a network of granaries/elevators, and a set of processes for accepting grain, preparing it for storage, as well as the storage technology itself [1].

An important part of the storage system is grain elevators, which represent complexes of structures designed for receiving, cleaning, drying, processing grain, and shipping it to consumers. A grain elevator is a complex system with a large number of operations that require precise accounting and control.

It should be noted that in agricultural enterprises, where the shortage of highly qualified labor is most noticeable, there is a fairly high need for partial or complete automation of technological processes, which in the contemporary conditions is an integral part of rising the competitive advantage of the enterprise because it will allow competing quite successfully both on the domestic and the world market [2]. Thus, according to a study by the California Farm Bureau, more than 40% of farmers over the past five years have not been able to employ all the workers needed to grow the main crop. It was revealed that about 56% of farmers started using mechanization in the last five years, and of the total, more than half noted this was initiated by a lack of skilled labor [3].

However, according to the researchers [4], the construction of grain elevators primarily focuses on equipment, its efficiency, and cost, while automation of grain elevator operations, as a rule, is postponed, although, with its implementation, agricultural enterprises could have saved

significant funds. Thus, the researchers [4] claim that the payback period of a fully automated newly built grain elevator is 1.5 years less than that of a similar non-automated grain elevator due to minimizing personnel costs, reducing energy consumption, and optimizing technological routes. At that, automation of an already operating grain elevator with a capacity of 40 thousand tons of one-time grain storage takes 3-4 months (from the programming process flows to the assembly of equipment and installing software).

Therefore, the grain elevator is the most relevant research object of automation systems in the industry.

## II. Literature Review

According to the researchers [5] the grain quality and properties are influenced by various factors that need to be taken into account already at the growing stage, during harvesting, primary processing of grain, and subsequent storage. A detailed description of these factors is presented in Table I.

TABLE I.        Factors Affecting Grain Quality

| Stage | Factor |
|---|---|
| Grain cultivation | The quality of the seed grain, in particular, the sowing and varietal characteristics. Thus, the grain of different wheat varieties has different flour-milling and baking qualities; different varieties of corn differ in feed properties; varieties of barley have various brewing qualities; different varieties of rapeseed and soy differ in oil content and the like. |
| | Reducing infestation of fields and the impact of pests |
| | Application of mineral fertilizers |
| Harvesting | Weather and climatic conditions. Thus, in the case of a large amount of precipitation, grain receiving plants receive highly moisture grain, which requires additional costs for drying. In dry years, during the grain maturation period the grain filling stage grows short reduced; in early frosts, grain is characterized by lower technological qualities and less resistance to storage. |
| | Harvesting with a combine. In Soviet times, as a basis for solving grain quality issues, namely, drying, maturing in rolls, and the ability to start harvesting 6-7 days earlier, a separate combining method was used. But with high prices for fuel and lubricants, as well as in adverse weather conditions, a separate combining method is often economically inefficient and can lead to a significant loss of grain. Therefore farms often use the direct combining method. Currently, the energy component is the main criterion for choosing the grain harvesting method. |
| Post-harvest grain processing | Grain fractionation by moisture. If the grain was harvested in different weather conditions, it is advisable to carry out grain fractionation by moisture (dry, medium-dry, wet and sodden grain) to facilitate post-harvest processing and storage of grain, and reduce energy costs. |
| | Grain cleaning and drying allows bringing the grain to the requirements of regulatory documents in terms of the foreign matter and moisture content of grain for further storage in granaries or further processing. |
| Grain storage | Complete set for the quality of individual grain batches |
| | Disinfection against pests |
| | Required temperature and humidity (climate control) in the granary |

Source: Compiled based on [6-9]

According to the researchers [10], the greatest influence on the grain quality has heat treatment, namely, grain drying, which, if the process is not properly conducted, downplays all measures to obtain a high quality of the crop.

At the present development stage of grain drying equipment, the convective drying method is most often used in continuously operating grain dryers of column, tower, vertical, and drum types. Also, for drying grain in small volumes, or grain for seed purposes, periodic grain dryers in a fixed layer or bunkers for venting grain are used [11]. The automation level of the drying process allows controlling and measuring the grain feed, level, moisture, and temperature, as well as heat carrier temperature in the grain dryer [12].

Recent practices in the field of automated process control systems make it possible to automatically predict the process of self-heating of grain, which is necessary to improve the efficiency of grain storage [12, 13].

However, the use of serial standard tools in automated enterprise control systems and automated process control systems of enterprises in the grain storage and processing industry has practically exhausted its potential [14, 15]. The inclusion of non-standard tools in standard automated enterprise management systems and automated process control systems makes it possible to simplify the solution of several topical automation problems [16, 17]. The creation of typical problem-oriented complexes of responsible decision-makers based on an integrated ACS, with the inclusion of certified object-oriented non-standard tools in their composition, is the most rational way to further improve the efficiency of the industry's automated control system [18, 19].

Thus, the issues of introducing control automation for grain storage at elevators relevant in Russia remain unresolved. They include factors constraining the automation of elevator operation and the possibility of creating an integrated ACS (ACS of technological processes and ACS of the enterprise).

The research hypothesis is formulated as follows. The implementation of automation in the grain storage process in elevators allows improving grain quality, increasing productivity, reducing or eliminating losses caused by theft and the grain storage peculiarities, saving energy resources, minimizing the impact of the human factor, and the risks of accidents.

The article reveals the factors affecting the grain quality; as well as the tasks implemented in the computerized process control system (CPCS) and management information and control system (MICS); the factors that hinder the automation of grain elevators; the tasks solved by the automation of grain elevators in the framework of autonomous subsystems and integrated automatic control systems.

## III. Research Objectives

The following research objectives were set:

*1)* To determine the factors affecting the quality of the grain should be taken into account already at the stage of grain cultivation, harvesting, primary processing, and subsequent storage.

*2)* To determine the factors that hinders the complex automation of grain elevators.

*3)* To specify the tasks implemented in the CPCS and grain elevator MICS using standard and non-standard means.

*4)* To consider the tasks solved by the integrated ACS of the grain elevator, whose solution within the local subsystems is difficult or impossible.

The article consists of an introduction, a literature review, research methods, results, discussion, and conclusion.

## IV. METHODS

### A. Research Design

To achieve the set goals, the following research methods were used in the article:

- Theoretical methods (generalization, analysis, and synthesis theoretical basis of the study). The theoretical basis of the study was grouped depending on the type of documents. The first group of sources of information consisted of studies devoted to the problem of grain quality and storage factors affecting it. The second group of information sources was devoted to the problem of automation of grain storage complexes. The considered sources of information were mainly articles from scientific peer-reviewed journals indexed in Scopus and Web of Science over the past 15 years (57 publications).

- Empirical methods (expert survey method) were employed to determine the factors that hinder the automation of grain elevators, as well as tasks implemented through CPCS and MICS, and solved using the integrated ACS of the grain elevator.

### B. The Procedure and Research Tools

The expert online survey was held as part of the annual comprehensive monitoring of the development of agriculture in Russia in 2021. The annual comprehensive monitoring was supported by six universities (Dagestan Federal Research Center of the Russian Academy of Sciences, Kemerovo State University, Moscow Aviation Institute, Russian State Social University, Moscow Polytechnic University, and Russian State University of Tourism and Service). The selection criteria for the work of experts included experience in the field of agricultural automation for at least seven years, a position at a level below a middle manager in engineering companies engaged in the design and maintenance of elevators, as well as heads of agricultural enterprises, whose interests include the use of ACS of technological processes and ACS of the enterprise of the elevator.

The expert online survey was attended by 35 experts' distribution by status and length of service is presented in Table II.

The experts were asked several questions concerning the automation of the grain elevator performance:

*1)* What are the main deterrents to the automation of elevator operation?

*2)* What tasks are subject to automation in the first place in the ACS of technological processes and the ACS of the enterprise?

*3)* What tasks can be solved by the integrated ACS of the elevator?

All participants were warned about the purpose of the survey and the planning of the organizers of the study to publish the survey results in a generalized form.

TABLE II.    DISTRIBUTION OF EXPERTS BY STATUS AND WORK EXPERIENCE

| Status | Work experience | Number, persons |
|---|---|---|
| Heads of engineering companies | 7 to 12 years | 9 |
| | Over 12 years | 10 |
| Heads of agricultural enterprises | 7 to 12 years | 4 |
| | Over 12 years | 12 |

### C. Statistical Analysis

During the mathematical processing of the research results, the percentage of expert mentions of the factors hindering the automation of grain elevators, as well as the tasks solved by the integrated ACS, was determined.

The ranking of the entire set of expert opinions consisted in their arrangement by each of the experts in the form of a sequence according to their decreasing preference.

At that, each of the opinions was evaluated by the rank (number) under which they were arranged in this sequence. The final rank represented the arithmetic mean of all the expert ranks in the sample of experts.

## V. RESULT

According to experts, despite the huge potential opportunities of the current market, the provision of a variety of automation services, the complex automation of grain elevator operations is constrained by the following factors (Table III).

According to experts, these factors predetermine the situation in which solutions to automation problems are performed within the established document flow with the same automation functions and a simple transfer, as a rule, only the technical support of the ACS to a more modern level.

TABLE III.    FACTORS HINDERING THE GRAIN ELEVATOR AUTOMATION

| Factors | % | Rank |
|---|---|---|
| Lack of objective knowledge about the potential capabilities of the ACS on the part of the customer; as a rule, decision-makers underestimate the importance of automation or, sometimes, have excessively high expectations | 74.3% | 1 |
| The lack of subject orientation of developer enterprises and, as a result, the lack of knowledge about the subject area on the part of specialists of leading enterprises specialized in providing IT services (technologies) using standard design solutions | 68.6% | 2 |

Note: compiled based on an expert survey.

Initially, the experts considered standard already functioning CPCS and MICS. According to experts, with respect to the CPCS of the grain elevator, automation should concern tasks implemented using standard (SCADA) and non-standard tools. In the MICS, tasks are implemented, as a rule, using 1C (Table IV).

TABLE IV.    TASKS IMPLEMENTED BY THE CPCS AND MICS

| Means | List of tasks |
|---|---|
| CPCS | |
| Standard | Controlling grain movement routes (several hundred, sometimes thousands of input/output signals); weighing, dosing (usually implemented using strain gauges); management of aspiration, ventilation, i.e. typical CPCS tasks implemented using SCADA systems. |
| Nonstandard | Measuring the temperature field of grain storage array (several thousand control points); grain drying control (a few dozen of the input-output signals); measuring the grain humidity in the flow; continuous grain level measurement in silos, etc. |
| MICS | |
| Standard | Accounting, tax, production accounting; as well as issues, such as personnel, salary, warehouse, trade, etc., i.e. typical MICS tasks, which are implemented using the 1C complex |
| Nonstandard | Quantitative and qualitative analysis of grain and grain accounting, grain movement accounting, decision-making support systems, etc. |

Note: compiled based on an expert survey

At that, in standard solutions, noted systems function locally, the CPS and MICS continue to remain autonomous and have no links. Meanwhile, according to experts, some automation tasks are successfully solved within the framework of autonomous subsystems.

However, the creation of an integrated ACS will allow solving problems that are difficult or impossible to solve within local subsystems (Table V).

TABLE V.    TASKS SOLVED BY THE INTEGRATED ACS

| No | Tasks | % | Rank |
|---|---|---|---|
| 1 | Grain drying in automatic mode | 82.6% | 1 |
| 2 | Performing grain acceptance and shipment operations with a given performance | 77.1% | 2 |
| 3 | Reducing or eliminating grain losses due to theft | 71.4% | 3 |
| 4 | Eliminating losses caused by the grain storage peculiarities | 62.9% | 4 |

Note: compiled based on an expert survey

## VI. DISCUSSION

Speaking about the automation of grain elevators in the framework of implementing autonomous subsystems, the majority of experts (82.6% of respondents) note that as a rule standard design solutions are developed by organizations that are official dealers of large developer enterprises. Thus, automated control systems are implemented using SCADA systems, which are collecting real-time information from remote points for processing, analyzing, and possibly managing remote objects. The requirements of real-time processing are determined by the need to deliver all the necessary events and data to the central interface of the operator (dispatcher). All contemporary SCADA systems include three main structural components:

- RTU (Remote Terminal Unit), which is the lower level of the CPCS: industrial computers, programmable logic controller (PLC).

- MTU (Master Terminal Unit), which is supervisory control center (upper level).

- CS (Communication System) [13].

The SCADA system solves the following main tasks: providing data exchange with controllers, terminal devices, and real-time data processing; visualization of the technological process progress on monitors and terminals; ensuring the storage of technical information in a real-time database; monitoring technological parameters; implementing warning alarm and alarm event protocol; generating reports on the progress of technological processes; providing data to external systems at the enterprise management level [14]-[16].

The characteristics of alternative SCADA systems are given in Table VI.

Free technical support is provided by the Russian company AdAstra Research Group LLC (TraceMode V6) – the only 100% Russian company in the SCADA systems market, as well as by JSC Klinkmann SPb, a distributor of AVEVA (InTouch V10), which has been trying to enter the Russian market since 2019.

According to experts, that is confirmed also in the works of researchers [17], the main drawback of standard design solutions is the replication of universal proposed tools without the proper orientation to a specific subject area. Besides, the functionality of the supplied equipment (software product) is due to the versatility, and therefore the excess of the means used, which leads to a decrease in reliability, the inability to take into account the specifics of the grain elevator, and leads to a lower level of automation.

TABLE VI.    CHARACTERISTICS OF ALTERNATIVE SCADA SYSTEMS FOR RUSSIA

| Name of the SCADA | The function of the process execution module | Cost of technical support, thousand USD | Availability of a free development environment | Price of the process execution module, thousand USD |
|---|---|---|---|---|
| InTouch V10 | Monitoring, management, archiving | Free of charge | - | 10.84 |
| Trace Mode V6 | Monitoring, management | Free of charge | + | 1.62 |
| Master SCADA V3.1 | Monitoring, management, archiving | 0.25 per year | + | 2.03 |
| iFix V4 | Monitoring, management, archiving | 2.2 per year | + | 8,64 |
| GENESIS32 V9 | Monitoring, management, archiving | 4.8 per year | + | 11.92 |

The second class of tasks is handled by small IT companies. Their products, as noted by one of the experts (Nikolai K., 12 years of experience), "are subject-oriented, often unique and belong to non-standard equipment". This allows them to create competitive, subject-oriented, non-redundant, unique, and in some cases significantly more reliable products that have no analogs in terms of price/quality ratio [18]. However, non-standard equipment requires additional costs for verification and metrological certification, which significantly narrows the scope of its application and, in the face of the risk of uncertainty of the final result, in the assessment of the customer, leads to insufficient funding and is usually limited to a small-scale or single-item production [19].

According to one of the experts (Alexander, 12 years of experience) "systems that are implemented using serial standard and unique non-standard tools today function locally and do not interact with each other in any way. Integrated systems that have proven themselves and are implemented using both standard and non-standard tools into a single integrated ACS will make it possible to minimize the disadvantages of each approach and maximize the benefits of each of them".

Speaking about the tasks solved by the integrated ACS of the grain elevator, experts put in the first place the possibility of drying grain in automatic mode (Table IV), since drying grain, according to one of the respondents, is "the most important stage of storage and processing technological processes, whose results depend on both consumer and technological characteristics of grain quality". As an argument, the fact is given that a deviation from the target value of the grain moisture towards increase can lead to fire-fanging of grain mass during storage, while a deviation towards decrease –to a deterioration in consumer characteristics, weight, etc. and thus, to the lost profit.

At that, the operator judges the technological process progress and the quality of grain subjectively, based on own experience. The reason for this is the inability to measure grain quality indicators directly during the technological process. This conclusion can be explained by the results of the study [20]. The operator monitors the technological process based on the current values of temperature and, in the best case, humidity, and can control the process only by setting the drying cycle time and the burner operating mode. Automatic control of the burner is impossible without an adequate control model.

Therefore, it is extremely difficult to build an adequate model for controlling the technological process of grain drying, which would allow judging the expected consumer characteristics of grain quality by the observed technological parameters, without the knowledge and experience of a qualified operator. According to experts, the drying process management using deterministic control models in practice is currently unknown. As a result, the grain drying process is controlled manually and depends entirely on the operator's qualifications.

Building a control model that would allow performing grain drying in an automated or automatic mode is an urgent task, whose solution would allow excluding unskilled actions of the operator, and therefore reducing the likelihood of deterioration of consumer characteristics of grain quality [21]. The solution of this problem is associated with the determination of the relationship between the observed parameters of the technological process and grain quality indicators, and the significance of these relationships [22]. The technological process parameters are controlled by the CPCS of the grain drying process, while the grain quality indicators are controlled by the laboratory assistant at his workstation in the quality laboratory.

According to one of the experts (Mikhail, 16 years of experience), a real alternative to deterministic models, is "building a knowledge model using the fuzzy logic instrument, which provides a link between the controlled technological parameters and the grain quality characteristics, determined in laboratory conditions. Therefore, the timely inclusion in the grain drying model of the quality characteristics of grain at the dryer inlet simplifies building a proper model and allows solving the main problem of grain drying: obtaining (or improving) the quality characteristics of grain according to their specified values".

At present, in the ACS, operating at grain elevators, there are no connections between local subsystems. Creating a knowledge model of a qualified operator, which would take into account the quality indicators and technological parameters, is an urgent task, whose solution will significantly improve the quality of grain drying [23].

Experts point out that executing grain receiving and shipping operations (Table IV) requires controlling the route of grain movement at given productivity. The grain shipment regulations require maximum possible specified performance, which can lead to congestion in problematic areas of transportation. To eliminate congestion, it is necessary to install conveyor (sectional) weighers on sections of the actuator control loop (ACL), which are functioning as intelligent shipment performance sensors. Depending on the measurement result, it is necessary to increase or decrease the shipment intensity by adjusting the rotation of the actuating mechanism (speed of the conveyor belt on the route). The solution of this problem within the framework of the ACS does not always lead to the necessary result [24]. The efficiency of solving the above-mentioned problem is significantly increased when applying a control model using data from grain movement control (MICS) and a subsystem for continuous grain level measurement in storage silos (CPCS), which is difficult or impossible to solve in the framework of SCADA systems [25].

Besides, the integration of the grain movement control subsystem and the route management subsystem allows performing technological operations providing the optimal route in terms of minimizing energy consumption, taking into account the state of technological equipment, the possibility of bypassing equipment units that have failed, by creating an alternative route, and suchlike.

According to experts, an effective solution to the problem of losses caused by theft (Table IV) is impossible without creating integrated systems based on a single information base CPCS and MICS, logical models for checking the grain movement starting from its reception operation through the

shipment operation, taking into account the identified bottlenecks and taking appropriate comprehensive measures to ensure mutual control of employees responsible for production process accounting and the technology of reception, cleaning, drying, movement, storage, and shipment (production).

In the course of grain storage, pockets of self-heating may appear (losses due to the storage peculiarities, Table IV), which can be revealed by the thermometry system indicators and eliminated by moving grain from one grain storage container to another with simultaneous cooling.

The integration of some subsystems (thermometry, grain movement, grain movement control, ventilation, and electricity metering subsystems taking into account the daily tariff variations) will allow identifying automatically the hotbeds of self-heating, determining the availability of free containers; finding the optimal route of grain movement and the time of its execution, and performing grain storage control processes in automatic mode [26]. All these measures will allow minimizing the impact of the human factor, leading to the exclusion of unjustified losses, improving grain quality, reducing energy consumption required for its movement, as well as significantly reducing the costs of controlling the systems of the ventilation system, aspiration, etc.

## VII. CONCLUSION

The research results confirmed the hypothesis that the implementation of automation in the grain storage process in elevators leads to an improvement of grain quality, increase in productivity, reduction or elimination of losses caused by theft and the grain storage peculiarities, saving energy resources, minimizing the impact of the human factor, as well as the risks of emergency situations.

The results of the study show that the main tasks solved by the integrated ACS are drying grain in automatic mode, performing operations of receiving and unloading grain with a given capacity, and reducing or eliminating losses caused by theft and features of grain storage.

The most effective practical implementation of these tasks is possible through the cooperation of organizations that specialize in the development of systems using standard tools, as well as organizations that develop non-standard automation tools.

A promising area for further research is the analysis of technologies based on reducing the volume of grain drying, ensuring high quality and reliable storage of grain products.

*Abstract*—Cloud Computing is getting popularized with the invention of latest technologies like Big Data, Artificial Intelligence, Data Science etc. The biggest challenge faced by researchers is efficient ways of accessing the data and acquiring the required results. The efficiency of the system will help the researchers to go one step further in the field of cloud computing. Alongside of storing the data in an optimal way, one biggest challenge faced by the researchers is security. How best security can be enhanced for this data in order to protect the end system from data thefts and illegal attacks. In this paper the proposed research concentrates on customized data visualization techniques that have been developed in order to store the data and also enhance the data security. These visualization patterns are dynamic in nature and can be further extended based on the need and level of the security required by the application. The proposed research in this paper will help researchers to implement the data visualization techniques with enhanced security in the real time data stored in the cloud from unauthorized access and various attacks like Malware etc. and these data patterns are dynamic in nature which will be selected based on the number of fragments need to be stored pertaining to particular cluster or region. The patterns will be selected based on two factors basically, one is the number of fragments and another important factor is how many nodes are available in the pattern. This proposed research will give an additional strength to the Cloud Computing Platforms like AWS and Google Cloud where the customers can feel that their data is in safe hands. Today when we are living in the data world, the need of this system is very much essential as it enhances the security of the data.*

*Keywords—Artificial intelligence; big data; cloud computing; data science; data visualization*

## I. INTRODUCTION

Data is the today's heart of IT companies and as data is growing day by day the major issue faced is what are the best ways to store data in order to later access it easily. The data has grown from KB's to MB's and MB's to GB, today the data produced is in Zeta and Peta Bytes from each individual source. There are two major issues faced by the cloud service providers when data is growing day by day. [15] The first one is how to store this data and the second one is what the possible ways to secure the data are. On top of it how fast the data can be accessed when needed. In olden days as the size of the data was not so huge and also the data which was getting produced was not so drastic, the industries were using servers and later moved to data centers etc., The problem again here is how fast the data can be accessed and how many data centers should be

established when data keeps on getting increased. So instead of working on physical resources, the concept of cloud computing has been introduced. In this cloud computing there is no limit on how much data is going to be stored and it's easy to access the data as data is stored virtually on the cloud.[3] The data which is getting generated might be structured or unstructured or semi structured. It might be string data or numerical or image data. And most of the cloud providers prefer third party to protect the data. The third party protection though it is preferred but cannot work all the times as it is difficult to trust the third party vendors. On top of it the data has to be protected again from these third party service providers. By considering all of the above scenarios and after extensive research, it is found that there is a need for a system which will help the cloud service providers easily to Store, Secure and Access the data easily from cloud [4].

The proposed research methodology utilizes the various data visualization techniques that are implemented in such a way that the data can be stored easily for providing highest level of security and also for the ease of access. The entire data will be stored in the cloud after proper conversion of quasi and unstructured data to structured data [5].

The final structured data will be stored in the form of fragments and these fragments will be stored in the form of customized patterns and preexisting patterns for providing high level security for the data [3]. In the proposed system if there is a need for third party, same can be involved without any hesitation. Though the third party is involved in controlling the cloud but they don't have any access to final data that is stored for future requirements, so the proposed system will work effectively to store and process the data when there is a need. [7].

## II. LITERATURE SURVEY

*1)* This Paper is referred to understand the data encryption techniques using code book.

*2)* This paper gives a clear insight on the how data visualization techniques can be implemented in light weight web pages and also scientific applications as a micro service.

*3)* The main take away from this paper is how data visualization techniques will be used for rain fall predictions and also understand what are the various default visualization images that can be used for this. The default visualization images are not up to the mark due to various reasons.

*4)* In this paper the main discussion is on how the sequential patterns will be recorded. And the sequential patterns of the objects will be stored for future data visualization patterns. It includes various objects which are static and dynamic in nature.

*5)* This paper gives an idea on how the data can be fragmented for easy storage. And also, how to encrypt this fragment to store in the cloud for security. And also gives an insight on how easily these fragments can be accessed.

*6)* In this paper the main take away is how d3 visualization can be used while decoding and storing the data. And once the data is stored how it can be extracted for future use. They built a search engine where user can give visual based inputs which will be stored in the form graphs, charts and data will be stored in that, in encoding format.

*7)* In this paper the main idea is how to generate evolutionary patterns using original data. These evolutionary patters are like data visualizations which will help in future for the urban planning.

*8)* This paper gives a clear idea on Data Visualization. Starting from what is data visualization to how these techniques can be useful in real time applications. What are the different ways this data visualization can be used like for predicting, analyzing, result, reports etc..

*9)* This paper is used to understand data encryption techniques using Siribhoovalaya and how data fragments can be encoded and decoded using such techniques.

*10)* This paper researches how the data stored in cloud can be utilized further for data visualization. In this paper the data taken is traffic data which can be used to generate data visualization patterns. After researching on this paper it is also clearly understood that most of the researches give much preference for data visualization while working on real-time data.

*11)* The main take away from this paper is how to work on behavioral lines which are getting generated in data visualization. These behavioural lines really help to understand the behaviors of objects or phenomena which is happening in real time. And also give insight on how to access cloud data for the same.

The literature survey on various papers gave clearly an idea to implement proposed research by avoiding few drawbacks faced by them.

### III. IMPLEMENTATION

In order to provide high level security for the data, the data has been encrypted using the concept of Siribhoovalaya. Once the encryption process has been done the first level of security is provided for the data [5]. The next level will be how and best the data can be stored and further accessed when it is required. To do this the concept of data visualization is used in which the data will be stored in various patterns [8]. And the patterns or either the fixed or customized patterns.

**Algorithm to Read and Store the Encrypted Data in Patterns:**

1. Start

2. Read the Encrypted Data

3. Load the Encrypted Data

4. Selection of Pattern based on Selection Function

5. Store the data as per the pattern technique.

6. Verify the final pattern.

7. Stop

In order to retrieve the data when needed just choose the pattern saved and get back the data.

**Pseudo Code to Read and Store the Encrypted Data in Patterns:**

```
Procedure RS_Encrypt()
Input: Encrypted Data
Output : Pattern Based on Encrypted Data
While not end of this document
    Data[]=datastore.getinstance()
if (Data[]!=null)
        for Data[] do
count =count+1
        else
            exit()
selection (count)
Nodes=count
Select pattern based on count value
For each node do
        Store(data[])
End procedure
```

**Algorithm to extract the data from the Pattern:**

1. Start

2. Select the solution pattern from which data needs to be extracted

3. Verify once again the pattern with Select Function.

4. Retrieve the data which is stored.

5. Cross check the Encrypted data.

6. Stop

**Pseudo Code to extract the data from the Pattern:**

```
Procedure Read(data[])
Select the pattern
        For each node
                read data at every node
                store(data[])
End Procedure
```

After these steps the data decryption algorithm will be applied in order to retrieve the original data. The main thing to observe here is that the data is not going to be stored as it is, instead, it will be stored in the form of fragments and each fragment will be assigned with a particular node in the data visualization pattern and in particular order so that it will be very easy to retrieve back the data when it is needed [9].

## IV. DATA VISUALIZATION PATTERNS

The data visualization patterns will really help in storing the data securely. And these patterns can be created and stored, which can be used basis the number of fragments and level of the security required and based on the Select Function as discussed later. Let us consider an example if the data is public that is should be shown to every customer in the organization, then normal data visualization patterns [6] will be chosen. If the data is a secured one which needs to be hid from all except the administrators, then it can use high level data visualization pattern in order to provide additional security [8].

Low Level Data visualization patterns and High-Level Data Visualization patterns will be decided basis the number of nodes available in the patterns and also it depends on the number of nodes available in the particular pattern to store the data [10].

The sample data considered here is already encrypted data using the code book algorithm pertaining to one particular category [1].

The Fragments might be a single letter or word, depending on the application it will be selected. Once the fragments are generated, in the next step data is encrypted using code book. The encrypted fragments are considered one by one to store it in the visualization pattern [12]. And for every fragment an individual ID will be generated to access it back easily when required. So the existing technology problems like Storing and Processing of cloud data will be solved in this system [1]. Also the performance of the system is tested with various factors like size of the fragment, number of fragments and Indexing. [6].

There are total 50 fragments which are encrypted. Each fragment has the encrypted data as per code book algorithm. By considering the number of fragments the following patterns are generated as a reference,

| Fragment No | Fragment Data |
|---|---|
| 1 | !#$^& |
| 2 | *&$%@ |
| 3 | !$&*# |
| 4 | )@#&* |

Fig. 1. Sample Encrypted Fragment Data for Data Visualization.

Based on the above encrypted fragments (Fig. 1), the below various visualization patterns (Fig. 2 to Fig. 8) are generated for the reference.

Fig. 2. Sample Data Visualization Pattern_Circular Structure.
Fig. 3. Sample Data Visulaization Pattern_Sequential Steps Architecture.

Fig. 4. Sample Data Visualization Pattern_Block Structure.

Fig. 5. Sample Data Visualization Pattern _Spiral Structure.

Fig. 6. Sample Data Visualization Pattern _Circular Architecture with Divisions.

Fig. 7. Data Visualization Pattern_Leaf Architecture.

Fig. 8. Data Visualization Pattern_Snail Architecture.

Fig. 2 to Fig. 8 are the sample visuals generated based on the encrypted fragment data based on the above sample data.

The above proposed method is an optimized way of storing the data into the cloud and also provides the enhanced security for the fragments in the cloud. [1].

The Encrypted Data will be stored into the cloud based on the size using either available visualization patterns or customized patterns. This data will be stored into the particular pattern based on the randomization algorithm [11].

Optimization

The optimization in this system is achieved by choosing the exact pattern which will store the data at various nodes depending on the size of the data. Here it is evident that the space will not be wasted unnecessarily by choosing the pattern of 100 nodes to store only three fragments data. And the level security plays very vital role while doing the optimization process.

## V. PATTERN SELECTION ALGORITHM FOR OPTIMIZATION

The pattern selection algorithm in this research is used to perform the optimization process on the secured data fragments which need to be stored in the cloud for further access [13]. The pattern selection algorithm will work on the select function which is defined as f(x). Based on this select function only the corresponding pattern is selected and fragments will be stored into the corresponding location of the nodes in the patterns for further accessing when it is required [7]. The select function is defined as:

f(x)= Number of Fragments (N) / Number of nodes available in the pattern (NP)

The Number of Nodes should be always greater than Number of Fragments.

The final randomization function is defined as

$f(x) = N/NP$ where $NP > N$

This Select function will be used to decide the optimization factor while storing the data into the cloud compared to the existing methods.

## VI. CUSTOMIZED PATTERN GENERATION

In the previous step the procedure of selecting the existing pattern has been discussed with respect to storing the data into the cloud. While doing the above process one more limitation the system faces after quite some time is that when all the available patterns are completed then the system is going to repeat same patterns or any new patterns are going to get generated. The proposed method will generate the customized data patterns and same will be stored in the system for further use. And also there is no harm in repeating the same patterns also as the data storing will be changed though the pattern is same.

In order to generate and store customized patterns various factors will be considered. The first and foremost factor is number of fragments which need to be stored in the pattern. Then comes the level of complexity or security. The pattern generation algorithm will consider above parameters majorly while generating the pattern.

Pattern Generation Algorithm

- Start.

- The number of fragments needs to be stored (n) (the value of n starts from 1,2,3,4,5…)

- Identify the Level of Complexity (L-Low Complexity, M-Medium Complexity, H- High Complexity)

o The complexity level can be fixed based on the level of security needs to be provided for example, L=3, M=5, H=7.

- Calculate the value of f(x), where f(x) = n*Level of Complexity

- Generate the pattern based on the value of f(x)

- Store the pattern into the system

- Stop

Once the new pattern stored into the system, again the pattern selection algorithm procedure applied in order to select the pattern based on number of fragments need to be stored.

Consider an example n=1 and L=3 then the value of f(x) = n*L = 1*3=3, means total 3 arcs need to be generated with 3 node places, out of which one is original node and remaining two will be dummy nodes.

So the default pattern will be generated and it can be customized as per the requirements. While generating the customized patterns based on the value of f(x), elements can be selected by the users like either they can use lines, boxes, QR-Codes, Circles, Some Special Images etc.,

Are the elements limited while generating pattern? Not really the user can choose various types of elements as it will be generated before storing the data, so that the system will be trained with the sample customized patterns as shown in Fig. 9, Fig. 10 and Fig. 11.

As shown above the customized data patterns can be generated by considering the f(x) value thereby storing the data further using pattern selection and randomization algorithm.

Fig. 9. Multi QR Code Based Pattern.

Fig. 10. Basket Ball Half Court Pattern.

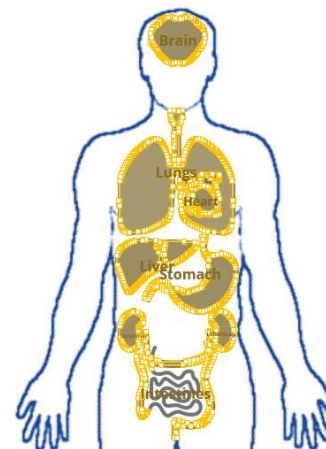

Fig. 11. Human Body – Pattern and Data can be Stored in various Parts.

## VII. COMPARATIVE STUDY

As most of the researchers working on cloud based data access and security, most of the researchers are using graph coloring process after data fragmentation process [2]. The main drawback of this algorithms is that the complexity will increase with the increase of degree of nodes (Number of Nodes) due to which the process of storing the data will be a hectic process and accessing also not so easy which will lead to NP-Hard problem [14]. To overcome this in the proposed method the pattern selection algorithm is defined in such a way that the complexity remains same though the degree of nodes will get increased continuously. Whatever might be the degree of nodes based on select function defined in Pattern selection algorithm, the pattern will be selected but the procedure to store and retrieve the data will remain the same. That means the select function can be used with various degree of nodes represented as Δ, where the value of Δ varies from 1 to n. After the process and various experiments performed are based on Δ values that the Select function derives as.

$$f(x) = \sum_{\Delta=1}^{n} N/NP \text{ where } NP > N$$

The proposed method will never lead to the NP-Hard problem as the procedure followed to generate patterns is independent to the Degree of Nodes [14].

The proposed method is very much optimized compared to the existing algorithms in order to store and access the data from cloud. Each and every pattern when storing in the cloud will be stored with a key reference for better access [5]. For example if the fragments are related to a company called A the key used to store these company fragments are represented as A_Frag_1.

Fig. 12. Comparison of Data Storage Time.

This graph (Fig. 12) depicts the time taken for storing the data onto the cloud based in the form of number of nodes. Ex: to store 10 nodes in Customized Data Pattern technique it will take 3ms whereas to do the same in existing graph coloring algorithm it will take 5ms.

This graph (Fig. 13) represents the time taken to retrieve back the nodes from cloud. Ex: in existing graph coloring algorithm it took approximately 12-13ms to retrieve 10 nodes whereas in the proposed system it took 6 to 7 ms to retrieve 10 nodes.

Fig. 12 and Fig. 13 clearly show that the results of the proposed system are satisfactory compared to existing methods.

Fig. 13. Data Retrieval Time Comparison.

## VIII. ENHANCED SECURITY

Coming to security as the hackers try to hack the data, the Encrypted data position is not known to the hackers as the size of the pattern i.e. number of node places will be decided by the service provider so that the select function value will be very difficult to identify. If suppose the hacker identified the random function again, he needs to work on decrypting the data as the encryption algorithm used in this paper is very secured which is called as Code Book based algorithm [1]. The proposed system compared to existing methods is optimized and enhances the security for fragments which are getting stored in the cloud. Fig. 14 gives the encryption time for different algorithms.

In the Table I the proposed Code Book (ref. Table II) algorithm is compared with the existing algorithms with respect to encryption time. And it is found that the code book algorithm will give very good results compared to existing algorithms with respect to encryption.

Fig. 14. Encryption Time for different Algorithms.

TABLE I. AVERAGE TIME TAKEN FOR ENCRYPTION OF DATA FRAGMENTS (BASED ON SIZE)

| Time in (ms) | 10KB | 100KB | 200KB | 400KB | 800KB | 900KB | 1024KB |
|---|---|---|---|---|---|---|---|
| Blow Fish | 1 | 1 | 2 | 5 | 11 | 17 | 21 |
| AES | 1 | 1 | 2 | 2 | 3 | 3 | 3 |
| RSA | 1743 | 17177 | 36814 | 73216 | 143206 | 162905 | 181246 |
| XOR | 1 | 2 | 4 | 6 | 356 | 358 | 489 |
| Code Book | 1 | 1 | 1 | 1 | 2 | 2 | 2 |

TABLE II.     SAMPLE CODE BOOK

| S. No | Letter/Number | Symbol |
|-------|---------------|--------|
| 1. | A | ↓ |
| 2. | a | € |
| 3. | B | ¥ |
| 4. | b | α |
| 5. | 1 | Ш |
| 6. | 2 | ꝙ |
| 8. | 3 | ɘ |
| 9. | , | ϒ |
| 10. | . | ✓ |

## IX. REAL TIME TESTING OF THE PROPOSED RESEARCH

In order to test the encryption technique used and data visualization techniques, the data has been shared with the certified ethical hackers to test it. The ethical hackers tried for almost 10 to 15 days and came back and said it is very difficult to crack the final data, so it is evident that the proposed research provides best security for the data which is getting stored in the cloud. The proposed method will provide multi-level security for the data which is getting stored on the cloud. One method is in the form of Encryption and another way using data visualization [6].

## X. CONCLUSION

It is evident that from the proposed research whatever data is getting stored on the cloud is very well protected from all the attacks which are expected while working in real time. And also the proposed solution will give ease of access to the data which is stored on the cloud. The patterns are selected basis the pattern selection algorithm based on the number of fragments and also the number of data node representations available in the particular pattern. So it is very clear that the data storing and processing will be an easy process with the proposed procedure.

## XI. FUTURE ENHANCEMENT

At present the proposed solution is working very well for the data which is stored as either individual data set or as a fragment without any limitation. In future, same system can be used to store the images for providing security. And also the data visualization patterns can be drawn in much more complex way in order to increase the level of security.

# Incremental Learning based Optimized Sentiment Classification using Hybrid Two-Stage LSTM-SVM Classifier

Alka Londhe, P.V.R.D. Prasada Rao

Department of Computer Science and Engineering
Koneru Lakshmaiah Education Foundation, Vaddeswaram, AP, India

*Abstract*—Sentiment analysis is a subtopic of Natural Language Processing (NLP) techniques that involves extracting emotions from unprocessed text. This is commonly used on customer review posts to automatically determine if user / customer sentiments are negative or positive. But quality of these analysis is completely dependent on its quantity of raw data. The conventional classifier-based sentiment prediction is not capable to handle these large datasets. Hence, for an efficient and effective sentiment prediction, deep learning approach is used. The proposed system consists of three main phases, such as 1) Data collection and pre-processing, 2) Count vectorizer and dimensionality reduction is used for feature extraction, 3) Hybrid classifier LSTM-SVM using incremental learning. Initially the input raw data is gathered from the e-commerce sites for product reviews and collected raw is given to pre-processing, which do tokenization, stop word removal, lemmatization for each review text. After pre-processing, features like keywords, length, and word count are extracted and given to feature extraction stage. Then a hybrid classifier using two-stage LSTM and SVM is developed for training the sentimental classes by passing new features and classes for incremental learning. The proposed system is developed using python and it is compared with the state-of-the-art classification techniques. The performance of the proposed system is compared based on performance metrics such as accuracy, precision, recall, sensitivity, specificity etc. The proposed model performed an accuracy of 92% which is better compared to the state-of-the-art existing techniques.

*Keywords—Sentiment analysis; natural language processing; incremental learning; long short-term memory; support vector machine; hybrid; dimensionality reduction; principal component analysis*

## I. INTRODUCTION

Sentiments play an important role in rational decision making, perception, memory, creativity, human intelligence, social interaction, learning and more. Sentiment analysis and Opinion mining is a subtopic of text mining and NLP (Natural Language Processing) that deals with the extraction of knowledge and automated discovery about people's opinions, evaluation and sentiments from textual data such as review websites, customer feedback forms and personal blogs [1,2]. Sentiment analysis and opinion mining is a region, which has received significant interest in recent times because of its application and practical usage in today's environment. Emotion analysis of text involves cautious modelling of context, association of words with different emotions and

contexts with changing levels of magnitude making the identification of words for document representation. Emotions are categorized into surprise, sadness, anger, fear, excitement and disgust [3]. For example, a sentence containing beautiful morning #amazing, the word amazing could be related strongly with emotion joy, morning could be weakly associated with emotion joy and beautiful will be related moderately to emotions such as joy and love. Emotion lexicons capture such word-emotion associations [4]. To organize the data and improve classification performance, lexicon dependent holoentropy is applied. It is created to reduce the computational risk associated with solving a multidimensional problem. The similarity score between the keywords of all sentiment classes and semantic words is determined using combined holoentropy [5]. However, these methods rely on lexical resources (external) which are concerned with mapping words to a numerical sentiment score or categorical (positive, negative, and neutral). Clearly, the efficiency of the entire method intensely depends on one of the best lexical resources, which relies on it [6]. As a significance, the efficiency of certain widespread is available on lexical resources, which is in the task for classification of microblog posts.

Sentiment analysis (SA) using supervised machine learning algorithms is popular and provides better results compared to unsupervised machine learning algorithms. However, supervised approaches require a labelled training set, which is time and labor-intensive operation [7, 8]. Whereas, the unsupervised approaches don't need labelled training set. The emotions can also be acquired by the reviews, which can be collected not only from applications but also provide comment features such as Google Play Store [9]. Platforms like Amazon, Flipkart are regularly used by users/customers to give their sentiments about numerous subjects, including the product quality [10, 11]. Nevertheless, social media does not have rating system and companies being observed cannot instantly detect the sentiment of these remarks. As a result, many businesses and companies have a strong claim for sentiment classification. By using a machine learning method, computer can learn emotion form text. In machine learning, computers cannot solve problems by applying pre-programmed rules, but rather by creating a model that can evaluate an example [12]. Hence, it can anticipate a sentiment or emotion. Machine learning is also a part of AI (Artificial Intelligence), which is a subset of deep learning.

Deep neural networks are utilized by deep learning to obtain input data that can be used for improved representation and to complete a task precisely [13, 14]. Likewise, sentiment analysis using deep learning techniques has a better accuracy compared to the traditional machine learning techniques such as SVM and Naïve Bayes (NB). Multiple or hybrid classifiers are mainly used for better training and better performance metrics than the single classifier. The error of single classifier will be greater than hybrid classifier because in hybrid, the trained data of one classifier will be given to the input of another. so, the trained net will be effective compared to the single classifier. Incremental learning technique is necessary to develop the learning models or trained net, which is capable of adding newly available classes without the need of retraining the models. Though many techniques had performed better but the error rate and performance of the existing technique is not achieved well [15]. So, in the proposed research effective feature selection is designed to enhance the classification performance.

The contribution of the paper is as below:

- To acquire extraction of data from the raw data, pre-processing technique is used that consists of sentence splitting, tokenization, spell correction, stop-word removal and lemmatization.

- To extract datasets more conveniently and effectively, the count vectorizer and dimensionality deduction is used.

- To attain an effective classification, the hybrid two-stage LSTM-SVM approach is used.

The upcoming portion of the paper is organized as follows; Section II illustrates certain research articles related to existing methods used for sentiment analyzing. Section III describes briefly about the proposed methodology. Section IV explains the results and performance metrics of the proposed framework. Section V concludes the entire research work.

## II. RELATED WORK

Several feature selection algorithms have been introduced for choosing the most relevant features that are required for better classification. The most commonly used feature selection techniques are SVM and LSTM. Some of the existing feature selection technique used in sentiment analysing is reviewed below.

Fu X et al. [17] has performed sentiment analysis using long short-term memory networks (LSTMs). This method is based on combination of LSTM with embedded words for representation of text. However, embedded words carry more semantic data than the sentiment data, so that the embedded word will cause inaccuracy to the sentiment analysis. To solve these issues, a lexicon-improved LSTM model is developed, which uses the sentiment-based lexicon as an additional data for sentiment classifier to pre-train a word and then include embedded sentiment words that are not inside the lexicon. The usage of a hybrid sentiment embedding and word embedding can improve word representation accuracy. Furthermore, without the intention of improving the LSTM's ability to gather global sentiment data, a new method for identifying the

sensitivity vector in common sentiment analysis is developed. The outcomes of this model have comparative or better results than the existing models. Londhe A et al. [18] proposed incremental approach using LSTM-RNN for aspect level sentiment analysis. Major outcome of the paper was automated aspect extractions with comparable accuracy.

Long F et al. [19] aim to investigate the sentiment interpretation of social media in Chinese text by incorporating the Multi-head Attention (MHAT) mechanism with Bidirectional Long-Short Term Memory (BiLSTM) networks, in order to overcome the lack of Sentiment Analysis, which is currently carried out using old machine learning techniques. BiLSTM networks retain the text's actual context and resolve the issue of long-term dependency. By performing numerous dispersed calculations, the MHAT process can obtain related data from a distinct illustration subspace, and impact weights are added to the generated text sequence. The numerical experiments reveal that the suggested model outperforms existing well-established approaches. Rhanoui M et al, [25] also investigate CNN-BiLSTM model for document level sentiment analysis.

Khanvilkar, G et al. [20] has designed sentiment analysis for product recommendation using random forest algorithm. Sentiment analysis is a tool for analysing natural language and determining human emotions. The purpose of emotion analysis is to identify the polarity of a person's textual opinion and it can also be used to provide product suggestions. Products can be recommended to another user based on user reviews. Sentiment analysis is used by major product websites to analyse the difficulties and popularity of the product. Sentiment analysis is usually described as a task with two classification classes: negative and positive. Using ordinal classification, this approach calculates the polarity of user-provided reviews. Using machine learning methods SVM and Random Forest, the system will determine polarity. Users will be given recommendations based on the polarity that has been attained.

Can, E. F et al. [21] has designed Multilingual Sentiment Analysis using RNN-Based Framework for Limited Data. Sentiment analysis is a type of NLP work that evaluates a user's feelings, opinions, and ratings of a product. The fact that sentiment analysis is primarily reliant on language is one of the most difficult parts of it. Language-specific word embedding's, sentiment lexicons, and even annotated data exist. Optimizing models for each language is very time consuming and labour intensive, especially for RNN (Recurrent Neural Network) models. From a resource aspect, gathering data for several languages is relatively difficult. A sentiment analysis approach based on RNN is trained with reviews in English and translated into other languages to do this. As a result, the model may be used to assess feelings in different languages. According to the experimental results, the robust technique of a single model trained on English reviews statistically achieves the benchmarks in other languages.

Anitha Elavarasi S. et al., [22] In the age of big data and internet technology, organisations can use sentimental analysis or opinion mining to collect feedback on their services or goods in a more accurate and effective manner. In this paper

linear regression and support vector machine are applied to the IMDB data sets. There are 50000 movie reviews in the dataset, with both negative and positive polarity remarks. SVM classifier and logistic regression were used as machine learning algorithms. The outcomes were analysed through accuracy, precision and recall. In comparison to SVM, which has an accuracy of 81%, logistic regression has a higher accuracy of 90 percent, making it more successful than SVM.

From the above-mentioned literature studied, various feature selection methods are designed based on LSTM [17, 18, 26], BiLSTM [19, 25], RF [20], RNN [21, 27], SVM [22] and hybrid LSTM-SVM [23] techniques. But rate of error is high and accurate prediction is lesser while using this existing method. At the same time optimal feature selection subset is not attained in the existing algorithm. Therefore, selection of hybrid feature algorithm is designed in this proposed research for effective selection of features from the dataset.

### III. PROPOSED METHODOLOGY

Natural Language Processing (NLP) technique is a Sentiment analysing process that contain extracting of sentiments associated with some raw texts.

Generally, on social media, people used to post customer reviews in order to automatically understand, whether it is positive or negative review but quality of these analysis is completely dependent on its quantity of raw data. So recently, researchers are trying to utilize large dataset for modelling the sentiment prediction. The conventional classifier-based sentiment prediction is not capable to handle these large datasets. So, for an effective and efficient sentiment prediction, hybrid models on hybrid platforms need to be used [16]. In this paper an efficient deep learning-based hybrid model for sentiment prediction is proposed.

Fig. 1 illustrates the architecture of proposed model. It consists of three phases: 1) Data collection and pre-processing, 2) dimensionality reduction and feature extraction, 3) classification and incremental learning are the three primary steps of the proposed system. The raw data for the input is initially obtained from the online platforms for product reviews such as Amazon, Flipkart and Snapdeal. The data is pre-processed to eliminate superfluous information as keywords, length, and word count are extracted after pre-processing. After pre-processing techniques, emotional features are extracted with count vectorizer and dimensionality reduction, which is used for extracting the unwanted words for reliable sentiment analysis and converting it to vector format. Then, for sentimental class prediction, hybrid two-stage LSTM-SVM approach is used for training the sentimental classes. The new classes and features are introduced during training phase for incremental learning.

#### A. Data Collection and Pre-processing

By reviewing the literature, it is found that aspect extraction and sentiment classification have not been studied satisfactorily on Yelp dataset [29]. This dataset is well described in results section. Pre-processing phase involves filtering noisy text using a variety of pre-processing techniques [24], such as sentence splitting, tokenization, spelling correction, lemmatization, case-conversion, stop-word removal

and anaphoric reference resolution. These steps are used to omit irrelevant phrases to offer better categorization.

- Splitting: The technique of breaking up a text string in a systematic way so that the individual parts of the text may be processed is known as string splitting. For example, a timestamp can be divided into hours, minutes, and seconds. So that those values can be used in the numeric analysis.

- Tokenization: Tokenization is an action of dividing a sequence of strings into pieces such as symbols, phrases, keywords, words, and other elements called tokens. Tokens can be individual phrases, words or even whole sentences.

- Stop word removal: Stop words are a group of terms that are regularly employed in any language. In English, "and", "is" and "the" would easily qualify as stop words. Stop words removal phase is used in NLP and text mining applications to remove unnecessary terms, enabling applications to concentrate on the subsequent words accordingly.

- Lemmatization: Lemmatization describes the process of gathering words with the same lemma or root, but different meaning derivatives so that they can be analysed as a single item.

- Spell correction: Spelling correction is a well-known task in NLP. It uses techniques of "noisy and correct word mappings" data from numerous sources for automated spell correction.

#### B. Pre-processed Data Extraction for New Features

The new features are updated with the pre-processed data by using the below mentioned feature extraction process.

Fig. 1.    Proposed Model of Sentimental Analysis and Text Classification.

- Words and Their Frequencies: The frequency counts of unigrams, bigrams, and n-gram models are considered as features. Additional research has been done to properly characterize this feature using the word presence rather than frequencies.

- Parts of Speech Tags: Adjectives, adverbs, and certain groups of verbs and nouns are excellent indicators of subjectivity and sentiment.

- Opinion Words and Phrases: Apart from individual words, phrases and idioms that can convey emotion as features. For example. Someone's arm and a leg,

- Position of Terms: The placement of a term in a text can have an impact on how much the term affects the overall theme of the text.

- Negation: Negation is a significant feature that can be difficult to interpret. When a negation is present, the polarity of opinion is usually altered.

- Syntax: Many academics employ syntactic patterns such collocations are used as features to learn subjective patterns.

If the pre-processed data is "best coffee" then the feature extraction of parts of speech will be 1, 1. This is because "best" is an adjective and "coffee" is a noun, both the parts of speech contain one word. So, the outcome of these pre-processed data is 1, 1. Likewise the other method such as opinion words and phrases, position of terms, negation and syntax are used for extracting the features. These extracted and the features are updated to the class.

### C. Feature Extraction

Feature extraction is a process of extracting the required features for sentimental classes. The features are retrieved using a countvectorizer and dimensionality reduction, which reduces a large amount of raw data into smaller groups for analysis. A disadvantage of huge data sets is that processing a higher number of variables which demands a lot of computational resources. So that, the dimensionality reduction technique is utilised to solve this issue.

*1) Countvectorizer*: Countvectorizer is a major tool used in the python for converting the given text into vector with the frequency of each word that occurs in the entire text. This is helpful in converting multiple texts into each vector [24]. Each text sample and unique word is represented in row matrix and column matrix. Though the sentences of data may be in different size, the conversion of word to vector will be of same rows and columns for each and every other sentence.

*2) Dimensionality reduction*: It is necessary to smooth the input text dataset before applying a feature extraction and reduction model using Principal Component Analysis (PCA). PCA's primary goal is to extract important features from a big dataset and produce a lower-dimensional feature space. It may be used to extract data from a large number of different datasets. In addition, if we use a bigger dataset for analysis, the classifier will take longer to run. For this reason, feature

extraction and dimension reduction are used to reduce the size and complexity of the data representation.

*3) Hybrid two-stage LSTM-SVM classifier*: In this proposed model, the hybrid two-stage LSTM-SVM approach is used for sentiment classification. Extracted features from dimensionality reduction are given as an input to this hybrid model.

*a) SVM Classification*: SVM is a state-of-the-art supervised ML algorithm which can be used for both regression and classification tasks. The SVM finds hyperplanes that differentiate the classes to perform classification task. For a set of training vectors belonging to separate classes, shown in (1):

$$\{(x^1, y^2), \dots, (x^m, y^m)\}, \qquad x \in R^n, y \in \{1, -1\} \qquad (1)$$

Mathematically a hyperplane for separating two classes can be represented as shown in (2):

$$\sum_{i=1}^{M} X_{ij}^l y_i^l + Bias^l \qquad (2)$$

This can be written more in vector format as $< W, X > + b = 0$. Here X is "an input vector or document", W is known as "a weight vector and corresponds to the normal vector" for separating hyperplane 'H', m represents "the number of input variables, in the case of text, this can be viewed as the number of words (or phrases, etc.) that are used to describe a document" and b denotes "the perpendicular distance from the hyperplane to the origin".

$$min|(w, x^i) + b| = 1 \qquad (3)$$

From the above equation, it be evaluated that the optimal separating hyperplane given by:

$$w^* = \sum_{i=1}^{l} \alpha_i y_i x_i \qquad (4)$$

$$b^* = -0.5(w^*, x_r + x_s) \qquad (5)$$

$\alpha_i$ is the multiplier, $x_s$ and $x_r$ are support vectors that satisfies each class $\alpha_r > 0, y_r = -1; \ \alpha_s > 0, y_s = 1$.

*b) LSTM Classification*: LSTM is a variant of RNN, it deals with the vanishing and exploding gradient problems. LSTM unit is consisting of a cell, forget gate, an input gate and an output gate.

$$f_i = \sigma(W_f x_i + U_f h_{i-1} + b_f) \qquad (6)$$

$$i_i = \sigma(W_i x_i + U_i h_{i-1} + b_i) \qquad (7)$$

$$o_i = \sigma(W_o x_i + U_o h_{i-1} + b_o) \qquad (8)$$

$$c_i = f_i * c_{i-1} + i_i * \tan h (W_c x_i + U_c h_{i-1} + b_c) \qquad (9)$$

$$h_i = o_i * \tan h (c_i) \qquad (10)$$

Here, $h_i$ represents hidden state, $c_i$ is the central state, $o_i$ is the output gate, $i_i$ is the input gate and $f_i$ is the forget gate.

Fig. 2 illustrates the combined architecture of the hybrid two-stage LSTM-SVM model. Extracted features are given to input layer. The hidden layer of the LSTM consists of N layers. These layers will get interacted and given to the fully connected layer. LSTM is similar to RNN, but it has only one

tanh layer. The LSTM has two tanh layers and 3 sigmoid layers. The output from the hidden layer is given to the fully connected layer. The softmax layer of the LSTM is replaced with SVM for classification. Softmax layer is a softmax function, which is mainly used for multi-class classification. The SVM first finds hyperplanes that differentiate the classes to perform classification task. Thus, the prediction of sentiment class will be acquired as an output from the classifier.

*c) Incremental Learning*: In incremental learning, first trained-net produces a classification of sentiment with a set of extracted features. The output from the trained-net (X) will be sentiment classes e.g. happy, sad, shock and angry as shown in algorithm.

Fig. 2. Hybrid Two-Stage LSTM-SVM Architecture.

Then for incremental learning the new features (Y) are added to the trained-net (X), it produces an updated trained-net output (Z=X+Y). This updated trained-net will predict the new features according to the sentiment classes such as happy, sad, shock and angry. Likewise, the new classes (N) are added to the trained net (X) for producing an updated trained-net (N1), these updated trained-net (N1=X+N) will be addition of new classes and existing classes. The new class consists of confident and confused and the existing class consists of happy, sad, shock and angry. These classes are added and produce an updated trained net (N1) output, which consist of happy, sad, shock, angry, confused and confident as mentioned in Fig. 1.

## IV. RESULT AND DISCUSSION

The acquired datasets consists of special characters, uppercase and keywords. These characters in the sentence are extracted by using the pre-processing technique, which consist of spell correction, tokenization, stop word removal, splitting and lemmatization. Next process is feature extraction for removing the unwanted words because large data will take more processing time, to overcome this issue the dimensionality reduction is used. The extracted features from the countvectorizer and dimensionality reduction are given to the hybrid two-stage LSTM-SVM classifier for sentimental analysis.

---

**Algorithm:      Incremental Hybrid Two-Stage LSTM-SVM Classifier for Sentiment Classification**

Input raw dataset = A

---

For all data in dataset

#Pre-processing (A)
 A1 = Splitting (A) // Sentence splitting into words for processing
 A2 = Tokenization (A1) // Breaking sequence of strings into pieces
 A3 = Stop word removal (A2) // stop words such as "the", "an", "a" are removed
 A4 = Lemmatization (A3) // Changing words with different derivatives
 A5 = Spell correction (A4) // auto correction of noisy to proper words for misspelled words

#Feature extraction
 A6 = Countvectorizer (A5) // Conversion of string to numerical
 A7 = Dimensionality reduction (A6)

#Hybrid Two-stage LSTM-SVM Classifier
 L = LSTM (A7) // Numerical value from Countvectorizer is classified with LSTM
 S = SVM (L) // Last layer output of LSTM is classified with SVM

#Incremental Learning
 Trained-net = S
 For (i=0, i=i+n, i++) // Initial value = 0, number of features = n, new features = i
 {      Z=S+i        // Adding trained-net and new features, Updated trained-net (Z)
 }
 For (j=0, j=j+n, j++) // Initial value = 0, number of features = n, new classes = j
 {      N=S+j        // Adding trained-net and new classes, Updated trained-net (N)
 }

---

Output: Prediction of sentiment classes based on reviews with incremental learning

---

*a) Datasets*: For Model evaluation four separate datasets were used. 1) Sentiment Labelled Sentences Data Set [28]: in this dataset, sentences are selected from three different websites: {imdb.com, amazon.com, yelp.com}. From each website, 500 positive and 500 negative sentences are randomly selected. 2) Large Movie Review Dataset [29]: this dataset is taken from Kaggle - IMDB dataset of 50000 movie reviews. 3) Amazon product review dataset [30]: this dataset contains product reviews (ratings, text, helpfulness votes). 4) The Yelp dataset [31, 32] is a subset of reviews, businesses and user data for use in personal, academic purposes and educational. This dataset consists of 8,635,404 reviews, 160,585 businesses, 200,000 pictures and 8 metropolitan areas.

Fig. 3 illustrates the extraction of input in the prepossessing step. Datasets is acquired and converted to lower case. Sentence will be extracted by the special character removal, which removes the special characters such as '@', '#', '_'. Then splitting and localization process will take place, this is used to split each and every word and localize it. After splitting and localization, the next step is removal of the stop words such as is, are, a, an, the etc. These are the steps involved in the pre-processing technique and the next step is data partitioning and feature extraction. The feature extraction is implemented by the Yake tool [33]. The extracted features are classified by a two-level classifier, which is a hybrid model that is combination of LSTM and SVM. The performance of state-of-the-art existing feature selection approaches is compared with proposed feature selection process. The performance attained using Accuracy, Precision, Recall, F-1 score, Specificity, False Negative Rate (FNR), False Positive Rate (FPR), Negative Predictive Value (NPV) and Error.

Table I and Table II illustrate the results obtained on datasets 1, 2, 3 & 4 for various metrics using the existing and proposed sentiment classification model. The values for parameters such as Error, FNR, FPR are smaller as compared to existing techniques and the metrics such as accuracy, precision, recall, F-1 score and NPV are greater as compared to existing techniques. The below section will explain graphical representation for the comparison of proposed and existing models.

| Input Review | Output Tokens |
|---|---|
| The food is always great here. The service from both the manager as well as the staff is super. Only draw back of this restaurant is it's super loud. If you can, snag a patio table! | 'food', 'always', 'great', 'service', 'manager', 'well', 'staff', 'super', 'draw', 'back', 'restaurant', 'super', 'loud', 'sang', 'ratio', 'table' |
| This place used to be a cool, chill place. Now its a bunch of neanderthal bouncers hopped up on steroids acting like the can do whatever they want. There are so many better places in davis square where they are glad you are visiting their business. Sad that the burren is now the worst place in davis. | 'place', 'used', 'cool', 'chill', 'place', 'bunch', 'neanderthal', 'bounce', 'hoped', 'osteoid', 'acting', 'like', 'whatever', 'want', 'many', 'better', 'place', 'davis', 'square', 'glad', 'visiting', 'business', 'sad', 'burden', 'worst', 'place', 'davis' |
| The setting is perfectly adequate, and the food comes close. The dining chains like Chilis and Victoria Station do barbecue better. It's no surprise you can always pick up coupons for Linwood at restaurant.com. | 'setting', 'perfectly', 'adequate', 'food', 'come', 'close', 'dining', 'chain', 'like', 'child', 'victoria', 'station', 'barbecue', 'better', 'surprise', 'always', 'pick', 'coupon', 'linwood', 'restaurant', 'com' |

Fig. 4 illustrates the comparison metrics as mentioned in Table II and Table III, for proposed approach with the existing approaches. In this the existing approach such as LSTM, SVM, ANN, and RF are compared with the proposed approach of hybrid two-stage LSTM-SVM. It is observed that hybrid two-stage LSTM-SVM performs well in comparison with approaches.

Table III illustrates the comparison of performance metrics for incremented classes and features on the proposed model.

Fig. 5 illustrates the accuracy comparison of incremented values for the proposed model. In this figure, the performance metrics for three class 50 features is smaller compared to incremented three class 75 features. The performance metrics of the incremented five class 50 features is smaller compared to the five class 75 features. From this, the incremented class and features of the proposed model attains a best performance metrics.

Fig. 4.   Comparison of Accuracy, Error, Precision, Recall, Specificity, F1-Measure, FNR and FPR Metric.
TABLE III.    COMPARISON OF PERFORMANCE METRICS FOR INCREMENTED CLASSES AND FEATURES ON THE PROPOSED MODEL

| Proposed method | 3 class with 50 features | 3 class with 75 features | 5 class with 50 features | 5 class with 75 features |
|---|---|---|---|---|
| Accuracy | 0.895 | 0.99 | 0.85 | 0.88 |

## V.    CONCLUSION

This paper aims to design best sentiment analysis for social media posts and review comments. Many researchers are trying to utilize the large datasets for sentiment analysis but the performance of conventional techniques is not satisfactory. In this technique, features are extracted and converted by the countvectorizer, then for classification a hybrid two-stage LSTM-SVM model is used to predict sentiments. The proposed hybrid two-stage algorithm is validated and compared with the state-of-the-art existing sentiment classification technique. The comparison analysis revealed that the proposed model has excellent performance metrics. The accuracy of the proposed model varies according to the incremental leaning, the accuracy for three class 50 and 75 features is 89 and 99 then, the accuracy for five class 50 and 75 features is 85 and 88. This analysis reveals that the incremented class and features attain a better accuracy.

# Data Recovery Approach with Optimized Cauchy Coding in Distributed Storage System

Snehalata Funde*, Gandharba Swain

Department of Computer Science and Engineering
Koneru Lakshmaiah Education Foundation
Vaddeswaram-522302, Guntur, Andhra Pradesh, India

*Abstract*—In the professional world, the impact of big data is pulsating to change things. Data is currently generated by a wide range of sensors that are part of smart devices. It necessitates data storage and retrieval that is fault tolerant. Data loss can be caused by natural calamities, human error, or mechanical failure. Several security threats and data degradation attacks attempt to destroy storage disks, causing partial or complete data loss. The data encoding and data recovery mechanisms is proposed in this research. To produce a set of matrices utilizing matrix heuristics, the suggested system proposes an efficient Optimized Cauchy Coding (OCC) approach. In this paper, the Cauchy matrix is used as a generator matrix in Reed Solomon (RS) code to encode data blocks with fewer XOR operations. It reduces the encoding algorithm's time complexity. Furthermore, in the event of a disk failure, missing data from any data block is made available through the Code word. In terms of data recovery, it outperforms the Optimal Weakly Secure Minimum Storage Regenerating (OWSPM-MSR) and Product-Matrix Minimum Storage Regenerating (PM-MSR) methods. For data coding, a 1024KB file with various combinations of data blocks $l$ and parity blocks m is evaluated. In the first scenario, $m$ is 1 and $l$ ranges from 4 to 10. The value of $l$ is 4 in the second scenario, while $m$ ranges from 1 to 10. The existing OWSPM-MSR approach takes an average of 0.125 seconds to encode and 0.22 seconds to decode, whereas the PM-MSR approach takes an average of 0.045 seconds to encode and 0.16 seconds to decode. The proposed OCC approach speeds up data coding by taking an average of 0.035 seconds to encode and 0.116 seconds to decode data.

*Keywords—Optimized cauchy coding; fault tolerant; data availability; reed solomon code*

## I. INTRODUCTION

Nowadays, social media is the primary source of data generation that we refer to as "big data," and it generates tremendous amounts of data. It is both enormous in size and intricate in nature. As a result of the current pandemic crisis, the use of the internet and smart phones is increasing every day. As a result, numerous businesses generate a high volume of records in the Petabyte or Exabyte range. Traditional systems are limited in their ability to capture, store, and analyze such large amounts of data, according to Wang et al. [1]. Large datasets can now be stored, compiled, and evaluated because of advancements in processing and storage capabilities. Big data analytics offers novel approaches to analyzing massive datasets. Few applications are rigorously found in the domains of healthcare, finance, traffic management, education, and retail [2]. Furthermore, the increase in data necessitates attention to several difficulties such as privacy, integrity, and access control, all of which are required to protect data from various attacks such as data degradation attacks and man-in-the-middle attacks. The current research uses a Cauchy matrix generation method to build and create models that can be used to manage data recovery for dispersed datasets.

Yang et al. [3] describe a multi-cloud storage system that optimizes security and affordability. Chervyakov et al. [4] proposed a distributed data storage system for processing encrypted data and controlling calculations. Furthermore, the Redundant Residue Number System is used to discover and remedy errors. For distributed cloud storage, a block chain approach to security architecture is being investigated. Li et al. [5] used a genetic algorithm to solve file block duplication among numerous users and data centers. Bhuvaneshwari & Tharini [6] argue that scalable and dependable distributed storage systems are essential due to the growing volume of data. For massive data storage, Low Density Parity Check (LDPC) codes are being investigated. Tang & Zhang [7] demonstrate how a Vander-monde matrix is concatenated with an identity matrix to ease encoder and decoder design. Furthermore, in bit matrices of the Cauchy matrix, several finite fields are explored to decrease one. Erasure-resilient codes are Cauchy Reed-Solomon (RS) codes. Makovenko et al. [8] describe the use of heuristic perturbation to optimize coding bit-matrices for fault tolerant data storage. The ability to serve multiple clients at the same time is one of the most significant requirements of cloud storage solutions. The help rate region is a new addition to the map. Kazemi et al. [9] defines a Quality of Service (QoS) metric for coded, distributed setups. It's a collection of information access requests that the system manages all at once.

Dai & Boroomand [10] offered a combination of big data and man-made consciousness technologies to improve security by detecting attacks on internet-connected devices. Ravikumar & Kavitha [11] demonstrate how to use adaptive hybrid mutation to optimize a black widow clustering approach. To improve remote sensing retrieval mechanisms, Li & Zhang [12] propose widely open datasets with evaluation metrics. Xiao & Zhou [13] propose classifiers based on resource optimization and framework to minimize data repair and update concerns in erasure coding schemes. Gong & Sung [14] introduce zig-zag codes as erasure codes for data decoding. The dependability vs. storage trade-off is examined. Dau et al. [15] consider the Cauchy and Vander-monde

---

*\*Corresponding Author.*

matrices while constructing maximum distance separable codes to tackle coding challenges. This method is used to select arbitrary Vander-monde/Cauchy matrix evaluation points. It necessitates the use of very small finite fields. The dimensions of the generator matrix are polynomial. Additional design limitations are implemented, rendering the Vander-monde/Cauchy matrix ineffective for code construction. Wu et al. [16] show how to use Cauchy RS codes to improve the efficiency of distributed storage systems. It starts by calculating the best post scaling encoder matrix based on the data migration policy. Following that, the data transfer process is optimized using the chosen post scaling encoder matrix. The Solomon code protocol for multi-party authentication is thought to improve the security of the system. When data is large, it can be difficult to construct Solomon code as matrix creation since it takes a long time. Another difficulty with several portions is space complexity. Information is securely stored in a wireless network using both local and geographic replication. It aids in the recovery after a disaster. Zhang et al. [17] discuss the architecture, as well as resource supply and replication technologies. It reduces the time it takes to deploy software and increases customer adoption. The disadvantage is that it necessitates a larger development pool.

Chen & Ma [18] present a disk recovery strategy that is both efficient and cost-effective. It decreases the amount of data that is read from the disk. Furthermore, the workload quantity on all surviving disks is the same. To recover the failed disk, only a few disk reads are needed. Recovery of all the data takes a long time. Shen et al. [19] demonstrate how to determine the optimal number of code word pictures for any XOR-based erasure code. It produces recapture rosters with the least amount of data possible. It also improves I/O performance for cloud document frameworks that use large square sizes. For the length of recuperation, it reduces the amount of data read. Its drawback is that it necessitates a significant amount of area. On database servers, it causes a heating problem. Burihabwa et al. [20] suggest using a flat XOR-code for data recovery. Recovery schedules are also generated. As a result, the execution time is minimized. Periodic system backup is not included in this system's configuration. Hadoop is a platform for storing and analyzing massive data sets. Hadoop Distributed File System (HDFS) is used to store the large amount of data. Partitioning a large record into blocks is considered a block position strategy. Following that, it was assigned to the homogenous cluster. Shah & Padole [21] offer a novel approach to updating the information blocks on explicit hubs. Total nodes are split into two categories: homogenous and heterogeneous, and high and low performing nodes. It improves node burden revision. Its drawback is that it requires a capacity approach that can work on both homogeneous and heterogeneous clusters. It requires apps that can run in a diverse and homogenous environment in a short amount of time.

Information is stored in a NoSQL database in a hub-like way. As a result, the information becomes skewed. These data sets should store information that is extremely accessible. It also has no reservations about the parcel's adaptability and durability. Pandey [22] introduces this strategy for balancing load in a circulating environment. It divides data into small parts, making it easier to move things around on their own. As erasure codes, Cauchy RS codes are gaining in use. It is preferred in Redundant Array of Independent Disks (RAID) arrays that use Solid-State Drives (SSDs). The use of Galois Field (GF) math to accomplish matrix-vector multiplication is necessary for such coding on a processor-based RAID regulator. The erasure coding performance of resistive RAM (ReRAM) can be improved. RAID controllers and SSD controllers use it as core memory. The Cauchy-Vandermonde matrix is used by Han et al. [23] as the encoding generating matrix. SSDs are used to distribute rebuilding efforts for a single failure. It boosts the speed of encoding and decoding. More memory accesses result from increased computation complexity. It has a high level of durability while requiring less storage space. To improve failure recovery performance, Xu et al. [24] introduce a PBD-based Data Layout (PDL). In the event of part failures, it clearly gives superior assistance to front-end applications. For mixed erasure codes, it provides a uniform data layout. Each lump containing different symbols from a coding strip resides in a different node and on a different disk in distributed storage. Pirahandeh & Kim [25] present a scalable, multisector scheduler that allows for three levels of adaptability to non-critical failure over time, plates, and nodes. It can now recover from multiple levels of failure. The innermost assembly of each node, which consists of total disks and segments for each node, is alarming. It raises encoder and decoder average performance. It has been determined that it is suitable for use in a distributed storage environment that is adaptive. To determine parity chunks, our approach uses fewer XOR tasks. It provides a consistent information layout for integrated Erase Code (EC).

The rest of the paper is written in the following format. The related work is discussed in Section II. The proposed Optimized Cauchy Coding (OCC) method is detailed in Section III. The evaluation findings are given in a real-time scenario in Section IV. The proposed OCC system benefits and potential scope are summarized in Section V.

## II. RELATED WORK

### A. Related Work

This section discusses relevant work in the data storage domain for fault tolerant systems that addresses time, space, and complexity issues in matrix formation.

In light of the equipment execution system for decoding, Wu et al. [26] suggested a novel high-speed Cauchy algorithm to construct an encoding calculation. To achieve the same results as Cauchy, this technique requires a less sophisticated calculating process. Ca-Co, a useful Cauchy coding method for information storage in distributed systems, was proposed by Zhang et al. [27]. To produce a scheduling sequence, it uses a Cauchy matrix with XOR operations. In comparison to existing systems, the system provides an effective data storage approach. It can quickly generate a Ca-Co matrix using the XOR operation. Tang & Cai [28] offer a novel erasure decoding approach. To protect against capacity node disappointments, erasure coding is preferred in the appropriate stockpiling framework. The data is first separated into data blocks, which are then coded to create encoding blocks. The decoding method is used to recover the lost data blocks. In

light of the changing system of the translating change matrix, the decoding failures are acknowledged. Erasure coding improves interpreting effectiveness while requiring less bandwidth for modernization. The hypothetical examination, on the other hand, demonstrates the method's accuracy. The system of data restoration benefits from available erasure-coded data insertion strategies. To recover data, the operator first replaces all unproductive nodes with one new node. The Node Replacement Process (NRP) takes hours or days in practice. Due to the lack of durability, the enhanced statistics are lost once more. Information accessibility and dependability are maintained by a few methods in circulating record systems.

The Erasure Coding (EC) method is popular for increasing space efficiency. It has incalculable execution encoding, decoding, and input/yield corruption elements in general. Kim [29] proposes a buffering and joining method in which several I/O demands that occur during encoding are combined and treated as one. It offers four recovery options for distributing the disk input/yield loads generated during decoding. Erasure coding is a generally complex technology used in the allocated storage framework to protect against capacity node disk failure. It improves resilience while also reducing repetitiveness. First, the data is separated into b chunks. The encoding technique is then used to convert the b blocks into c blocks. The decoding technique recovers the $c - b$ blocks that were missed. Clients of distributed storage typically assign different redundancy configurations to the repetitiveness settings (b, c, and d) of EC. It is based on the perfect balance of execution and internal failure adaption. This work aids in the observation of a very low likelihood encoding approach for a design with available configurations that produces superior results. With low data repetition, EC codes are used in the cloud. Just a hypothetical investigation demonstrates the Ca-Co technique's accuracy.

The Optimal Weakly Secure Minimum Storage Regenerating (OWSPM-MSR) [31] approach was proposed by Bian et al. Its implementation is based on Jerasure, and the test was run on a Linux machine with an Intel Core i5 CPU and 4GB RAM. A Galois field size of 28 and a block size of 1024 are used in the implementation. They compared many factors, such as calculation time and storage overhead, with the previous system. This method use the Cauchy-network based RS coding algorithm. Over constrained fields, division and multiplication may be converted into subtraction and addition tasks, and they can be recognized by XOR tasks. Furthermore, they calculated the aforementioned during data recovery in terms of translating time. In the most pessimistic case, it takes a little longer than Product-Matrix Minimum Storage Regenerating (PM-MSR). The time between techniques became longer as the number of data blocks (k) and parity blocks (p) increased (m). Because it takes longer to invert a matrix, the time consumed by the OWSPM-MSR approach is longer than the time necessary to encode the data.

Shah et al. [32] proposed a technique which is based on a product matrix structure. PM-MSR uses the Vandermonde network to reconstruct information that has been lost due to a disc crash. Two special characteristics of the Product-Matrix structure make the codes used in this system desirable from a

security standpoint. For starters, several standards in the literature, including those in, take functional repair into account. The data placed in the replacement node might vary from the data stored in the failed node in this form of repair as long as the replacement node meets the system's rebuilding and appropriate working requirements. This enables a snoop to get a greater amount of data by examining the information stored in a core over several instances of repair. PM codes, on the other hand, provide a precise fix, with information stored in the substitute node indistinguishable from that stored in the bombed node. Second, regardless of whether the fix is exact, the information downloaded during the repair of a given server may be dependent on the arrangement of n nodes cooperating in the maintenance with handling, and therefore may alter between fixes of that node. By default, the PM system ensures that the data retrieved by the substitute node is independent of the helper nodes' personalities. The Vandermonde-based has a high level of complexity in terms of duplication and division in a Galois field, resulting in a long calculation time.

The approach proposed by Wang et al. [30] involves replacing some submatrices of the polarizing change with networks on the decoder side, resulting in a less difficult evaluation of log-probability proportions. This strategy allows for a reduction in complexity for the sequential termination, list, and successive translation calculations. Later, it was suggested that an improved decoding technique for polar codes with large kernels be used. It entails replacing the instances of large kernels in the polarizing change with more straightforward frameworks in a specified way. The methodology does not require any sideways encoder enlargements and has no effect on decoder operation. It can also be used in conjunction with list and consecutive translation calculations. For efficient polar codes, many encoding computations are addressed. In comparison to previous non-recursive algorithms, an improved encoding approach reduces the number of calculations due to an iterative property of the generating matrix and a specific lower three-sided design of the lattice. When compared to current non-recursive approaches, it reduces the number of XOR processing units, which is advantageous for numerous executions over existing algorithms. Many limiting or figure units haven't been changed. This makes the framework less stable.

### B. Problem Identification

In the above related work, many techniques are introduced to find a way to deal with fault tolerance with Cauchy matrix in combination with RS code. Several existing approaches require a long computation time to conduct XOR operations in encoding and decoding user data. In existing work, erasure codes like Cauchy RS use Galois Field (GF) to accomplish matrix-vector multiplication, which causes CPU overhead due to an exponential increase in read/write operations. We present an Optimized Cauchy Coding method with RS coding to overcome this problem. Proposed method makes it easier to create Cauchy matrices because it reduces the number of XOR operations in data recovery.

## C. Research Contribution

The main objectives of this paper are as per the following:

- To reduce the number of read/write operations in the encoding process while storing data in a distributed environment with a certain redundancy configuration.

- To minimize XOR operations for various combinations of matrices as well as schedule fewer iterations for data recovery on the data blocks with logarithmic functions.

- To handle unnecessary resource utilization problems in a distributed environment, replica formation of the same block is replaced with a single block with fault tolerance ability to recover data.

### III. METHODOLOGY

The Optimized Cauchy Coding (OCC) technique proposed is based on RS coding. The OCC paradigm for data recovery is depicted in Fig. 1. The encoding and decoding procedure here involves a number of different entities.

The entities engaged in the coding process are listed below:

1) Client
2) Data files
3) Data blocks
4) Parity blocks
5) Server nodes

In the block diagram of OCC approach at first when a client wants to write a data file, the write data request will first travel via the encoding block, where the files from the client side F1, F2, F3, and F4 can be written on server nodes.

The source file that the client wants to write on the server node will no longer be written in the original format of the source data file, but will instead be translated into a different format to secure the data. The encoding procedure encodes the file received from the client to make the system fault resistant and increases data availability in the event of a disk failure. To produce a check matrix, the OCC technique examines redundancy configurations (l, m, n) during the encoding process. The number of data blocks is represented as one, the number of parity blocks is represented as m, and the number of coding unit bits per word is represented as n in this system. The experiment considers the trade-off between matrix creation time and resource utilization. In a distributed environment, the system is emulated. XOR operations are used to produce each Ca-Co coding matrix for each chunk. Cauchy matrices are built on GF. Using the Cauchy matrix and XOR operations, GF additions and multiplications are also minimized. In terms of time, the Cauchy matrix density determines encoding performance. Algorithm 1 explains the check matrix construction process. Data blocks and parity blocks for the input files will be written on the servers S1 through S6 after the encoding procedure is completed. When clients want to read the files, the data is decoded by the decoding process. If any data blocks are missing, the data can be recovered using the decoding process, which uses the check matrix established during the encoding process to reassemble the data.

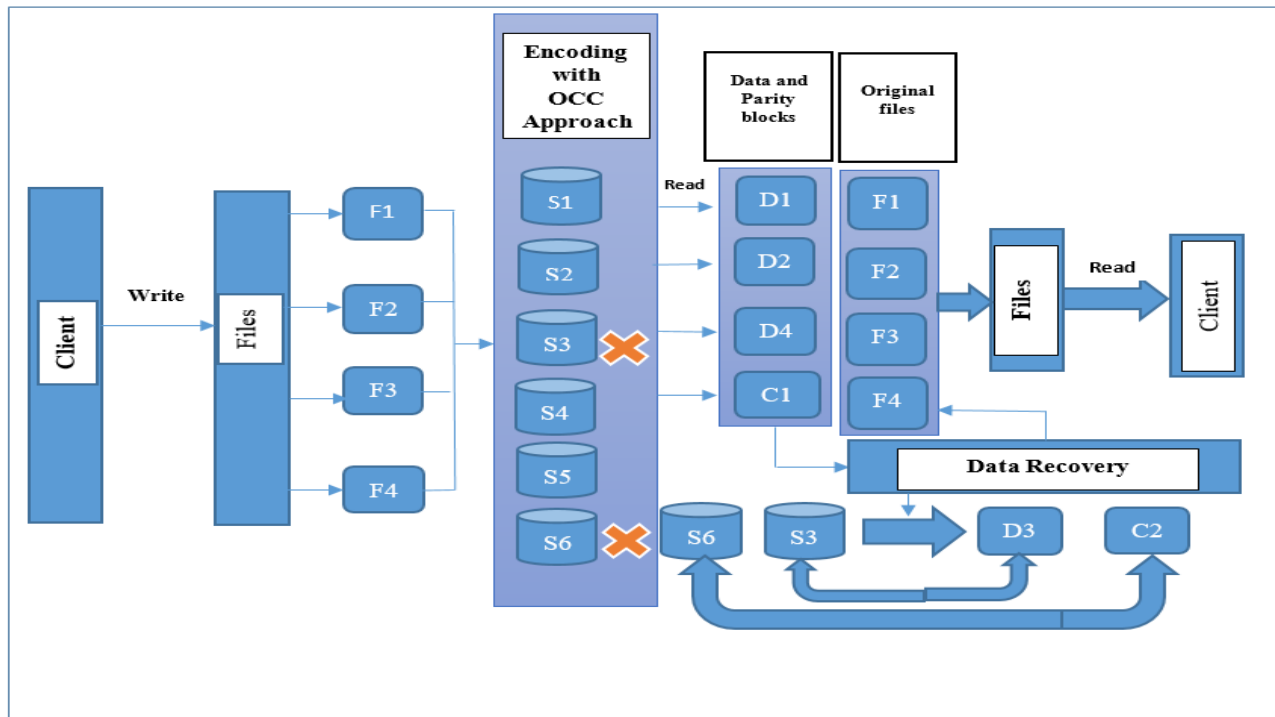

Fig. 1.   OCC Data Recovery Approach.

The suggested method lets users control their access in a safe and private way. Algorithm 1 shows how to make an optimized Cauchy matrix and encode data blocks in a data write operation in a step-by-step way.

The proposed OCC data recovery technique converts the Cauchy encoding entities into Boolean form and stores them as a binary matrix. Further binary XOR operations are performed for the elements obtained from Galois Field $GF(2^n)$. It helps in reducing the time complexity of XOR calculations. Here in the encoding algorithm, three parameters $l$, $m$ and $n$ are considered to generate the Cauchy matrix, where $l$ is the number of data blocks, $m$ is the number of parity blocks and $n$ is the coding unit bits per word.

---

**Algorithm 1: OCC encoding algorithm**
Input: $\{l, m, n\}$ where $l = data\ blocks$, $m = parity\ blocks$ and $n = coding\ unit\ bits\ per\ word$
Output: Code word check matrix

---

The following are the steps for the encoding strategy.

Step 1: We need to generate elements of $GF(2^n)$ with the help of specific polynomial then generate its binary form matrix. So first we need to generate polynomial to generate a $GF(2^n)$.

For different value of $n$ different polynomials are there as below. If we have prime polynomial of degree $n$ over $GF(2)$ then $GF(2^n)$ can be constructed. For $n = 3$ generate $GF(2^3)$ from $GF(2)$ using prime polynomial $p(x) = x^3 + x + 1$.

To calculate elements of $GF(2^3)$: As $p(x) = x^3 + x + 1$, polynomial elements over $GF(2^3)$ is as below:

$GF(8) = GF(2^3)$

$z^0 \qquad 1$

$z^1 \qquad z$

$z^2 \qquad z^2$

$z^3 \qquad z + 1$

$z^4 \qquad z^2 + z$

$z^5 \qquad z^2 + z + 1$

$z^6 \qquad z^2 + 1$

$z^7 \equiv z^0 \qquad 1$

This shows set of elements generated on $GF(2^n)$ using polynomial.

As per binary matrix rules $BM(d)$ is generated using $d$ elements of polynomial and coefficient vector $V(d)$.

Step 2: Generate a Cauchy coding matrix.

In the binary Cauchy coding matrix, the count of ONES decides how many operations of XOR will be required. A lower number of ONES yields better performance. In this matrix generation, the Cauchy Good (CG) method is used for enhancing the performance because the generated matrix will have a lower number of ONES as compared to other heuristic methods.

With the help of CG, constructing the Cauchy matrix, which is defined as MG. Furthermore, we divide each element of MG, as in column j by $MG_{0,j}$: *MG is modified and row 0 elements are all ONES.* For other rows like row i, present number of ONES are calculated which are considered as N. Further by dividing row i, elements by $MG_{i,j}$ and record the number of ONES count, which is represented as $N_j (j \in [0, l-1])$.

Select a minimum of $\{N_0, N_1, \ldots, N_{l-1},\}$ which generates CG position one. Repeat step 2 for the remaining matrix elements of CG.

Step 3: Expand the Cauchy coding matrix of size $l \times m$ to the binary matrix of size $ln \times mn$. Consider the extended matrix as a matrix $E$.

Step 4: Create an array.

Divide $m$ data blocks into $n$ parts similar to $d_1, d_2, \ldots d_m$ into $d_{1,1}, d_{1,2}, \ldots d_{m,n}$.

$C = E \times D$

$$C = \begin{bmatrix} E_{1,1} & E_{1,2} & \ldots E_{1,mn} \\ E_{2,1} & E_{2,2} & \ldots E_{2,mn} \\ \vdots & \vdots & \vdots \\ E_{ln,1} & E_{ln,2} & \ldots E_{ln,mn} \end{bmatrix} \times \begin{bmatrix} d_{1,1} \\ d_{1,2} \\ \vdots \\ d_{m,n} \end{bmatrix} = \begin{bmatrix} C_{1,1} \\ C_{1,2} \\ \vdots \\ C_{l,n} \end{bmatrix} \qquad (1)$$

$C_{1,1} = (E_{1,1} \cdot d_{1,1}) \oplus (E_{1,2} \cdot d_{1,2}) \oplus (E_{1,mn} \cdot d_{m,n})$

The result array is as below:

$$R1 = \begin{bmatrix} d_{1,1} & d_{2,1} & \cdots & d_{m,1} C_{1,1} & C_{2,1} \ldots & C_{m,1} \\ d_{1,2} & d_{2,2} & \cdots & d_{m,2} C_{1,2} & C_{2,2} \ldots & C_{m,2} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ d_{1,n} & d_{2,n} \ldots & d_{m,n} C_{1,n} & C_{2,n} \ldots & C_{l,n} \end{bmatrix} \qquad (2)$$

Further XOR operations are calculated then sorted. Further result is replaced with new data as $R2$.

Algorithm 2 shows how to write data to a cloud storage service using the OCC approach.

---

**Algorithm 2: Data recovery algorithm**
Input: Code word check matrix
Output: Plain text

---

Step 1: The client sends a request to the server for data extraction.

Step 2: The decoding matrix generation phase.

As R1 has been partitioned into the blocks of (m +l) ×n and matrix BM(d) which has (m +l) n× (m +l) w in size is formed.

$$BM(d) = \frac{Identity\ matrix | Zero\ matrix}{Parity\ matrix\ of\ R1} \qquad (3)$$

Step 3: Evaluate the missing data blocks.

i: When a data node fails, the information for the whole segment is lost. So while re-establishing information, a relating list L of missing components is made for the missing node.

ii: The component d in the missing component list L is iterated through. Assuming it has a place in the data component; continue to step iii.

If it has a place in the redundant component, skip it.

iii: The r is the row set whose element d is one in the parity check matrix H. Assume that there is no component in r, set row d to zero. In case there is a component in r, then, at that point, we select the row with the little load of hamming subsequent to eliminate the missing component from r as $r_1$. The row corresponding to the component in r and the row d performs XOR with $r_1$ and $r_1$ is set to 0.

iv: After handling each component of the list L, the values in the column corresponding to the redundant components in the list can be set to zero.

Step 4: Data recovery phase

Now, line $r_d$ is an analogous row to the component d of the missing component list with the name L which is the relating matrix BM(d). $C_d$ is a set of columns with 1 in $r_d$. The information block relating to the component in $C_d$ is the data block expected for restoring the component d.

As per the above component list with the name L and the binary matrix BM(d), all missing records can be recovered as before. Lost data can be recovered with XOR operations with available dataset.

## IV. RESULT

This section examines performance in terms of the amount of time it takes to encode and decode data in a distributed system. The requirement to run a test-engine to evaluate system performance is shown in Table I.

At the output, it encodes these data blocks into m parity blocks. The storage system is resistant to numerous disk failures in this case. The OCC code works with binary data. Each word consists of n bits such that $2^n \geq l + m$. For data encoding, redundancy configuration$(l, m, n)$ varies by keeping different combinations of data blocks and parity blocks.

TABLE I. SYSTEM REQUIREMENT

| Particulars | Specifications |
|---|---|
| CPU with RAM | Pentium 2.5 GHz with 4 GB RAM |
| Language | Java |
| Operating system | Linux |

The work of the proposed system is compared to that of the present system in terms of encoding and decoding times, utilizing various redundancy configurations. Encoding time refers to the time it takes to convert the contents of a file into a specified format that allows data to be securely sent and stored in a specific data node. The time it takes to convert an encoded data sequence back to its native format is known as decoding time. Table II demonstrates the time necessary to code files ranging in size from 1MB to 50MB using the proposed OCC coding technique in seconds.

TABLE II. ENCODING AND DECODING TIME FOR VARIOUS SIZE INPUT FILE FOR PROPOSED OCC (L=10, M=20)

| File size | Encoding Time | Decoding Time |
|---|---|---|
| 1 MB | 0.12 | 0.145 |
| 5 MB | 0.26 | 0.31 |
| 10 MB | 0.54 | 1.3 |

In the event of a disk failure, Table III outlines the various criteria, such as data availability, recoverability, efficiency, and storage overhead. It displays great data availability, high recoverability, and high efficiency for the inputs l = 4 and m = 1. For the same arrangement, the storage overhead is minimal. The amount of storage space required grows as the number of parity blocks grow.

TABLE III. PERFORMANCE ANALYSIS OF PROPOSED OCC FOR VARIOUS INPUT PAIR VALUES (L, M)

| Encoding | Availability | Recoverability | Efficiency | Storage Overhead |
|---|---|---|---|---|
| $l$=4, m=1 | High | High | High | Low |
| $l$=5, m=1 | High | High | Medium | Low |
| $l$=6, m=1 | High | High | High | Low |
| $l$=7, m=1 | High | High | High | Medium |
| $l$=4, m=2 | High | High | High | Low |
| $l$=4, m=3 | High | Medium | High | Low |
| $l$=4, m=4 | High | High | Medium | Low |
| $l$=4, m=5 | High | Medium | Low | High |

## V. DISCUSSION

Table IV demonstrates the encoding time required for various ways to encode the data when different numbers of data blocks (l = 4 to l = 10) and parity block (m = 1) are examined. For comparison of the proposed OCC with the existing approaches of Optimal Weakly Secure Minimum Storage Regenerating (OWSPM-MSR) [31] and Product-Matrix Minimum Storage Regenerating (PM-MSR) [32], a total of seven different combinations are evaluated.

TABLE IV. ENCODING TIME FOR VARIOUS NUMBER OF DATA BLOCK (L)

| Techniques | Encoding Time(s) | | | | | | |
|---|---|---|---|---|---|---|---|
| | $l$=4, m=1 | $l$=5, m=1 | $l$=6, m=1 | $l$=7, m=1 | $l$=8, m=1 | $l$=9, m=1 | $l$=10, m=1 |
| OWSPM-MSR | 0.0065 | 0.0065 | 0.0082 | 0.0119 | 0.0125 | 0.0119 | 0.0135 |
| PM-MSR | 0.0065 | 0.0077 | 0.039 | 0.053 | 0.098 | 0.27 | 0.38 |
| Proposed OCC | 0.006 | 0.0063 | 0.008 | 0.0084 | 0.009 | 0.0096 | 0.01 |
Fig. 2.    Comparison of Encoding Time with Various Number of Data Blocks.

Fig. 2 depicts an encoding time plot, with the X axis representing input and the Y axis representing encoding time for a single input. The inputs are the number of data blocks (l = 4 to 10) and the number of parity blocks (m = 1). The OCC encoding procedure outperforms the previous OWSPM-MSR and PM-MSR algorithms for various combinations of one and m. Fig. 3 depicts an encoding time plot, with the X axis representing input and the Y axis representing encoding time for a single input. The number of data blocks (l = 4) and the number of parity blocks (m = 1 to 10) are used as inputs. The OCC encoding procedure outperforms the previous OWSPM-MSR and PM-MSR algorithms for various combinations of l and m.

Table V shows the encoding time required for various approaches to encode the data when m = 1 to m = 10 parity

blocks and data blocks l = 4 are examined. For comparison of the proposed OCC with the existing approaches OWSPM-MSR and PM-MSR, a total of seven different combinations are explored.

Table VI demonstrates the decoding time necessary for various ways to decode the data when different numbers of data blocks (l = 4 to l = 10) and parity block (m = 1) are examined. For a comparison of the new OCC with the existing OWSPM-MSR and PM-MSR approaches, seven different combinations are tried.

Fig. 4 depicts a plot for decoding time, with the X axis representing input and the Y axis representing decoding time for a certain input. The inputs are the number of data blocks (l = 4 to 10) and the number of parity blocks (m = 1). OCC outperforms the previous OWSPM-MSR and PM-MSR algorithms for various combinations of l and m decoding.

TABLE VII.   AVERAGE ENCODING AND DECODING TIME OF DIFFERENT METHODS (FILE SIZE 1024KB, L=4, M=10)

| Techniques | Encoding Time(s) | Decoding Time(s) |
|---|---|---|
| OWSPM-MSR | 0.125 | 0.22 |
| PM-MSR | 0.045 | 0.16 |
| Proposed OCC | 0.035 | 0.116 |

Fig. 5 depicts a plot for decoding time, with the X axis representing input and the Y axis representing encoding time for a certain input. As inputs, the data block count ($l = 4$) and the $m$ parity block count ($m = 1$ to $10$) are used. OCC outperforms the previous OWSPM-MSR and PM-MSR algorithms for various combinations of $l$ and $m$ decoding.

Fig. 6 and Fig. 7 provide a comparison graph for average data encoding and decoding times for various techniques, showing that the proposed OCC outperforms existing techniques with a 0.035 second encoding time and 0.116 second decoding time for a 1024KB data file.

The OCC data recovery strategy outperforms the OWSPM-MSR and PM-MSR data recovery strategies. Because PM-MSR employs the Vandermonde matrix in the encoding process, the encoding time is longer than the OCC technique, which uses the Cauchy matrix in conjunction with the RS code. In the encoding process, the OCC technique employs a Cauchy Good matrix with fewer ONES, which decreases the time required for the XOR operation. Ultimately it optimized overall processing time for encoding and decoding. As a result, the OCC technique outperforms the OWSPM-MSR and PM-MSR strategy.

Table VII compares the average time required for encoding and decoding 1024KB of data using different approaches. In comparison to the existing two methodologies, the proposed system takes less time.

Table VIII demonstrates the decoding time required for various ways to decode the data when $m = 1$ to $m = 10$ parity blocks are used in combination with data block $l = 4$. For a comparison of the new OCC with the existing OWSPM-MSR and PM-MSR approaches, seven different combinations are tried.

TABLE VIII.   DECODING TIME FOR VARIOUS NUMBER OF PARITY BLOCKS

## VI. CONCLUSION AND FUTURE WORK

This paper proposed an optimized Ca-Co approach to utilize matrix as well as schedule heuristics to attain an optimal coding structure. In terms of data recovery, it outperforms the OWSPM-MSR and PM-MSR approaches. For data coding, a 1024KB file with various combinations of data blocks l and parity blocks m is evaluated. For coding, two data block and parity block combinations are evaluated. In the first scenario, m equals 1 and l ranges from 4 to 10. The value of l is 4 in the second scenario, while m ranges from 1 to 10. The existing OWSPM-MSR approach takes an average of 0.125 seconds to encode and 0.22 seconds to decode, whereas the PM-MSR approach takes an average of 0.045 seconds to encode and 0.16 seconds to decode. The proposed OCC enhances data coding performance by taking an average of 0.035 seconds to encode and 0.116 seconds to decode data. In future, we intend to use the system in a hybrid cloud environment to balance energy savings with resource virtualization using punctured Cauchy RS code, which can further optimize network resources like power and bandwidth.

*Abstract*—**Due to the COVID-19 pandemic, intensive controls were put in place to prevent the pandemic from spreading. People's habits have been altered by the COVID-19 measures and restrictions imposed such as social distance and lockdown measures. These unexpected changes created a significant impact on cellular networks, such as increased use of online services and content streaming, which increased the burden on wireless networks. This research work is basically a case study that aims to examine and investigate cellular network performance, including upload speed, download speed, and latency, during two periods (MCO, CMCO) in three different regions, including Kuala Lumpur, Selangor (Cheras), and Johor Bahru, to observe the effects of lockdown enforcement and other restrictions in Malaysia on cellular network traffic. We used the phone application Speedtest™ as a tool for data collection within different times during the day, considering the peak times, including morning, evening, and night times. The research findings show how COVID-19 has affected internet traffic in Malaysia significantly. This research would help perspective developers and companies to better understand and be prepared for tough times and higher load on cellular networks in future pandemics such as COVID-19.**

*Keywords*—*Cellular networks; COVID-19; network performance; pandemic*

## I. INTRODUCTION

COVID-19 has shifted public perceptions about pandemics, with far-reaching repercussions for the global health and economic systems that was started in Wuhan, China [1]. In barely six months (from January to June 2020), 210 nations and territories worldwide reported more than ten million sick persons, including more than 500 thousand deaths [2]. COVID-19 has caused huge economic losses in addition to the worldwide health catastrophe (e.g., a projected 25% unemployment rate in the United States) [3], as a result of that, one million Canadians lost their jobs in March 2020 [4]. The Australian economy shed 1.4 million jobs [5], as well as a global GDP loss of 3% [6]. Because of this, several analysts have projected a worldwide recession [7], [8]. Since there was no cure or vaccine back in 2020 and the virus was spreading rapidly, many countries have implemented various measures of social distancing [9], [10], [11], [12] to slow the spread of the pandemic and give more time for the pharmaceutical industry to develop a cure or vaccine. Few of these scenarios are contact tracing [13], tracking and monitoring [14], quarantine [15], and lockdown [16]. Specifically, such scenarios aim to reduce the

transmission of illness by limiting the frequency and closeness of human physical contacts, such as closing public locations (e.g., schools and universities workplaces), avoiding large crowds and maintaining a safe gap among the people [9], [15]. However, the closure of schools and businesses means that many more people will have to work or study online, which will lead to an overwhelming rise in Internet traffic and online service needs, such as new Zoom users. Therefore, the load on the cellular networks has increased significantly [12], [17].

The social distancing and measures have a significant impact in reducing the spread of the virus. Malaysia was one of the countries that implemented social distancing solutions in early March 2020 [18], such as lockdown and restricted movement and measurements for individuals in outdoor areas, namely Movement Control Order (MCO) and Conditional Movement Control Order CMCO [18]. During that time, a substantial increase happened in data traffic and this has adverse effects on the network experience for the users in Malaysia. Note that Umobile, Maxis, Celcom, and Digi are the cellular networks providers in Malaysia. As soon as the MCO was launched, Malaysian smartphone users' average mobile data usage hit the roof, and this was followed by dramatic declines in the consumers' average 4G Download Speed Experience. Fig. 1 shows the recent social distancing scenarios [12] that were deployed during COVID-19 pandemic around the world.

In [19], Comcast, one of the major US operators, claims a 32% rise in upstream traffic growth and an 18% increase in downstream traffic growth outside of Europe as shown in Fig. 2, and Fig. 3 shows the increase of gaming downloads, streaming, and web video consumption and video conferencing.

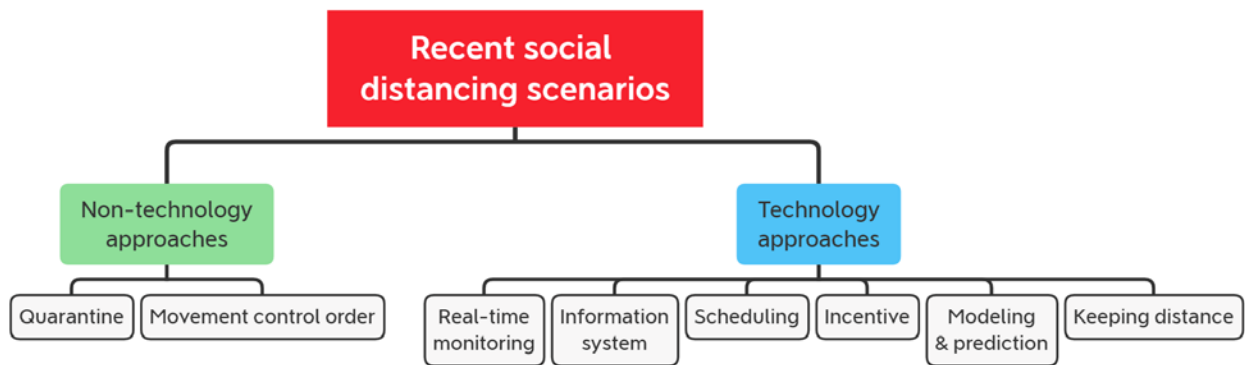
It's worth noting that throughout that period in Malaysia, 4G Download Speeds for U Mobile customers increased by almost two times compared to pre-MCO levels. Until the week of May 18, data usage on most Malaysian networks was at its highest point. On average, Celcom's network experienced a 44 percent rise in data usage, followed by Maxis's 36 percent increase [18]. Compared to the beginning of the year, U Mobile subscribers' 4G download speeds were more than twice as fast by September 30th. According to [20], U Mobile has been bolstering its network infrastructure in recent months to keep up with the soaring demand for data by expanding its capacity and fine-tuning the performance of its current cells.


Fig. 1. COVID-19 Measures and Social Distancing Scenarios.

Fig. 2. Network Growth Over Time.

Fig. 3. Entertainment, Streaming, and Gaming Increase Rates.

This study aims to investigate and analyze the usage of internet services, including networks traffics, latency and speed of internet, to understand the pandemic's impact on our daily use of internet applications and services and to support future researchers and developers for maintaining and improving the digital infrastructure or services. By doing this, countries and authorities can avoid the negative side of social distancing in the future pandemic, such as negative economic impacts and disturbances of services provided by companies that rely on online connections.

The rest of the paper is organized as follows: Section II shows related research works. Section III introduces an overview of mobile data in response to the COVID-19 measures and cellular network service providers in Malaysia. Section IV presents the methodology and data collection method of this research. Section V illustrates the results and discussion. Limitations and future directions are shown in

Section VI. Finally, Section VII summarizes the work as a conclusion.

## II. RELATED WORK

Microsoft claims that there has been an increase of 755% in the use of cloud servers [21], which means an increase in usage during the pandemic. Moreover, companies such as Netflix and YouTube concentrated the streaming quality in Europe to prevent network overload [22]. Moreover, since the shutdown in Italy, Cloudflare [23] and Fastly [24], two of the world's largest content delivery networks, have reported a 20–40 percent spike in daily traffic. Furthermore, according to ISPs, the rise in network traffic has been reported in public news and blog reports.

According to Vodafone [25], fixed broadband use has increased by more than 50% in Italy and Spain. With a 100% increase in upstream traffic and a 44% increase in downstream traffic during the pandemic. In [26], Telefonica IP networks had a traffic growth of about 40%, while mobile phone usage rose by approximately 50% and data usage increased by about 25% [27]. Moreover, in [26] and [28], traffic increased by 10–40% at European Internet Exchange Points. In [27], Malaysia's internet traffic increased by 23.5 percent during the first stage of the pandemic due to the additional burden of online education and video conferencing. Many cities have started using online shopping such as Lazada and grab car for food delivery and many people used streaming video services like Netflix to pass the time while they were confined to their homes.

Few studies have considered reporting some variations and statistics during COVID-19 pandemic. In the research work [29], the authors investigated the impact of the lockdown on Politecnico di Torino's campus network in Italy. They also noticed that inbound traffic had fallen significantly, but it has more than doubled outgoing traffic.

In [30], using data from a diverse set of vantage points (one ISP, three IXPs, and one metropolitan educational network), the authors examined the effect of these lockdowns on traffic shifts. We can observe that the Internet infrastructure was able to handle the new volume, as most traffic shifts occur outside of traditional peak hours. While many networks saw increased traffic demands, in particular, those providing services to residential users, academic networks experience major overall

decreases. Yet, in these networks, we can observe substantial increases when considering applications associated to remote working and lecturing. The study also included the effect that government-mandated lockdowns had on the Internet by analyzing network data. Since all data sources exhibit vastly differing traffic characteristics and volumes, the authors normalized the data to make it easier to compare.

The Internet was a gateway to the world; the study [31] used data from Internet speed tests, consumer complaints, search engine optimization tools, and logs of Internet use from public libraries to understand the effects of the pandemic on Internet use and performance. Despite reports that the Internet handled the surge in traffic well, we find that complaints about Internet speed nearly tripled, and performance was degraded. The study stated that many people without Internet at home turned to public Wi-Fi hotspots during the pandemic. We find that this occurred disproportionately in neighborhoods with more students. Future distance learning initiatives should consider the challenges some students face in obtaining Internet access.

Mobile sensing has played a key role in providing digital solutions to aid with COVID-19 containment policies, primarily to automate contact tracing and social distancing measures. Many COVID-19 technology solutions leverage positioning systems, generally using Bluetooth and GPS, and can theoretically be adapted to monitor safety compliance within dedicated environments. However, they may not be the ideal modalities for indoor positioning. The study [32] conjectures that analyzing user occupancy and mobility via deployed WiFi infrastructure can help institutions monitor and maintain safety compliance according to the public health guidelines. Using smartphones as a proxy for user location, their analysis demonstrated how coarse-grained WiFi data can sufficiently reflect the indoor occupancy spectrum when different COVID-19 policies were enacted. They have demonstrated how their data source can be a practical application for institutional crowd control and discussed the implications of their findings for policy-making.

The study [33] evaluated the impact on the Internet latency caused by the increased number of human activities that was carried out on-line. Their analysis of the impact of COVID-19 pandemic relied on the results generated by both Anchoring Measurements (AMs) and User-Defined Measurements (UDMs). Beside ICMP-based latency, an evaluation of latency as seen at the HTTP level was provided. Latency is particularly important not only because it has a profound effect on some classes of applications, but also because it is, by itself, an excellent indicator of the health status of the network. We believe that the provided numbers and the related analysis will definitely help in better understanding this previously unseen event in the history of the Internet.

The article [34] provided a perspective of the scale of Internet traffic growth and how well the Internet coped with the increased demand as seen from Facebook's edge network. They have used this infrastructure serving multiple large social networks and their related family of apps as vantage points to analyze how traffic and product properties changed over the course of the beginning of the Covid-19 pandemic.

The pandemic has significantly changed people's mobility and habits, subsequently impacting how they use telecommunication networks. The study [35] has investigated the effects of the COVID-19 emergency on a UK Mobile Network Operator (MNO). The authors have quantified the changes in users' mobility and investigate how this impacted the cellular network usage and performance. Their findings brought insights at different geo-temporal granularity on the status of the cellular network, from the decrease in data traffic volume in the cellular network and lower load on the radio network, counterposed to a surge in the conversational voice traffic volume.

Table I shows a summary of related works. The motivation for this study is that no study has investigated the impact of COVID-19 restrictions and measures on cellular network traffic in different times during the day and through the year 2021 in Malaysia. Moreover, the COVID-19 restrictions and measures such as social distancing and lockdowns have increased our daily use of internet services and applications; therefore it is important to study the variations of data speeds and usage.

TABLE I.    RELATED WORK SUMMARY

| Ref. | Focus | Findings | Location | Time frame From | To | Network type |
|---|---|---|---|---|---|---|
| [29] | Analyzed the changes in the traffic patterns. | 1. Reveals the importance of using different lenses to fully understand the COVID-19 pandemic's impact at the traffic level: Mornings and late evening hours see more traffic. 2. Conclude that the Interne did its job and coped well with unseen and rapid traffic shifts. | The Politecnico di Torino campus network / Italy. | February 2020. | April 2020 | WiFi |
| [30] | Analyzed network flow data from multiple vantage points, including a large academic network and a large ISP at the edge, and, at the core. | 1. They found that the traffic volume increased by 15-20% almost within a week-while overall still modest, this constitutes a large increase within this short time period. 2. Traffic increases in applications that people use when at home, such as Web conferencing, VPN, and gaming. | Three IXPs located in Europe and the US. | January 1, 2020. | June 24, 2020. | The core of the Internet (IXPs), and at the edge (a metropolitan university network). |
| [31] | To understand the effects of the pandemic on Internet use and performance. | 1. Downstream data rates changed little, but median upstream data rates at midday dropped by about a third. 2. Significant increases in the use of many important categories of online content, including those used for work communications, education, grocery shopping, social media, news, and job searches. | Wi-Fi in 73 public libraries in Western Pennsylvania/ US. | December, 2019. | September, 2020. | WiFi |
| [32] | Analyzes staff and students' mobility data. Seeks to investigate if location data that is passively sensed from existing WiFi infrastructure can, in fact, show the real-world effects of various COVID-19 policies on institutions. | Show that online learning, split-team, and other space management policies effectively lower occupancy. However, they do not change the mobility for individuals transitioning between spaces. | 2 campuses in Singapore, and 1 in the Northeastern United States. | January 6, 2020. | April 7, 2020. | WiFi |
| [33] | Analyzed the impact of the COVID-19 pandemic on the latency of the Internet. The analysis focuses on Italy. | 1. The analysis of a large set of measurements shows that the impact on the network can be significant, especially in terms of increased variability of latency. 2. The impact is not negligible also for Italy and the other countries in the whole of Europe. 3. The major changes have been observed in the evening, the time of the day when most of the on-line activities are related to entertainment. | Italy, Spain, France, Germany, Sweden, and whole of Europe. | February 08, 2020. | March 28, 2020. | Not specified |
| [34] | Used Facebook's edge network serving content to users across Facebook's family of apps to provide a perspective on how the Internet coped with and reacted to the surge in demand induced by Covid-19. Assessed the impact of this traffic surge on network stress and performance. | 1. Showed that there have been changes in traffic demand, user behavior and user experience. 2. Different regions of the world saw different magnitudes of impact with predominantly less developed regions exhibiting larger performance degradations. 3. North America and Europe did not show any signs of stress in their networks, India and parts of Sub-Saharan Africa and South America did witness signs of network stress translating into degraded video experience, higher amount of traffic overflowing to indirect links and secondary CDN locations, and higher network round trip times. 4. Found that traffic increases occurred mainly on broadband networks. | Facebook servers around the world with 2.5 billion monthly active users. | January, 2020. | Late July, 2020 | Facebook's Edge Network |
| [35] | The study focused on presenting an analysis of the changes in mobility and their impact on the cellular network traffic. | 1. An overall decrease of 50%, with non- uniform changes across different geographical areas and social backgrounds. 2. Despite significant pattern changes, the MNO was able to provide service maintaining quality standards: the radio load was below common values and per user throughput was likely application limited. 3. Identified one issue in voice traffic packet loss due to excess of congestion in the interconnection infrastructure MNOs use to exchange voice traffic. | The entire country to specific regions (London). | February 23, 2020. | May 31, 2020. | Cellular network |

### III. MALAYSIA'S RESPONSE TO COVID-19: PROBLEM DEFINITION

On March 18, the Malaysian government issued a continuous Movement Control Order (MCO) [36]. Throughout the crisis, as more Malaysians stayed at home to obey the order, they rely on mobile networks for business, education, information, and pleasure expanded. The Malaysian Communications and Multimedia Commission (MCMC) detected a significant rise in data traffic and suspected that this has significantly impacted consumers' network services in a variety of ways; furthermore, with students and staff working from home [37], as well as variations in user activity during the lockdown [38], [39]. Normal internet speed may have reduced during non-peak hours, reducing total speeds. Furthermore, in order to avoid being confined in the city and to save expenses, many city workers returned to their home towns in the suburbs or rural regions.

This swing in mobile usage geography suggests that users were spending additional time in places where the network infrastructure was not designed to support such a large number of users and their increasing mobile data consumption. Following that, Beginning April 1, 2020, until restrictions were reduced, the MCMC announced that few cellular companies such as Celcom, Digi, Maxis, and U Mobile would offer all of their customers (prepaid and postpaid) 1GB of free data each day between 8 a.m. and 6 p.m., while Unifi offered various unlimited plans to support its customers [1].

As data demand grew during the early months of the outbreak [40], more users experienced poorer average 4G download rates. Given the challenges, Malaysia's mobile operators have supplied consistent coverage to their customers in this extraordinary situation. However, mobile network service is not always steady or of high quality. Several basic Quality of Service (QoS) requirements for mobile broadband have been defined by the MCMC. While there was significant dissatisfaction with network speeds, Malaysians mainly accepted their situation until the COVID-19 epidemic triggered the MCO, which restricted people to their homes and increased their dependency on high-speed internet connection for business, school, and entertainment [2]. Malaysia's internet traffic grew by 23.5 % in the first week of the MCO. Median download speed fell from 13.7 Mbps in early February to 8.8 Mbps in late March, as each additional activity imposed at strain on the entire digital infrastructure. Local telecommunications and internet service companies moved quickly to upgrade wireless backhaul to fiber optic connections in order to reduce internet disruptions and increase network performance.

Malaysian internet traffic had shifted to residential areas and increased by 30-70% by September 2020, yet internet speed had declined by 30-40% [2]. Malaysia's internet speed has significantly decreased as a result of increased bandwidth demand since the MCO's implementation [3]. Congestion may occur as a result of increased data usage, resulting in slower speeds. This has had an effect on the user experience, with longer loading times noted, particularly when accessing bandwidth-intensive media such as High-Definition (HD) streaming services. However, comparable trends have been reported worldwide, according to MCMC, with operators experiencing an unprecedented increase in bandwidth demand as a result of this behavioral shift. The vast majority of today's leisure activities, such as streaming services [41], video chats, and online gaming, take a significant amount of data. All of this puts a considerable strain on existing infrastructure.

Furthermore, E-commerce is a massive platform that is expanding at an unprecedented rate around the world. E-commerce has experienced a huge increase in sales [42], as more shoppers turn to online grocery platforms to purchase their daily necessities. Digital media providers such as Netflix are becoming popularity [43]. Malaysia ranks fifth in the world and first in Southeast Asia in terms of social media adoption, according to Hootsuite's Digital 2020 research [44]. Fig. 4 shows meaningful statistical data on internet users as well as other important elements.

The employees who are working from home rely heavily on various online conference call platforms to continue their business discussion. Every day, the ordinary Malaysian internet user spends 7 hours and 57 minutes online, which equivalent to roughly 100 days per year. This is greater than the global average user time spent. Google, YouTube, Facebook, WhatsApp, and Maybank2u are the leading five most visited websites in Malaysia [44].

The use of E-wallets in Malaysia such as Touch and Go, Grab, Fave, Samsung Pay, and others has grown [45]. The ratio dipped to 55% at the beginning of 2020, but due to the "new normal, 70% of users now feel they will use e-wallet services even if no benefits are offered [46]–[48]. Fig. 5 shows the number of payments and E-wallets statistics as well as types of E-wallets in Malaysia. People are turning to online grocery platforms to purchase their daily requirements, which have resulted in a significant surge in e-commerce sales.

In China, for example, Carrefour China recorded a 600 percent year-over-year rise in vegetable deliveries during the Lunar New Year period, and JD.com observed a 215 percent growth in online grocery sales to 15,000 tonnes in just the first ten days of February 2020 [44].

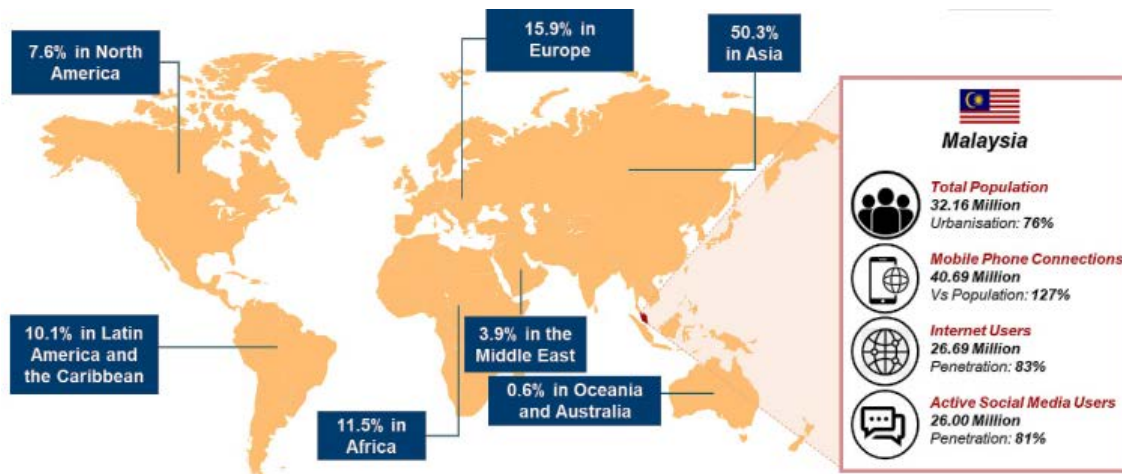
Note that the growth of ecommerce before the crises of COVID-19 has increased significantly. According to the Worldwide Ecommerce Report 2019, global retail e-commerce sales are worth US$3.535 trillion and are predicted to hit US$6.5 trillion by 2023. Malaysia is among the top five fastest-growing e-commerce countries, indicating that the country has significant e-commerce potential. Fig. 6 presents some fast facts about online shopping growth in some countries [46].


Fig. 4.    State of Internet in January 2020 Around the World and in Malaysia.

(a)                                                                                  (b)

Fig. 6.    State of Internet in January 2020 Around the World and in Malaysia.

## IV. METHODOLOGY

In this section, the methodology process details are presented. In addition, the tool used for the data collection process with the details is explained. In this work, we have by used Speedtest phone application Ookla [49] for the data collection. Every day, approximately ten million individual tests are performed by users in places and at times when their connectivity is vital to them. Speedtest has delivered almost 35 billion tests since its establishment in 2006. After the data collection process, all data gathered and analyzed using Excel sheets, then converted to graphs as results. Customers are linking to networks everywhere such as on the road, in their cars, at home, at work, and everywhere else.

When paired with data on cell site locations, tools to priorities optimization and rollout efforts, and competitor comparisons, Cell Analytics offers an entire solution for mobile network operators to examine their networks and determine areas that demand upgrading. The data collected for this study was conducted by using different phone types.

The data were collected in three different times during the day, namely morning, afternoon, and evening. The data collection for the morning time starts from 10 am to 12pm, afternoon time 4pm to 6pm and evening 10 pm to 12 pm. An iPhone 12, Samsung galaxy s8 and Poco F2 Xiaomi were used. Details of data are summarized in Table II.

Fig. 7(a) and (b) shows a snapshot of an example of the application used in this study during the data collection process including testing the download speed and upload speed. The coverage areas of Umobile cellular networks in Kuala Lumpur and Johor Bharu provided by Speedtest are shown in Fig. 7(c) and (d), respectively. Fig. 8 shows the methodology steps and details. All the data were collected and analyzed using excel sheets.

TABLE II. DATA COLLECTION DETAILS

| Matrices | | Details |
|---|---|---|
| Country | | Malaysia |
| Cities | | Johor Bahru, Kuala Lumpur, and Cheras (Selangor) |
| Network type | | Umobile |
| Performance matrices | | Download speed, upload speeds, and latency |
| Smartphone types | | iPhone 12, Samsung galaxy S8, and Poco F2 Xiaomi |
| Time of collection | Morning time | 10-11:50 am |
| | Afternoon time | 4-6 pm |
| | Evening time | 10-11:59 pm |
| Date of collection | Phase 1 | 13 January – 13 February |
| | Phase 2 | 5 March – 2 April |
| Data collection tool | | Speedtest phone App |
| Lockdown periods | | MCO and CMCO |

Fig. 7. (a): Snapshot of Speedtest Application showing the Collection of Download Speed Data, (b) Collection of Upload Speed Data, (c): UMobile Cellular Network Coverage in Kuala Lumpur, and (d): UMobile Cellular Network Coverage in Johor Bharu.

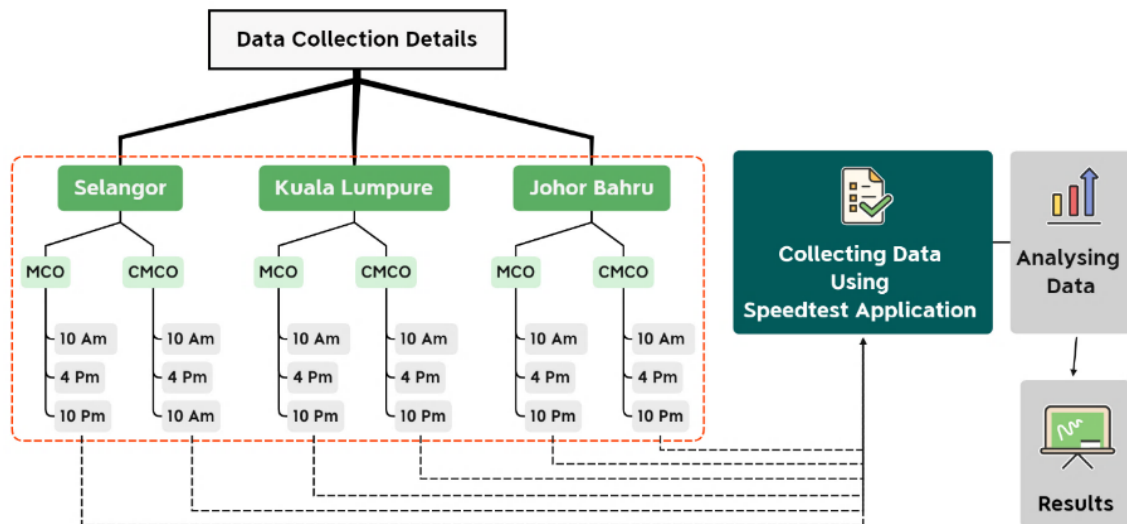

Fig. 8. Snapshot Methodology Process Details.

## V. RESULTS AND DISCUSSION

This section presents the results and discussion. The main data gathered for this study including the download speed rate and upload speed rate. In addition, the latency was also measured. All data were collected, transformed to readable graphs then analyzed. We evaluate the performance of cellular networks during two time periods, namely MCO and CMCO. In order to describe the data being studied, all data were analyzed and compared. Specifically, download speed in the morning is compared with afternoon and evening time within same period, same for the upload speed, then the latency. In addition, all performance metrics during MCO is compared with the performance during CMCO. Finally, an overall comparison is presented as final findings.

The first period, MCO started from 13 January 2021 to 13 February 2021, and the second-period CMCO began from 5 March 2021 to 2 April 2021.

Microsoft Excel was used to combine and compare the data from three cite to measure the network speed and latency in (LTE cellular, U-mobile). It should be noted that the variations of data taken into consideration may be caused by the traffic volume and the peak hours for people using the internet for example work, online study or video streaming.

Since the performance of the considered cellular networks presented in this study is highly dependent on network parameters and a few other variables such as i) number of users connected to the BS [50], ii) time of data collection where speed and data traffic varies from time to time based on the density of users which relies on population when comparing different cellular networks performance from different areas. The data rate requirements per user also play an important role in load variations on the BS which represents the data usage [51]. In the data collection phase, we had to collect data from three different cities in Malaysia in order to make a fair comparison of cellular networks within different user density, and to simulate diverse network conditions and verify the impact of COVID-19 measures and restrictions.

All data collection were conducted on smartphones (iPhone 13, Samsung S8), with 60 GB of RAM memory. Exceptionally in this scenario, since the phone application used by the client is making calculations and data measurements, it is affected only by network conditions and the server connected nearby the cellular BS. To verify the use of different smartphone types, we had to utilize all smartphones on same network operators that is popular in Malaysia and subscribed to the same broadband subscription which is Umobile. Note that the average download speed while using a cellular network during normal times (before the crises of COVID-19) was around 4-8Mb/s.

Since download speed rates are the most important aspect of the network speed, our focus will be on the download speed rates in this discussion. Fig. 9 describes the network performance during MCO at 10 am from 13 of January to 13 of February.

It is shown that the download and upload speed in KL and JB increases in some days especially weekends, and decreases in weekdays. This is because the necessity for services and applications for business, education, and/or online meetings is higher on weekdays; therefore the load on the network is higher. In addition, it can be seen the download and upload speed rates are higher in KL. This is because the population there is much higher than other areas in Malaysia, thus there are more cellular networks installed in the area. The highest download speed during this period is around 23Mbps in KL, while the lowest is near to 0 Mbps on some days for KL and JB.

(a) Download Speed at 10 AM.

(b) Upload Speed at 10 AM.
(c) Latency at 10 AM.

Fig. 9.  Network Performance during MCO at 10AM.

Fig. 10 presents the network performance during MCO at 4 pm from 13 of January to 13 of February. It is obvious that there is performance differences compared with the 10 am rates. Specifically, during this period all rates were quite low except in 6 of February and 13 of February (weekends) in KL and JB. The highest rate measured during this period was 30-40Mbps for download speed.

(a) Download Speed at 4:00 PM.

(b) Upload Speed at 4:00 PM.

(c) Latency at 4:00 PM.

Fig. 10.  Network Performance during MCO at 4PM.

On the other hand, most of the weekdays during this peak time (4 pm) has the lowest rates, this is because most services and online meetings shifted afternoon in MCO.

Fig. 11 presents the network performance during MCO at 10 pm from 13 of January to 13 of February. The download speed is low overall, mostly in KL. This is because the usage of online services and streaming such as Netflix has risen after the pandemic, especially in the evening. Moreover, it can be seen that the rates are lower when comparing it with the morning and afternoon rates. This is because the government of Malaysia ordered people not to go out in the evening, and most of the markets were closed, therefore the usage of the internet has increased. It can be seen that from 8 of February,

the download speed rates increase as the MCO period is about to finish.

Fig. 12 presents the network performance during CMCO at 10 am from 5 of March to 2 of April. This figure shows the decreased download speed rate in the morning time (10 am) compared with the morning time of MCO. This is because the restrictions were less during CMCO and people could go out shopping and more businesses opened after the MCO period. In addition, during CMCO, the users of cellular networks service increased compared with MCO due to the fact that in the MCO period, people spent more time at home which means most of the users change their connection to WiFi network.

(a) Download Speed at 10 PM.

(b) Upload Speed at 10 PM.

(c) Latency at 10 PM.

Fig. 11. Network Performance during MCO at 10PM.
(a) Download Speed at 10:00 AM.

(b) Upload Speed at 10:00 AM.

(c) Latency at 10:00 AM.

Fig. 12. Network Performance during CMCO at 10AM.

While in the CMCO period when people had the chance to go out, they shifted back to the cellular network connections. The rates of the download speed for the morning time were more stable than MCO, as well as for the upload speed. The highest value measured was on 20 of March (weekend) and 25 of March. On the other hand, the latency value increased near and on the weekend as well on 12, 21 and 26 of March for KL, and on 13 and 31 of March JB. Overall latency in this period is higher than the latency measured in the morning of MCO due to the increased usage during the CMCO.

Fig. 13 presents the network performance during CMCO at 4 PM from 5 of March to 2 of April. The download speed during this period has slightly increased compared with the morning time. This is because in the CMCO time, the peak time has shifted mostly in the morning to the afternoon because the measures and restrictions has been minimized by the government, therefore the load on the network is expected to be less in the afternoon and evening times. The highest rate achieved by the network for the download speed is around 25-30Mbps on 12 of March and 1 of April during the weekend (Saturday and Sunday) and in Friday.
(a) Download Speed at 04:00 PM.

(b) Upload Speed at 04:00 PM.

(c) Latency at 04:00 PM.

Fig. 13. Network Performance during CMCO at 4PM.

For the latency, due to the increased number of users of the cellular networks, the rates of latency have increased significantly, especially in KL in 24 of March and 2 of April.

Fig. 14 presents the network performance during CMCO at 10 PM from 5 of March to 2 of April. Overall rates including download, upload and latency are higher than the morning and afternoon times. The download speed rate in this period is slightly higher when comparing it with the evening time of the MCO period. This is because people had to go home after 8 pm, which means the number of cellular users decreased significantly. The highest upload speed rate achieved was around 45Mbps on 27 of March (weekend) in KL and Cheras. The lowest value of latency is around 0-50ms, and the highest has reached 200ms same as the value of latency in the MCO evening time.

This is because of the increased number of users during the CMCO than the MCO period. In addition, the number of people subscribed to a broadband subscription plan has increased during CMCO.
(a) Download Speed at 10:00 PM.

(b) Upload Speed at 10:00 PM.

(c) Latency at 10:00 PM.

Fig. 14. Network Performance during CMCO at 10PM.

To summarize and extract the findings from all the above results, the average rates are presented in Fig. 15. In addition, the highest and the lowest values of all times for all cities are shown and highlighted in red and yellow colours, respectively. The highest value of all rates within all times among the three cities is highlighted in blue colour. While the lowest values are highlighted in yellow color. Specifically, the average rates of the download speed are presented in Fig. 15(a). As shown in the figure, the highest value in the MCO period was in KL in the morning time. This is because, as mentioned earlier, the cellular towers and BS deployed in that area are much more than in other areas, and the peak time of workers who relied on the internet connection in the morning time of the MCO was shifted to work from home in fixable times. The lowest value

was in the evening time in JB. On the other hand, the highest value in the CMCO period was in SL (Cheras) in the morning time. While the lowest value was in KL in the evening time.

Fig. 15(b) shows the upload speed rates. The highest value in the MCO period was in JB in the Afternoon time and the lowest value was in SL (Cheras) in the morning time. On the other hand, the highest value in the CMCO period was in JB during morning time, and the lowest value was in SL (Cheras) during the evening time.

Fig. 15(c) presents the latency values for all cities in all times. The longest time of latency in the MCO period was in JB during the morning time, which expresses the best value, and the highest time of latency was in SL (Cheras) in the

morning time as well, which was the worst value. The highest time of latency in the CMCO period was in KL in the evening time, while the lowest time was in JB during the afternoon time.

In Fig. 16, the total volume values of downloads, uploads, and latency in a percentage manner are presented. In Fig. 16(a) during MCO, the biggest volume of downloads was in KL which is 45%, while the rates in JB and SL are almost the same. On the other hand, during CMCO, the biggest overall value of downloads was in SL which is 42%, and the lowest value was in Kl which is 25%. In Fig. 16(b), the upload speed total value is presented. During MCO, the higher values were in both KL and JB which are 46%, and the lowest was in SL which is 8%. In addition, during the CMCO, the greatest value of upload speed total value was in JB which is 54%, and the lowest was in SL at 10%. In Fig. 16(c), the overall latency is shown. The highest volume of latency during the MCO was in SL at 42%, and the lowest was in JB at 22%. Moreover, the greater value during the CMCO was in KL at 42%, and the

least value was in JB at 27%. That means the total volume of downloads was at the highest value in KL during MCO at 45%, and the biggest total volume of uploads was in JB during CMCO at 54%. In addition, the worst value of total latency was in the SL during MCO and in KL during CMCO at 42%. Therefore, to accelerate the performance of cellular networks, and to decrease the burden, it is important to use another wireless technology such as WiFi, visible light communication, and other types of optical wireless communications to support the network and to deliver higher data rates [52].

To conclude, for the overall evaluation of cellular networks during the two periods, it can be seen that the performance of cellular networks has decreased especially in the peak times and during weekdays during the CMCO more than the MCO times. The speed rates depend on the number of computing devices that work concurrently in addition to the user requirements and the usage of data. The processing of such a big amount of data requires intensive computing tasks.

| Times | | Download rate | | |
|---|---|---|---|---|
| | | JB | KL | SL |
| MCO | 10AM | 4.94 | 7.88 | 4.83 |
| | 4PM | 3.15 | 6.24 | 3.23 |
| | 10PM | 2.16 | 2.31 | 2.66 |
| CMCO | 10AM | 4.43 | 3.43 | 5.69 |
| | 4PM | 5.35 | 2.83 | 4.20 |
| | 10PM | 4.04 | 2.71 | 3.69 |

(a)

| Times | | Upload rate | | |
|---|---|---|---|---|
| | | JB | KL | SL |
| MCO | 10AM | 8.19 | 8.26 | 1.37 |
| | 4PM | 8.96 | 4.35 | 1.51 |
| | 10PM | 8.07 | 5.79 | 1.55 |
| CMCO | 10AM | 9.17 | 6.16 | 1.61 |
| | 4PM | 7.34 | 4.24 | 1.92 |
| | 10PM | 7.24 | 7.92 | 1.60 |

(b)

| Times | | Latency | | |
|---|---|---|---|---|
| | | JB | KL | SL |
| MCO | 10AM | 18.41 | 30.72 | 36.22 |
| | 4PM | 29.44 | 33.72 | 28.09 |
| | 10PM | 34.03 | 27.88 | 33.44 |
| CMCO | 10AM | 19.10 | 29.97 | 21.59 |
| | 4PM | 12.83 | 30.17 | 23.34 |
| | 10PM | 22.69 | 38.86 | 35.76 |

Fig. 16. Overview of Total Values of All Rates during MCO and CMCO.

## VI. Limitations and Future Directions

The main limitation of the study can be divided into few points as follows: i) data collection: only three cities were taken into account, ii) only Umobile network service provider was considered, iii) the exact location of users and distance to the cellular BS was neglected due to some difficulties, especially during the mobility around the city in the CMCO period. According to the above limitations, it is only possible to make further steps for future directions related to this study, where similar situations and circumstances would be available during a pandemic similar to COVID-19. Therefore, when studying cellular network traffic during a pandemic in Malaysia or any other country, more cities can be taken into account in addition to other factors. However, when a pandemic happens, lockdown and other types of movement restrictions take place immediately which makes it hard to conduct such research study.

## VII. Conclusion

A new age in wireless networks has been accompanied in by the COVID-19 pandemic. Computer wireless communications is a complex challenge since multiple features are involved. The present pandemic situation and the debate in this paper clearly describe the need for efficient impact analysis in this digital era. In this paper, we investigate the effect of COVID-19 measures and restrictions on cellular network traffic in Malaysia. The results show a significant impact on our daily use of network services and applications including download speed, upload speed, and latency. Moreover, three cities were taken into account which is Kuala Lumpur, Johor Bahru, and Selangor (Cheras) using Speedtest phone applications during two periods namely MCO and CMCO. In addition, Umobile was taken into account as a cellular network provider which is one of the most popular network service providers in Malaysia. This study used a simple approach as a method of calculation and analysis of cellular networks performance. The proposed analysis is presented as a case study that consists of different components and factors for the presented findings. Companies will also be required to optimize budgets and accelerate their digital revolutions as they adjust to the new normal post-crisis. By leveraging the emerging technologies and service models transformed to do more with less, communications leaders would have to embrace these initiatives.

*Abstract*—**Early Diagnosis has a very critical role in medical data processing and automated system. In medical diagnosis, automation is focused in different area of applications, in which heart disease diagnosis is a prominent domain. An early detection of heart disease can save many lives or criticality issues in diagnosing patients. In the process of heart disease diagnosis spatial and frequency domain features are used in making decision by the automation system. The processing features are observed to time variant or invariant in nature and the criticality of the observing feature varies with the diagnosis need. Wherein, the current automation system utilizes the features extracted in a large count to attain a higher accuracy, the processing overhead, and delay are considerable. Different regression approaches were developed in recent past to minimize the processing feature overhead the features are optimized based on gain performance or distance factors. The characteristic variation of feature and the significance of the feature vector are not addressed. This paper outlines a method of feature selection for heart disease diagnosis, based on weighted method of feature vector in consideration of feature significance and probability of estimate. A new optimizing function for feature selection is proposed as a dual function of probability factor and feature weight value. Simulation results illustrate the improvement of accuracy and speed of computation using proposed method compared to other existing methods.**

*Keywords—Deep learning approach; heart disease diagnosis; feature fusion model; ECG analysis; weighted clustering; F-Score*

## I. INTRODUCTION

The real time world is tending towards automation with the emergence of new technologies. To improve the system performance, different technologies were proposed to attain higher performance in the process of technologies in automation. The medical data processing is an emerging area of automation. In processing the medical data in making decision, the diagnosis systems were developed based on the captured samples which were passed to the processing unit using advanced processing algorithms. In the processing of medical data for automation, heart disease diagnosis has evolved as an area of interest in recent past. Various approaches have evolved in recent time in diagnosis of an early prediction of heart disease using electrocardiogram (ECG) or physiological parameters defined in Cleveland data set. Cardiac activity is measured as a rapid variation in the process

of heart which is based on the physical or mental working condition of a person. ECG signals are measured for the variation of electrical impulses in the heart operation based on the contraction or expansion of heart functioning. This is one of the most dominantly used observations in the diagnosis of heart disease. The process of ECG signal processing requires a high precision of storage and computation to provide an exact prediction of the heart condition. ECG processing has been now observed as a most common observation of various heart disease diagnosing such as arterial fibrillation, post-operative complication in cardio surgery [1,2], etc. The post diagnosis complications and delay in diagnosis results in longer hospitalization leading to critical illness and increases a high cost of treatments as well [3]. High risk of heart disease is observed in older age persons [4], however in recent time a rapid increase in the cases of aged between 40 and 50 is also observed. Different diagnoses of heart disease use ECG signal were presented in literature. R-peak detection for ECG analysis is outlined in [5] square double difference method for the QRS segment localization was outlined. This process is developed for feature extraction from ECG using three steps of operations. Process of sorting, thresholding and approximation of the relative region is presented. The R-peak detection is developed based on the magnitude difference of the RR peak values. The external inference has however limited the decision performance. In [6] a feature extraction process with signal denoising is presented. This method proposed soft thresholding approach in processing of ECG signal. Wavelet based method is used in the extraction of feature vectors and processed for signal denoising. The spectral decomposed bands are processed using soft threshold. The selection of feature vector is improved using K-nearest neighbor (KNN) approach outlined in [7]. This approach developed a classifier model using KNN approach in categorizing QRS patterns in ECG signal analysis. This approach applied a band pass filter in selection of feature vector and noise filtration process. In [8] band pass FIR filter was used in extracting the feature vectors. Totally six features were extracted for QRS pattern using a sliding window approach. An approach of signal denoising using modified Weibull distribution for ECG is presented in [9]. This is a blind method defined for the extraction of signal from the source using independent component analysis. In deriving line patterns Hilbert transformation were used. The extraction of

feature vector was processed with normalized multi derivative wavelet used for detection and denoising. The classification of the extraction feature is developed using Euclidian distance where a Nyman Pearson classification is developed in [10]. In [11] a wavelet-based transformation is developed for feature extraction and a temporal relation is used in the developing the feature selection. A feature extraction and selection approach are outlined in [12] where P, T peaks were used in diagnosis of heart disease. The presented approach develops a multi classification for heart disease diagnosis. A geometrical feature extraction is outlined in [13]. These approaches extract the feature based on the structural representation of ECG signal. The structural variations were derived using 1-D discrete wavelet transformation. The extracted features are however biased with noise effects which lead to misclassification. In classification model, various classifier such as support vector machine (SVM), probabilistic neural network (PNN) and multi-layer perceptron (MLP) back propagated network is outlined in [14, 15, 25]. Artificial intelligence (AI) methods have been used in the diagnosis and early alarming of cardiovascular diseases. The usage of AI in the diagnosis of cardiology application is outlined in [16,17]. These approaches significantly eliminate the baseline wandering and using the linear mapping the classification is performed. In [18] a new classifier model based on kernel driven classifier is presented. The authors in [19, 20] outlines the application of artificial neural network (ANN) and SVM model in classification. Similarly, a cross wavelet transform (XWT) is outlined in [21], where two distinct signals are correlated in deriving the correlation. Other method such as wavelet entropy [22, 23] and signature descriptors [24] were presented in automation of heart diseases diagnosis. In [28, 29] different deep learning techniques based on MRI sample processing for early detection of brain tumors and gliomas is presented. However, the feature overhead, accuracy of feature selection and a proper relation of trained features is constraint. In developing a new feature representation for heart disease diagnosis, a new approach of feature fusion using the property of discrete monitored data with the continuous ECG signals features. The overhead of feature representation is addressed ad significant feature vectors were selected in processing the system faster and more accurate. The contribution to the presented work is listed as:

*1)* Developed a new feature fusion approach using regression and weighted clustering.

*2)* Developed a classifier model using deep neural network model using feature selected.

*3)* Integrated electronic record data with ECG feature vector.

The rest of this paper is outlined in seven sections. Characteristic of the features for a heart disease diagnosis is presented in Section II. Section III outlines the existing approach of feature representation and the proposed approach is outlined in Section IV. Section V present the simulation result obtained for developed work. Section VI outlines the conclusion for the developed work.

## II. FEATURE REPRESENTATION IN HEART DISEASE DIAGNOSIS

The diagnoses of heart diseases are affected by multiple factors. There are multiple observations which are inter-relative in nature. A proposed selection others feature can improve the estimation performance as well, the accuracy of estimation. The two dominant features used in the diagnosis of the heart disease are the discrete monitoring vector and the continuous varying ECG signal. The observation of the discrete feature vector is presented with 14 dominant feature representations. These features are listed as:

*1) Age*: Patients age in year.

*2) Sex*: represent the patient is Male/female gender.

*3) Chest pain (CP)*: define type of chest pain in a patient.

*a)* Patient having a past record of chest pain referred as typical angina (angina).

*b)* The patient past record is not effective however current observation of chest pain termed as atypical angina (abnang).

*c)* Patient with short period chest pain with painful condition termed as non-anginal pain (notang).

*d)* Patient with illness but with low possibility of heart disease termed as Asymptomatic (asympt).

*4) Trestbps*: Resting blood pressure of a patient at initial monitoring.

*5) Chol*: patient's density of cholesterol in mg/dl.

*6) Fbs*: it is a Boolean representation reflecting the fast state of blood sugar with higher value of 120mg/dl.

*7) Restecg*: Reflect patient ECG on rest state. This is reflected in 3 states having normal, abnormal or hypertrophy.

*8) Thalach*: this represents the patient maximum value of heart rate obtained.

*9) Exang*: this is s Boolean value which indicates the angina pain when exercise.

*10) Oldpeak*: value of ST variation when rested from exercise.

*11) Slope*: indicates the variation in the slope when in exercise.

*12) Ca*: indicate major vessels numbers.

*13) Thal*: indicate the status of heart condition which could be reversible or non-reversible condition.

*14) Num*: indicate the class attributes which indicate patient health condition which varies from 0-4 value.

These UCI features are readily available at (https://archive.ics.uci.edu/ml/datasets/Heart+Disease) Cleveland database, which describe the measured discrete coefficient of automation system. A feature selection approach of the monitoring feature of Cleveland data set is presented in our past work [27]. In addition to the measured discrete parameter, a continuous signal monitoring of ECG is used for representation. ECG reads the impulse of heart muscle variations. This reflects the functionality of the heart and the rhythmic repetition indicates the variation of heart movements. A typical ECG signal is measured for a continuous monitoring which could extend from 24-48 hours. For a detail monitor

about 12 different observations can be used with different placed sensors. The ECG signals are recorded for a 125Hz to 500 Hz sampling rate which are buffered in 8–12bit binary representation. The volume of discrete samples buffered into a file for processing could range from few Kb's to a large Mb. The interference during the capturing of ECG or buffering is an additional overhead to the buffered data. Basically a ECG signal is captured a 0.05-100Hz frequency range for a value of 1-10mV. ECG signal is characterized by five peaks and valleys which are termed as P, Q, R, S, and T representing the variation of heart movement. The estimation of ECG features defining the PQRST time period, peak values etc. the variation of a P-R interval could extend for 0.2 to 0.2 seconds for a normal heart condition. The duration of the ECG peaks and the amplitude variations in QRST representation diagnosis different heart disease cases such as cardiac arrhythmias, ventricular hypertrophy, myocardial infection, Arterial fibrillation etc. A representation of an ECG is signal is presented in "Fig. 1".

The ECG signal is characterized by the varying coordinates of the signal and the 12 features used in the process of diagnosis are as listed:

1) R_pk_cnt – Number of R peaks in the signal
2) Q_Dur – Q time period
3) R_Dur – Period of R-R time interval
4) R_Ampl – Amplitude for R peak
5) Q_Ampl - Amplitude for Q peak
6) S_Ampl - Amplitude for R peak
7) P_Loc – location of P
8) Q_Loc - location of Q
9) R_Loc - location of R
10) S_Loc - location of S
11) T_Loc - location of T
12) ST_dev- ST deviation

The variations of these parameters reflect the variation in heart movement which is used in the diagnosis of heart disease. The automation system developed in diagnosis of heart disease read these features as an input parameter in making decisions and diagnosis of different heart disease. In recent [26] a fusion model for ECG feature and medical record data is presented. The feature fusion model is developed based on the cluster information gain for a normalized factor. The presented approach of feature fusion is presented in following section.

Fig. 1. Figure Illustrate ECG Signal Representation with Feature Representation. different Segment of ECG Shown in Figure P Wave, PR Interval, QRS, ST Segment and T Wave [25].

## III. EMBEDDED FEATURE FUSION APPROACH

The representing features for diagnosis are very important in representing the variations in observing data. Features for heart disease diagnosis are observed by recording sensor interface or by recording physical or medical history of a patient. As multiple sources of feature vector exist developing different processing and classification system is very complex and overhead for automation system. Fusion of multiple observations can reduce the overhead in automation process. Fusion can be developed based on data, feature or decision level. A feature based fusion approach is proposed in [26]. This approach attempts to fuse the patient record data with the sensor monitoring features. The framework for feature fusion approach proposed in [22] shown in "Fig. 2". An integration of physiological data observed via sensors with the electronic recorded data is developed.

The data recorded are preprocessed for its representation and improve the quality of representation. A signal denoising, missing data filtering and normalization. The presented approach developed a feature fusion selection method based on information gain and entropy of information. Here, a set of feature vectors are structured obtained from sensors and record data. The feature selection is optimized by observing the information gain factor (IGF). IGF of the feature vector is represented as,

$$IGF\ (f, f') = \ v(f) - v(f, f') \qquad (1)$$

Where $f, f'$ are the feature vectors of sensor and recorded data, respectively. $v(.)$ is the entropy function of the variable. The entropy $(v)$ of a feature set is measured based on the redundancy parameters of the feature vectors in a class given by,

$$v(f_i) = \ -\sum_{i=1}^{k} P(f_i) log_2\big(P(f_i)\big) \qquad (2)$$

Where $P(.)$ is the probability factor for a feature entering into cluster. The selection of the feature vector is governed by the distance metric of the entropy value of the two observing feature vectors. An optimization is observed when the distance is minimal. The information gain is then defined by,

$$IGF\ (f, f') = \ -\sum_{i=1}^{k} P(f_i) log_2\big(P(f_i)\big) - \big(-\sum_{i=1}^{k} P(f_i) - \sum_{i=1}^{k} P(f_i)\ log_2\big(P(f_i, f_i')\big)\big) \qquad (3)$$

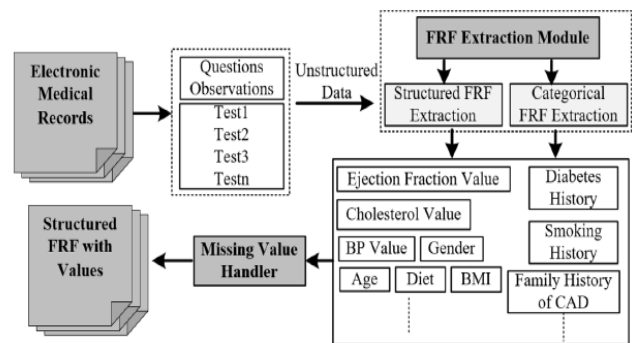

Fig. 2. Work Flow for Feature Fusion and Decision for Heart Disease Analysis. Figure Illustrate the Extraction of Features from Unstructured Electronic Medical Record.[26].

The presented work discards the features with low information gain and select only features with high information gains. The selection is based on the higher values of $IGF$ which is relative to the entropy of a feature value. The presented work discards the features based on the redundancy of the feature vector in the set. A weight-based feature selection is also presented in prioritization of feature selection. However, the outline work though improves estimation accuracy discard the features with reference to redundancy factor. The process of low entropy feature elimination reduces the processing overhead but, the criticality of the feature set is not observed. Secondly, the redundancy wrt. Vector magnitude is observed but the diversity in feature vector in fusion is not considered. This discard features of importance due to similar magnitude values. To overcome the addressed issue, a new regression model with divergence factor is presented. The outlined method is presented in the following section.

## IV. WEIGHTED FEATURE FUSION MODEL AND CLASSIFICATION

Feature fusion based on entropy eliminates features of low magnitude or higher redundancy; however, the significance of such features was not observed with the criticality of heart disease. Elimination of feature of higher critical features having higher entropy could lead to lower estimation performance and hence should be selected based on feature criticality. An approach based on the divergence of feature vector and its importance based on its criticality called weighted feature fusion model (WFM) is presented. The proposed feature selection is developed based on an auto regressive model. The auto regression approach has a significant means of selecting appropriate fusion of record data with ECG features simultaneously. The auto regression method is developed based on the information theory approach where the optimization is achieved using burg's method. The method minimizes the information loss based on feature vectors and the approximation of test feature with the registering group $(Gi)$. For a given set of feature vector $\{f, f'\}$, where f is the features derived from the grouping of ECG signal $(f_{ECG})$ and the record values $(f_R)$ of patient physiological details and f' is the feature set of other classes.

$$f = \{f_{ECG}, f_R\} \tag{4}$$

An auto regression for the feature set is computed to derive the variation $(\gamma i)$ using distance metric for all 'j' features set in the group given as,

$$\gamma_i = (f_i - f'_{i,j})^2 \tag{5}$$

To observe the criticality of the feature vector a weight value is associated with different class of heart disease based on the severity factor. Severity of the heart disease is defined in 5 different classes as listed in Table I, where each class group is associated with a weight value indicating its criticality. The weight value of each class is allotted based on its criticality. Here a higher value of 0.5 is given to class-4 type of heart disease and 0.1 is given to the healthy class. The associated weight value for each class is presented in Table I.

TABLE I. WEIGHT ASSOCIATION WITH CLASS ATTRIBUTE FROM ELECTRONIC RECORD DATA. THE WEIGHT VALUE OF EACH CLASS IS ALLOTTED BASED ON ITS CRITICALITY

| Group ($G_i$) | Class | Infection level in % | Categorize | Weight allotted ($\omega_i$) |
|---|---|---|---|---|
| $G_0$ | Healthy | Nil | Healthy | 0.1 |
| $G_1$ | class -1 | 0-20% | starting level | 0.2 |
| $G_2$ | class -2 | 20-40% | Effective with-Low | 0.3 |
| $G_3$ | class -3 | 40-60% | Effective with – High | 0.4 |
| $G_4$ | class -4 | 60-max% | Significant level | 0.5 |

A regression model is developed for the selection of fusion feature where a Bergman divergence approach is applied for selecting the best suitable feature values. The optimization of feature selection is defined as a minimization function given as,

$$Arg\ min(P[\gamma_i(f, f')]) \tag{6}$$

Features with minimum probability of diversity are eliminated and features with higher diversity are considered for selection. The two-feature set $f$ and $\tilde{f}$ are processed for computing diversity $(\gamma i)$ based on squared distance. The Probability function $P(.)$ defines the probability of diversity among the set of fusion features. The diversity factor is computed as,

$$\gamma_i(f, f') = (f - f')^2 \tag{7}$$

The features with higher diversity factor have a higher probability of selection. However, the proposed approach measures the criticality of the feature in selection based on the class of severity. For the measure of class severity, a weight value is associated listed in Table I.

The features are processed for computing an aggregated weight factor $(A\omega)$ for all k-classes given by,

$$A\omega = \sum_{i=1}^{k} \omega_i \tag{8}$$

Where, $\omega_i$ are the associated weight values for each class value. An aggregated class weight $(\omega_{kc})$ for each group $(c)$ is computed given by,

$$\omega_{kc} = \sum_{i=1}^{k} \omega_{i_c} \tag{9}$$

The selection of feature vector in fusion is optimized by the minimization of divergence factor and having feature vector with relative higher weight value. the optimization for feature selection is given by,

$$Fsel \Rightarrow \{arg\ min(P[\gamma_i(f, f')]), ((\sum_{i=1}^{k} \omega_{i_c}) > \frac{A\omega}{k})\} \tag{10}$$

The process of feature selection presented optimizes the features with higher diversity and having weight associated higher than the relative weight value of all class $A\omega/k$. This condition selects features which has a variation in feature and are of more significance. The proposed feature fusion approach based on divergence factor and aggregated weight is outlined in the algorithm below.

## ALGORITHM

Input: Feature set $(f, f')$
Result: selected fusion features
Process 1: Diversity feature selection
1. for each class,
2. Compute fusion feature for each patient 'i',
$$f_i = \{f_{ECGi}, f_{Ri}\}$$
3. Compute divergence of feature vector,
$$\gamma_i(f, f') = (f - f')^2$$
4. Converge the feature with the minimal factor
$$\arg\min(P[\gamma_i(f, f')])$$
5. Update the feature fusion for each group with minimal divergence,
$$G_u = f_i \Rightarrow G_u$$
Where 'u' define the group label varying 1-5.
6. Update the feature selection using weight allocation using process 2.

Process 2: Weighted selection approach $(G_u, \omega i)$
1. Associate weight $(\omega i)$ for each group $G_u$
$$G_u \Leftrightarrow \omega i$$
2. Compute aggregated weight factor $(A\omega)$,
$$A\omega = \sum_{i=1}^{k} \omega_i$$
3. compute each class aggregated weight,
$$\omega_{kc} = \sum_{i=1}^{k} \omega_{i_c}$$
4. Converge the feature selection of fusion,
$$Fsel \Rightarrow \{\arg\min(P[\gamma_i(f, f')]), (\left(\sum_{i=1}^{k} \omega_{i_c}\right) > \frac{A\omega}{k})\}$$

    end Process1
    end Process0
    end

Selected features are distinct with variations and higher weight associated which is passed to a classifier unit. The classification operation is developed based on Ensemble deep learning model. The Neural Network is developed with training and testing phase. The network is trained for minimum class error and the NN model is developed with multiple layers with input, hidden and output layers. The network layout of the NN model is show in "Fig. 3".

The input to the NN model is the selected fusion features xi and weight value $\upsilon i$. For a given input set a set of weight is associated given as, $\upsilon = [\upsilon_1, \upsilon_2, \ldots, \upsilon_v]$ for the input $X = [x_1, x_2, \ldots, x_v]$

The output of the network is given by,

$$Y = f(\upsilon_t x)$$

 or

$$Y = \sum_{i=1}^{v} \upsilon_i x_i \tag{11}$$

Fig. 3. Network Layout of the NN Model. Figure Illustrate the General Form of Neural Network with n-Input Nodes, N-Output Nodes and K Hidden Layers.

The output of the network is given as a bipolar representation of the NN model output given by,

$$Y = f(\upsilon t \, x) \tag{12}$$

$$Y = \begin{cases} -1, & x < 0 \\ 1, & x \geq 0 \end{cases} \tag{13}$$

A multi-level NN model is used for transition as illustrated in "Fig. 4".

The multi-level model process for error minimization based on the weight updation where a feed forward back propagated network for error minimization is developed. A weighted input-output relation with bias $(g)$ passed to activation function $(a)$ is used for mapping the output to input based on the updation. The relation of the input to output is given as,

$$Y_i = f\left(\sum_{i=1}^{n} \omega_i a\left(\sum_{i=1}^{k} \Phi_i x_i + g_i\right)\right) \tag{14}$$

The output is obtained as a function of updating weight variable $\Phi$ and bias value $(g)$ and the class weight value is applied with the weight updation of NN model.

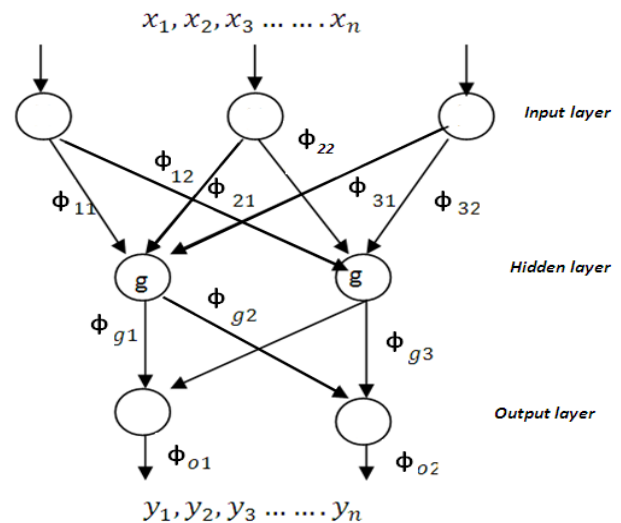

Fig. 4. Multi-Layer Network for Classification is Shown in Figure with Input X1-Xn and Output y1-yn.

## V. EXPERIMENTAL RESULTS

The presented approach of weighted feature fusion model (WFM) is tested for the presence or absence of heart disorderness. Simulation is developed for electronic records (ER) from updated Cleveland database consisting of 600 patient records, where each patient has 14 records of entry. The records are updated for time line observation and selected for fusion. ECG signals of 600 patients are taken from MIT database. ECG features are computed for peak values and time periods, which are used for fusion with the ER data. The proposed approach WFM is compared with the existing approach of embedded fusion model [26] and classifier models for performance evaluation. Few sets of ECG signals and ER used in training the network is shown in "Fig. 5" and Table II, respectively.

Fig. 5. ECG Signals from Database used for Training. The ECG Signals from MIT Database are used to Compute Peak Values and Time Periods.

Feature for each ECG signal is computed and fusion approach is applied with selective approach as outlined in Section IV. For testing an ECG signal is randomly selected from the database and corresponding ER record is read.

The ECG signal is processed for feature extraction, where the features are processed for fusion and selection and mapped to classifier model. NN classifier performs the classification for detection of disease diagnosis. The processing ECG signal is shown in "Fig. 6".

The ECG signal is processed for peak detection and time period computation. Magnitude and time interval in reference to QRST measurement is computed. The magnitude plot for the peak values is illustrated in "Fig. 7".

Computed features for the processing ECG signal are listed and a Mean value is computed to observe the variation of computing features for different ECG signals. Table III list the feature values for different test samples where the R peak counts (F1), Q-duration(T1), RR interval (T2), R-peak(F2), Q-peak(F3), S-peak(F4), P-location(F5), R-location(F6), S-location(F7), T-location(F8) and ST deviation(F9) is computed.

TABLE II. ER RECORD FOR THE PATIENTS USED IN TRAINING. THIS ER RECORD CONTAIN 14 DIFFERENT ATTRIBUTES FIELDS

| ER-Values | ER-filed | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | age | sex | Chest pain | Trestbps | Chol | Fbs | Restecg | Thalach | Exang | Oldpeak | Slope | Ca | Thal | Num |
| P1 | 64 | 0 | 3 | 140 | 313 | 0 | 0 | 133 | 0 | 0.2 | 1 | 0 | 7 | 0 |

TABLE III. OBSERVATION FOR DIFFERENT FEATURE VECTORS COMPUTED FROM ECG SIGNAL. TABLE SHOWS THE LIST OF THE FEATURE VALUES FOR THE DIFFERENT TEST SAMPLES.

| Sample | T1 (ms) | T2(ms) | F1 | F2 | F3 | F4 | F5 | F6 | F7 | F8 | F9 | Mean |
|--------|---------|--------|-------|------|------|------|-----|-----|-----|-----|------|--------|
| S1 | 585 | 578 | 2 | 0.86 | 0.62 | 0.66 | 273 | 351 | 347 | 361 | 0.13 | 227.2 |
| S2 | 576 | 567 | 0.392 | 0.81 | 0.62 | 0.61 | 254 | 323 | 332 | 323 | 0.14 | 216.14 |
| S3 | 534 | 573 | 0.37 | 0.85 | 0.62 | 0.66 | 251 | 356 | 343 | 334 | 0.12 | 217.60 |
| S4 | 561 | 543 | 0.395 | 0.83 | 0.62 | 0.62 | 276 | 376 | 346 | 367 | 0.15 | 224.69 |
| S5 | 588 | 571 | 0.36 | 0.89 | 0.62 | 0.69 | 212 | 398 | 323 | 369 | 0.16 | 223.97 |
| S6 | 579 | 577 | 0.31 | 0.81 | 0.62 | 0.63 | 265 | 312 | 364 | 362 | 0.12 | 223.77 |
| S7 | 565 | 567 | 0.67 | 0.80 | 0.62 | 0.67 | 223 | 353 | 368 | 367 | 0.16 | 222.35 |

The features are processed for fusion with ER and selection using WFM approach. The selected features passed to classifier model result in the classification of heart diseases. To observe the performance of the developed method retrieval accuracy, recall rate, precision and F-Score of the system is computed for 5-random test iterations. The accuracy of the system is measured as,

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \qquad (15)$$

The four parameters of observation (TP, TN, FP, FN) is derived from the confusion matrix presented in Table IV given as,

Where,

TP is the true positive.

TN is true negative

FP is false positive and

FN is false negative.

The precision for the developed system is defined by,

$$P = \frac{TP}{TP+FP} \qquad (16)$$

Recall factor for the system is computed by,

$$R = \frac{TP}{TP+FN} \qquad (17)$$

and the F-Score of the system is measured given by,

$$F = \frac{2*R.P}{R+P} \qquad (18)$$

Observation for the developed system is listed in Tables V to VIII.

System accuracy of the proposed approach is shown in "Fig. 8" and it is observed to be improved by 0.7%. The accuracy is observed based on the selected feature due to divergence and weighted feature. As the features of critical observations are retained rather than entropy measure the accuracy of the proposed system is improved.

TABLE IV. CONFUSION MATRIX FOR THE ANALYSIS

| Diagnosis | Effective | Not-Effective |
|-----------|-----------|---------------|
| Effective | TP | FN |
| Not-Effective | TN | FP |

TABLE V. SYSTEM ACCURACY OF THE WFM APPROACH. THE PROPOSED WFM APPROACH HAS 99.2% ACCURACY, WHICH SHOWS 0.71% INCREASE IN ACCURACY THAN THAT OF FUSION MODEL

| SVM [26] | L-Regression [26] | Decision Tree [26] | Naïve Bayes [26] | Fusion model [26] | Proposed WFM |
|----------|-------------------|--------------------|------------------|-------------------|--------------|
| 84.4 | 92.2 | 77.6 | 83.4 | 98.5 | 99.2 |

TABLE VI. SYSTEM RECALL RATE OF THE DEVELOPED APPROACH. THE PROPOSED WFM APPROACH HAS 1.97% INCREASE IN RECALL THAN THAT OF FUSION MODEL

| SVM [26] | L-Regression [26] | Decision Tree [26] | Naïve Bayes [26] | Fusion model [26] | Proposed WFM |
|----------|-------------------|--------------------|------------------|-------------------|--------------|
| 81.5 | 95.2 | 77.7 | 78.5 | 96.4 | 98.3 |

TABLE VII. SYSTEM PRECISION OF THE DEVELOPED APPROACH. THE PROPOSED WFM APPROACH HAS 98.9% PRECISION

| SVM [26] | L-Regression [26] | Decision Tree [26] | Naïve Bayes [26] | Fusion model [26] | Proposed WFM |
|----------|-------------------|--------------------|------------------|-------------------|--------------|
| 87.5 | 89.2 | 84.6 | 88.8 | 98.2 | 98.9 |

TABLE VIII. SYSTEM F-SCORE OF THE DEVELOPED APPROACH. THE PROPOSED WFM APPROACH HAS 98.4% F-SCORE

| SVM [26] | L-Regression [26] | Decision Tree [26] | Naïve Bayes [26] | Fusion model [26] | Proposed WFM |
|----------|-------------------|--------------------|------------------|-------------------|--------------|
| 84.5 | 92.2 | 77.6 | 83.4 | 97.2 | 98.4 |

Fig. 8. Figure shows the Accuracy Plot for WFM Approach. The Developed System Achieves 99.2% Accuracy.

System recall, and precision shown in "Fig. 9, 10" is observed to have an improved by 2%, and 0.7% respectively. The selective approach by weighted method results in improvement of the system parameters. The F-Score of the system is improved by 1.2% as shown in "Fig. 11".

Observation for the developed approach for different time period of observation is listed in Table IX. The variation of time period in ECG monitoring has significance on the classification performance is shown in "Fig. 12". For a short period, observation of 10ms the accuracy obtained is 97%, wherein for 15ms observation it is obtained to 98% and for a higher time period observation of 20ms the accuracy is retained to 98%, signifying an average period observation has a maximum accuracy and long period observation has same effect as redundant features are observed. The time period for longer period is observed to be higher compared to short period observation. Selection of the features with high divergence and weight parameter result in selection of feature vectors which result in lower time for classification.

TABLE IX. OBSERVATION FOR ECG SIGNAL WITH DIFFERENT TIME PERIODS. THE OBSERVATIONS OF ECG SIGNAL WITH TIME PERIODS 10MS, 15MS, 20MS

| Observing time period | Accuracy (%) | Recall | Precision | F-Measure | Time (sec) |
|---|---|---|---|---|---|
| 10ms | 97.3 | 95.3 | 98.1 | 96.8 | 10.6 |
| 15ms | 98.6 | 97.4 | 98.6 | 98.2 | 14.5 |
| 20ms | 98.7 | 97.6 | 98.8 | 98.4 | 18.3 |

Fig. 12. Observation for different Time Period of Sample. The Figure Illustrates the Observations of ECG Signal with Time Periods 10ms, 15ms, 20ms.

## VI. CONCLUSION

An approach for feature fusion based on the selection of feature vector and class attribute is presented. The process of weighted clustering based on information gain and updated feature is presented. This approach illustrated an enhancement of feature selection and improvement in accuracy of the system based on the observations obtained. The system accuracy is obtained to be improved based on the selected feature and fusion of multiple parameters in observation. The significant illustration of feature selection has given dual advantage of feature selection and classification performance for heart disease diagnosis. The selective method of feature selection based on divergence and weighted method provide a more accurate selection of fusion feature as the criticality factor is monitored based on associated weight factor which results in the improvement of system performance. In future, the proposed approach will be extended with varying conditions of heart monitoring with patient having multiple diseases and varying signal input conditions such as magnitude variations and signal wandering distortions.

Fig. 9. Recall Rate Plot for WFM Approach. Figure shows the Recall Rate of Developed System Up to 98.3%.

Fig. 10. Precision Plot for WFM Approach. Figure Shows the System Precision of Developed System Up to 98.9%.

Fig. 11. F-Score Plot for WFM Approach. Figure shows the F-Score of Developed System Up to 98.4%.

*Abstract*—The transportation network service quality is generally depends on providing demand based routing. Different existing approaches are focused to enhance the service quality of the transportation but them fails to satisfy the demand. This work presents an effective demand based objectives for optimal route generation in public transport system. The importance of this work is providing demand based optimal routing for large city transportation. The proposed demand based optimal route generation process is described in subsequent stages. Initially the passengers in each route are clustered using Distance based adaptive Fuzzy C-means clustering approach (DFCM) for collecting the passengers count in each stop. Here the number of cluster members in each cluster is equivalent to the passenger count of each stop. After the clustering process, adaptive objectives based beetle swarm optimization (ABSO) approach based routing is performed with the clustered data. Then re-routing is performed based on the demand based objectives such as passenger's count, comfort level of passengers, route distance and average travel time using ABSO approach. This ABSO approach provides the optimal routing based on these demand based objectives. The presented methodology is implemented in the MATLAB working platform. The dataset used for the analysis is Surat city transport historical data. The experimental results of the presented work is examined with the different existing approaches in terms of root mean square error (9.5%), mean error (0.254%), mean absolute error (0.3007%), correlation coefficient (0.8993), vehicle occupancy (85%) and accuracy (99.57%).

*Keywords*—*Clustering; optimization; demand based objectives; comfort level; optimal routing*

## I. INTRODUCTION

The increased population rate in large cities is one of the major transportation issues in developing countries. The unplanned organization in those cities increases the mobility demand and improves the tendency of private vehicle transport ownerships [1, 2]. This issue is common for all large cities have to deal with hundreds of vehicles running through their street each day. The congestion of traffic is increasing day by day even in rural areas also. Moreover, the traffic congestion associated delays are happening more often [3, 4]. A public transport network plays an important role in changing the demand from private to effective transportation and reduced traffic congestion [5]. The better public transportation can avoid the traffic congestion. To enhance the

cooperation in public transport systems, different demand based models are introduced. Passenger comfort [6] is one of the vital indexes used to validate the quality of public transport system.

The quality of the public transport system is depends on increasing the passenger comfort. Therefore, enhancing the bus comfort is a great attention by the public transport to attract the passengers [7-9]. The passenger's choice of transport is depends on various factors like comfort ability, travelling time, expense and reliability. Therefore, transport authorities are making attention to attract the passengers by providing passengers demand based transportation [10, 11]. The comfort of transportation is categorized into two classes. One is based on the performance of vehicle and the other one is depends on the operation of transport. Various studies are presented for providing demand based public transportation [11]. The investigated works states that uncertainties in travel times and traffic increases the passenger's stress level and reduces the passenger's quality [12, 13]. Some of the researchers proved that the comfort is depends on the passenger's load. So, accurately determining the bus comfort and providing demand based effective bus routing is important for improving the quality of transportation [14]. The load factor of passenger's and the bus travel time is an important and foremost for the quality of transportation [15]. The proficient public transport system can lessen the negative issues of private transport network.

Moreover, the quality of transport is mainly depends on minimization of travel time and waiting time. This effectively increases the performance of transportation [16]. The transportation authorities are responsible for generating the optimal routes. Based on the different objectives, transport authorities are determining the demanded bus routes and schedules [17]. The main concern of public transport is satisfying the public needs and the transport authorities are focussing on their profit. Moreover, different constraints are considered in the existing researches for the generation of transportation routes [18]. But the optimal route generation is still in demand.

Numerous optimization approaches are utilized in the existing works to enhance the transportation framework. Some of the existing optimization approaches are, genetic algorithm

*Corresponding Author.

(GA) [19, 20], simulated annealing (SA), Tabu search (TS) and Swarm intelligence (SI) [21]. These optimization approaches are proved their capability, effectiveness in optimal route generation in transportation network. But all the major issues of transportation are not solved as a whole and optimal route generation is still in demand. Moreover, demand based optimal route generation is not performed in the existing works.

The main motivation of proposed work is providing demand based transportation in large cities. Therefore, the quality of transportation can be achieved by considering major objectives such as passenger's count, comfort level of passengers, route distance and average travel time. In the presented work, demand based optimal route generation is proposed to improve the quality of transportation network. The major contributions of the presented methodology is described as,

- To effectively cluster the passengers in the transportation network, distance based fuzzy c-means clustering (DFCM) approach is utilized. This approach is utilized to gather the accurate passenger's count of each station in the transportation network.

- Optimal routing is generated by using effective objective based adaptive beetle swarm optimization. Re-routing is performed based on the different objectives such as comfort level of passengers, passenger's count, route distance and average travel time.

- Demand based effective routing is obtained by the proposed ABSO optimal routing approach. Here, the performance of the proposed approach is enhanced based on the considered effective objectives. This enhances the quality of the transportation by providing demand based vehicles.

The organization of this research work is described as: Section 2 surveys the recent related works, the presented approach is described in section 3, results and their discussion is provided in section 4 and the section 5concludes the paper respectively.

## II. RELATED WORK

Ovidiu Cosma et al. [22] presented an innovative methodology for two-stage transportation issues with fixed costs related to the routes. The developed heuristic algorithm solves the investigated transportation issues and it was attained by integrating the linear programming optimization issue within the genetic optimization process. Moreover, an effective local search process was incorporated with genetic optimization algorithm able to enhancing the global search. The proposed methodology effectively solves the transportation issue and enhances the quality in transportation. The performance can be enhanced further by using other optimization approaches in transportation.

Jiangtao Liu et al. [23] developed a routing based on the integration of travel demand, vehicle supply and restricted infrastructure. Based on these constraints, vehicles were optimally assigned in the routes to satisfy the passenger's. Various decomposition techniques were adapted in this research. Vehicle based integer linear programming model was presented for space time state (STS) with Dantzig Wolfe decomposition methodology. The presented methodology effectively increases the efficiency and reduces the congestion in transportation. But the proposed methodology was challenging to predict the optimal routes based on the travel demand.

Jishnu Narayan et al. [24] developed an integrated bus route selection and scheduling framework for static and dynamic public transport networks. The introduced framework based on the dynamic demand based route generation using an iterative learning framework. The effective routing based on this proposed approach effectively reduces the average waiting time of passengers. The combination of fixed and flexible transport networks enhances the routing ability and satisfies the passengers. Moreover, the day to day learning was considered to effective selection of routes and allocation of transport vehicles. The proposed approach can be improved in future by incorporating the time and reliability of passenger's.

Mahmoud Owais and Abdullah Alshehri [25] developed a pareto optimal route generation in transportation networks. Instead of considering the travel time like existing approach, the presented approach considered the relation among the traffic flow and the respective trip time. Based on the demand based information, the initialized routes were changed and select the traffic allocation approach. Finally, different objectives based approach was conducted with pareto optimal route generation. Further, the research performance can be enhanced by using effective recent techniques in future.

Philipp Heyken Soares [26] developed a zone based optimized routing in an urban network. Node based optimization was introduced on transportation routes by predicting the passenger trips for each stops. Here, the hybrid methodology was utilized for evaluate the journey times of source to destination. The travel time of each stop was determined by the node based procedures. The developed optimization procedure was applied on input considered real world database and the enhancement was shown existing routing framework. Further enhancements were possible in various factors based on passenger's comfort and satisfaction.

The investigated existing approaches are tried to solve the issues in the transportation system. But still, the existing approaches are not reached the satisfaction level by solving all the issues. Some of the approaches are focused on increasing the passenger's while decreasing the comfort of passengers. Therefore, the quality of transportation is needs to be enhanced by considering major objectives. The proposed work considered the four effective objectives such as passenger's count, comfort level of passengers, route distance and average travel time to provide the demand based routing. This resolves the issues present in the existing routing. Based on the proposed demand based routing, the service quality of the transportation can be increased.

### III. PROPOSED METHODOLOGY

This work presents an effective demand based optimal route generation in transport system. At first, Distance based adaptive Fuzzy C-means clustering approach (DFCM) is utilized for clustering the passengers in each stop. Here, the number of cluster members in each cluster is equivalent to the passenger's count of every station. Afterwards, adaptive beetle swarm optimization approach based routing is performed based on the clustered data. Further, re-routing is performed based on the effective objectives such as passenger's count, comfort level of passengers, route distance and average travel time using ABSO approach. In the optimal route generation approach, objectives are analysed in each pair of stations in the route using the ABSO approach. This ABSO approach enhances transportation system by providing demand based routing. The schematic diagram of the presented methodology is depicted in Fig. 1.

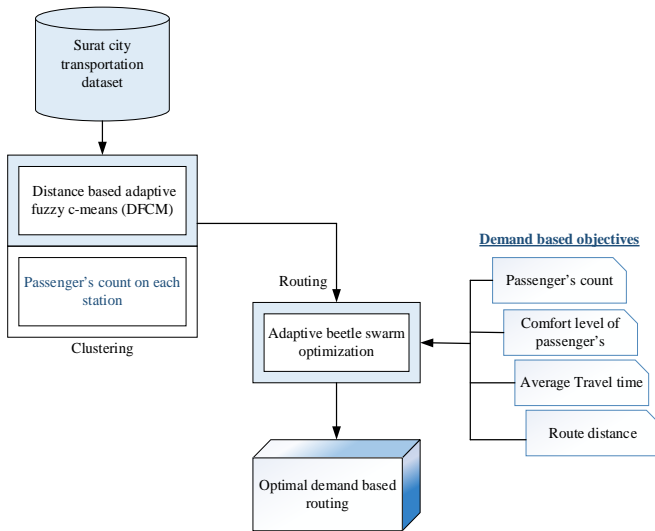

Fig. 1. Schematic Diagram of Presented Methodology.

The process of demand based optimal routing in the transportation system is described in the subsequent sections. Initially, the input Surat city transportation history data is considered and the passenger of each station is obtained by the proposed DFCM clustering. Afterwards, routing is performed by the proposed ABSO approach and demand based objectives are updated in this optimization approach to effectively performs the re-routing. This methodology effectively provides the demand based routing.

#### A. Distance based Adaptive Fuzzy C-Means (DFCM) Clustering

The proposed DFCM clustering approach minimizes the objective function through the iterative process. Consider, $Q = \{q_1, q_2, q_3, \ldots q_p\}$ represents the vectors of cluster centre, $\overline{U} = [\overline{\mu}_{kp}]^{m \times P_{opt}}$, $\overline{\mu}_{kp}$ represents the membership degree of input data $y_k$ to the cluster centre $q_p$, $\overline{\mu}_{kp} \in (0, 1)$. The objective function of the presented DFCM approach is described as,

$$\overline{J}_{DFCM} = \sum_{p=1}^{P_{opt}} \sum_{k=1}^{m} \overline{\mu}_{kp} \left\| y_k - q_p \right\|^N + D(k) \tag{1}$$

Here, $N$ represents the constant to control the fuzzy function of clustering results $N \in [1, +\infty)$. Here, the cluster membership function is updated by the subsequent condition (2),

$$\overline{\mu}_{kp} = \frac{1}{\sum_{l=1}^{P_{opt}} \left( \dfrac{D_{kp}}{D_{kl}} \right)^{\frac{2}{n-1}}} \tag{2}$$

The cluster centre vectors are updated by the subsequent condition (3),

$$q_p = \frac{\sum_{k=1}^{m} \left( \overline{\mu}_{kp} \right)^n y_k}{\sum_{l=1}^{m} \left( \overline{\mu}_{kp} \right)^n} \tag{3}$$

The fuzzy c-means clustering is processed into different steps to minimize the objective function $\overline{J}_k$ with the update of $\overline{U}$ and $\overline{Q}$.

The effectiveness of the fuzzy c-means clustering is based on the initial means. The means are having great impact on the final clustering. The existing FCM approaches are based on the arbitrary initialization to examine the centroid for clustering. But, the proposed DFCM approach centroids are selected according to the dense nodes positioning. The nearest neighbouring nodes are considered as a dense nodes. The nearest neighbouring nodes are the nodes with minimum distance. The distance of the nodes is evaluated based on the dense nodes to estimate the passenger's count in each station. Distance is evaluated by the subsequent condition (4),

$$D(k) = \sum_{l=1}^{M} \exp\left[ -\left\| y_k - y_l \right\|^2 * \left( \frac{1}{Dense\ cluster} \right)^2 \right] \tag{4}$$

Here,
$$Dense\ cluster = \frac{M}{P_{opt}} \tag{5}$$

Here, $P_{opt}$ represents the optimal cluster center. Based on these evaluations, the high dense data points are considered as a first cluster centre, and the farthest from the first centre is considered as a second centre and so on. The $P^{th}$ cluster centroid is satisfied with the condition $Maximum\left\{ \prod_{k=1}^{p-1} (q_p - q_k) \right\}$. The evaluated distance using condition (4) is updated in the condition (1). Then, the objective function satisfies the condition $\left| \overline{J}_k^{(t)} - \overline{J}_k^{(t-1)} \right| < \delta$, and then forms the optimal clustering. Here, $\delta$ represents the threshold function. The

initial cluster centre is needs to be changed to overcome the issue of distance among the node position and the cluster centre is zero. The cluster centres are updated based on the consideration that if the neighbouring node centre is far from $q_1, q_2, q_3, \ldots q_p$ is then considered as the updated cluster centroid. Clusters are formed by assigning nearest sensor nodes to the cluster based on this DFCM approach. The nearest sensor nodes are considered based on the minimum distance of sensor nodes. The pseudo code of the DFCM clustering is described in algorithm 1.

In algorithm 1, the proposed DFCM clustering steps are provided. This effectively clusters the historical data of passengers. Evaluate the objective function $\overline{J}_{DFCM}$ as per the condition (1), if the condition satisfies $\left| \overline{J}_k^{(t)} - \overline{J}_k^{(t-1)} \right| < \delta$ then the optimal clustering is obtained. The passenger's count details of each station are obtained in this clustering approach.

---

**Algorithm 1: Pseudo code of DFCM clustering**

**Input:** Initialize the passenger data in the transportation network $S = \{s_1, s_2, \ldots s_n\}$ and the initial centres $Q = \{q_1, q_2, \ldots q_p\}$

**Output:** Optimal clustering

**Begin**

    **Initialization** of passenger's data $S = \{s_1, s_2, \ldots s_n\}$ and centroids $Q = \{q_1, q_2, \ldots q_p\}$.

    **Compute** the objective function $(\overline{J}_{DFCM})$ utilizing condition (1).

    **Evaluate** membership nodes and cluster centres with conditions (2) and (3) at $\overline{J}_{DFCM}$ computation step.

    **Compute** the adaptive distance evaluation for passenger data using the condition (4)

    **Update** the cluster centroids by utilizing the condition (3),

    **If** the clustering process attains best outcome at maximum iterations, then the iteration is terminated.

    **Else**

    **Repeat** the above procedure until reaches the best solution.

    **Return** optimal clustering

**End**

---

### B. Demand based Optimal Routing in Transportation System

The demand based optimal routing is attained by the proposed adaptive objectives based beetle swarm optimization approach. Optimal re-routing is performed by updating the demand based objectives such as passenger's count, comfort level of passengers, route distance and average travel time are described in the subsequent sub sections.

*1) Demand based objective measures*: In this section, effective objectives are evaluated based on the transportation demand is described in the subsequent sections,

*a) Comfort Level of Passengers*: The passenger' comfort level is depends on the number of passenger's in the vehicle and the capacity of the vehicle. Comfort level of passenger is estimated by the subsequent condition (6),

$$\overline{C}_\alpha = \frac{\overline{P}_N}{\overline{V}_C} \tag{6}$$

Here, $\alpha$ represents the passenger's comfort level, $\overline{P}_N$ represents the number of passengers in the vehicle and $\overline{V}_C$ represents the vehicle's capacity.

*b) Passenger's Count*: The number of passengers in each station is computed based on the count between source and destination. Passenger's count is computed by the subsequent condition (7),

$$\overline{P}_m = \frac{\overline{K}}{\sum_t \overline{K}_t} \tag{7}$$

Here, $\overline{P}_{count}$ represents the passenger's count, $\overline{K}$ represents the number of passengers arriving in the station in a specified time. Similarly, number of passengers in vehicle based on the passenger count is computed by the subsequent condition (8).

$$V_m = V_{m-1}\left(1 - \overline{P}_m\right) + \frac{R_m \overline{K}}{N} \tag{8}$$

Here, $N$ represents the average number of trips in a specified time, $R_m$ is computed by the subsequent condition (9),

$$R_m = \begin{cases} \dfrac{M-m}{M-1} & \text{for direction}: m \to M \\ \dfrac{m-1}{M-1} & \text{for direction}: m \to 1 \end{cases} \tag{9}$$

Here, $m$ and $M$ represents the two consecutive stations.

*c) Route Distance:* Route length represents the sum of the distance among all the mid stations. The route distance is estimated by calculating the distance among each stop from source and destination. The distance between two adjacent nodes are computed by the subsequent condition (10),

$$\overline{D}_{route} = a \frac{\overline{S}_j \overline{D}_k}{dist_{j,k}} \tag{10}$$

Here, $\overline{D}_{route}$ represents the route distance, $a$ signifies the adjustment factor, $\overline{S}_j$ represents the source point of trip at $j$,

$\overline{D}_k$ represents the destination point trip at $k$, and $dist_{j,k}$ signifies the distance between the two station points.

*d) Average Travel Time:* The travel time is the starting and stopping time of vehicle from source to destination. The travel time of passenger is varies based on the different stations. The average travel time is computed by the various transport stations. The travel time of passengers are computed by the subsequent condition (11),

$$\overline{T}_{avg} = \sum_{i=1 \text{ to } n} TS_K$$
(11)

Here, $\overline{T}_{avg}$ represents the average travel time, $TS$ represents the travel time between two stations. The travel time is increases based on the increasing distance.

*2) Optimal routing in transport network using adaptive objective based beetle swarm optimization (ABSO)*

Initially, starting and target points are initialized in the transport network. Moreover, the general attributes of beetle swarm optimization approach is initialized. The beetle swarm optimization approach is the combination of beetle foraging mechanism and swarm optimization. Two beetle antennae of the beetles are used to explore the nearby regions. If the one side antenna finds the more valuable data, then the beetle will move to that antenna side. This optimization approach is based on the behaviour of beetles. The flow diagram of the presented ABSO process is depicted in Fig. 2.

Initially, the input optimization parameters are initialized and the fitness is evaluated based on the average weight of four objectives by utilizing the condition (17). Then the swarm attributes of the optimization algorithm is updated. If the maximum iteration is reached then the optimal global best solution is considered as the optimal routing.

Fig. 2. Flow Diagram of ABSO Routing.

*a) Parameters Initialization:* The input population of optimization approach is expressed as $\overline{Y} = \left(\overline{Y}_1, \overline{Y}_2, \overline{Y}_3 ..... \overline{Y}_m\right)$. Here, $m$ represents the population size. The position $(\overline{P}_a)$ and speed attribute $(\overline{S}_a)$ of beetle is first arbitrarily initialized in a $m$ dimensional search space. Speed attributes of beetle $k$ is expressed as $\overline{V}_k = \left(v_{k1}, v_{k2}, v_{k3} .... v_{kS}\right)^T$. The set of individual best is expressed as $b_i = \left(b_{i1}, b_{i2}, b_{i3} .... b_{iS}\right)^T$. The global best set signified as $\overline{b}_g = \left(b_{g1}, b_{g2}, b_{g3} .... b_{gS}\right)^T$. The speed update of the optimization approach is described in the subsequent condition (12),

$$y_{js}^{t+1} = y_{js}^t + \overline{\lambda} v_{js}^t + \left(1 - \overline{\lambda}\right) \in_{js}^t$$
(12)

Here, $$\in_{js}^{t+1} = \partial^t \times v_{js}^t \times F(\overline{Y})$$
(13)

$$y_{rs}^{t+1} = y_{rs}^t + v_{is}^t \times \frac{\overline{d}^t}{2}$$
(14)

$$y_{ls}^{t+1} = y_{ls}^t - v_{ls}^t \times \frac{\overline{d}^t}{2}$$
(15)

The position attribute of every beetle individual is updated by the subsequent condition (16),

$$v_{js}^{t+1} = \overline{\omega} v_{js}^t + \overline{c}_1 \overline{r}_1 \left(p_{is}^t - \overline{y}_{is}^t\right) + \overline{c}_2 \overline{r}_2 \left(p_{gs}^t - \overline{y}_{gs}^t\right)$$
(16)

Here, $s = 1, 2, .... S$ and $j = 1, 2, .... m$, $t$ represents the iteration time, $\in_{js}$ signifies the displacement increment examined by the strength of data predicted by the beetle antennae, $\overline{\lambda}$ signifies the decrement factor, $\overline{\omega}$ signifies the inertia weight, $\overline{r}_1$ and $\overline{r}_2$ are arbitrary function with value ranging from 0 to 1, $\overline{c}_1$ and $\overline{c}_2$ signifies the degree of impact of individual and global best on the beetle, $\partial^t$ signifies the searching step size of beetle, $\overline{d}$ represents the predicted distance of antennae, $F(\overline{Y})$ signifies the fitness function, $y_{ls}^{t+1}$ signifies the predicted distance of left antenna, $y_{rs}^{t+1}$ signifies the predicted distance of right antenna.

*b) Fitness Evaluation:* Fitness function is evaluated based on four different objectives such as, passenger's count, comfort level of passengers, route distance and average travel time. Fitness of optimal route generation using the proposed optimization approach is described in the subsequent condition (17),

$$F(\overline{Y}) = \min\left(\frac{\overline{P}_m + \overline{D}_{route} + \overline{C}_\alpha + \overline{T}_{avg}}{4}\right)$$
(17)

Here, $\overline{P}_m$ represents the passenger count computed by the condition (6), $\overline{D}_{route}$ represents the route distance computed by the condition (10), $\overline{T}_{avg}$ represents the average travel time computed by the condition (11), $\overline{C}_\alpha$ represents the comfort level of passengers computed by the condition (9), $F(\overline{Y})$ represents the fitness function for the evaluation of optimal route. The minimum values of fitness function are considered as the global best value ($\overline{b}_g$).

*c) Update of Optimization Attributes in Beetle Swarm Optimization*: The position and speed attributes of every beetle swarm is updated by the conditions in (12) to condition (16). Further, the fitness function is computed for each updated beetle individuals. Also, the individual best ($\overline{b}_i$) solutions are updated and attains the global ($\overline{b}_g$) solution.

*d) Iterative Optimization*: The variables $\partial^t$ and $\overline{d}$ of the optimization is updated by the subsequent conditions (18) and (19).

$$\partial^t = 0.95\partial^{t-1} \tag{18}$$

$$\overline{d}^t = 0.95\overline{d}^{t-1} + 0.01 \tag{19}$$

Here, $\overline{d}$ represents the predicted distance of antennae, and $\partial^t$ signifies the searching step size of beetle. Iterations are performed to the maximum by updating these variables to end optimization. Finally, optimal demand based routing is obtained according to the global best output.

## IV. RESULTS AND DISCUSSION

The experimental results of the proposed demand based on the optimal route generation in transport system is implemented in the working platform of MATLAB. The dataset used for the implementation is Surat city historical transport data. The performance of the presented technique is analyzed with the existing Inverse distance weighting (IDW), and Empirical Bayesian Kriging (EBK) [27], XGBoost, gradient boosting regression model (GDBR), support vector machine regression (SVR), and multiple linear regression model (MLR) [28], agent based scheduled routing [29] techniques in terms of Root mean square error, mean square error, mean absolute error, correlation coefficient, accuracy, vehicle occupancy. The performance metrics utilized for analyzing the presented work is described in the subsequent sections.

### A. Dataset Description: Surat City Historical Data

Surat city transportation system historical data is considered for the evaluation of optimal demand based routing performance in the presented work. The passenger detail for this prediction process is taken from Surat city dataset. The passenger details are taken for one year (June 2017 to June 2018) for passenger flow prediction in transportation. The passenger details are taken for one year (June 2017 to June

2018) for optimal route prediction in transportation. The presented DFCM clustering approach output is depicted in Fig. 3.

In Fig. 3, the proposed DFCM clustering output of passenger's count is provided. This provides the accurate details of passengers in every station. The number of passengers in each station is gathered by using this clustering process. Each cluster provides the passenger details of each station. Based on the predicted passenger's count, each route passenger's flow for august month is depicted in Fig. 4.

In Fig. 4, august month data of Surat city transportation dataset is examined for evaluating the Passenger's count variations of route 1. The passenger count of route 1 is depicted in Fig. 4 for each day in a month. Here, RAST, SAHD, KADB, UDHD and ADGS represent the different stations in the considered route 1. The passenger count of each day is calculated by adding the passenger details of each trip of the day. The passenger count in RAST station is higher than the other stations. Similarly, passenger's count variations of route 2 are analyzed with august month data and it are depicted in Fig. 5.

Fig. 3. DFCM Clustering Output.

Fig. 4. Passenger's Count Variations of August Month with Route 1.
Fig. 5.   Passenger's Count Variations of August Month with Route 2.

In Fig. 5, Passenger's count variations of route 2 are examined for evaluating the august month data of Surat city transportation dataset. In Fig. 5, the passenger count of each station of route 2 is depicted. Here, RAST, SAHD, KADB, UDHD and ADGS characterize the different stations of the considered route 2. The passenger counts in route 2 with different stations are provided. This demonstrates that the passenger count in station name ADGS is higher than other stations. Similarly, the daily passenger flow is analyzed for different stations with various trip timings are depicted in Fig. 6.

In Fig. 6, daily passenger's flow of different stations such as, 10, 1003, 1015, 2040, and 2799 is analyzed with various bus timings from morning 6 O' clock to night 9 O'clock. This demonstrates that the daily passenger flow of the station number 10 is higher than the other stations. Moreover, the passenger count is at peak at 9 o clock timing than other timings. Here, the daily passenger flow of each trip timing details is demonstrated for a month. The passenger count of each trip for one month is illustrated for various stations. Moreover, the passenger's demand for one month data is depicted in Fig. 7.

Fig. 7.   Passenger Demand in August Month.

The Fig. 7 depicts that the demand of passengers for a month. Based on the passengers demand, transport needs to be allocated with optimal routing approach. Here, the passenger demand is calculated based on the passenger data for 30 days. Furthermore, routing is performed based on the adaptive beetle swarm optimization approach for august month data. The effective objectives such as passenger count, travel time, comfort level and distance are considered for re-routing. In this way, an optimal demand based routing is generated to enhance the quality of service. Moreover, the passenger demand for a week based data for a month is depicted in Fig. 8.

In Fig. 8, passenger demand is evaluated for an august month data. Here, the passenger demand is evaluated for each day in a week for a month. This figure provides the passenger demand data for a month on weekly basis. The demand based objectives are considered for each pair of stops in the transportation system. The demand based objective measure for the pair of stations 1 and station 5 is depicted in Fig. 9.

Fig. 6.   Daily Passenger's Flow of different Stations with Various Trip Timings.

Fig. 8.   Passenger Demand of Week based Data for an August Month.
Fig. 9. Demand based Routing with Pair of Station 1 & 5.

In Fig. 9, august month data is considered to predict the demand based routing. Here, the daily passenger flow is illustrated by considering various parameters like passenger count data, travel time, comfort level and distance. Finally, daily passenger is depicted by considering all these parameters. Here, pair of stations 1 and station 5 is illustrated to prove the effectiveness of proposed demand based routing. The proposed route 2 is obtained as an optimal routing. Similarly, optimal routing based on the effective objectives with pair of station 3 and station 4 is depicted in Fig. 10.

In Fig. 10, demand based routing with pair of station 3 and station 4 is provided. Here, august month data is considered to analyze the routing based on different objectives. The combined objectives output is providing higher performance than the single objectives. This illustration proved that the effectiveness of proposed demand based routing. Similarly, optimal routing based on the effective objectives with pair of station 1 and station 2 is depicted in Fig. 11.

Fig. 10. Demand based Routing with Pair of Station 3 & 4.

Fig. 11. Demand based Routing with Pair of Station 1 & 2.

In Fig. 11, optimal routing is evaluated with pair of station 1 and station 2. Here, the prediction performance is analyzed without objectives and with objectives such as passenger count, travel time, comfort level, distance. The final predicted output is based on all the combined objectives. Optimal routing based on the effective demand based objectives for the pair of station 4 and station 5 is depicted in Fig. 12.

In Fig. 12, routing performance is evaluated with the pair of stations 4 and station 5. This proves that the proposed demand based optimal routing achieves enhanced performance than the single objective based predictions. The passenger's flow with the proposed demand based routing is enhanced. This enhancement proves that the service quality of the transportation system.

### B. Performance Metrics

In this section, different performance metrics such as Root mean square error, mean square error, mean absolute error, correlation coefficient, accuracy, vehicle occupancy are described in the subsequent sub sections.

Fig. 12. Demand based Routing with Pair of Station 4 & 5.

*1) Correlation coefficient*: Correlation coefficient is evaluating the correlation among the considered variables. The correlation coefficient range is 0 to 1. The performance is proved by obtaining the value closer to 1. The correlation is estimated between the attained optimal route and the other existing routes. It is computed by the subsequent condition (20),

$$\overline{C}_C = \frac{Cov(y_k, z_k)}{\sqrt{Var[y_k] - Var[z_k]}}$$

(20)

Here, $y_k$ and $z_k$ represents the predicted optimal and original routing, $Cov(y_k, z_k)$ represents the covariance of $y_k$ and $z_k$, $Var[y_k]$ represents the variance of $y_k$ and $Var[z_k]$ represents the variance of $z_k$. In the optimal routing prediction, correlation coefficient is used to examine the linear correlation among the predicted optimal data and original data.

*2) Root means squared error (RMSE)*: This RMSE measure is used to examine the variation between predicted and the original values. This demonstrates the model accuracy from the perception of predicted deviation. This is computed by the subsequent condition (21).

$$\overline{R}_{MSE} = \sqrt{\frac{\sum_{k=1}^{m} |y_k - z_k|^2}{m}}$$

(21)

Here, $\overline{R}_{MSE}$ represents the root mean squared error. This measure is used to prove the prediction accuracy rate by minimizing the error in optimal routing.

*3) Mean absolute error (MAE)*: The mean absolute error performance is the average of absolute values of the variation among all the predicted values and the original values. This accurately predicts the error of the predicted output. The MAE measure is computed by the subsequent condition (22).

$$\overline{M}_{AE} = \frac{1}{m} \sum_{k=1}^{m} |y_k - z_k|$$

(22)

Here, $\overline{M}_{AE}$ represents the mean absolute error. The minimum value of mean absolute error proves that the proposed demand based optimal routing is effective technique demand based optimal route prediction.

*4) Mean squared error (MSE)*: This measure is similar to the MAE performance metric but only the difference is taking square in the mean differences of the input and predicted data. It is calculated with the mean of the square difference among the original input and the predicted data. It is evaluated with the subsequent condition (23).

$$\overline{MsE} = \frac{1}{T} \sum_{k=1\dots T} (z_k - \tilde{z}_k)^2$$

(23)

Here, $\overline{MsE}$ represents the MSE, $T$ represents the total considered data, $z_k$ and $\tilde{z}_k$ denotes the original data and predicted data correspondingly.

*5) Accuracy*: Accuracy measure is the ratio of correctly predicted data to the total number of observations. Moreover, it is the percentage of accurateness for predicting the data. It is evaluated utilizing the subsequent condition (24).

$$\overline{A}_y = \frac{\overline{c}_P}{T_P}$$

(24)

Here, $\overline{A}_y$ represents the accuracy, $\overline{c}_P$ represents the correct predictions, and $T_p$ represents the total predictions.

*6) Vehicle occupancy*: Vehicle occupancy is determined by the occupancy rate and it is equivalent to average number of passengers in the vehicle. It is computed based on the average numbers of passengers used the vehicles in the same route. The average computation is attained from the number of trips in the same route for a day. The passenger's count of each trip is estimated to attain the vehicle capacity. The vehicle occupancy is computed by the subsequent condition (25).

$$V_O = \frac{\sum T_N(P_C)}{N}$$

(25)

Here, $V_O$ represents the vehicle occupancy, $T_N$ represents the number of vehicle trips, $N$ represents the Trips number, and $P_C$ represents the passengers in each trip.

*C. Performance Analysis*

In this section, performance of the presented approach is examined with the existing strategies in terms of Root mean square error, mean square error, mean absolute error, correlation coefficient, accuracy, vehicle occupancy. The performance metrics and their validations are examined with the various existing approaches. The RMSE performance evaluation is analyzed with the existing approaches for each station is depicted in Fig. 13.

In Fig. 13, the RMSE performance demonstration is provided with existing approaches for each station. The RMSE value of the presented approach for each station is station 1 (0.2629), station 2 (0.2217), station 3 (0.2474), station 4 (0.2629), and station 5 (0.0768) respectively. The presented demand based route prediction is examined with the existing XGBoost, gradient boosting regression model (GDBR), support vector machine regression (SVR), and multiple linear regression model (MLR) approaches. Here, the RMSE performance is evaluated for 5 stations with the

existing approaches. The RMSE performance on varying stations is portrayed in Table I.

In Table I, RMSE measure values are lesser than the different existing approaches. The obtained RMSE of presented approach for each station is station 1 (0.2629), station 2 (0.2217), station 3 (0.2474), station 4 (0.2629), and station 5 (0.0768) correspondingly. The performance analysis of the proposed demand based routing with existing approaches is depicted in Fig. 14.

Fig. 13. Performance Analysis on RMSE for Each Station.

TABLE I. RMSE PERFORMANCE ON DIFFERENT STATIONS

| Technique | XGBoost | GDBR | SVR | MLR | Proposed |
|---|---|---|---|---|---|
| STATION 1 | 1.1043 | 1.1131 | 2.5570 | 3.0657 | 0.2629 |
| STATION 2 | 1.4011 | 1.0558 | 1.6021 | 3.1922 | 0.2217 |
| STATION 3 | 0.8773 | 1.3297 | 1.3851 | 3.0004 | 0.2474 |
| STATION 4 | 0.6586 | 0.9369 | 3.0113 | 2.7080 | 0.2629 |
| STATION 5 | 1.0901 | 1.5924 | 2.7080 | 3.5162 | 0.0768 |

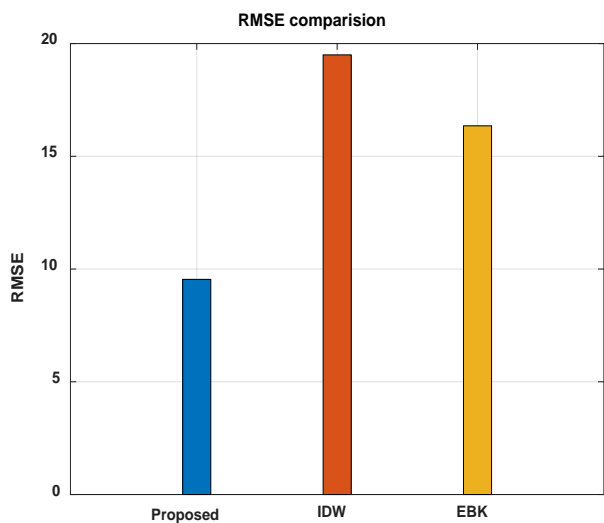

Fig. 14. Performance Analysis on RMSE.

In Fig. 14, RMSE performance evaluation is provided with existing Inverse distance weighting (IDW), and Empirical Bayesian Kriging (EBK) [27] approaches. The existing EBK, and IDW approaches are used Orissa dataset, which is overcome by the proposed approach with surat city dataset. Here, the RMSE value of presented approach is 9.5. This error value is much lesser than the existing IDW (19.4994) and EBK (16.3527) approaches. This demonstrates that the presented approach provides reduced RMSE than the existing approaches to prove the efficiency of the proposed approach. The comparison analysis on RMSE is mentioned in Table II.

In Table II, the RMSE of the presented approach is compared with the existing approaches. The proposed approach attains reduced RMSE than the existing IDW, EBK [27] approaches. The presented approach attains enhanced performance than the existing techniques by reducing the error rate. The comparison analysis of MSE is examined with the existing approaches are depicted in Fig. 15.

In Fig. 15, performance of the presented approach in terms of MSE is analyzed with the different existing approaches like XGBoost, GDBR, SVR, and MLR. The MSE value of presented approach for each station is station 1 (0.3007), station 2 (0.2548), station 3 (0.2500), station 4 (0.3007), and station 5 (0.2544) respectively. This clearly demonstrates that the presented demand based optimal routing approach provides enhanced performance with less error. The performance comparison on MSE is mentioned in Table III.

TABLE II. COMPARISON ANALYSIS ON RMSE

| Techniques | Dataset | Root Mean squared error (%) |
|---|---|---|
| Inverse distance weighting | Orissa dataset | 19.4994 |
| Empirical Bayesian Kriging | Orissa dataset | 16.3527 |
| Proposed | Surat city historical dataset | 9.5 |

Fig. 15. Performance Analysis on MSE.

In Table III, the performance comparison on MSE is provided. Here, the performance of the presented approach is compared with the different existing approaches like GDBR, SVR, XGBoost, and MLR. The attained MSE value of presented approach for each station is station 1 (0.3007), station 2 (0.2548), station 3 (0.2500), station 4 (0.3007), and station 5 (0.2544) correspondingly. Moreover, the comparison on mean absolute error is depicted in Fig. 16.

In Fig. 16, mean absolute error performance of the proposed and the existing strategies for each station is provided. This proves that the presented demand based routing provides enhanced performance than the existing XGBoost, GDBR, SVR, and MLR approaches. The attained MAE value of presented approach for each station is station 1 (0.2007), station 2 (0.3548), station 3 (0.2500), station 4 (0.5007), and station 5 (0.3544) correspondingly. The performance on MAE for varying stations is portrayed in Table IV.

TABLE III.     MSE Performance on Different Stations

| Technique | XGBoost | GDBR | SVR | MLR | Proposed |
|---|---|---|---|---|---|
| STATION 1 | 1.2195 | 1.2390 | 6.5384 | 9.3988 | 0.3007 |
| STATION 2 | 1.9630 | 1.1147 | 2.5669 | 10.1900 | 0.2548 |
| STATION 3 | 0.7697 | 1.7681 | 1.9185 | 9.0023 | 0.2500 |
| STATION 4 | 0.4338 | 0.8778 | 9.0681 | 7.3333 | 0.3007 |
| STATION 5 | 1.1884 | 2.5357 | 4.9333 | 12.3639 | 0.2544 |

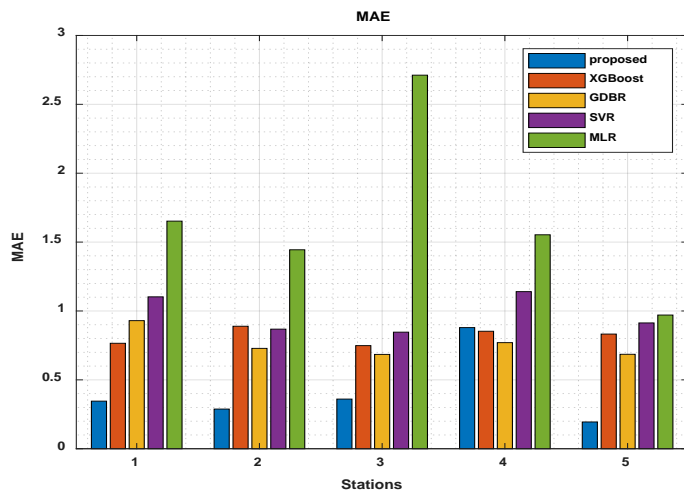

Fig. 16. Performance Analysis on MAE (%).

TABLE IV.     MAE Performance on Different Stations

| Technique | XGBo-ost | GDBR | SVR | MLR | Proposed |
|---|---|---|---|---|---|
| STATION 1 | 0.7415 | 0.5089 | 0.8601 | 2.0907 | 0.2007 |
| STATION 2 | 0.7542 | 0.6676 | 0.8905 | 2.3933 | 0.3548 |
| STATION 3 | 0.8470 | 0.5624 | 1.2911 | 1.4605 | 0.2500 |
| STATION 4 | 0.8975 | 0.8437 | 1.4642 | 0.9596 | 0.5007 |
| STATION 5 | 0.8760 | 0.5943 | 0.9015 | 1.2081 | 0.3544 |

The Table IV proves that the presented methodology provides enhanced performance in terms of MAE than the XGBoost, GDBR, SVR, and MLR approaches. Moreover, the performance efficiency is examined by the vehicle occupancy is depicted in Fig. 17.

In Fig. 17, vehicle occupancy performance is demonstrated with the existing agent based scheduled routing [29]. Here, the vehicle occupancy is evaluated based on the number of passengers used the vehicle for a month. This illustrates that the presented routing process increases the usage of passengers. This proved that the performance of demand based optimal routing is effective than the other transportation routings. The vehicle occupancy is enhanced by the better quality service of the transportation based on the presented methodology. The performance on accuracy for varying stations is portrayed in Table V.

The Table V proves that the presented methodology provides enhanced performance in terms of accuracy than the deep neural network (DNN), Random forest (RF), Linear regression (LR) approaches. The attained accuracy of presented approach for each station is station 1 (99.51%), station 2 (98.14%), station 3 (98.69%), station 4 (97.61%), and station 5 (98.19%) correspondingly. The accuracy performance of the proposed optimal routing is depicted in Fig. 18.

Fig. 17. Performance Analysis on Vehicle Occupancy (%).

TABLE V.     Accuracy Performance on Different Stations

| Technique | DNN (%) | LR (%) | RF (%) | Proposed (%) |
|---|---|---|---|---|
| STATION 1 | 98.26 | 94.52 | 94.08 | 99.51 |
| STATION 2 | 98.58 | 94.52 | 94.08 | 98.14 |
| STATION 3 | 98.5858 | 94.52 | 94.088 | 98.69 |
| STATION 4 | 98.58 | 94.52 | 94.087 | 97.61 |
| STATION 5 | 98.58 | 94.52 | 94.089 | 98.19 |

In Fig. 18, the presented approach is analyzed with the existing approaches in terms of accuracy performance. This proved that the presented approach provides enhanced accuracy performance than the existing strategies. The performance on correlation coefficient for varying stations is mentioned in Table VI.

The Table VI proves that the presented methodology provides enhanced performance in terms of correlation coefficient than the XGBoost, GDBR, SVR, and MLR approaches. The attained correlation coefficient of presented approach for each station is station 1 (0.8993) station 2 (0.1000), station 3 (0.2800), station 4 (0.2000), and station 5 (0.4800) correspondingly. The comparison analysis in terms of correlation coefficient is depicted in Fig. 19.

In Fig. 19, the correlation coefficient performance is examined with the different existing approaches. The correlation coefficient of presented approach for each station is station 1 (99.51%), station 2 (98.14%), station 3 (98.69%), station 4 (97.61%), and station 5 (98.19%) correspondingly. Here, the proposed approach achieved a high correlation coefficient for each station than the existing the XGBoost, GDBR, SVR, and MLR approaches. Here, this validation is evaluated for each station in the considered Surat city transportation dataset. This proposed methodology provides enhanced results in demand based optimal routing. Furthermore, this methodology enhances the quality of transportation service.

Fig. 18. Performance Analysis on Accuracy (%).

## V. CONCLUSION

This paper presented a demand based effective routing in transportation network. At first, Distance based adaptive Fuzzy C-means clustering approach (DFCM) is utilized for clustering the passengers in each stop. Here, the number of cluster members in each cluster is equivalent to the passenger's count of every station. Afterwards, adaptive beetle swarm optimization approach based routing is performed based on the clustered data. Further, re-routing is performed based on the effective objectives such as passenger's count, comfort level of passengers, route distance and average travel time using ABSO approach. In the optimal route generation approach, objectives are analysed in each pair of stations in the route using the ABSO approach. This ABSO approach enhances transportation system by providing demand based routing. The presented work is examined with the various existing approaches in terms of different performances like RMSE (9.5%), Mean error (0.254%), vehicle occupancy (85%), MAE (0.3007%), correlation coefficient (0.8993), and accuracy (99.57%). This proved that the presented approach provides better performance than the existing routing approaches in transportation system. In future, this demand based transportation is further enhanced with improved deep learning based approaches to decrease the time consumption. Increasing number of objectives will further improve the performance of demand based routing. Moreover, the demand based transportation will be examined with other larger datasets.

# Implementation of Electronic Health Record and Health Insurance Management System using Blockchain Technology

Lincy Golda Careline S, Dr.T.Godhavari

Dr. MGR Educational and Research Institute, Chennai, India

*Abstract*—**Electronic health records (EHR) play an important role in digital health transition. EHRs contain medical information such as demographics, laboratory test results, radiological images, vaccination status, insurance policy, and claims. EHR is essential for doctors and healthcare organizations to analyze a patient's profile and provide appropriate therapy. Despite this, current electronic health record (EHR) systems lag with difficulties such as Interoperability and security. Better and faster care may be provided with an integrated and secure health record for each patient that can be transmitted easily in real-time across countries. People having health insurance policies are often confronted by insurance jargon and the insurer's cumbersome requirements while filing a claim for treatment. There are times when the claims processing takes longer than expected. The insurer, Third-Party Administrators (TPAs), and network provider hospitals examine, approve, and initiate the sum claimed. The use of blockchain in the process allows for more efficient information sharing at a lower cost and with more security. Only authorized individuals have access to the shared ledger on a blockchain, making it more confidential and secure. All parties engaged in a health insurance policy, including the insurer, the insured, the TPA, and the network provider hospital, may be members of the blockchain network and have access to the same set of policy data. In our proposed work we implemented a Blockchain-based EHR and Health insurance management system using Ethereum and deployed smart contracts using solidity and created a web application with web3js and React Framework.**

*Keywords*—*Electronic health records; insurance policy and claim processing; smart contracts; Ethereum; homomorphic encryption; edge computing*

## I. INTRODUCTION

Blockchain transforms the healthcare sector by storing and sharing patients' electronic health records, insurance policies, and claims to provide more secure, transparent, and traceable data [1]. The technology integrates diverse data management systems resulting in an electronic health record system that is connected and interoperable. The doctor treats the patient and enters the patient's report into their existing health information system, which includes tests, prescriptions, and significant notes. The data fields connected with the patient's public ID are then redirected to the blockchain using APIs. In the blockchain, each transaction is authenticated and given a unique identity (public key). APIs can be used by doctors and health organizations to make a query and retrieve encrypted patient data using the patient's public key. Patients can give

the doctor or the healthcare facility permission to decrypt their data by supplying the private key (which functions as a password). The data remains encrypted for those who do not have access to the private key [4]. Blockchain is a distributed network of computers that is governed by a time-stamped collection of immutable data records that are not held by a single person, company, or government entity. Because the blockchain network is decentralized, data may be exchanged and updated, but it cannot be copied, modified, or erased, making it public and accountable [2]. As a result, the best platform for storing and distributing electronic medical records is blockchain. An Electronic Health Record (EHR) is an electronic representation of a patient's medical history [6]. Blockchain is the next big thing in healthcare and it will revolutionize how it is supplied and administered. The fundamental issue is information asymmetry, which means that not everyone has the same easy access to the data [5]. Blockchain and smart contracts safeguard data, increase interoperability, and allow numerous entities to access the medical information that makes up the EHR by providing a secure distributed network, a shared ledger, and the ability to add independent blocks of medical transactions [3]. Blockchain has four main benefits in an EHR system.

- Longitudinal patient records: Data is assembled progressively, ensuring that no data is lost or tampered with.

- Master patient indices: A single master patient file contains all of the different blocks of information, reducing the chances of medical errors or mismatches.

- Claims adjudication: Instead of relying on a central authority, automated smart contracts can assist handle claims more quickly and efficiently.

- Interoperability: Only approved authorized providers have access to the data and the capacity to edit it, allowing for greater data reconciliation and care quality improvement.

The advantages of electronic health records extend far beyond cost savings. An EHR system provides quick access to accurate and up-to-date patient information. This lowers long-term healthcare costs and improves efficiency, especially if a patient is transferred between departments during treatment [11]. Blockchain technology ensures that every participant has their own copy of the digital ledger, which is updated in real-time as transactions occur. Hacking is nearly impossible due

to the lack of a centralized server. Because a recorded transaction cannot be reversed in theory, the ledger is an immutable source of truth, regardless of how many copies are kept by participants [10]. It is possible to confirm data, records, and participant identities while keeping their identities disguised. Our digital environment is rapidly changing in the pursuit of excellence. Without a doubt, technology has a significant impact on our daily lives and other elements of our lives, with the potential to dramatically improve them. One of the industries that potentially benefits from the adoption of blockchain is insurance [17]. Many blockchain insurance firms are working to improve the end-user experience as well as the businesses that handle people's insurance. Because most underwriting and claims work requires collaboration among numerous parties, blockchain will assist the insurance sector [18]. While blockchain adoption is still in its infancy, the applications covered here are a good place to start for insurers interested in taking advantage of its potential. When it comes to technology, it has the potential to affect the lives of millions of people all over the world. Because life insurance procedures differ from country to country, finding a consistent manner to manage all claims and processes is vital [22].

## II. Literature Survey

More than 4,000 years ago, the Sumerians penned medical data on a clay tablet. The Egyptian papyrus was next, followed by the thick folders. The first medical electronic information system was established by Lockheed in 1960. The Decentralized Hospital Computer Program (DHCP) and the Computerized Patient Record System (CPRS) were implemented by the Department of Veterans Affairs in the 1970s. President Bush first mentioned the term "Electronic Health Record" in 2004. The usage of the EHR system allowed increased payments to physicians and hospitals under President Obama's American Recovery and Reinvestment Act of 2009, which was part of the Health Information Technology for Economic and Clinical Health Act (HITECH) [10]. In Estonia, 99 percent of health records have been digitized. E-Health Records are even accessible to first responders and paramedics [7]. It's useful for non-responsive individuals when further information about their medical history and probable sensitivities is needed quickly. Currently, systems in many countries are scattered and do not communicate with one another. By integrating scattered systems across countries and regions, a blockchain-based electronic health record can enable real interoperability [14]. Instead of being saved in a single database, healthcare data can be stored immutably in a decentralized fashion using blockchain. As a result, a hacker would not be able to access the data through a single point of entry. This is how blockchain improves the security of health-related data. Homomorphic encryption can be used since blockchains do not provide anonymity [12], [16]. However, complete anonymity in healthcare is neither essential nor desirable. Instead, alternatives should be found that allow patients to choose who to reveal their name to, whether to remain pseudonymous and what data to provide. They can, however, be improved to improve patient care and accessibility to information. An electronic health record (EHR) is a collection of patient-related data that is maintained

electronically [15]. The growth of screening tests, medical imaging, and diagnostics has resulted in an avalanche of information on patient health. EHR (electronic health record) systems are a fantastic approach to boosting patient care. As more patient data becomes digital and an increasing number of consumers seek mobile access to health records, the function of EHR is improving and digitizing in healthcare [13]. In general, electronic health records (EHR) features and frameworks have long been seen as a surefire means to improve medical care delivery systems. The current life insurance claims system is inefficient, as it might take a long time to process a claim. It means that the claimant will have to deal with a lot of red tapes before their claims are handled [24]. All of these issues can be mitigated with blockchain life insurance. To ensure that claims are processed more quickly and efficiently, a good blockchain-based life insurance model can work in combination with the hospital, insurance company, death certificates, and burial licenses.

## III. Challenges in Existing Electronic Health Records and Health Insurance

According to research, 50-60% of physicians experience burnout, which results in lower patient satisfaction, decreased patient safety, and more malpractice claims [23]. A large amount of time is necessary to incorporate data into EHR systems. As a result, physicians are unable to devote sufficient time to improving patient communication. As a result, the quality of patient treatment declines, and physicians grow increasingly frustrated and dissatisfied. Furthermore, EHRs are believed to be a cost burden on both providers and practitioners in some cases. Interoperability refers to an EHR's capacity to communicate data and information to other devices so that it can be used by a large number of individuals. The systems must communicate well with one another to obtain a complete picture of a patient's medical history as in Fig. 1. Data communication in an EHR is frequently delayed due to a lack of interoperability between segments of the same EHR or between the EHR and another system. The information held in an EHR and shared on a blockchain's distributed ledger would be updated and secured, ready to be used by anybody with authorization [8]. A blockchain-based EHR solution will improve data quality and interoperability thus reducing the time it takes to obtain a patient's information [9]. Furthermore, using blockchain for electronic health records will help to reduce costs, especially in terms of software development and health record system maintenance.

Fig. 1. EHR Framework.

When information is maintained within an EHR and shared on a distributed blockchain ledger, it may be updated, safeguarded, and made ready for use by anybody authorized to access it [12]. A blockchain-based EHR system reduces the amount of time it takes to get information on a patient. It will also improve data quality and provide seamless and safe interchange. As a result, blockchain for EHRs (electronic health records) may result in lower costs [19]. Insurance clients, who are frequently perplexed by plans, have grown skeptical of insurers and have developed a rising suspicion of them. The issue of trust is a huge one for insurance companies. The majority of the time, insurance companies do not have access to all of a patient's information, resulting in higher processing costs or incorrect plan assignments. Documents are occasionally incorrectly filled or not submitted, and sometimes lost, due to the distributed paperwork and filings among the numerous parties in the insurance network [24]. Customers are dissatisfied when insurance firms fail to process claims within specified deadlines [25]. Insurers are under increasing pressure to decrease administrative expenses, and blockchain technology have the potential to assist by upgrading fragmented legacy IT systems, improving efficiency, and increasing competitiveness [26]. Increased automation is required in the insurance industry, which blockchain technologies can help with. New systems, processes, security protocols, and business models are necessary to meet rising customer demands for tailored services, increased privacy, innovative products, added value, and competitive pricing from their insurers.

## IV. BLOCKCHAIN IMPLEMENTATION IN ELECTRONIC HEALTH RECORDS AND HEALTH INSURANCE SYSTEMS

The IoT healthcare sensors such as temperature, humidity, airflow, pressure, SpO2, heart rate, and pulse sensors are used to collect the patient's real-time data and store it in edge computing devices [12]. The data stored in the edge device is then retrieved and the transaction is processed in the blockchain as shown in Fig. 2 and Fig. 3. This might lead to healthcare providers and academics having access to enormous amounts of anonymized patient data for research reasons. Every blockchain node has a copy of the data that is constantly updated. As a result, any tampering or manipulation of health information will be discovered right away. Every transaction is also signed with a cryptographic stamp, allowing each piece of data to be traced back to its source. This means that a doctor can monitor a patient's recovery from surgery or sickness in real-time recognizing potential problems or concerns with eating, exercise, and vital indicators like heart rate without having to see them in person. It allows a doctor to monitor a patient's recovery after surgery or illness in real-time.

Fig. 2. Sensor Data is Stored in the Blockchain.

Fig. 3. Transaction is processed and Hash is generated for the Appended Sensor Data in the Blockchain.

Customers may encounter time-consuming paper forms when applying for insurance or reporting a claim. They may need to talk with the insurance companies and hospital employees to get medical insurance claims reimbursed [17]. Claims processing, data verification and reconciliation, and documentation procedures are shown in Fig. 4 and Fig. 5. Blockchain can help make selling and servicing insurance better, faster, and cheaper by improving fraud detection [19], claims administration, health insurance, and reinsurance. As a result, customers may see lower costs and have a better experience. The Blockchain has the potential to assist in the resolution of present property and casualty insurance issues. The strategy is to digitally manage physical assets. Smart contracts allow claims to be processed automatically. All modifications can also be tracked for authenticity, making them auditable. Smart contracts are crucial because they provide the functionality of converting paper contracts into programmable code [20]. The smart contracts, in turn, can be automatically performed by ingesting all of the data and acting on it as needed [21].

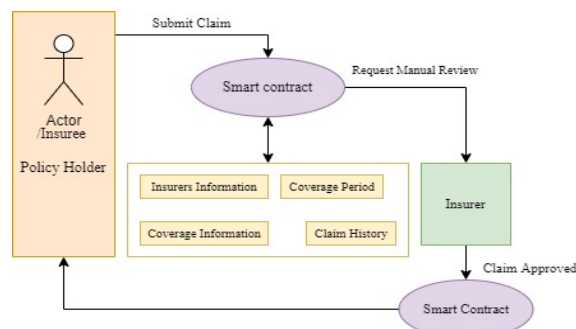

Fig. 4. Proposed Insurance Claim Processing.

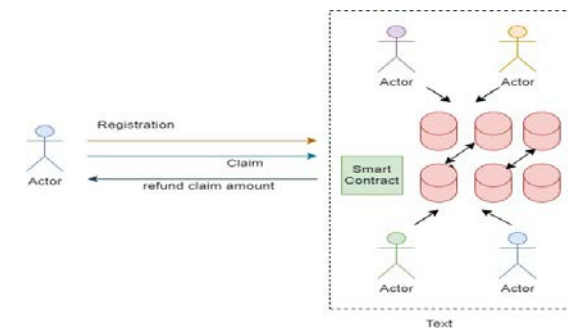

Fig. 5. Health Insurance Framework.

Deploying blockchain on healthcare networks will improve patient diagnostics and medical expenditures by expediting and improving patient diagnosis. The patient is the owner of his or her medical information and has the right to give it as needed without relying on any other parties. Because hospitals and clinicians would have immediate and complete access to a patient's data, the need for additional testing and long or incorrect diagnoses would be greatly reduced. Smart contracts will automatically initiate transactions, making claim processing and denial even easier and faster. This would greatly boost the level of trust in insurance companies. Sharing data across the network's many providers on a distributed ledger ensures that data will be retrieved quickly at any time, while also reducing the danger of improper documentation and data/documentation loss to nearly zero. This would help insurance firms save money on processing costs. The widespread adoption of blockchain by insurance companies throughout the world brings up a slew of prospects for distributed ledger technology validation services.

Blockchain is quickly gaining attraction as a technology that has the potential to alter the insurance sector. For accuracy and credibility, insurers rely largely on information and data acquired by various devices. Insurers should make sure that blockchain is linked with IoT as the best way to assure that the data captured is accurate. The interplay of blockchain, IoT, and big data in this way has the potential to transform the insurance sector. The idea is to automate the entire process, including premiums, claims, and other issues. With the ability to streamline the insurance sector while simultaneously increasing transparency and confidence.

## V.  RESULTS AND DISCUSSION

In our proposed work we implemented a Blockchain-based electronic health record and Health insurance management system using Ethereum Framework, smart contracts are deployed using a solidity debugger and the transaction are processed through truffle-based Ganache Test network. Created a web application with React framework as shown in Fig. 6.

Patients' and recipients' electronic health records such as demographics, laboratory test results, vaccination status, insurance policy and claims are stored in the React framework as in Fig. 7 and Fig. 8. Delegations are created and the electronic health records can be updated using the React framework as shown in Fig. 9 and Fig. 10.

The electronic health records are stored in the blockchain using Django REST Framework. The promise of blockchain technology is enormous, and integrating it with EHR will ensure that we all benefit from a better, more equitable, and healthier future.

Fig. 9.    Delegations are created in React Framework.

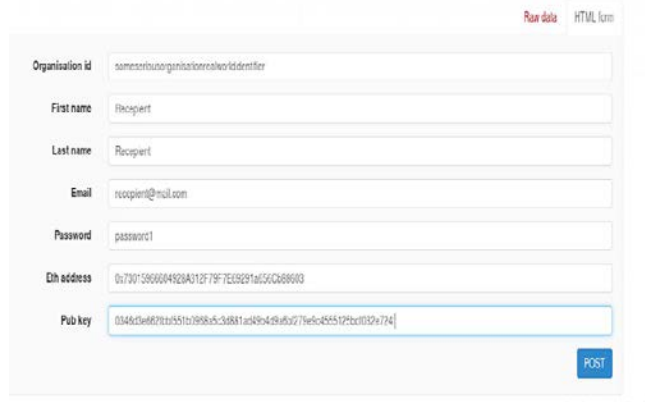

Fig. 10.  Patients Heath Records are Uploaded in React Framework.

## VI. Advantages and Limitations of Proposed System

There are major advantages that blockchain can offer to the traditional health record system. Patients have more control over their data because they can provide just the relevant authorities access to the data. Health data may be collected, saved, secured, and shared using blockchain for EHRs, which also allows for real-time utilization. It might lead to the selection of anonymized patient records for use in research by healthcare practitioners and researchers. When a blockchain is used to maintain electronic medical records, it offers a long-awaited standardized solution for the management of digital health data. To access patient data, hospitals and care providers will no longer need separate software or databases. EHRs give clinicians access to a patient's medical history. Patients no longer need to fill out the same paperwork at each visit to the doctor. The convenience of e-prescriptions provided straight to pharmacies is increased. The usage of a dashboard also makes it easier for patients to communicate with their doctors and streamlines their care. Patients and doctors can communicate directly because they use the same platform. Different specialists, hospitals, laboratories, and even pharmacists will be able to share the same information. Treatment providers will have a better understanding of how to improve patients' care if data is less scattered. Automated claim management aids in the seamless processing of reimbursements. It also reduces the administrative expenditures of hospitals or offices. Efficiency and expenses are improved by automating administrative processes and automatic clinical documentation.

The advantages of electronic health records are vast, but they also have a few limitations, most of which are related to the implementation and learning of EHR systems. The cost of implementing an EHR system is not insignificant. The majority of these costs are directly tied to the implementation of hardware and software. When new systems are implemented, the workflow is inevitably disturbed, resulting in a temporary loss of productivity. In the end, these losses will be only temporary, and revenues will rise. Because of increased productivity and faster claim reimbursements. The entire medical history of a patient is readily available, which is beneficial for diagnostic purposes but possibly dangerous for keeping sensitive information private.

## VII. Conclusion and Future Work

The potential of blockchain technology has already been recognized by the majority of forward-thinking healthcare industries. More importantly, blockchain will improve patient care by standardizing how parties manage and access electronic medical records. It can aid in the detection of health trends and the improvement of treatment. Blockchain technology has enormous and thought-provoking possibilities and the deployment of EHR on the blockchain has the potential to alter the healthcare industry. Using blockchain to standardize the management and access to electronic medical records, on the other hand, would elevate patient care to new heights. Patients will receive more accurate diagnoses and have complete ownership over their digital health information. And, if electronic health metadata has been collected and reconciled securely, it can be used to identify health patterns,

improve treatment, and eradicate diseases. Insurance is no exception, and blockchain has a lot of potentials. The most prevalent use cases are fraud detection and prevention, claims management. The 'quickest win' for blockchain in the insurance sector is cost savings. The enhanced security of blockchain, as well as its capacity to establish trust between entities, are two reasons why it may be able to tackle the interoperability challenge more effectively than current solutions. Existing EHRs in hospitals and physician offices would most likely be used to create a blockchain-based interoperable and comprehensive health record.

Combining Electronic Health Records (EHR) with Artificial Intelligence and Voice Recognition is beneficial to EHR systems because it allows clinicians to enter information and patient data. Artificial Intelligence has a history of transforming the healthcare industry by supporting clinicians in analyzing prior trends in a patient's condition and establishing a diagnosis. The predictive analytics application has a significant impact on the healthcare industry. Predictive analytics technology is being employed in a wide range of applications, from cancer treatments to emergency staffing optimization, and it will soon be embraced even more widely. With features like real-time data monitoring, telemedicine, and more, 5G has a lot of potential in the healthcare sector. Healthcare personnel will be able to access data via a tablet or smartphone through mobile computing and cloud-based infrastructure to securely store and retrieve data. As a result, devices like smartwatches will be used in the healthcare industry to automatically upload and track patient data as well as enable remote patient monitoring.

*Abstract*—**The application of machine learning (ML) techniques to predict blocking bugs have emerged for the early detection of Blocking Bugs (BBs) in software components to mitigate the adverse effect of BBs on software release and project cost. This study presents a systematic literature review of the trends in the application of ML techniques in BB prediction, existing research gaps, and possible research directions to serve as a reference for future research and an application insight for software engineers. We constructed search phrases from relevant terms and used them to extract peer-reviewed studies from the databases of five famous academic publishers, namely Scopus, SpringerLink, IEEE Xplore, ACM digital library, and ScienceDirect. We included primary studies published between January 2012 and February 2022 that applied ML techniques to building Blocking Bug Prediction models (BBPMs). Our result reveals a paucity of literature on BBPMs. Also, previous researchers employed ML techniques such as Decision Trees, Random Forest, Bayes Network, XGBoost, and DNN in building existing BB prediction models. However, the publicly available datasets for building BBPMs are significantly imbalanced. Despite the poor performance of the *Accuracy* metric where imbalanced datasets are concerned, some primary studies still utilized the *Accuracy* metric to assess the performance of their proposed BBPM. Further research is required to validate existing and new BBPM on datasets of commercial software projects. Also, future researchers should mitigate the effect of class imbalance on the proposed BB prediction model before training a BBPM.**

## I. INTRODUCTION

Software bugs are inevitable occurrences in the development and maintenance of software products. Hence, software engineers rely on bug reports generated by bug tracking tools such as Bugzilla, BugHead, and Trac to manage and resolve errors in software components, an activity aimed at improving and maintaining the quality of software projects. In Bugzilla, for instance, errors encountered by a software tester or user are logged in the bug tracking system and assigned the state NEW. The state of the bug report then changes to ASSIGNED when the bug is allocated to a suitable developer to resolve. Once the bug is fixed, a developer other than the one to whom the bug was assigned then ascertains the fixing and closes the bug report. At this point, the state of the bug report changes to CLOSED. However, the status of a bug report may remain at the ASSIGNED state for a long time because of another bug preventing the bug from being resolved. This type of bug is referred to as a Blocking bug [1]. In this context, blocking bugs are defined as bugs that prevent other bugs from being fixed. Thus, the time for fixing such a bug depends greatly on how long it will take to detect and resolve the blocking bug. Previous work by Valdivia-Garcia and Shihab [2] confirms that fixing a BB is almost three times the amount of time needed to fix a non-BB. Consequently, the debugging process may be impacted negatively, affecting software release and increasing the cost of software maintenance. Furthermore, Bohm et al. [3] found that locating and fixing a bug in a software product after the deployment stage is about 100 times more expensive than addressing it during the early phase of the software development life cycle. Hence, the early detection of Blocking Bugs (BBs) in software projects is critical to software maintenance. While there are criteria for detecting BBs in bug reports, the method is manual and heavily reliant on the bug reporters' and the developer assigned's competence in providing suitable labels [1]. However, the skills of the software user or bug reporter to accurately label a bug as BB is intrinsically in doubt, hence the heavy dependence on the developer (i.e., to whom the bug was assigned) to label such bugs.

Additionally, the unstructured nature of the text in some bug reports makes the manual BB classification process by developers laborious and error-prone. Meanwhile, large software projects are likely to have enormous bug reports; for instance, Valdivia-Garcia et al. [1] collected 609,800 bugs from eight software projects, out of which 77,448 were blocking bugs and 532,352 non-blocking bugs. The researchers further discovered that manually identifying blocking bugs takes 3–18 days. Therefore, the over-reliance on software developers prolongs the process of identifying BBs in bug reports and is also time-consuming as the number of bug reports increases. These fundamental challenges present the opportunity to apply ML techniques to predicting BBs (i.e., classifying and detecting BBs). Although some peer-reviewed articles have been published on using ML techniques to predict BBs [1], [2], [4]-[7], there is a dearth of literature on the subject. For instance, a thorough search in databases of well-known publishers such as Scopus, SpringerLink, IEEE Xplore, ACM digital library, and ScienceDirect produced only six papers. Unfortunately, none of these six papers was an SLR. Yet, SLR is crucial in a specific domain of studies for discovering research questions and rationalizing future research [8]. Even though a recent SLR[9] on the broader topic of bug severity acknowledged BBs as a severe bug, there has been no SLR published on the specific area of applying ML techniques to predicting BBs since the

field was first found introduced in 2014 [1]. Thus, to promote further research and increase the quality of literature in this domain, a systematic review that comprehensively discusses the existing BBPMs, research gaps, and possible research directions to serve as a point of reference for research and practice is critically important. Additionally, this research will contribute to a better understanding of the trends in characterizing and predicting blocking bugs. In other words, the goal of this study is to find out the recent trends and directions in this field and to identify opportunities for future research by researchers and practitioners within the software engineering domain and also to appreciate how the research space has evolved over time with regards to BBs. Finally, the approach presented in this study can serve as a guide for researchers and practitioners (e.g. Ph.D. Student, Master students) when seeking to predict instances of bugs that are BBs based on various data miners.

Based on the aforementioned needs and motivations, in this work, we systematically present a detailed analysis of the trends in the application of ML techniques in BB prediction. Thus, the study aims at answering the following five research questions (RQs):

RQ1: What are the publication trends in BB prediction research?

RQ2: Which datasets are used to train the proposed prediction model?

RQ3: What kind of ML learning techniques is adopted in building the proposed BB prediction model?

RQ4: Which evaluation criterion is used to measure the performance of the BB prediction model?

RQ5: Which ML classifiers are used as baselines to benchmark the proposed model?

The remainder of study is organized as follows: Section 2 describes the proposed research method, including the overall process and the goal and research questions addressed in this study. Section 3 discusses the findings of the meta-analysis of the study. Section 4 presents the results of the systematic. Section 5 summarizes and concludes the study and provides future research directions.

## II. RESEARCH METHOD

This SLR follows the software evidence-based engineering (SEBE) guidelines proposed by kitchenham and Charters [10]. The SEBE guidelines have increasingly gained popularity and acceptance in the software engineering research space [11]-[16]. The SEBE provides an all-inclusive outline of how software engineering researchers can conduct SLR using evidence-based research and practice models. Therefore, we segmented the SLR into four major phases with subdivisions to conform with the prescriptions by kitchenham and Charters [10]: plan search, search procedure, search, and report. Fig. 1 depicts the SLR process of this study.

Fig. 1. Process Flow Diagram.

### A. Phase 1: Search Plan

This phase of the SLR process presents the research questions addressed in this study and the databases where primary studies were collected.

*1) Data sources*: This section captures the academic databases and repositories where the search was conducted. Five databases of famous academic publishers, namely Scopus, SpringerLink, IEEE Xplore, ACM digital library, and Science Direct, were the data sources for the collection of primary studies for this paper. Also, a few portions of publications were retrieved from Google Scholar to achieve thorough coverage of article collection. Table I displays sampled data sources and the number of results returned by search queries in those academic databases on 18th February 2022.

### B. Phase 2: Search Procedure

This phase of the SLR describes how search strings were constructed. It also captures the inclusion and exclusion criteria used in selecting primary studies.

TABLE I.    DATA SOURCES AND SEARCH RESULTS

| Data Source | URL | Result |
|---|---|---|
| Scopus | https://scopus.com | 61 |
| SpringerLink | https://link.springer.com | 246 |
| | | |
| IEEE Xplore | https://ieeexplore. ieee.org | 20 |
| ACM Digital Library | https://dl.acm.org | 152 |
| ScienceDirect | https://ieeexplore.ieee.org | 31 |
| Google Scholar | https://scholar.google.com | 169 |
| | Total Result | **679** |

*1) Search string*: Keywords were extracted from research questions and related papers. Then synonyms and alternate words were identified for creating search strings by using Boolean *OR* for alternative words and Boolean *AND* for linking search keywords. The keywords and their alternatives are shown in Table II. The resulting search phrases were tweaked to conform with the format required by each online database. Table III shows the search string for each database. Additionally, the Table IV shows the search strings per the data sources that were used in this study.

*2) Inclusion criteria*: Peer-reviewed articles about blocking bugs published in journals, conferences, technical reports, or book chapters from 2012 to 2022 were targeted for review. Whereas 2014 marked the first application of machine learning to predict blocking bugs [1], 2012 was chosen as the start date to widen the scope of our search. Also, the focus was on publications in English that used ML to detect and classify blocking bugs or predict a phenomenon related to blocking bugs. Moreso, studies that constructed prediction models based on binary data classification of blocking bugs were selected. The authors ensured that all selected publications reported their data source, performance evaluation, baseline techniques, and the challenges and limitations of their studies.

*3) Exclusion criteria*: Mendeley [17], a reference management software, was used to delete duplicate papers which were 274 in number. Next, the papers that were not peer-reviewed and for which the complete text was not available in English were excluded. An article that was not about blocking bugs in computer software or was not written regarding predicting a phenomenon of blocking bugs with machine learning was not considered. Articles were mainly excluded based on titles and abstracts, full-text reading, and later quality evaluation. The data sources and the corresponding number of publications after the exclusion criteria are captured in Table III.

TABLE II.    KEYWORDS AND ALTERNATIVE WORDS/PHRASES

| Keyword | Alternative word/phrase |
|---|---|
| Blocking Bug | ('blocker bugs' OR 'severe bugs' OR 'Bug Severity') |
| Prediction | ('Identifying' OR 'Classifying' OR 'Detection' OR 'Characterizing') |
| Machine Learning | ('machine technique' OR 'method' OR 'model' OR 'algorithm') |

TABLE III.    NUMBER OF PUBLICATIONS AFTER EXCLUSION CRITERIA

| Data Source | Number of shortlisted Publications |
|---|---|
| Scopus | 2 |
| SpringerLink | 0 |
| IEEE Xplore | 3 |
| ACM Digital Library | 1 |
| ScienceDirect | 0 |
| Google Scholar | 0 |
| Total | 6 |

TABLE IV.    SEARCH STRINGS PER DATA SOURCE

| Data Source | Search String |
|---|---|
| Scopus | ("Blocking Bug" OR "Severe Bugs" OR "Bug Severity" OR "Blocker Bug") AND ("Identifying" OR "Prediction" OR "Classifying" OR "Detection" OR "Characterizing" ) AND ("machine learning" OR "method" OR "model" OR "algorithm") |
| SpringerLink | ("Blocking Bug" OR "Severe Bugs" OR "Bug Severity" OR "Blocker Bug") AND ("Identifying" OR "Prediction" OR "Classifying" OR "Detection" OR "Characterizing" ) AND ("machine learning" OR "method" OR "model" OR "algorithm") |
| IEEE Xplore | ("Blocking Bug" OR "Severe Bugs" OR "Bug Severity" OR "Blocker Bug") AND ("Identifying" OR "Prediction" OR "Classifying" OR "Detection" OR "Characterizing" ) AND ("machine learning" OR "method" OR "model" OR "algorithm") |
| ACM Digital Library | [[All: "blocking bug"] OR [All: "severe bugs"] OR [All: "bug severity"] OR [All: "blocker bug"]] AND [[All: "identifying"] OR [All: "prediction"] OR [All: "classifying"] OR [All: "detection"] OR [All: "characterizing"]] AND [[All: "machine learning"] OR [All: "method"] OR [All: "model"] OR [All: "algorithm"]] |
| ScienceDirect | ("Blocking Bug" OR "Severe Bugs" OR "Blocker Bug") AND ("Prediction" OR "Classifying" OR "Detection" OR "Characterizing" ) AND ("machine learning" OR "algorithm") |
| Google Scholar | ("Blocking Bug" OR "Blocker Bug") AND ("Identifying" OR "Prediction" OR "Classifying" OR "Detection" OR "Characterizing" ) AND ("machine learning" OR "method" OR "model" OR "algorithm") |

*C. Phase 3: Search*

This phase of the SLR explains the approach adopted for sampling relevant primary studies.

*1) Study selection*: To sample relevant primary studies that meet the needs of this study, the tollgate method proposed by Afzal et al. [16] was adopted. Fig. 2 depicts the tollgate approach used. This approach is made up of five steps which were traced by the authors as follows:

Step 1: Data was collected from selected online data sources via the use of search strings generated in Table III.

Step 2: Duplicate studies were excluded using Mendeley.

Step 3: Inclusion/ exclusion criteria were applied by perusing the titles and abstracts.

Step 4: Inclusion/ exclusion criteria were applied by reading the introductions and conclusions.

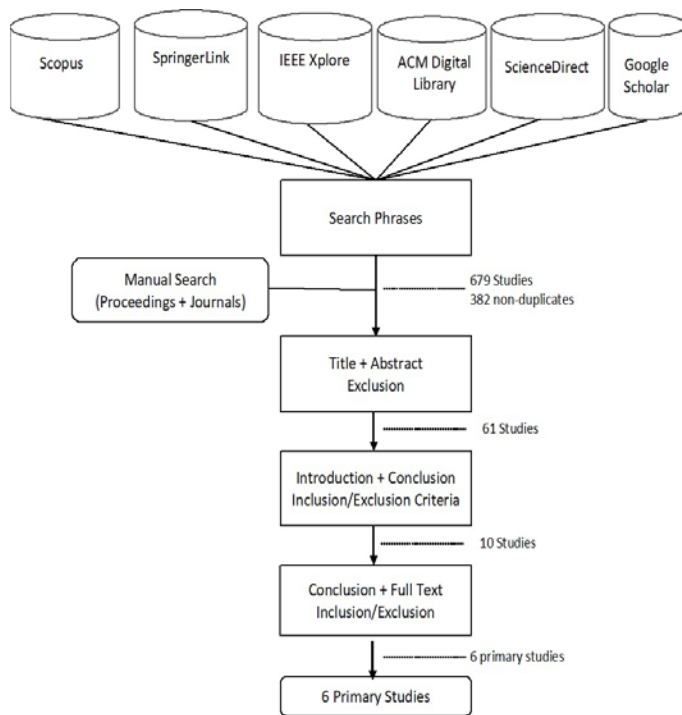
Step 5: Inclusion/ exclusion criteria were applied by reading the full text of sampled studies.


Fig. 2. The Tollgate Approach.

The search strings established in Table III were used to collect 679 from the selected data sources for this study (i.e. Table I) in the first step. At the end of the tollgate approach, six primary studies [1], [4]-[7] were selected. Table VII shows the shortlisted primary studies.

*2) Quality assessment of selected studies*: The purpose of the study quality assessment was to ensure that the sampled primary studies could adequately answer the research questions. It also aids in interpreting findings for data analysis and synthesis [18]. Hence, each quality criterion was designated by the prefix 'QC' and a number. The QC and data extraction activities were performed at the same time. Table V shows a quality assurance checklist for selected primary studies. A mathematical approach was used to assign quality scores, as in Kitchenham [10]. Thus, attributes of the quality criteria outlined in **Table V** were extracted for each primary study and scored on how well they met the requirements. For each attribute there are three possible values: Yes (Y) = 1 point, Partial (P) = 0.5 point, No (N) = 0 point. A study is allocated a score of 1 if the article clearly answers the QC question and a score of 0.5 if it partially answers the QC. Studies that do not answer the QC questions receive a score of 0. The six QC scores were added together to get the total quality score. As a result, the overall quality score of each selected study ranged from 0 (extremely poor) to 6 (very good). This approach to quality score has been widely used by SLR researchers in the software engineering domain [14], [19], [20], and related domains [21]. Each selected article in this study received a score greater than 70%. This percentage score shows that the primary studies can sufficiently answer the research questions.

TABLE V. QUALITY CHECKLIST FOR SELECTING PRIMARY STUDIES

| Serial Number | QC Checklist |
|---|---|
| QC1 | Does the selected study give details of the machine learning techniques applied in the study to answer RQ1? |
| QC2 | Does the selected study give details of the dataset and the data source used in the study to answer RQ2? |
| QC3 | Does the selected study benchmark its results with the performance of other prediction techniques to answer RQ3? |
| QC4 | Does the selected study provide information about the performance metrics used to evaluate results to answer RQ4? |
| QC5 | Does the selected study report the ML classifiers used as baselines to benchmark the proposed model to answer RQ5? |

*3) Data extraction*: A structured extraction form created with Microsoft Excel was used to extract the information needed for data synthesis. Table VI indicates the items extracted from each primary study.

TABLE VI. DATA EXTRACTION FORM ITEMS

| Data Item | Description |
|---|---|
| Reference | Title, Author,Type (i.e Journal/conference/workshop) |
| Technique | ML technique was applied in building the proposed model in the study. |
| Pre-processing | Preprocessing methods for machine learning technique |
| Dataset | Source of datasets used in training ML models |
| Evaluation | Metrics used for model evaluation |
| Results | The outcome of the model performance evaluation |
| Baseline | Baseline techniques with which proposed models were compared |
| Future works | Future works proposed by the study |

TABLE VII. SHORTLISTED PRIMARY STUDIES

| Ref. | Year | Library | Journal/Conference |
|---|---|---|---|
| Valdivia-Garcia and Shihab [23] | 2014 | ACM | Conference: MSR'14, May 31 – June 1, 2014, Hyderabad, India |
| Xia et al | 2015 | Elsevier | Journal: Information and Software Technology |
| Valdivia-Garcia et al[2] | 2018 | Elsevier | Journal: Journal of Systems and Software |
| Din et al. | 2020 | IEEE Xplore | Conference: 2018 IEEE 42nd Annual Computer Software and Applications Conference (COMPSAC) |
| Cheng et al. [24] | 2020 | IEEE Xplore | Conference: IEEE 44th Annual Computers, Software, and Applications Conference (COMPSAC) |
| Brown et al. [25] | 2021 | IEEE Xplore | Conference: 2021 International Conference on Cyber Security and Internet of Things (ICSIoT) |

*4) Data synthesis*: At this stage, the relevant extracted data were synthesized using the thematic approach [22] to answer the research questions outlined in Table V.

### D. Phase 4: Report

The final phase of the SLR summarizes and examines the review results. Then, in distinct sub-sections, the full summary of the findings of this review is discussed and interpreted in relation to the research questions.

### III. FINDINGS

RQ1: What are the publication trends in BB prediction research?

Our search following the SEBE SLR methodology identified six primary studies that applied ML to predicting BB. The publication period of these studies spans from January 2014 to February 2022. Table VII presents the selected publications, while Fig. 3 depicts the publications over the years or distribution of primary studies. Observing Table VII, conference publications or proceedings seem to dominate the publications over the period with four articles, while journal articles account for two publications. This distribution further suggests the paucity of publications on the use of ML for predicting BBs over the years.

RQ2: Which datasets are used to train the proposed prediction model?

The performance of a machine learning technique is heavily reliant on the quality of the dataset used in training the prediction model. To train BBPM, all the six selected primary studies in this work utilized datasets extracted from publicly available bug reports about specific software projects. These bug reports were retrieved from Bugzilla, IssueTracker, and monorail issue tracking systems. The ones obtained from Bugzilla are Eclipse, NetBeans, Gentoo, Fedora, Mozilla, and NetBeans. While bug reports of Chromium and OpenOffice were retrieved from Montrail and IssueTracker. Table IX shows the web locations where these bug reports about the various projects were extracted. Also, studies used bug reports from authentic projects with actual proportions of blocking bugs (BBs) and non-blocking bugs (Non-BBs). Table VIII and Fig. 4 show blocking bug and non-blocking bug distribution within the extracted datasets and the distribution of projects from which datasets were extracted per the studies, respectively.

From Table VIII, it is observed that the chosen primary studies made use of at least two sets of datasets from the open-source application domain. For instance, Ding et al. [5] validated their method on two open-source projects, namely, Mozilla Firefox and Netbeans, which contained 132,584 bugs. 18900 were Blocking Bugs and 113,684 Non-Blocking Bugs. Also, Cheng et al. [7] gathered a total of 214873 bugs from Eclipse, FreeDesktop, NetBeans, and OpenOffice, of which 16,402 were Blocking Bugs. Both Valdivia-Garcia and Shihab [1] and Xia et al. [4] selected a total of 402,962 bugs from six (6) open-source projects (i.e. Chromium, Eclipse, FreeDesk Mozilla, NetBeans, and OpenOffice). 18,422 of the total bugs were blocking bugs. Similarly, Valdivia-Garcia et al. [2] and Brown

et al. [6] mined a total of 609,800 bugs which had 77,448 blocking bugs from eight projects (i.e., Chromium, Eclipse, FreeDesktop, Mozilla, NetBeans, OpenOffice, Gentoo, and Fedora) in their studies. The open-source projects used by the selected primary studies in this paper, as well as their corresponding bug tracking systems, are as follows:

Fig. 3. Distribution of Primary Studies.

TABLE VIII. DISTRIBUTION OF DATASET UTILIZED BY PRIMARY STUDIES

| Studies | No. of Projects | Projects | No. of Bbs | No. of Non-Bbs |
|---------|-----------------|----------|------------|----------------|
| Valdivia-Garcia and Shihab [1] | 6 | Chromium, Eclipse, FreeDesktop, Mozilla, Net-Beans, and OpenOffice | 18,422 | 384,540 |
| Xia et al. [12] | 6 | Chromium, Eclipse, FreeDesktop, Mozilla, Net-Beans, and OpenOffice | 18,422 | 384,540 |
| Valdivia-Garcia et al. [11] | 8 | Chromium, Eclipse, FreeDesktop, Mozilla, Net-Beans, OpenOffice, Gentoo, and Fedora | 77,448 | 532,352 |
| Cheng et al. [14] | 4 | Eclipse, FreeDesktop, NetBeans, and OpenOffice | 34,892 | 229,729 |
| Ding et al. [13] | 2 | Mozilla Firefox and Netbeans | 16,402 | 198,471 |
| Brown et al. [15] | 8 | Chromium, Eclipse, FreeDesktop, Mozilla, Net-Beans, OpenOffice, Gentoo, and Fedora | 18,900 | 113,684 |

TABLE IX.        SOURCES WHERE DATASETS OF OPEN-SOURCE PROJECTS WERE EXTRACTED

| Project | Source |
|---------|--------|
| Chromium | https://bugs.chromium.org/p/chromium/issues/list |
| Eclipse | https://bugs.eclipse.org/bugs/ |
| NetBeans | https://netbeans.org/bugzilla/ |
| OpenOffice | https://bz.apache.org/ooo/ |
| Gentoo | https://bugs.gentoo.org/buglist |
| Fedora | https://bugzilla.redhat.com/ss |
| Mozilla | https://bugzilla.mozilla.org/ |
| free desktop | https://bugzilla.freedesktop.org/ |

Fig. 4.    Distribution of Projects Studied by the Selected Studies.

- Chromium is a popular open-source web browser developed by Google and used mainly as the codebase for Google Chrome. C++ and C programming languages dominate it; however, it comprises other programming languages such as JavaScript and Python, amongst others. Chromium has its bug tracking mechanism in Google code, called Monorail, which has a feature called "Blocking." The "blocking" feature can identify if a bug is a blocking bug or not.

- Eclipse is a well-known integrated development environment (IDE) developed mainly with Java yet supports many programming languages, including Python, Ruby, and C/C++. In addition, eclipse uses Bugzilla for reporting and tracking bugs. This issue tracking system has a feature called "Blocks." This is used for identifying a bug as a blocking bug. GNU/Linux or FreeBSD. Gentoo also uses Bugzilla in reporting and tracking bugs; hence the "Blocks" field identifies a blocking bug.

- Mozilla is an open-source project that hosts and develops products such as Firefox, Thunderbird, Bugzilla, Gecko layout engine, and others. The programming languages used in its development are C, JavaScript, and C++. In addition, Mozilla tracks its bugs in Bugzilla software and uses the "Blocks" field to show if a bug is a blocking bug.

- NetBeans is an open-source IDE for developing applications in the java programming language for Windows, Mac, Linux, and Solaris. However, it supports PHP, C, and C++, amongst others. NetBeans was developed with the Java programming language. Bugzilla is an issue tracking system used by Netbeans; hence the "Blocks" field indicates whether a reported bug is a blocking bug or not.

- OpenOffice is an office suite created by Sun Microsystems and is now maintained by Apache. It is maintained with its programming language called OpenOffice.org Basic. IssueTracker, a derivative of Bugzilla, was used by OpenOffice when these primary studies were undertaken. Just like Bugzilla, it has a "Blocks" feature which indicates whether a bug is a blocking bug or not. At the time of this study, Bugzilla had succeeded IssueTracker, which was also known as IssueZilla.

Valdivia-Garcia et al. [2] and Brown et al. [6] used the most extensive dataset with the most bugs (i.e. 609,800 bugs), which they extracted from Chromium, Eclipse, Free Desktop, Mozilla, NetBeans, OpenOffice, Gentoo, and Fedora. The open-source project that most of the studies included in their dataset is Netbeans, while Gentoo and Fedora were the least utilized by the studies, as captured in Fig. 6. Although the six primary studies used datasets from popular and well-supported open-source projects with a substantial number of bug reports, the distribution of dataset sizes in Fig. 5, coupled with the unequal distribution of Blocking bugs and non-blocking bugs in Table VIII, suggests the challenge of class imbalance. Thus, in most studies, BBs account for less than 12% of the total available dataset [2]. However, extensive research exists about the challenges an imbalanced dataset, also referred to as the class imbalance phenomenon [23], poses to the performance of classifiers that use them in training. Also, it is worth noting that all the studies considered in this work used datasets related to open-source projects; hence their findings may not apply to closed and commercial software projects.

RQ3: What kind of ML learning techniques is adopted in building the proposed BB prediction model?

The primary studies considered in this SLR proposed new methods for identifying a bug as blocking bugs or non-blocking bugs based on an existing classification technique. Fig. 7 shows the distribution of the classification techniques employed in the various studies.
Fig. 5.    Distribution of Datasets by Selected Studies.

Fig. 6.    Distribution of Projects and their Frequency of use in Primary Studies.

Fig. 7.    Distribution of Classification Techniques.

TABLE X.          DISTRIBUTION OF ML TECHNIQUES UTILIZED BY PRIMARY STUDIES

| ML Techniques | Studies |
|---|---|
| Decision trees (C4.5) | Valdivia-Garcia and Shihab[1], Valdivia-Garcia et al [11] |
| Ensemble learning | Xia et al. [12] |
| Bayes Network | Ding et al. [13] |
| Deep Learning (DNN) | Brown et al. [15] |
| XGBoost | Cheng et al. [14] |

Valdivia-Garcia and Shihab [1] and Valdivia-Garcia et al. [2] used a re-sampling technique to pre-process the training data to resolve the data imbalance issue; non-blocking bugs outnumber blocking bugs. Even though random forest performed better in terms of F1 measure than their proposed model, which was based on Decision trees (C4.5), they recommended their model as the most appropriate for practitioners.

Xia et al. [4] built a classifier called ELBlocker based on the random forest technique. They separated the training data into many disjoint sets and developed different classifiers, which they then merged to identify an appropriate threshold for classifying bugs as blocking or non-blocking. Also, Cheng et al. [7] presented a new classification framework called XGBlocker, consisting of two stages. XGBlocker captures more features from bug reports in the first stage to construct an improved dataset. In the second stage, XGBlocker employs the XGBoost technique to build an efficient model for performing the prediction task. Ding et al. [5] proposed a Bayes Network-based classifier for forecasting the breakability of the blocking bug pairs.

The classifier is identical to the Bayes Network classifier; as the threshold lowers from 0.5 to 0, the classifier becomes

stricter and removes more boundary instances to improve precision. In Brown et al. [6], researchers proposed a DeepLabb classifier based on deep neural networks for predicting blocking bugs. Three deep neural networks were developed and trained independently, each with a different number of hidden layers. The first DNN had two hidden layers, the second DNN had three hidden layers, and the third DNN had four hidden layers. Bayesian optimization was used to estimate the best learning rate for each model. It is worth mentioning that apart from Brown et al. [6], who employed a deep learning approach in this domain, at the time of this work, the rest used Decision Trees, Random Forest, Bayes Network, and XGBoost for building Blocking bug prediction models in the selected primary studies. Table X shows the studies and the classification techniques adopted in building their classifiers. While the most frequently used ML technique in building BB classifiers is based on the Decision Trees, Random Forest was reported by two studies [1][11] to have performed better than Zero-R, Naive Bayes, and KNN.

RQ4: Which evaluation criterion is used to measure the performance of the BB prediction model?

The primary studies assessed the prediction abilities of their proposed BB prediction model using various combinations of evaluation metrics. Fig. 8 depicts the distribution of research based on performance metrics. In Valdivia-Garcia and Shihab [2], Precision, Recall, F1-Score, and Accuracy were used to measure the effectiveness of their proposed classifier and reported 9-29% precision, 47-76% recall, and 15-42% F1-Score.

The F1 score and cost-effectiveness were used to assess the efficiency of ELBlocker in Xia et al. [12], which attained an F1-Score up to 0.482 and EffectivenessRatio@20% scores of 0.831.In Valdivia-Garcia et al. [11], the researchers utilized Precision, Recall, and F1-Score to evaluate the performance of their proposed model. The proposed model achieved 13%–45% precision, 47%–66% Recall, and 21%–54% F1-Score. Ding et al. [13] used ROC Area, Accuracy, F1-Score, Recall, and Precision to assess the efficiency of the classifier they recommended. In Mozilla Firefox the proposed BayesNet model achieved 0.629, 0.729, 0.676, 0.831, and 76.54 % for Precision, Recall, F-measure, Roc Area, and Accuracy, respectively. However, it recorded Precision, Recall, F-measure, Roc Area, and Accuracy of 0.488, 0.583, 0.531, 0.764, and 73.45%, respectively, in the case of the NetBeans dataset. To compare the performance of XGBlocker to other classifiers, Cheng et al. [14] employed AUC, Cost-Effectiveness, and F1-Score. XGBlocker reported an F1-score of 0.808, ER@20% of 0.944, and AUC of 0.975.

Brown et al [15] used MCC, F1, and AUC to compare DeepLaBB with other classifiers. DeepLaBB recorded an MCC of 0.8504%, F1 Score of 0.4292%, and AUC of 2.9459%.

The following is a summary of the various performance metrics used in the primary studies considered in this work:
Fig. 8. Performance Metrics and the Corresponding Number of Primary Studies.

Accuracy refers to the proportion of correctly categorized instances to the total number of instances. It can be calculated using the formula below with the aid of True positives (TP), False negative (FN), False positives (FP), and True negative (TN) extracted from the confusion matrix.

Accuracy= (TP+TN)/ (TP+FP+ TN+ FN)

MCC refers to Matthew's Correlation Coefficient. To measure the quality of binary categorization, MCC examines all true and false positives and negatives [29]. It can be computed as:

MCC= (TP*TN-FP*FN)/√ ((TP+FP) (TP+FN) (TN+FP) (TN+FN))

Recall is the ratio of accurately categorized positive cases to the total number of positive instances. Recall can be calculated as:

Recall= TP/ (TP+FN)

Precision is a measure of the proportion of correctly categorized positive instances among all positive samples. It can be computed as follows:

Precision= TP/ (TP+FP)

F1-Score if the harmonic mean of precision and recall. F1's best value is 1, and its worst value is 0. It can be represented mathematically as:

F1-Score= (2*Precision*Recall)/ (Precision Recall)

The AUC-ROC refers to AUC (Area under Curve)-ROC (Receiver Operating Characteristic). It is a trade-off between the True Positive Rate (TPR) and the False Positive Rate (FPR) and represents the classifier's ability to predict classes correctly.

It can be generated by charting TPR (True Positive Rate), i.e., Sensitivity or recall vs. FPR (False Positive Rate), i.e., 1-Specificity, at different threshold values.

Cost-Effectiveness [24] is a cost-sensitive indicator of prediction performance. It assesses a method's prediction performance under a cost limit. Even though research findings [25] discourage the use of Accuracy for evaluating classifiers trained with an imbalanced dataset, Valdivia-Garcia and Shihab [1] and Ding et al. [24] employed Accuracy in their works; the F1 score is the most common evaluation metric utilized among the studies in this SLR, followed by Precision and Recall. The least common measure employed is cost-effectiveness.

RQ5: Which ML classifiers are used as baselines to benchmark the proposed model?

The studies considered in this work compared the performance of proposed BB prediction models to baseline techniques to assess their efficacy. Fig 8 shows the baselines to which the proposed techniques were compared. After reviewing the primary studies in this work, it can be concluded that the proposed BB prediction models outperformed individual baseline classifiers in the vast majority of cases at the time of this study. The C4.5 Decision tree algorithm-based BB prediction model proposed in Valdivia-Garcia and Shihab [1] and Valdivia-Garcia et al. [2] performed better than Naive Bayes, kNN, and Zero-R baselines.

The C4.5 based model was chosen over the random forest because it is an explainable model that practitioners can easily understand. To forecast the possibility of a blocking bug, Xia et al. [4] used an ensemble of various classifiers. The ELBlocker showed a significant improvement compared with Valdivia-Garcia and Shihab's methods [1], SMOTE, one-sided selection (OSS), and bagging. In Cheng et al. [7], the proposed XGBlocker was compared with Gradient Boosting Decision Tree (GBDT), AdaBoost, ELBlocker, XGB_14, CART, Logistic Regression, and Valdivia-Garcia and Shihab's approaches. The proposed method displayed superior performance in all instances. Ding et al. [5] offered a method for describing and forecasting the breakability of the blocked bug pairs, which performed better compared with the Zero-R Classifier's performance, Naïve Bayes, BayesNet, KNN, and Random Forest. Brown et al. [6] introduced DeepLaBB for predicting blocking bugs in open-source projects. DeepLaBB showed improved performance compared with the performance of Random Forest, KNN, CART, and ANN on the same datasets. The performance of proposed BB predicting models was compared with that of base classifiers such as RF, KNN, NB, Zero classifier, and Valdivia-Garcia and Shihab's approaches in the majority of the research articles. Generally, the choice of baseline varied from one study to another. However, as shown in Fig. 9, RF was the most utilized baseline classifier in most studies, closely followed by KNN. Even though most of the proposed BB prediction models in the various studies performed better than the baseline classifiers, some BB prediction models have not improved performance compared with traditional classifiers. For instance, in Valdivia-Garcia and Shihab [1], when it comes to chromium and Eclipse data sets, the proposed model had recall values of 49% and 47%, slightly below the 50% recall value of the baseline. In the same paper, random forest performed better than the proposed model in precision across all project datasets. Also, Zero-R outperformed all the classifiers in terms of Accuracy. Similarly, in Valdivia-Garcia et al. [1], the Zero-R model

had the highest Accuracy across all project datasets except for Fedora. Also, in Brown et al. [6], a baseline classifier, Random Forest, performed better than the proposed DeepLaBB in the FreeDesktop dataset in terms of MCC and F1-Score.

Fig. 9. Distribution of Baseline Classifiers and Primary Studies.

## IV. SUMMARY

This SLR traced the research advances in applying ML techniques to predict Blocking Bugs. After a rigorous analysis of the most pertinent research papers published between January 2012 to February 2022 in the databases of five famous academic publishers, namely Scopus, SpringerLink, IEEE Xplore, ACM digital library, and Science Direct, six (6) BB primary papers/studies were identified and reviewed. The findings regarding the research trend, variety of proposed ML techniques, baseline classifiers, evaluation metrics, and sources of datasets for predicting BBs during this study are captured in Fig. 3, Table X, Fig. 9, Fig. 8, and Table IX, respectively. The existing studies confirm that proposed ML techniques (i.e. BBPMs) significantly improve the detection of BBs in software bug reports and that they generally outperform the traditional classifiers. Also, this study concludes that there is a paucity of literature on the application of ML to BB prediction. Further research is required to validate existing and new prediction models on bug reports of commercial or closed software projects. In addition, new researchers should explore the effect of parameter tuning and the efficiency of ML approaches such as deep learning and ensemble learning in improving the classification of BBs. Furthermore, before training a classifier, researchers should take steps to mitigate the effect of class imbalance on the proposed BB prediction model.

*Abstract*—E-learning platforms propose pedagogical pathways where learners are invited to mobilize their autonomy to achieve the learning objectives. However, some learners face a set of cognitive barriers that require additional learning objects to progress in the course. A mediating recommendation system is one of the efficient solutions to reinforce the resilience of online platforms, while suggesting learning objects that will be interesting for them according to their needs. The objective of this contribution is to design a new mediator recommendation model for e-learning platforms to suggest learning objects to the learner based on collaborative filtering. To this end, the proposed system relies on the implicit behaviors estimation function as an underlying technique to convert tacit traces into explicit preferences allowing to compute the similarity between learners.

*Keywords—e-learning; recommendation system; learning objects; tacit behaviors*

## I. INTRODUCTION

E-learning has become, in recent years, the fundamental pillar of any educational system [1], as it allows everyone to learn easily, at any time, from any place and through any tool (laptops, smart phones, ...). In addition, several universities, institutes and schools have started using e-learning platforms to evolve their educational systems under any circumstances.

E-learning is considered as a process by which a set of educational activities and resources are delivered through digital devices to help learners achieve their learning objectives in the best possible conditions [2]. Moreover, these platforms are based on two fundamental aspects: the technological aspect (platform infrastructure) and the pedagogical aspect (learning content and its exploitation) [3], moreover, they are generally designed for heterogeneous learners with diverse pedagogical characteristics, including those related to experience levels, preferences, learning styles, etc. To this end, it is necessary to take full advantage of new technologies to improve the context of the pedagogical tool and also to adapt the learning strategies according to the learners' profiles.

Today, the application of recommender systems in e-learning has become an important field of research, as learning platforms have grown considerably, resulting in a massive increase in online digital resources. As a result, learners face great difficulty in choosing the most relevant and useful learning resources. Recommender systems are promising new technologies in online learning environments, as they can mitigate the problem of information overload [4-5], while highlighting what is most relevant and interesting based on the learner's profile. The recommendation of personalized learning resources is based on the different types of knowledge identified in the learner's profile, such as: preferences, learning styles and contextual information [6]. Several works have been proposed in the application of recommender systems, which help users to get the desired information through some filtering processes, such as: recommending movies on Netflix, videos on Youtube, articles on Amazon and courses on Byju and Gooru.

This paper presents a recommendation system based on Tacit Learner Preferences (TLP), supported by a new methodological approach for extracting their tacit preferences, in order to provide learners with learning resources that perfectly match their preferences without the tutor's intervention. The recommendation system is based on a learner model that gathers all personal information (age, education level, language, ...), pedagogical characteristics (learning styles, ...) and competency profiles (prerequisites, performance, expertise level, ...). All this information is extracted from the learner's interactions within the online platform. However, the problem is the difficulty of extracting tacit traces from the learning platform.

The objective of this paper is to convert the tacit traces into explicit ratings, in order to estimate the learner's preferences for a resource in the learner model of the recommender system.

The rest of the paper is organized as follows. In Section II, we highlight the main techniques proposed in the literature. In Section III, we represent related research work. In Section IV, we describe our proposed approach: Model for Converting Tacit Behaviors into Explicit Behaviors and in Section V, we conclude the paper and suggest possible future work.

## II. TYPES FOR RECOMMENDER SYSTEMS

Recommender system is defined as a strategy that helps users make decisions in complex and evolving information

spaces [7-8]. The recommender system suggests items for the user to evaluate based on their profile and the target domain. In addition, recommender systems address the problem of information overload and lack of domain knowledge, which users usually encounter, by providing personalized and exclusive content and service recommendations [9]. Recommender systems are classified into three main categories namely: Content-Based Filtering (CBF), Collaborative Filtering (CF), Hybrid Filtering (HF).

## A. Content-Based Filtering

Content-based filtering (CBF) is used to suggest articles similar to those previously liked by the user [10]. For example, the recommendation of research articles is based on the content-based approach, where the procedure uses the descriptive content of the articles and the users' needs without considering the ratings of other users [11]. The main problem with the content-based filtering recommender method is serendipity

*1) This problem of serendipity* is more known in content-based recommender systems, as these systems only recommend items that match the user's profile. At this point, the user has no chance to receive unexpected recommendations, which leads to a certain weariness with the proposed recommendations.

## B. Collaborative Filtering

Collaborative filtering (CF) is the most common and effective technique in recommender systems, as it compares users' ratings with other users' ratings to find the users who are "most similar" based on a similarity criterion and to recommend the articles that similar users have previously liked [12]. In 2016, QusaiShambour et al. developed a personalized recommendation system based on collaborative multi-criteria filtering of articles, while exploiting multi-criteria ratings and semantic information of articles, to overcome the problem of data sparsity and cold start of articles [13]. Collaborative filtering is considered the most popular and widespread method in recommender systems. They have been massively exploited in companies and universities. Some of these systems include PHOAKS [14], which helps users find accurate and relevant information on the web, GroupLens [15], BellcoreVideoRecommender [16], etc.

The main problem with the collaborative filtering recommendation method is data sparsity and the cold start problem:

*1) The cold start problem [17-18]:* is caused by the lack of data on new items or new users. Indeed, a new item cannot be recommended until a user has evaluated it. Similarly, for a new user, we cannot predict his preferences without knowing his item evaluation history.

*2) The sparsity problem [19-20-21]:* is generated when the number of items rated by users is very small compared to the total number of items available in the system. Parity results in a very low density of the matrix (items/user). This

affects the ability of the system to recommend less accurate items.

## C. Hybrid Filtering

Hybrid filtering (HF): aims at combining the strengths of the previously explained recommendation approaches in order to benefit from their complementary advantages and to overcome the problems identified before. Several techniques have been proposed to combine the basic techniques to create a new hybrid system. In 2018, R. Shanthi and colleagues proposed a hybrid recommender system to recommend products to users based on users' opinions and ratings [22]. In 2002, Burke describes a taxonomy that proposes seven ways of hybridization: weighted, switching, mixed, feature combination, cascade, feature augmentation, and meta-level [23].

## III. RELATED WORK

Several recommender systems have been developed for online learning, such as: In 2018, Feng Zhang et al. proposed a recommender system based on the collaborative filtering approach to recommend learning resources that are valued by learners most similar to the active learner [24]. In 2018, Hayder Murad et al. designed a recommender system that detects students' profiles and knowledge levels, with the aim of automatically recommending online video learning materials that are perfectly suited to students' needs [25]. In 2017, Tarus et al. propose a hybrid ontology-based recommender system with sequential pattern mining to recommend online learning resources to learners [26]. In 2015, Bokde et al. develop an academic recommender system, which provides engineering school students with recommendations that meet their past preferences, based on a hybrid technique that combines article-based multi-criteria collaborative filtering with a dimensionality reduction approach [27]. In addition, a tutoring system based on a recommendation engine Protus (ProgrammmingTUtorting System) [28] was designed to recommend materials of interest to learners, while taking into account their pedagogical differences such as: preferences, knowledge, learning goals and learner progress, etc. The initial recommendation in Portus is based on the default sequence of lessons and the surveys previously assigned to the lessons.

Most of the works proposed in e-learning context are based on collaborative filtering, with the aim of recommending educational resources based on the profile and explicit evaluations of similar learners. These recommendation systems are designed to provide a personalized list of suggestions (educational resources, learning activities or videos). However, these systems ignore the importance of assisting learners in their learning journey, through the recommendation of additional resources to help them overcome cognitive difficulties and also to maintain their perseverance throughout the online training. Moreover, these recommender systems only exploit explicit user ratings to make recommendations.

Explicit evaluations are sometimes poorly expressed or ignored by users, which leads to a decrease in the performance of recommender systems [29]. In other words, implicit user

feedback is poorly considered in most existing recommender systems compared to explicit feedbacks, knowing that implicit behaviors can serve as a means to overcome several problems that plague recommender systems, such as: data sparsity and cold start.

Moreover, to improve the accuracy of recommendations, several works have been done to better capture and know users' preferences based on their behaviors in the system; In 2009, Rendle et al. proposed an article recommendation system based on users' implicit comments to predict a personalized ranking on a set of articles [30]. In 2008, Hu et al. developed a recommender system based mainly on implicit user interactions which are considered as user preferences, the proposed approach is based on converting expressed trust into user preference [31]. In 2006, Zigoris et al. proposed a Bayesian model technique to combine implicit and explicit user behaviors [32]. In 2005, Adomavicius et al. focused on exploiting implicit user interactions to make relevant recommendations [33].

Designing a recommender model based on a preference matrix that generates the different implicit interactions and explicit evaluations of learners is one of the challenges. Indeed, implicit feedbacks represent an objectivity towards a learning resource, while explicit feedbacks indicate a subjectivity, through the learners' rating of the learning objects. This combination allows for a more personalized learning environment that is more appropriate to the learners' expectations.

## IV. PROPOSED MODEL

The model proposed illustrates the general recommendation process that is based on the tacit behaviors (objective preferences) and explicit evaluations (subjective preferences) of learners in e-learning, in order to build a preference matrix that represents the set of learning objects with their ratings. In addition, this model also allows to suggest learning objects that help learners to overcome cognitive obstacles and to progress easily in their training path, without any personal experience required in the search of alternatives (see Fig. 1).

First, the implicit user data is extracted from the log files. Then, this data is processed in such a way that it is combined with the explicit evaluations stored in the database of the LMS used. Subsequently, the prepared data are used in a learner preference matrix for learning objects "LPLO" that combines objective and subjective learner preferences. Then, a classification of learners into virtual communities of similar interest is done, using the clustering approach. Finally, the recommended learning objects are presented to the learner in order to help him in his learning path. In this way, the learner can interact with the recommended learning objects and start to exploit the ones that match his cognitive level and preferences.

### A. Model of Conversion from Tacit to Explicit Behaviors

Our proposal is based on the exploration of the log files and the database of the used LMS, which record the learners'

traces during their interactions with the e-learning system. Furthermore, the preference matrix is generated based on these interactions, in order to select the most relevant learning objects. Tacit behavioral indicators and explicit ratings are used to build a model of the learner in an e-learning system by analyzing the learner's interactions with the learning objects implicitly or explicitly.

In order to maintain interoperability of CEHL, a set of standards have been considered in the literature to model learners [34] such as:

- The PAPI Learner Model (Public and Private Information for Learner) is a standard developed by the IEEE P1484.2 Learner Model Working Group and is one of the first proposals to model the learner. Various information is presented in this model: personal or demographic information, relational information, information on preferences, information on the learner's history and learning progress, etc.

- The IMS-LIP Learner Model ((IMS Learner Information Package), is a standard that allows the necessary characteristics of a learner to be modeled using XML technology in order to ensure interoperability between CEHL. The characteristics presented in this model are the learner's personal information, acquired skills, information related to qualifications, information about the learner's preferences and interests, etc.

Our system is based on the PAPI model for modeling the learner in the learning system, because, the objective of this contribution is to collect and exploit the information about the learner's history in the recommendation process (see Fig. 2). Thus, we used the demographic information as initial information to start the learner profiling process, and the behavioral information to describe the objective preferences in his profile [35].

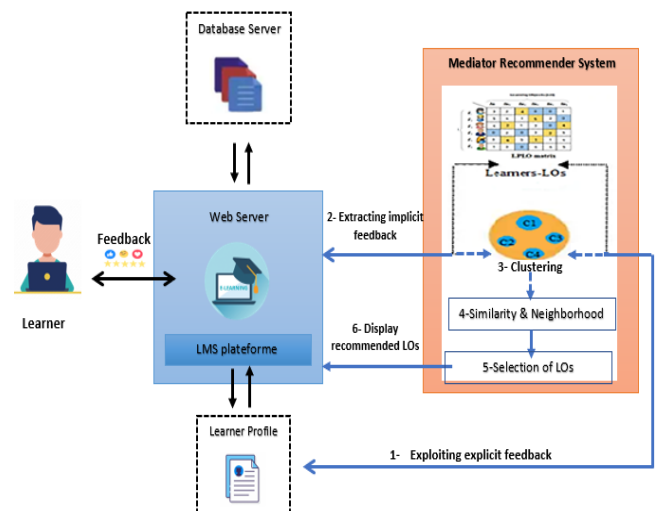

Fig. 1. Recommender System Model.
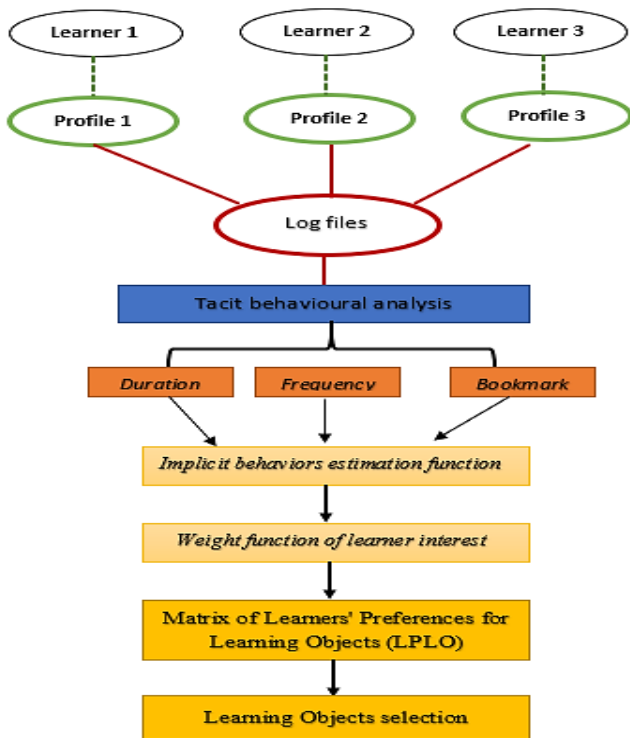

Fig. 2. Behavioural Analysis for LOs Selection.

*1) Learner demographic information*: name, gender, age, nationality, languages, education level, etc. This type of information is used during the learner's first interactions with the system, in order to overcome the cold start problem. Demographic filtering is used to begin the process of building the learner's profile.

*2) Behavioral information:* duration of use of a learning object, frequency of access to a learning object, learning object marked as important to the learner. This type of information is used to transform tacit behaviors into explicit preferences.

*3) Estimation function for implicit behaviors:* The learner's browsing history is recorded in a log file, hence the need to prepare the log file (their extraction and analysis), in order to generate a scoring matrix based on the following indicators:

- Duration (D): indicates the time a learner spends when operating a learning object.

- Frequency (F): indicates how often the learner requests the learning object.

- Bookmark(s): indicates the learning objects that are marked by the learner as important.

The implicit interest estimation function (1) allows to define the implicit score for each learning object, visited or consulted by the learner through the use of the indicators mentioned above; In this respect, we have relied on the "Page

InterestEstimator" formula, to compute the implicit scores defined by Philip K. Chan in 2003, in an e-learning context, which uses the user traces to define the interest of a user for an article (web page) [36-37]. In our context, the implicit interest estimation function is defined as follows:

$$Imp(l_{a,}lo_k) = D(l_{a,}lo_k) + F(l_{a,}lo_k) + B(l_{a,}lo_k) \qquad (1)$$

Where**:**

$l_a$ is active learner, $lo_k$ is a learning Object, $D(l_a,lo_k)$ indicate the duration, $F(l_a,lo_k)$ the frequency and $B(l_a,lo_k)$ denotes the bookmarks.

*4) Learner interest weighting function:* The learner interest weighting function (Wli) (2) is used to combine tacit behavioral indicators and variant ratings between 1 and 5 (see Table I).

TABLE I. THE LEARNING OBJECT RATING SCALE

| Linking | Rating scale |
|---|---|
| Very like | 5 |
| Like | 4 |
| Normal | 3 |
| Not like | 2 |
| Do not like | 1 |

On the other hand, the value 0 indicates that the learning object is not evaluated by the learner.

The learner interest weights function (2) is defined as follows:

$$Wli(l_{a,}lo_k) = 1/2 \ (Imp(l_{a,}lo_k) + Exp(l_{a,}lo_k)) \qquad (2)$$

Where:

$Exp(l_a, lo_k)) \ l_a$ is the current learner and $lo_k$ is the learner's explicit score, where k is the number of learning object, the rating is normalized according to the scale [1-5], in case the $lo_k$ is no longer rated by the learner, the value assigned to the $Exp(l_a, lo_k)$ function is '0'.

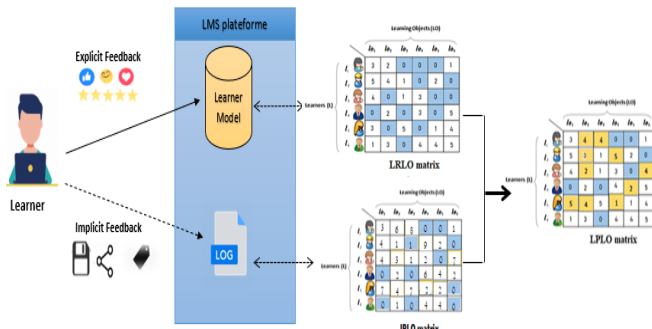
*5) Matrix of learner preferences for learning objects (LPLO):* After the normalization of ratings, the basic matrix LRLO (Learners' Ratings for Learning Objects) contains the explicit ratings of the learners, this matrix is transformed into matrix LPLO (Learners' Preferences for Learning Objects) contains the implicit and explicit preferences of the learners, where the rows represent the learners L {l1,l2,l3,...}. And the columns represent the learning objects LO {lo1,lo2,lo3,...}. Moreover, the unknown notations are defined by the function $Wli(l_{a,}lo_k)$, which is computed based on the implicit interest estimation function (1), with the aim of defining the implicit score for each learning object, visited or accessed by the learner through the exploitation of the following indicators: Duration, frequency and bookmark (see Fig. 3).


Fig. 3.    Matrix Transformations.

The LPLO matrix is less sparse compared to the basic LRLO matrix , the saprsity level (3) is calculated as the ratio of the number of unevaluated learning objects (empty entries) to the total number of learning objects in the matrix (LxLO) (Matrix Size).

$$level\,of\,sparsity = \frac{UnratedLOsnumbers}{MatrixSize} \qquad (3)$$

The number of missing ratings for the LRLO matrix is 14, while for the LPLO matrix is 7, moreover the size of both matrices is 36. The level of sparsity for the LRLO matrix is 39%, however for the LRLO matrix is 19%. Also, when the matrix is less sparsity data, i.e. the number of missing ratings is low; the recommendations will be more accurate.

*6) Preference matrix weighted by educational criteria;* Learning objects are tagged with a set of pedagogical criteria, which are defined by the course designer. These criteria are transcribed by values and are used to personalize the recommendations according to the learner's level of involvement in the learning system and his preferences expressed in his profile.

The Table II illustrates the different educational criteria with their values.

So, for each learner 'cl', there exists in his profile a set of learning objects $LO_{cl} = \{lo^{cl}_i \in LO, i=1\ldots m_{cl}\}$, where $lo^{cl}_i$ are the learning objects consulted by the current learner 'cl', the values of the pedagogical criteria are described by $v^{cl}_i$ and the notations generated on the basis of the function Wli (2) for the pair {learner, learning object} are expressed by $r^{cl}_i$. (see Table III).

### B. Classification of Learners into Clusters

*1) Pearson correlation coefficient (PCC): i*s one of several measures such as: Manhattan distance, Jaccard similarity, Cosine similarity and Euclidean distance [38], all these measures are used to calculate the degree of similarity between learners based on a set of criteria, where similar learners are assigned to the same cluster; each of these measures has been applied to millions of clustering applications in the measure of creating virtual communalities of similar interest.

TABLE II.    EDUCATIONAL CRITERIA AND THEIR ASSOCIATED VALUES

TABLE III.    LEARNING OBJECTS-PEDAGOGICAL CRITERIA-RATING MATRIX BY LEARNER

| | **c₁** | **c₂** | **c₃** | **..** | **..** | **cₚ** | **r_cl** |
|---|---|---|---|---|---|---|---|
| **lo₁** | $v^1_1$ | $v^1_2$ | $v^1_3$ | | | $v^1_p$ | $r^{cl}_1$ |
| **lo₂** | $v^2_1$ | $v^2_2$ | $v^2_3$ | | | $v^2_p$ | $r^{cl}_2$ |
| **lo₃** | $v^3_1$ | $v^3_2$ | $v^3_3$ | | | $v^3_p$ | $r^{cl}_3$ |
| **lo₄** | $v^4_1$ | $v^4_2$ | $v^4_3$ | | | $v^4_p$ | $r^{cl}_4$ |
| **..** | .. | .. | .. | | | .. | .. |
| **..** | .. | .. | .. | | | .. | .. |
| **loₘ** | $v^m_1$ | $v^m_2$ | $v^m_3$ | | | $v^m_p$ | $r^{cl}_m$ |

In our context, we use the Pearson correlation; given that the variables of the matrix are associated in a linear way, i.e. when a change is made to one variable, a proportional change is made to the other variable. Moreover, since the values of the variables are quantitative and have a Gaussian distribution, the use of the Pearson correlation is adequate to define the degree of similarity between the learners. On the other hand, the De Jaccard similarity coefficient is sufficiently appropriate for use in documents or word similarity measurement.

Pearson Correlation Coefficient (PCC) known as Pearson Product-Moment Correlation Coefficient "r", PCC is one of the most popular coefficients for measuring the dependence of two variables, i.e. the relationship between two quantitative variables and the degree of similarity between these two variables.

- Dependency Coefficient (DC): is calculated through the Pearson Correlation Coefficient in order to identify the degree of association between the ratings provided by the learner for all the learning objects consulted.

- Pearson Correlation Coefficient (PCC) (8): is a statistical measure of the linear relationship between two variables and it ranges between [-1,+1]; the positive correlation indicates that the variables increase or decrease in parallel, however a negative correlation means that one variable increases while the other decreases. Furthermore, correlation (4) is a measure of effect where the strength of the correlation is described as follows, with $-1.0 \le r \le +1.0$ (see Table IV).

TABLE IV. INTERPRETATION OF R VALUES

| r value | Interprétation |
|---------|----------------|
| +.80 to +1.0 | Very strong positive relationship |
| +.60 to +.79 | Strong positive relationship |
| +.40 to +.59 | Moderate positive relationship |
| +.20 to +.39 | Weak positive relationship |
| +.01 to+.19 | Negligible relationship |
| 0 | No relationship |
| -.01 to -.19 | Negligible relationship |
| -.20 to -.39 | Weak negative relationship |
| -.40 to -.59 | Moderate negative relationship |
| -.60 to -.79 | Strong negative relationship |
| -.80 to -1.0 | Very strong negative relationship |

The correlation value 'r' is calculated as follows:

$$r_{x,y} = \frac{\delta xy}{\delta x \, \delta y} \tag{4}$$

Where:

$$\delta xy = \frac{1}{n}\sum_{i=1}^{n} x_i y_i + \bar{x}\bar{y} \tag{5}$$

$$\delta x = \sqrt{\sum_{i=1}^{n} \frac{x_i^2}{n} - \bar{x}^2} \tag{6}$$

$$\delta y = \sqrt{\sum_{i=1}^{n} \frac{y_i^2}{n} - \bar{y}^2} \tag{7}$$

Based on the formula proposed by Manuel J. Barranco and Luis Martinez, the Pearson correlation coefficient is associated with two variables (see Table V):

- $r_{cl}$ : The ratings assigned by the current learner 'cl' for the learning objects.

- $v_{cl}$ : The pedagogical criteria of the learning objects consulted by the current learner.

$$PCC_{cl\,j} = \frac{\sum_i r_i^{cl} v_{ij}^{cl} - \frac{\sum_i r_i^{cl} \sum_i v_{ij}^{cl}}{n_{cl}}}{\sqrt{(\sum_i (r_i^{cl})^2 - \frac{(\sum_i r_i^{cl})^2}{n_{cl}})}\sqrt{(\sum_i (v_{ij}^{cl})^2 - \frac{(\sum_i v_{ij}^{cl})^2}{n_{cl}})}} \tag{8}$$

TABLE V. DETAILS OF NOTATIONS USED IN PCC METRIC

| Notation | Description |
|----------|-------------|
| $r_i^{cl}$ | Score assigned by the learner 'cl' for the learning object 'lo$_i$' |
| $v_{ij}^{cl}$ | Pedagogical criterion 'vj' for the learning object ' lo$_i$' consulted by the learner 'cl' |
| $n_{cl}$ | Number of learning objects consulted by the current learner 'cl' |

*7) K-means clustering:* The main goal of clustering is to divide learners into groups based on similarity characteristics with the aim of recommending learning objects that the active learner has never visited [39]. In a first step, learners with similar interests will be grouped in the same cluster, in order to recommend them appropriate learning objects, for this purpose, we opt for the K-means algorithm which refers to the preference matrix "LPLO" (learner-learning object) generated in the previous step.

The K-means algorithm is well known for its efficiency and power in clustering a large data set compared to other k-nearest neighbors' algorithm [40]. Moreover, it is considered one of the most popular clustering algorithms for unsupervised learning.

The procedure for assigning learners into clusters via the k-means algorithm is done according to the following pseudo code:

**Input:** k // Number of desired clusters
L= {l$_1$,l$_2$,l$_3$,……...L$_n$) // Set of learners

**Output:** a set of k clusters

**Process:**

Arbitrarily select k learners form L as the initial cluster centers;

**Repeat:**
1-(re) assign each learner to the clusters with the most similar interests based on the Pearson correlation coefficient 'PCC' of the current learner and the mean value of the learners in the cluster
2-Update the cluster means; calculate new mean value of learners for each cluster;

Until no change;

*8) Selecting learning objects:* The learning objects recommended to the current learner is made, by the association between the profile of the current learner and the learning objects repository. Moreover, the learning objects that are well evaluated by the closest neighbors' to the active learner and having a score higher than three will be recommended to the current user (see Fig. 4).
Fig. 4. The Selected Learning Objects.

Rate [lo20] = 4 ✓ Rate [lo6] = 1

Rate [lo12] = 2 Rate [lo15] = 5 ✓

Rate [lo29] = 6 ✓ Rate [lo80] = 2

## V. EXPERIMENTATION

This section presents a performance analysis of the proposed methodology. The performance of this work is evaluated against the recommendation based only on the explicit preferences of the users.

The participants in this experiment are 100 learners from a high school in the delegation of Chefchaouen, Morocco. However, the learners had to study four modules in the computer science subject, namely: "Generalities of Computer Systems", "Software", "Algorithms and Programming" and "Networks and the Internet"; each module consists of a set of lessons, which are well defined in the pedagogical guidelines of computer science in high school. Our first experiment is based on the first module "Generalities of Computer Systems", which contains three lessons: lesson 1 "Basic Definitions and Vocabulary", lesson 2 "Basic Structure of a Computer" and lesson 3 "Software and Application Areas of Computer Science" (see Table VI).

The Table VII expresses the degree of depth of the concepts for each notion.

Our approach is tested on learning objects stored in the LMS database. The first module "General Computer Systems" provides an assessment dataset of 50 learning objects containing 36 ratings from 26 learners. The ratings are integers ranging from 1 to 5. The experiments are performed on an HP computer with CORE i5 processors.

The Sum Squared Error (SSE) (8) is used to find an appropriate k by plotting the number of clusters against the SSE, while evaluating SSE for different values of k.

$$SSE = \sum_{i=1}^{n}(y_i - \hat{y}_i)^2 \qquad (9)$$

Where:

i is test set, $y_i$ is predicted value and $\hat{y}_i$ is actual value.

| Degree of depth | Descriptor |
| --- | --- |
| 1 | Initiation |
| 2 | Appropriation |
| 3 | Master |

Fig. 5. The Appropriate Number of Clusters in respect to the Matrices.

From the above graph (see Fig. 5), we notice that the SSE value is high in the sparse matrix unlike the dense matrix. For both matrices, when the number of cluster increases, the SES

value decreases. This means that the number of clusters is independent to the type of matrix. For this distribution of 100 learners, the most appropriate number of clusters for both matrix types (sparse or dense) is 4 clusters.

The silhouette is used to determine the degree of separation between clusters. The silhouette plot in (Fig. 6), illustrates the proximity of learners in neighboring clusters using a measure of [-1 , +1]. A value of +1 indicates that the learners are far apart, 0 indicates that the observations are very close, and -1 indicates that the learners can be assigned to the wrong cluster.

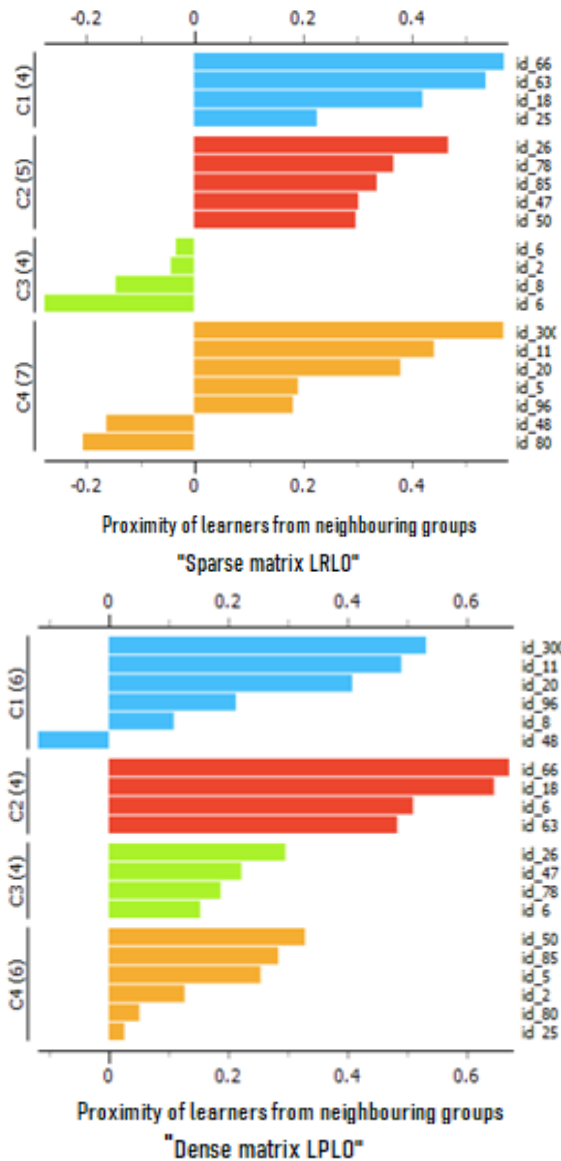

Fig. 6.   Silhouette Analysis for Sparse and Dense Matrix.

For the sparse matrix LRLO "Learners Ratings for Learning Objects", we find that some learners are assigned to the wrong cluster, due to lack of ratings of learning objects in this Matrix. Since, some learners do not rate all these objects, their assignments to some clusters may be inappropriate. However, for the dense matrix LPLO "Learners Preferences

for Learning Objects", the majority of learners are classified in the appropriate clusters, thanks to the elicitation of preferences through the combination of explicit ratings and implicit interactions of learners with the learning objects.

The mean absolute error (MAE) "(10)" is a measure of prediction accuracy. It indicates the absolute value of the difference between the predicted value and the actual value.

This measure is used to indicate the effectiveness of our recommendation system based on implicit and explicit learner feedback and recommendation systems based on explicit feedback only. The lower the MAE value, the smaller the magnitude of the error.

$$MAE = \frac{\sum_{(u,i)\in test}|prediction_{u,i}-real_{u,i}|}{n_{test}} \tag{10}$$

Where:

n is the total number of ratings-prediction pairs in the test set, $prediction_{u,i}$ is the predicted rating for learner $u$ on learning object j, and $real_{u,i}$ is the actual rating in the real dataset (see Table VIII).

In the graph (see Fig. 7), we see that with the variation of the number of clusters, the magnitude of the error is gradually decreased for the dense matrix "LPLO", which is based on the implicit and explicit preferences of the learners; contrary to the LRLO matrix where the magnitude of the error gradually increases. This is due to the insufficient ratings explicitly expressed by the learner, which leads to a loss of accuracy when assigning learners to clusters. This is also shown in Fig. 6, where we can infer that the less sparse the matrix is, the better the learners are assigned to clusters with similar learning needs. Therefore, the recommendations will be more appropriate.

TABLE VIII.   MAE Value According to the Type of Matrix

| Number of cluster | Mean Absolute Error | |
|---|---|---|
| | Dense Matrix LPLO | Sparse Matrix LRLO |
| 2 | 0.18386 | 1.7154 |
| 3 | 0.08716 | 2.4421 |
| 4 | 0.06501 | 2.6225 |

Fig. 7.   The Accuracy of Clustering the Learners by Matrix.

## VI. Conclusion and Future Work

Recommender systems have become a promising solution for improving the efficiency of e-learning systems. Preference matrices are the basic inputs of recommender systems, because based on these matrices, systems can suggest personalized learning objects and adapt them to the learner's profile. On the other hand, the lack of ratings in the preference matrices can handicap their functioning and consequently the recommendations will be less personalized.

To this end, we have proposed a model of a mediating recommendation system based on a matrix that combines the tacit and explicit behaviors of the learner. Through the exploration of the log file, while exploiting some indicators such as duration, frequency and bookmarks in the preference matrix, in order to obtain better performances.

The k-means clustering algorithm is used to group learners with similar preferences into clusters, in order to recommend to the active learner new learning objects that have not yet been viewed or visited by him and that have been well rated by his closest neighbors.

The results obtained in the experimentation phase illustrate the importance of hybridizing implicit traces and explicit ratings of learners to improve the accuracy of assignment of learners to appropriate clusters.

In our future work, we plan to study the recommendation of sequences of objects and learning activities, based on the dynamic prediction of the learning strategy adapted to the active learner, through evolutionary meta-heuristic algorithms such as: Ant Colony Optimization (ACO) and Particle Swarm Optimization (PSO). This will allow recommending the learner a personalized learning path (scenario).

# DDoS Intrusion Detection Model for IoT Networks using Backpropagation Neural Network

Jasem Almotiri

Department of Computer Science, College of Computers, and information Technology
Taif University, Taif, Saudi Arabia

*Abstract*—In today's digital landscape, Internet of Things (IoT) networking has grown dramatically broad. The major feature of IoT network devices is their ability to connect to the internet and interact with it through data collecting and exchanging. Distributed Denial of Service (DDoS) is one form of cyber-attacks in which the hackers penetrate a single connection and then multiple machines are operating together to attack one target. The direct connectivity of IoT devices to the internet makes DDoS attacks worse and more dangerous. The more businesses adapted IoT networks to streamline the operations, the more allowing of DDoS intrusions at small and large scales to take place. Therefore, the intrusion detection module in the IoT networks is not optional in today's business environment. To achieve this objective, in this paper, an intelligent intrusion detection model is proposed to detect DDoS attacks in IoT networks. The intelligent model is a backpropagation neural network-based framework. The results are analyzed using different performance measures. The proposed model proves a detection rate of 99.46% and detection accuracy of 95.76% using the up-to-date benchmark CICDDoS2019 dataset. Furthermore, the proposed model has been compared with the most recent DDoS intrusion detection schemes and competitive performance is achieved.

## I. INTRODUCTION

IoT networks are considered a considerable movement in the world of networking and data communication. This movement is majorly driven by the fifth-generation network (5G), which is expected to broaden todays' IoT functionalities. As the adaption of IoT networks is in a dramatic increase, IoT network is expected to be a huge growing market.

However, this growth is thwarted by DDoS attacks which are the most prevalent cyber threats. Some cybersecurity experts consider IoT networks as the major force behind DDoS attacks. These types of attacks have a distributive nature; in particular, they depend on one vulnerable device in the IoT network to create an opening for intruders to make use of any other IoT devices to drive a huge amount of traffic.

IoT platform security is embedded in the process of product development of IoT-based devices. However, when it comes to cybersecurity, no data processing unit is an island. From data production, data transmission, data processing, data visualization to data analysis and prediction, all of these major stages of IoT networking are considered open gates for intrusions and hackers to perform their attacks especially

DDoS and Botnet attacks. The botnet is a collection of hijacked internet-connected devices that are used to execute a large-scale attack. The infected devices are controlled by attacks actors who they often cybercriminals and are used to perform particular malicious duties in an unobserved manner from the user. One of the major tasks to be done by a botnet is to generate malicious traffic for DDoS attacks.

DDoS attacks are carried out when multiple machines (devices) are operating together for sake of attacking one target device. Using control and command software, DDoS attacker avails of the weaknesses and security vulnerabilities of one IoT device to control several IoT network devices. Once the target device is in control, DDoS attack admits exponentially requests to be sent to the target device, which enhances the power of attack on one hand and boosts the difficulty of detecting attribution on the other hand, where due to the distributive nature of the DDoS attack, the original source of the attack becomes harder to be identified. DDoS attacks are easy to deal with in the short term, but it becomes very difficult in the long term. Due to the distributed nature of the DDoS attack, it is considered one of the most fatal enemies of the internet of things platform. In principle, if internet-connected devices get hacked, the DDoS malware could easily spread to other devices in the network [1], [2].

Although IoT has used a variety of protocols for security purposes, hackers and intruders developed more complex and intelligent techniques to fulfill their penetrations ending up with misalignment between the speed of IoT development and IoT cybersecurity. In the case of dealing with sensitive data processing and management through IoT platforms, there is a pressure to close the gap that caused an increased vulnerability, especially for crucial data where security becomes the single most cardinal factor that companies, and organizations consider when purchasing IoT products.

In response, a new generation of artificial intelligence-based intrusion detection techniques to address the limitations of the conventional intrusion detection techniques has emerged and adapted as a major building block of IoT security systems. Recently, the awareness to use the machine learning in general and artificial neural networks in particular to secure network traffic against DDoS attacks has increased rapidly. DDoS Detection systems based on artificial neural networks are such typical solutions to model and predict malicious behavior over network traffic flows and Backpropagation neural network are considered one of the powerful yet flexible supervised training algorithms.

In the context of supervised neural networks, backpropagation neural network is considered one of the powerful classifying and filtering engines in this field. Much of the power of backpropagation arises from the fact that the repeated composition of specific types of nonlinear functions boosts the abstract representation power of the neural network. Moreover, an efficient computation of the gradient at each layer can be highly performed by the backpropagation training algorithm. Therefore, backpropagation neural network can efficiently learn the abstract representation of the behavior of network flows in general, and the pattern of the malicious flows in particular.

Some researchers, in this field, deployed backpropagation in its original form to design and develop different schemes for intrusion detection systems. However, the majority of researchers tend to use the enhanced versions of backpropagation in order to address the shortcomings of the classical backpropagation algorithm in an attempt to lower the time and the computational overhead of the training phase or to remedy the convergence difficulties of the classical version. Other scenarios use a standard backpropagation neural network that heavily depends on a variety of features engineering techniques in prior.

These scenarios come at the expense of higher design complexity associated with new born issues related to time cost and resources. Furthermore, in the context of intrusion detection, the overall performance of many of the predictive models based on the enhanced versions do not exceed that can be achieved by the classical one.

With minimal neural network architecture, and without any features preprocessing, the main aim of this work is to prove that the conventional standard backpropagation can be used to build an accurate yet robust predictive model for DDoS attacks. We have achieved this by conducting the training using modern up-to date DDoS dataset and conducting rigorous testing analysis while the performance of the predictive model is benchmarked using highly indicative standard performance metrics.

The major improvements that we presented in this article are reviewed as follows:

- Propose an intelligent DDoS intrusion detection system that can predict DDoS malicious network traffic in IoT networks by exploiting the predictivity power of the standard backpropagation neural network.

- In this work, CICDDoS2019 dataset is used to verify that the proposed detection model applies to different types of DDoS malicious traffic flows.

- We have proved that using low-complexity standard version of backpropagation based neural network can achieve comparable detection performance even though no form of features engineering (such as feature weighting or features selection), was considered.

The rest of the paper is organized as follows: Section II presents related works; Section III describes our proposed DDoS intrusion detection methodology followed by the experimental performance evaluation in Section IV and Section V concludes this paper and suggests future directions.

## II. RELATED WORK

Exploiting the very basic form of backpropagation algorithm applied on multi-layered perceptron neural network, an intrusion detection model seeking a reduction in false alarm rate as a major performance aspect was proposed by [3] where it shows the intrusion recognition capability of the backpropagation algorithm despite the rudimentary framework.

Using internet packet traces as an experimental dataset, authors in [4] used the standard backpropagation neural network to thwart DoS and DDoS attacks in IoT environments.

As a precise and efficient classifier [5] used a standard backpropagation network to classify DDoS traffic after an initial judgment of the characteristics of the abnormal network traffic.

Using a backpropagation-based autoencoder, [6] designed a joint anomaly and signature-based DDoS intrusion detector implemented in the cloud. Based on a behavioral study that collected a variety of DDoS signatures in one database, the targeted traffic was first compared to the known DDoS attacks. If no matching has occurred, then the traffic fed to the backpropagation autoencoder to be classified into DDoS or benign. If a DDoS attack was detected, the signature of this attack was used to update the database of DDoS signatures.

Despite the vivid versatility of backpropagation in designing intelligent intrusion detection models/systems, it has some downsides such as local minima, slow convergence, and network paralysis. These downsides moving the wheel of extension around the axel of standard backpropagation were enhanced versions of backpropagation emerged and implemented for harder predictive tasks such as DDoS/DoS detection. As an example of using an enhanced version of backpropagation in the domain of intelligent intrusion detection, [7] presented an intrusion detection system composed of hybrid phases of misuse detection and anomaly detection by applying the Levenberg-Marquardt algorithm as a technique to optimize the backpropagation-based network that was used as the classification engine of the proposed predictive system.

Applying the same backpropagation customization, authors in [8] used multi-core technology to detect DDoS intrusions via neural networks. Multi-core uses one CPU that combines a couple or more independent cores into a single circuit. Their IP flow-based DDoS intrusion detection technique is built based on the idea that an IP packet holds information of the upper layer which can be exploited into special attributes representing the special characteristics of DDoS attacks in a well-posed manner. Then, attributes vectors are fed into a Levenberg-Marquardt based backpropagation neural network as input to be classified into DDoS or benign traffic.

Authors in [9] proposed a DDoS intrusion detection algorithm composed of two main phases: a training phase and a detection phase. In the training phase, a non-linear time series model called GARCH was used to evaluate the normal traffic

prediction, whereas a feed-forward backpropagation neural network was used as the benign/DDoS classifying engine.

For cloud security, based on backpropagation neural networks, authors in [10] proposed a DDoS detector model that offered a solution to tracing back a given cloud traceback for the sake of finding the source of the real attack. Moreover, they introduced a cloud protector built using a feedforward backpropagation neural network.

## III. METHOD

As IoT networks are broad, the attack surface for this type of network is even broader. This has been reflected in various methodologies and techniques designed to fall under the umbrella of IoT network security. Public Key Infrastructure (PKI) authentication, securing Application Program Interface (API), and network intrusion detection systems, the lists long are just a few of the techniques IT leaders can use to combat the growing malicious penetrations rooted in vulnerable devices of IoT networks. As a rule of thumb, as the ways available for devices to be able to connect, the more ways attackers and hackers can intercept them.

Therefore, one of the most harmonious security techniques that can be deployed for IoT network security is the security gateways, which act as intermediary units between the IoT network devices and the outside world (internet, cloud computing, etc.). These units are equipped with processors chips with more computational capabilities, memory, and processing power rather than that exists in the IoT devices themselves. These additional features enable gateway units to run artificial neural network-based intelligent intrusion detection systems to ensure intruders cannot access the IoT network devices they connect.

Fig. 1 shows the general high-level framework of our proposed DDoS intrusion detection model in the context of IoT networking where at the heart of the IoT securing gateway lies

the proposed intrusion detection model. Fig. 2 illustrates the flow pipeline of our proposed system, which is built using the backpropagation feedforward artificial neural network that trained, validated, and tested using a real benchmark CICDDoS2019 dataset [11]. As illustrated in Fig. 2, once the dataset is pre-processed in a way harmonious to the format accepted by the neural network, it is split into two datasets: training and testing. Then, a backpropagation neural network is trained to obtain the optimal parameters and meta parameters of the network structure. Afterward, the network is ready to be used as intelligent DDoS intrusion detection, where a new set of flow traffic (DDoS and normal traffic) is presented to the network, where it detects the DDoS attack traffic and raises an alarm. The following subsections elaborate each module of our proposed model shown in Fig. 2 in detail.

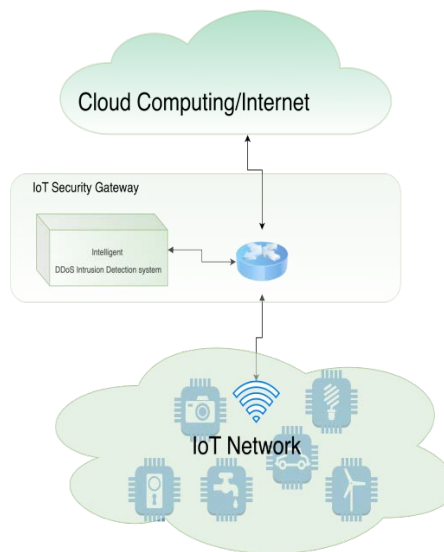

Fig. 1. High-Level Framework of the Proposed DDoS Intrusion Detection System in the Framework of IoT Networks.

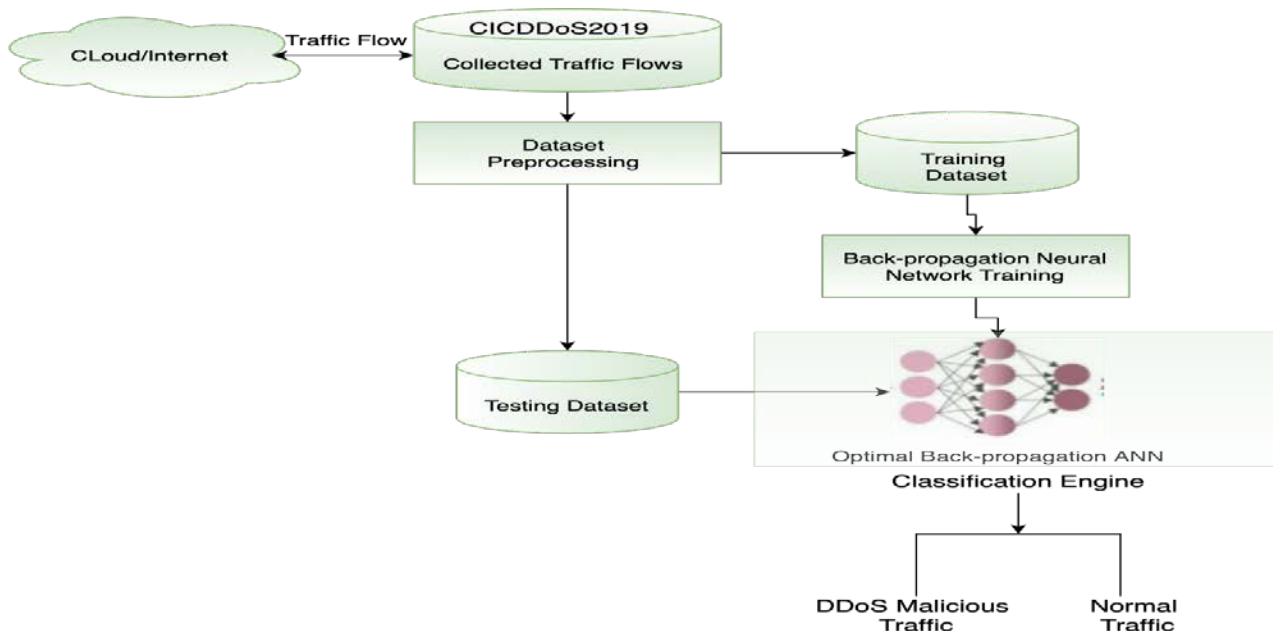

Fig. 2. Proposed DDoS Intrusion Detection System using Standard Backpropagation Neural Network.

## A. Dataset Pre-Processing

To evaluate our backpropagation network-DDoS detection model, the real benchmark CICDDoS2019 dataset [11] is used. This dataset is composed of two types of DDoS attacks: reflection and exploitation in form of both malicious and normal network packets.

Even though the CICDDoS2019 dataset is major consists of numerical values, dataset preprocessing is an essential step to validate its suitability for both: as input to the neural network and for the classification task of the model. Fig. 3 illustrates the basic steps that applied to the raw CICDDoS2019 dataset which include: dataset cleansing, features selection, and dataset normalization.

Initially, the total number of raw dataset features is 81, in the dataset cleansing, we select the features that have zero values, which have no impact on the classification output of the neural network and dropped them out resulting in 22 unique features. Moreover, all dataset samples that contain infinity or misleading values have been removed as well. The label column of the dataset is converted into a numerical representation where 0 represents the benign traffic and 1 represents the DDoS one.

As the last step of dataset preprocessing, the dataset values are normalized using the standard min-max normalization [12], [13] as illustrated in (1):

$$\acute{v_i} = \frac{v_i - min_{DB}}{max_{DB} - min_{DB}} \cdot (new_{DB}^{max} - new_{DB}^{min}) + new_{DB}^{min} \quad (1)$$

where (1) represents the min-max normalization step that linearly transformed the raw database $DB = CICDDoS2019$ values $v_i \in DB$ into new values $\acute{v_i}$ in the range $[new_{DB}^{max}, new_{DB}^{min}]$.

## B. Proposed Model

At the core of the proposed model, a backpropagation feedforward neural network is used to model the behavior of the flows of the network traffic. The basic annotated structure of the backpropagation neural network is shown in the simplest form of the feedforward network structure composed of input units at the left, any number of intermediary hidden layers, and a layer of output units at the right.

Connections from the second hidden layer to the last $L$ hidden layers are hidden whereas the connections from higher layers to lower layers are forbidden. Backpropagation comprises two major phases: (1) Forward phase, and (2) Backward phases. In the forward phase, the outputs of all nodes are computed, the local derivatives of the nodes 'activation function relative to the net inputs are computed as well.

On the other hand, the main task of the backward phase is to aggregate the products of these local values over all paths from the nodes to the network outputs. In the forward phase, the components of an input training vector are fed into the neural network. This results in driving a forward cascade of computations across network layers using the current state of weights to yield the network output, which represents the predicted output of the network. Afterward, the predicted output is compared to the label associated with the training instance and the derivative of the loss function concerning the output is computed.

The derivative of the resulting loss is fed to the backward phase where it is used to compute the loss concerning the weights in all layers in the backward path.

As pictorially illustrated in Fig. 4, Let $\mathfrak{D} = \{y, d\}$ refers to the training dataset composed of the input-output (label) pairs and let $x_j$ refers to the net input of the $j^{th}$ unit where $x_j$ is a linear combination function of the $i^{th}$ weighted outputs $y_i$ of $i^{th}$ layer as in (2):

$$x_j = \sum_i^I y_i w_{ji} \quad (2)$$

Where

$I$ : refers to the number of features of input vector (for our case, $I = 63$).

$w_{ji}$: is the weight of the connection between the layer $(j)$ and the layer $(i)$.

$y_i$ : is the output of the layer $(i)$.

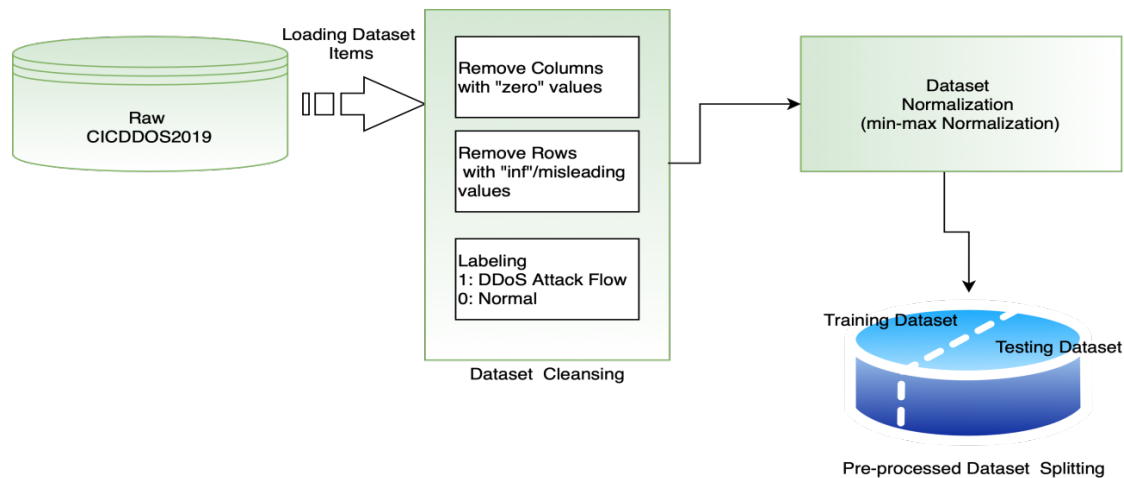

Fig. 3. CICDDoS2019 Dataset Pre-Processing Steps.
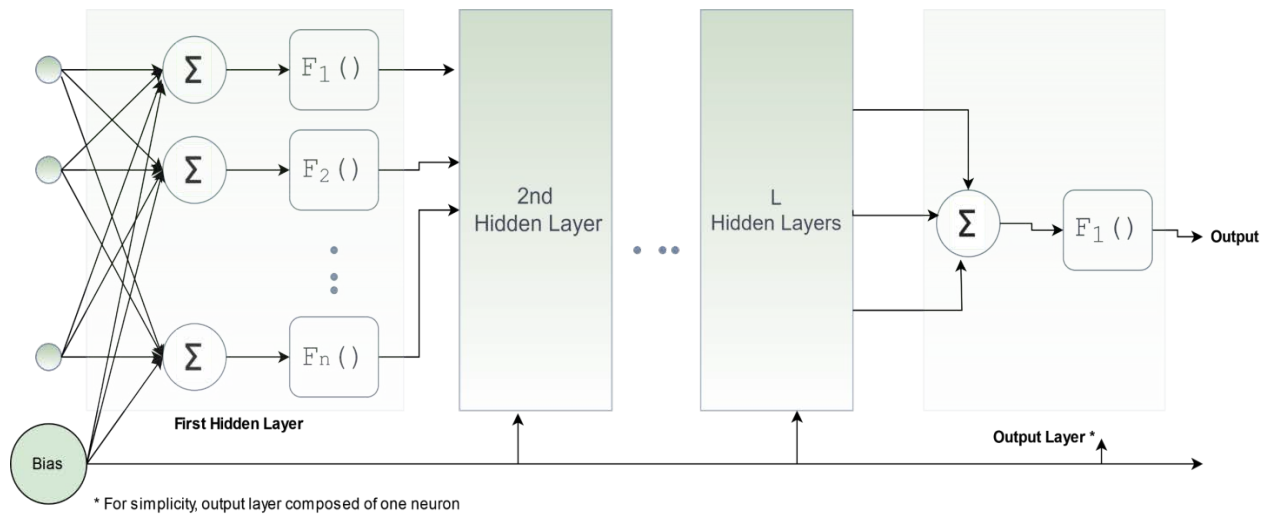

Fig. 4. Backpropagation Neural Network Layers Structure.

As shown in Fig. 4, all neurons are given biases by introducing an extra input line with no input but of a constant output (always has a value of 1) and it treated as an extra weighted input connection. Each neuron in the network has a real valued nonlinear function of its total input as in (3):

$$y_j(x) = \frac{(1-e^{-\alpha x_j})}{(1+e^{-\alpha x_j})} \qquad (3)$$

*where* :

$\Delta w$ : represents the updated value of the weight vector **w**.

$\gamma$: is a positive learning step (learning rate) parameter.

The target is to find a set of weights parameters generated the network that is same as (or sufficiently close to) the desired output, the network model has the given set of weights parameters which used to make predictions and the differences between those predictions and the actual outputs are computed as error values. Typically, we seek to minimize the error of the function given by in (4):

$$x_j = \sum_i^I y_i \, w_{ji} \qquad (4)$$

Where, $E$ is the error function, $d$ is the index over target outputs, $j$ is an index over the output units of the output layer.

Gradient decent of the error function $\nabla E$ lies at the heart of backpropagation, where it seeks to change the weights parameters through multiple evaluations where the optimization algorithm ($\nabla E = 0$) navigates down the gradient of error function till the minimum is found.

## IV. EXPERIMENTAL RESULTS AND DISCUSSION

This section analyzes the performance of the proposed DDoS intrusion detection framework using backpropagation-based predictive model. This system is implemented, and experimentation is performed on Intel(R) Core (TM) i7-4500U CPU @ 1.80GHz and 2.40 GHz with 8GB of RAM and 64-bit Windows operating system. For more deeper experimental analysis and more controllability, we use MATrix LABratory (MATLAB)®2021b to build the back propagation neural network-based model from scratch where the available built-in neural network toolbox has not been used.

### A. Performance Metrics

For purpose of model analysis, we used a subset of CICDDoS2019 dataset [11] we conducted many simulation trials, where the training dataset volume almost equals the volume testing dataset. In order to evaluate the detection performance of the system, we first established the confusion matrix, as shown in Table I. Then, the confusion matrices of the training and testing results are obtained. Based on the confusion matrices we considered the performance metrics that include Accuracy, Precision, F1-measure, False Positive Rate (FPR), Recall, Mathew Correlation coefficient and Kappa coefficients as in (5)-(11).

$$\text{Accuracy (Acc)} = \frac{(TP+TN)}{(TP+TN+FP+FN)} \qquad (5)$$

$$\text{Precision (Pr)} = \frac{TP}{TP+FP} \qquad (6)$$

$$\text{Mathew Correlation Coefficient (Mcc)} =$$
$$\frac{TP*TN-FP*FN}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \qquad (7)$$

$$\text{Kappa Coefficient (K)} = \frac{Obs^{agree} - Expect^{agree}}{1 - Expect^{agree}} \qquad (8)$$

Where

$$Obs^{agree} = ACC = \frac{(TP+TN)}{(TP+TN+FP+FN)},$$

$$Expect^{agree} = \frac{A+B}{(TP+TN+FP+FN)},$$

TABLE I. CONFUSION MATRIX

|  | Predicted | |
|---|---|---|
| **Actual** | Normal | DDoS |
| Normal | TN | FP |
| DDoS | FN | TP |

$$A = \frac{(TP + FN)(TP + FP)}{(TP + TN + FP + FN)},$$

$$B = \frac{(FP + TN)(FN + TN)}{(TP + TN + FP + FN)}$$

$$\text{FPR} = \frac{FP}{FP+TN} \qquad (9)$$

$$\text{F-Measure (F1)} = \frac{2}{\frac{1}{Recall}+\frac{1}{Pr}} \qquad (10)$$

$$\text{Recall (Sensitivity)} = \frac{TP}{TP+FN} \qquad (11)$$

where, False Positive (FP) and False Negatives (FN) refers to misclassified events. In contrary, True Positive (TP) and True Negative (TN) refers to the events that are correctly predicted by the model, i.e., if the model predicts normal events as normal, then, it is recorded as TN, whereas, if the model predicts the DDoS attack traffic flow as a DDoS malicious attack traffic, then it is recorded as TP.

*B. Results*

In this section we performed a series of experiments to determine the optimal network model architecture of the proposed backpropagation-based model along with varying many networks' hyper-parameters.

Afterwards, we performed another set of experiments that analyze the impacts of varying specific network parameters on the detection performance of the proposed intrusion detection model. We used four layers backpropagation neural network with two hidden layers of 64 neurons with $tanh(x) = (\frac{2}{1+exp(-\alpha x)} - 1)$ as activation function, where the optimal value of the sigmoid slope $\alpha$ parameter is to be determined through the experimental analysis.

Table II shows the architecture of this network whereas Table III shows the optimal values of hyper-parameters of the backpropagation neural network used in our proposed intrusion detection model. Dataset was normalized via min-max normalization with [0.5, +0.5] range and then have been split

into training and testing sub-datasets with normal/DDoS distribution as shown in Fig. 5.

Although in the real-time applications, the number of DDoS attack traffic is much less than the normal one, for a robust intrusion detection system, we used a training dataset composed of about 50% DDoS attacks and the same scenario was used for test dataset as can be noted from Fig. 5.

Table IV and Table V show the confusion matrices of both training and testing phases respectively, meanwhile, Table VI represents the detection performance of both stages in terms of performance metrics listed in (5)-(11).

From Table IV, Table V, TPR and TNR are high whereas FPR and FNR are low. Moreover, besides the high detection performance shown in Table VI, it is noticeable that there is a subtle difference in the detection performance between the training and testing phases, therefore, our backpropagation model is not underfit or overfit.

In terms of True positive rate, True negative rate, False positive rate, and False negative rate illustrated in (12)-(15), Table VII summarizes a comparison between our approach and a recent work proposed by Liu et al. [14].

TABLE II. NETWORK LAYERS ARCHITECTURE

| Layer | Neurons number | Activation Function |
|---|---|---|

TABLE VI.    AVERAGE DETECTION PERFORMANCE OF THE PROPOSED BACKPROPAGATION NN-BASED DDoS INTRUSION DETECTION MODEL

| Performance Metric | Training Phase | Testing Phase |
|---|---|---|
| Accuracy | 0.9595 | 0.9576 |
| Detection Rate (Recall) | 0.9946 | 0.9945 |
| Specificity | 0.9242 | 0.9207 |
| Precision | 0.9293 | 0.9261 |
| FPR | 0.0758 | 0.0793 |
| F1-Score | 0.9609 | 0.9591 |
| MCC Coefficient | 0.9212 | 0.9177 |
| Kappa Coefficient | 0.9189 | 0.9152 |

$$True\ Positive\ Rate\ =\ \frac{TP}{TP+FN} \qquad (12)$$

$$True\ Negative\ Rate\ =\ \frac{TN}{TN+FP} \qquad (13)$$

$$False\ Positive\ Rate\ =\ \frac{FP}{FP+TN} \qquad (14)$$

$$False\ Negative\ Rate\ =\ \frac{FN}{FN+TP} \qquad (15)$$

As can be noted from Table VII, detection performances achieved by our proposed BP-based model were higher compared to those achieved by the different ML-based listed in Table VII. Although Liu *et al.* [14] had considered only the results of the neural network and disregarded the other approaches due to the unacceptable results, our proposed model still has higher performance. On the other hand, In contrary to the simple preprocessing of neural network inputs required by our proposed model, Liu *et al.* [14] used the Fast Fourier Transform (FFT) coefficients and the information entropy as input features to the input layer of the neural network which entails extra computational overhead and preprocessing of the network traffic before the detection takes place.

Furthermore, we compare our proposed DDoS intrusion detection model with various related Machine Learning approaches as shown in Table VIII.

TABLE VII.    THE AVERAGE PERFORMANCE OF OUR PROPOSED BACKPROPAGATION ANN MODEL IN TERMS OF FPR, FNR, TPR, TNR METRICS

|  | Year | FPR | FNR | TPR | TNR |
|---|---|---|---|---|---|
| Random Forest [14] | 2021 | 0.844 | 0.0001 | 0.999 | 0.156 |

| | | | | | |
| Bandwidth Control Mechanism + Extreme Gradient Boosting Algorithm (XGBoost) [15] | 2020 | 0.997 | 1.000 | 1.0000 | 1.0000 |
| Logistic Regression [15],[16] | 2020 | 0.8000 | 0.8000 | 0.8000 | 0.8500 |
| Naive Bayes [15],[17] | 2020 | 0.7700 | 0.7700 | 0.7600 | 0.8400 |
| ID3 [15],[18] | 2020 | 0.9850 | 0.9990 | 0.9900 | 0.9900 |
| Random Forest [15],[19] | 2020 | 0.9855 | 0.9900 | 0.9900 | 0.9900 |
| | | | | | |
| Autoencoder [20] | 2021 | 0.8945 | - | - | - |
| Restricted Boltzmann [20] | 2021 | 0.5651 | - | - | - |
| K-means [20] | 2021 | 0.7538 | - | - | - |
| Expectation-Minimization (EM) [20] | 2021 | 0.7096 | - | - | - |
| | | | | | |
| Proposed Model | - | 0.9576 | 0.9946 | 0.9591 | 0.9261 |

As shown in Table VIII The obtained results show that the detection performance of our proposed BP-based DDoS predictive model is far superior to that had been reported by the authors of the CICDDoS2019 dataset [11] using ID3, RF, NB, and LR algorithms owing to the nonlinear modeling power of the backpropagation neural network. The same findings can be noticed if the detection performance of our proposed BP-model is compared to Autoencoder, Restricted Boltzmann, K-means, and Expectation-minimization machine learning algorithms adopted by [20].

Even though ID3, RF, NB, and LR algorithms were re-generated by [15], they have achieved superior detection performance to that had been achieved by [11]. Authors in [15] attributed their higher results to the performed preprocessing steps they adapted. However, in comparing our results to that reported by [15] for LR and NB-based algorithms, we can conclude that the influence of the pre-processing is limited because our BP-model that processed by the simple classical pre-processing steps was able to achieve superior results in comparison with these algorithms.

A regular BP-based detection model and the detection performance of [15] built is based on sequential steps of preprocessing and a combination of the bandwidth control mechanism and Extreme gradient boosting algorithm.

### C. Experiments on Different Network Parameters Tunning

Since backpropagation network is a gradient-descent based learning algorithm, the first steps that come into consideration while building the network architecture is the initial state of the network as well as the network parameters tunning of the network in order to converging to the optimal minima of loss function gradient in least number of epochs.

Therefore, in the following subsections, we investigate the influence of the required number of Epochs, learning rate $\gamma$ and sigmoid slope $\alpha$ on the detection performance of the system in training and testing phases and then analyze for the most appropriate values of these parameters.

It is worthy to mention that the backpropagation network is highly sensitive to the initial state of their weight's metrices, we have turned the initial weights to random values in the range $-0.285 \leq w^{ini} \leq -1.06$ before we are conducting these experiments. Otherwise, improper weights initialization can drive the network to saturate at a static accuracy threshold and stuck in a static local minimum.

*1) Impact of increasing number of epochs*: To examine the effect of increasing epochs number of the training phase on the detection performance in the prediction phase of the proposed BP-based model in terms of accuracy, recall, FPR, Precision, Kappa and MCC coefficient. First, we set the span of epoch to be from 200 to 9000 and fix other parameters such as learning rate, initial weights, and sigmoid slope, then a comparative analysis between the impact of epochs number on the detection performance on both training and testing phases is conducted as illustrated in Fig. 6. and Fig. 7.

As illustrated in Fig. 6 and Fig. 7 the predictive behavior of the proposed model in training and testing phases is almost the same, which ensures that our model is not underfitting or overfitting. To emphasize this behavior further and to ensure the stability and robustness of the prediction performance, the difference of accuracy performance between these phases are zoomed in as illustrated in Fig. 8 where it can be noted that the differential behavior decreases steadily to less than 0.1e-3 and in unison manner as the number of the training epochs increases.

As can be noted from Fig. 6, the accuracy of detection increases steadily as the training epochs increases until it hits $Epoch = 2000$, where beyond this value, the rate of change in detection is saturated and cannot be traced without zooming in effect. At $Epoch = 4500$, the accuracy behavior shows a temporary tenuous decrease; however, it is not exhibited by the Recall and FPR performance behavior. It is clear that by epoch 4000, almost accuracy, recall, and FPR performances start to converge quickly to a steady-state behavior, therefore 4000 is a sufficient number of training epochs for sake of optimal performance. Although FPR, as shown in Fig. 6, reaches the minimum at $Epochs = 2000$, the accuracy and sensitivity of the predictive model do not show the same characteristic, and as a compromised solution, Epochs = 2000 was not adapted.

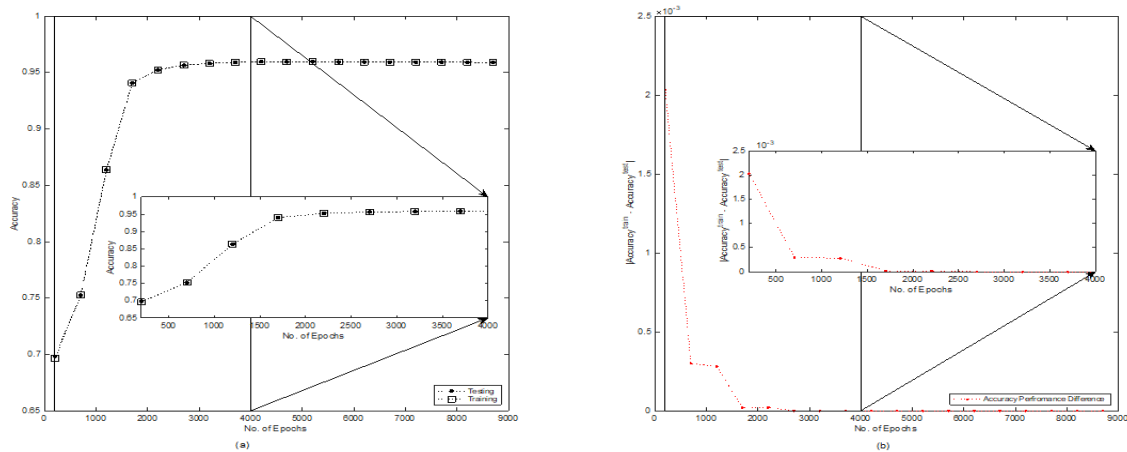

Fig. 6. (a) Accuracy Performance of the Proposed Model in Training and Testing Phases Versus Number of Training Epochs Zoomed in from Epoch No = 4000 to 8000. (b) Difference between the Accuracy Detection of Training and Testing Phases Zoomed in from Epoch No =4000 to 8000.
Fig. 7. Accuracy, Recall (Sensitivity), and FPR Performance of the Proposed Model in Training and Testing Phases Versus Number of Training Epochs Zoomed in from Epoch No = 4000 to 8000.

Fig. 8. Precision, Kappa and MCC Coefficients based Performance of the Proposed Model in Training and Testing Phases Versus Number of Training Epochs Zoomed in from Epoch No = 4000 to 8000.

Epochs number of 4000 may appear as a large number of training iterations that required for the neural network to reach a steady detection performance which insinuates a computational challenge appertains to the running time required to train the network. However, due to the simple and efficient network architecture, the entire training phase takes less than five minutes (299 seconds at rate of 13 seconds per epoch). On the other hand, the prediction stage of the system is more time-crucial in comparison to the training phase. Most of the computational overhead is front-loaded during the training phase, the prediction process for 50,000 traffic flows takes less than 0.068 second (in a rate of 1e-6 second per each traffic flow), which is considered as highly computational efficient.

*2) The variation of sigmoid slope experiment*: In this experiment, the slope of sigmoid function (activation function used in all network neurons) was changed in the range $0 \leq \alpha \leq 1$ and the detection accuracy, sensitivity and FPR metrics were recorded.

As shown in Fig. 9, the performance of the system shows a noticeable enhancement as $\alpha$ parameter is increased from 0.1 to 0.2, however, as the value of $\alpha$ transcends 0.2, the system shows a degradation in terms of accuracy and FPR. Furthermore, as the value of $\alpha$ transcends 0.5, the network fails to converge.

On the other hand, even though detection rate shows an enhancement as value of $\alpha$ transcends 0.2, it is unnoticeable and in comparison, to the FPR-based behavior, it cannot be adapted. Thus, based on the experiment we have adapted $\alpha = 0.2$.

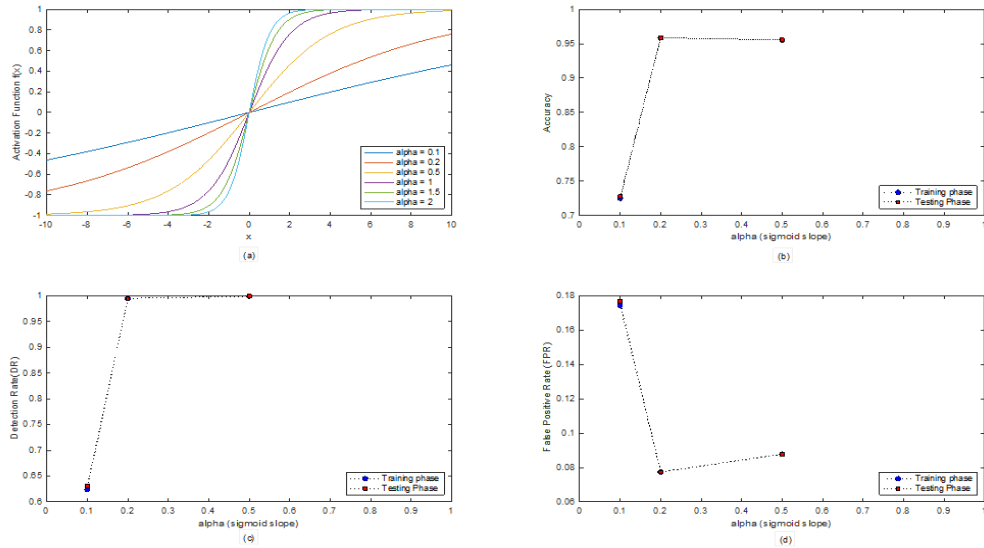
*3) The variation of learning rate experiment*: In this experiment, the effect of learning rate on the system performance is investigated. As shown in Fig. 10, the detection performance is decremental as the learning rate exceeds $\gamma > -10$, whereas, system performance, for all metrics, shows almost a saturated behavior against increasing learning rate in the range $-30 \leq \gamma \leq -10$. Therefore, $\gamma = -10$, was adapted.


Fig. 9. System Performance (in Terms of Accuracy, Detection Rate and FPR) Under different Values of Sigmoid Slope $\alpha$. (a) Sigmoid Activation Function Profiles for Different Values of Slope $\alpha$. (b) Detection Accuracy versus Changing Sigmoid Slope $\alpha$ Parameter. (c) Detection Rate versus Changing Sigmoid Slope $\alpha$ Parameter. (d) FPR versus Changing Sigmoid Slope $\alpha$ Parameter.

Fig. 10. Accuracy, Recall (Sensitivity), and FPR Performance of the Proposed Model in Training and Testing Phases Under Different Values of Learning Rate Parameter $\gamma$.

## V. CONCLUSION

In this paper, we have proposed a backpropagation neural network-based methodology for DDoS attacks detection in IoT networks. CICDDoS2019 dataset has comprehensive categories of reflective DDoS attacks that have been considered, so our scheme uses this dataset for model training and evaluation. In contrast to many machines learning-based DDoS intrusion detection models that adapt numerous preprocessing steps and multiple stages and hybrid types of machine learning algorithms to attain high detection performance, our proposed model requires a simple preprocessing step used the standard backpropagation neural network only as a detection engine where we have achieved competitive detection performance. Results show that our model achieves a recall of 0.9946 and accuracy and FPR of 0.9576 and 0.0793 respectively. In our experimental results, we have conducted extensive comparisons with other up-to-date DDoS intrusion detection schemes, and we examined the effect of changing epoch parameter on the overall performance of the backpropagation neural network, however, for further detection performance amelioration, tunning other hyperparameters and examining their impact can be offered as a future work where different approaches such as Bayesian optimization and Random search can be utilized for this purpose.

*Abstract*—Recently, Sentiment analysis from Twitter is one of the most interesting research disciplines; it combined data mining technologies with natural language processing techniques. The sentiment analysis system aims to evaluate the texts that are posted on social platforms to express positive, negative, or neutral feelings of people regarding a certain domain. The high dimensionality of the feature vector is considered to be one of the most popular problems of Arabic sentiment analysis. The main contribution of this paper is to solve the dimensionality problem by presenting a comparative study between two feature selection algorithms, namely, Information Gain (IG), and Chi-Square to choose the best one which may lead to improve the classification accuracy. In this paper, the Arabic Jordanian sentiment analysis model is proposed through four steps. First, a preprocessing step has been applied to the database and includes (Remove Non-Arabic Symbols, Tokenizing, Arabic Stop Word Removal, and Stemming). In the second step, the TF-IDF algorithm is used as a feature extraction method to represent the text into feature vectors. Then, we utilized IG and Chi-Square as feature selection steps to obtain the best subset of features and decrease the total number of features. Finally, different algorithms have been used in the classification step such as (SVM, DT, and KNN) to classify the views people have shared on Twitter, into two classes (positive, and negative). Several experiments were performed on Jordanian dialectical tweets using the AJGT database. The experimental results show the following: 1) The information acquisition algorithm outperformed the Chi-Square Algorithm in the feature selection step, as it was able to reduce the number of features from 1170 to 713 and increase the accuracy of the classifiers by 10%, 2) SVM classifier shows the greatest classification performance among all the classifiers tested which gives the highest accuracy of 85% with IG algorithm.

*Keywords—Sentiment analysis; Information Gain (IG); Chi-Square; AJGT database*

## I. INTRODUCTION

In the past few years, people have been able to interact and share comments across a variety of social media platforms. People all around the world use social media websites to share their ideas and feelings, exchange information, and share news in an easy way. Twitter is a social media website that was launched in 2006 and quickly grew in popularity throughout the world, with over 313 million monthly active users and more than 40 languages supported [1].

The Twitter platform allows users to upload short posts known as tweets to share their feelings, opinions, and thoughts on a wide range of topics. The number of Twitter users in the Arab world is growing rapidly, and a huge amount of Arabic tweets are generated daily. Because of the Extensive use of the Twitter website, media organizations and companies are interested in learning what people think and feel about their commodities, services, and products through their tweets by using sentiment analysis systems.

Sentiment analysis (SA), often defined as opinion mining, is a Natural Language Processing (NLP) process that contains automatically detecting an attitude from a text that is connected to a specific issue. Oueslati et al. in [2] described sentiment analysis as a "method used to determine favorable and unfavorable opinions toward specific products and services using large numbers of textual data sources". The main purpose of SA is to discover people's feelings, opinions, beliefs, emotions, and attitudes expressed in natural language whether positive, negative, or neutral about a person, an organization, a product, a location, or an event, and how this changes over time.

Machine learning and lexicon-based techniques are the two main strategies used in the literature to create SA systems. The lexicon-based technique uses a predetermined vocabulary with weighted terms and their sentiment inclination to estimate the sentiment tendency of text data. In this strategy, the process of classifying the text is done using its set dictionary as described in [3]. While the Machine Learning (ML) strategy uses well-known ML algorithms to solve SA as a classification problem [3]. In several literatures, we discovered that the two methodologies were blended to create a hybrid approach.

Sentiment analysis research in English has made significant progress, but it is still restricted in the Arabic language. The Arabic language has a complicated structure, according to its ambiguity and extensive morphological properties. This, along with having wide range of dialects and resource scarcity, makes progress in Arabic SA research difficult. Because of the significance of the Arabic language, this research focusing on assessing the sentiment of Arabic tweets shared by a huge number of users on Twitter by using machine learning approach.

One of the difficult issues that machine learning methods encounter in sentiment analysis and more generally in text classification is a large number of the features in the using dataset. Where a feature can have a favorable or negative impact on classification performance based on its relevance and redundancy with regard to the class labels. Therefore, feature selection approaches are necessary to enhance the accuracy and efficiency of classification algorithms by picking the most relevant and discriminating feature vectors. Feature selection methods determine the most useful features by measuring the quality of a features subset with which the best performance can be obtained.

This work examined the impact of two feature selection techniques (Chi-Square, and Information Gain (IG)) on the performance of three classifiers (DT, KNN, and SVM) that trained on Jordanian Arabic Tweets to create a sentiment analysis model. The Arabic Jordanian General Tweets (AJGT) Dataset is used in this study to classify Jordanian tweets in two classes (negative, and positive). The AJGT dataset involves 1,800 tweets that are categorized as (900 positives, 900 negatives) represent people's opinions on different topics.

The study is conducted as follows. The associated study is discussed in Section II. The technique of the proposed model is explained in Section III. Section IV discusses the experiments and their outcomes. Section V concludes with a summary of the study's findings.

## II. RELATED WORK

In the sentiment analysis literature, a variety of machine learning techniques have been utilized [4-6]. In the classification task, the feature selection approach is used to increase performance by reducing dimensionality. There is a substantial amount of published work in the English language that uses several feature selection techniques to increase the performance of the sentiment analysis model [7]. On the converse, the influence of feature selection on dialectal Arabic sentiment analysis has received less attention.

Duwairi and El-Orfaili [8] examined the effect of feature correlation, stemming, and n-gram models on sentiment analysis of Arabic text. For text representation, several N-gram models of words and characters were utilized. In this research, two datasets were utilized to conduct experiments. The first dataset is named the Politics dataset it contains 300 reviews of which164 are categorized as positive reviews and 136 are categorized as negative reviews. The authors gathered these reviews from Aljazeera webpage. While the second dataset is known as the Movie dataset and is open to the public. Three classification algorithms were employed to classify the reviews (SVM, Naïve Bayes, and K-NN). From the result, SVM and Naïve Bayes classifiers achieve better performance. Substantial improvement has been achieved by using the top 1200 correlated features and word N-gram with Naïve Bayes algorithm to produce the most increased accuracy with 97.2%.

Baker et al., [9] introduced the first research of epidemic illnesses based on tweets in the Arabic language by developing a novel sentiment analysis system that aims to identify Influenza from Arab countries' tweets. The authors of this work obtained, labeled, filtered, and analyzed Arabic-language influenza-related tweets. The following algorithms were used to evaluate the system's quality and performance: DT, K-NN, NB, and SVM. From the tests, the best accuracy value of detecting influenza was 83.20%, which was achieved in the NB algorithm.

Altaher Taha [10] proposed a novel technique for sentiment analysis of Arabic tweets using features weighting and deep learning. In this work, stop word removal, tokenization, and stemming are utilized as preprocessing methods, followed by the use of two feature weighting methods (Chi-Square and Information Gain) to give high weights to the most important features of Arabic tweets. Second, the deep learning approach is used to efficiently and correctly classify Arabic tweets as either positive or negative. The suggested methodology was compared to the performance of different classification algorithms such as Neural Networks (NN), Support Vector Machine (SVM), and Decision Tree (DT) using the same data gathered from Arabic tweets. The suggested method exceeds the others, achieving the maximum precision and accuracy of 93.7% and 90%, respectively.

El Rahman et al., [11] developed a model that can classify tweets as negative, positive, or neutral using different techniques to improve the classification accuracy. The authors of this study used Twitter API to extract Tweets on two topics: KFC and McDonald's, in order to determine which restaurant is more popular. This presented methodology combined the use of both unsupervised and supervised machine learning techniques. Firstly lexicon-based algorithms have been used to create previously unlabeled data. After that data was input into several supervised models for training purposes, including (SVM, NB, DT, and RF). Different testing measurements, such as f-score and cross-validation, were used to test the outcomes of the suggested models. As a consequence, both positive and negative reviews show that McDonald's is more popular than KFC.

Ghallab et al., [12] presented a deep survey of the current literature related to Arabic sentiment analysis (ASA). The major aims of this review are to encourage research and to identify new areas for future study in ASA, Analyze and compare the methods used in each study and its results, also to make it easier for other researchers to find similar works. After filtering, this review focused to analyzed 108 published studies from 22 conferences and 11 journals proceedings. The conclusions of the review indicate that there is little study on creating standard datasets and using promising classifiers. Furthermore, the review shows limited research interested in designing a novel feature representation that appropriates for the Arabic language characteristics. Finally, the review highlights future research in the development of recommender systems in several areas with the goal of an improved framework for ASA.

## III. PROPOSED METHODOLGY

In this part, we will clarify the parts of the suggested sentiment analysis model for Twitter in more detail. As seen in Fig. 1, the suggested model is divided into two parts: Training and Classification. The goal of the training part is to create a classification model that can discriminate between negative and positive tweets based on input labeled tweet collections.

Then during the classification part, the previously trained classification model will apply to assign a negative or positive label to the new unlabeled tweets. This proposed model includes four steps: Preprocessing, Feature Extraction, Feature Selection, and the Classification Model for Sentiment Analysis. The overall steps of the proposed model are shown in Fig. 1.

### A. Arabic Jordanian General Tweet (AJGT) Dataset

Arabic Jordanian General Tweets is a new dataset Created 6in 2017 by Alomari et al., [13] for the purpose of sentiment analyses, and it contains 1,800 tweets that are categorized as (900 positives, 900 negatives) represent people's opinions on different topics. The AJGT has been written in Jordanian dialect and MSA, and it's publicly available as a Github project.

### B. Preprocessing

The major goal of this step is to process the input tweet text by using natural language processing approach to prepare it for the next step of appropriately extracting the features. In this study, there are different preprocessing steps adapted in the data like filtering, tokenization, and stemming. These steps are clarified in more detail as below:

*1) Remove non-arabic symbols*: Most Arabic tweets on Twitter involve noise, like elongations, diacritical marks, mixed language, and special characters. Therefore, one of the most crucial stages in preparing Arabic text for Twitter is to clean up the tweets by eliminating this kind of noise [14]. AJGT dataset has some special characters like (!, ., ?, %). To eliminate the noise from the text, non-Arabic characters are removed by using the cleaning method. As illustrated in Fig. 2, The cleaning procedure checks if each character in the text of the tweet belongs to the Arabic alphabet by reading it character by character. If a character belongs to the Arabic alphabet, it is chosen; otherwise, it is replaced with white space by.

*2) Tokenizing*: Tokenization is only a segmentation technique of the sentences. The goal of this process is to divide sentences into smaller pieces called "tokens", whether that is words or phrases [15]. There are several ways for dividing the phrases in RapidMiner, including using the n-gram approach. The n-gram is a type of graph that is based on the number of letters in a word (n-number-of-tokens) and is utilized to keep the sentences at its meaning [16]. When n=2, it's referred to as diagrams, and when n=3, it's referred to as trigrams. For n=3, a sequence of three consecutive words (tokens) is created for every Arabic tweet in the dataset. In this study, we used a unigram option which means dividing the sentence into single words, each part representing a word.

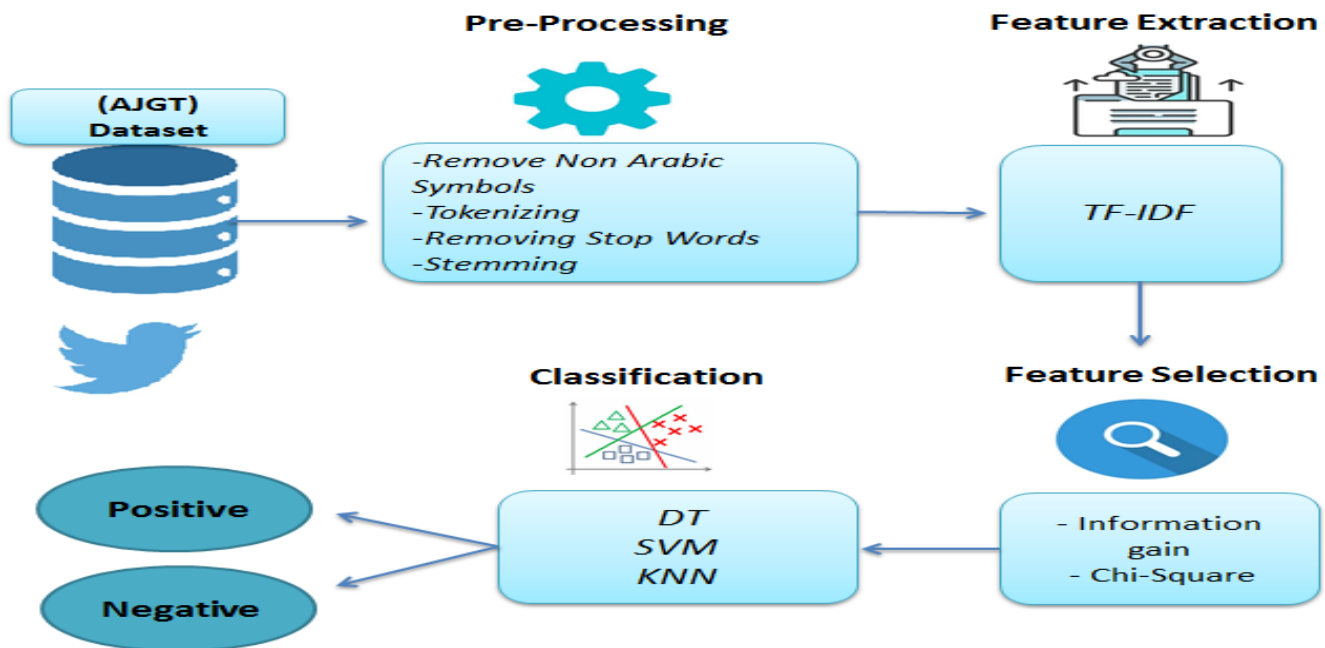

Fig. 1. The Proposed Model Framework.
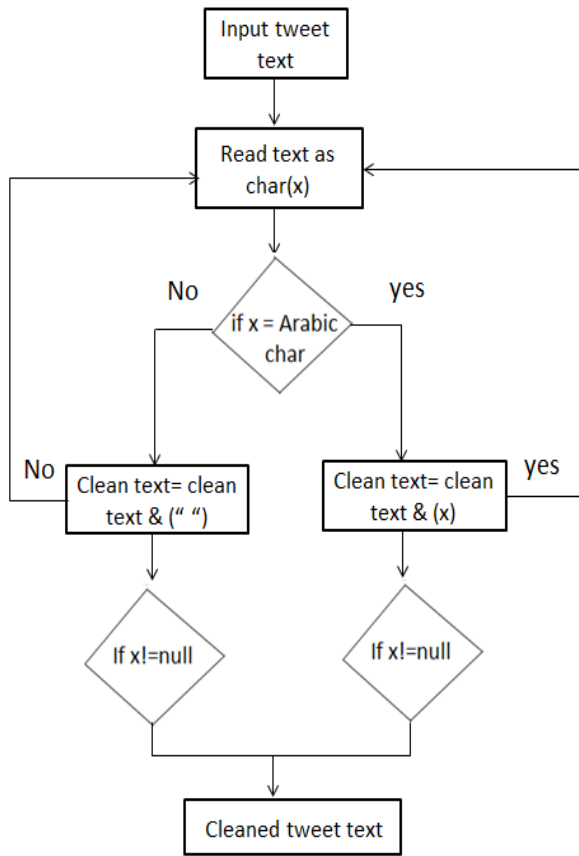

Fig. 2. Cleaned Method.

*3) Arabic stop word removal*: This step is one of the most popular used preprocessing techniques in different NLP applications. This task is employed to eliminate unnecessary and meaningless words [17]. Stop words refer to phrases that appear frequently in Arabic writings, such as (i.e. الى , من ,بعد, قد ,كما , لهم ). In this step, each token is compared to the stop word list that already exists. If it's on the list, it will be removed.

*4) Stemming*: Replacing a word with its stem means returning it to its original form. this strategy has a significant influence on reducing storage requirements and eliminating redundant terms. Because many Arabic words have the same stem, converting words with the same stem will eliminate redundant terms, for example, the words تعمل, يعمل, يعملون have the same stem which is عمل so all of these words will be replaced with the word عمل. There are two ways to stem a word: reducing it to its three-letter root and light stemming, which eliminates frequent suffixes and prefixes but does not reduce it to its root. In this study, we used root stemming (Porter's Stemmer algorithm).

*C. Feature Extraction*

After the preprocessing step, the text should be converted into a numeric representation that the ML classifier can interpret. A vector model, often called a feature model, is a model that is represented by a matrix of word weights. Weighting Word is a method of assigning a score to the

frequency with which a phrase occurs in a text document [18]. TF-IDF (Term Frequency-Inverse Document Frequency) is one of the popular methods for weighting words. The idea of TF-IDF is that it calculates the frequency of each token in a tweet [19]. Because each tweet is varied in length, a term may occur more frequently in a long tweet than in a short tweet. As a result, term frequency is frequently split by the document's length (the total words in the document). The TF-IDF value shows how important a token is to a document in the tweets.

*D. Feature Selection*

The classification's performance is heavily influenced by the feature vector. Notably, that features if, by excluding or including them, the performance would improve or decrease. The relevant features are critical to the training phase because it has an informative aspect that would enhance the classification. On the other hand, the irrelevant ones are less informative, thus including them may have an adverse effect on performance. Determine which of the features are irrelevant or relevant is the objective of this step [20]. In this section, two feature selection strategies were used to extract the most relevant and meaningful features which are Information Gain and Chi-Square (IG).

*1) Information Gain (IG)*: IG is a useful feature selection method that assesses how informative a feature is about the class. IG denotes the reduction of uncertainty in selecting a category by knowing when the value of the feature. IG is a ranking score algorithm which can be computed for a term as shown in (1) [21]:

$$IG = \sum_{i=0}^{m} P(c_i) \log(P(c_i)) + P(t) \sum_{i=0}^{m} P(c_i|t) \log(P(c_i|t)) + P(\bar{t}) \sum_{i=0}^{m} P(c_i|\bar{t}) \log P(c_i|\bar{t}) \quad (1)$$

$c_i$ Represent the $i$th category, the probability of the $i$th category is $P(c_i)$. The probability that the word $t$ will occur or not appear in the documents are represented by $P(t)$ and $P(\bar{t})$. $P(c_i|t)$ Represents the probability of the $i$th category if the term $t$ appeared, while $P(c_i|\bar{t})$ represents the likelihood of the $i$th category if the word $t$ did not exist.

*2) Chi-Square*: The Chi-Square of independence is a statistical hypothesis test that calculates the difference between predicted and observed frequencies for two events [22]. The purpose of this test is to see if a difference between observed and predicted data is due to chance or if there is a link between the events. In feature selection, the two events to know the relationship between are the occurrence of the term and the occurrence of the class. Few studies have looked into the impact of utilizing the Chi-Square feature selection approach in Arabic sentiment analysis, such as [23]. In this study, The value for each term concerning the value of the class is calculated as shown in (2).

$$X^2(t,c) = \frac{D \times (PN - MQ)^2}{(P+M) \times (Q+N) \times (P+Q) \times (M+N)} \quad (2)$$

Where $D$ represented the total number of tweets, $P$ denotes the count of tweets in class $c$ that include the term $t$. $Q$ is the number of Arabic tweets containing $t$ occurring without $c$.

While the number of tweets in class c that occur without t is M. While, $N$ is the number of tweets from other classes that do not include term $t$.

### E. Classification Algorithms

*1) Decision Tree (DT):* It is a hierarchical tree that divides data into groups depending on attribute value conditions. according to another definition, it is the technique of recursively partitioning training data into smaller pieces based on a series of tests that are displayed at each branch of the tree [24]. Every node in the tree represented a feature training test, and each branch dropping from the node matched the feature value. For example, to categorize an instance, start with the parent node, verify its feature, and then move down the tree branch to the value of the feature for the specific instance which knows the leaf node (or terminal node) and represents the class label [25]. In the text situation, decision tree nodes are usually represented by words in tweets. several techniques are employed in the decision tree to improve classification accuracy. We used a DT with a maximum depth of 10 in this work. This algorithm is based on a gain ratio-based selection criterion for deciding which characteristics to separate.

*2) K-Nearest neighbor (K-NN):* It's a ranking approach that uses a method based on the number of nearest neighbors and the distance between both the training data and the target data. [26]. Therefore, to make a prediction task, kNN utilizes similarity measures to make a comparison between a particular test entry and the training data set An n-featured record is displayed for each data entity. Each data entity displays an n-featured record. To guess a class label for an unidentified record, The kNN algorithm selects k recodes from the training data set that are the nearest to the unknown records. One of the most widely used for calculating this distance is called Euclidean measurement. In this study, the value of k is set at 5 and the used distance measure is Mixed Euclidean Distance.

*3) Support vector machine (SVM):* The SVM method was chosen because it is one of the most well-known classifiers in latest years. In the sentiment analysis research area, the SVM classifier outperformed other classifiers in several studies such as in [27,28]. The goal of SVM is to discover the Highest Marginal Hyperplane, which is the maximum margin between the hyperplane and the points on the hyperplane border. In general, SVM provides the benefit of overfitting protection and the ability to handle huge feature spaces. In this study, a radial basis function kernel SVM (RBF SVM) was used.

### IV. PERFORMANCE EVALUATION METRIC

To analyze the efficiency of the suggested strategy, the following standard assessment measures were used:

*1) Accuracy:* It's an important metric to assess the achievement of the classification task. It is represented as the percentage of correctly classified samples to the total samples. thus, it can be calculated mathematically by using the formula shown in (3) [29]:

$$Accuracy = \frac{TP+FP}{TP+FP+TN+FN} \tag{3}$$

*2) Precision:* It determines how strict the classification output is. It is described as the percentage of samples accurately classified as positive compared to the total number of samples classified as positive. thus, it can be calculated mathematically by using the formula shown in (4) [30]:

$$Precision = \frac{TP}{TP+FP} \tag{4}$$

*3) Recall:* this metric is used to determine the quality of the classifier's output. It can be calculated mathematically by using the formula shown in (5) [30]:

$$Recall = \frac{TP}{TP+FN} \tag{5}$$

Where:

(TP) is the number of Arabic tweets properly classified as belonging to the correct class by the classifier.

(TN) is the number of Arabic tweets successfully classified as not belonging to the right class by the classifier.

(FP) is the number of Arabic tweets wrongly classified as belonging to the correct class by the classifier.

(FN) is the number of Arabic tweets wrongly classified as not belonging to the correct class by the classifier.

### V. RESULT AND DISCUSSION

In this work, three experiments were undertaken to examine the Impact of feature selection techniques and some classification algorithms on the dialectal Arabic sentiment analysis. In the first experiment, we applied classification algorithms directly to the AJGT database, while we applied two methods of feature selection (information acquisition and Chi-Square) in the second and third experiments to compare them and choose the best method that enhances the accuracy of sentiment classification. In the next part, the experiments are explained in more detail.

### A. First Experiment

The goal of this experiment is to It is to find the most accurate classification algorithm based on all the features in the database. In this experiment, we compare the accuracy of the most used classifiers in sentiment analysis systems without employing feature selection methods. First, we prepared the data set using the preprocess approaches mentioned in Section B. After that, numerous classifiers were used, including SVM, DT, and k-NN for sentiment classification. To avoid dataset overfitting and improve model performance, we verified the models using the cross-validation approach, which randomly separates the dataset into a training dataset and a testing dataset depending on the k-fold value [31].

The first experiment employed a different number of K-fold that was chosen as (5, 10, 15, and 20). Whereat each time the tweets are tested with various folds and various classifiers. Fig. 3 shows the average accuracy for the various folds (5, 10, 15, and 20) using the DT, KNN, and SVM classifiers. The results are as follows: the average accuracy of the DT is 62.8%, 62.4%, 62.8%, and 62.4%, respectively. The average accuracy

of the KNN is 62.6%, 62.6%, 62.7%, and 62.8%, respectively. Also, the average accuracy of the SVM is 62%, 62.6%, 62.7%, and 63.2% respectively. After comparing all of the accuracy values, we observed that the SVM RBF method achieved the greatest accuracy value of 63.2% at 20-folds.

### B. Second Experiment

The purpose of this experiment is to study the effect of employing the Information Gain approach on the suggested system in two aspects: accuracy improvement and dimension reduction. In the first portion of the experiment, the accuracy of the classifiers (DT, KNN, and SVM) is computed after applying the Information Gain approach as a feature selection algorithm to obtain the best subset of features from all features. In the second portion of the experiment, we are interested in assessing the reduction ratio achieved by using the IG strategy, because the IG technique is primarily utilized to choose features that better match the given classes. Based on that, the IG algorithm was able to reduce the total number of features from 1170 to 713 and the results were presented in Table II. Table II demonstrates the performance of the proposed approach for Arabic sentiment analysis based on the IG feature selection algorithm at 20-folds (determined based on previous experience as in 4.1).

Fig. 3. Accuracy Comparison of Different Classifiers before using Feature Selection.

TABLE I. EXAMPLE OF THE CLEANING ALGORITHM OUTCOMES

| Tweet text before cleaning | Tweet text after cleaning |
|---|---|
| "ما شاء الله ... ونعم التعليم في الاردن .... ابدعوا الشباب !!!" | "ما شاء الله   ونعم التعليم في الاردن   ابدعوا الشباب " |
| " الجمال : ليس فقط شيئا نراه بل هو شيء نكتشفه ، روح جميله ، وفكر جميل ، اخلاق جميله ، وادب جميل" | " الجمال   ليس فقط شيئا نراه بل هو شيء نكتشفه   روح جميله  وفكر جميل  اخلاق جميله   وادب جميل" |
| "وانا 100% بس شكلها هاي مو مدرسه" | "وانا     بس شكلها هاي مو مدرسه" |

TABLE II. COMPARISON OF ACCURACY AFTER USING IG WITH SEVERAL CLASSIFIERS

| Algorithms | Accuracy % | Precision % | Recall % |
|---|---|---|---|
| DT | 75 | 74 | 75 |
| KNN | 72 | 75 | 70 |
| SVM | 85 | 85 | 84 |

As demonstrated in Table III, using the IG technique increased the accuracy of the proposed model by about 15% on average in all employed classifiers. Furthermore, utilizing the IG approach decreases the AJGT dataset's feature vector length by around 61%. This allows the classifiers to distinguish efficiently between positive and negative classes with lower computational requirements. Furthermore, applying the IG approach in the feature selection step reduces the feature vector length for the AJGT dataset by around 61%. This enables the classifiers to discriminate between positive and negative classes more effectively while using fewer computational requirements. Based on the findings in Table I, we can observe that using the IG technique not only reduces the dimension of the feature vector but also significantly improves the performance of all classifiers.

### C. Third Experiment

In this experiment, we aim to evaluate the performance of the proposed model after using the Chi-Square approach as a feature selection method. After applying the same evaluation process described in the second experiment on the AJGT dataset, the Chi-Square Algorithm was able to reduce the total number of features from 1170 to 750 features and the results were presented in Table III. Table III shows the performance of the proposed approach for Arabic sentiment analysis based on the Chi-Square feature selection algorithm at 20-folds (determined based on previous experience as in Section 4.1).

After comparing the results of previous experiments, we conclude the following:

- The SVM classifier shows the greatest classification performance among all the classifiers tested, but its performance decreases as the number of features increases. In the second and third tests, the D-tree classifier's performance appears to remain stable, despite the low number of features. In all experiments, K-NN had the worst results.

- The proposed approach based on the Information Gain Algorithm in the feature selection step achieved a 2% improvement overall classifiers compared to the Chi-Square Algorithm.

TABLE III. COMPARISON OF ACCURACY AFTER USING CHI-SQUARE WITH SEVERAL CLASSIFIERS

| Algorithms | Accuracy % | Precision % | Recall % |
|---|---|---|---|
| DT | 73 | 73 | 71 |
| KNN | 70 | 72 | 70 |
| SVM | 83 | 84 | 82 |

- The efficiency of this proposed approach is due to two main factors: First, we utilized a preprocessing step to improve the quality of the data we used, which leads to an increase in the quality of the results. Second, using feature selection algorithms to select the best subset of features reduces the total number of features and improves the classification model's accuracy. An IG algorithm outperformed the Chi-Square Algorithm as it was able to reduce the number of features from 1170 to 731, whereas the Chi-Square Algorithm reduced it to 750.

## VI. CONCLUSION

This study examined the impact of two feature selection approaches (IG, and chi-squire) on the performance of the (DT, KNN, and SVM) classifiers for dialectal Arabic sentiment analysis. The experiments are implemented in the RapidMiner data mining tool by using an AJGT dataset and a 20-fold cross-validation technique. The dataset consists of 1800 Arabic Jordanian tweets labeled by two different classes (negative and positive). The experimental results showed the Information Gain Algorithm outperformed the Chi-Square Algorithm in the feature selection step, as it was able to reduce the number of features by 61% and increase the accuracy of the classifiers by 10%. Moreover, the SVM classifier shows the greatest classification performance rather than DT, and KNN among all the experiments which give the highest accuracy of 85% with the IG algorithm.

*Abstract*—As a key research subject in the fields of health and human-machine interaction, human activity recognition (HAR) has emerged as a major research focus over the past few decades. Many artificial intelligence-based models are being created for activity recognition. However, these algorithms are failing to extract spatial and temporal properties, resulting in poor performance on real-world long-term HAR. A drawback in the literature is that there are only a small number of publicly available datasets for physical activity recognition that contain a small number of activities, owing to the scarcity of publicly available datasets. In this paper, a hybrid model for activity recognition that incorporates both convolutional neural networks (CNN) are developed. The CNN network is used for extracting spatial characteristics, while the LSTM network is used for learning time-related information. Using a variety of traditional and deep machine learning models, an extensive ablation investigation is carried out in order to find the best possible HAR solution. The CNN approach can achieve a precision of 90.89%, indicating that the model is suitable for HAR applications.

*Keywords—Human recognition; deep learning; hybrid model; CNN; HAR*

## I. INTRODUCTION

Human activity recognition (HAR) is a well-established research topic that requires the correct identification of a wide range of activities that are collected in a variety of ways. Sensor-based HAR makes use of inertial sensors such as accelerometers and gyroscopes to measure the acceleration and rotational velocity of a body. There are numerous advantages to employing sensors to capture a person movement rather than cameras and microphones, including the fact that they are less sensitive to noise, less invasive for the user, and less expensive. Sensors are also less expensive than cameras and microphones [1]-[5]. Furthermore, as a result of the growing use of sensors embedded in cellphones, these devices have become virtually ubiquitous in our lives.

Aspects of sensor-based HAR that are particularly challenging are the encoding of information and the representation of time. Previous classification systems depended on features extracted from kinetic signals that were first constructed and then implemented into the system. Please keep in mind that these characteristics are largely picked on the basis of heuristics, which are determined by the nature of the work at hand. If you have a deep grasp of the application area or extensive human experience, you may find that when you extract the characteristics from the data collection, you only get a shallow set of characteristics. As previously stated,

standard HAR techniques do not scale well to complex motion patterns and do not perform well on dynamic data, which is defined as data gathered from streams that remain forever outside of the lab [6]-[9].

Automated and deep approaches to human-computer interaction are becoming increasingly prevalent in the field of human-computer interaction. Most deep learning research in biometrics has been focused on face and speaker recognition [12]. The selection of significant characteristics from the data is delegated to the learning model through the use of data-driven signal classification methods, which are used to train the learning model on the data. CNNs are particularly useful when it comes to detecting spatial and temporal correlations between signals [10]. Efficient features are first extracted from raw data. The features include mean, median, autoregressive coefficients, etc. [11].

This paper presents the construction of an activity recognition model that incorporates convolutional neural networks (CNNs). The CNN network is used to extract spatial features, whereas the LSTM network is used to learn about time-related information. It is necessary to do a thorough ablation analysis utilizing a variety of classical and deep machine learning models in order to determine the most effective HAR solution possible. The CNN technique can be employed for HAR applications because of its high precision of 90.89%.

## II. RELATED WORK

When it comes to common supervised machine learning techniques, the generic Activity Recognition Chain [13] includes steps such as preprocessing, extraction of features, and classification. When it comes to deep learning (DL), CNNs are an example of a technique that does not require the extraction of features from raw data before classification [14]. CNN feature extraction is accomplished through the convolution of the input signal with a kernel [15]. The outcome of the convolution technique is a feature map that contains information about the data.

Both advantages and drawbacks arise from the ability of CNNs to automatically learn properties. It streamlines the ARC [14] by automating jobs that would otherwise require domain-specific expertise, like the identification of a suitable feature collection. In contrast to the feature selection approach, which starts with the largest number of features feasible and narrows it down to only those that provide the

best discrimination across target classes, CNNs do not require any of these phases. Instead, the use of a CNN incorporates the feature extraction phase into the classifier model, requiring an extended training period to generate adequate features and exposing the approach to problems such as those arising from cold starts. In order to mitigate this problem, it is common in computer vision to use pre-trained CNN models for feature extraction, such as those developed by Raja Raman et al. [16].

In the MLP classifier, there are numerous dense, fully connected layers that lead to an output layer with as many n-nodes as the number of target classes present in the input. A vector of HCF is used as an input to a regular MLP in order to feed it (a). In the CNN scenario (b), convolutional layers are employed to extract features from the data [17].

An alternative is to do a max-pooling operation after each of the convolutional layers, which will result in a further reduction in the feature map size due to down sampling of the data [17]. A 1D vector that has been flattened from the output of the previous convolutional layer is supplied into the MLP layer just as it was in the HCF example. While IMU signals frequently contain a temporal component, 2D convolution is more commonly used in the processing of picture audio [18] and video audio [19].

Rectified Linear Unit (ReLU) activation functions are one of the most frequently used activation functions for convolutional layers, while Softmax activation functions are commonly applied in multi-class classification settings [15]. It is possible to employ alternative activation functions in the case of multi-label classification, such as the sigmoid function [20].

## III. PROPOSED METHOD

A two-pronged approach will be used to experiment with CNN in this section. In the first phase of this work, CNN automatically retrieved features with a variety of hyper parameters and topologies, which are then analyzed and the results were presented. A real-world dataset was utilized for the second aim, which investigated the viability of employing a pre-trained CNN feature extractor for HAR. It is useful to take advantage of a CNN ability to automate feature extraction while avoiding the cold-start difficulty.

Two steps in a case study were recommended, which are depicted in Fig. 1.

In the first stage, a CNN feature extractor is trained to extract features from images [Fig. 1(a)]. This step involves experimenting with different topologies and hyper parameter combinations. The best-performing HAR models have been discovered as a result of this research. It is only used as a feature extractor in the second stage, in order to convert raw data into a suitable input vector for a second classifier model in the third phase. The flattening layer generates feature vectors as a result of a succession of convolutional processes, and the weights of the CNN networks are fixed at the beginning of the first phase.

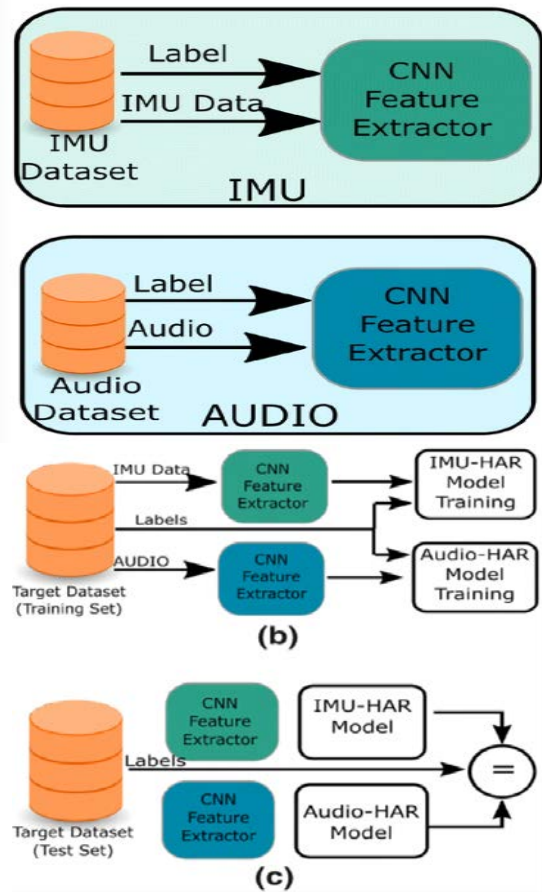

Fig. 1. Two-pronged Approach will be used to Experiment with CNN.

Following an aim similar to transfer learning, the feature vector formed by taking the output of the flattening layer can be used to represent raw data in a different context by using the feature vector created by taking the output of the flattening layer. As seen in Fig. 1(b), the characteristics generated by the pre-trained classifier are utilized to train the second model, which is subsequently used to train the first model. Finally, as illustrated in Fig. 1(c), the second model is put to the test.

In several preliminary experiments, HCF and CNN were compared. However, the breadth of the current case study was restricted due to the nature of the data. For example, CNN feature extractor for HAR is used in this work to explain how to use the tool, and some additional data and analysis are included that was not included in the previous study to demonstrate how to utilize the tool.

As a result of the prior investigation, several key data requirements for the case study were identified. For the first phase, it was found that data collected in controlled environments was the most appropriate choice. The likelihood of noisy labels being introduced into these datasets is low due to the fact that they are developed in a controlled laboratory environment. Consider that the comparison with HCFs may be influenced by issues such as label noise, which could result in an incorrect rating.

## A. Network Architecture

Because each sensor samples six different signal components, the type of input examples that the network receives is determined by the sensor design. These six different signal components are then organized into a single channel image matrix of size 6×204×N, which is the largest size available. Consequently, the network input takes the shape of 6×204×N, where N is the number of channels and is equivalent to the number of sensors used for sampling in the network. Model-driven input adaptation is the term used to describe this technique, which is capable of recognizing both spatial and temporal patterns within the signal components.

The convolutional model is illustrated in its entirety in Fig. 3. Following the input layer, there are three convolutional layers and three max-pooling layers. Following this procedure, each input channel receives a collection of multiple feature maps, each with kernels of sizes 3×5, 2,4×2, and 2×2 according to the size of the input channel. It is necessary to pad the input of each convolutional layer correctly in order to ensure that there is no resolution loss caused by the convolutional process. A batch normalization procedure is employed during the creation of each convolutional layer. In the three max-pooling layers, kernels with sizes of 3 3, 2×2, and 3×2 are employed. Following that there are three dense layers of 500, 250, and 125 units apiece, which together form a network that is entirely connected. During the training phase, neurons have a 0.5% chance of being dropped from the thick layers.

It is true that the cross-entropy function is used to measure loss; however, it is also used as an activation function for all of the network nodes as well. The Adam optimizer is a stochastic approach to optimization that uses a random number generator. Units in the output layer correspond to the number of actions performed by each group, and there are m units in total. The softmax method will return the class of the input windows that is the most likely to be encountered.
The Fig. 2 represents the CNN Architecture. The input results in fully convolutional network (FCN).We have chosen a set of hyper parameters that are consistent across all activity groups and sensor configurations. These parameters were chosen based on best practices in the literature and empirical evidence. It has been discovered that a batch size of 1024 can significantly speed up the learning process when compared to smaller batches, while not being computationally prohibitively complex to maintain.

Depending on the behavior of specific combinations, there are between 150 and 300 training epochs available. The starting rate of learning is set at 0.005% each minute. Rather than attempting to construct the most efficient network, our goal is to assess the classification potential of various sensor technologies.

We make our architectural decisions as a result of a very normal network configuration, which is based on modest kernels, standard regularisation methods, and a small number of hyperparameters. If no regularisation process is employed, three convolutional layers will result in overfitting if no regularisation procedure is used. The inclusion of extra convolutional or dense layers has little effect on the performance of the network, but the introduction of dropout helps to stabilise learning and improve stability.

## IV. RESULTS AND DISCUSSION

The Tensor Flow 1.7 framework is utilized in the construction of the network. Following the recording of the activity, the signal is decomposed into 204 points, each of which corresponds to roughly two seconds of movement, with a stride of five points between each point. Reduced window sizes are associated with enhanced classification performance, and in the context of CNNs, the limited structure of the network input data makes the training process easier. The shape of the generated matrix is determined by the number of sensors employed to sample the window: 6N×204 in this case. This has resulted in a significant increase in the quantity of training and testing samples available. It is uneven because the activities have varying execution periods and because different subjects may complete the same activity at various rates, which makes the dataset unbalanced.

For the purpose of evaluating the performance of our classification system, we employ a typical 5-fold cross-validation approach. To separate the accessible datasets, we employ topics rather than windows as a division method. As a result, this prevents overfitting and enhances the generalization of model outputs as a result. In order to produce each fold, an 80/20 split is achieved by separating four people from a group of 19, as mentioned previously.

Through this case study, which is shown in Fig. 3 to Fig. 7 were able to investigate the impact of various hyper parameters and CNN settings on the feature learning capabilities of our model. Regarding feature learning in HAR, this experiment provided an excellent overview of the main elements that determine a CNN ability to learn new features and how these aspects interact with one another. While the results from the first phase of the case study demonstrated that CNNs can perform at least as well as the best HCFs, the

Fig. 2. CNN Architecture.

results from the second step demonstrated that CNNs can perform at least as well as the best HCFs. This is why CNNs must be trained before being used, and as a result, they are susceptible to the cold-start problem.

Fig. 3.   Accuracy.

Fig. 4.   Precision.

Fig. 5.   Recall.

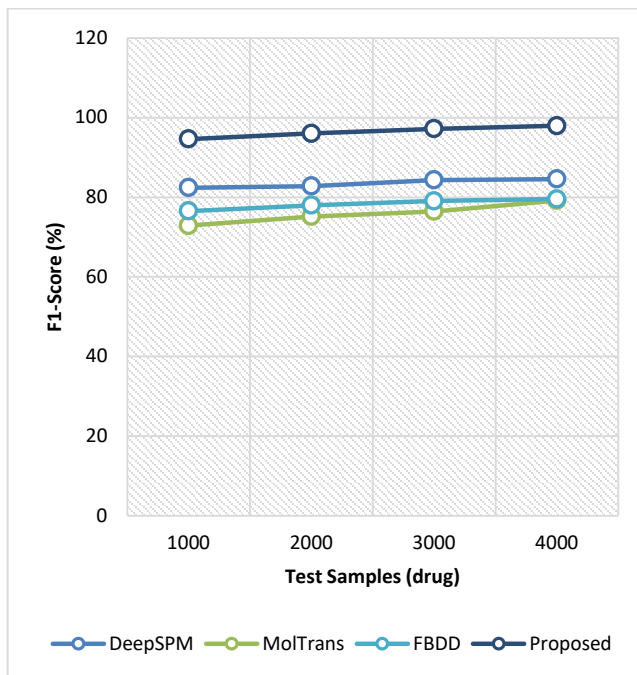

Fig. 6.   F1-Measure.

To evaluate CNN feature learning methods for dataset test cases, a pre-trained CNN feature extractor was employed on a real-world dataset to extract features from it. Real-world datasets enable the evaluation of CNN automatic features in a more realistic environment than was previously possible. The problem of dealing with uncontrolled environments was brought to light through realism-based testing.
Fig. 7. Computational Time.

Although a larger number of training epochs were required, it was demonstrated that SGD enabled the model to be trained with greater accuracy on the test set, leading to an F-Score of 94% in the more challenging target activities, which included transitions as a NULL class. We were successful in identifying a suitable network architecture that matched our feature learning criteria while also keeping the model complexity under control. The architecture was evaluated using data from a large real-world dataset that was made available to the public.

## V. CONCLUSION

This paper presents the construction of an activity recognition model that incorporates both convolutional neural networks (CNNs) and convolutional neural networks (CNNs). This work was primarily intended to demonstrate the usage of a CNN pre-trained feature extractor rather than to provide a comprehensive analysis of the hyper parameters and settings used in the training process. The optimization of models, on the other hand, is subject to several restrictions. When analyzing designs with varied numbers of convolutional layers and convolution kernel sizes, for example, only the ReLU activation function was used to achieve the best results.

Other modes of activation may be investigated in future investigations. In a similar vein, the default Keera's learning rate of 0.001 was employed. The CNN network is used to extract spatial features, whereas the LSTM network is used to learn about time-related information. It is necessary to do a thorough ablation analysis utilising a variety of classical and deep machine learning models in order to determine the most effective HAR solution possible. The CNN technique can be employed for HAR applications because of its high precision of 90.89%.

# Tourist Reviews Sentiment Classification using Deep Learning Techniques: A Case Study in Saudi Arabia

Banan A.Alharbi, Mohammad A. Mezher, Abdullah M. Barakeh

Dept. of Computer Science, Fahad Bin Sultan University, Tabuk, Saudi Arabia

*Abstract*—Now-a-days, social media sites and travel blogs have become one of the most vital expression sources. Tourists express everything related to their experiences, reviews, and opinions about the place they visited. Moreover, the sentiment classification of tourist reviews on social media sites plays an increasingly important role in tourism growth and development. Accordingly, these reviews are valuable for both new tourists and officials to understand their needs and improve their services based on the assessment of tourists. The tourism industry anywhere also relies heavily on the opinions of former tourists. However, most tourists write their reviews in their local dialect, making sentiment classification more difficult because there are no specific rules to control the writing system. Moreover, there is a gap between Modern Standard Arabic (MSA) and local dialects. one of the most prominent issues in sentiment analysis is that the local dialect lexicon has not seen significant development. Although a few lexicons are available to the public, they are sparse and small. Thus, this paper aims to build a model capable of accurate sentiment classification in the Saudi dialect for Arabic in tourist place reviews using deep learning techniques. Machine learning techniques help classifying these reviews into (positive, negative, and neutral). In this paper, three machine learning algorithms were used, Support -Vector Machine (SVM), Long short-term memory (LSTM), and Recurrent Neural Network (RNN). These algorithms are classified using Google Map data set for tourist places in Saudi Arabia. Performance classification of these algorithms is done using various performance measures such as accuracy, precision, recall and F-score. The results show that the SVM algorithm outperforms the deep learning techniques. The result of SVM was 98%, outperforming the LSTM, and RNN had the same performance of 96%.*

*Keywords—Sentiment classification; Saudi dialect; support -vector machine; recurrent neural network; long short-term memory*

## I. INTRODUCTION

Due to the astounding and quick expansion of social networking sites, an increasing number of individuals are sharing their experiences and opinions on various issues, including travel, hotels, physical items, movie reviews, and health. One cannot deny that social media sites play a role in people's daily and social lives. Additionally, they assist tourists in selecting the appropriate destination via their comments on tourist destinations' social media sites, as mentioned by [1].

Moreover, social media sites have gained a significant attraction on the web. These sites have evolved into an indispensable resource for travelers whose decisions are influenced by the reviews and opinions of other travelers. Human emotions and emotional cognition influence purchasing decisions, travel, and other variables. Online reviews can help researchers and business owners understand tourists' needs and preferences correctly. It was further noted that the tourism industry's primary reliance on the opinions and perceptions of former travelers is universal. They emphasized that [2] the views expressed by tourists in the comments play a role in influencing the choices of other tourists for their travel destinations.

Moreover, travelers frequently desire to know the attractions for which a city they wish to visit is renowned. They research social media sites for recommendations, opinions, and reviews to visit tourist destinations. Given the plethora of information and evaluations, it is difficult for travelers to obtain reliable judgments and select the best hotels, restaurants, and attractions. Many people share their experiences and views spontaneously and more credibly about the tourist places they visit without a financial return. Therefore, it will be challenging for the reader to locate relevant websites when researching, rewriting, and summarizing the facts and viewpoints vital to them.

Consequently, the significance of sentiment classification reduces the time and effort required to extract relevant information for travellers. The sentiment classification process studies people's emotional state and their assessments of a particular topic or their attitudes towards a specific event, and sentiment classification is used in tourism applications, products, shopping and other areas of life. Consumers place greater credence on online reviews, personal recommendations, and comments and thus are more likely to provide product reviews after purchasing. The classification process aims to determine the polarity of the text and determine whether a person feels optimistic about a particular product, negative or neutral. Classifying reviews (positive or negative) is the goal of sentiment classification, and like the use of text, analysis has proven cost-effective. The classification is mainly based on an explained supervised learning approach [3].

As a result, sentiment classification is one of the most active and prosperous research areas in Natural Language Processing (NLP). Many researchers and those interested in this field use deep learning for sentiment classification. Data technologies reduce sentiment classification errors to ensure the highest accuracy on social media [4]. This study aims to develop a model capable of accurate sentiment classification in the Saudi dialect of Arabic by analyzing tourist location reviews using deep learning techniques.

## A. Sentiment Classification

Sentiment classification refers to analyzing textual data on social media and extracting people's sentiments about different topics. The sentiment classification also provides a more understanding of people's views on a particular topic. We can observe the sentiment classification in action when determining consumer satisfaction with a specific product based on their input. In addition, we may learn about people's preferences for top attractions through their recommendations on social networking sites and by assessing the quality of hotels through reviews. These reviews can also classify opinions as positive, negative or neutral. Many English, Chinese and other languages have made remarkable progress and are high-performance using sentiment classification [5]. Likewise, as the volume of unstructured data generated by social media grows, the demand for sentiment classification has skyrocketed. There are three different levels of sentiment classification: document level, sentence level, and feature level.

- Document-level: The document is classified by general feeling, either positive, negative or neutral, and the paper is supposed to contain an opinion on one topic.

- Sentence level: At the sentence level, the classification determines whether the opinion in this sentence is positive, negative or neutral.

- Feature level: Feature level makes a more accurate analysis. Instead of looking at the structure of language (documents, paragraphs, sentences, or phrases), it directly looks at the same opinion.

It is also called aspect-based sentiment analysis. This level examines multi-opinionated sentences to determine the attitude towards entities or their aspects by examining the opinion and the entity's purpose or one of its features.

## B. Sentiment Classification Techniques

It has developed classification methods in machine learning. There are roughly three classification strategies for sentiment: machine learning, lexicon-based, and hybrid.

- Machine Learning-based approach: Two proposed sets of classification sentiment problems are traditional and deep learning models [6]. Traditional models apply to classic machine learning algorithms: Naïve Bayes (NB) classifier, Maximum Entropy (ME) or SVM. Algorithm inputs also use language features such as N-grams, bi-grams, bag-of-word, parts of speech, or adjectives and adverbs. Consequently, choosing features in traditional models can affect the accuracy of the results. In contrast, sentiment analysis employing deep learning models such as Deep Neural Networks (DNN), Convolutional Neural Networks (CNN), and RNN can get better results than conventional methods. Accordingly, we can address classification problems at the document level, Sentence level, or Aspect or Feature level.

- Lexicon-based approach: this technique was the first to use sentiment analysis [6]. It consists of a set of sentiment terms that are translated and pre-known. It is also divided into two approaches: dictionary-based and corpus-based. In the first form of sentiment classification, a dictionary of terms is used to locate the first sentiment words, using a synonym and antonym dictionary such as WordNet SentiWordNet. In the second type, the sentiment classification corpus-based does not depend on the dictionary of pre-defined sentiment terminology but on statistical or semantic analysis for the polarity sentiment. The corpus-based uses a technique such as neighbours (k-NN), Conditional Random Field (CRF).

- A hybrid approach is prevalent and confuses both approaches, and sentiment dictionaries play a significant role in most methods [7]. The more effectively the classifier is trained, the easier and better is the future predictions. We can divide text classification methods into supervised and unsupervised learning using machine learning. Conversely, unsupervised learning is used when it is challenging to find classified training documents.

## C. Deep Learning

Deep learning is a branch of machine learning as it depends on neural networks that resemble the human brain. Deep learning refers to the deep neural network introduced in 2006 by G.E. Hinton. Accordingly, deep learning can recognize speech, analyse images, and process natural language. Deep learning networks also provide supervised and unsupervised groups. Consequently, many companies have been interested in machine learning in handling big data, and models have been created to analyse big and complex data faster and more accurately [8]. However, there are many networks in deep learning, such as CNN and Deep Belief Network, and there are many benefits for neural networks in vector representation, sentence classification, sentence modelling, and text creation.

## D. Models

*1) Long short-term memory model*: LSTM is a developer version of RNN. They were developed to overcome the problems of RNN in the vanishing and exploding gradient. They were introduced by [9]. Consequently, LSTM has achieved great success in various NLP tasks. Accordingly, [10] designed to model temporal sequences and their long-range dependencies more accurately than conventional RNNs of three basic gates: the input gate, the output gate $o_t$, and the forget gate $f_t$.

- The input gate controls the amount of information transferred from the input to the current cell.

- Forget gate $f_t$. This gate decides what information should be thrown away or kept. Data from the previous hidden state and information from the current input are passed through the sigmoid function. Values come out between 0 and 1—the closer to 0 means to forget, and the closer to 1 means to keep.

- The output gate $o_t$ controls the amount of information transferred to the output.

*2) Recurrent neural network model*: RNNs are artificial neural networks that process and use sequential data. In a

conventional neural network, each input and output is treated as independent of the other, which might result in poor performance. Hence, the idea of a repetitive neural network predicts the following word in the sentence based on the previous word. RNNs have the concept of 'memory' that helps them store the states or information of prior inputs to generate the following output of the sequence. In this way, the network can use history to understand the sequential nature of the data. According to this, RNNs have shown great success in many NLP tasks. Mainly concentrating on sequential data applications, such as text classification and speech recognition. On the other hand, RNNs have also shown notable success in image processing.

*3) Support vector machine model*: SVM algorithm is one of the supervised machine learning algorithms used for classification and regression, developed by Vapnik. SVM is used to solve various classification problems, such as the recognition of fonts, images, text classification, and other fields [11]. The concepts used in SVMs, like hyperplane, optimal margin, Kernels, etc. There are two types of SVM: linear classification and non-linear classification. Liner classification: divides the two groups of data linearly. SVM picks the hyperplane with the most significant margin to achieve maximum separation between the two classes. The margin equals the sum of the shortest distances between the separating hyperplane and the closest data point of both categories. Non-linear classification in SVM has been extended using Kernels. Kernels are mathematical functions that transform the data from a given space (known as Input Space) to a new high dimensional space (known as Feature Space) where data can be separated with a linear surface (called hyperplane).

## II. Related Work

Social media sites generate vast reviews about travel, products, movies, etc. In addition, social media sites provide a suitable space for people to share their experiences more freely. Today, people are increasingly making their views and experiences available online. Therefore, millions of web pages will appear when you search for any topic online. It is challenging and time-consuming to gain an overall understanding of these reviews. A few reviews may influence an individual's perspective. Accordingly, sentiment classification aims to solve such problems by automatically classifying people's views into negative, positive, and neutral opinions. This makes it an important field of research for consumers, companies and Governments. However, resources are not always available for all areas or languages. While there has been a great deal of study on sentiment classification in English, very few scholars have examined sentiment classification in Arabic, despite the growing number of Arabic speakers.

### A. Tourist Place Reviews Sentiment Classification

With the radical change in social lifestyle and people's general decisions, sentiment classification has become the subject of long-term research. A study analyzing sentiment

classification revealed that numerous studies use movie or restaurant reviews as a proxy for sentiment categorisation. [12] stated that traditional sentiment classification methods often require significant human efforts. With the growing volume of web reviews, people have a big problem increasing information. The author in [1] has focused on analyzing and organising unstructured data from social media sites. In light of this, unstructured data from social media has increased the demand for sentiment analysis. The author in [13] explained that sentiment analysis could be at different levels, such as document level, sentence level, and aspect-based. The results of experimental studies [14] also showed that one of the tasks of sentiment classification at the document level is to consider the importance of sentences.

Moreover, as explained by [15], many studies use classification algorithms such as NB, ME, and, particularly, SVM to classify the polarity of reviews. Accordingly, [16] compared two approaches to supervised machine learning methods regarding sentiment classification of reviews between SVM and NB, which was highly accurate. The results indicated that NB outperformed SVM, as the training data set consists of many reviews. The approach of NB has reached a high degree of accuracy compared to SVM.

In addition, [17] compared five machine learning algorithms, K-Nearest Neighbors (KNN), Decision Tree, Artificial Neural Networks (ANNs), Naïve Bayes and SVM are used for the classification of sentiments. These algorithms are analysed on Twitter's dataset, and the performance of these methods has been compared based on different performance metrics such as accuracy, precision, recall and F measure. The results showed that SVM outperforms others and has a higher predictive ability than other algorithms. So, all the metrics, Accuracy, Precision, Recall and F-score, are high in the case of SVM.

The author in [18] compared the accuracy of LSTM and CNN by looking at the different designs of each. The training sample was taken from Booking and TripAdvisor. Thus, the results showed that LSTM neural networks outperform CNN in performance. LSTM produces higher accuracy. They also show that combining convolutional layers with recurrent LSTM layers does not benefit.

The author in [19] suggested a hybrid model using LSTM and a profound CNN model named hybrid CNN-LSTM model. Suggested results showed hybrid CNN-LSTM model outperforms traditional deep learning and machine learning techniques in precision, recall, f-measure, and accuracy. The training sample was IMDB movie and Amazon movie reviews.

The author in [20] has widely explained the importance of online reviews. The authors in [21], [22] have also dealt with the impact of online comments on tourist decision-making. The author in [23] shows the importance of recognizing the impact of online reviews on tourist behaviour. The intensity and effects of internet reviews on users' purchasing behaviour and decision-making have been demonstrated [24], [25]. Furthermore, [26] presented several tourists' satisfaction, while some studies employed internet reviews. Hotel visitors'

satisfaction [27] and feelings about a film [28]. Others also stated that traveller reviews are more up-to-date, entertaining, and trustworthy than those published by travel service providers [29].

### B. Deep Learning Sentiment Classification

In recent years, deep learning has become an effective way to solve sentiment classification problems. Consequently, several studies have recommended deep learning-based models for sentiment classification that outperform conventional machine learning models [30]. Many deep learning models include DNN, CNN, and deep Restricted Boltzmann Machine (RBM).

One study suggested CNN for sentiment classification. The sample of training datasets was divided into three groups (movie review data, customer review data, and Stanford Sentiment Treebank data). Experimental results showed that CNN layers contributed to better performance of relatively long texts [31].

Another compared traditional models such as Logistic Regression, SVM, and deep learning models such as CNN and the simple LSTM. The results showed that the larger the data set, the better the deep learning models were than traditional models, as the LSTM results were 95.55% better accurate. The training sample was Amazon reviews [32].

### C. Reviews Arabic Language Sentiment Classification

Research has been done on sentiment classification in English. Although Arabic is one of the most widely used languages on social media, few studies have focused on sentiment classification in Arabic. According to statistics Internet World Stats, Arabic is the fourth most commonly used language online after English, Chinese and Spanish [33]. Although Arabic-speaking users have increased online in recent years, sentiment analysis research in Arabic has not yet evolved.

The author in [34] applied the sentiment analysis of Arabic tweets from Twitter. They used unsupervised methods. They examined preprocessing methods of text and similarity to compile algorithms and discussed how they affected the results. Moreover, they used a k-means algorithm. Therefore, the brevity of the language in this context presents a challenge to the likelihood of ambiguity. In this investigation, root-based derivation yielded the best degree of accuracy, as indicated by the findings.

The author in [35] compared two supervised learning algorithms, SVM, and RNN, in terms of ability to face the challenges of Aspect-Based sentiment analysis. The training sample was Arabic hotel reviews. The results showed that the SVM approach outperformed the RNN approach in all tasks in terms of accuracy, but RNN was faster at implementation.

The author in [36] analyse the collected twitter posts in different Arabic dialects and compare the various algorithms. The measurement of performance of different algorithms is evaluated in terms of recall, precision, f-measure, and accuracy. Experimental results showed that unigram gives a higher accuracy of 99.96%, with Passive-Aggressive (PA) or Ridge Regression (RR).

The author in [37] uses two models of deep learning, CNN and LSTM. The training sample was the Arabic Sentiment Tweets Dataset (ASTD) dataset. The best results for an LSTM model. Sayed et al., 2020 used nine supervised machine learning algorithms: namely, Gradient Boosting, Logistic Regression, Ridge Classifier, SVM, Decision Tree, Random Forest, KNN, Multi-layer Perceptron (MLP) and NB. The training data sample on evaluations written in Arabic was manually prepared through hotel evaluations from Booking.com. The Experimental results showed that the Ridge Classifier (RC) appears to have the best performance in accuracy, recall, precision, training time and F1 score.

The author in [38] applied K- means and Hierarchical unsupervised learning approaches. The training sample was sentiment analysis from the tourism website TripAdvisor for Arabic reviews of Saudi hotels. Used clustering, features and preprocessing strategies to find the best models. The results showed that k-means clustering achieved the best accuracy. The author in [39] suggested combining linguistic and statistical features and sentiment classification using a tweets dataset in Arabic. They used three classifiers: SVM, KNN and ME. The results showed that SVM achieved the highest accuracy in the classification.

### D. Saudi Dialect for Arabic Review Sentiment Classification

We have been increasingly interested in analyzing Arabic texts on social media sites over the past few years. However, most social media users write their comments in the local dialect of their countries rather than MSA. In addition, some work has been done to build MSA sentiment lexicons. There has been a limitation in building a dialectal Arabic lexicon, especially for the Saudi dialect. This is mainly due to the limitation in the existing natural language processing tools and the resources available for Arabic, which is developed to deal with MSA only.

The author in [5] applied deep learning to sentiment classification Saudi dialect data on Twitter. Deep learning techniques were used to compare LSTM and Bidirectional Long Short-Term Memory (Bi-LSTM) and algorithm SVM. The data sample was from 32,063 tweets. The results showed that deep learning techniques outperform the algorithm SVM. The experimental result of Bi-LSTM was 94% exceeding the LSTM's 91%, while the SVM had the lowest performance of 86.4%.

The author in [40] presented a new sentiment dictionary in the Saudi dialect called the Saudi Dialect Sentiment lexicon (SauDiSenti). The SauDiSenti comprises 4,431words, a hybrid between MSA and Saudi dialects. They compared SauDiSenti performance to that of AraSenTi. The first experience, which used only positive and negative tweets, showed the first experiment AraSenTi outperformed SauDiSenti in precision, recall, and F measure. The second experiment evaluated SauDiSenti and AraSenTi using positive, negative, and neutral tweets. The results showed that SauDiSenti outperformed AraSenTi for two values because AraSenTi identified most neutral tweets as either positive or negative. Despite the small size of SauDiSenti, they also added promising results in sentiment analysis of the Saudi dialect tweets.

The author in [41] they introduced a system to analyse the tweets of Saudi users on Twitter about Saudi universities. They used two different models suggesting sentiment analysis on Twitter. The first model depends on the use of SVM. The second model is based on using different classifier models. The results showed that SVM outperformed all other classification models.

The author in [42] compared two strategies. The first applied a translation that transforms from dialect to MSA. The second involved the designing of sentiment analysis on the resulting MSA text. Use tweets in the Saudi dialect. Use seven classifiers Logistic Regression, Passive Aggressive, SVM, Perceptron, Multinomial NB, SGD and KNN. The results showed that they proved that applying sentiment analysis techniques yields better results on MSA data than on dialect data.

In addition, there are studies on sentiment classification reviewed in other dialects such as Jordanian, Algerian, Sudanese and Egyptian. The author in [43] studied the effect of five methods of testing features on the performance of the SVM classifier. Sentiment classification was carried out on dialectical Jordanian reviews using an SVM classifier. The feature selection methods are Information Gain (IG), correlation, SVM, Gini Index (GI), and Chi-Square. He integrated some test methods to explore their ability to improve and choose the feature. The results showed that the best performance of the SVM and correlation feature selection methods was produced by combined with the uni-gram model.

The author in [44] compared the results of accurate deep learning models with classic models CNN, LSTM, SVM, and NB. They used two datasets: posts and comments collected from Algerian Facebook pages, and the second was the corpus of Algerian labelled tweets. The results showed that deep learning models are accurate compared to the classical approaches.

The author in [45] used machine learning methods for sentiment classification for text in the Sudanese dialect on Facebook. The Sudanese colloquial has no grammatical or morphological rules, as they have been made clear. Moreover, they used two different classifiers were applied SVM and NB. The results showed that SVM with lemmatisation libraries improved sentiment classification accuracy, as SVM achieved a measurement accuracy of 68.6%, while NB achieved 63.1%.

The author in [46] provided a sentiment analysis system MSA and Egyptian dialect. A different dataset (tweets, product reviews, TV program comments and Hotel reservations) was used. They demonstrated that expanding the polarity lexicon automatically affects sentiment classification. They also showed that exploitation idioms and saying lexicon with a high coverage polarity lexicon have the most significant impact on classification accuracy. Experimental results showed that the SVM classifier indicates high-resolution performance levels.

## III. METHODOLOGY

### A. Sentiment Classification

Many social media sites have gained tremendous popularity in the tourism and hospitality industry, such as TripAdvisor, Citysearch, Virtual Tour, Booking, and Foursquare. Consequently, these sites provided space and opportunity for people to express their opinions freely [47]. These reviews written by people across social media sites are a unique opportunity for sentiment analysis. According to this, sentiment classification aims to classify reviews into three (positive, negative, neutral) or more (positive, very positive, very negative, negative, neutral). However, without human intervention, it is difficult for a machine to discern the polarity and strength of a feeling.

### B. Pesudocode of Model Sentimental Classification

Sentiment classification for tourism reviews has been accomplished by developing an algorithm called Sentiment_classification. Firstly, text Preprocessing on reviews data &lexicon, cleaning, tokenising, removing stopword, stemming text. Secondly, reviews that have been preprocessed will determine the sentiment polarity using the Saudi Sentiment Lexicon. The polarity values will determine every word in the reviews, and then the value is calculated to know the reviews' sentiment (negative, neutral or positive). We no longer need to manually label sentiments to each review (because there are too many reviews). The dataset that has been processed will be used for sentiment classification with deep learning models.

```
Algorithm.1: Sentimental _Classification
1.  Start
2.       Load Raw Data
3.       Load Saudi Lexicon
4.       Text Preprocessing:
5.       Raw Data &Lexicon → cleaning text, text tokenisation, removing
    stop word, Stemming, normalisation
6.       # Determine Sentiment Polarity of Reviews Dataset
7.         Score=0
8.         for word in text:
9.            if (word in lexicon_positive)
10.              score = score + lexicon_positive[word]
11.          for word in text:
12.             if (word in lexicon_negative):
13.                score = score + lexicon_negative[word]
14.       # Calculation of Polarity reviews
15.         if (score >0)
16.            polarity = 'positive'
17.         elif (score <0)
18.            polarity = ' negative'
19.         else
20.            polarity= 'neutral'
21.            return score, polarity
22.       Modelling (Reviews Dataset):
23.  # Split the Data (with composition Training Data 80%, Testing Data 20%)
24.            Classifier ←Training Data
25.            Predict Model← Testing Data
26.       # Model is evaluated using its confusion matrix of test data
27.            Confusion matrix →Accuracy, Precision, Recall, F1-score
28.  End
```

### C. Proposed Modification

The flowchart in Fig. 1 shows the methodology followed in this research, which begins with extracting data for Arabic reviews in the Saudi dialect from Google Maps, including 14 cities in Saudi Arabia and 55 different places. After that

processing and cleaning are done for the extracted reviews. The processing process for the lexicon. The polarity of reviews is calculated. Hence, the dataset is ready for classification. Splitting the dataset is used for 80% of training data and 20% of test data. Finally, predict the model and results.

### D. Dataset

Dataset is the first step of sentiment classification. The paper aims to classify Arabic reviews of tourist places in the Saudi dialect. According to this, Google Map web scraping was used to collect the dataset containing 22433 reviews and save it in a fixed format CSV [48]. The dataset included 14 cities in Saudi Arabia, thus covering most dialects in Saudi Arabia (Hijazi, Najdi, Northern, Eastern, and Southern). Given the dataset, it turned out that most of the comments were written in Najdi, Hijazi dialect and MSA. Tourist places in every city included museums, archaeological sites, Islamic places, exhibitions, parks, and recreational places. Reviews were automatically classified as positive, negative, and neutral.

### E. Text Preprocessing

The text preprocessing process plays a vital role by applying the steps:

- Cleaning Text: Removing non-Arabic letters, numbers, punctuation marks, replacing newlines into space, remove characters space from both left and right text.

- Text Tokenisation: Divides text into words, for example (يستحق الزيارة منتزه جميل) after the tokenisation process ('يستحق', 'الزيارة', 'منتزه', 'جميل').

- Removing Stop-word: non-semantic words are called stop words, such as (ampersand pronouns, prepositions, and nouns). In addition, it does not affect the meaning and overall feeling of the text.

- Normalisation: The scientific of replacing some letters with other letters standardises the character forms used in writing. For example, the letters (إ،أ،آ،ا) are replaced by (ا), (ي) is replaced by (ى), (ه) is replaced by (ة), (ء) are replaced by (ئ،ؤ) and (ك) is replaced by (گ). Replace some characters that appear more than once with a two-character such as (ممتاااااز) converted to (ممتااز).

- Stemming: Stemming of words is one of the essential steps in text preprocessing; for example: removing suffixes and prefixes from words.

- Remove Prefixes: ال، وال، بال، كال، فال، لل

- Remove Suffixes: ها، ان، ات، ون ، ين ، ية ، ه، ي

### F. Polarity of Reviews

This study used a Lexicon-based method to identify polarity, and evaluations are classified as positive, negative, and neutral, Table I. Although more polarity categories might more precisely define the polarity of the evaluation, the model has been limited to the three categories of positive, negative, and neutral. According to this, the polarity of reviews is determined based on the majority of opinion words. If the number of positive words in the review is more, it will be classified as positive.

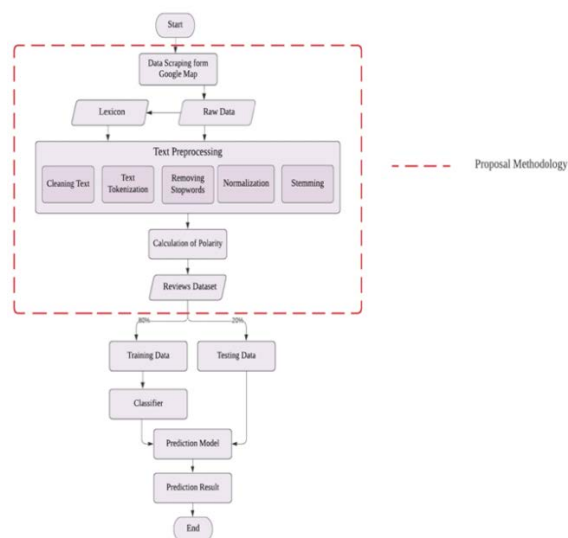

Fig. 1. Main Methodology Flowchart.

Conversely, if the number of negative words is high, the polarity of the review will be rated negatively. If the number of positive and negative words is equal, the review is neutral. In addition, if the opinion word is preceded by negation "مش،غير،لا", then the polarity of that review is reversed. Finally, the polarity of sensations is computed using the remaining poles and gathered in order to forecast the polarity of positive, negative, and neutral emotions. The Fig. 2 shows how the model calculates the scores polarities of sentiments to sentiment score calculation in reviews. Each positive word is greater than 0, and every negative word is smaller than 0. If neutral, it is equal to 0.

TABLE I. SAMPLE OF POSITIVE, NEGATIVE, NEUTRAL REVIEW

| | |
|---|---|
| حديقة هادئة وجدا خلابة | **Positive** |
| لا يستحق الزيارة مبالغ في قيمة التذكرة | **Negative** |
| بحيرة جميله تحتاج إلى صيانة أفضل | **Neutral** |

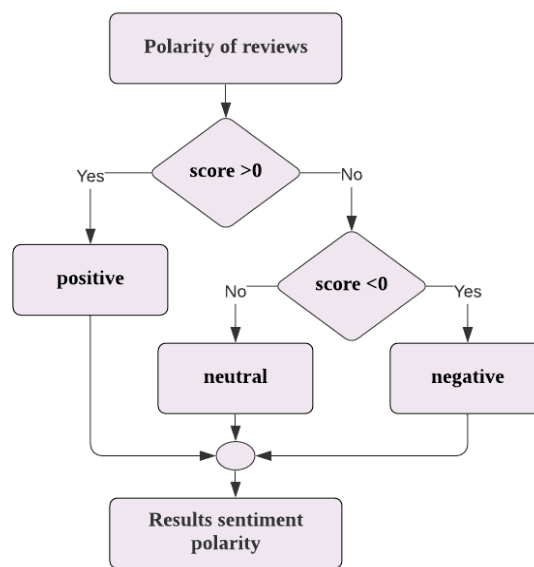

Fig. 2. Polarity of Reviews.

## IV. RESULTS AND DISCUSSION

The dataset consists of 68.8% positive, 14.6% negative, 16.6% neutral. Fig. 3 shows the number of reviews for each class.

In the Fig. 3 above, positive reviews are far more than negative and neutral reviews in the dataset. When one category is greater than the other, the data is skewed. Therefore, classification accuracy is not an appropriate statistic to optimise when dealing with imbalanced categories. Thus, accuracy may be artificially relatively high. Majority categories are favoured, while minority categories are not recognized. They result in a biased model for a particular category. Most machine learning algorithms work best when the number of samples in each category is almost equal. There are different ways to balance data: random oversampling and SMOTE. To balance the data, random oversampling was utilised to replicate the minority class samples. It also does not result in any data loss.

Evaluating the model after applying all stages is one of the most critical steps. In addition to this, there are many metrics to assess the quality of deep learning models. This research used two methods to evaluate the confusion matrix, K-Fold Cross-Validation. Indeed, the confusion matrix is one of the most informative performance measures a multi-class learning system can rely on [49]. The most commonly used measure for sentiment classifications is accuracy, precision, recall, and F1-score. They are briefly described below. There it is indicated as True Positives (TP), False Positives (FP), True Negative (TN) and False Negative (FN).

Accuracy is one of the most frequently used metrics. The ratio is expected reviews relative to the total number of reviews correctly. Calculation of the accuracy is made according to the equation.

$$Accuracy = \frac{TP+TN}{TP+FP+FN+TN} \qquad (1)$$

The ratio of properly expected positive reviews to the total expected positive reviews. The precision measure is calculated using an equation.

$$Precision = \frac{TP}{TP+FP} \qquad (2)$$

It tells what fraction of all positive samples was correctly predicted as positive by the classifier. This value is calculated according to the equation.

$$Recall = \frac{TP}{TP+FN} \qquad (3)$$

It combines precision and recall into a single measure. Mathematically it is the harmonic mean of precision and recall.

$$F1\ Score = \frac{2*Precision*Recall}{Precision+Recall} \qquad (4)$$

The results shown in Table II proved that some machine learning algorithms outperform each other in terms of accuracy, precision, recall, and F1-score, their ability to classify, discriminate and recognize reviews to be classified into (positive-negative-neutral). It was noted that the SVM model was more accurate than other classification models, with 98% accuracy.

Fig. 3. Number of Reviews for Each Class.

TABLE II. CLASSIFICATION METHODS

| Classification Method | Accuracy | Precision | Recall | F1-score |
|---|---|---|---|---|
| SVM | 98% | 98.16 | 98.08 | 98.09 |
| LSTM | 96% | 95.63 | 95.58 | 95.58 |
| RNN | 96% | 95.99 | 95.96 | 95.95 |

The Fig. 4 below shows the results of Table II of the models used and compares the best results in terms of accuracy, precision, recall and F1-score. It also shows the superiority of the SVM model over the models used.

K-Fold Cross-Validation is one of the most common ways to validate ML models and bolster and corroborate our findings. The available dataset is partitioned into subsets of approximately equal size. The "K" refers to the number of producing several subsets. The first subset serves as a validation set, and the remaining four subsets serve as a training set.

Table III represents the accuracy obtained by implementing the Stratified K-Fold Cross Validation Technique on the dataset used: 99% accuracy for the SVM model, 94.7% for the LSTM model, and 93.9% for the RNN model. The accuracy obtained by each algorithm is almost similar to our findings from this confusion matrix.

Fig. 4. A Comparison of Various Performance Measurements.

TABLE III. ILLUSTRATION OF K-FOLD CROSS-VALIDATION

| Model | 1-Fold | 2-Fold | 3-Fold | 4-Fold | 5-Fold |
|---|---|---|---|---|---|
| SVM | 97.5% | 98.51% | 99.6% | 99.7% | 99.7 % |
| LSTM | 94.2% | 95.3% | 95.2% | 94.5% | 94.5% |
| RNN | 90.0% | 91.0% | 90.5% | 99.4% | 99.2% |

One of the functions of machine learning is the prediction and classification of data, for which we employ one of the many machine learning models. Are tuning the parameters of models so that their behaviour can be adjusted for a given problem. According to this, a parameter can be described as a configuration variable intrinsic to the model. Multiple experiments are performed to obtain the best parameters. Table IV shows the best parametric settings for models used in the paper.

The Fig. 5 shows the training and testing accuracy score of the classifiers used in this paper.

Fig. 5 shows that the highest training accuracy score was 99% for the SVM model, and the training accuracy score for the LSTM and RNN models was 98%. Finally, the highest testing accuracy is 99% of the SVM model. Accordingly, the SVM model outperformed the rest of the classification models, as the training and testing data ratio was the highest among the classifiers; consequently, the SVM model was the best model performing among the models used.

Accordingly, almost all prior research has used machine learning algorithms to classify the Arabic text into positive, neutral or negative. Since this paper focuses on Arabic reviews in the Saudi dialect, Table V below shows the results obtained by other researchers.

TABLE IV.    PARAMETRIC SETTINGS FOR THE USED MODELS

| Model | Parametric settings |
|---|---|
| SVM Model | kernel='rbf' |
| | degree=3 |
| | gamma=0.5 |
| | C=1.0 |
| | class_weight='balanced' |
| LSTM Model | dropout_rate=0.002 |
| | embed_dim = 32 |
| | hidden_unit = 160 |
| | optimizers = RMSprop |

TABLE V.    A BENCHMARK OF STUDIES USING SAUDI DIALECT DATASETS

| Paper Name | Model Name | Accuracy |
|---|---|---|
| Sentiment Analysis of Saudi Dialect Using Deep Learning Techniques [5]. | Bi-LSTM | 94% |
| Arabic tweets sentiment analysis – a hybrid scheme [50]. | SVM | 84% |
| SDCT: Multi-Dialects Corpus Classification for Saudi Tweets [51]. | SGC and LSVM | 91.5% |
| Effect of Saudi dialect preprocessing on Arabic sentiment analysis [52]. | KNN | 73.3% |
| Sentiment Analysis of Twitter Data for Saudi Universities [41]. | SVM | 93.5% |
| Tourist Reviews Sentiment Classification Using Deep learning Technigues: A Case Study in Saudi Arabia | SVM | 98% |

Table V shows that all previous studies dealt with the problem of classifying reviews in the Saudi dialect. It also shows that the highest accuracy was 94 for the model Bi-LSTM [5]. Previous studies used the same models used in this paper with varying degrees of accuracy, and that is naturally due to how they processed the data. In this paper, we compared the three models after processing the dataset to see which model gives the highest accuracy results in addressing the problem of sentiment classification in the Saudi dialect. We noticed that SVM gave the best results in different places such as accuracy, precision, recall and F1-score. In addition, although the dataset used in this paper was very poor compared to previous research, the study achieved good results. Most prior research has shown that Twitter, as well as Amazon and Tripadvisor, is the most often utilized dataset source in sentiment categorization.

## V. CONCLUSION

There is continued growth in tourists' search for online tourist services. This has led to an increase in the volume of online reviews, but manual reviews are time-consuming and useless. Reading a few reviews provides an incomplete understanding. Accordingly, this paper aimed to build a model capable of accurately sentiment classification in the Saudi dialect for Arabic review in the tourist place reviews using deep learning techniques. A Saudi dialect lexicon was created. The created lexicon was used to classify web scraping reviews from Google Map.

The classification of reviews was limited to (positive, negative, and neutral). This article has also provided: a summary of how-to sentiment categorization. The second section of the study is a literature survey on machine learning approaches. Thirdly, the study introduced three classification algorithms: SVM, LSTM, and RNN. The proposed algorithms' performance was measured and compared through performance metrics such as accuracy, precision, recall, and F1-score. The results showed that SVM achieved the highest classification accuracy of 98%, outperforming RNN and LSTM. All the metrics: Accuracy, Precision, Recall and F1-score high in case of SVM.

Future study will entail locating the optimal method to categorise the Saudi tone with greater precision and gathering

additional tourism ratings to expand the dataset. In addition, more classifications are needed than positive, negative, or neutral as they do not provide sufficient information about the reaction given by people and classify phrases with different emotions such as sadness, neutral, worry, love, fun, hate, happiness, and anger. This would help extract the person's natural feelings and hope to expand our lexicon by adding more slang terms for the Saudi dialect.

*Abstract*—**Automated classification of each heartbeat class from the ECG signal is important to diagnose cardiovascular diseases (CVDs) more quickly. ECG data acquired from the real-time or clinical databases contains exceptional values or extreme values called outliers. The separation and removal of outliers is very much useful for improving the data quality. The presence of outliers will influence the results of machine learning (ML) methods such as classification and regression. Outlier identification and removal plays a significant role in this area of research and is a part of signal denoising. Also, most of the traditional ECG-signal processing methods are facing the difficulty in finding the essential key features of recorded signal. In this work, an extreme outlier detection technique known as improved inter quartile range (IIQR) filtering method is used to find the outliers of the signal for the feature ranking process. In addition, an optimized random forest (ORF) based heterogenous ensemble classification model is proposed to improve the true positive and runtime on the ECG data. The classification of each heartbeat type is classified with majority voting technique. Ensemble learning and majority voting rule is used to enhance the accuracy of heart disease prediction. The proposed feature ranking based ORF ensemble classification model (LR + SVM + ORF + XGBoost + KNN) is evaluated on the MITBIH arrhythmia database and produces an overall accuracy of 99.45% which significantly outperforms the state-of-the-art methods such as, (LR + SVM + RF + XGBoost + KNN) with 96.17% accuracy, ensemble deep learning accuracy of 95.81% and ensemble SVM accuracy of 94.47%.**

*Keywords*—*Feature ranking; improved inter quartile range; majority voting; outlier detection; optimized random forest*

## I. INTRODUCTION

World health organization (WHO) reported that globally cardiovascular diseases (CVDs) are the leading cause of death, having a significant impact on the nation's financial and health-care systems. The people residing in low-and middle-income countries are most affected with CVDs due to lack of access to effective and equitable healthcare services, resulting the increased mortality rate at a younger age [1]. An electrocardiogram (ECG) is a non-invasive tool for detecting CVDs that produces reliable findings with affordable cost. But the beat-by-beat analysis of ECG waveform data manually is tedious, inaccurate, and overwhelming [2]. So, efficient, and precise automated methods for beat classification have gotten significant interest recently. Due to the enormous data quantity and sparseness of medical data, obtaining an essential feature set for classification problems is becoming increasingly difficult. The performance of most classifiers is improved by eliminating the irrelevant or redundant features [3, 4]. Feature selection helps to avoid overfitting and high dimensionality problems in machine learning by reducing the number of features in the model and tries to optimize the model performance [5]. Most conventional classification methods are independent of dynamic feature selection due to large data size and high dimensionality. Feature selection through ranking tries to reduce the computational complexity of the model by compromising the classifier performance [6]. ECG "feature ranking and classification" are the significant tasks to medical and scientific researchers due to its higher-dimension feature space and small sample size. Existing techniques reviewed in the literature concentrates on using single base classifiers and independent of feature ranking process for feature selection. These models are limited to small data size and suffer with high dimensional feature space.

In this study, an extreme level outlier detection filtering approach is proposed for the detection of outliers from the ECG data taken from MITBIH Arrhythmia dataset [7]. The proposed outlier technique is an improvement to the traditional inter-quartile range outlier detection method [8, 9]. The extreme level outliers are removed to improve the error rate in the classification. After filtering, a hybrid kernel-based feature selection approach is developed to find the ranks of the features. The features with highest ranks having highest probability are considered for classification and the features with lowest ranks are neglected. These optimal set of features are used to predict the abnormality using classification model. In this research, we have developed an ensemble learning model involves five base classifiers with majority voting mechanism. The proposed ensemble method outperforms the state-of-the-art base classification techniques with an accuracy of 99.45%.

The rest of the paper is organized as follows: Section 2 gives a comprehensive review on various feature extraction and classification techniques reported in the literature. Section 3 discusses the proposed extreme level outlier detection-based hybrid random forest ensemble classification model. This section is divided into four subsections, where Section 3.1 deals with the ECG dataset used for training and testing the model. Section 3.2 explains the extreme outlier detection-based filtering approach used to find the outliers present in the data, while Section 3.3 describes the enhanced entropy-based feature ranking process, and Section 3.4 discusses the proposed optimized random forest ensemble learning model to classify the individual classes of ECG heartbeats. Section 4 report the results and discussions obtained for proposed ensemble classification model. Finally, the conclusions are drawn in Section 5.

## II. MOTIVATION TOWARDS ENSEMBLE LEARNING

High dimensional biomedical data includes large amount of redundant and irrelevant features. If all the features are considered of equal importance, then the accuracy, time and spatial complexity of the model can be severely impacted. Hence, feature selection is considered as a significant step in the diagnosis of diseases based on high-dimensional biomedical data. The idea behind feature selection is to select an appropriate feature subset [10] which will act as a suitable foundation for future classification. It enhances the generalization capability of the prediction model, optimizes the homogeneity of the prediction algorithm, improves the computational performance, and avoid overfitting.

Feature selection algorithms are categorized into three types i.e., filters, wrappers, and embedded methods. Filter methods evaluate each feature independently of the classifier, rank the features according to some evaluation criterion and select the best ones [11]. This evaluation can be performed by using entropy for instance [12]. Wrappers methods evaluate the classifier's performance on various subsets of features and select the subset with maximum performance. These approaches are slower than filter methods and are dependent on the classifier used. Furthermore, feature subset selection is an NP-hard process that requires significant computation time and memory [13]. Genetic algorithm, Random search and greedy stepwise are some traditional algorithms used for feature subset selection. Embedded approaches on the other hand select the features during the learning process like artificial neural networks do [14]. Some studies on the other hand, applied various dimensionality reduction techniques on high dimensional database to diminish the size of the feature space. Most popular techniques such as principal component analysis (PCA) [15], singular value decomposition (SVD) [16] and linear discriminant analysis (LDA) [17] are used for biometric authentication applications.

The optimized feature set is given as input to the classifier to recognize the information about cardiac diseases from ECG. Abnormal classification has become a valuable and promising technique for early assessment of arrhythmia. Mohebbanazz et al., [18] proposed an optimized decision tree (DT) and adaptive boosted optimized decision tree method for classification of six types of ECG beats and evaluated the

performance of the model on MITBIH arrhythmia database achieved an effective accuracy of 98.77% compared to state-of-the-art techniques. [19] introduced a time-efficient, reliable, and low-complexity resource-saving architecture with random forest (RF) classifier to classify two major types of arrhythmias such as supraventricular ectopic beats ventricular ectopic beats (VEB) and (SVEB). Classification performance of the model reaches to the f1 scores of 81.05% for SVEB and 97.07% for VEB. Another popular classifier known as, Support Vector Machine (SVM), [20] is a linear classifier that separates the classes linearly by creating a hyperplane from high-dimensional space. It captures the non-linear relationships of the ECG signal, detects the heartbeats, and classifies the data as normal/abnormal with high accuracy. Researchers proposed several SVM based classification techniques to detect arrhythmias in literature which involves Multi-class SVM [21], SVM with NN [22]. However, due to its high dimensionality space, it suffers with computational constraints. An efficient real-time time series cardiac disease prone weight (CDPW) Naive Bayes classification technique is implemented in [23] that estimate the posterior probability of different features using fuzzy rule and measures the CDPW value. The model performance was evaluated using 15000 records of real-time ECG data, and greater precision values were produced with less time complexity. The author in [24] employed K-Nearest Neighbour classifier on MITBIH arrhythmia database to classify five types of ECG beats and attained an accuracy of 98.40% for isolating the signals. A robust extreme gradient boosting technique is utilized in [25] to classify five ECG beat classes from both MITBIH data and self-collected single-lead wearable ECG dataset. The developed model outperforms the traditional models with an accuracy of 99.14% on MITDB and 98.68% on wearable ECG dataset. Ahmed et al., in [26] employed artificial neural network (ANN) to classify the ECG heartbeats from two imbalanced datasets MITBIH arrhythmia and PTB databases. They focus on penalising the loss value of ANN by assigning the class weights which outperforms the state-of-the-techniques. However, researchers have demonstrated that the ensemble system can increase the performance of a base classifier.

Motivated by the development of several ML models, and a bid to improve accuracy, we propose a heterogeneous ensemble learning framework. Ensemble learning is the process of integrating various learners together to improve the stability and prediction ability of the classification model. It has been successfully applied in solving various machine learning problems includes feature selection, classification, and prediction. Fig. 1 shows a typical block diagram of an ensemble classification model, which includes three primary blocks: training datasets, base classifiers, and a combiner. In recent studies, researchers have proved that performance of the base classifier can be improved with ensemble classification method. Jose et al., [27] proposed random forest ensemble classification technique to diagnose cardiac arrhythmia. In this model the more informative features were selected using ranking criteria on training dataset. The performance of the learning model is evaluated on MITBIH arrhythmia database and obtained an accuracy of 96.14% and f1-score of 97.7%, 90.5% and 73% for normal, ventricular and

supraventricular beats. An ensemble of random forest and support vector machine is implemented in [28], to classify five types of cardiac arrhythmia's and obtained an accuracy of 98.21%. Recent advances in technology proposed deep learning-based ensemble classification technique for improved cardiac diagnosis [29]. Experimentation is carried out on PTBDB and MITBIH database and found an accuracy, F1 score and area under curve (AUC) of 0.98, 0.93 and 0.92 for MITBIH datasets and 0.99, 0.986 and 0.995 for PTB dataset. A hybrid heterogeneous ensemble classification model for the prediction of heart disease is proposed in [30]. The performance of the model is evaluated on the Kaggle dataset and reports 98% accuracy which outperforms the weak learners. As many ensemble classification techniques reported in the literature, developing a robust ensemble learning model with lowest error and greater accuracy is still becoming a challenging task.

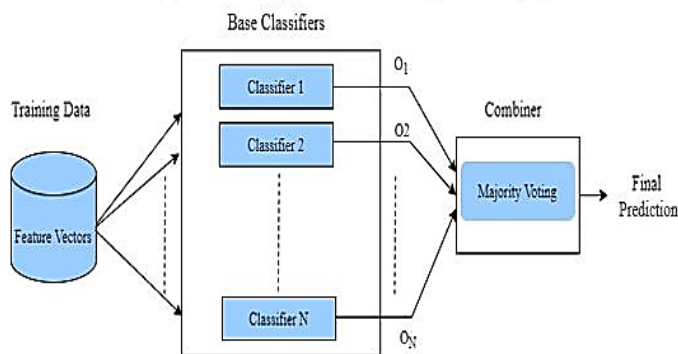

Fig. 1.    Architecture of Ensemble Learning System.

### III.   EXTREME LEVEL OUTLIER DETECTION AND ORF BASED ENSEMBLE CLASSIFICATION

The outlier detection-based ensemble classification framework is shown in Fig. 2. It includes the following stages: 1) Data Acquisition, 2) Preprocessing, 3) Feature Ranking and 4) Classification.

#### A.  Data Acquisition

The ECG data used for this proposed framework is taken from the clinical pre-recorded MITBIH Arrhythmia database. It consists of 48 ECG recordings, each spanning 30 minutes and captured at 360 Hz per channel with an 11-b resolution and a 10-mV range. In this work, we have evaluated the proposed model on two datasets i.e., dataset1 and dataset2. The dataset1 is the DWT processed training data taken from [24] having the specified features of amplitude, RR intervals, Speed, etc., and dataset2 consists of raw DWT processed coefficients of MITBIH arrhythmia dataset. Most recent studies concentrated on the evaluation of four classes such as N (Normal), S (Supraventricular), V (Ventricular) and F (Fusion) beats. In this work, we focus on detecting the N (Normal Synus Rhythm), and three arrhythmia's such as B (Ventricular Bigeminy), T (Ventricular Trigeminy) and VT (Ventricular Tachycardia). The waveform representation of ventricular bigeminy, ventricular tachycardia and ventricular trigemini is shown in Fig. 3(a), 3(b) and 3(c), respectively.

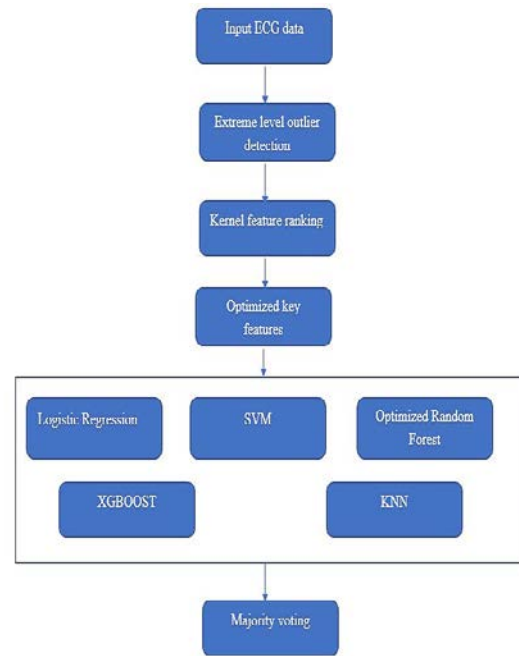

Fig. 2.    Framework for Extreme Outlier Detection-and ORF based Heterogenous Ensemble Learning.

#### B.  Data Preprocessing

Data preprocessing is the foremost step before implementing any machine learning technique. It improves the quality of data and makes it useful for modelling. The outlier technique used in this model is extreme value outlier detection. In this approach, the extreme level outliers are removed to improve the error rate in the classification problem. This approach is an extension to the traditional quartile-based filtering approach. The mathematical equation for finding the outliers is represented as follows:

At first, the data is sorted in ascending and split into three quartiles,

$$A[] = SortedAttIndices(); \qquad (1)$$

The $25^{th}$, $50^{th}$ and $75^{th}$ percentile of data represented in three quartiles in the form of $\lambda_1, \lambda_2, \lambda_3$, and is represented as,

$$\lambda 1 = V(F(|A|/4)); \qquad (2)$$

$$\lambda 2 = (V(F(|A|/2) + V(F(|A|/2+1)))/2; \qquad (3)$$

$$\lambda 3 = (V(F((|A|-|A|/4-1))) + V(F((|A|-|A|/4))))/2; \qquad (4)$$

Inter Quartile Range (IQR) between the first and third quartiles can be calculated as,

$$\theta = \lambda 3 - \lambda 1; \qquad (5)$$

The upper and lower extreme values of the outliers can be detected using,

$$UE[] = \lambda 3 + \eta . \log(\Gamma \theta) \qquad (6)$$

$$LE[] = \lambda 1 - \eta . \log(\Gamma \theta) \qquad (7)$$

Fig.3(b). Wave representation for ECG signal record 106 of MITDB representing ventricular tachycardia condition.

Fig.3(c). Wave representation for ECG signal record 106 of MITDB representing ventricular trigeminy condition.

Fig. 3.   Waveform Representation of Bigeminy, Ventricular Tachycardia and Ventricular Trigeminy Conditions.

$$\Gamma(v/2, x/2) = \int_{x}^{\inf} r^{v-1}.e^{-r}dr \tag{8}$$

$$UOutlier = \lambda 3 + \eta.\max(\Gamma(\lambda 3 + \lambda 1, 9)), \log(\Gamma\theta)) \tag{9}$$

$$LOutlier = \lambda 3 - \eta.\max(\Gamma(\lambda 3 + \lambda 1, 9)), \log(\Gamma\theta)) \tag{10}$$

### C. Feature Ranking

After filtering approach, feature rankings are evaluated for better classification accuracy in the machine learning algorithms (e.g., support vector machines, logistic regression, Naive Bayes, random forest and artificial neural networks). For each feature, the usual technique of calculation is to estimate the distribution mean and standard deviation. Feature selection is a technique of eliminating redundant and nonessential data from the dataset discovering those features from those which have a significant effect on the outcome (e.g. higher accuracy in learning, lower computational cost, and better model interpretability).

In the proposed feature selection approach, an advanced kernel estimator is used to improve the hyper-parameters of the algorithm. The kernel estimator calculates the correlation values of each individual feature corresponding to the input dataset. In the proposed model, the hyperparameters were initialized using the kernel estimator and probabilistic based entropy measure. Here, each feature is ranked using the probability algorithm. The subset of top k features is selected as essential key features of the classification problem. Gaussian Estimator uses the kernel probability function to estimate the conditional variance of input data features.

$$B_f = uniqueCV(D); // Unique column values \tag{11}$$

$$HB_f = Histobins[] = histogrambin(D) \tag{12}$$

$$GaussianKernel : GK(f, \theta) = e^{-\theta^2}/(2*f^2) \tag{13}$$

$$\psi = gkv = GK(\sum HB_f, \sum B_f); \tag{14}$$

$$KernelProbability = KP(D) = | HB_f / (\sum \psi * HB_f) | \tag{15}$$

$$GaussianEntropy : GE(d_i) = -GK(\sum_i d_i.\log(d_i), \mu_d) \tag{16}$$

The Conditional Gaussian Estimator (CGE) can be calculated as,

$$CGE : CGE(d_i) = -GK(\sum_i d_i.\log(d_i), \mu_d) - GE(\sum_i d_i) \tag{17}$$

$$KernelProbEstimation(kp) : IPSO(kp) = GE(\sum_i kp) - CGE(kp) \tag{18}$$

Gaussian entropy is used to find the entropy value of the feature based on the Gaussian Estimator. Conditional Gaussian Estimator is used to check the conditional probability of each feature value based on the Gaussian probability estimator. Finally, improved optimization hyperparameters are computed using the Gaussian Kernel Estimator and Conditional Gaussian Estimator.

### D. Ensemble Classification

In this phase, an optimized random forest approach is proposed by using the key features. A heterogenous ensemble learning model is implemented by using a set of base classifiers. we have developed an ensemble learning model comprised of four base classifiers and one optimized random forest (ORF) classifier with majority voting mechanism. The standard random forest (RF) technique employs its own entropy measure for classification, but the proposed ORF uses an enhanced entropy measure for beat classification. Ensemble learning and majority voting rule is used to enhance the accuracy of heart disease prediction.

| Algorithm Steps: |
| --- |

Step 1: Input ECG data
Step 2: Pre-process input data for missing values.
Step 3: Gradient filter is used to transform the data from unequal distribution
Step 4: For each randomized sample $S_i$
        Do
        Enhanced entropy:

$$Pr = -Prob(D_i).\log(Prob(D_i))$$

$$Ent(D) = \sum_i Pr$$

  PE=Math.cbrt(entropy(data)*total*GHDSplitCriter

  ion.computeHellinger(data)) *Pr/ (chiVal(data)).

  for each sample in the test data check
     If (PE>0)
     Then
$$S' = Classify((D_i, D_j));$$

     else
     continue
     end for

## IV. RESULTS AND DISCUSSION

On the heart ECG dataset, experiments are run in the python environment. On large, high-dimensional datasets, the extreme level outlier detection technique is used improve the true positive rate and accuracy. A hybrid heterogeneous ensemble classification framework is developed in this work to improve the overall classifier performance. Majority voting technique is employed to find the appropriate decision of individual base classifiers.

The proposed ensemble learning method compares the results using the entire training data set. As a result, each cross-validation model's prediction accuracy tends to be higher than base classification models. The proposed kernel-based feature selection-classification model outperforms conventional models, according to experimental results. A confusion matrix contains information about a classification model's actual and predicted classifications. The data in the matrix is commonly used to evaluate the performance of such a model. The classification results are displayed in the Confusion matrix shown in Table I. It depicts the connection between the actual and predicted classes. It also demonstrates how many true features were predicted as true as well as false.

TABLE I. CONFUSION MATRIX

| Actual Values | | |
|---|---|---|
| **Predicted Values** | TN | FP |
| | FN | TP |

True Negative (TN): The predicted values were correctly identified as true negatives.

True Positive (TP): The predicted values turned out to be true positives.

False Positive (FP): The predicted values were misinterpreted as true positives. i.e., the negative values were predicted to be positive.

False Negative (FN): The predicted values were incorrectly predicted as actual negatives, i.e., positive values were incorrectly predicted as negatives.

We can deduce the following statistical measures from the confusion matrix:

*1) Precision*: Refers to the percentage of correct positive cases.

$$Precision = \frac{TP}{(TP + FP)} \tag{19}$$

*2) Recall or sensitivity*: Represents the number of correctly identified positive cases.

$$Recall = \frac{TP}{(TP + FN)} \tag{20}$$

*3) F1 score*: Defined as the harmonic mean of precision and recall.

$$F\text{-}measure = 2*\left[\frac{Precision * Recall}{Precision + Recall}\right] \tag{21}$$

*4) Accuracy*: It is the percentage of correct predictions out of a total number of predictions.

$$Accuracy = \frac{(TP + TN)}{(TP + TN + FP + FN)} \tag{22}$$

The following figures and tables show the experimental results of the MIT-ECG Data

Table II describes the sample ECG signal data with specified number of features such as RR, speed, age, sex, medicine, and class. This dataset is used to train the model using the proposed classification framework.

Fig. 4 illustrates the existing ensemble learning model on the input MITDB dataset. From the figure, it is observed that the experimentation is carried out on the dataset with ensemble of several base classifiers such as LR, SVM, RF, XGBoost and KNN. The learning model correctly classifies the instances of bigeminy, normal tachycardia and ventricular tachycardia beats with 96.17% accuracy.

Fig. 5 explains the proposed ensemble learning model on the input MITDB dataset. Here an optimized random forest (ORF) based heterogeneous ensemble learning model is developed and experiment is conducted on the dataset. From the figure, it is observed that the ORF ensemble learning model optimizes the relevant and redundant features based on entropy value and correctly classifies the instances with 99.455accuracy compared to existing ensemble learning models.

Table III lists out the comparison of proposed ensemble learning method with state-of-the-art classification techniques. The proposed optimized random forest-based ensemble model exhibits the superior performance among all the state-of-the-art methods stated.

Fig. 6 shows the comparative analysis of proposed ensemble heat-beat detection to the conventional models for accuracy metric. In this figure, as the number of samples increases along with features space, proposed model has better heat-beat detection accuracy than the previous models. Here, the cross validation is performed for 10 samples, 20 samples, 30 samples, 40 samples and 50 samples and accuracy performance for proposed model is observed.

Fig. 6.   Comparative Analysis of Proposed Framework to the Conventional Frameworks for ECG Heartbeat Detection for Accuracy Metric.

Fig. 7 depicts the comparative analysis of proposed ensemble heartbeat detection to the conventional models for recall metric. In this figure, as the number of samples increases along with features space, proposed model has better recall than the previous models. Here, the cross validation is performed for 10 samples, 20 samples, 30 samples, 40 samples and 50 samples and the recall for proposed model is observed.

Fig. 8 presents the comparative analysis of proposed ensemble heat-beat detection to the conventional models for F-measure metric. In this figure, as the number of samples increases along with features space, proposed model has better heat-beat detection F-measure than the previous models.

Table IV lists the comparative analysis of proposed ensemble heartbeat detection to the conventional models for AUC metric. Here, the cross-validation test of 10 samples to 50 samples is done and classification result is observed over various classifiers. In this table, as the number of samples increases along with features space, proposed model has better heartbeat detection AUC than the previous models.
Fig. 7. Comparative Analysis of Proposed Framework to the Conventional Frameworks for ECG Heartbeat Detection for Recall Metric.

Fig. 8. Comparative Analysis of Proposed Framework to the Conventional Frameworks for ECG Heartbeat Detection for F1-Score Metric.

Table V lists the comparative analysis of proposed ensemble heartbeat detection to the conventional models for precision metric. In this table, as the number of samples increases along with features space, proposed model has better heartbeat detection precision than the previous models.

## V. CONCLUSION

In this paper, an optimized ensemble learning approach is implemented on the MITBIH arrhythmia dataset for better decision making. Since most of the base classifiers are independent of data size and outliers, the proposed improved inter quartile range outlier detection-based optimized random forest ensemble learning model has better efficiency in terms of outliers filtering and data classification problem. This outlier technique proposed in this work is an improvement to the traditional inter quartile range outlier detection method which removes the extreme level outliers and improves the accuracy in the classification process. After filtering, a kernel-based feature selection approach is implemented to find the ranks of the features. In addition, this paper proposed an enhanced entropy measure used in decision trees of random forest algorithm to get the optimal set of features. Finally, the ensemble learning classifies each class of heartbeat by majority voting principle and achieved an accuracy of 99.45% which outperforms the various state-of-the-methods.

*Abstract*—**Software size estimation plays an important role in project management. According to the report given by Standish Chaos, about 65% of software projects are beyond companies budget or overdue; which could have been saved if an early estimation was imposed. Though the software size can't be measured directly, but it is related to effort and hence a low effort will lead to low size. The calculation of effort depends upon how the data is organized or segmented. This research paper focuses on the improvement of data segmentation in order to reduce the effort and parallel the size. In order to improve the segmentation architecture, the project data is divided based on the similarity indexes which the projects have in between their attributes. Three similarity measures were used namely Cosine Similarity (CS), Soft Cosine Similarity (SC) and a hybrid similarity index which combines CS and SC. Based on these similarity indexes, the project data is divided into groups by K-means algorithm. In order to estimate the size, the co-relation between the formed groups are calculated. To calculate the correlation, Mean Square Error (MSE), Square Error (SE), and Standard Deviation (STD) is calculated and the normalized parameters are used to evaluate the software size.**

*Keywords*—*Cosine similarity; hybrid similarity; machine learning; size estimation and soft cosine similarity*

## I. INTRODUCTION

Software size estimation has always been a favorite area for the researchers as the wrong estimation of effort and size will lead to high computation risk and project failure. If the company does not earn from a project, even if the project is complete, it is termed as failure. Therefore, to overcome this problem, an early stage prediction model is designed based of the past project experience [1]. Underestimation and overestimation both leads to high project risk completion. In case, if size of the software project is estimated at the earliest stage, then, project handling team can provide better plan. Conventional software development mainly goes through four levels namely requirements elicitation, design, coding and testing [2]. After designing early size estimation model, most of the systems have better response. If the project estimation is terminated just after first level, then it affects directly the project management. Therefore, early size estimation of project is a crucial task not only for conventional software development bust also for agile development, as it makes the projects more manageable. Software size metrics play an important role in the success of this task [3]. In the conventional approach, Lines of Code (LOC), evaluation has been a way to evaluate the size of the projects [4]. Function Point (FP) sizing also evolved as a method to acquire the

details of the project but being a object oriented concept again, the usage of FP will also require code oriented metrics [5], [6]. Early size estimation requires the attributes which does not involve post coding methods. Any estimation method, requires a learning model and as it is described earlier, code oriented metrics will be only attained once the project is complete. In order to train the system, the Ground Truth (GT) of the data is the foremost requirement. GT refers to the class label of the data. As for example, suppose a project had 5000 LOC ,10 team members,1 team lead and 50 hours of development and the effort from the team in order to develop the project was "high", then the GT for Project Attribute(PA)→{5000 ,10,1,50} is high. Unfortunately, these type of metrics can be only evaluated after the development and does not suit early size estimation. In the early age of development of early size estimation, authors introduced learning methods using machine learning and its extension. [7]. used machine learning oriented neural networks to train the system based on the feedback from the engagements of the company but the generation of GT through machine learning failed here.

### A. Machine Learning

The machine learning architecture needs a training data algorithm with its ground truth value. The material methods which involves statistics are called machine learning. Common machine learning algorithms are as follows.

1) K-means.
2) Regression.
3) Linear Propagation Model.

This research article uses K-means clustering algorithm with the enhancement of base architecture. The k-means clustering algorithm selects a random centroid out of the provided set of attributes. If there are three attributes, then the centroid of the clusters will also have three attributes. The adjustment in the centroid takes place when the co-relation between the attributes and centroids varies and goes to the adjustment into another cluster. In order to calculate the distance between centroid and attribute values, Euclidian distance is calculated. The data is always divided into 'k' number of clusters and in order to decide 'k', there are multiple ways of advisory. This research work does not focuses on the calculation of 'k' as there are two sections for the entire data namely 'high size' and 'low size' which is further subdivided into two sub-segments namely 'moderate' and 'high' . The size before the development can't be directly evaluated and hence this research article refers to the

statement that high effort will lead to high size and low co-relation will lead to high effort.

$$Effort \propto cost \,||size \qquad (1)$$

The rest of the paper is organized as follows: Section 2 represents the related work in the field of size estimation. Section 3 presents the proposed work including technique used and process of work. The result and discussions are presented in Section 4. Conclusion is presented in Section 5.

## II. RELATED WORK

Ahn et al. (2003) have presented a metric analyses based methodology tool to estimate effort at early stage of software project. Using this model, a project manager can analyzed, software system like as analyzed by FP analysis. In addition, relation between UML point and effort has also been observed [8]. Baskeles et al. (2007) have presented ML based software estimation model to resolve the problems related to cost and schedule extension. The test has been conducted on the collected data obtained from software industry in Turkey. Principle Component Analysis (PCA) has been applied as data dimension reduction approach. ML technique has been trained by 50 and 40 projects, and test later using 10 and 20 projects respectively. From the test results it has been concluded that the parametric models are not sufficient for software effort estimation [9]. Nassif et al. (2013) have presented a new logarithmic based linear regression model, which works on the basis of use case point model (UCP). This approach is used case diagram to determine software effort. To regulate the productivity factor of regression model Fuzzy logic is used as Fuzzy Interface System (FIS). Based on software size and project group productivity, neural network is design and used to estimate software effort. At last comparison between ANN and log-linear regression based model has been presented. The results show that NN outperformed compared to regression model while estimating small project, but for large scale projects regression algorithm performed better [10]. Satapathy et al. (2016) have used Random Forest (RF) as ML approach to enhance the performance of effort prediction model. UCP approach has been used for estimating project effort, the parameters of which has been improved using RF approach. Among various ML techniques like NN, log-linear regression scheme, stochastic approach, and radial function method, RF surpass among all [11]. Sharma et al. (2017) have presented a review on various ML techniques used for software effort and size estimation. LOC and FP are the two main metrics used for effort estimation. There are various validation methods that can be considered in the expansion of research to confirm the consequences of software effort assessments. The main validation methods are Cross Assessments, Jacknife method and Iterative method. In addition, research trends have shown that assessment methods need to be explored and improved. In addition, other ML approaches, such as size metrics and regression trees, can also be utilized using real-life data sets [12]. Spikol et al. (2018) have presented ML based effort estimation model using International Software Benchmarking Standards Group (ISBSG) dataset. For cross validation, three ML techniques SVM, ANN, and generalized Linear Model has been used [13]. Lavazza et al. (2019) have empirically studied the COSMIC early size estimation scheme using historical dataset. Average Functional Process along with the Equal Size Bands methods have been used for the prediction of effort estimation. Results shows that sometimes functional process provides better results that can be accepted but sometimes the error is so large, which is not to be acceptable for better performance of any project. On the other hand, band method provides better results [14]. Nassif et al. (2019) have compared three FIS systems namely, Mamdani, Sugeno with defined output, and Sugeno with linear output. The performance of the system has been analyzed based on standard sized accuracy, error, effect size and statistical tests. The designed model is trained using ISBSG dataset, and results show that FIS are very sensitive to outliers. Authors also concluded that when fuzzy logic is used in combination to regression model, the system outperforms [15]. Silhavy et al. (2021) had proposed a method for size estimation based on the use case and the number of actors. In the process, stepwise regression was performed that minimized the number of errors adjoining the size estimation of the software system. This is also added that the predictions were independent of the use case points to avoid inaccurate estimations [16]. Daud and Malik (2021) had aimed at quantitative analysis of the effect of precise software size estimations when the project transits to the designing phase. To achieve this Analysis to Design Adjustment Factors were introduced in the proposed work that demonstrated improved accuracy of the proposed model [17]. Suresh (2022) had integrated Artificial Neural Netowrk (ANN) to generate precise estimations in the initial stages of development cycle. It was observed that the work offered optimal and automated predictions based on training and classification using ANN architecture. The work exhibited better and more accurate software effort estimations in comparison to the existing works [18].

### A. Problem Formulation

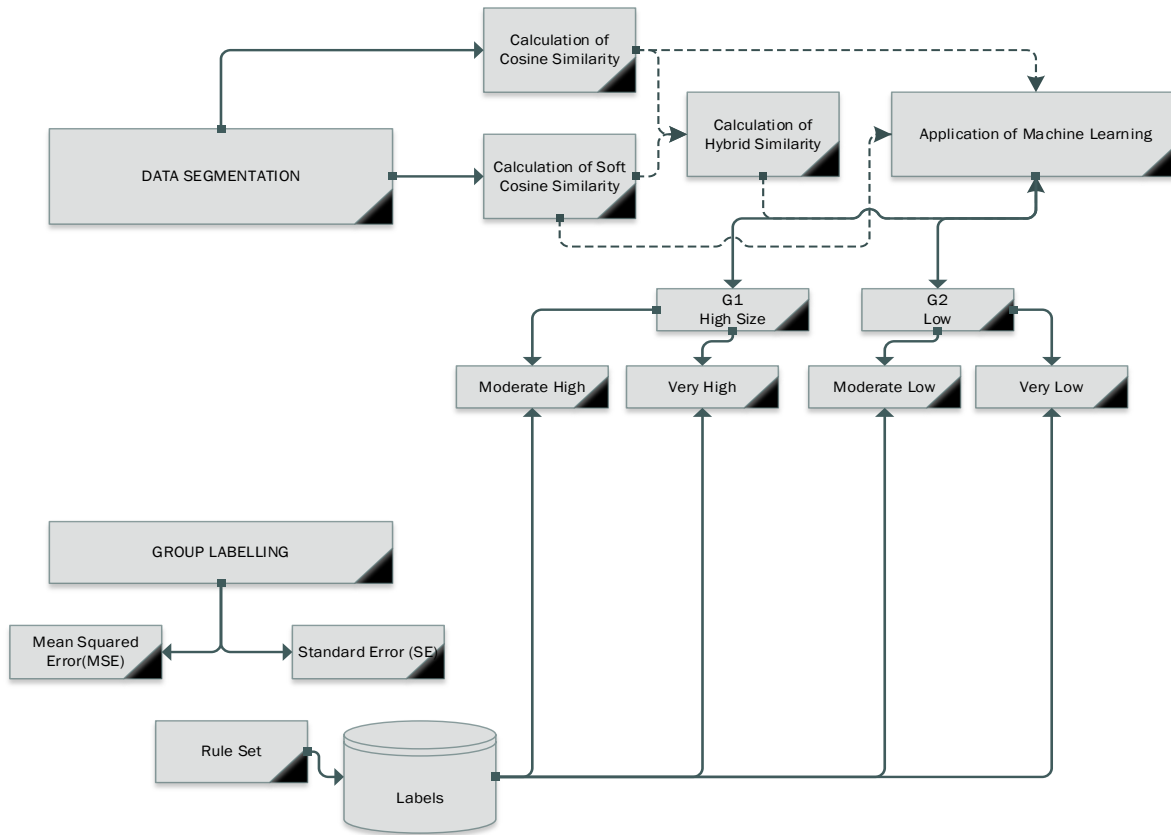
It becomes easy to the train a system when the GT of the data is available but, if there is no GT, the system remains uncertain in order to make the system understand what the data represents for. In case of post size estimation, the GT is easy as the developers speaks themselves and the outcome defines the GT but, in case of early size estimation, GT is not present. This articles focuses on the development of automatic GT for improved segmented section in order to quantify low size and high size based on the co-relation between the groups as shown in Fig. 1.


Fig. 1. The Proposed Work Model.

## III. PROPOSED WORK

The proposed work is divided into two segments, namely, segment generation and group labelling. The architecture of the proposed work is illustrated using Fig. 2. The data segmentation involves the application of Cosine Similarity (CS), Soft Cosine Similarity (SC) and hybrid similarity which is a summed value of CS and SC. The formation of groups utilizing K-means is also a part of this section. The K-means algorithms divides the entire attribute set in two groups and their labelling is done by the group labelling section of the proposed algorithm.

### A. Calculate Similarity Indices

Here data, segmentation is used to obtained ground truth value. Here, data is fragmented based on their size into two parts high fragments and low fragments after finding the centroid for each row in the dataset. The available dataset contains irrelevant information, therefore need to be rectify before used for analysis process. Hence, need to be isolated from the available data for any project for size estimation. Therefore clustering using K-means play an important role for cluster formation. Before applying clustering, we need to find out similarity indices, which are obtained using three similarity measures (i) Cosine Similarity (CS), (ii) Soft Cosine (SC) measure, (iii) Hybrid similarity measure.

*1) Cosine similarity:* It is similarity measurement approach used to find out the similarity metric between two entities based on their size using the concept of the cosine angle between entities in an n-dimensional space. Exactly, to calculate the cosine similarity between two entities in an n-dimensional space, the given formula is used:

$$Cos\ (\theta) = \frac{\vec{M}.\vec{N}}{\|\vec{M}\|\|\vec{N}\|} \tag{2}$$

Hare, 'M' and 'N' are two entities may be array or vectors; cosine equation gives the angle between them using the written equation:

$$\vec{M}.\vec{N} = \sum_{k=1}^{n} M_k \times N_k \tag{3}$$

$$= M_1 \times N_1 + M_2 \times N_2 + \cdots + M_n \times N_n$$

$$\|\vec{M}\| = \sqrt{M_1{}^2 + M_2{}^2 + \cdots + M_n{}^2}$$

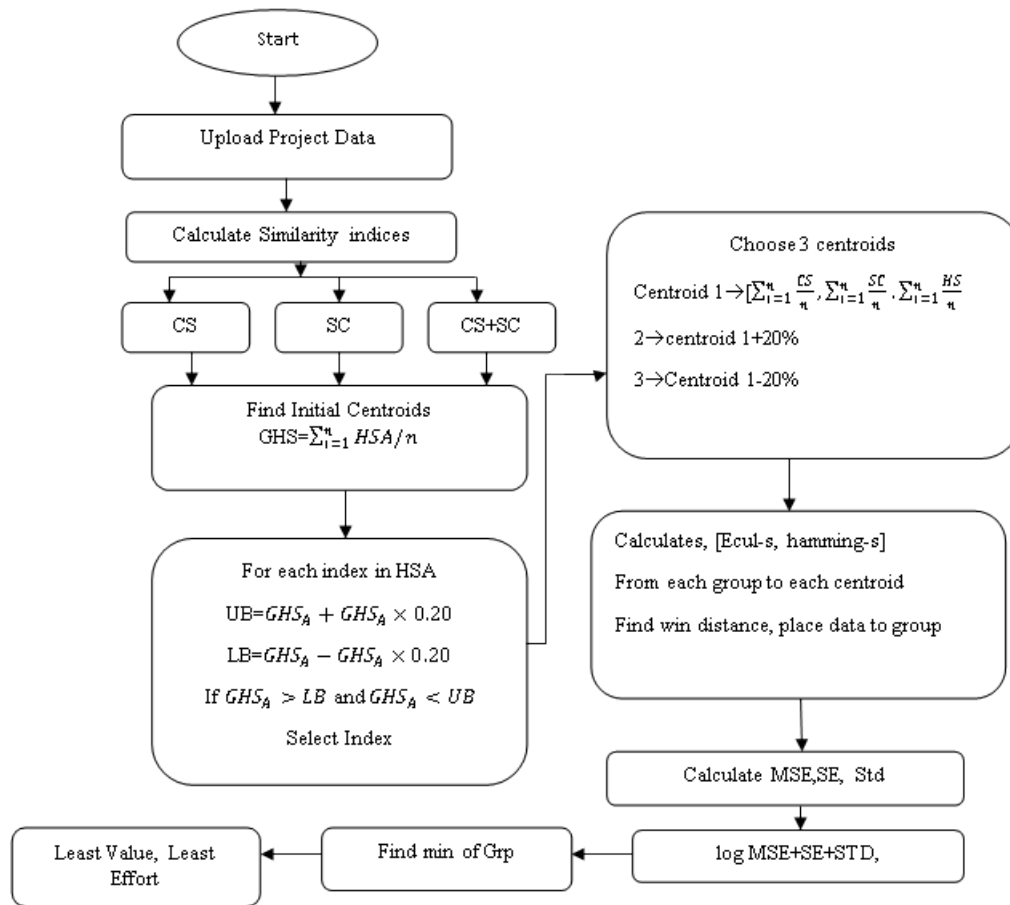
$$\|\vec{N}\| = \sqrt{N_1{}^2 + N_2{}^2 + \cdots + N_n{}^2}$$


Fig. 2. Proposed Work.

We consider an example to calculate the similarity between two sample data such as M and N, where

M = [1, 1, 0]

N = [1, 0, 1]

$$\vec{M}.\vec{N} = 1 \times 1 + 1 \times 0 + 0 \times 1 = 1 + 0 + 0 = 1 \qquad (4)$$

$$\|\vec{M}\| = \sqrt{1^2 + 1^2 + 0^2} = \sqrt{2} \qquad (5)$$

$$\|\vec{N}\| = \sqrt{1^2 + 0^2 + 1^2} = \sqrt{2} \qquad (6)$$

So, the value of cosine similarity is;

$$Cos\ (\theta) = \frac{1}{\sqrt{2} \times \sqrt{2}} = \frac{1}{2} = 0.5 \qquad (7)$$

$$\theta = cos^{-1}(0.5) = 60° \qquad (8)$$

Cosine similarity is used to measure the closeness between the data elements. It is a measurement of similarity between two non-zero arrays or vectors of an inner product space that measures the cosine of the angle between them. The cosine of 0° is 1, and it is less than 1 for any angle in the interval $(0, \pi)$ radians. It is thus a judgment of orientation and not magnitude: two vectors with the same orientation have a cosine similarity of 1, two vectors oriented at 90° relative to each other have a similarity of 0, and two vectors diametrically opposed have a similarity of -1, independent of their magnitude. These bounds apply for any number of dimensions, and the cosine similarity is most commonly used in high-dimensional positive spaces. Some important points related to the cosine similarity is written as:

*1)* Always applicable for two non-zero arrays or vectors.

*2)* The cosine similarity considers the Vector Space Model (VSM) features as independent or completely different.

*3)* The time complexity of cosine similarity is non quadratic.

*4)* Cosine similarity use the concept of Term Frequency–Inverse Document Frequency (TF-IDF) to calculate the similarity between documents

*5)* Cosine Similarity uses the Euclidean Distance to measure the closeness between two entities.

The designed algorithm for CS is written.

**Algorithm: Cosine Similarity**

**Input:** PD →Uploaded project data to calculate similarity
**Output:** $SIM_{COS}$ → Cosine Similarity for PD
$SIM_{COS}$ = [()] // to store cosine similarities values
Sim-count = 0
**For m = 1 → Length (PD)**
Current-PD = PD (m)
   **For n = m+1 →Length (PD)**
     Reference-PD = PD (n)
Calculate the cos similarity using given equation

$$\overrightarrow{Current-PD}.\overrightarrow{Reference-PD} = \sum_{k=1}^{n} Current-PD_k \times Reference-PD_k$$

$$\|\overrightarrow{Current-PD}\| = \sqrt{Current-PD_1{}^2 + Current-PD_2{}^2 + \cdots + Current-PD_n{}^2}$$

$$\|\overrightarrow{Reference-PD}\| = \sqrt{Reference-PD_1{}^2 + Reference-PD_2{}^2 + \cdots + Reference-PD_n{}^2}$$

$$Cos(\theta) = \frac{\overrightarrow{Current-PD}.\overrightarrow{Reference-PD}}{\|\overrightarrow{Current-PD}\|\|\overrightarrow{Reference-PD}\|}$$

$SIM_{COS}$[Sim-count]=Cos($\theta$)
Increment in index of array, Sim-count = Sim-count + 1
   **End – For**
**End – For**
**Return:** $SIM_{COS}$ as an output in terms of Cosine Similarity for PD
**End – Algorithm**

*2) Soft cosine similarity:* Soft cosine or the soft similarity approach is used to calculate the similarity between two entities similar to the cosine similarity approach. Cosine similarity has the VSM (Vector Space Model)features as completely different or independent whereas the soft cosine measures considers the VSM similarity features that assists in the generalization of cosine and soft cosine with similarity idea. For the computation of soft cosine, S as matrix is utilized for the indication of similarity among features. It could be measured by Levenshtein distance and Wordnet similarity. Soft cosine similarity finds the most common between two document sets.

$$Soft\ Cosine = Cos\left(\frac{n}{i=1}|X \cap Y|\right) \tag{9}$$

Where, X and Y are the two entities in n dimensional space and the some important points related to the soft cosine similarity is written as:

*1)* A soft cosine similarity between two vectors considers similarities between pairs of features.

*2)* The soft cosine similarity measures the similarity of features in Vector Space Model (VSM) as dependent.

*3)* The time complexity of Soft Cosine Similarity is quadratic, which makes it perfectly applicable to real-world tasks but it can be reduced to sub quadratic.

*4)* Soft Cosine similarity uses the concept of n-grams which is a contiguous sequence of n items.

*5)* Soft Cosine Similarity uses the Levenshtein Distance.

The algorithm for soft cosine similarity index is written below.

**Algorithm: Soft Cosine Similarity**

**Input:**PD → Uploaded project data to calculate similarity
**Output:** $SIM_{SOFTCOS}$ →Soft Cosine Similarity for PD
$SIM_{SOFTCOS}$ = [()] // to store soft cosine similarities values
Sim-count = 0
**For m = 1 → Length (PD)**
Current-PD = PD (m)
   **For n = m+1 →Length (PD)**
     Reference-PD = PD (n)

$$SIM_{SOFTCOS} = Cos\left(\frac{n}{i=1}|Current-PD \cap Reference-PD|\right)$$

$SIM_{SOFTCOS}$[Sim-count]=$SIM_{SOFTCOS}$
Increment in index of array, Sim-count = Sim-count + 1
   **End – For**
**End – For**
**Return:**$SIM_{SOFTCOS}$ as an output in terms of Soft Cosine Similarity for PD
**End – Algorithm**

*B. Hybrid Similarity*

When CS and SC measures are used in combination, then the measure form is known as hybrid similarity indices. By comparing average of each row with remaining rows, an average value is obtained. Suppose we have 100 rows in the project, therefore, to find similarity either applying CS, SC, or hybrid similarity average value obtained for each row (1st row) is compared to the remaining 99 rows. This process will provide an average value, which is used to find initial centroid of data that is given by equation (10).

$$GHS_A = \sum_{i=1}^{n} HS/n \tag{10}$$

Where, $GHS_A$ represents Gross Hybrid Similarity, HS indicates hybrid similarity value.

For each index in HS, determined upper bound (UB), and Lower Bound (LB) values by multiplying 20 % of data to the obtained GHS average, adding and subtracting the obtained value to GHS. The added value is indicated by UB, and, subtracted value is represented by LB. Both UB and LB values are represented by equation (11), and equation (12), respectively.

$$UB = GHS_A + GHS_A \times 0.20 \qquad (11)$$

$$LB = GHS_A - GHS_A \times 0.20 \qquad (12)$$

If the obtained average values of is greater than LB or less than UB ($GHS_A > LB$ and $GHS_A < UB$), then index value is selected.

The algorithm for hybrid similarity measure is written.

---

**Algorithm: Hybrid Similarity (Soft Cosine Similarity)**

**Input:** PD → Uploaded project data to calculate similarity
**Output:** $SIM_H$ → HybridSimilarity for PD
$SIM_H$ = [()] // to store cosine similarities values
Sim-count = 0
**For m = 1 → Length (PD)**
Current-PD = PD (m)
  **For n = m+1 → Length (PD)**
    Reference-PD = PD (n)
Calculate the cos similarity using given equation

$$\overrightarrow{Current - PD} . \overrightarrow{Reference - PD} = \sum_{k=1}^{n} Current - PD_k \times Reference - PD_k$$

$$\|\overrightarrow{Current - PD}\| = \sqrt{Current - PD_1{}^2 + Current - PD_2{}^2 + \cdots + Current - PD_n{}^2}$$

$$\|\overrightarrow{Reference - PD}\| = \sqrt{Reference - PD_1{}^2 + Reference - PD_2{}^2 + \cdots + Reference - PD_n{}^2}$$

$$Cos(\theta) = \frac{\overrightarrow{Current - PD} . \overrightarrow{Reference - PD}}{\|\overrightarrow{Current - PD}\| \|\overrightarrow{Reference - PD}\|}$$

$$SIM_{SOFTCOS} = Cos\left(\frac{n}{i=1}|Current - PD \cap Reference - PD|\right)$$

$SIM_H[Sim\text{-}count] = \{Cos(\theta) + SIM_{SOFTCOS}\}$
Increment in index of array, Sim-count = Sim-count + 1
    **End – For**
**End – For**
**Return:** $SIM_H$ as an output in terms of HybridSimilarity for PD
**End – Algorithm**

---

Now, apply K means as ML approach for centroid selection.

ML is a branch of artificial intelligence (AI). In more detail, it is a method of data analysis that allows a machine / robot or any analysis system to learn independently by solving a number of similar problems. Machine learning aims to develop computer programs that can access information and use it to learn. The training process begins with a specific set of information, such as examples, direct experience, or instruction, to look for examples in the data and make better decisions in the future based on the examples we provide. The main purpose is to ensure that computers automatically learn without human intervention and outside help, and to regulate actions accordingly.

ML algorithms are often classified as supervised, semi-supervised or un-supervised. In general, these algorithms can apply past data to new data, using the noted examples to predict future events. Starting with the analysis of a known training database, the learning algorithm creates a resultant function to predict the output values. In doing so, the learning algorithm can also compare the result with specific "correct" samples of the latest data and find errors to change the development model accordingly. In semi-supervised ML approach small amount of data (labeled) is merged to the huge dataset (unlabeled). It lies between supervised (labeled data), and un-supervised learning (un-labeled data). In contrast, unsupervised ML algorithms are used when the information used for training is not classified or marked in any way. The system examines the data and can draw conclusions from the datasets.

Improving machine learning algorithms is used to interact with the environment - trial and error search is the most important learning characteristic of this method, which allows programs to automatically detect ideal behavior in a specific context to maximize its performance.

K-means is a clustering approach used to partitioned N number of data into k number of groups known an clusters. The process is followed as:

- Initially, select K centroid, which is the center point of each fragmented data.

- Allocate data point to the closest centroid.

- Reallocate centroid value as the calculated average value for each group.

- Reallocate the data points to the adjoining centroid.

- Repeat until the data points remain in the same group.

After dividing data into different groups on the bases of boundary conditions as mentioned above, three centroids have been selected for the divided data. The process of centroid selection is as follows:

Consider an initial set of k means (centroids) $(C_1, C_2, \ldots \ldots \ldots C_n)$ in clusters $(S_1, S_2, \quad S_n)$. At the first stage, the centroids of the clusters are selected randomly or according to a certain rule (for example, choose the centroids that maximize the initial distances between the clusters). We refer observations to those clusters whose mean (centroid) is closest to them. Each observation belongs to only one cluster, even if it can be assigned to two or more clusters. Then the centroid of each i-th cluster is recalculated according to the equation (13).

$$C_j = \frac{1}{S_j} \sum_{x(j) \in S_i} X(j) \qquad (13)$$

Thus, the k-means algorithm consists in recalculating the centroid at each step for each cluster obtained in the previous step. The algorithm stops when the value $C_j$ does not change the maximum and minimum value. The three centroids are formed and named as centroid 1, centroid 2, and centroid 3, each represented by equation (14), equation (15), and equation (16) respectively.

$$\text{Centroid 1} = [\sum_{i=1}^{n} \frac{CS}{n}, \sum_{i=1}^{n} \frac{SC}{n} \cdot \sum_{i=1}^{n} \frac{HS}{n} \qquad (14)$$

$$\text{Centroid 2} = \text{centroid 1} + 20\% \qquad (15)$$

$$\text{Centroid 3} \rightarrow \text{Centroid 1} - 20\% \qquad (16)$$

The designed algorithm for K-means is written.

| Algorithm: K-means |
| --- |
| **Input:** PD $\rightarrow$ Uploaded project data for clustering |
| **Output:** C-Data and C $\rightarrow$ Clustered Data and their centroids |
| Initialize an estimated Centroid C = C1, C2 and C3 |
| Where, $C1 = \frac{SIM_{COS}}{Count\ of\ PD} + \frac{SIM_{SOFTCOS}}{Count\ of\ PD} + \frac{SIM_H}{Count\ of\ PD}$ |
| $\qquad\qquad C2 = C1 + 20\%\ of\ C1$ |
| $\qquad\qquad C3 = C1 - 20\%\ of\ C1$ |
| Calculate size of PD in terms of [Row, Col.] = size (PD) |
| **For i$\rightarrow$1 to all Row** |
| $\quad$ **For j$\rightarrow$1 to all column** |
| **If PD (i,j)==C1** |
| $\quad$ C-Data 1=PD (i,j) |
| $\quad$ **Else if PD (i,j)==C2** |
| $\quad$ C-Data 2=PD (i,j) |
| $\quad$ **Else** |
| $\quad$ C-Data 3=PD (i,j) |
| $\quad$ **End** |
| $\quad$ Adjust Centroid C using their mean |
| $\quad$ C = Average (C-Data 1, C-Data 2 and C-Data 3) |
| $\quad$ **End – For** |
| **End – For** |
| **Return:** C-Data and C as a Clustered Data and their centroids respectively |
| **End – Algorithm** |

After selecting centroid, next step is to calculate Euclidian distance and hamming distance as metrics. The k-means method is a method of cluster analysis, the purpose of which is to divide m observations (from space $P^n$) into k clusters, with each observation referring to the cluster to the center (centroid) of which it is closest. Euclidean distance is used as a measure of proximity, which is given by equation (17).

$$p(x,y) = \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2 + \cdots \ldots \ldots \ldots (x_n - y_n)^2} \quad (17)$$

$$= \sqrt{\sum_{i=1}^{n}(x_i - y_i)^2}$$

Where x, y represent the Euclidean vector.

### C. The Group Labelling

As shown in Fig. 1, once the group is formed, the correlation between the group elements is calculated using Mean Square Error (MSE), Standard Error (SE) and Standard Deviation (STD) for both the groups. In order to neutralize, the evaluated parameters for every group, log scale is considered which joins summative of MSE, SE and STD. A ruleset for labelling the group is designed as follows.

| Algorithm Labelling |
| --- |
| Input: Groups , Evaluated Parameters |
| Foreach grp in Groups |
| $\qquad$ Calculate $\frac{\sum_{i=1}^{n1} MSE}{n}, \frac{\sum_{i=1}^{n1} STD}{n}, \frac{\sum_{i=1}^{n1} SE}{n}$ |
| $\qquad Judgement_{Level}.Append = \log(\frac{\sum_{i=1}^{n1} MSE}{n} +$ |
| $\frac{\sum_{i=1}^{n1} STD}{n} + \frac{\sum_{i=1}^{n1} SE}{n})$ |
| End For |
| Find $\min(Judgement_{Level})$ and label it low effort as the co-relation is high and viceversa. |

## IV. ANALYSIS AND DISCUSSION

In size and effort estimation in software project, there are a number of measures on the basis of which evaluations has performed. In this research, we have used three metrics to measure the performance of designed size estimation of software project as given by equation (18), equation (19), and equation (20). These are as follows:

Mean Square Error (MSE):

$$\text{MSE} = \frac{1}{n} \sum_{i=1}^{n} \varepsilon_i^2 \qquad (18)$$

Standard Error (SE):

$$\text{SE} = \sum_{i=1}^{n} \varepsilon_i^2 \qquad (19)$$

Standard Deviation (STD):

$$\text{STD} = \sqrt{\frac{1}{n-1} \sum_{i=1}^{n}(x_i - \tilde{x}_i)^2} \qquad (20)$$

In this research, we have applied data fragmentation approach in addition to K-means approach. The results evaluated based on above mentioned parameters is listed in Table I.

TABLE I.        EVALUATED PARAMETERS

| Attributes | MSE | SE | STD |
|---|---|---|---|
| Project | 0.0572 | 0.1247 | 0.472 |
| TeamExp | 0.0269 | 0.1345 | 0.136 |
| ManagerExp | 0.0378 | 0.2365 | 0.257 |
| YearEnd | 0.0472 | 0.3254 | 0.369 |
| Transactions | 0.0952 | 0.1025 | 0.158 |
| Length | 0.0360 | 0.2456 | 0.354 |
| Effort | 0.0761 | 0.6582 | 0.648 |
| Entities | 0.0871 | 0.7251 | 0.756 |
| PointsNonAdjust | 0.0675 | 0.6981 | 0.597 |
| Adjustment | 0.0752 | 0.5368 | 0.694 |
| PointsAjust | 0.0697 | 0.4865 | 0.486 |
| Language | 0.0315 | 0.3785 | 0.697 |

Fig. 3.   MSE.

Fig. 3 represents the MSE value analysed for 12 different attributes. X-axis and y-axis represents the number of attributes taken for software project and evaluated MSE value. It is observed that for transaction attribute, designed system show highest error, whereas for team expert error is analysed as minimum. The average mean square error obtained for the designed system is observed as 0.05895, which is very small, and the system can be considered as accepted one for the early size estimation of project using ML technique.

SE is an estimate of the standard deviation of its sample distribution that roughly shows how much the value of a analyzed project rows can differ from its mean. The standard error of estimation is a value equal to the square root of the root mean square error (MSE) regression .MSE, in turn, is equal to the sum of the squares of the differences between the observed parameter (x) and the regression-estimated values ($\check{x}$) calculated from all observations and referred to their number n as represented by equation (19). The standard error value has been measured to find out the degree of deviation of the values obtained using the regression, from the actually observed, and thus assess the accuracy of the corresponding model. The deviation has been represented in Fig. 4, in which the graph shows maximum and minimum SE value of 0.7251, 0.1025 for attribute Entities and transaction respectively. Overall, the average SE analyzed for the proposed work is observed as 0.3877.

The standard deviation is a statistical characteristic of the distribution of a random variable, showing the average degree of dispersion of the values of the quantity relative to the mathematical expectation, denoted by greek σ (sigma).The standard deviation is measured in units of the random variable itself and is used to calculate the standard error of the arithmetic mean, when constructing confidence intervals , when statistically testing hypotheses , when measuring the linear relationship between random variables. It is defined as the square root of the variance of a random variable. Fig. 5 represents the examined STD for different attributes individually. The results show that for entities attribute, the designed early size estimation system using ML approach shows maximum STD, whereas, for 0.158 and 0.136 respectively.
Fig. 4.   SE.

Fig. 5.   STD.

## V.   Conclusion

This paper represents a novel segmentation method in order to labels the projects as high size and low size. In order to do so, three similarity indexes namely CS, SC and a hybrid similarity which is a combination of CS and SC is designed. The value of 'k' which is total number of groups that can be formed from a supplied set of data is set to be 2 for "high" and "low" size. Once the data is divided, the proposed work model goes for group labelling which is based on machine learning parameters namely MSE, STD and SE. As the parameters are different in nature, a log scale neutralization is performed. A rule architecture was developed to judge the labels and over 500 projects were labelled for high and low software size. A detailed evaluation of parameters is presented in section 4 and the current segmentation architecture will help in establishing Q-Learning mechanism for future project size estimations.

*Abstract*—Despite the reduction of restrictive measures imposed due to the COVID-19 pandemic, the problem of organizing distance learning continues to be topical. Distance learning imposes a much greater responsibility on teachers, giving them more of a workload as learning technologies change rapidly and teachers have to actively adapt to innovations, devoting a lot of time to preparing appropriate materials to ensure the best learning outcomes. The aim of the study is to detect the use of the most effective means of organizing distance learning by teachers. The study is based on a survey of university professors who were teaching in the distance mode during 2020-2021 active administrative restrictions. Opportunities for the use of various services in the organization of distance learning are analyzed and the drawbacks and advantages of the distance learning system are highlighted. The study reveals previously unapparent issues that arose in the course of distance work in quarantine. These include, first and foremost, the high physical workload of teachers, the many technical problems that arose in the transition to distance learning, the lack of teachers' competencies, which needs to be urgently addressed, and the complicated coordination of the learning process. Despite the problems identified, the authors argue that the system of distance learning can and must be adopted and further developed as an additional supporting direction in the organization of the learning process, which will allow educational institutions to promptly shift to distance learning as needed.

*Keywords—Distance learning; teachers; electronic service; online class*

## I. INTRODUCTION

The COVID-19 pandemic forced universities to shift to the mode of distance learning (DL), which required them to use all the powers of the infrastructure, employ specialized software, expand the functionality of the existing educational platforms, and work on the development of databases and teachers' competence [1], [2]. In essence, it was a complex systemic task that covered virtually all parts of the educational process.

Contemporary ICT and web technologies are moving to ever more advanced levels of operation, and DL is becoming more than just an online session or webinar as it incorporates many more student activities, such as data collection, data processing, communication, and interaction with the interface and the external environment [3]–[5].

Research on the peculiarities of using the DL system by teachers of information and computer technologies acquired particular significance when all educational institutions faced the need to fully shift to DL due to the introduced quarantine measures caused by the COVID-19 pandemic. In this light, of special interest are the issues of the use of various means of organizing DL by teachers and practical recommendations on the implementation of DL that could be used by universities during the period of restrictions caused by the COVID-19 pandemic [6].

## II. LITERATURE REVIEW

In the course of the quarantine, there appeared a considerable amount of papers with practical advice and recommendations on the introduction of DL. For instance, one study [7] reveals that the teachers who most easily rearranged their style of work and got more enjoyment from the introduction of the DL work at the institutions that had clear systemic communications and algorithms for action formed prior to the pandemic and implemented and maintained at the level of the management of the individual educational institution.

Scientific research actively discusses new approaches to the organization of DL, which requires substantiation of such provisions as the motivational, technological, and process support for the education system as an integral pedagogical system that accounts for the individual interests, abilities, and aptitudes of students and the newest teaching strategies [8]. At present, the most acute are the issues of using electronic services and platforms to successfully employ DL in the educational process [9], [10].

In the present study, we define DL as a part of web-oriented education – a type of education that fundamentally relies on the use of ICT and in which the participants of the learning process primarily engage in individualized educational communication [11].

In accordance with the research problem, researchers consider cases of DL implementation during the COVID-19 pandemic at various universities around the world [7, 8, 9] and in various areas of study [10, 11, 12]. Researchers analyze the factors that facilitate and hinder the implementation of distance

education during the COVID-19 pandemic [13], study the perception of distance learning by students during the pandemic [14], the satisfaction of teachers and students of distance education and their understanding of the opportunities and problems of distance learning during the period of quarantine restrictions [15] ; determine the existing educational and technological barriers to distance education [16] and the relationship between digital transformation, satisfaction and the intention of students to continue learning online [17] during quarantine restrictions; prove the advantages of organizing DL in order to prevent the spread of a pandemic [18]; justify the benefits of distance learning during the crisis, which are the use of technology, improving the communication skills of students and saving time on teaching and learning [19]; determine the priorities of learning after the removal of restrictions to find a balance between distance learning and full-time education [20].

Nevertheless, a full picture of the realities of DL cannot be painted without considering the position and feedback of teachers as those who put the system into operation.

In view of the above, the goal of the present study is to detect the use of the most effective means of organizing DL by teachers during the period of active restrictions caused by the COVID-19 pandemic.

Research objectives are:

*1)* To analyze the opportunities to use various services in the organization of DL during quarantine measures.

*2)* To define the advantages and drawbacks of the DL system.

*3)* To identify previously unapparent problems in the process of distance work during quarantine.

Further, the article describes the methodology of the study, presents the results of the study and analyzes their significance. In conclusion, the conclusions of the work carried out are drawn.

### III. METHODS

The established research goal entails the following approximate list of theoretical and empirical research methods: the theoretical methods of analysis, synthesis, comparison, and summarization used in the study of scientific literature on the organization of DL during the period of quarantine restrictions caused by the pandemic. The theoretical base of the study was grouped depending on the type of documents. The first group of information sources consisted of studies devoted to the problem of the possibility of introducing distance learning into the educational process. The second group of information sources was devoted to the consideration of the specifics of the use of DL during the period of active restrictions caused by the COVID-19 pandemic. The considered sources of information were 30 articles from scientific peer-reviewed journals Scopus and Web of Science for the last 3 years; the empirical method of a survey employed to analyze the existing peculiarities and problems of organizing DL.

The primary method of research was an expert survey, the sample of which consisted of 100 teachers sampled by the method of criterion-based selection. The survey method was the most appropriate for the purpose of the study, since determining the use by teachers of the most effective means of organizing distance learning during the period of active restrictions caused by the COVID-19 pandemic was most accurately feasible when analyzing the opinions of the teachers themselves, as direct participants in this process. The survey included the following questions:

"What services do you use to post educational and methodological support materials during the organization of DL?" (multiple choice possible), followed by a discussion of the experience;

"What services do you use for hosting video conferences?" (multiple choice possible);

"In your opinion, what are the main disadvantages of DL?" (multiple choice possible);

"In your opinion, what are the main advantages of DL?" (multiple choice possible);

"In your opinion, what are the major problems in the process of DL during quarantine that were not apparent beforehand?" (multiple choice possible).

Thus, the surveyed teachers were asked to identify the main resources they had used to post educational and methodological materials for students to access and the services most often used for communication with students and hosting online conferences. The survey also enabled the teachers to describe the advantages and disadvantages they see in the DL system and to identify major problems in the DL process during quarantine that were not evident beforehand. In addition, the teachers were able to give their opinions on opportunities for improvement.

Further on, the opinions of teachers about the services preferred for posting educational and methodological materials and hosting video conferences, the main drawbacks of DL, and the problems discovered in the course of distance work were ranked by popularity. The consistency of teachers' opinions was assessed by the concordance coefficient:

$$w = \frac{12S}{n^2(m^3 - m)}$$

where S is the sum of the squared deviations of all rank estimates of each evaluated object from the mean value; n – the number of respondents; m – the number of assessment objects.

Statistical processing of the survey results and calculation of descriptive statistics (percentage of expert mentions) and the concordance coefficient were performed using the SPSS software product.

### IV. RESULTS

The conducted survey reveals that in posting educational and methodological materials as part of DL, the respondents give preference to Moodle (45%) and Google Classroom (44%) due to their convenient subdivision of topics and classes and easy access for students (Table I).

TABLE I. SERVICES FOR POSTING EDUCATIONAL AND METHODOLOGICAL SUPPORT MATERIALS

| № | Service | Response rate*, % | Rank |
|---|---|---|---|
| 1 | Moodle | 45% | 1 |
| 2 | Google Classroom | 44% | 2 |
| 3 | Google Drive | 31% | 3 |
| 4 | Microsoft Teams | 8% | 4 |
| 5 | Other | 29% | |

multiple choice possible

An object-oriented DL environment Moodle relies on contemporary information and computer technology. The service can also be used by students to receive feedback, as they can post their completed laboratory assignments and other documents to be checked by the professor.

Google Drive as a platform for storing materials with an opportunity to share access to them ranks third in the respondents' choice (31% of the respondents choose this option). Microsoft Teams is used by only 8% of those surveyed. Meanwhile, 29% of the professors do not use any of the mentioned services.

The concordance coefficient for the question is W = 0.78 (p < 0.01), indicating strong consistency of the teachers' responses to the question.

Subsequent additional questions focus on teachers' experiences with the most popular services (Tables II and III).

TABLE II. EXPERIENCE WITH MOODLE

| № | Teachers' judgment | Response rate, % |
|---|---|---|
| 1 | Use a lot | 39% |
| 2 | Use little | 13% |
| 3 | Not use at all | 36% |
| 4 | Consider it convenient to use | 43% |
| 5 | Consider it inconvenient to use | 7% |
| 6 | Recommended for use | 43% |
| 7 | Not recommended for use | 7% |

TABLE III. EXPERIENCE WITH GOOGLE CLASSROOM

| № | Teachers' judgment | Response rate, % |
|---|---|---|
| 1 | Use a lot | 24% |
| 2 | Use little | 23% |
| 3 | Not use at all | 36% |
| 4 | Consider it convenient to use | 26% |
| 5 | Consider it inconvenient to use | 3% |
| 6 | Recommended for use | 37% |
| 7 | Not recommended for use | 26% |

Considering the above services from the point of convenience, 43% of the surveyed teachers consider Moodle to be quite usable and recommend it for use in the educational process (Table II). However, commenting on their experience using Moodle, 7% of the respondents do not recommend using

it as the main system for organizing DL in educational organizations (Table II), explaining their position by the fact that teachers and students voice many complaints about its operation.

The Google Classroom service is used in working with educational and methodological materials by 24% of teachers and recommended for use by only 26% (Table III). Moreover, 36% do not use Moodle and Google Classroom in the learning process at all and consider them inconvenient.

In the organization of DL, of importance are video conferencing platforms, which allow students to attend lectures in real time and actively discuss the materials presented while physically being in different places. This model approximates online learning to study in a real classroom as much as possible.

The responses of teachers to the question "What services do you use for hosting video conferences?" are presented in Table IV.

TABLE IV. SERVICES FOR HOSTING VIDEO CONFERENCES

| № | Service | Response rate*, % | Rank |
|---|---|---|---|
| 1 | TrueConfServer | 55% | 1 |
| 2 | VideoMost | 34% | 2 |
| 3 | Google Meet | 17% | 3 |
| 4 | Google Hangouts | 10% | 4 |
| 5 | Microsoft Teams | 8% | 5 |
| 6 | Cisco Webex Meetings | 3% | 6-7 |
| 7 | Big Blue Button | 3% | 6-7 |
| 8 | Skype | 2% | 8 |
| 9 | Discord | 1% | 9 |

multiple choice possible

The survey results show that the most popular video conferencing service is TrueConfServer, which gained popularity after Russian universities ceased cooperation with Zoom, with the selection rate of 55% (Table IV). Another Russian product, VideoMost, has 34% of the vote.

Free video chat services Google Meet and Google Hangouts are used by 17% and 10% of respondents, respectively. The Microsoft Teams service is approved by 8% of university professors; such a low rate may be explained by a fairly high subscription fee charged for most Microsoft services. Among other video conferencing resources mentioned by the teachers are Cisco Webex Meetings (3%), Skype (2%), and Discord (2%).

It should be noted that conferencing directly in Moodle is not a typical solution. Only 3% of the respondents use the Big Blue Button service, which integrates with Moodle, although the previous question reveals that 39% of the respondents use Moodle to post educational and methodological materials (Table II).

The value of the concordance coefficient W = 0.76 (p < 0.01) indicates a high coherence of the teachers' opinions on this issue.

The main disadvantages of DL as viewed by teachers are presented in Table V.

TABLE V.        PRIMARY DISADVANTAGES OF DL

| № | Primary disadvantages of DL | Response rate*, % | Rank |
|---|---|---|---|
| 1 | round-the-clock load | 65% | 1 |
| 2 | lack of a unified platform | 37% | 2 |
| 3 | lack of unified standards and requirements, as well as unified software | 35% | 3 |
| 4 | unequal access to high-speed Internet | 19% | 4 |
| 5 | difficulties in objectively assessing knowledge | 16% | 5 |

multiple choice possible

The value of the concordance coefficient $W = 0.82$ ($p < 0.01$), which suggests a strong consistency of opinion on the issue.

Additionally, the survey of teachers during the DL process while in quarantine revealed problems that were not apparent beforehand (Table VI).

TABLE VI.        PROBLEMS DETECTED WHILE WORKING IN THE DISTANCE MODE

| № | Problem | Response rate*, % | Rank |
|---|---|---|---|
| 1 | teachers' technical competence | 68% | 1 |
| 2 | optimization of class schedules and workload in the distance mode | 44% | 2 |
| 3 | multitasking | 37% | 3 |
| 4 | content structuring of information flows | 24% | 4 |
| 5 | electronic deanery | 20% | 5 |

multiple choice possible

For this item, the concordance coefficient is $W = 0.75$ ($p < 0.01$), indicating a strong concordance of the teachers' views on the matter.

## V. DISCUSSION

According to the survey results, the main drawback of DL for teachers is a round-the-clock load caused by the need to adjust educational and methodological materials for online classes, post them online, hold consultations and video conferences, maintain contact with students and their parents (special attention should be paid to the professor's actions in the case of prolonged absence of students who do not attend classes and do not contact them), as well as to conduct control and assessment of the level of students' knowledge, which is consistent with previous research [13]. A particular factor in the higher workload of teachers is the increased amount of reporting documents required in the course of DL.

Among the key disadvantages of the organization of DL, the teachers also note the lack of a unified platform, lack of uniform standards, requirements, and unified software, lack of student motivation, unequal access to high-speed Internet, plagiarism, and difficulties in assessing students' knowledge objectively.

Further on, the study reveals an ambiguity in the teachers' perspectives on the advantages of DL over classroom teaching, or, conversely, classroom over DL. Those advocating for the advantages of DL justify their position by the following arguments: DL provides an opportunity to learn for those unable to attend classes for objective reasons, allows saving time and money for transportation, results in more comfortable working conditions, and gives an opportunity to train the self-discipline and self-organization of students, as well as to develop their skills of independent information search and processing and self-learning.

Discussing the problems detected in the course of remote work, the teachers prioritize in the organization of DL the need for teachers to acquire specific competence, which includes: 1) knowledge of the opportunities and available resources to conduct DL: learning platforms, software, techniques, and instruments; 2) mastery of the methodology of adjusting traditional courses for the electronic format; 3) mastery of the technology of digitizing learning tasks. What can become a solution to the above problem, researchers suggest, is the organization of training and masterclasses as part of professional development programs [20], [21].

The need for content structuring of information flows owes to the fact that the transition to an exclusively distance form of work in the quarantine majorly increased the flow of information from various sources and university departments [22]. The lack of the competence and culture of online communication has resulted in too much noise and spam in professional correspondence, which made coordination and timely access to the necessary documents difficult. To resolve this issue, researchers suggest [16], [23], it is enough to develop a system of labeling documents by content according to an agreed-upon standard in order to structure them and move them to appropriate databases and to provide guidelines for professional online communication for university staff, faculty, and students.

The problem of optimization of class schedules and workload in the distance format consists in the fact that in DL, the number of students in a group does not depend on the size of the classroom and the number of seats. This gives an opportunity to optimize the schedule by merging the student groups studying in the same program. Educational platforms allow one to simultaneously engage all students in different types of tasks during the class. This measure ensures the high quality of the educational process, but also considerably increases the intensity of the teachers' work and the time required to prepare for distance classes and check students' assignments on the platform. Scholars believe that in order to alleviate these issues, it is appropriate to optimize the schedule without reducing the number of classes for students by assigning the courses of one specialty to a single professor [14], [24], [25]. Reducing the teacher's workload by merging student groups can enhance the quality of DL classes by freeing up the professor's time to prepare and check assignments on the platform.

The problem of multitasking consists in the fact that while holding classes in the form of webinars, aside from their regular function of transmitting and controlling the assimilation

of knowledge, teachers also acquire the functions of: an organizer of communication who informs and invites the group to a webinar; a webinar moderator who manages communication in a DL environment; a technical assistant who provides technical support for the process. Simultaneous performance of all these functions, which in traditional teaching are split between the professor, dean's office, and laboratory assistants and require the professional skills of a moderator, significantly increases the load and stress on one faculty member and leads to exhaustion [19].

The problem of multitasking can be solved by means of a specially developed methodology for organizing and holding webinars for systematic DL. This requires, first, to define the specific goals and functions of the participants and those responsible for the organization and support of the process; second, to automate the processes when needed and possible; third, to account for the increased workload of teachers in the remote format [14].

Finally, management of the learning process in DL necessitates the creation of an electronic deanery, which would serve the functions of information support, feedback, learning process organization, control, collection, and analysis of statistical data, sharing the experience gained, and more.

## VI. CONCLUSION

In general, in the context of active restrictions caused by COVID-19, the most effective way to organize the educational process is to switch to an emergency distance learning mode. However, for both teachers and students, long-term training in this mode raises a number of problems, the solution of which requires continued research in this area. In the context of our study, we identified, first of all, the problems of the lack of a single platform, common standards and requirements, as well as unified software.

The issue of relevant organization of DL needs to be studied further since there is a need to reconsider and reorganize the entire learning process, renew the content of educational programs, and develop new integral programs for DL to support the mobile vector of learning, strengthen students' interest, and eliminate the factors of disorganization, distraction from the learning process, and loss of interest.

It is advisable to continue using DL periodically to collect teachers' feedback and recommendations to improve DL since teachers are the key objects and subjects of educational activities who experience the development of DL first-hand at its initial and early stages.

Most universities' learning systems are more oriented toward developing the organization of the in-classroom learning process rather than the DL system. Meanwhile, a system of prompt transition to DL cannot be developed without repeated practice and specialized software. The current state and prospects for the development of technology and remote work, as well as the epidemiological situation, bring to light the need for methodological support for programs, as well as technical and human resource capacity, to ensure self-sufficient DL.

The prospect of further research may be the development of recommendations for teachers on the practical solution of problems arising from the use of educational services and technologies caused by the need to switch to emergency distance learning.

*Abstract*—The occurrence of coronavirus (COVID-19), which causes respiratory illnesses, is higher than in 2003. (SARS). COVID-19 and SARS are both spreading over regions and infecting living beings, with more than 73,435 deaths and more than 2000 deaths documented as of August 12, 2020. In contrast, SARS killed 774 lives in 2003, whereas COVID-19 claimed more in the shortest amount of time. However, the fundamental difference between them is that, after 17 years of SARS, a powerful new tool has developed that could be utilized to combat the virus and keep it within reasonable boundaries. One of these tools is machine learning (ML). Recently, machine learning (ML) has caused a paradigm shift in the healthcare industry, and its use in the COVID-19 outbreak could be profitable, especially in forecasting the location of the next outbreak. The use of AI in COVID-19 diagnosis and monitoring can be accelerated, reducing the time and cost of these processes. As a result, this study uses ANN and CNN techniques to detect COVID-19 from chest x-ray pictures, with 95% and 75% accuracy, respectively. Machine learning has greatly enhanced monitoring, diagnosis, monitoring, analysis, forecasting, touch tracking, and medication/vaccine production processes for the Covid-19 disease outbreak, reducing human involvement in nursing treatment.

*Keywords*—*Machine learning; COVID-19; ANN; CNN; X-ray images*

## I. INTRODUCTION

Throughout history, there has been widespread of infectious disease among our places of residence. This has caused deterioration of every aspect of our economics and well-being as a whole. This effect has caused solutions being found through the use of machine learning as a division of artificial intelligence. Over the years there has been the existence some pandemics such as the Athenian plague [1], Ebola pandemic [2], HIV pandemic [3], Zika virus [4], black death [5], etc. Coronavirus which is a happening contactable epidemic that is all over the spheres of the world is a virus belonging to the family Coronaviridae [6].

In fighting covid-19 there has been many solutions being proffered through the use of different machine learning techniques [7]. It has also aided in various studies, including the ensemble of machine learning for the simulation of covid19 deaths [8], as well as identifying who is prone to being the next victim, diagnosing suspected individuals, developing medicine vastly, and being able to predict the next occurrence of such a remerging virus.

Some computer scientists have used machine learning to test coronavirus presence such as [9] who worked on automated detection of Coronavirus disease-2019 (COVID-19) from X-ray images and used YOLO (You only look once) machine learning technique. However, his model misdiagnosed COVID-19 patients as pneumonia and predicted incorrectly in low production of X-ray images and patients with other diseases. Research uses Convolutional Neural Network (CNN) and the deep learning approach to detect multi-class brain disease using MRI images. There was no feature extraction, collection, or classification in this process because it was fully automated [10]. A system created from machine learning techniques was also created to diagnose coronavirus [11].

Artificial intelligence (AI)-based models have effectively used current noticeable data to learn the cause of current therapies on humans, provided their unique characteristics. All this will help in detecting various diseases based on each individual's characteristics. Recent advancements in machine learning models optimized for making research through noticeable information setting can be used to learn customized treatment outcomes.

However, although these models can produce correct diagnosis and predict other ailments and infectious diseases. Furthermore, regardless of how accurate most machine learning models relating to covid19 prediction appear to be, they appear to be difficult to interpret. The difficulty in detecting Covid19 infection at an early stage is also attributed to the high similarity of its symptoms to those of pneumonia. As a result, distinguishing cases of coronavirus from pneumonia is easy, which could save a patient's life.

This research uses chest X-ray images to classify Coronavirus disease using machine learning classifiers (convolutional neural networks) implemented in Python, as well as rectified linear units (ReLU) to help overcome image non-linearity (in this case chest x-ray images). This research, on the other hand, suggests using a Convolutional neural network (CNN) and Artificial Neural Network (ANN) method to develop a model to detect coronavirus disease.

## II. REVIEWS OF RELATED WORK

With the support of imaging and image-based classification methods, machine learning is now a highly important and flexible technique for detecting terminal diseases in recent years.

Research that used machine learning was proposed [12] to classify skin cancer at the dermatologist stage (CNNs). The use of a single CNN qualified end-to-end from photographs directly, with only pixels and disease labels as inputs, to classify skin lesions.

An epilepsy detection system based on this technique is proposed [13]. The proposed method has an accuracy of 100% for all of the tested signals when it was used to identify electroencephalogram (ECG) recordings using ECG signals into epileptic and non-epileptic.

A deep convolutional neural network was developed with long-term ECG signals to create a system for detecting arrhythmia [14]. Instead of the hand-crafted feature extraction and selection used in conventional approaches, a full end-to-end structure was developed. Their key achievement is the development of a new 2D-convolutional neural model that can recognize 17 cardiac arrhythmia disorders with a high level of accuracy.

Deep neural networks with chest visuals were used [9] to automate the prediction of coronavirus disease instances. He proposed a model called "DarkCovidNet model," and the model does not involve any handcrafted feature extraction techniques, and it was accurate and fast. However, the model misdiagnosed COVID-19 patients as pneumonia and predicted incorrectly in bad-quality X-ray images and predicting of wrong diseases not aimed at.

A study using CNN and the deep learning approach to identify multi-class brain disease using Magnetic resonance imaging (MRI) images was proposed [15]. There was no feature extraction, collection, or classification in this process because it was fully automated.

The deep learning model was created [16] using 224 verified COVID-19 images. Their model had success rates of 98.75% and 93.48% in two and three grades, respectively.

Using chest X-ray images and the ResNet50 model, [17] achieved a COVID-19 detection accuracy of 98%.

Using X-ray images, [18] categorized features obtained from various convolutional neural network (CNN) models with the aid of a support vector machine (SVM) classifier.

A deep learning approach was proposed to detect Pneumonia in chest X-ray images efficiently [10]; transfer learning is used to fine-tune the deep learning models to achieve higher training and validation accuracy; however, large datasets for chest X-rays were not usable, and the results of the deep learning models could not be clarified properly. The final prediction of the model must also be properly explained, which is one of the disadvantages of deep learning-based models.

A study used whole-slide images and deep transfer learning to detect invasive ductal carcinoma. COVID-Net, a deep model for COVID-19 detection proposed [19], correctly identified normal, non-COVID pneumonia, and COVID-19 cases with 92.4 % accuracy.

A deep learning model for detecting covid19 in CT-scan images was proposed [20]. The Python programming language was used to carry out this research. Python Deep Learning libraries such as Keras and TensorFlow 2.0 were used to develop and train the Convolution Neural Network (CNN) model. The open-access archive of COVID-19 chest computed tomography (CT) images was used as the dataset.

A model was developed for automated voice-based detection of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) [21] that could help with COVID19 screening. However, the cough dataset was not included in any of his input datasets because the transformer was built on speech data and was intended to improve non-speech input efficiency.

A model to efficiently classify the COVID-19 infected patients and normally based on chest X-ray radiography using Machine Learning techniques was proposed [22]. The proposed system involves pre-processing, feature extraction, and classification. The results show that among the four classifiers, SVM has the highest accuracy of 96 % (K-Nearest Neighbors and Random Forest had 92% accuracy, Nave Bayes had 90 % accuracy, and Decision Tree had 82 % accuracy).

A study involving the use of machine learning detects COVID-19 infection from regular blood tests [23]. His model had a sensitivity of 92 to 95 % and an accuracy of 82 %. However, the study had two major limitations: the study had a small number of cases considered, and the accuracy of his test could be harmed by issues such as insufficient procedures for collecting, handling, transporting, and storing swabs, sample contamination, and the presence of interfering substances.

A deep learning model for improving the characterization of covid19 from chest X-ray images using CNN was developed [24], but their limitations include improving the proposed deep learning model's design and, most importantly, testing the model's robustness on some large-scale datasets. In addition, his qualified CNN-based deep learning model has been deployed to both web and Android applications for clinical use.

A study was proposed using used transfer learning and a convolutional neural network to detect covid19 from x-ray images automatically [25]. However, they were unable to differentiate mild symptoms from pneumonia symptoms, even though these symptoms may not be visible on x-rays or may not be visible at all.

For covid19 detection based on x-ray images, [26] proposed a concatenation technique in convolutional neural networks. The model, however, was not tested on a large number of datasets and was ineffective in medical diagnosis.

A study that used deep learning to classify covid19 in chest x-ray images was developed [27]. The accuracy of this study's classification was 99.5 %, but the dataset was too limited.

## III. MATERIAL AND METHODS

### A. Data Description

This study makes use of dataset retrieved from the Kaggle repository (https://www.kaggle.com/praveengovi/coronahack-chest-xraydataset).

Kaggle is an online data science platform for developers and techies, with a variety of crowdsourced datasets and frameworks. The dataset was found by searching for the

"corona chest x-ray dataset" on Google. It contains a corona chest x-ray dataset with 6 features and 5935 samples, as well as attributes such as the image name of the x-ray, a label that indicates x-ray (normal or healthy, and person affected with pneumonia), dataset type, and another label called label 2 that holds information about the person affected with pneumonia. This dataset of chest x-rays will be used to analyze my data with CNN and ANN to achieve the following performance metrics sensitivity, time, and speed.

The suggested model below focuses on using a convolutional neural network to implement a model. The dataset, which consists of chest x-ray (pneumonia cases included) images obtained from Kaggle, will be fed into a trained CNN model and also a trained ANN model to predict which of the model will give better accuracy results. The analysis will be evaluated using the following performance metrics: accuracies, precision, and recall.

### B. Convolutional Neural Network

Convolutional Neural Networks, often known as ConvNet, are a type of deep learning used to assess visuals [28]. The employment of the layered arithmetic operations by the system is referred to as a CNN. Convolution is a unique sort of linear operation. CNN's concealed structures consist convolutional layers that convolve using multiplication and perhaps other dot multiplication. Backpropagation is done in this algorithm and it gives a better result in terms of accuracy. The Convolution layer employs small filters (e.g., $3*3 \, or \, 5*5$), a stride of S=1, and, most significantly, padding the input volume with zeros in such a way that the convolutional layer does not alter or modify the input's spatial dimensions. That is, if F=3, using P=1 would keep the input at its original size. P=2 when $F=5$. $P=(F-1)/2$ holds the input size for a general F. It is only natural to see this on the first convolutional layer that is looking at the input image while using larger filter sizes (such as $7x7$). Convolution is a numerical method for calculating the integration of the combination of two functions while one of the indicators is flipped (also known as signals). After one of two functions g and f is passed over the other, it specifies the sum of their overlap. It is a device that combines two components into one. To begin, rotate the signal g 180 degrees horizontally, then slide the flipped g across f, multiplying and maintaining all of its values.

### C. Artificial Neural Network

This deals according to the neurons present in the brain of human and these neurons are arranged in layers. It makes use of similar pattern recognition that solves the problem fed to it. This algorithm mimics the operation of a human brain.

ANNs are used to predict a variety of processes. Numerous disciplines of mathematics, engineering, medicine, economics, neurology, and many others have successfully used ANNs. They can handle noisy and incomplete data, which are typical of most renewable energy data, among their many other benefits. They can handle a vast array of data and are adaptable in handling changes in parameters. They can also correlate the hidden data in a large pile, which may significantly influence the model. Once an artificial neural network (ANN) has figured out the pattern, it can carry out complicated tasks like prediction, modeling, identification, optimization, forecasting,

and control. Although this has been discussed by a number of researchers, most biomass models do not use random selection of hidden nodes, which can lead to overfitting and underfitting. The majority of biomass prediction models have been created through trial and error. An artificial neural network (ANN) is a complex network made up of interconnected neurons, which are simple processing units. Three elements—Structure, Learning Algorithm, and Activation Functions—can be used to define ANN. The input and output parameters are connected to a complex stratum of neurons in the hidden layers. A connection that is inbound has two values attached to it: an input value and a weight. The added value influences the unit's output. To learn the pattern, ANNs are trained using data sets. Once trained, they might be shown fresh patterns for prediction or classification. Whether it is a non-linear regression, classification, or optimization task, the network architecture is determined by the way in which neurons are connected to one another. The majority of modeling research up until the year 2000 were primarily based on the linear regression method, according to a summary of the studies on prediction models for the heating value of various biomass-based materials employing proximate analysis components. However, there is a nonlinear relationship between several proximate analysis biomass components and their High Heating Value, HHV. As a result, the prediction of models based on linear regression may not be accurate enough, especially when the models are tested on several data [29].

### D. Development and Evaluation of Model

A variety of techniques will be used to incorporate various aspects and functionalities of the system during the implementation process. The model, which is the engine that runs the app/system, will be built/developed using the Python programming language, Kaggle, and Tensorflow software. This includes libraries such as the Keras library, Numpy, Sklearn, and Mataplotlib, among others This research will be carried out on a Windows 10 computer with a Python programming language running on an Intel Pentium Core i3 2GHz processor and 4GB RAM (64bit).

## IV. Result and Discussion

The covid-19 dataset was gotten from the Kaggle repository (https://www.kaggle.com/praveengovi/coronahack-chest-xraydataset) and was implemented using goggle colaboratory, thereafter classification techniques were performed. Specifically, this chapter shows the result of the studies for the proposed model. This study implements a coronavirus disease detection from chest x-ray images using a convolutional neural network and artificial neural network. The data contains corona chest x-ray dataset with 6 features and 5910 samples, as well as attributes such as the image name of the x-ray, label that indicates x-ray (normal or healthy, and person affected with pneumonia), dataset type, and another label called label 2 that holds information about the person affected with pneumonia. The "!pip install'' keyword was used to import libraries that are not in collab by default. Different libraries were imported such as; Keras, Tensorflow, NumPy, glob, shuttle, sklearn, imutils, matplotlib, argparse.

Because of the large size dataset, the kaggle Application Programming Interface (!mkdir-p~/.kaggle/ && mv

kaggle.json ~/.kaggle/ &&chmod 600 ~/.kaggle/kaggle.json) was used in importing the dataset.

The data used was categorized into "Normal" which refers to chest x-ray images with coronavirus symptoms and "Pneumonia". Due to the close resemblance of COVID-19 infection to Pneumonia hence a need to distinguish between them in other to have a high level of accuracy and precision as earlier discussed in the aims and objectives of this study. The COVID-19 dataset is then being passed into the ReLU activation function which is a non-linear function that solves problem of vanishing gradient associated with the use of CNN thereby giving better and faster results and known to be better than the use of sigmoid activation function. Data augmentation simply means creating prototypes of data in other to add to the quantity of the training set and to also regularize the network, classification of the images into "normal" or "COVID" is also being done.

The model is then trained with the train images and by the number of epochs which was 25 and batch size which was 32 provided. During the training, the model tries to learn and recognize patterns of a particular disease for better accuracy. During this training much is taken into consideration to avoid inaccuracy of the model as this can result in inaccurate predictions.

Fig. 1 and Fig. 2 depict the confusion matrix of the CNN trained model which is 74% respectively. For each chop, it explores the correlation among clinical specificity and sensitivity. A confusion matrix is a table that shows how well a classification model (or "classifier") performs on a number of test data for which the true data have been collected.

In this experiment coronavirus chest x-ray dataset was used to experiment with the detection of COVID-19 through chest x-ray images using CNN approach. However, it was shown that ANN outperforms CNN in terms of 95% accuracy. Table I shows the performance evaluation measures for the study.

Fig. 1.    Confusion Matrix for the COVID-19 Dataset using CNN (TP=32 ; TN=240 ; FP=202 ; FN=150 ).

Fig. 2.    Confusion Matrix of the ANN Trained Model (TP=178; TN=244; FP=16; FN=3).

TABLE I.        PERFORMANCE EVALUATION OF STUDY

| Performance Measures (%) | COVID-19 Data + CNN | COVID-9 Data+ ANN | Formula |
|---|---|---|---|
| Accuracy | 70.83 | 95.69 | ACC = (TP + TN) / (P + N) |
| Sensitivity | 57.39 | 98.34 | TPR = TP / (TP + FN) |
| Specificity | 88.24 | 93.85 | SPC = TN / (FP + TN) |
| Precision | 86.32 | 91.75 | PPV = TP / (TP + FP) |
| Negative Predictive Value | 61.54 | 98.79 | NPV = TN / (TN + FN) |
| False Positive Rate | 11.76 | 6.15 | FPR = FP / (FP + TN) |
| False Discovery Rate | 13.68 | 8.25 | FDR = FP / (FP + TP) |
| False Negative Rate | 42.61 | 1.66 | FNR = FN / (FN + TP) |
| F1-Score | 68.94 | 94.93 | F1 = 2TP / (2TP + FP + FN) |
| Matthew's Correlation Coefficient | 46.73 | 91.36 | TP*TN-FP*FN/ Sqrt((TP+FP) * (TP+FN) * (TN+FP) * (TN+FN)) |

The significance of this study for medical professionals and researchers is critical. The identification of coronavirus with the help of this study will enable human radiologists to make more informed decisions about coronavirus prevention and treatment. Furthermore, since this research focuses on having a higher degree of accuracy, it will support both patients and medical professionals, as well as researchers working on further research and prediction for coronavirus care. It is life-saving for both patients and physicians, and it is much more important in countries where laboratory kits for testing are unavailable. Since there is no need for touch until diagnosing COVID-19, the protection of both uninfected individuals and medical practitioners is guaranteed. Table II compares this study with the state-of-the-art.

TABLE II.    COMPARATIVE EVALUATION

| Authors | Algorithm/Method | Results |
|---|---|---|
| Nusra Rouf et al, 2020 | Logistic regression and Multinomial Naive Bayes | 80% Accuracy |
| Wang and Wong, 2020 | CovidNet from CXR images | 93.3% Accuracy |
| Shuai Wang, 2020 | Modified transfer learning technique | 89.5% Accuracy |
| Ioannis,2020 | Transfer learning and CNN | 96.78% Accuracy |
| Chuansheng Zheng, 2020 | Weak label | 90% Accuracy |

## V. CONCLUSION

The ability to recognize COVID-19 from chest X-ray pictures is critical for both physicians and patients in order to cut testing expense. Artificial intelligence. and deep learning can recognize pictures for the tasks that have been learned. Numerous tests were carried out in this paper to identify COVID-19 in chest X-ray pictures with extreme accuracy using a CNN. The classification was divided into three categories: COVID-19/Normal, COVID-19/Pneumonia, and COVID-19/Pneumonia/Normal. In this research, both CNN and ANN were employed to detect COVID-19, and the artificial neural network's accuracy was determined to be 95% greater than the convolutional neural network. To combat the challenges of vanishing gradient regarding the usage of CNN, the COVID-19 sample was fed into the rectified linear unit. Furthermore, the next system design, ANN, which has the highest accuracy, can detect COVID-19 in two classes, COVID-19/Pneumonia/Normal pictures, with a 95% accuracy. As a result, clinicians may find that using Artificial intelligence operating systems solutions can help them diagnose COVID-19. Ongoing research based on the result of this research would further to our understanding of the use of CNN architectures with COVID-19 chest X-ray images and improve the study's findings. People may also consider employing real-world data and wider samples in the long term, as well as developing new algorithms such as enhancing DCNN and RNN. A wider sample should be examined, as should the usage of other machine learning algorithms, with the goal of improving accuracy in the long term. Activation maps can be used in conjunction with the intended machine learning technique to make the findings and framework more readable.

# A Novel Region Growing Algorithm using Wavelet Coefficient Feature Combination of Image Dynamics

Tamanna Sahoo, Bibhuprasad Mohanty

Department of Electronics and Communication Engineering
ITER, Siksha 'O' Anusandhan, Deemed to be University, Bhubaneswar, India

*Abstract*—**Moving object detection has versatile and potential applications in video surveillance, traffic monitoring, human motion capture etc., where detecting object(s) in a complex scene is vital. In the existing background subtraction method based on frame differencing, the false positive and misclassification rate increases as the background becomes more complex and also with the presence of multiple moving objects in the scene. In this piece of work, an approach has been made to enhance the detection performance of the background subtraction method by exploiting the dynamism available in the scene. The resultant differencing frame so obtained by the spatial background subtraction method is subjected to wavelet transformation. By extracting and combining wavelet features from the dynamics of the scene, a novel method of region growing technique has been further utilized to detect the moving object(s) in the scene. Simulation of various video sequences from CDnet, SBMnet, AGVS, I2R and Urban Tracker database has been applied and the method provides satisfactory detection of the moving object in a complex scene. The quantitative measure like Recall, Precision, F1-measure, and specificity computed for the algorithms, have indicated the algorithms can be a suitable candidate for surveillance applications.**

*Keywords—Moving object; dynamism; wavelet transformation; region growing*

## I. INTRODUCTION

Identification of moving objects and localizing them in a video scene has become crucial as well as an initial task for many complex visual processing algorithms such as detection, classification, tracking, and analysis. This has lead researchers to work in this area and various models (parametric and non-parametric) have been already proposed in the spatial domain.

Using the benefit of the multiresolution analysis, two moving object detection methods have been proposed. The first one being object detection based on image dynamics subtraction [1], and the second one is to develop a novel region growing algorithms by extracting the wavelet features from the resultant subtracted image frames. In both algorithms, along with the dynamics creation, traditional background subtraction has been utilized in the transformed domain. In the second method, wavelet coefficient features of image dynamics are combined selectively to obtain a seed-based region growing process [2] for detecting the moving object in the scene. The methods have been applied to different video sequences available in CDnet [3], SBMnet [4], AGVS [5], I2R [6], and UrbanTracker [7] dataset. The result obtained by extensive simulation, has been compared with the reported results of several well-known techniques like ViBe [8], PCP [9], TD-2DDFT [10], and TD-2DUWT [11].

The rest of the paper is organized accordingly, wherein Section II provides survey papers related to both methods, Section III discusses the algorithm used in discrete wavelet transform domain and the creation of dynamics. Further in Section IV, the results of both the methods have been presented for various datasets and it has been discussed, both qualitatively and quantitatively using performance measure.

## II. RELATED WORK

Various techniques have been reported for the detection of moving object(s), such as, Paisitkriangkrai et.al.,[12] presents a study of moving targets like humans in pedestrian detection, using local feature extraction and support vector machine. In [13], a dual model (self and neighborhood model) which is a non-parametric-based background segmentation method has been proposed.

The generation of background becomes difficult for a complex scene or when there is a sudden change in illumination. This problem is tackled by Elharrouss et al., [14], by using the block-based Sum of Absolute Difference (SAD) method for background utilization as well as block-based entropy evaluation for background modeling purposes.

In the wavelet domain, the detection problem is addressed by Huang et al., [15], [16], by using change detection methods. Tsai et al., [17] applied 2-dimensional discrete Fourier transform (2D-DFT) where each Spatio-temporal slice of the gradient image is processed to detect the foreground objects.

According to Khare et al., [18], Daubechis Complex Wavelet Transform (DCWT) along with double change detection are the techniques used for detecting moving objects. Li et al. [19], estimated the models of foreground and background in wavelet domain using the likelihood of wavelet coefficients. Huntsberger et al. has used a wavelet-based algorithm for recognition and detection of objects in anti-submarine warfare using Logan radar data [20, 21]. Wavelet packet decomposition method has been applied for the analysis of sonar images, which are of quite large formats. Further, Tian et al. [22] have used wavelet coefficient characterization, namely spectral statistics and wavelet coefficients characterization (SSWCC) in spectral images for detecting targets. Boccigone et al., [23] have used Renyi's information as well as wavelet transform and region growing process for the detection in mammographic images. The camouflaged target

images using wavelet coefficient features have also been proposed by Chennasetty et al., [24].

### III. PROPOSED METHODOLOGIES

We have tried to obtain optimal detection results in the transformed domain by proposing a technique (Method I), named as Image Dynamic Subtraction (IDS). By utilizing this technique with the wavelet features, another novel region growing technique has been proposed (Method II), named as Image Dynamic Subtraction using Region Growing (IDS-RG). Below the detailed discussion has been presented.

#### A. Method I: Image Dynamics Subtraction (IDS)

The conventional background subtraction method suffers from the disadvantage of misdetection (detection of static object(s) along with moving object) which requires extensive further processing. First, the dynamics of the frame is created (Fig. 1) and then by using the algorithm of background subtraction, the difference is taken between the current dynamic frame and background dynamic frame.

*1) Dynamic extraction:* In a scene, when the dynamics, which is the motion of an object, are extracted by only using high-frequency components, is known as dynamic extraction. The high-frequency component gives information about the required edge and high contrast values of the moving objects.

Fig. 1. Dynamic Extraction Process using Two-dimensional Discrete Wavelet Transform (2D-DWT).

Fig. 1 above depicts the dynamic extraction process using 2D-DWT where the decomposition of the image [25] is at a spatial level.

After decomposing into sub-bands (LL, LH, HL, and HH), the approximation coefficient (LL subband) is masked to zero and inverse DWT is applied to only higher frequency components to obtain the dynamics of that image. The following equation of creation of dynamics is presented below:

$$W^{-1} = [W] - F_{KA}^{-j}(x,y) \tag{1}$$

Where the $F_{KA}$, $F_{KH}$, $F_{KD}$, and $F_{KV}$ represent the approximation, horizontal, diagonal, and vertical coefficient of the two-dimensional discrete wavelet transform at the jth level. The W represents the wavelet decomposition and $W^{-1}$ represents the inverse decomposition.

Fig. 2, shows the experimental setup of image dynamic subtraction (IDS) [19].

Fig. 2. Setup of Image Dynamic Subtraction using Two Dimensional Discrete Wavelet Transform (IDS-2DWT).

Group of frames is taken as input, the very first frame being referred as background frame. The dynamic extraction of background and the current frame is processed, using thresholding and morphological operation the detection result is produced. The advantage of this method is to avoid further processing of the detected result to get rid of misdetection due to the presence of a static object in the frame. The proposed method algorithm is provided below.

| **Step-1 Image Pre-processing** |
| --- |
| *For input image* |
| *Do* |
| ➢ *Convert color image to grayscale image.* |
| ➢ *Resize it to 512x512.* |
| *End* |

| **Step-2 Frame selection** |
| --- |
| *Do* |
| ➢ *Select B(x,y) as the background frame.* |
| ➢ *$F_k$ as the current frame.* |
| *End* |

| **Step-3 Dynamic extraction of both frames** |
| --- |
| *Do* |
| ➢ *Apply 2 level 2D-DWT.* |
| ➢ *Mask LL subband to zero.* |
| ➢ *Apply 2 level inverse 2D-DWT* |
| *End* |

| **Step-4 Background Subtraction** |
| --- |
| *Do* |
| ➢ *Using frame difference method* |
| $D_K(x,y)=F_{kdy} - B_{dy}$ (2) |
| *End* |

**Step-5 Thresholding and binarize**

*Do*

- *Apply Otsu thresholding to $D_K(x,y)$.*
- *Get the value $T_H$.*
- *Binarize the difference image.*

$$D(x,y)=\begin{cases} 1, D_k(x,y) \geq T_H \\ 0, \text{otherwise} \end{cases} \quad (3)$$

*End*

**Step-6 Morphological Operation**

*Do*

- *Using dilation operation.*

$$MO = D(x,y) \oplus B \quad (4)$$

- *Where B is the structuring element and MO is the moving objects detected.*

*End*

### B. Method II: Image Dynamic Subtraction with Region Growing (IDS-RG)

The region growing process [26] is a technique where the regions are grown depending on some criteria. The most appropriate way to grow a region is by identifying the proper seed points.

*1) Seed point computation:* In this work, the selection of seed points is carried out based on the maximum featured value [27]. This present methodology avoids the Otsu thresholding and morphological operation that has been carried out in the previous method. After the selection, adjacent neighboring pixels which are satisfying the user-defined threshold condition, are included in the region.

A threshold value is taken to stop the region from growing and an optimal region is obtained. But one needs to keep in mind that the threshold value taken should be high enough so that the whole region is extracted [28]. This may also lead to the growth of a region much larger than the actual region, so the choice of threshold value must be a little higher than the optimal value so that the region grown is the actual region boundary.

The proposed technique of image dynamic subtraction using region growing is presented below in Fig. 3. In first step, a difference frame is computed by subtracting the reference background fame from the current frame. The difference input image of size N x M is then resized to 512x512. Image resizing is done so that the image can be divided into sub-region, in form of power 2 .Then it is converted to a gray-scale image (if the image is a color image). It is then divided into non-overlapping sub-blocks of 32x32 or 16x16.

Each of the above non-overlapping sub-block is converted to a 'dynamic' sub-block by adopting the procedure enumerated previously.

Wavelet coefficient features (WCF) like contrast, cluster prominence, energy, cluster shade, maximum probability, entropy, autocorrelation, variance, inverse difference normalized are extracted by using the popular GLCM method. With lots of experimentation, the initialization of the GLCM for 0-degree orientation, and separation vector (d) as one has been taken. The normalized linear values of contrast feature values are acquired along with normalized logarithmic values of cluster shade and cluster prominence, depending upon their dynamic ranges of the features. Three of the wavelet coefficient features are combined. From extensive possible combinations, it has been found that cluster shade, cluster prominence, and contrast combination provide maximum values for each sub-block as compared to other combinations.

For seed block selection, the selection is based on the criterion that the high value of the W.C.F represents the moving object in the spatial domain. Accordingly, the maximum of combined feature values is chosen as the reference seed sub-block. The purpose of selecting the seed block is that the higher value of the wavelet coefficient feature represents that it is a part of the target region. Then the coordinate of the seed point is computed based on the criteria that it is available at the midpoint of the seed sub-block at $(r/2,c/2)$ point of the seed block[38], where r is the row and c is the column.

On selection of the seed block and subsequent seed point, the region [24] with the presence of the moving object is grown by selecting a suitable threshold value and merging the pixels with the seed points. The following Fig. 4 depicts the region growing algorithm undertaken for the purpose.

In the process, using the suitable pixel distance, pix_dist required is selected. It is done by creating a difference between the neighborhood pixels present in form of array in (k) and the R_mean (which is initially taken as the pixel value of seed point in I(r/2, c/2)) is satisfied for threshold. If the pixel distance is minimum of all and less than the threshold value (T) is added to the region. The next new R_mean is calculated using (5).

$$\text{New (R\_mean)} = \frac{R_{mean} \times R_{size} + k(index)}{R\_size + 1} \quad (5)$$

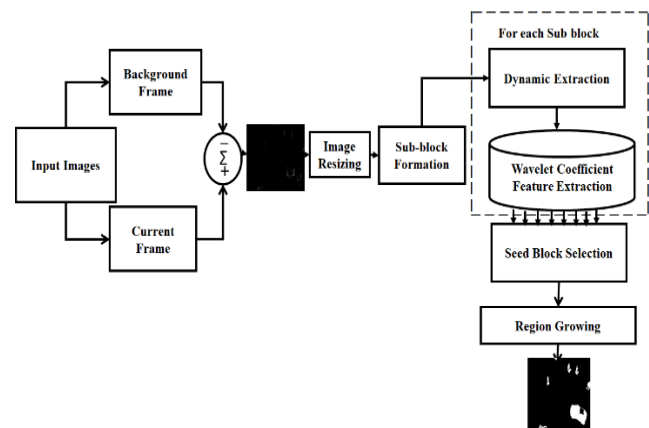

Fig. 3. General Setup of Image Dynamic Subtraction using Region Growing Algorithm.
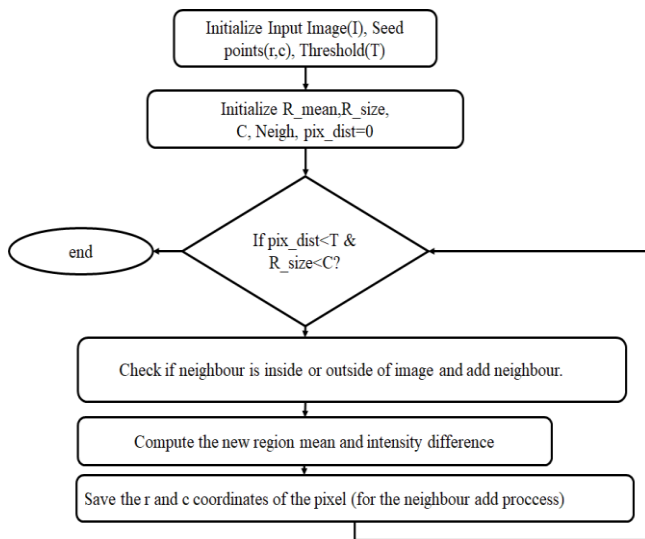

Fig. 4.    Steps to Carry out Seed-based RGA.

Here R_size represents the number of pixels in the regions. The process continues until all the regions satisfying the threshold condition are added to the region.

## IV.    RESULT AND DISCUSSION

Extensive simulations are carried out on different video sequences with multiple and complex challenges for the detection of moving objects from a video frame. The experimentation is carried out on MATLAB environment (R2016a) by using Intel Core i5 CPU with 2.20GHz).

### A. Test Sequence

Both of the methodologies are simulated on different frames of a particular test sequence, by carefully selecting the reference frames as background frames. The choice of sequence number, taken arbitrarily, but the complexity involved in the frames is considered. The major challengeable complexities are multiple moving objects, multiple static objects which changes as the sequences progress, camera movement, shadow for the static object occluding the moving object, complex background due to snowfall or rain, etc. In this paper, the detection results for different video sequences (one from CDnet [3], one each from UrbanTracker [7], I2R [6], AGVS [5], and SBMnet database [4] has been presented in this paper. Further, four more video sequences from CDnet has been compared with different state-of art methodologies.

### B. Experimental Results (Method-II)

The next proposed method is image dynamic subtraction using a region growing algorithm. Here in this method, the current and reference frames are subtracted first. Then difference frame is divided into sub-blocks. The creation of dynamics (using 2D-DWT) is done on each sub-block, where wavelet coefficient features (WCF) using gray level co-occurrence matrix are extracted.

The maximum of each WCF from the sub-blocks is chosen as a seed block. The purpose of selecting the seed block is that the higher value of the wavelet coefficient feature represents

that the region is part of the target. The moving object regions are grown using the seed point region growing algorithm from where the seed block the midpoint pixels are considered as the seed point. In the proposed technique, the combination of features like contrast, cluster prominence, and cluster shade are considered and the results are presented in Fig. 5 and Fig. 6.

*1) Combined feature:* The combination of features [32] is done to strengthen multiple complementary features and yield a more powerful feature. Features like contrast, cluster prominence, and cluster shade have been used.

The Contrast feature measures the local variations present in an image where it provides a correlation between the highest and lowest value of a continuous set of pixels [29]. Cluster shade is used for measuring the skewness of the matrix and is believed to gauge the perceptual concept of uniformity [30]. If the value is high the image is asymmetric [31]. Similarly, cluster prominence is the measure of asymmetry where if it is high, it is less symmetry.

*2) Background updation:* The process of background subtraction is about the difference between the current and reference (also known as background) image. Here for the experimentation, two types of reference or background image have been used where one is like the clear background image and the other one is the background updated reference image.

The need for background updation is in the practical application where the background of the frame changes with the change of light and the motion of the local background. Thus new background of moving objects becomes static. Thus the background should be updated in real-time [33].

Challenges like illumination change have to be overcome, for which the background is updated and it is given in (6):

$$B_{t+1}=(1-\alpha)\ B_t+\alpha.\ I_t \tag{6}$$

Where $B_{t+1}$ is the updated background, It is the current video frame, $B_t$ represents the previous background frame and $\alpha$ is the learning rate, ranging from [0, 1]. Here, the '$\alpha$' is chosen through trials. According to [34], the higher the value of alpha, the presence of foreground in the background is a must and the lower value cannot overcome the sudden change of illumination in a scene. This background model obtains a threshold that can be applied over the distance between corresponding pixel values of $I_t$ and $B_t$. The method is best in terms of speed, simplicity, and memory requirements than other methods like mean, median, histogram, and Min-max. To elaborate the idea of background updation, in the next Fig. 5, an example of Rouen video has been presented.

The first row in Fig. 5 represents the original frames (27, 50, and 173). The second and third-row represent the detection result of the proposed method without and with background updation. Using without background updation, the presence of ghostly artifacts of moving pedestrians, present in the background frame, are also present in the detection result. But while using the method with background updation, only the moving objects of the current frame have been detected in the result.
Fig. 5. Multiple Moving Object Detection using Method II .1st Row: Test Frames in Rouen (Traffic) Sequence,2nd Row: Corresponding Detection Results with Background Updation, and 3rd Row: Detection without Background Updation.

## C. Qualitative Performance Measure

The visual comparison of the two methods of image dynamic subtraction using region growing algorithm (IDS-RG) with and without background updation with the ground truth has been presented in Fig. 6. The first row represents the

original image of the current frames of test sequences, the second row represents the ground truth of that frame. The results of all frames are quite similar in this technique, that is, only the contours of moving objects are present and even the static lines of the background image are also present in the output detection result of IDS-RG without background updation. The method-II using a combined wavelet coefficient feature (WCF) with or without background updation has been applied to test sequences: Rouen (from Urban Tracker); bungalow (from CDnet); advertisement board (from SBMnet), bootstrap (from I2R) and S1 (from AGVS). The results with background updation are quite better than without background updation in Rouen, bootstrap, and bungalow video. The experimental results of IDS-2DDWT and IDS-RG are also compared with the four state-of-art background subtraction method below from Fig. 7 and Fig. 8 respectively.

Although in advertisement board and S1 video, without updation have shown a better result than with background updation as in later one only the contour is present but the presence of ghostly artifacts like snow and few static lines in the resulting image is also present. Further, addition of three crowded video sequences having complex scenario and multiple moving objects has also been used for comparison with the state-of-art results [37]. It includes skating sequence from bad weather category where snow is regarded as dynamic background, a tramcrossroad sequence from low frame rate category from the ChangeDetection.net (CD.net) benchmark dataset [3].

Fig. 6. More Detection Results for Algorithm II with different Datasets, 1st Row: Test Frames of Sequences (The Number in the Parenthesis Indicate the Frame Number of that Sequence), 2nd Row: Ground Truth of Frames, 3rd Row: Corresponding Detection Results without Background Updation and 4th Row: Detection with Background Updation.
Fig. 7. Detection Result of Skating Frame (Frame Number-1953) (a) Input Frame (b) Ground Frame Reference; (c) ViBe; (d) PCP; (e) TD-2DDFT; (f) TD-2DUWT;(g) IDS-2DDWT;(h) IDS-RG + BU.

In Fig. 7 it has been shown that the proposed methodology (IDS-RG + BU) provides significantly better detection results than other methods. Since, the tree is available in the foreground, and is misdetected as in the Fig. 7(g) with IDS-2DDWT, the IDS-RG + BU method properly detects it as *not* moving object and hence clear detection of moving object (in this case, three human being in caps and gloves) are obtained. It is interesting to note that the proposed method is capable of eliminating the dynamic background due to continuous snowfall during the entire video sequence (as compared to ViBe and PCP). Due to low contrast the two human beings are not distinctly distinguishable against the black backdrops. Accordingly, the proposed method also fails to exhibit the entire contour of both persons in Fig. 7(h).

The video frame chosen for Fig. 8 is complex as it contains multiple numbers of moving small sized cars in the static background of high raising building and road with leveling as in Fig. 8(a). A careful observation of the frame reveals that the small sized moving cars are really indistinguishable against the backdrop. But the ground truth reference frame as obtained from the dataset [3], provides only the clearly visible and distinguishable three moving cars. It has been observed that both of our methods are capable of detecting almost all available moving objects [Fig. 8(g) and (h)]. But better visual representation is obtained in IDS-RG+BU method. The IDS-2DDWT method has some mis-detection and ghostly artefacts.

The reported results of ViBe (c), PCP(d) and TD-2DDFT(e) have significant detection errors as shown.

### D. Quantitative Performance Measure (QPM) Comparison

The performance of the proposed techniques and state-of-art is measured using four generalized metrics namely: Recall, Precision, F1- measure, and Specificity. Recall [35] can be defined by the percentage of detected true positive as compared to the total number of true positive in the ground truth which is given by (7). Precision [36] presented in (8), presents the percentage of true positives detected in comparison with the total number of items detected by the method. The above-mentioned metrics are used and usually, a method is considered to be good if it gives a high recall value without sacrificing the precision. F1-measure [39] is considered as the weighted harmonic mean of recall and precision using (9). Equation 10 is specificity which is defined as the number of correct negative predictions which is divided by the total number of negatives.

$$Recall = \frac{TP}{TP+FN} \tag{7}$$

$$Precision = \frac{TP}{TP+FP} \tag{8}$$

$$F1\text{-}Measure = \frac{2 \times Recall \times Precision}{Recall+Precision} \tag{9}$$

$$Specificity = \frac{TN}{TN+FP} \tag{10}$$

Fig. 8. Detection Result of Tramcrossroad Frame (Frame Number-502) (a) Input Frame (b) Ground Frame Reference; (c) ViBe; (d) PCP; (e) TD-2DDFT; (f) TD-2DUWT;(g) IDS-2DDWT;(h) IDS-RG + BU.

Table I presents the quantitative performance measure of videos of different datasets used for the experimentation purpose. The results of QPM determine that IDS-RG with background updation shows better results in most of the video sequences (Recall value of Rouen, Bungalow Advertisement board sequences is greater than IDS and IDS-RG (without background updation).

The results of IDS-2DDWT and IDS-RG with background updation are further compared with well-known state-of-art techniques. From skating and tramcrossroad test sequences, short clips of 96 frames are taken as input. To be specific, two

short clips consist of 96 frames from skating sequence (from frames 1905 to 2000), from tramcrossroad sequence (from frames 413 to 508) and their quantitative performance measure has been presented Table II and Table III. In all videos, the result in IDS-RG has shown better. Table II and III presents the average metrics for all 96 frames, respectively. ViBe produces very low metrics especially in tramcrossroad video (as shown in Table III); further due to foreground aperture problem TD-2DUWT method also suffer as shown in Table II. Image Dynamic Subtraction using region growing with background updation metrics shows better result in overall indicators.

TABLE I.     QPM RESULTS OF ALL DATASETS USED FOR THE PROPOSED TECHNIQUES

| Dataset | Method I:Image Dynamic subtraction | | | | Method II: Image Dynamic Subtraction using Region Growing(without Back- ground Updation) | | | | Method II: Image Dynamic Subtraction using Region Growing(with Background Updation) | | | |

## V. CONCLUSION

Two new methods of multiple moving object detection in a video sequences have been proposed in this paper. Instead of adopting the conventional background subtraction method by means of frame differencing in spatial domain, the present work proposed the subtraction of dynamism available in the current and reference frame, thereby making it a potential technique for video surveillance. The use of discrete wavelet transform solves the localization of motion pixels associated in a frame by keeping those into high frequency subbands on decomposition. The exploration of these pixels are the dynamics of the frame which provide the necessary information of the moving object. Hence, instead of background subtraction, we refer to it as Image Dynamic Subtraction (IDS). The method of IDS exhibit better detection results both quantitatively (Table II and III) and qualitatively (Fig. 7 and Fig. 8). By suitably choosing wavelet coefficient feature (WCF), and adopting the region growing technique over and above it, the proposed method IDS-RG+BU exhibit enhanced detection results. The second method is capable of eliminating ghostly artefacts, occlusion, static lines, cluttering due to dynamic background as has been reported in this paper. Further, it has been observed that, the method of IDS-RG +BU is capable of detecting the moving object (even multiple objects) irrespective of size (for example tramcrossroad video). However, this method fails to provide the requisite results if the colours of the moving object and the background objects are the same and if the contrast between them is insignificant (for example skating video). In addition, this method fails to provide a complete binary image of the moving object(s) in some cases. Even if it detects the moving object by eliminating occlusion due to static object, the present proposed method does not exhibit acceptable result in case of occlusion made by another moving object. Attempts are being made to address these issues.

*Abstract*—The purpose of this paper is to develop a driver drowsiness and monitoring system that could act as an assistant to the driver during the driving process. The system is aimed at reducing fatal crashes caused by driver's drowsiness and distraction. For drowsiness, the system operates by analysing eye blinks and yawn frequency of the driver while for distraction, the system works based on the head pose estimation and eye tracking. The alarm will be triggered if any of these conditions occur. Main part of the implementation of this system will be using python with computer vision, while Raspberry Pi, which is uniquely designed, for the hardware platform and the speaker for alarming. In short, this driver drowsiness monitoring system can always monitor drivers so as to avoid accidents in real time.

*Keywords—Distraction; drowsiness; eye blink; yawn; head pose estimation; eye tracking; computer vision; Raspberry Pi*

## I. INTRODUCTION

Driver distraction and drowsiness are the major public health concerns and have led to road accident that have become one of the major causes of death and injuries in Malaysia. The Bukit Aman Investigation and Traffic Enforcement has reported that in the first six months of 2019, the country reported 281,527 road accidents, an increase of 2.5%, compared to 274,556 in the same period last year. These often stem from peoples' mistakes that occur in different activities related to vehicle driving. The term "drowsy" indicates "sleepy," as in prone to falling asleep. Drowsiness is commonly induced by a lack of sleep, certain medications, and boredom produced by driving a vehicle for extended periods of time. The driver will lose control of his vehicle when sleepy, resulting in an accident. Driver distraction is defined by the National Highway Traffic Safety Administration (NHTSA) as the process through which drivers redirect their attention away from driving duties. Drivers are often distracted by activities taking place around them, such as texting, talking on cell phones, or conversing with others. All these activities divert drivers' attention away from the road, which can lead to accidents that threaten drivers, pedestrians, and even other vehicles on the road.

Many efforts have been made to reduce all these numbers such as developments in computers that can be used to track drivers' conditions with the ability of alerting in dangerous situations [1]. Using physiological measures, ocular measures,

and performance measures, a variety of methods have been investigated and applied to describe driver drowsiness and distraction. Despite the effort, since many studies are focused on referring to the non-direct function, driver drowsiness and monitoring systems have not become widespread. Thus, this paper describes the design and development of a Driver Drowsiness and Monitoring System using Raspberry Pi minicomputer with a webcam making the system cost-effective and portable. The objective of the work is to develop driving assistant system that can help driver to stay alert while driving so that numerous accidents can be reduced or prevented. This paper is organized as follows.

In Section II, this paper presents the previous works. Section III presents the proposed Driver Drowsiness and Monitoring System. In Section IV, the paper discusses the results of the experiments to show accuracy of the system. Finally, the conclusion and future work will be explained in Section V.

## II. RELATED WORK

### A. Driver Drowsiness and Monitoring System

Due to large number of accidents occurring over time, the ability to detect driver's distraction and drowsiness, then alarming them in real time becomes challenging. In order to improve the system development, a few existing systems in the market have been studied and discussed. Majority of the applications are integrated with the single functionalities only. Anti-Sleep Pilot is the dashboard device that will monitor both driver and their driving condition. It will let the driver know when it's time to take a ten-minute rest and pull over. The device continuously calculates the driver's fatigue level once driving started and status displayed. Driver alertness is also maintained and measured through occasional reactive tests in which the device must be touched as soon as indicated. If the combination of variables approaching the limit, the visual and audible signals from the Pilot will be activated to the fact that the driver need to take a break- the system is adaptive to light and sound, so that its monitor and warning automatically change for cabin conditions.

In industry, systems based on near-IR are the most common. The Saab Driver Attention Warning System detects visual inattention and drowsy driving. The system uses two

*Corresponding Author.

miniature IR cameras integrated with Smart Eye technology to accurately estimate head pose, gaze, and eyelid status. When a driver's gaze is not located inside the primary attention zone (which covers the central part of the frontal windshield) for a predefined period, an alarm is triggered. When the cameras detect a pattern of long duration eye-lid closures, indicating the potential onset of drowsiness, a series of three warnings is initiated. This can only be cancelled when the driver presses a reset button in the fascia. The system is then immediately reactivated. [10] In this paper the author provides facts and figures of road accidents due to driver's drowsiness. Study reveals that in United States of America near about ten million fatal accidents occur in a year. In order to find safety precautions and road accident prevention, real time driver's drowsiness monitoring must be done. Author claimed 80% correct results of the suggested structure by focusing on the facial expressions of the driver and to propose a lightweight model using Android application.

The authors [12] used a lightweight Convolutional-Neural-Network model to categorize facial sleepiness patterns of drivers while driving on road. With glasses, the accuracy level range between 85% to 88% with and without glasses along with the overall average of 83%. [13] Driver sleepiness is one of the main reasons for road accidents and the number of such accidents can be minimized with the help of driver drowsiness monitoring system. A lot of research has been done and variety of alarm models and frameworks were deployed for this purpose including capturing facial and head movements along with yawn frequency. The paper itself is a survey and it presented a comprehensive comparative analysis for the detection of driver sleepiness and preventive measures adopted. The authors [13] reviewed multiple approaches SVM (Support Vector Machine), HMM (Hidden Markov Model) and CNN (Convolutional Neural Networks) along with their positive and negative impacts and limitations associated with each approach to help researchers in finding gaps. They concluded that SVM is comparatively cheap but doesn't work best with large data sets whereas HMM and CNN has less error ratio, but they are costly. The authors [14] presented a detailed comparison betouren invasive and non-invasive sleepiness detection methods. Invasive method like electrooculogram (by recording eye movements) and non-invasive method like electrocardiogram (by recording heart rhythm and activity) of the driver. The authors used hybrid approach by combining both EOG and ECG, but this strategy has limitations associated with it as there are many other reasons for change in heart rhythm except for drowsiness only.

The authors [15] proposed a framework to estimate in advance about the number of possible road accidents which could happen according to the road condition by using the random variable function and Taylor's series. The authors [16] described another approach by breaking down the proposed model in four steps. Started by capturing movements of the driver from the real time video after then categorizing different sleep conditions by considering other factors like with putting glasses on or off and movements of mouth, head, and eyes. The authors are using any two conditions to get to know the sleepiness state of the driver. Another research based on measuring heart rhythm to detect driver's sleep state as

heart-rate-variability (HRV) has already been used to determine the brain disorder [17]. Therefore, the authors recommend using HRV to detect sleep state of the driver as change in sleep state changes the involuntary physiologic process of the man which directly effects HRV. But again, the reason for change in HRV may not be only the drowsiness as presence of other factors can never be ignored and this becomes the limitation of the suggested approach.

Driver's face expressions recorded, and alert sent to the driver when found in drowsy state. It works by extraction of facial expressions and then running an algorithm to check and detect the drowsy position and finally alert sent to driver to make him/her conscious [18].

### B. Eye Blink Detection Method

For the blink detection, Mandeep and Gagandeep [2] had proposed a method using Mean Shift Algorithm. In this algorithm, eyes are identified in each frame, and each eye blink is compared to a mean value. The system analyzes the eye opening at each blink to a standard mean value, and an alert is generated if the eye opening exceeds this value for a certain number of consecutive frames. Compared to the algorithm in this study, the system does not need to store information from previous frames because eye blinking measurements from a collective number of frames are utilized to assess drowsiness. The algorithm proposed is simple but efficient to detect eye blink. The system monitors the EAR which is the ratio between the height and the width of the eye contour in the real time. This value can represent the level of the eye opening by comparing to threshold value.

The research [11] was focused on capturing eye movement with the help of cameras by using CNN which is used to identify real time patterns in images and videos. The eye movement pattern from the video helps in categorizing sleepy or non-sleepy driver and consequently generates an alarm in order to provide protection from road accidents. Although, the researchers [11] provided more accuracy when compared to conventional CNN but it works with only capturing eye movement and not considering yawning and head movement. [19] This paper covered other factors along with detection of driver's drowsiness by capturing eye-blink. Upon drowsiness detection, the system sends an alarm to make the driver alert. Location monitoring was done by GPS and driver's alcohol, temperature and heat rhythm were measured to monitor health by putting a check on vehicle speed and informing about the current status to other vehicles [19]. The authors [20] advocate to smartly monitor driver drowsiness without conditioning it with other factors like steering-angle, pedal-pressure and electrocardiogram etc. In fact, it used a USB camera to capture video and extract facial traces for sleep pattern monitoring by using iris area and eye closure period. In [31] researchers presented a solution to a challenge normally faced in driver drowsiness detection that is capturing driver's different facial images like frequency of eye-closure and yawning at night or when light is low. To solve this issue, infrared camera was used to capture facial images with adequate visibility. More than 3000 facial images were used for testing purpose and researcher claims the result was more than 90% accurate for both eye-closure and yawn frequency monitoring in low light.

## C. Yawn Detection Method

On the other hand, the yawn detection in [3] describes a system in which the face is found in a video frame using the Viola-Jones face detection approach. Then, from the face region, a mouth window is generated, and lips are searched using spatial fuzzy c-means (s-FCM) clustering. However, this algorithm has complex classifier, as a result, it is impractical to install the system inside the vehicle with little processing power, and training on datasets with huge samples is required. Compared to the algorithm in this study, the system utilizes some mouth geometrical characteristics to identify yawning which is detected by the ratio of mouth height and width. The authors [21] used an algorithm to record video and trace facial behavior like yawning, eye-closure period and frequency of eye-blink from that recorded video instead of measuring the functioning of any other device attached with the vehicle to simplify the algorithm. In [22] the authors tried to focus on driver drowsiness and to propose such an algorithm which not only detects driver's drowsiness but also finds a safe place nearby to park the vehicle there and inform the transportation authority about the problem to ensure road safety. The authors in [23] tried to enhance their previous work related to detect sleepiness with the help of machine learning. They suggested to capture face expressions and position to detect sleepiness of the driver by using a simple algorithm resulting 88% accuracy with driver wearing no glasses and 85% with driver wearing glasses. The authors also described that their proposed algorithm is more efficient in terms of storage, model-size and complexity than the benchmark-model and is capable of implementing in real time driver's sleep detection vehicle applications.

The authors [24] presented an approach to analyze the magnitude of relation of different facial parts to detect driver drowsiness. These facial parts include movements and changes in eyes, nose, ear, eyebrows, mouth, and face wrinkles. In analyzing the magnitude, relation of all these facial parts, the authors proposed the use of SVM classifier. In this research paper, the authors [25] endorsing the fact that use of images for driver's sleepiness detection is one of the main focus of research nowadays. Images of facial expressions and movements can be the best way to detect driver drowsiness and to ensure road safety. The researchers are using four types of CNN based image recognition and classification methods to process data containing yawn frequency along with variable mouth positioning. In this research the authors [26] proposed a model which needs prior training as it works on two main streamlines. One is to reduce light effect from the face images with the help of contrast limited adaptive histogram equalization and second one is to extract maximum information from the eye images using the 3D SE-blocks. The researchers used 3D-depthwise separable sensing framework instead of 3D image extraction to minimize overall cost. It comes with one limitation that face images may not be always clear as sometimes driver may wear cap or driver's hairs may cover the face resulting in the poor visibility of extracting sleepiness patterns from driver's facial images. In [27] proposed a framework where Support Vector Machine algorithm was used to monitor driver sleepiness by extracting facial expressions like eye-blinking frequency for a specific period of time or mouth opening due to yawning from the pictures captured by a built-in camera in the vehicle. This proposed model sends an alert to driver upon drowsiness detection by using Euclidean-distance function to ceaselessly monitor eyes-mouth space approaching to sleepiness.

In [28] researchers advocated that road accidents can be avoided with driver drowsiness monitoring using MATLAB for image processing. System works on visual concept by using a camera for face recognition and detection. After that it focuses on eye blink and then information about eyes open/close was extracted by MATLAB using Hough-transform and Viola-Jones algorithms. Eye movement observation was recorded continuously using camera and driver was declared sleepy if more than five frames show closed eyes consecutively. It consequently sends alert to the driver with the help of alarm. Authors [29] presented a detailed analysis of recently used techniques and algorithms for driver's drowsiness monitoring/detection as drowsiness is one of the main reasons of road accidents and is more harmful than any other technical fault in vehicle. Authors used the analysis approach by dividing latest drowsiness detection algorithms and techniques into three categories. First one is to analyse the driver's driving style, secondly driver's mental state or psychological patterns are observed. Third and last is the detailed analysis of different visual monitoring systems used to scan and then to extract required information to alert driver and ensure road safety. Specifically focusing analysis on the data sets available to work on for driver drowsiness detection and results found are there is still plenty of attention required to add more driver drowsiness images to comprehensively monitor human yawning patterns. In [30] authors presented an approach to monitor real-time driver's sleepiness with the help of magnitude relation of driver's eye-closure along with yawn frequency and head positioning by observing the mouth and eyes movements. As the proposed model is intended for real-time environment, therefore, to achieve accuracy it runs 15 frames/second which is justifiable. The best results showed accuracy level of eye-movement/blinking was 97% and the results for yawn frequency was 96% and head positioning accuracy level was 63.4% detected.

## D. Gaze Detection Method

Lastly, the gaze detection in [4] explained that the face detection was done using the Viola-Jones algorithm. The eye area is next localized using the integral projection function, followed by pupil detection and gaze classification. The pupil position and eye corner location information are utilized to identify the direction in which the subject is looking. The distance from pupil boundary to eye corner line segment is measured to find whether the driver is distracted or not. Compared to the algorithm in this study, the system is able to handle the head movement while this algorithm is done only for frontal face images. In [32] researchers proposed a framework to optimize gaze detection using data transfer learning with the help of deep-learning models. It used a small camera to capture images of eyes and mouth and then extract the required information from the centre of the eyes and mouth.

In [33] researchers proposed a framework for eye gaze detection with the use of Convolutional-Neural-Network

model and claimed better accuracy results when it comes to road safety. Along with this claim, the paradigm for the possible execution of proposed algorithm, real time eye gaze controlled autonomous vehicle can be used. The authors [34] described that real time road safety applications must deal with some challenges, like driver drowsiness, glass, and lighting reflections. Therefore, chance to get false result may increase when driver does not move his head and gaze an object with only eyes movement and gaze detection based only on head movement will not be sufficient and accurate. It presented a deep learning gaze detection without prerequisite of driver standardization with the help of an infrared small sensor.

## III. PROPOSED SYSTEM

Fig. 1 shows the flowchart of the operation of Driver Drowsiness and Monitoring System in detecting drowsiness and distraction among the drivers. This system will be split into three modules which are blink detection, yawn detection and gaze detection. For all the module to operate, the system must successfully detect driver face. If there is any face detected, then it will go through each module simultaneously and begin the detection. If the driver shows any sign of drowsiness or distraction, the system will immediately sound the alarm to alert the driver.

Driver Drowsiness and Monitoring System is an automobile application that have the purpose to alert the driver when signs of drowsiness or distraction are detected. Based on Fig. 2, this system comprises a camera-based driver drowsiness and monitoring system aimed at the driver's face, which enables a real-time evaluation of the driver's presence and state. For the hardware part, the system will use Raspberry Pi 4 as the main component to make a compact embedded system. All the algorithms will be implemented in it. Webcam is installed on the car dashboard for video feed purpose to track features of the driver (8FPS). Portable speaker will be used as an alarm device. When the system detects drowsy or distracted driver condition, it makes a sound alert from the speaker. Image's processing algorithm is developed in Python and OpenCV to detect the drowsiness sign based on rate of eye blinking, eye closing period and rate of yawning while gaze detection to estimate where the driver is looking for the distraction sign.

### A. Face Detection using Dlib Library

To detect the face in the image, HOG + LinearSVM face detector from dlib library will be used. The function that had been used for face detection is: dlib.get_frontal_face_detector(). This function will return the pre-trained HOG + Linear SVM face detector which is used for obtaining the face bounding box (i.e., the (x, y)-coordinates of the image's face). Given the face region in the face bounding box, the key facial structures in the face region can be detected. Facial landmark detection will be applied using pre-trained facial landmark detector inside the dlib library. This method is used to localize and labels mouth, right eyebrow, left eyebrow, right eye, left eye, nose and jaw. Each facial structure on the face has its own specific (x, y)-coordinates.

There are 68 coordinates (shown in Fig. 3). Those coordinates represent each facial structure mentioned above. These coordinates can be used to detect eyes, nose, mouth and left and right eyebrow and will be used for the next section.

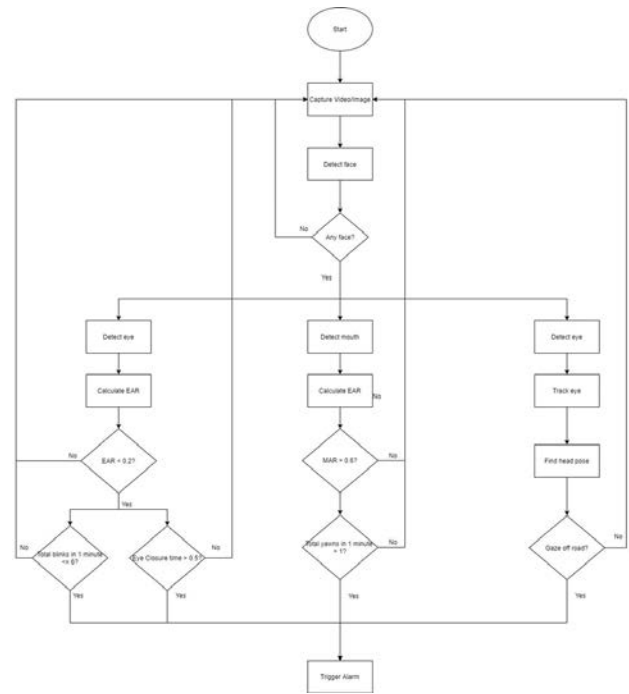

Fig. 1. Flow Chart of Driver Drowsiness and Monitoring System.

Fig. 2. System Architecture Diagram.

Fig. 3. 68 Facial Landmark Coordinates.

## B. Blink Detection System

For the blink detection method, Eye Aspect Ratio (EAR) algorithm will be used. EAR is defined as the ratio of the height and width of the eye. First, extraction of the eye region from a set of facial landmarks. Based on Fig. 3 there are six coordinates for each eye. These six coordinates (as shown in Fig. 4) will be used for calculation of EAR value. The calculation is done for both left and right eye.

Fig. 4. The 6 Coordinates of an Eye represent in P1, P2, P3, P4, P5 and P6.

According to [5], the equation for EAR can be derived as the following:

$$EAR = \frac{|P2-P6|+|P3-P5|}{2\,|P1-P4|} \qquad (1)$$

Where, P1, P2, P3, P4, P5 and P6 are the facial landmark coordinates that have been obtained before. Next, the system calculates the average of two EAR together (assumption that a person blinks both eyes at the same time). EAR value will be compared with the threshold value (Te) taken as 0.2 [5]. If the EAR value is below than Te, the eye will be considered as closed. When eye is closed, the two types, which are eye closure and eye blink will be differentiated. When the duration of eye closed is more than 0.5 seconds, it will be considered as eye closure or else as eye blink.

$$EyeState = \begin{cases} Closed, EAR < Te \\ Open, EAR > Te \end{cases} \qquad (2)$$

Alarm will be triggered in two conditions. Firstly, when the eye is closed for more than 0.5 seconds. This is because the typical duration of a single blink for the human eye is 0.1 to 0.4 seconds [6]. If it more than 0.5 seconds, then it is considered as eye closure. When the EAR value remains less than Te for more than 0.5 seconds, it can consider that the driver is drowsy or tired. Secondly, when the total number of blinks per minute is equal or less than six. This is because the typical blink rate for a normal individual is 10 blinks per minute, whereas it is 4-6 for a sleepy person [7].

## C. Yawn Detection System

For the yawn detection method, Mouth Aspect Ratio (MAR) algorithm will be used. MAR is defined as the ratio of the height and width of the mouth. First of all, extraction of the mouth region from a set of facial landmarks. Based on Fig. 3, there total 20 coordinates for both outer and inner mouth. To calculate the MAR, only those coordinates will be used at which are at the outer mouth [8]. There are 12 coordinates (as shown in Fig. 5).

Fig. 5. The 12 Coordinates of Mouth Represent in P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11 and P12.

According to [8], the equation for MAR can be derived as the following:

$$MAR = \frac{|P3-P11|+|P5-P9|}{2\,|P1-P7|} \qquad (3)$$

Where, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11 and P12 are the facial landmark coordinates that this study obtained before. MAR value will be compared with the threshold value (Tm) taken as 0.75. The value of Tm was established by trial and error, with several values of Tm being tested to ensure that the algorithm accurately classifies an instance of yawning and closed mouth. It shows that if the MAR value is bigger than Tm, the mouth will be considered as yawning. Every time MAR value exceeds the Tm, total threshold will be increased by 1 and will be reset back to 0 after 1 minute.

$$MouthState = \begin{cases} Close/Talking, MAR < Tm \\ Yawn, MAR > Tm \end{cases} \qquad (4)$$

Alarm will be triggered when the total number of yawns per minutes is more than 1. This is because a driver becomes tired when he or she begins to yawn more than once per minute [9].

## D. Gaze Detection System

For yawn detection method, the system will combine both head pose estimation and eye tracking. This combination will allow the system to detect whether the driver eyes are off the road or not. Drivers have a habit of changing their head position while driving. To determine which direction the driver is looking, 3D head pose estimation is necessary. In head pose estimation, it is typical to predict relative orientation and position with respect to camera, in calculating the Euler angles. Euler angles can be represented as roll (tilt), pitch (up and down) and yaw (left and right) as shown in Fig. 6.

Fig. 6. Roll, Pitch, and Yaw of Euler Angles.

Out of three Euler angles, the system only extracted and used yaw angle only. This is due to the system's sole concentration on determining the left and right direction of the driver's gaze. After that, initializing the frontal face angle will be done. Frontal face is a face with a head yaw angle ∈ [-15°; 15°]. If the yaw angle is in between -15° and 15° it means that the driver is looking at the centre while if the yaw angle is less than -15°, it will be considered as looking in left direction and if it more than 15°, it will be considered as looking in the right direction. Eye tracking is needed because during driving, the driver's eye look is continuously shifting, based on the surroundings. As a result, identifying eyes is insufficient. Real-time tracking of eyes is required by isolating the eyes from the face using facial landmark detection mentioned. Then, detection of the iris by using image processing method such as blurring, eroding, thresholding and contour will be done. After getting the iris, the coordinate and calculate, the horizontal distance will be found to determine which direction driver is looking. The direction of the driver's gaze is determined by a combination of eye tracking and head pose estimation algorithms. Alarm will be triggered when the driver is looking other than centre for more than two seconds. This is because drivers should never move their gaze away from the road for more than two seconds at a time.

## IV. RESULT AND DISCUSSION

The Driver Drowsiness and Monitoring System is tested in a variety of conditions that a driver would encounter in real life. The factors considered when developing test conditions are as follows:

- Appearance: With and without spectacles

The average frame rate of image capture throughout testing ranged between seven and eight FPS. All the people will be captured for one minutes on each function. Table I show final interpretation of the test performed on the system in terms of accuracy.

$$Truepositive = \frac{No\ of\ frames\ correctly\ detected}{Total\ numbers\ of\ frames} X100 \quad (5)$$

The testing result in Fig. 7, Fig. 8 and Fig. 9 show that the system performs quite well under different condition that have been considered. Based on Fig. 7, the use of spectacles by driver has affected a lot in terms of accuracy. As a result, blink detection suffers from the problem of detecting false positive. This may be because system miscalculated the EAR value of the driver when he/she is wearing the spectacle. While based on Fig. 8, the system utilizes some mouth geometrical characteristics to identify yawning by detected by the ratio of mouth height and width. On the other hand, based on Fig. 9, gaze detection had lower accuracy on the spectacles driver because the system cannot track the eye properly.

TABLE I.    SYSTEM ACCURACY CALCULATED FROM TESTING

|          | Blink/Eye closure | Yawn  | Gaze  |
|----------|-------------------|-------|-------|
| Person 1 | 68.3%             | 95%   | 48.3% |
| Person 2 | 91.7%             | 98.3% | 90%   |
| Person 3 | 67%               | 91.7% | 46.7% |
| Person 4 | 96.7%             | 100%  | 93.3% |
| Average  | 80.9%             | 96.3% | 69.6% |

## V. CONCLUSION AND FUTURE WORK

Driver Drowsiness and Monitoring System is all in one software application for driver that can perform many functionalities in one application. This Driver Drowsiness and Monitoring System provides significant benefits to driver for them to track their behavior while driving. I really hope that this project can give benefit to driver so that driver can avoid fatal accident caused by driver negligence and sleepiness. The proposed method easily detects eye blink, yawn and gaze. Image processing provides a non-invasive method of detecting drowsiness and distraction that is free of irritation and interference. Whenever the system meets the requirement, it will set off the alarms. As a result, in this study the system is dependable, efficient, and cost-effective. The detection of drowsiness and distraction in its early phases not only assists the system in delivering timely warnings, but also warns the driver ahead of time, potentially saving lives from tragic mishaps.

In future, this Driver Drowsiness and Monitoring System could be upgraded even further when more systematic functions will be added to give ease to the vehicle driver while driving their vehicle. For instances, implementation of night vision to avoid the effect of poor detection due to insufficient light will obtain a better result that is unaffected by lack of brightness. Besides, the face detection algorithm must account for head movements and detect the face in all conceivable face orientations. So, that the system can be extended to include non-frontal face images. Then, to improve the accuracy of the system, the algorithm should include classifier that is trained on set of sample images. Lastly, to deliver a more comfortable driving experience, the system providing the function such as tire pressure monitoring, lane change assistant, etc. In a nutshell, this system will be useful to the driver by making their journey safer, more engaging, more convenient, and more fun.

# BiDLNet: An Integrated Deep Learning Model for ECG-based Heart Disease Diagnosis

S.Kusuma, Dr Jothi.K. R

School of Computer Science and Engineering
Vellore Institute of Technology
Vellore, India

*Abstract*—**Every year, around 10 million people die due to heart attacks. The use of electrocardiograms (ECGs) is a vital part of diagnosing these conditions. These signals are used to collect information about the heart's rhythm. Currently, various limitations prevent the diagnosis of heart diseases. The BiDLNet model is proposed in this paper which aims to examine the capability of electrocardiogram data to diagnose heart disease. Through a combination of deep learning techniques and structural design, BiDLNet can extract two levels of features from the data. A discrete wavelet transform is a process that takes advantage of the features extracted from higher layers and then adds them to lower layers. An ensemble classification scheme is then made to combine the predictions of various deep learning models. The BiDLNet system can classify features of different types of heart disease using two classes of classification: binary and multiclass. It performed remarkably well in achieving an accuracy of 97.5% and 91.5%, respectively.**

*Keywords*—*Heart disease; ECG; deep learning; machine learning models; discrete wavelet transform*

## I. INTRODUCTION

According to statistics, around half of all deaths caused by cardiovascular disease are due to sudden cardiac arrests [1,2]. The most common tool used for detecting arrhythmias is the electrocardiogram, which is a non-invasive method of monitoring the heart's activity. Unfortunately, diagnosing arrhythmias using an electrocardiogram is usually time-consuming and challenging for cardiologists. That is why a lightweight arrhythmia detection system is designed to help busy cardiologists identify and treat patients with irregular heart rhythm conditions. The ability to perform efficiently and accurately is a vital component of computer-assisted diagnosis (CAD) technology, which is used to treat cardiovascular disease.

In the past few decades, various machine learning algorithms have been extensively studied for detecting arrhythmias. These include the multi-perceptron, extreme gradient boosting, and support vector machines. The development of open-source electrocardiogram datasets such as those from MIT-BIH has greatly improved the performance of these systems. One of the most common approaches to arrhythmia detection is to identify the shape of the heartbeats in five different types according to the AAMI standard. This method usually takes three steps to implement. These include signal preprocessing, data augment, feature engineering, and linear or nonlinear classification.

Unfortunately, noise removal techniques are prone to losing valuable information about physiological signals. Also, the varying signal waveforms can lead to poor performance in the construction of features. That is why machine learning models must be designed to perform well in this field[3-6]. Due to the increasing number of data sources, the performance of machine learning models has improved significantly in detecting different types of heartbeats. This is because the increasing number of features and the complexity of the classification process have been greatly improved by the use of deep neural networks. Deep models have been able to improve the performance of various applications such as machine vision and natural language processing.

The paper shows how BiDLNet, an automatic tool for analyzing and visualizing electrocardiograms, works by taking advantage of four deep learning techniques. It first takes advantage of two different techniques to perform deep features and then combines them using a wavelet to reduce their size.BiDLNet then combines the deep learning techniques' deep features with the higher-layer features to perform a feature selection procedure. It then improves its classification performance by using an ensemble learning algorithm. BiDLNet can classify different types of heart disease from the traces of electrocardiograms. It can classify it in two categories: binary classification and multiclass classification. The first one aims to distinguish between normal and abnormal patients, while the second one focuses on the different cardiac findings.

The development of BiDLNet has been regarded as a major contribution to the advancement of the pipeline.

- It is a cost-effective, fast, and sensitive tool that can help in the detection of heart disease.

- BiDLNet can also perform a new approach to diagnosing heart disease by analyzing the 2-D image of the ECG. This method is considered to be a novel technique to perform diagnosis.

- BiDLNet is built on a network of deep learning networks that are composed of distinct structures. Due to the varying architecture of these networks, it can get two levels of deep features from each layer.

- Due to the varying dimensions of the features extracted from each layer, they are mined through deep learning techniques to reduce their size. They are then merged into a single feature in a simplified manner.

- The level of a feature that's extracted from each layer affects the performance of BiDLNet. To improve its performance, it should also consider incorporating bi-level features.

The article begins with the related literature survey in Section 2. Overview of the materials and methods used in the study in Section 3 and then moves on to introduce the experimental results. Section 4 presents the results of the study, and then Section 5 concludes with a discussion of the limitations and strengths of the proposed study.

## II. LITERATURE REVIEW

Various studies have been conducted on the use of signal processing, data mining, and soft-computing techniques to analyze and visualize CADx for various applications [7]. One of these studies utilized a flexible algorithm known as FAWT to extract statistical features from the electrocardiogram signals [8]. A study conducted by Acharya et al. extracted high-order spectra from the electrocardiogram signals [9]. They then trained and tested a deep convolutional neural network for analyzing and visualizing CADx [10]. The researchers used a variety of parameters to test and improve the model's performance [11]. The researchers then explored the use of a tunable-Q wavelet transform algorithm for analyzing and visualizing CADx. They found that it performed well in the detection task [12]. In another study, the authors analyzed the performance of two deep neural networks on the same task [13].

In another study, the researchers explored the use of a joint time-frequency representation scheme for analyzing and visualizing CADx [14-16]. They found that it performed well. The results of their study led to the development of a filter bank that can be used for optimal performance. Many studies have been proposed for the analysis and visualization of CADx, CAD using HR or electrocardiogram signals. One of the techniques that is commonly used in this field is the use of multi-dimensional signal processing [17,18]. While the conventional methods of analyzing and visualizing CADx rely on matrix-based transformations and vectors, the use of tensor-based techniques can provide a powerful tool for improving the performance of these techniques [19]. In a study, the researchers proposed 33 layers of a deep convolutional neural network that can be used to classify 12 rhythm types [20]. They found that it performed well in performing diagnostic tasks on a large single-lead ECG dataset. Their models performed well in various public datasets [21]. In another study, researchers explored the use of discrete wavelet transforms to extract 3,072-dimensional features from an electrocardiogram dataset. The results of this study were superior to deep learning and ensemble learning methods [22].

In another study, the researchers proposed a CNN (Convolutional Neural Network) that was able to detect myocardial infarction using electrocardiogram beats with noise [23,24]. Unfortunately, the researchers found that the temporal properties of the signals were not taken into account properly. In some studies, the use of well-designed structures to cope with the time series has been presented. For instance, in a study, the researchers were able to distinguish five types of arrhythmias using a deep-coded feature network and an LSTM network. They found that the LSTM network performed well under raw electrocardiograms. Despite the success of the deep model, the researchers found that the models were not able to perform well in certain types of arrhythmias. They noted that the deep model often overfittings due to its lack of cross-correlation operation[25]. To improve the performance of deep models, the researchers suggested that they should be tested with more electrocardiograms.

## III. MATERIALS AND METHODS

### A. Algorithms and Dataset

Deep learning is a type of machine learning that involves building various structures using recurrent neural networks, belief networks, and autoencoders. These are then utilized for a particular kind of data, the most common deep learning model is the CNN. This is used in the design and construction of medical images, and it is also used in the diagnosis and classification of medical images. In this study, four CNN namely ResNet, DenseNet, Inception and Xception architectures are used to implement a proposed model for diagnosis called BiDLNet.

The PTB-XL is a recently published electrocardiogram data set that is used in this research[26]. This dataset was originally recorded from 1989 to 1996. It was made available online in 2020. The data was initially made available to the public in 2020. This dataset consists of over 20,000 electrocardiograms (ECGs) taken from 18885 individuals. The gender balance is equal between male and female patients, with ages ranging from 1 to 95 years. It also contains various heart diseases and single-disease conditions. This dataset includes a single-class label for patients with only one heart disease or a multi-class label for those with multiple heart diseases as given in Table I. The number of healthy subjects in the dataset is also impressive. A sample Heart patient dataset is shown in Fig. 1.

TABLE I. THE NUMBER OF RECORDS FOR INDIVIDUAL CLASSES

| Records | Class | Description |
|---|---|---|
| 9528 | NORM | Normal ECG |
| 2655 | HYP | Hypertrophy |
| 4907 | CD | Conduction Disturbance |
| 5250 | STTC | ST/T Change |
| 5486 | MI | Myocardial Infarction |

Fig. 1. Sample ECG Image.

## B. Proposed BiDLNet

The paper aims to investigate the potential of deep learning techniques to diagnose heart disease using electrocardiogram data. It proposes a pipeline that aims to explore the possibility of achieving high performance in this field. The BiDLNet framework uses electrocardiogram trace images to perform the real-time clinical study. It includes four phases: Data preprocessing, Extraction of features, classification, and finally, integration. During the preprocessing stage, the image size is modified and augmented. After training four CNNs, deep features are extracted from each CNN layer. Lastly, with the fully connected layers, the obtained features are then combined in the integration stage. Through the use of deep learning techniques, such as DWT, the features can be fused seamlessly. During the feature selection stage, the number of integrated features decreases. In the classification stage, a set of schemes is then constructed to diagnose heart disease. The second scheme consists of multiple classification systems that are built on voting ensemble classification. The proposed BiDLNet Architecture is represented in Fig. 2.

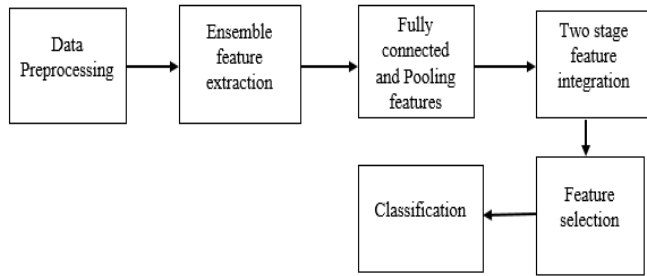

Fig. 2. BiDLNet Architecture.

*1) Data preprocessing:* The tracing image of ECG size is changed to correspond to the input layer of a deep learning model. Table II shows the sizes of the extracted features and the input layers of varied deep learning models. After extracting the features, the data augmentation procedure is applied using various approaches to improve their size and reduce overfitting issues during the training process. These include scaling, translation, and folding in y and x directions.

*2) Phases of proposed methodology*

*a) Phase 1: Feature Extraction:* Some problems can occur during the training of CNNs. These include convergence and overfitting. To avoid these issues, the layers should be modified to ensure that their learning rates are similar. Transfer learning can then be used to improve the performance of these layers. This study focused on a small dataset with a few images. Pre-trained CNNs are commonly used to improve the classification performance of images by training them on attributes from a large number of images. They can also be used to perform similar tasks more accurately when compared to the models that are used in the study. Four of these CNNs are currently being used with the transfer learning framework, and some of the parameters will be explained in a later section.

In this study, the size of the output layer was modified to perform multiclass and binary diagnosis tasks for heart disease

classification. After the CNNs have been trained, deep features are extracted using the method. The extracting of features is done from the CNN's two layers. The first layer is a collection of layers that accepts the raw images, while the other layers perform various functions. These include calculating the output volume, performing a convolutional process, and analyzing the regions of the image. The first layer is then joined with the other layers to form a pooling layer. This allows the CNN to minimize the size of its earlier convolutional layer and generate class scores. At last, the fully connected layers perform various functions, such as generating class scores and learning input image patterns.

Due to the different performance of deep learning techniques, the deeper layers of CNN were used in this study. The extracted sizes of the feature sets from each model were studied in Table II. To ensure that the benefits of deep learning are integrated, feature integration was also performed. The DWT method was also used to reduce the size of the features. This method can also explain the time-frequency illustration of the data. The cluster of wavelet functions in this study takes advantage of the data's low and high pass filters to produce smaller output sizes. It then passes the resulting details and approximation coefficients through various low and high pass filters. The paper uses three decomposition levels to analyze the features. The lowest level, which is known as the DWT, has a frequency range of 0 to 2.3 kHz. The cluster of wavelet functions was then combined with the deep feature sets extracted from the last layer of the CNN to perform a more accurate image classification. The "Haar" wavelet was chosen as it is an efficient tool for analyzing ECG data. The number of decomposition levels achieved by the cluster was three. The authors of the study noted that the results of the analysis of the medical signals using the approximation coefficients performed better than the details coefficients.

*b) Phase 2: Feature Selection:* After the integration step, it is important to perform a feature selection process to minimize the space occupied by various features. This process can be carried out through automated tools that can identify and eliminate redundant variables. In this step, a feature selection process is carried out using a symmetrical uncertainty method. This method takes into account the relevance of various variables and classes and computes the redundancy among them. It takes into account the information gain and the entropy of two features by measuring the relation between these two variables.

$$\text{Information Gain}(P/Q) = \text{Entropy}(P) - \text{Entropy}(Q) \qquad (1)$$

$$\text{Symmetric uncertainty} = 2 \times \text{Information Gain}(P/Q)\ \text{Entropy}(P) + \text{Entropy}(Q) \qquad (2)$$

TABLE II. DEEP LEARNING ARCHITECTURES INPUT SIZE

| CNN Architecture | Size of Input |
|---|---|
| ResNet 101 | 224X224X3 |
| DenseNet 121 | 224X224X3 |
| Inception V3 | 299X299X3 |
| Xception | 299X299X3 |

Where Entropy(P) and Entropy(Q) are the entropy of variables P and Q, and Information Gain(P\Q) is the information gain of P once examining variable Q.

*c) Phase 3: Classification:* The classification stage involves selecting three or more individual classifiers to be used for the different classification categories. These are The Linear Discriminant Analysis(LDA), Support Vector Machine(SVM), and Random Forest(RF). The process is performed using a combination of schemas that are designed to classify the various classes. The first four schemas are composed of the deep features from CNN. The next three are composed of the various features from the last average pool layer. The fourth and final version of the framework consists of the multi-classified system. Cross validation is performed on a 5-fold scale to split a dataset into two parts. For each iteration, the model is trained with 4 folds, while the 5th fold is used for testing. The average performance of the models is compared with the performance of the binary class. For the normal class, 20% of the images were used. During the multiclass classification phase, 75% of the images were used. This includes 25% of heart disease and 25% of cardiac disorders. This ensures that 25% of the images were used during every iteration of the test.

## IV. RESULTS AND DISCUSSION

### A. Simulation Procedure and Results

The parameters of the four CNNs are changed based on the classification category and the number of epochs. For instance, the learning rate for a multiclass and a binary class is 0.001. The mini-batch size is also changed to 4. The training process is carried out through stochastic gradient descent. The experiments are performed using Google colab. The results of the Multi-Classified System (MCS) are shown in this section. It combines the predictions of various statistical techniques such as the LDA, SVM, and RF classifiers. After feature selection, the two components were fully connected. The results of the system are shown in Fig. 3. The improved accuracy of the system is compared to that of the SVM classifier. The accuracy of the three classification techniques improved with the use of the multi-classified system. The results of the system show that the accuracy of the three techniques improved, which is higher than the result of the SVM, LDA, and the RF. The results of the system suggest that the use of the multi-classified system can improve the performance of these techniques. The classification performance of the various classes of the binary and multiclass tasks is shown in Table III. The obtained results indicate that the ensemble classification performed better than the individual classification. The accuracy of the ensemble classification was also greater than that of the individual classification as indicated in Table IV. The achieved results of the study also suggest that the use of the multi-classified system can improve the performance of these techniques.

In this the following performance measures are used to evaluate the performance of the model:

*1) Accuracy(Acc):* It is calculated by the number of successfully classified points (predictions) divided by the total number of predictions in the ratio. Its value ranges from 0 to 1.

Acc=(True Positive+True Negative)/(True Positive+False Positive+False Negative+True Negative)

*2) Sensitivity(Sen):* Calculates the number of positives returned by our model. This is also termed Recall.

Sen=(True Positive)/(True Positive+False Negative)

*3) Precision(Pr):* The number of successful points returned by our model can be described.

Pr=True Positive/(True Positive+False Positive)

*4) Specificity(Spec):* In contrast to recall, specificity can be defined as the number of negatives returned by our model.

Spec=(True Negative)/(True Negative +False Positive)

*5) F1 Score:* The F1 Score can be derived by taking the harmonic mean of precision and recall and giving them equal weight.

F1 Score=2*((Precision*Recall)/(Precision+Recall))

Fig. 3. Accuracy Results of the Multi-classified System.

TABLE III. THE CLASSIFICATION PERFORMANCE OF THE VARIOUS CLASSES OF THE BINARY AND MULTICLASS TASK

| Classifiers | Sensitivity | Precision | Specificity | F1 score |
|---|---|---|---|---|
| **Binary Classification** | | | | |
| Linear Discriminant Analysis | 0.97 | 0.973 | 0.97 | 0.97 |
| Random Forest | 0.965 | 0.965 | 0.966 | 0.965 |
| Support Vector Machine | 0.976 | 0.977 | 0.978 | 0.977 |
| Voting classifier | 0.976 | 0.977 | 0.978 | 0.977 |
| **Multi Class Classification** | | | | |
| Linear Discriminant Analysis | 0.803 | 0.805 | 0.845 | 0.803 |
| Random Forest | 0.78 | 0.791 | 0.838 | 0.789 |
| Support Vector Machine | 0.796 | 0.798 | 0.842 | 0.797 |
| Voting classifier | 0.803 | 0.805 | 0.845 | 0.803 |

TABLE IV. EACH CLASS'S MULTICLASS CLASSIFICATION ACCURACY

| Class | Linear Discriminant Analysis | Random Forest | Support Vector Machine | Voting classifier |
|---|---|---|---|---|
| Normal | 87.7 | 87.5 | 87 | 88.2 |
| Abnormal | 90.3 | 88.3 | 87.9 | 91.2 |

## B. Discussion

The literature has shown that various types of cardiovascular abnormalities can occur in patients with heart disease, such as arrhythmias and QRST anomalies. It has been suggested that the novel coronavirus could be a potential cause of these conditions, but other studies have suggested that it could also degrade them. The studies conducted on the whole electrocardiogram (ECG) data have shown that various findings have been observed. The main objective of this study is to distinguish the data from other types of ECGs and identify heart disease cases. A new tool has been proposed that can be used to perform a diagnosis of heart disease using 2D images captured from 12 leads. Although there are many studies on the use of electrocardiograms (ECGs) data for diagnosing heart disease, little is known about the techniques utilized in deep learning to analyze these images. In this study, we present a new method that uses AI techniques to analyze these images.

The proposed pipeline, BiDLNet, is based on a set of pre-trained deep learning models that are capable of extracting features from different deep layers. It was able to perform a feature extraction process by extracting large features from the former and the latter layers. The paper first looked into the various features that emerged during the recording of the ECG data. They were then studied to determine how these features affected the accuracy of diagnosis. Due to the fusion of the various features, their dimension increased. Then the feature dimensions are reduced by using the symmetric uncertainty feature selection approach to improve its classification accuracy. The paper then created a classification system that was designed to study the effects of voting on the accuracy of diagnosis. It was then used to find the optimal scheme for the BiDLNet pipeline.

The proposed tool was able to perform a multiclass classification task with good accuracy. The results of the binary task revealed that the proposed tool was able to distinguish between normal and abnormal images. The results of the study revealed that the accuracy of the classification process was significantly affected by the differences between the normal and abnormal ECGs. For instance, the accuracy of the classification for the abnormal ECG was 91.2%, while that of the classification for the normal ECG was 88.2%. The results of the study revealed that the proposed tool was able to identify an abnormal ECG compared to the other images. However, it was not able to diagnose other cardiac abnormalities. The results of the study also revealed that the proposed tool was not able to distinguish between normal and abnormal images due to the similarities between the different cardiac variations. The proposed pipeline's ability to classify heart disease electrocardiograms (ECGs) could be a promising tool for the early detection of cardiovascular variations.

## V. CONCLUSION

The paper proposes a pipeline called BiDLNet that can be used to automatically diagnose heart disease using data from an electrocardiogram. It features two classification categories: multiclass and binary. The BiDLNet framework separates normal and abnormal patients by classifying them as either binary or multiclass. It then combines these features with fully connected ones. The two levels of deep features were extracted from four CNNs. To do so, it used a discrete wavelet transform to reduce the dimension of the pooling features and merge them with fully connected ones. The framework then explored the effects of integrating these features on the accuracy of its classification. It also looked into the possibility of reducing the number of features while improving its performance. After creating a multi-class classification system, the paper was able to improve the accuracy of the BiDLNet framework's classification by integrating various features. It also performed better when it selected the appropriate features. The results of the study revealed that the accuracy of the BiDLNet framework's classification was improved even further by using the multiclass classification feature, the MCS. The results of the study showed that the system achieved a sensitivity of 97.6%, specificity of 97.8%, and accuracy of 97.5% for the binary classification category. The proposed tool for analyzing cardiac variations in images was validated by an SVM classifier. The proposed pipelined system was able to correctly classify 95.2% of the abnormal ECG images as heart disease, while 91.7% of the images were categorized as normal. This means that it has been able to identify 98.8% of the patients as having heart disease. Only 1.2% of the abnormal images were misclassified as normal by the proposed pipeline while 4.8% of the images were labelled as other cardiac abnormalities. The results of the study suggest that the proposed system can accurately identify cardiac disorder ECGs. The results of the study revealed that the proposed system was able to accurately classify 95.2% of the abnormal ECG images as heart disease, while 91.7% of the images were categorized as normal. This means that it can now help identify patients with heart disease. The ability of the BiDLNet framework to distinguish between normal and abnormal findings further validates the potential of this technology to diagnose heart disease. It can be used to improve the efficiency and sensitivity of existing imaging techniques. For instance, it can be used to automatically classify images of patients with heart disease. It can also help reduce the number of unnecessary visits to the hospital. However, the tool was not able to perform a class imbalance analysis. Other deep learning techniques could also be utilized in the future to improve the accuracy of the proposed system.

# Deep-Learning Approach for Efficient Eye-blink Detection with Hybrid Optimization Concept

Rupali Gawande, Sumit Badotra*

Department of Computer Engineering, Lovely Professional University
Phagwara, Punjab India

*Abstract*—**In this research work, a novel eye-blink detection model is developed. The proposed eye blink detection model is modeled by following seven major phases: (a) video–to-frame conversion, (b) Pre-processing, (c) face detection, (d) eye region localization, (e) eye landmark detection and eye status detection, (f) eye blink detection and (f) Eye blink Classification. Initially, from the collected raw video sequence (input), each individual frames are extracted in the video –to-frame conversion phase. Then, each of the frames is subjected to pre-processing phase, where the quality of the image in the frames is improved using proposed Kernel median filtering (KMF) approach. In the face detection phase, the Viola-Jones Model has been utilized. Then, from the detected faces, the eye region is localization within the proposed eye region localization phase. The proposed Eye region localization phase encapsulates two major phases: Feature extraction and landmark detection. The features like improved active shape models (I-ASMs), Local Binary pattern are extracted from the detected facial images. Then, the eye region is localization by using a new optimized Convolution neural network framework. This optimized CNN framework is trained with the extracted features (I-ASM and LBP). Moreover, to enhance the classification accuracy of eye localization, the weight of CNN is fine-tuned using a new Seagull Optimization with Enhanced Exploration (SOEE), which is the improved version of standard Seagull Optimization Algorithm (SOA). The outcome from optimized CNN framework is providing the exact location of the eye region. Once the eye region is detected, it is essential to detect the status of the eye (whether open or close). The status of the eye is detected by computing the eye aspect ratio (EAR). Then, the identified eye blinks are classified based on the computed correlation coefficient as long and short blinks. Finally, a comparative evaluation has been accomplished to validate the projected model.**

*Keywords—Eye localization; CNN; Seagull Optimization with Enhanced Exploration (SOEE); improved active shape model (I-ASM); eye aspect ratio (EAR); eye-blink detection*

## I. INTRODUCTION

Recently, the Eye-tracking and/or -blinking detection algorithms are playing a significant role in the all the spheres of the world, more particularly in the smartphones that are revalorizing the entire globe. The smart phones have become ubiquities in our routing life style. We rely upon the smartphones for storing our confidential information. In the smartphones, the spoofing attacks can be avoided by utilizing the eye blink detection techniques within the face recognition systems [1-4] Moreover, the eye- blink detection systems in the smartphones provides information regarding the eye-blinking habits of the users, and provides advices [5-8]. In

fact, eye blinking is said to be the partly subconscious quick closing as well as reopening of the eyelids. The eye blinking is carried out with the aid of multiple muscles. The eye opening as well as closing is managed by the *orbicularis oculi* and *levator palpebrae superioris* [9-11]. In fact, the eye corona moistens by the eye blinking process. The frequency and duration are the prime factors for blinking. For an adult, the Average blinking frequency is 15-20 blinks/min, while the blinking frequency of the children is lower [12-15].

In literature, massive count of researchers has been devoted for eye blink detection. The outcome from them is either blink detection or eye status reorganization (open/closed eye). Most of the eye-tracking and eye-blinking detection algorithms rely upon the video input [16]. However, the techniques developed for desktop environments are not suitable for mobile/smartphone environments, owing towards the major shortcoming in terms of computational resources. A promising solution to this problem is to make use of the region of interest (ROI), wherein a smaller region is alone examined rather than searching for the location of eye in the whole image. For real-time processing, the eye localization is indeed a suitable approach for ROI-based solution. Once, the eye region is localized, its status is tracked using the deep learning models like convolutional neural network (CNN) and Artificial Neural Network (ANN) as well. Among the entire deep learning model utilized for eye blink detraction, the CNN is a renowned one [17]. Although the CNN is successful in eye blink detection, it is till been considered to be a computational complexity model, owing towards its higher time consumption in training the parameters.

On the basis of this research gap is identified objective are identified as below:

- To propose an enhanced model for face localization from video frame.

- To propose an effective technique for eye pair localization from captured frame.

- To propose eye blink detection technique for left, right and double click instance.

- To evaluate effectiveness of the proposed technique.

The major contribution of this research work is: The research work Introduces a Kernel median filtering (KMF) approach for de-noising the image frames. Work also Introduces an improved active shape models (I-ASMs) in the Eye region localization phase to exactly localize the eye

---

region. It introduces an optimized CNN model for precise Eye region localization. The weight of CNN is fine-tuned using the newly projected Seagull Optimization with Enhanced Exploration (SOEE) model. This Seagull Optimization with Enhanced Exploration (SOEE) is the improved version of standard Seagull Optimization Algorithm (SOA) . At the end of the research the accuracy of the system is compared with previously present technologies.

The leftover parts of this paper are arranged as: The literature review on eye blink detection is manifested in Section II. The proposed eye-blink detection framework: an overview is addressed in Section III. The video-to-frame conversion and pre-processing via proposed kernel median filtering, face detection via viola Jones model and eye localization via optimized CNN is portrayed in Section IV, Section V and Section VI, respectively. Moreover, eye status detection and eye blink detection and classification are portrayed in Section VII and Section VIII, respectively. The results acquired   as well are discussed comprehensively in Section IX. This paper is concluded in Section X.

## II. RELATED WORK

In 2019, Sharmila et al. [1] have proposed a new technique for Eye Blink Detection model for preventing Computer Vision Syndrome (CVS). The proposed work uses Viola Jones algorithm for detecting the eyes, eye blink using background subtraction, gradient based corner detection and it is capable of detecting common cases of fatigued behaviour linked with prolonged computer use by tracking the eye blink rate. Hence, this proposed system could significantly reduce the symptoms among regular computer users leading to improved health habits.

In 2021, Rajamohana et al. [2] have proposed a novel automated, real-time driver's drowsiness detection framework using the proposed hybrid framework. The proposed model has formulated by blending the CNN and Bidirectional Long Term Dependencies (BiLSTM). The driver's facial image and eye blinks have been tracked using the Video camera. The projected model has encapsulated three major phases: identification of the driver's face image using a web camera, extraction of eye image features using the Euclidean algorithm and continuous eye blinks monitoring. As a n outcome, the status of the eye is exhibited as either open or close.

In 2021, Quddu et al. [3] have proposed a novel eye-tracking system using the RNN and LSTM. The authors have utilized the RNN to detect the drowsiness. In addition, the eye movements were modelled using the LSTM. Two types of LSTMs: 1-D LSTM (R-LSTM) and convolutional LSTM (C-LSTM) has been utilized.

In 2020, Liu et al. [4] have proposed a fatigue detection algorithm on the basis of the analyzed deeply-learned facial expression. Initially, the multi block local binary patterns (MB-LBP) and Adaboost classifier has been utilized for training the face key point detection model. In addition, the 24 facial points were identified using the trained model. Moreover, the proportion of the closed eye time within the unit time (PERCLOS) and yawning frequency were computed. The driver's fatigue state was deduced using the fuzzy inference system. The projected model could detect the degree of the driver fatigue accurately as well as quickly.

In 2019, Wang et al. [5] have presented a robust fatigue detection system based on the binocular consistency using the deep learning. The eye gaze has been detected using the dual-stream bidirectional convolutional neural network (BCNN). The GP-BCNN was constructed by including the vectorized local integral projection features within the Gabor filters and the projection vectors for overcoming the orientation and scale changes. Further based on the pupil distance, the eye screening mechanism (ESM) was projected with the intention of eliminating the detected errors. The projected model has yielded a higher accuracy rate.

In 2019, Selvathi et al. [6] have proposed a fatigue and drowsiness detection system in FPGA using the deep neural network. Initially, the collected images were pre-processed via median filtering. Then, the facial regions were identified using the Viola Jones face detection algorithm. Further, the authors have extracted the Local Binary Pattern features from the detected faces, and have employed the Max pooling to lessen the level of complexity. The final detection was carried out using the SVM classifier. The results acquired had exhibited that the projected model is applicable for real time driver's vigilance monitoring.

In 2020, Lamba et al. [7] have utilized the feature level fusion (MmERMFLF) for precise multimodal eye blink recognition. The status of the eye was computed using the eye-eyebrow facet ratio (EEBFR), and eyebrow to nose facet ratio. From eye blinks, pulse rate as well as behavioral patterns (emotions), the authors have sensed the emergency state using the improved intellectual framework. Moreover, the count of eye blinks was detected using the novel multimodal method (MmERMFLF). The projected model had achieved improved reorganization accuracy.

In 2019, Zemblys et al. [8] have developed gazeNet for event detector's generation. The projected model has encapsulated an end-to-end deep learning approach, which was trained using the raw eye-tracking data and have classified it as fixations, saccades and post-saccadic oscillations. The projected model hasn't been utilized in large scale owing to its expanded training time. Table I summarizes the comparison between the existing approaches.

TABLE I.     COMPARISON OF EXISTING APPROACHES

| Ref No | Published Year | Approach | Advantages | Disadvantages |
|---|---|---|---|---|
| [2] | 2021 | Convolution neural Network | Convolution neural network is useful in facial recognition CNN is having higher accuracy | It is not more useful in speech and voice recognition CNN requires lots of data |
| [4] | 2019 | Facial Feature | It reduces computational cost | Vector used for facial feature finding is high |
| [15] | 2017 | Template Marching | It is easier to implement | If template used is not proper then accuracy of output is hampered |
| [22] | 2016 | Component Based | It is faster and more accurate face detection | For more accuracy larger vector should be used. |
| [28] | 2015 | Knowledge based | It reduces computational complexity | Detection rate of this technique is slower |

## III.  PROPOSED EYE-BLINK DETECTION FRAMEWORK: AN OVERVIEW

### A. Architectural Description

The proposed eye blink detection model will be modeled by following seven major phases: (a) video–to-frame conversion, (b) Pre-processing, (c) face detection, (d) eye region localization, (e) eye landmark detection and eye status detection, (f) eye blink detection and (f) Eye blink Classification. The architecture of the proposed work is manifested in Fig. 1.

- Initially, from the collected raw video sequence (input), each individual frames are extracted in the video –to-frame conversion phase.

- Then, each of the frames is subjected to pre-processing phase, where the quality of the image in the frames is improved using proposed Kernel median filtering (KMF) approach. At the end of the pre-processing phase, noiseless and higher quality video frames are acquired. These pre-processed frames are subjected to face detection phase.

- In the face detection phase, the facial region (ROI) in the pre-processed frames is detected by suppressing the rest of the regions (Non- ROI). The face detection is accomplished via Viola-Jones Model.

- Then, from the detected faces, the eye region is localization within the pro-posed eye region localization phase. The proposed Eye region localization phase encapsulates two major phases: Feature extraction and landmark detection. The features like improved active shape models (I-ASMs), LBP are extracted from the detected facial images. And then the eye region is localization by using a new optimized CNN framework. This optimized CNN framework is trained with the extracted features (I-

ASM and LBP). Moreover, to enhance the classification accuracy of eye localization, the weight of CNN is fine-tuned using a new Seagull Optimization with Enhanced Exploration (SOEE), which is the improved version of standard Seagull Optimization Algorithm (SOA) [9].

The outcome from optimized CNN framework is providing the exact location of the eye region. Once the eye region is detected, it is essential to detect the status of the eye (whether open or close).

Eye status detection: The status of the eye is detected by computing the eye aspect ratio (EAR). The aspect ratio is calculated between the points of eye to check whether eyes are opened or closed.

Eye-blink detection: It is performed onto the computed eye landmarks using the normalized cross-correlation method. Then, the identified eye blinks are classified based on the computed correlation coefficient as long and short blinks.

## IV. Video-to-Frame Conversion and Pre-Processing Via Proposed Kernel Median Filtering

### A. Video-to-Frame Conversion

Let the collected input video sequence be denoted as, which includes count of frames. The video is indeed a medium that has become more important in today's society. It is made up of a series of frames, each of which is divided into shots and scenes, with the video being made up of a mixture of these scenes. To evaluate any video, we must first examine the features of the frames and then assess the video's attributes, which is accomplished using python' (OpenCv library) video to frame converter. Let the extracted frames be denoted as. The noise in is removed in the pre-processing stage using the proposed Kernel Median Filtering (KMF). Here, are the pixels.

### B. Pre-Processing via Kernel Median Filtering

Preprocessing is a set of processes that aim to rectify or compensate for systematic mistakes in input before it is analyzed further. Owing to low collected integrity, every sort of information need pre-processing to improve it for future processing.

Pre-processing is required for the following reasons:

*1)* Light propagation qualities like scattering and absorption cause image deterioration.

*2)* Video captures with a high level of specificity, such as an unknown stiff scene, un-known hue, or poor light sensitivity. As a consequence, an initiative has been taken to discover the perfect filtering for pre-processing the frames. Filtering reduce noise by reducing statistical variances. It contributes to the reduction of visual noise. Noise affects the acquisition or capture of an image. Filtering methods are used to process the image. The ultimate focus of the filter has always been to minimize picture noise and improve the input image. Prior to further analysis and processing, it's indeed vital to optimize image quality.

The pre-processing stages utilized in this research work are

*a)* Read the image in the frames

*b)* De-Noise using proposed KMF

Each of the frames in is read using the OpenCV Library Cv2.imread() function From this , the noise is removed in the pre-processing stage using the proposed Kernel Median Filtering (KMF).

Median filtering is a nonlinear procedure that may be used to reduce impulsive noise, sometimes known as salt-and-pepper noise. It also is beneficial for retaining picture borders despite decreasing random noise. A random bit error in a line of communication may cause spontaneous or salt-and-pepper noise. Across an image frame, a window is moved in the median filter, and then for each pixel inside the window, its median intensity value is computed. This median intensity value is output intensity of the pixel being processed. The median filter has a significant drawback in that every outcome has always been bound by specification to have been the window's median value. The centre value substituted also isn't

evaluated to see whether it's an impulse or not. Whenever the intensity of the noise is considerable, the median filter works miserably. Therefore, a new Kernel Median Filtering (KMF) is introduced in this research work.

The steps followed in the Kernel Median Filtering (KMF) are manifested below:

*1)* The Kernel Median Filtering (KMF) detects the noisy pixels at first and then filters it as shown in Fig. 2.

*2)* Once, the noise is filtered; the pixels are validated to check whether it is a thin line or an edge pixel.

*3)* The input frame is convoluted with 4 convolutional kernels (sigmoid, RBF, Lapla-cian, Chi2). The minimal difference of these four convolutions is used for edge detection. (1)

$$C_{ij} = \min\{V^{F_i(a,b)} \otimes W_k| : K = 1-4\}$$

(1)

*4)* Compare the value of with Threshold (say 1000). If the minimal value of the pixel is less than the threshold value, then the current pixel value is the same as it, else the standard median filtering is applied, and the median value is returned as the pixel value. This is mathematically shown in Eq. (2).

$$V^{KMF} = \begin{cases} Y^{MF} & ; If\ C_{ij} \geq T \\ V^{F_i(a,b)} & Otherwise \end{cases}$$

(2)

The pre-processed outcome is subjected to face detection phase, wherein the facial region is detected using the standard Viola-Jones Model.

Fig. 2. Proposed Kernel Median Filtering.

## V. Face Detection via Viola Jones Model

### A. Viola-Jones Model

The pre-processed image is subjected to viola-jones model for face region detection. The Viola-Jones algorithm, created by Paul Viola and Michael Jones in 2001, is indeed an object-

recognition framework that enables for real-time identification of visual properties. Although becoming an obsolete paradigm, Viola-Jones seems to be remarkably efficient, as well as its applicability in real-time face identification has conclusively demonstrated to be particularly noteworthy [10].

The Viola-Jones Algorithm has two stages:

*1)* Training
*2)* Detection

*1) Training*: Training data is the initial dataset used to train machine learning algorithms. Models create and refine their rules using this data. It's a set of data samples used to fit the parameters of a machine learning model to training it by example.

*2) Detection*: Viola-Jones had been created for frontal face images; therefore this detects them superior over face images that are oriented sideways, upwards, or downwards. The image is transformed to grayscale before its being used to recognize a face since it is necessary to focus with less data to analyze. The Viola-Jones method discovers the position on the coloured picture after detecting the face in the grayscale image. Viola-Jones constructs a box and explores for a face within it. It's obviously looking for haar-like characteristics, which would be detailed later. After moving through each and every square inside the picture, the box advances a step to the right. A multitude of boxes recognize face-like characteristics (Haar-like features) employing smaller steps, and the information from all of those boxes aggregated supports the algorithm towards determining in which the face resides.

*3) Haar-like features*: The characteristics underneath depict a box with such a dark and bright side, which the machine helps to define whatever the feature represents. As in the edge of a brow, one side may well be brighter than another at sometimes. The central area of the box may be brighter than that of the neighboring boxes, which might be misinterpreted for a nose. Viola and Jones observed three sorts of Haar-like characteristics in their research: • Four-sided features • Edge features • Line features [11]

*4) Integral images*: The integral picture aids us in performing these time-consuming computations fast enough that we may determine if a feature of a group of features meets the requirements [12].

*5) Training classifiers*: We're training the machine to recognize these characteristics. We're feeding it data and then training this to understand from it in order to make predictions. In the end, the algorithm produces whether any of the frames may be categorized as a feature or not by defining a minimal threshold [13-16].

*6) Adaptive boosting (AdaBoost)*: In general, the boosting is an Ensemble method that is formulated by means of combing several weak learners. As a resultant a strong learner is formulated. The most popularly utilized boosting models is the Adaptive Boosting approach. The adaboost solves the problem of "curse in dimensionality" issue. Even though, the formulated integral image has reduced the dimensionality of the image, still its features remain quite higher, and this tends

to lessen the training accuracy. Therefore, the adaboost has been implied [17].

*7) Cascading*: The cascading takes place next to the adaboosting model. In the cascading model, each of the sub-windows is validated to check whether the most important features are available within it or not. If the corresponding sub-window has the most important feature, then the second important features are explored, else the sub-window is discarded. This process is referred as cascading. By using this approach, the amount of computational time spends on the false windows.

From the detected facial images $V^{face}$, the eye region is localized in the proposed eye region localization phase.

## VI. Eye Localization via Optimized CNN

The proposed Eye Region Localization phase includes two major phases: (a) feature extraction and (b) face region identification. Initially, from the identified faces using viola-jones model, the facial features like improved ASM (I-ASM) and LBP (texture features) are extracted.

### A. I-ASM Features

In ASM local texture feature and shape models are used. The deformation begins with the models shape. The shape is designated as a "point landmark". Eq. (3) is obtained by rotating, scaling and translating and as shown in Eq. (4).

$$G = \left(g_1, o_1, \dots g_n, o_n\right)^H \tag{3}$$

$$g = H_{wg, wo, d, \upsilon}(G) \tag{4}$$

For ordered shapes, the average shape is formulated as in Eq. (5).

$$\overline{g} = \sum_{i=1}^{m} g_i$$

The differences of each shape are indicated as Eq. (6).

$$dg_i = g_i - \overline{g}$$

The covariance matrices are indicated as Eq. (7). Here, points to the count of histogram curves.

$$S = \frac{1}{m} \sum_{i=1}^{m} dg_i dg_i^T \tag{7}$$

The variable indicates major axes that provides divergence modes of all points of shape, and signifies the unit eigenvectors. The principal component analysis of provides eigen vectors and eigen values, and these eigen values forms the mode of variation. During the training process, the histogram curve can be modelled as the sum of the mean model and weighted modes of variation. As shown in Eq. (9), a new shape is generated using the mean of the weighted matrix sum, the mean shape of the eigenvector, and the weight vector.

$$g = \overline{g} + Eb \tag{8}$$

$$b = E^T(S - \overline{S}) \tag{9}$$

The initial deformation weight is set as zero.

Find a new preferred curve shape: the pixel in that is nearest to the corresponding pixel on the histogram curve of the test image is a new preferred choice of landmark.

Compute new values for the weight changes: $\Delta g = E.\Delta b$ Here, $\Delta g = V^{face} - V^F$. Moreover, we acquire $b_{new} = b_{old} + \Delta b$

Limit the formulation: b is limited with the intention of guarantying the additional deformation. The weight can be chosen such that Euclidean distance is less than maximal distance.

Calculate the new shape

Repeat the process until the convergence is reached.

The extracted I-ASM feature is denoted as $f^{I-ASM}$

### B. LBP

LBP is a measure of the correlation between pixels in a local region, which mostly represents local data. Many studies and research been published that combine more global or more local data with LBP in order to provide a more discriminative description from various feature levels. The LBP is less difficult to programme and has a higher discriminative potential. The image pixel, including the decimal numbers, is also labelled by the LBP operator. Each image pixel is computed with its surrounds during the labelling procedure by subtracting the value of the centre pixel. Furthermore, negative values are encoded as 0, and positive and zero values are encoded as 1. All of the binary codes are concatenated clockwise from the top-left to form a binary number, and these binary numbers are referred to as LBP codes [18]. The texture descriptor is used to create the local descriptions, which are then combined to create the global description. Furthermore, the distinguishable capability is used to extract characteristics from these texture objects. $S_{pl}$ and $S_{cl}$ in Eq. (10), respectively, denote the centre pixel intensities and the image centre pixel from the adjacent $pl$. The pixel's LBP descriptor is written as $LBP(\bullet)$, with $NE_{Pl}$ denoting the number of neighbours. Eq. (11) gives the LBP descriptor function $f^{LBP}$.

$$LBP(S_{cl}) = \sum_{pl=0}^{NE_{pl}} FE_{LBP(pl,cl)} 2^{pl-1}$$

(10)

$$f^{LBP} = \begin{cases} 1, if \ S_{pl} - S_{cl} \geq 0 \\ 0, otherwise \end{cases}$$

(11)

The final detection takes place in CNN< which is trained with the extracted features $F = f^{LBP} + f^{I-ASM}$

### C. CNN

The CNN is a deep learning model with three layers: "fully-connected layers, convolutional layer, and pooling layer". A lot of convolution kernels together makeup the convolution layer, which assist in computing the feature maps. A significant number of convolution kernels are included in the convolution layer, which aid in the calculation of various feature maps. The surrounding neurons of the previous layer are linked to each of the neurons in the feature map [19]. Finally, several kernels are employed in order to acquire the whole feature maps. At location $(d,e)$ of the $B^{th}$ feature map residing in the $A^{th}$ layer is $Z^A_{d,e,B}$, which is computed as per Eq. (I2). In this same layer and location, the nonlinear activation function $act(\bullet)$ is computed as per Eq. (13). "Sigmoid, tanh, and ReLU" are the activation functions.

$$Z^L_{d,e,B} = W_B^{A^T} Q^A_{d,e} + bias^A_B$$

(12)

$$act^A_{d,e,B} = act\left(Z^A_{d,e,B}\right)$$

$W$ and the $bias$ term denotes the weight and bias of CNN, respectively. This weight function is fine-tuned using SOEE model [20]. The patched input is denoted as $Q^A_{d,e}$. Shift-invariance has been achieved successfully by reducing feature map resolutions in the pooling layer. "The pooling layers of the CNN execute down sampling operations utilising the results collected from the convolutional layers." The pooling function is referred to as $pol()$.

The pooling function $M^A_{d,e,B}$ is then calculated for $act^A_{:,:,B}$. Here, $\Re_{d,e}$ denotes the local area in $(d,e)$. At the conclusion of the convolutional and pooling layers, there are multiple fully-connected layers.

$$M^L_{d,e,B} = pol\left(act^L_{d,e,B}\right), \forall (m.n) \in \Re_{d,e}$$

(14)

The loss() function is used to compute CNN's loss, which is represented by Eq.(15). This $Loss()$ function should be as small as possible, which is the goal of the current study. The goal function can be expressed formally as Eq. (16). A new SEEO model is used to fine-tune CNN's weight in order to achieve this objective.

$$Loss = \frac{1}{N} \sum_{n=1}^{N} l\left(\theta; M^{(n)}, O^{(n)}\right)$$

(15)

$$Obj = Min(Loss)$$

(16)

The total number of input-output relations $\left\{\left(J^{(n)}, M^{(n)}\right); n \in [1, \cdots, N]\right\}$ is indicated by $N$, and the CNN's overall parameter is denoted by $\theta$. In addition, $J^{(n)}$ represents the $n^{th}$ input data, $M^{(n)}$ represents the matching target labels, and $O^{(n)}$ represents the CNN output.

### D. Seagull Optimization with Enhanced Exploration (SOEE)

The SOA model is a novel bio-inspired algorithm that is based on the migration and attacking behaviours of a seagull.

In general, the SOA model is good in solving the complex optimization model with lower computational complexity. In literature, it has been said that the convergence speed of the solutions increases, when the adaptive meta-heuristic operators are utilized. Therefore, the Seagull Optimization with Enhanced Exploration (SOEE) is introduced in this research work. The input to SOEE is the weight of the CNN, which is fine-tuned by the SOEE to enhance the eyeblink detection accuracy. The solution fed as input to SOEE is the weight of CNN, which is shown in Fig. 3.

The steps followed in the SOEE model is furnished in the upcoming section:

Step 1: Initialize the $N$ search agent's population P.

Step 2: Initialize the parameters $A, B, itr, Max^{itr}$. Here, $itr, Max^{itr}$ points to the current iteration and the maximal iteration, respectively.

Step 3: Set the value of $f_c \leftarrow 2; u \leftarrow 1; v \leftarrow 2$

Step 4: While $itr < Max^{itr}$ do

Step 5: Compute the fitness of the search agent using Eq. (16).

Step 6: Move to the migration behaviour of SOA model. Our contribution resides in this phase. In fact, three different processes take place in the Migration (exploration) phase: Collision avoidance, Movement along the direction of the best neighbor and stay closer with the best search agent.

- With the intention of avoiding the collision amongst the search agent, a new variable $A$ referred as the movement behaviour of search agent is added.

$$C = A * P(X) \tag{17}$$

Here, $C$ is the search agent's non- colliding position and $P$ is the current position of the search agent. In addition, $A$ can be computed as per Eq. (), wherein $f_c$ is a variable that has been introduced to control the frequency of the employing $A$.

$$A = f_c - \left\{ X, \left[ \frac{f_c}{Max^{itr}} \right] \right\} \tag{18}$$

- During the movement along the best neighbor's direction stage, our contribution has been included. Once the collision between the search agents is avoided, they are moved along the direction of the best neighbour. To make this movement more precise and to avoid the solutions from getting trapped into the local optima, a new mathematical model withy levy function $Levy(\beta)$ has been introduced in this research work. The newly developed mathematical expression is shown in Eq. (19).

$$M = B * \left[ P_{best}(X) - P(X) \right] + Levy(\beta) \tag{19}$$

Here, $Levy(\beta)$ is the levy function undergone by the search agents while searching the global best solutions. In addition, $P_{best}(X)$, $P(X)$ and $M$ points to the global best position of the solution, current position of the search agent, position of the search agent, respectively. With the intention of having a proposed balance between the exploration as well as exploitation phase, the variable $B$ is computed as per Eq. (20). Our contribution resides in this computational phase also. In the existing SOA model, the random variable $S$ has been generated within the limits $[0,1]$. But, here we've computed the value of $S$ using the newly proposed expression given in Eq. (21).

$$B = 2 * A^2 * S \tag{20}$$

$$S = 1.07(7.9S_i - 23.3S_i^2 + 28.7S_i^3 - 13S_i^4) \tag{21}$$

- Remain close to the best search agent: finally the position of the search agent is updated with respect to the best search agent as per Eq. (22) of SOA model.

$$\vec{D} = \left| \vec{C} + \vec{M} \right| \tag{22}$$

In addition, $\vec{D}$ is the distance in between the best search agent and the current search agent.

Step 7: Move to the Attacking (exploitation) phase: in the attacking phase, the search agents undergo a spiral movement in the air. This spiral movement can be modelled in the three axes $X, Y, Z$ as per Eq. (23)- Eq. (25), respectively.

$$x' = r * Cos(K) \tag{23}$$

$$y' = r * Sin(K) \tag{24}$$

$$z' = r * K \tag{25}$$

Step 8: The random variable $K$ is modelled using the newly proposed expression given in Eq. (26). The proposed expression is based upon the singer map.

$$M = 1.07(7.9M_i - 23.3M_i^2 + 28.7M_i^3 - 13M_i^4) \tag{26}$$

Step 9: The updated position of the search agent is modelled as per Eq. (27). And eye region is located on that basis as shown in Fig. 4.

$$P(X) = (D * x' * y' * z') + P_{best}(x) \tag{27}$$
Step 10: Return $P(X)$

Step 11: Terminate

Fig. 3.    Solution Encoding

(a)                                              (b)

Fig. 4.    An Illustration of Eye Landmark Detection: (a) Landmark Detection and (b) 68 Located Points.

## VII. EYE STATUS DETECTION

Once, the eye region is localized, its status (open/ close) is identified by computing the eye aspect ratio. In this research work, the eye aspect ratio is computed between the eye points using Eq. (28). The eye computation for open and close eye is shown in Fig. 5.

$$EAR = \frac{\|P_2 - P_6\| + \|P_3 - P_5\|}{2\|P_1 - P_4\|}$$

(28)

Here, P1,P2 ,P3 ,P4 ,P5 and P6 are the 2D landmark locations.

*a)* The eye is considered to be open if the Eye Aspect Ratio is greater than the threshold [21].

*b)* If the Eye Aspect Ratio is less than the threshold, the eye is considered closed.

*c)* The EAR of both eyes is averaged since eye blinking is produced simultaneously by both eyes.

A poor monetary worth the presence of an EAR value does not imply that a person is blinking. It can happen when a person closes his or her eyes for a prolonged period of time or makes a facial expression, such as yawning, or when the EAR records a brief random fluctuation of the landmarks.

Fig. 5.    EAR Computation of (a) Open and (b) Close Eye.

## VIII. EYE BLINK DETECTION AND CLASSIFICATION

### A. Eye Blink Detection

Once the eye's state has been determined, it is monitored for eye blink detection. For eye-blink detection, the normalized cross correlation technique is used in this study. The normalized cross correlation can be calculated using Eq. (29). In general, the correlation coefficient is used to assess the similarity of the present eye picture to the preserved template of the opened eye. As a result, the correlation coefficient is generally referred regarded as a measure of eye openness [22]. The template image matching to the user's eye is automatically obtained during the system's startup.

$$R(X',Y') = \frac{\sum_{X',Y'} \left[ T'(X',Y').I(X + X',,Y + Y') \right]}{\sqrt{\sum_{X',Y'} \left[ T'(X',Y')^2 . \sum_{X',Y} I(X + X',,Y + Y')^2 \right]}}$$

(29)

Here, $R$ points to the correlation coefficient of the image and $T$ is the template image. In addition, the original image is $I$ ; and the co-ordinates are $X , Y$ .

### B. Eye Blink Classification

To identify deliberate eye-blinks with a length more than 250 milliseconds, the correlation coefficient is shifted over time. The on-set of the eye-blink is identified whenever the value of the coefficient is less than the predetermined threshold level of TL (2ms) for consecutive frames. If indeed the correlation coefficient value is greater than the threshold value TH, the off-set of the eye-blink is discovered (250ms). Experimentation was used to determine the TL and TH threshold values. Whenever a detected eye-blink lasts more than 250 milliseconds but less than 2 milliseconds, it is considered a "control" blink [23].

## IX. RESULT AND DISCUSSION

### A. Experimental Setup

The proposed work has been implemented in PYTHON. The dataset for evaluation has been collected from [32]. The collected sample images are shown in Fig. 6. And open eye sample image are shown in Fig. 7. The assessment has been carried out in terms of MAE, MAPE, MSE, MSLE, RMSE and Optimization error as well. the proposed work (CNN+SOEE) has been compared over the existing models like the CNN+Bi-LSTM [2], C-LSTM [3], Bi-LSTM, RNN, MFO+CNN, GOA+CNN, SLnO+CNN and SOA+CNN, respectively. The correctly detected eye-blinks are denoted as True Positives (TP), false detections are denoted as False Positives (FP), and missed eye-blinks are denoted as False Negatives (FN) [24].

## B.  Convergence Analysis

In literature, it has been portrayed that the convergence of the solutions increases with adaptive parameter tunings in the standard optimization model. However, it is highly significant to have a mathematical evaluation, in order to show that the newly introduced SOEE model is highly convergent over the existing ones. Therefore, a convergence analysis has been undergone for the proposed work by varying the count of iterations. Since, the prime objective behind this research work is to minimize the loss function of CNN, which localizes the eyes accurately. Once, the eyes are localized with higher accuracy then the status of the eyes can be detected more precisely [25]. Since, the objective function is a minimization function, the approach that achieves the least cost function is said to be the best approach, as it has converged sooner. The resultant of the convergence analysis of the projected model is manifested in Fig. 8.

On observing the acquired outcomes, the proposed work is identified to be successful even at the highest iteration counts. This clearly says that the projected model is applicable for huge databases. Initially, at the 0th iteration count, the cost function of the proposed as well as existing model is found to be higher. And then as the count of iterations got expanded, there seems to minimization in the cost function [26]. At the 6th iteration count, the projected model has recorded the least cost function than the existing models. Most interestingly, the proposed work has recorded the most least cost function as 4.6 at the 25th iteration count, and at this count the cost function recorded by the existing models are identified to be greater than 4.9. As a whole, the projected model is said to be highly convergent, and hence solved the optimization problems effectively.
## C.  MAE Analysis

The MAE is the most commonly utilized for forecasting the accuracy of the model. In general, the Mean absolute error is the measure of the average absolute difference between the actual and predicted values in the eyeblink dataset. Mathematically, the MAE is given as per Eq. (30).

$$MAE = \frac{1}{N} \sum_{i=1}^{N} \left| Y_i - \hat{Y_i} \right|$$

(30)

Here, $Y_i$ is the actual outcome and $\hat{Y_i}$ is the predicted outcome.

In this research work, the MAE of the proposed work has been computed, and its results acquire are compared over the existing models like the CNN+Bi-LSTM [27], C-LSTM [3],Bi-LSTM, RNN, MFO+CNN, GOA+CNN, SLnO+CNN and SOA+CNN, respectively. This evaluation has been carried out by varying the learning percentage from 60, 70, 80 and 90, respectively. The results acquired are shown in Fig. 9. On observing the outcomes, the projected model has recorded the least MAE value for every variation in the learning percentage. Among the recorded results, the proposed work has recorded the least MAE value as 1.2 at 90th learning percentage. The Mae of the projected work recorded at the 60th learning percentage is 64.2%, 78.5%, 62.5%, 81.2%, 75%, 83.3%, 50% and 57.14% improved over the existing models like the CNN+Bi-LSTM [2], C-LSTM [3], Bi-LSTM, RNN, MFO+CNN, GOA+CNN, SLnO+CNN and SOA+CNN, respectively. As a whole, the projected model is said to be less prone to errors, and this is owing to the fine-tuning of the weight function of the CNN using the newly projected SOEE model. Since, the prime objective behind this research work is minimization of the loss function of the CNN, the minimized MAE acquired with the projected work has said that the defined objective has been successfully satisfied by the projected model [28].

Fig. 9.    MAE Analysis of SEEO Model.

## D.  MAPE Analysis

The MAPE also known as the mean absolute percentage deviation (MAPD) has been utilized for measuring the detection accuracy. Mathematically, the MAPE can be given as per Eq. (31).

Fig. 8.    Convergence Analysis of SEEO Model.

$$MAPE = \frac{1}{N}\sum_{k=1}^{N}\left|\frac{Y_i - \hat{Y_i}}{Y_i}\right|$$

(31)

The MAPE of the proposed work has been computed, and the results acquired are manifested in Fig. 10. This evaluation has been undergone by varying the learning percentage. The graphical results acquired have exhibited a reduced MAPE value for the projected work. The projected model had recorded the minimal MAPE values as 0.03, 0.035, 0.038 and 0.015at the 60th, 70th, 80th and 90th learning percentage. At the 60th learning percentage, the MAPE of the projected work is 37.5%, 64.2%, 34.2%, 68.75%, 69.5%, 80.7%, 41.8% and 51.9% improved over the existing models like the CNN+Bi-LSTM [2], C-LSTM [3], Bi-LSTM, RNN, MFO+CNN, GOA+CNN, SLnO+CNN and SOA+CNN, respectively.

### E. MSE Analysis

MSE is the measure of the measure of the average of the squares of the errors (i.e. the averaged squared difference between the actual and the estimated value.

$$MSE = \frac{1}{N-M}\sum_{k=1}^{N-M}\left(Act - \Pr e\right)^2$$

(32)

The MSE of the proposed work is the lowest one for every variation in the learning percentage. The MSE of the projected work is found be below 8% for every variation in the learning percentage. The results acquired are shown in Fig. 11. The MSE value recorded by the existing works is above 15%. The proposed work has recorded the least MSE value at the 90th learning percentage. Moreover, all the existing models has recorded the MSE value as 50, 140, 42, 170, 70, 162, 19, 22 and 9 for CNN+Bi-LSTM [2], C-LSTM [3],Bi-LSTM, RNN, MFO+CNN, GOA+CNN, SLnO+CNN and SOA+CNN and proposed work, respectively. From the acquired values, it is clear that the projected model has recorded the least MSE value. On observing the overall evaluation, it is clear that the presented work is less prone to errors [29].

### F. MSLE Analysis

The Mean squared logarithmic error (MSLE) of the projected model has been shown in Fig. 12. The MSLE is the ratio of the measure between the actual and the predicted outcomes.

$$MSLE = \frac{1}{N}\sum_{i=1}^{N}\left((\log(Y_i + 1) - (\log(\hat{Y_i}+1))\right)^2$$

(33)

The results acquired are shown in Fig. 12. On observing the outcomes, the projected model had exhibited lower MSLE values. The major reason behind this reduction owes towards the fine-tuning the weight function using the newly proposed optimization model [30].

### G. RMSE Analysis

"The RMSE is a frequently used measure of the differences between values (sample or population values) predicted by a model or an estimator and the values observed". RMSE can be computed mathematically per Eq. (34).

$$RMSE = \sqrt{\frac{1}{N-M}\sum_{k=1}^{N-M}\left(Act - \Pr e\right)^2}$$

(34)

The RMSE performance is evaluated for both the proposed and the extant techniques by varying the learning percentage. The results acquired are shown in Fig.13. The proposed work has recorded the least value for every variation in the learning percentage. The RMSE of the projected model at 60th learning percentage is 71.4%, 83.3%, 70.2%, 85.7%, 77.7%, 81.8%, 50% and 53.4% improved over the existing models like the CNN+Bi-LSTM [2], C-LSTM [3],Bi-LSTM, RNN, MFO+CNN, GOA+CNN, SLnO+CNN and SOA+CNN, respectively [31].

## H. Performance Analysis of Proposed Work: With vs Without Optimization

The optimization algorithm deployed in this research work for eye landmark detection is said to play a major role in enhancing the detection accuracy of the eye blinks. It is essential to exhibit the supremacy of the optimization algorithms. Therefore, the proposed model has been validated with and without optimization logic. The results acquired are shown in Table II. The proposed work (KMF + I-ASM) with ESSO is compared over the existing models like Conventioanl Model (standard median filtering + Standard ASM) + ESSO and Conventioanl Model (standard median filtering +Standard ASM). The assessment has been carried out in terms of MAE, MAPE, MSE, MSLE, RMSE, respectively. The MAE of the projected model is 5.240172259, which is the least value when compared with the existing models. The MAE of the projected model is 16.3% and 15.5% better than the MAE of the conventional model + optimization and conventional model, respectively.

Fig. 13. RMSE Analysis of SEEO Model.

TABLE II. OVERALL PERFORMANCE ANALYSIS

|  | proposed work (KMF+I-ASM) with ESSO | Conventioanl Model (standard median filtering+Standard ASM)+ESSO | Conventioanl Model (standard median filtering+Standard ASM) |
|---|---|---|---|
| MSE | 5.240172 | 6.261141 | 6.204798 |
| MAE | 1.754693 | 1.890539 | 1.909948 |
| MAPE | 0.025316 | 0.02734 | 0.027585 |
| MSLE | 0.001008 | 0.001201 | 0.00117 |
| RMSE | 2.289142 | 2.502227 | 2.490943 |

The MAPE of the projected model is 7.1% and 8.12% improved over conventional model + optimization and conventional model, respectively. In addition, the MSE of the projected model is 0.025316349, which is the least value when compared to conventional model + optimization = 0.027340005 and conventional model = 0.027584814. In addition, the projected model with optimization has recorded the least MSLE and RMSE also. Thus, from the overall evaluation, it's obvious that the major improvement behind the projected work in precisely detecting the eye blinks is only due to the fine-tuning of the weight of CNN via the optimization model [32].

## I. Performance Analysis

The performance of the projected model has been validated in terms of MSE, MAE, MAPE, MSLE and RMSE,

respectively. On observing the outcomes, the projected work has recorded the least error measures. The results acquired are shown in Table II. The MSE of the projected work is 5.71662, which is indeed the least6 value when compared to CNN + Bi-LSTM [2] = 24.57614, C-LSTM [3] = 64.39177, Bi-LSTM = 14.25622, RNN = 80.51956, MFO + CNN = 65.42977, GOA+CNN = 12.47136, SLnO+CNN = 13.40547 and SOA+CNN = 8.938489. In addition, an improvement of 54.1%, 71.6%, 52.6%, 74.8%, 67.6%, 77.3%, 33.1% and 44.19% has been recorded by the projected model over the existing models like CNN + Bi-LSTM [2], C-LSTM [3], Bi-LSTM, RNN, MFO+CNN, GOA + CNN, SLnO + CNN and SOA+CNN, respectively in terms of MAPE. The MSE of the proposed work is 37.9%, 59.9%, 35.7%, 64.7%, 64.8%, 78.7%, 38.2% and 42.2% better than the MSE value recorded by existing models like CNN + Bi-LSTM [2], C-LSTM [3], Bi-LSTM, RNN, MFO + CNN, GOA+CNN, SLnO + CNN and SOA+CNN, respectively. The MSLE of the proposed work is 74.09%, 91.1%, 71.8%, 93.04%, 90.2%, 98.2%, 62.6% and 65.5% better than the MSE value recorded by existing models like CNN + Bi-LSTM [2], C-LSTM [3], Bi-LSTM, RNN, MFO+CNN, GOA+CNN, SLnO + CNN and SOA + CNN, respectively. Moreover, the RMSE of the projected model is also lower. The major reason behind this reduction in the error measures is owing to the utilization of the appropriate techniques for blink detection. Moreover, the prime objective of this research work is minimization of the error measures, which has been found to be achieved [33].

## J. Overall Performance Analysis

The overall performance of the projected model is validated in terms of MSE, MAE, MAPE, MSLE and RMSE, respectively. The results acquired are shown in Table III. On observing the outcomes, the projected work has recorded the least error measures. The MSE value recorded by the projected model is 5.71662, which is 76.7%, 91.1%, 59.9%, 91.9%, 91.2%, 54.1%57.3% and 36.04% better than the MSE value recorded by existing models like CNN + Bi-LSTM [2], C-LSTM [3], Bi-LSTM, RNN, MFO + CNN, GOA + CNN, SLnO + CNN and SOA + CNN, respectively. In addition, the projected model has recorded the least MAPE as 1.847275453, MSE as 0.026834139, MSLE as 0.001152411 and RMSE as 2.390945437. The major reason behind this improvement is owing to the utilization of the optimized deep learning model for eye landmark detection [34].

## K. Analysis on Optimization Error

The optimization error measures recorded by the projected as well as existing models for 60, 70, 80 and 90 percent of learning are manifested in Table IV. At 60th learning percentage, the MSE value recorded by the projected model is 6.235624262, which is the least value than the existing models [35]. The MSE of the projected work at 60th learning percentage is 87.4%, 95.4%, 86.3%, 96.2%, 91.65%, 96.16%, 51.7% and 70.4% better than the MSE value recorded by existing models like CNN + Bi-LSTM [2], C-LSTM [3], Bi-LSTM, RNN, MFO + CNN, GOA + CNN, SLnO + CNN and SOA+CNN, respectively.

TABLE III. OVERALL PERFORMANCE ANALYSIS OF THE PROPOSED WORK

*L. Analysis on Optimization Metrics*

The performance of the projected work is evaluated in terms of Accuracy, Precision and F-Measure, respectively. This evaluation has been carried out for varying learning percentage. The results acquired are shown in Table IV. The proposed work has attained the highest accuracy as 92% in case of eye blink detection at 60th learning percentage. The accuracy of the projected work at 60th learning percentage is 4.3%, 5.97%, 5.97%, 7.06%, 4.3%, 2.7%, 1.9% and 4.3% improved over the existing models like CNN + Bi-LSTM [2], C-LSTM [3], Bi-LSTM, RNN, MFO + CNN, GOA + CNN, SLnO + CNN and SOA + CNN, respectively. In addition, at the 70th learning percentage [36-39], the projected model has recorded 89% of accuracy in eye blink detection. Moreover, at 90th learning percentage, the proposed work has recorded accuracy as 85%, which is found to be 11.7%, 1.1%, 10.5%, 8.23%, 3.5%, 4.7%, 2.3% and 9.4% improved over existing models like CNN + Bi-LSTM [2], C-LSTM [3], Bi-LSTM, RNN, MFO + CNN, GOA + CNN, SLnO + CNN and SOA+CNN, respectively.

## X. CONCLUSION

In this research work, a novel eye-blink detection model is developed. The proposed eye blink detection model is modeled by following seven major phases: (a) video –to-frame conversion, (b) Pre-processing, (c) face detection, (d) eye region localization, (e) eye landmark detection and eye status detection, (f)eye blink detection and (f) Eye blink Classification. Initially, from the collected raw video sequence (input), each individual frames are extracted in the video –to-frame conversion phase. Then, each of the frames are subjected to pre-processing phase, where the quality of the image in the frames are improved using proposed Kernel median filtering (KMF) approach. In the face detection phase, the Viola-Jones Model has been utilized. Then, from the detected faces, the eye region is localization within the proposed eye region localization phase. The proposed Eye region localization phase encapsulates two major phases: Feature extraction and landmark detection. The features like improved active shape models (I-ASMs), LBP are extracted from the detected facial images. Then, the eye region is localization by using a new optimized CNN framework. This optimized CNN framework is trained with the extracted features (I-ASM and LBP). Moreover, to enhance the classification accuracy of eye localization, the weight of CNN is fine-tuned using a new Seagull Optimization with Enhanced Exploration (SOEE), which is the improved version of standard Seagull Optimization Algorithm (SOA) [31]. The outcome from optimized CNN framework is providing the exact location of the eye region. Once the eye region is detected, it is essential to detect the status of the eye (whether open or close). The status of the eye is detected by computing the eye aspect ratio (EAR). Then, the identified eye blinks are classified based on the computed correlation coefficient as long and short blinks. Finally, a comparative evaluation has been accomplished to validate the projected model.

# A Hybrid Quartile Deviation-based Support Vector Regression Model for Software Reliability Datasets

Y. Geetha Reddy[1], Dr. Y Prasanth[2]

Research Scholar[1], Professor[2]
Department of Computer Science and Engineering
KLEF, Guntur District, A.P., India

*Abstract*—Software reliability estimation using machine learning play a major role on the different software quality reliability databases. Most of the conventional software reliability estimation model fails to predict the test samples due to high true positive rate of the traditional support vector regression models. Most of the traditional machine learning based fault prediction models are integrated with standard software reliability growth measures for reliability severity classification. However, these models are used to predict the reliability level of binary class with less standard error. In this paper, a hybrid support vector regression-based quartile deviation growth measure is implemented on the training fault datasets. Experimental results are simulated on various reliability datasets with different configuration parameters for fault prediction.

*Keywords*—*Software fault detection; reliability prediction; support vector machine; exponential distribution; quartile deviation*

## I. Introduction

Reliability, in its simplest form, means that a failure cannot occur within a certain period of time. The reliability concept thus stresses the probability, expected function (s), time, and operating conditions of four components. Reliability also depends on the conditions of the system that may or may not change over time. Software systems have increased significantly in size and complexity in recent decades, and the trend is expected to continue in the future [1]. Computer reliability and accessibility, usability, performance, serviceability, capabilities, and documentation are important attributes of software quality. Software reliability is difficult to achieve since software complexity seems to be high. While it is difficult to achieve a certain degree of reliability for any highly complex system, including software, system developers tend to upgrade the software layer with complexity and rapidly developing system sizes. The Software Reliability Growth Model (SRGMs) is a software reliability model (SRMs) design recognition class which is converted into a mathematical model. The reliability assessment of recent system updates is an important challenge in IT software management [2].

The probabilistic models are based on dynamic models and are represented as time-based statistical distributions. All these models are used to predict current trends and predict future trends in reliability. Probabilistic software reliability prediction models use statistical methods to estimate variables such as system error numbers, failure rates, software complexity, programme failures, etc. There are a number of

software models in the literature, but none of them is ideal. The selection of an appropriate estimate model based on a specific application is a major research problem [3]. A data set that includes instances of defined classes and a test data set for which the class must be decided must therefore be entered. The quality of the data provided for learning, and also the type of algorithm used in machine learning, depends greatly on the ability to classify successfully. Categorical labels (discrete, unorderly) estimate classification results of continuously valued function models. It implies that numerical data values are expected instead of class marks to be incomplete or inaccessible. Regression analysis is the most widely used statistical method for numerical forecasting. Although other methods are available, the prediction also consists of identifying distribution trends based on available data. Genetic algorithms are also implemented to maximise the number of delayed input neurons and the number of neurons in the neural network's hidden architectural layer. We have demonstrated, using the software model for online adaptation that good-fitness and next-step predictability are better than traditional methods when cumulative software failure times are forecast because those variables' meanings are certainly not known. Many potential values can be equated to the likelihood of occurrence. Therefore, we really don't know when the next loss will happen. We know only a few possible failure times and their likelihood. "T" Two types of fault data, namely, time-domain data and interval-domain data, are widely used in software reliability modeling. The time-domain form is determined by the time the failure occurred. Learning supervised is a methodology for machine learning to build a data structure for preparation. Maximum Likelihood Assessment (MLE) is a common statistical method for the determination of the probability distribution parameters underlying a given dataset. Throughout the literature, there are many predictive models of the reliability of software-based neural networks, which are better known than certain statistical models [4-6]. Computer reliability is one of the key factors taken into account in maintaining the accuracy of the computer. Simply put, software reliability is about system failure or failure [7]. "Success and success" are two distinct variables commonly included in our software development. A fault could be identified as a fault or error during the development phase. As software constraints and modular complexity increase, the manufacture of a quality finished product is too difficult. Software defects may lose cash and time, so bugs for good performance products and decision-makers need to be predicted in advance. As a consequence, these bug accounts contain comprehensive data on bugs along

with the seriousness level [8] within different bug tracking frameworks. Generally, software bugs are defective limitations that trigger inaccurate outputs. These limitations can be described as a collection of characteristics to discover the bugs. These features affect the bug prediction model's effectiveness. Applications for software defect detection include decision trees, multifunctional regressions, neural networks, SVM, nave Bayes, and various classification types and selection models. But the relevant flaws for suitable classification could not be selected in these designs. Nave Bayes is a highly efficient method of classification for predicting flaws based on samples of practice. A naive Bayes system sees bug predictions as binary classifiers, i.e., by evaluating historical measurement information, it trains and predicts the predictor. If the attribute kinds in the metric information are blended, errors owing to lacking values or uncertain data are hard to estimate. Three separate layers of dynamic analysis can be classified. A systemic testing layer is the first layer. This layer is designed into the policy to run target programs. These strategies are designed to efficiently achieve error states. The second layer is a layer of data retrieval. In order to check programme correctness, data on the inner behaviour of the target programmes is collected. In the third level, monitors create from the information collected an abstract model of the destination programme and then check for possible errors in the programme on the abstract model. The test limits are fundamental to all dynamic analysis techniques. Dynamic analysis cannot support full target-program analysis because it uses monitored partial programme compliance. The other restriction is that it is hard to implement dynamic analysis methods except for the completion of the target programs. Executable environments and sample instances involve dynamic analysis methods. [9] the significance of various software prediction-model metrics. In this model, correlations and metric events were introduced using distinct algorithms in the bug forecast model, and bug counts were calculated in each metric. Object-oriented measurement metrics for object-oriented quality software A model for bug-projection was proposed and its levels with high, medium, and low severity defects were found to be lower than traditional models with various severe values. The technique of regression is intended to predict the quantity and density of software defects. The technique of classification aims at determining whether or not a software module (e.g. a package, code, or file) has a higher risk of defect than another. This approach [10] uses fuzzy logic with neural networks in software reliability prediction. The recurrent neural network is trained using the back-propagation algorithm. The number of failures and cumulative execution time in the failure dataset are used as inputs to the network to predict the next step failure.

The rest of the paper is organized as follows. Section II describes the related works of the SRM and its limitations. Section III describes the proposed solution to the SRM based machine learning framework on different dataset. Section IV describes the experimental results and analysis. Finally, we conclude the paper in Section V.

## II. Related Work

Lazarova et al. have developed various SRGMs concerning the growth rate software reliability index for error detection [11]. Li et.al, proposed a measuring method as an indicator collection, gathering data for the testing of all those metrics [12]. Mirchandaniet al. suggested the non-homogeneous Poisson method-based software reliability growth pattern because the detection of these errors might also lead to detection of other errors without failure [13]. Nagaraju proposed an evolutionary model of the neural network to estimate and predict the software reliability based on a multimedia architecture input and output. In this study, the development of neural network models for software-reliability predictions was proposed using an Exponential and Logarithmic Encoding Scheme. Neural network models with the two encoding schemes above have shown a better prediction of cumulative failures than some statistical models. However, [14] the value of the encoding parameter is calculated by repeated hit / test experiments. This paper presents recommendations for encoding parameter selection, which provide consistent results for various data sets. The proposed solution is implemented using 18 separate data sets and a clear result for all datasets is observed. The method was compared to known statistical models using three sets of change points.

Rani [15] proposed a neural network approach focused on predictions of software reliability. He compared the approach to parametric model recalibration with some meaningful predictive measures with the same data sets. We concluded that better predictors are neural network methods.

Rizvi et al. [16] proposed a system in which software reliability based on the neural network would be expected. They used the reverse propagation algorithm for instructions. They used several failure times in the last 50 to estimate the next failure as output. The performance of approaches was calculated by changing the number of input nodes and hidden nodes. We concluded that the success of the strategy usually depends on the quality of the data sets.

Sagar [17] submitted a neural network approach focused on the evolutionary prediction of device reliability. They used single output architecture with multiple delayed inputs. Vojdani [18] suggested two models for cumulative system failure estimation, such as exponential neural network encoding (NNEE) and logarithmic encoding (NNLE). He encoded the data with the above two encoding scheme, i.e. the time of execution. He used the four dataset method and compared the results with some statistical models and found better results than those models.

Wang et al. [19] have proposed to reuse data from previous projects / releases for failure to boost early reliability for current projects / releases. Wang et al.[20] proposed the combinational dynamic weighted model (DWCM) based on a neural network for the prediction of device reliability. Based on the software-reliability growth model (SRGM), they used various activation functions within the secret layer. The method was used on two sets of data and the effect was compared with certain statistical models. The experimental results indicate that the DWCM approach is more successful

than traditional models. The neural network is a methodology for performance computation. The machine performance can previously be predicted on the basis of our neural network architecture. The system is also trained unless its desired output or destination can be achieved. For training purposes, we use different learning techniques that are freely described as supervised and unattended learning [21]. Software reliability is a quantitative study of every software designed since it affects directly software quality [22]. An efficient software reliability model is required in order to achieve good results. The previously developed reliability model is based on the analysis of faults linked to the code and context in which it was implemented [23]. All software reliability models are designed based on the execution time and calendar time. The time required or spent by the processor in the execution of instructions from the program is the execution time of any program [24].

Research Gaps: From the literature works, the main gaps identified for the software reliability estimation process are:

*1)* Difficult to predict the new reliability test data using machine learning approach.

*2)* Traditional SVM require different hyper parameters in order to improve the classification optimization.

## III. PROPOSED GEOMETRIC PERTURBATION BASED PRIVACY PRESERVING CLASSIFIER

In this section, a statistical quartile deviation-based improved SVR prediction model is proposed on the software reliability datasets. In this work, a novel approach to predict the software reliability on the training and test software fault data. This model is integrated with the quartile deviation growth function in order to fit the S shaped curve. In the proposed model, reliability estimation is performed in two phases. In the initial phase, quartile deviation based error estimation is calculated on the training data for software reliability prediction. In the second phase, a hybrid support vector regression model is designed and implemented on the computed S-shaped training data as shown in Fig. 1.

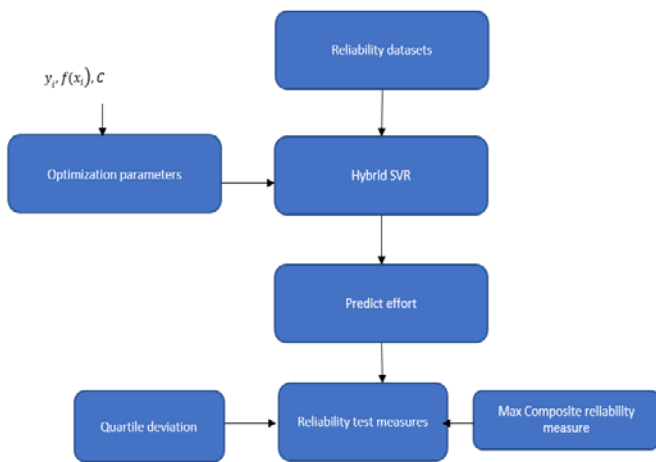

**Figure 1: Max composite based SVR Framework**

Fig. 1.  Proposed Ensemble Deep Learning Framework for Privacy Preserving.

In the proposed model, an enhanced support vector regression is designed and implemented on the software fault dataset to improve the prediction rate and to minimize the error rate. The following proposed SVR model is implemented on the fault data. Initially, input data is given to hybrid SVR model to predict the effort rate. The prediction values of the SVR are tested using the Quartile deviation model and maximized composite reliability measures. These measures are used to find the deviation, skewness and shape of the dataset. The impact of failures on decision making is calculated using traditional software metrics. Extensive research was done using one or two software stage metrics to discover the error models. However, redundant and meaningless characteristics affect the effects of traditional designs. Also, the relationship between the new metrics and the traditional metrics is becoming too complex to make decisions as the number of software metrics increases. Generally, software metrics are used to gain quantitative insight into the software or its characteristics. The value of metrics is an ordinal, an interval, or a nominal scale. Software quality is assessed by the various features such as performance, documentation, easy maintenance and system soundness. Software reliability is considered as it is difficult to achieve with the complex nature of software. The software is therefore layered by the system developers throughout the design process to achieve a certain level of reliability, to support the later update of the software system and also to incorporate elasticity for increased system size. The reliability of software is inversely linked to the level of software complexity, since complexity is directly associated with enhanced capacity and strong software system features with enhanced functions. The main objective of this paper is to improve the software reliability prediction using the hybrid SVR model.

Let m(x) be the input data, m be the estimation function. M value is estimated by using multiple linear regression method. Then the objective function of the proposed SVR model is given as

$$C(x) := \frac{1}{2} \| w \|^2 + \xi \cdot \psi(x) \cdot \phi(x)$$

Where

$$\psi(x) = | m(x) - m(x) | = | m(x) - MLR(x) |$$

MLR(x) = Multiple linear regression

$$\phi(x, x') = e^{-\|x - x';\|^2 / 2 \cdot \sigma^2}$$

$$\min_{\xi_k, \xi_k^*} C(x) = \frac{1}{2} \| w \|^2 + \lambda \cdot \psi(x) \cdot \phi(x) + b$$

$$\min_{\xi_k, \xi_k^*} C(x) = \frac{1}{2} \| w \|^2 + \lambda \cdot | \xi_k - \xi_k^* | \cdot \phi(x) + b$$

## IV. EXPERIMENTAL RESULTS

In this work, experimental results are simulated with java environment for different software reliability datasets. The first, second, third and fourth datasets DS1, DS2, DS3, and DS4 are taken from Rome air development centre (RADC)

projects. Each dataset and its type are given in Table I, Table II, Table III and Table IV.

## V. CONCLUSION

Software reliability fault prediction plays a vital role in small- and large-scale software applications. In this paper, a hybrid support vector regression-based quartile deviation model is implemented on the different software reliability datasets. Most of the traditional machine learning based fault prediction models are integrated with standard software reliability growth measures for reliability severity classification. However, these models are used to predict the reliability level of binary class with less standard error. Experimental results proved that the proposed reliability fault prediction model has better performance in terms of prediction and time is concerned.

## VI. FUTURE WORK

In future work, a supervised learning model is integrated to the SVR model in order to predict the reliability for the new unclass labelled data.

*Abstract*—Under poor light conditions or improper acquisition settings, the image degrades due to low contrast, poor brightness and suffer poor visual quality of the picture. An enhancement is required to manipulate the scale of pixel intensity for significant improvement in the image. This paper proposed the method of gamma correction with a self-adaptive value in accordance with the intensity scale of the image. After transformation to HSI (hue, saturation and intensity) channel, a multi-scale wavelet transform is implemented on the intensity component of the image. The gamma scale is computed from the combination of reformed scale constant of logarithm function and Minkowski distance measure. Lastly, wavelet based de-noising technique is applied to suppress high noise coefficients to improve quality of the image. The proposed method is evaluated in terms of visual appearance, measure of information content, signal to noise ratio, and universal image quality index. It demonstrated that the proposed method showed its efficacy in terms of quality and improved visibility.

*Keywords*—*Low scale intensity images; discrete wavelet decomposition; gamma correction; quality metrics*

## I. INTRODUCTION

The demand for video surveillance, medical imaging, and extensive photography has tremendously risen the challenges in the enhancement of low intensity images. Low intensity refers to illumination whose physical characteristics don't satisfy the normal image [1]. With improper light conditions and poor acquisition settings of imaging devices, the picture is affected by low contrast [2]. Such images exhibit the narrow distribution of intensity values across the intensity scale and are considered to be under/over-exposure scenes. Explicit exposure consists of a broad range of intensity values grouped narrowly into a narrow intensity range [3]. Fig. 1 displays the image with low luminance where most of its values are at the left portion of the intensity scale. Here, the intensity scale refers to the x-axis of histogram values, and the frequency of occurrence is at the y-axis. So, the intensity values at the darkest region (left portion) reflect the low visibility. Due to poor brightness, the image suffers the loss of texture features that define the content or shape of the image. The texture feature is the spatial variation of brightness across the intensity values of the pixels. With poor texture features, usability in applications like computer vision, medical analysis, and object recognition become difficult to characterize the image. So, the enhancement plays a significant role in adjusting the distribution of intensity values for better visibility in the image.

It involves modifying the intensity value for uniform distribution of pixel values at every pixel position along the intensity scale. Such processing enhances the hidden details and improves the contrast in the image. Also, the transformation to a new scale provides various advantages like suppression of noise, brightness preservation, and sharpening of the edges to make the original image more adaptable to human visual perception. The process of enhancement adjusts the luminance value. Here, the 'luminance' denotes the brightness and intensity in the single-channel obtained from RGB (red, green, and blue) color space. The various modifications had been developed taking both hardware and software methods into account. This paper presented the algorithm based on a software approach to improving picture visibility and overall quality.

Fig. 1. The Image of Low Intensity Image.

The non-uniformity in an image occurs due to the random distribution of pixel values across the intensity scale. The uniform distribution could be obtained by applying the histogram equalization (HE). It is required to retain the maximal information for improved visibility with optimal quality. But the serious limitation of over-enhancement in HE degrades the quality of an image. Apart from HE, the point processing techniques deliberately balance the non-linear nature of pixel distribution. Most significantly, the gamma correction is the popular approach to produce quality improvement in an image. It is an intensity transformation technique to enhance the image. In simple terms, the input and output are related as:$I_{(u,v)} = I_{x,y}^{\gamma}$, where Iu,v and Ix,y represent the input and output image. The scale value '$\gamma$' is the scale factor in gamma correction. It modulates the luminance value to transform the image into better quality. The challenging task in gamma correction is the optimal choice of the scale factor. To overcome limitation of HE, the work is focused to auto-

adjust the scale factor of gamma for the low-intensity image. The scale factor must be automated in such a way to produce better visibility with improved contrast.

The rest of the paper is as follows: Section II discusses the related work on histogram equalization (HE) and other state-of-the-art techniques. Section III presents the key steps to the proposed method, including the conversion to HSI, multi-scale analysis, adaptive gamma correction, and auto-tuning to colour correction. Section IV describes the experimental results evaluated and compared with relevant techniques. Finally, the conclusion is followed by the future scope of the proposed method.

## II. RELATED WORK

The piece-wise contrast stretching is the linear approach to scale the brightness. The image with intensity on both sides of the scale (dark and bright) is stretched to obtain the enhanced image. The stretch limit is calculated from the maximum and minimum intensity scale from the reference image. Though the linear stretching method is simple and easy but is entirely suitable for situations in which low and high scales are prominent. So, the non-linear approach of conventional histogram equalization (cHE) is implemented, defined as the frequency distribution technique based on statistical information in the image. The distinct peaks in Fig. 2 displayed the over-enhancement of the low contrast image.

The improved method of cHE based on clipping by mean-median approach on sub-division of HE is commonly used. The approach significantly improved the quality of the over-exposure images. For the image with dark scale values, this method failed to provide scalability in brightness. The MMSICHE[4]sub-divided the image based on median clipped HE. The method claimed to preserve the brightness and information contained in the image. But the method showed its inefficiency in improving the visual appearance of an image. The other method of cHE is the exposure-based sub-regions division of HE, proposed by Tan S and Isa N[2]. The sub-division of cHE in terms of very dark, dark, mid-tone, and lighter regions of a histogram's value were implemented. Most of the pixel values concentrated on the darkest region of the intensity scale. Additionally, Shiguang Liu and Yu Zhang [5] proposed the application of multi-exposure fusion to preserve the detailed information in the image. Other state-of-the-art techniques, such as Brightness Preserving Dynamic-HE (BPDHE) [6], [7] aimed to preserve the mean brightness without severe artifacts. It mapped the sub-histogram into a new dynamic range. The partitions were obtained by calculating the local maximum of the input image. The limitation of this method was that it could not handle the under/overexposed regions in the intensity values. Hence, the modified form of [8]i.e. Fuzzy HE is proposed to overcome the limitation of BPDHE through the implementation of fuzzy crisp values. In the fuzzy-based histogram approach, the partitions were calculated by computing the local maximum. The range of partitions also increased, as the number of pixels count is increased. Since illumination is non-uniform, fuzzy logic lacks a systematic approach to enhance visual appearance. Zuo C. et al[9], [10] proposed a mean-based estimation of object and background from HE. The locally

segmented approach was utilized by Hussain et al. [11] to map the shadow scales over brighter regions. The histogram equalization was implemented by dividing the images into small segments. The process of segmentation was concluded for dark images. If the dark region's scale is variable, over-enhancement could degrade the quality. As a result, the method focused on selecting segments and mapping them to more prominent regions. Recently, dynamic HE [12] was proposed for low illumination MRI images. It followed the same technique of partitions as proposed by previous two methods. Based on a novel multi-scale decomposition, bright regions were separated from dark regions with the domain as non-sub sampled transform. It is a combination of pyramid and directional filter banks. The proposed algorithm had showed the efficacy in handling MRI images. The HE approaches could be effective for natural or for images where pixel distribution is moderate. Most of the HE proposed is focused on preserving the mean brightness and improving the contrast. As shown in Fig. 2, while improving the visual appearance the image is degraded with low contrast. The application of HE and its modified approaches either under-enhanced or degraded the quality of the picture.

The alternate approach of non-linear transformation techniques are gamma correction, logarithmic and exponential function. The sigmoid is an 'S' shaped logistic function that process the image pixel by pixel to enhance the contrast. Srinvas and Bhandari [13] proposed adaptive sigmoid transfer function to achieve enhanced resolution. The sigmoid was utilized as a scale parameter to boost the lower intensity values and adjusted the high intensity values. Similarly, Gupta and Aggarwal [14] proposed a newly developed sigmoid function for contrast improvement in the image. After the transformation to YCbCr model, the normalization parameter was designed using Gaussian based sigmoid function to adjust the illumination. The contrast was enhanced for better colour compensation in the reference image. Other than sigmoid, the transformation of RGB image to extract luminance and chrominance as proposed by Priyanka S et al. [15] used principal component analysis (PCA). Due to direct analysis of raw images, there are colour saturation effects. Hence, the method could not be used for low-intensity images. The improved approach of principal component analysis was suggested by Singh and Bhandari [16]. The authors implemented PCA after the transformation of raw image into HSV channel. This fusion image had a higher quality but with a poor structure similarity index. Also, the global and local contrast adaptive model was proposed by Zhou Z et al. [17] for compensation in brightness. After transformation to HSI, the 'H' component was modified to compensate the low illumination.

Fig. 2. Histogram Equalization of Low Intensity Image.

Fig. 3.   Flow Diagram of EAGL

Since, the luminance is low, the computed mean could not compensate the poor brightness. Recently, algorithms developed with gamma correction had been the thrust area in image enhancement. The improved gamma correction was developed by Veluchamy and Subramani [16] and computed from cumulative density function. In this method, the detail information was preserved while the contrast was improved. In the previous published work [18], preserving the mean brightness can improve the contrast in the image. Hence, the method was effective for natural and contrast distorted images with moderate intensity values. Rahman S. et al. [19] proposed a mean-based approach to automate the selection of gamma values. The other way was proposed by Parihar [20] and Mahamdioua and Benmohammed [21] to estimate the scale through the computation of entropy and mean of the image. Wang Wencheng [22] proposed an adaptive gamma transform calculated after linear stretching of the corrected brightness in the image. Alternately, the discrete wavelet transform is utilized by Wenyung Yu et al [23] for gamma correction. The illumination was extracted from a low-light image using wavelet decomposition. The contrast value was improved with the computation of global and local spatial illumination. The recent approach for visual correction was proposed with the implementation of principal component analysis (PCA) by Singh and Bhandari [16]. In this approach principal components are adjusted to compute the gamma scale. However, PCA is widely used in image compression. Also, self-adaptive gamma scale was used in the previous work [18] . But the approach was limited to contrast distorted images.

Most of the research is focused on visibility improvement, regardless of simplicity and ease of use. The proposed work is developed to produce simple and effective algorithm for improved visibility. In this paper, multi-scale approach of enhancement is proposed with self-adjustable gamma scale. From the above discussion, the selection of scale parameters plays a significant role in improving the quality of the image. The gamma scale is computed by the combination of the Minkowski distance measure and scale-power (ScP) function. This scale parameter is further used in the gamma correction of the image. To improve the texture features, multi-scale enhancement using 2D discrete wavelet transform is implemented to estimate the intensity component in the image. Finally, the median based noise estimator suppressed high

noise coefficients to minimize the loss of information content in the image.

## III. PROPOSED METHOD

### A. *Flow Diagram (EAGL)*

The flow diagram shown in Fig. 3 illustrates the enhancement of low intensity images. It includes two stages: (1) the estimate of illumination and (2) noise correction in the final image. The purpose of the EAGL is to extract detailed information to obtain better visibility of the image. Firstly, the original image is transformed into HSI (hue, saturation and intensity) channel [24]. Mostly, global mean, variance or entropy was used to estimate luminance. Since multi-resolution preserved the maximum amount of detail (energy), a 2D-discrete wavelet transforms at a scale level of '2' [24] is used to obtain luminance value from the intensity component of the input image. The scale value is computed by combining the scale-power function and Minkowski distance measure (MDM) from the contrast stretched and wavelet coefficients of the original image. The combination provided the self-adaptive scale for gamma correction. Finally, threshold-based wavelet shrinking is implemented to suppress any noise artefacts due to transformation in the input image.

### B. *RGB to HSI Conversion*

The image consists of sRGB (standard red, green and blue) combined to form a visual representation. Because of the non-linear nature of true colour, the image is usually transformed into other space channels like HSI [25]. Each of these parameters contains the dominance of wavelength known as hue (H), purity of colour as saturation (S) and the brightness/intensity value (I). The intensity part 'I' in the HSI (shading space) is isolated from and irrelevant to the chrominance part H, i.e., the shading data of a picture. To manipulate a shading picture independently, the 'I' can be improved while keeping the 'S' and 'H' the same. HSI is a 2D representation that approximates the way humans perceive colour. As a result, it retains a higher degree of brightness (for better visual perception). The relation is given as:

$$l_{(x,y)} = \max[R, G, B] \qquad (1)$$

Where '$l_{(x,y)}$' is denoted luminance component comprises of maximum intensity of red, green, and blue channel.

As it could be observed from Fig. 4, 'I' component is the exact brightness represented in the original image. In our experiments, hue and saturation remained unchanged and intensity value is further processed for image enhancement.

### C. 2D -Discrete Wavelet Transform

After transformation to HSI, intensity component is further processed with 2D-discrete wavelet transform (DWT) to down-sample the intensity from the '$l_{(x,y)}$' (refer Eq. 1). The wavelet domain is considered to be high energy compaction tool for image processing. The decomposition in wavelet domain explores the directional variation (horizontal, vertical and diagonal) in image. The image is decomposed at a scale level of two to obtain wavelet coefficients as low-low pass (LL), high-low pass (HL), low-high pass (LH) and high-high (HH). The coefficients of LL are used for computation of scale-power function (as shown in Fig. 5). In our experiments, 'sym5' is considered as mother wavelet. The 'sym5' is a symmetrical mother wavelet mostly used for the non-linear content in the information.

The Fig. 5 shows the implementation of wavelet transform to separate the luminance from detail coefficients. The 2D-DWT is implemented in row- column form computed from one dimensional DWT. For a given image '$l_{(x,y)}$'is filtered to obtain two '$l_a$ as approximation and $l_d$ detail (each of size NxN/2 (N is the number of pixels)) coefficients.

The visible region in the Fig. 4 (after 1-level decomposition) is the low-low pass filter coefficients and the other dark portion is the corresponding

$$l^i_{d(j',m,n)} = \frac{1}{\sqrt{mn}}\sum_{\substack{1\le x \le m \\ 1 < y < n}} L(x,y)\, d^i_{j,m,n}(x,y) \tag{2}$$

$$l_{a\,(j',m,n)} = \frac{1}{\sqrt{mn}}\sum_{\substack{1\le x \le m \\ 1 < y < n}} L(x,y)\, a_{j',m,n}(x,y) \tag{3}$$

Where $l^i_{d(j',m,n)}$ and $l_{a\,(j',m,n)}$ are the detail and approximation coefficients of Eq. 1, j is the scale value. The decomposition is for one scale level and the mother wavelet used is 'sym5'.

### D. Scale-Power Parameter (Sc-P)

From the obtained coefficients at a level of '2', scale value is computed. The value is the modified form of scale constant in logarithmic function. It is well known that logarithmic function is defined by the relation as s=clog(1+r) [3]. The scaling constant 'c' is chosen such that input intensity is mapped to high values and is calculated as: $c = \frac{255}{\log(1+J_m)}$, where'255' is the maximum scale level, '$J_m$' is the maximum intensity in the reference image. The scale constant 'c' produces loss of information for higher range of pixel values in the image. So, the proposed method modified the scale constant with the combination scale and power function.

Firstly, the scale is modified into the given relation as:

$$\xi^{ScP} = \frac{[J_m - l'_{a(j',m,n)}]}{\log(1 + l'_{a(j',m,n)})} \tag{4}$$

$\xi^{ScP}$ is the scale computed from modified scale constant of logarithmic function where in the numerator value is modified

from '255' to $[J_m - l_a(j',m,n)]$ where '$J_m$' is the maximum intensity in the $l_{a\,(j',m,n)}$ and $l'_{a(j',m,n)}$ is the mean computed as: $l'_{a(j',m,n)} = \sum_{\substack{0\le m\le M-1 \\ 0<n<N-1}} l_{a\,(j',m,n)}$ . Similarly, the denominator value is modified to $\log(1 + l'_a(j',m,n))$ . Next, to avoid the exaggerated intensity variation, $\xi^{ScP}$ is further decimated to the power of 0.005. This value is taken as constant for the images whose intensity scale varies from dark to medium range of pixel distribution.

### E. Minkowski Distance Measure (MDM)

For the gamma-based correction, the value of gamma greater than one will increase the intensity of the dark region. Since, the focus of the paper is to scale the intensity in the image, hence $\xi^{ScP}$ is combined with the value of Minkowski distance measure ($M^{em}$). The $M^{em}$ is a generalized form whose properties are computed from Euclidian and Manhattan distance formula. The final scale value computed for gamma is related as:

$$\gamma = \xi^{ScP} + M^{em} \tag{5}$$

### F. Adaptive Gamma Correction

The gamma correction is the non-linear transformation function in which the compression and expansion is attained by changing the value of scale parameter. Finally, the improved gamma correction is implemented with the given relation as below:

$$l^{new}_{(x,y)} = (l_{(x,y)})^{1/\gamma} \tag{6}$$

where $l^{new}_{(x,y)}$is the newly constructed luminance component of HSI channel.

Fig. 4. Representation of 'I' Component of the Reference Image.

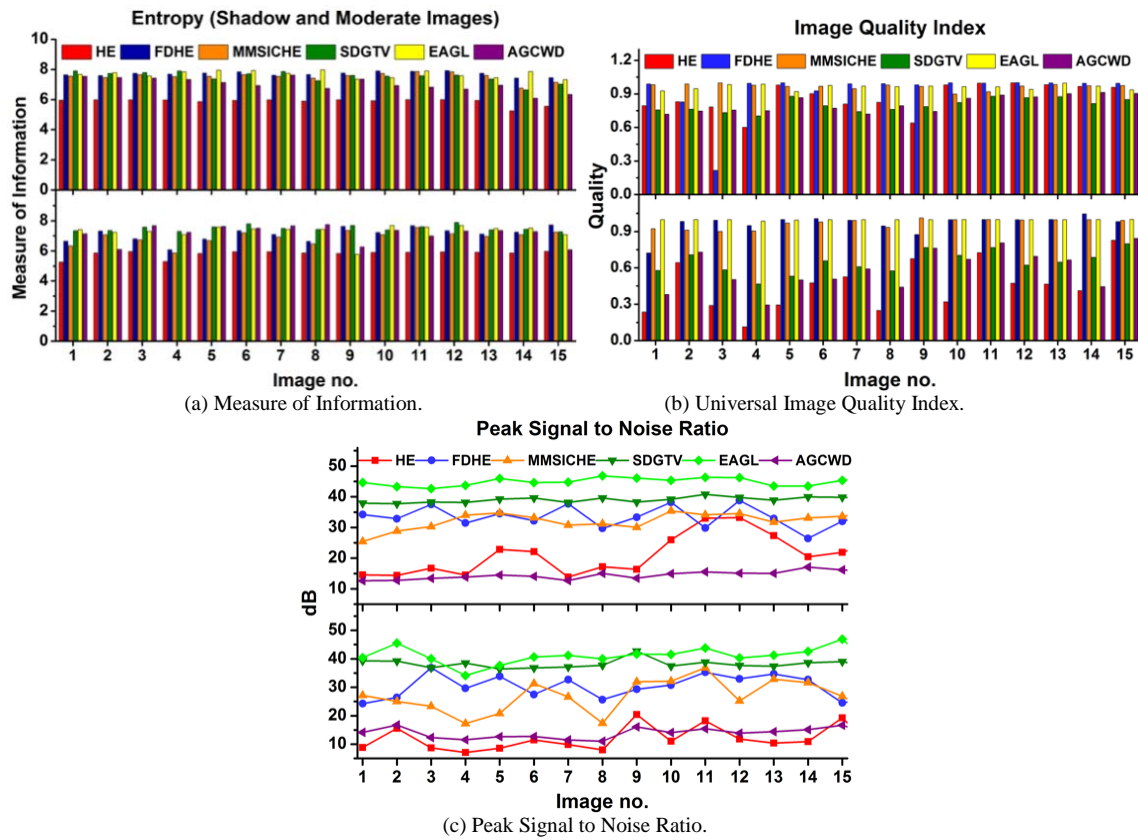
(b) Universal Image Quality Index.



(c) Peak Signal to Noise Ratio.

Fig. 6. Comparison of Image Quality Measures (a) Entropy, (b) Universal Image Quality Index and (c) Peak Signal to Noise Ratio for Set of Shadow (Top) and Moderate (Bottom) Images with HE, FDHE, MMSICHE, SDGTV and Proposed Method (EAGL).

## G. Noise Compensation

Despite the non-uniform distribution of illumination, the hue contains the dominant wavelength of colours. Before the transformation, the hue component is adjusted from the mean square error. The self-adjusted hue compensation is computed from the mean square error between the reference and contrast stretched image. The new intensity component is transformed back to its original channel space by combining it with other channels. The transformation often degrades the quality of the image. Most of the techniques like median/mean filtering and Gaussian filter often process the noise by individual filtering. Due to high-frequency noise, the final image is blurred near the edges. So, wavelet based de-noising technique is implemented in the proposed method to effectively preserve the quality in the image. With the similar process of multi-scale 2D DWT, the adjusted threshold value is computed (Eq. 7). For any pixel value in the sub-band which is less than the threshold is set to zero and otherwise shift to the other pair of sub-bands. The threshold is calculated by the general equation as:

$$Th = \frac{\sigma^2}{\sigma_{sb}} \tag{7}$$

Where $\sigma^2$ is the median estimator computed from the sub-bands and $\sigma_{sb}$ is the standard deviation of the sub-bands.

The proposed algorithm can be summarized as below:

---

**Input Image**: $l_{(x,y)}$ ;**Output Image**: $l_{(x,y)}^{new}$

Step I:     Transformation of standard (sRGB) image to HSI as given in Eq.1

Step II:    Decompose the 'I' component using 2D- discrete wavelet transform (keeping saturation unchanged). From Eq. 2 and Eq. 3

Step IV:    Estimate the scale parameter from image decomposition (Eq. 4) and confidence scale from contrast stretched image (Eq. 5)

Step V:     Implement gamma correction as stated in Eq. 6 on the luminance component.

Step VI: The final enhanced image is obtained after conversion to sRGB channel.

StepVII: Perform the noise compensation using Eq. 7 and Eq. 8 to obtain output image as '$l_{(x,y)}^{new}$'.

---

The value obtained from Eq. 7 is used to suppress the noise coefficients through wavelet based bivariate shrinking [26]. The soft thresholding as stated in Eq. 8 is used to regulate the visibility for better texture features in the image. The Fig. 7 shows the basic illustration of threshold-based noise compensation. Since the noise is at finer level of scales, hence the wavelet coefficients represent the noise at higher scales. So, the soft thresholding scales down the coefficients that are less than the threshold value. After gamma correction, the $l_{(x,y)}^{new}$ is transformed to its original sRGB channel.

$$T^S(w|t) = \begin{cases} 0 & for \ |w| \le t \\ w - t & for \ |w| > t \\ w + t & for \ |w| < -t \end{cases} \quad (8)$$

$T^S(w|t)$ is the soft-threshold equation. Where 'w' is the wavelet coefficients and 't' is the threshold value.

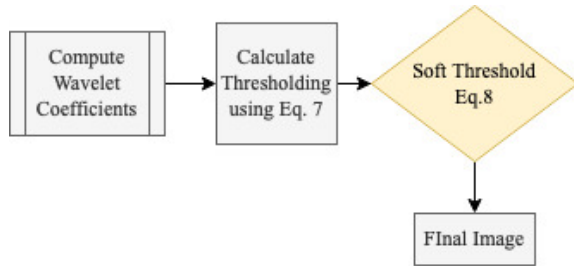


Fig. 7. Process of Wavelet Shrinking.

## IV. EXPERIMENTAL RESULTS

In this paper, the experiments were conducted on Intel (R) Core (TM) i5-6th generation with 8 GB of RAM, and the software

### A. Image Quality Assessment Measure (IQA)

An objective measure is based on certain criteria to assess the quality of the enhanced image. Although the quantitative metrics are not the perfect way to analyze the quality of enhancement. However, objective evaluation is usually an indicator of image quality. Because with no reference of precise image, the measure of quality is difficult to predict. To the best of our knowledge, there is no IQA method specifically designed to evaluate low-light image enhancement techniques. But, however, such metrics quantify the distortion content in the image. As a result, in various research articles [13], [16], [27], different objective assessment is used to evaluate final image. The quality measure is based on full reference methods and non-referenced methods dependant on reference image. With extensive study of research articles [29], [30], [19], [22] the following metrics were considered for our method. In our metrics, both no-reference and full reference measure had been quantified. The below listed metrics are briefly discussed.

### B. Entropy (E)

It is the measure of information content in the resultant image. In cases, like low light images, higher the entropy more will be the information content in the image. With the increase in information, detail of the image too will become finer. The entropy of the image is calculated by the formula:

$$H = -\sum_{i=0}^{L-1} p(i) \log p(i). \quad (9)$$

where H is the entropy, L is the overall gray-scales of image, p(i) is the probability of gray level 'i'.

As per the measure of entropy, the higher the E value, the more information the image contains and the richer would be the image detail.

### C. Peak SNR (PSNR)

It quantifies the quality of a reconstructed image with reference to the original image. The final image is compared to input image to estimate the noise content in the information signal. Higher the value of Peak SNR [29], better will be the quality of image. It is calculated from mean square error and is given as:

$$P_{SNR} = 10 \log_{10}\left(\frac{255}{\sqrt{MSE}}\right) \quad (10)$$

where MSE is the mean square error calculated between $l_{(x,y)}$ and $l_{(x,y)}^{new}$

### D. Universal Image Quality Index (UIQI)

It is a quality index to measure loss of correlation, luminance and contrast distortion. It is proposed by Wang et al. [31] that quantifies the quality more effectively than mean square error. With the increase in the index value, better will the quality of image.

The visual and histogram representation of some randomly chosen images is shown in Fig. 8. The selected images were divided into three groups, viz. shadow, moderate and low intensity images. For comparison, the random selection of 15 images in each group was chosen. By shadow, it means the images have variational illumination as shown in Fig. 8(b), whereas the moderate images are represented in Fig. 8(c) and Fig. 8(d). And lastly, the low visibility image as illustrated in Fig. 1 and Fig. 8(a). The images shown in Fig. 8 showed the non-uniform distribution of histogram values. Hence, if the intensity scale is widespread, it will degrade the quality of the image. The EAGL enhanced image showed the optimal shifting of scale values to improve the visibility with the desirable amount of contrast. A bell-shaped Gaussian curve could be observed in the 'airport' image. In case of 'shadow' image, the uniform distribution of pixel values is observed. The 'cart' image has dual peaks both at the dark and light scale. The peaks were retained to avoid any loss in detail information and with the shift of intensity scale, visibility is improved. Further, Fig. 6 is the qualitative comparison of shadow and moderate intensity images. In comparison to other well-known algorithms, high PSNR, better quality and preservation of information is found in the proposed method (as summarized in Table I).

*E. Comparison of Enhancement Algorithm with EAGL*

The original image (Fig. 1) is a low intensity (mean =46.89) image with the size of 524x800, where the intensity values is concentrated on the left (dark) extrema of the intensity scale. The purpose of enhancement in the image is to scale the hidden details (background and the girl) without introducing any artificial artefacts.

Fig. 10 illustrates the comparison with the classical techniques HE, and the improved HE as developed by [4], [28] and the recent published algorithms by [13], [22], [27]. The fusion-based algorithm developed by Fu et al. [27] had quoted that the 'girl' image constituted both bright and dark scale (dress) that had been preserved simultaneously. But with the over enhancement, the image produced is low in sharpness. The HE is the simplest and computationally fast technique to enhance the distorted image. It statistically increases the contrast of the images having detailed intensity values. However, the finished image produced by HE and others related to HE showed poor preservation of details and contrast wrapped in the image. The similar nature of 'dullness' and over enhancement could be observed in the recent published

algorithm. Whereas in EAGL, the 'girl' in the image and its background had significantly improved the intesnity of the low intensity image while preserving the details in the image. Fig. 9 is the histogram representation of enhanced image obtained from EAGL method. The shift in histogram values from dark scale to relatively bright region showed the global improvement in the image. The resultant image of the other HE based approach showed the effects of under and over-exposure of illumination which results in poor contrast. The resultant image of fuzzy-based HE (FDHE) showed under-exposure which results in poor visibility.

Fig. 9.    Enhanced (EAGL) Image.

Fig. 10.  Comparison of EAGL with the Recent Developed Algorithms based on Low Intensity Images.

Fig. 11.  Comparison of 'Swan' Image with other Relevant Algorithms.

Fig. 12.  Comparison of Shadow (House) Intensity Image.

In case of MMSICHE [4], effect of color saturation had degraded the quality of the image. But in case of EAGL, the global brightness is achieved to improve the visual quality and contrast in the image. The steepness in the intensity of the pixels is improved without the loss of information (entropy). With better visibility, the background details in the image (shadow in the glass window) is improved while preserving the contrast color transition from the object with the background, whereas Fig. 12 shows the visual comparison of shadow images. The main criterion of shadow images is to produce a balance between brightness and contrast for a better visual appearance. The compared results were obtained by the default settings of the published algorithms. The method of semi-decoupled decomposition [33] produced over enhancement and degrade the quality of the image. In the case of a fusion-based algorithm [27], the haziness in the image had degraded the

overall appearance in the image. The HE and MMSICHE had not shown any significant improvement in the overall picture. With improved contrast and optimal brightness, high PSNR and quality index proved the efficacy of EAGL.

Table II summarized the comparison of visually compared images shown in Fig. 10, Fig. 11 and Fig. 12. The comparison is made with the standard enhancement technique HE, fusion based and semi-decoupled decomposition method. The proposed method is found to have high PSNR, quality index and better retention of information.

## F. Comparison with Recent Published Methods

Fig. 11 is 'swan' image that illustrated the visual comparison of the proposed algorithm with other recent published methods. The different methods were based on multi-fusion, principal component analysis, sigmoid transfer function and other HE based algorithms. The proposed method differs on its effective implementation of gamma and noise compensator. The focus is to devise the method that should be simple and effective to produce better quality in the image. From Fig. 11, the sharpness and the retention of colours produced by the EAGL outperformed the other algorithms. The HE produced over-enhancement and the MMSICHE showed a low luminance image. In case of sigmoid transfer function (ASTF) [13], the image failed to retain the sharpness and thus degraded the quality of the image. The principal component analysis is a dimensionality reduction technique to produce a scaling in brightness. But implementing principal component analysis (PCARM) [16], the loss of details could be visualized near the swan (shadow at the ground) and failed to preserve the variation of shadow to light region. The fusion method [27] lacked sharpness and failed to preserve the detailed information.

Image enhancement is a challenging task in the field of image processing. In continuing efforts of many researchers, the adaptive scale value for gamma correction is proposed. The first abstract the computation of gamma scale using log-power and Minkowski distance measure. The second abstract is the suppression of noise content using a median-based noise estimator and bivariate shrinking. The threshold is computed statistically for the optimal suppression of noise coefficients. Fig. 10, Fig. 11 and Fig. 12 showed the original image and the reconstructed image from the EAGL. The proposed algorithm is designed in a way to effectively enhance the low with a fast response time. The response time and PSNR affects the universal quality of the image.

Table III summarized the result of the proposed method with the algorithms for 100 images in terms of information preservation, quality index, suppression of noise coefficients and the response time.

TABLE III.    AVERAGE COMPARISON OF EAGL

| IQA Method | Entropy | UIQI | PSNR | Response Time (sec) |
|---|---|---|---|---|
| HE | 5.79 | 0.65 | 16.24 | 0.17 |
| SDVTG | 6.90 | 0.67 | 38.34 | 0.65 |
| FUSE | **7.69** | 0.92 | 19.03 | 2.09 |
| FPDHE | 7.13 | 0.93 | 30.21 | 0.43 |
| EAGL | 7.36 | **0.98** | **46.46** | **0.29** |

*Bold indicates better results

## V.    CONCLUSION

Our experimental results focused on low visibility images due to non-uniform illumination. The prime advantage is (1) improved visibility in texture features, (2) low noise, and (3) improved contrast. In comparison to histogram equalization and other recent algorithms, the self-adaptive gamma scale had shown better improvement in retaining the texture features. The images were chosen in a way that the range of intensity scale should lie in between extreme low to moderate values. The HE is a simple method but not effective to improve the quality of the image. The other algorithms showed low response time and PSNR which affects the universal quality of the image.

It is concluded that the adaptability to variations in shadow from moderate to low illuminated images is fast in EAGL to produce effective visibility and improved quality.

*Abstract*—Nowadays, using the social network Twitter, a subject can easily access, post, and share information about news, events, and incidents taking place currently in the world. Recently, due to the high number of users and the capability to transfer information instantly, Twitter had attracted the interest of politicians with the goal to interact with their followers and to communicate theirs polices. Fearing the disagreements and disturbances that the application of some policies might cause, usually politicians use surveys to support their actions. However, such studies still use traditional questionnaires to recover information and are costly and time-consuming. Recent advances in automatic natural language processing have allowed the extraction of information from textual data, like tweets. In this work, we present a method to analyze Twitter data related to Peruvian politicians and able to score the latent sentiment polarity of such messages. Our proposal is based on an embedding representation of tweets, which are classified by a convolutional neural network. For evaluation, we collected a new dataset related to the current President of Peru, where the model achieved 91.2% of sensibility and 94.4% of specificity. Furthermore, we evaluated the model in two politic topics, that were totally unknown for the model. In all of them, our approach gives comparable results to renowned Peruvian pollsters.

*Keywords*—*Twitter data analytic; sentiment analysis; Peruvian politicians; approval rating; convolutional neural networks*

## I. INTRODUCTION

Nowadays, it is undeniable that social networks are playing an increasing role of importance in the dissemination of information. Daily, millions of people around the world access to social networks to share information and to communicate. A social network is an internet-based application that allow people to communicate between their families, friends, colleagues, circles of interest, and followers [1]. Actually, there are many social networks and usually they are oriented to specific topics, e.g., news, entertainments, movies, podcasts, professional networks, relations, etc.

Among social networks to disseminate news, Twitter registers the highest daily activity and popularity. In Twitter, a subject can easily share short messages or tweets about current events, that can be accessed by to tens of thousands of people. A subject can also reply and discuss the messages, contributing the message to become "viral". These short messages of at most 280 characters, also named tweets, can be accompanied by a few photos and a short video. According to the report in [2], more than of 500 million of tweets are published in

a day, which highlight the importance of Twitter in people's day-to-day communication.

Due to high popularity of Twitter and its capability to transfer information between ten of thousand people instantly, social leaders, influencer, politicians, companies, and governments have started using this social media to interact with their followers, clients, political adherents, and citizens. Once a subject gets registered in the social network, he can send and receive tweets and participate into virtual communities of his interest.

Recently, many investigations are being done aiming to analyze the stored data in social networks automatically [3]. However, the large amount of data and its non-structured nature still challenges the proposed methods [4]. The research objective is to discover hidden patterns into data and forecast trends in order to make decisions. Among the diversity of topics, the analysis of posts related to politicians becomes a hot topic of study, where the goal is to predict the approval rating of an important politician (e.g. the president, the prime minister, and others) or to measure the people satisfaction related to government policies carried out. This makes sense, actually, many governments are concerned about their approval rating. A high approval rate indicates a successful and healthy govern, both for their own citizens and foreigner's eyes. In contrast, a low approval rate reflects a weak govern, without major importance for people, even with detriment for the state itself.

Despite the social media network offers a rich source of information, studies of approval rating of politicians still reside on traditional paper-based questionnaires, which are too slow, time-consuming and expensive studies. On the other hand, an automatic analysis system offers an agile and less expensive manner to predict approval rating. Recent advances in Natural Language Processing (NLP) had produced the technique of sentiment analysis [5]. Sentiment analysis enables to gain insights of opinions in published tweets related to a particular discussion topic [6]. Furthermore, sentiment analysis can help to reveal the psychological and mental state of the subject who wrote a particular tweet, the emotional state, level of education, and others features [7].

In this work, we present a method to predict the approval rating of politicians based on Twitter data, focusing specifically to forecast the popular endorsement the President of Peru. The proposed model consists of an embedding representation,

followed by a Convolutional Neural Network (CNN). The embedding is itself a neural network pretrained in one billion of Spanish words [8]. The model is able to learn a rich diversity of tweet messages and classify them according to their sentiment polarity content, as positive/negative or approval/disapproval. Positive and negative outcomes are weighted according to the number of messages that were fed in the model to provide the final approval or disapproval rate. The model was designed to be political agnostics, so it was trained once and tested in multiple politic topics. To evaluate the model, a new dataset of 1150 tweets was collected. Collected messages include tweet posted in Spanish related to the current President of Peru, Pedro Castillo, that were retrieved from August 2021 to February 2022. Data was manually labeled as of positive or negative sentiment, resulting in a balanced dataset.

For evaluation, the model was assessed in a hold-out validation manner, with a ratio 80:20. Testing the ability of the model to predict the approval rating of the Peruvian president, it outputs 91.2% of sensibility and 94.4% of specificity. Due to the large corpus of the pretrained embedding layer, data augmentation was not required during training. Furthermore, to assess the model agnostic feature, a new data was collected in April 2022 about two widely discussed policies in that month: the approval/disapproval rating of the Peruvian Congress and the agreement/disagreement with a new State Constitution. The model, without further training, predicts 84.0% of disapproval rating for the Peruvian Congress and 75.0% of disagreement with a new State Constitution. Comparing the obtained results against those reported by the specialized Peruvian pollsters, the model predictions correlate to the pollsters' issues. Therefore, the proposed method can be offer as an on-demand tool for text message analysis in social networks.

The remainder of this paper is organized as follows. Section II presents fundamental concepts of sentiment analysis. Section III outlines the literature review related work. Section 4 explains the proposed method. Section V details the experimental results and discussions. Finally, Section VI presents conclusions and future work.

## II. FUNDAMENTALS

### A. Sentiment Analysis

Sentiment analysis or opinion mining is a method into the field of NLP to teach machines to learn, detect and recognize emotional and sentimental information from a given text message [9]. Given an opinion, sentiment analysis can extract its meaning, sense, and emotional charge of the subject who wrote it. Usually, input data for opinion mining consists of text messages stored in structured spreadsheets or in unstructured repositories, such as, text document, web pages, web forums [10].

A common way to detect the sentimental charge of messages is to classify them into categories according their satisfaction or agreement scores. Typical categories can be positive, neutral, or negative sentiment, reflecting a higher satisfaction, none, or dissatisfaction of the subject related to the studied variable [11], [12]. There are many applications using sentiment analyses techniques in the social domain, including the recommendation systems [13], movie reviews

[14], identification of cyber-aggression [15], racism [16] and violence against women [17].

### B. Twitter

Twitter is a messaging service in which subjects can post and interact by means of short messages or tweet [18]. Tweets consist of written opinions related to current topics of interest and can be used as a source of news and information for decision making [19]. Actually, Twitter is the social network most used by politicians because its capability to allows them to communicate massively with thousands of millions of followers [20].

### C. Politician's Approval Rating

In the last decades, it has become a common practice for governments and politicians to know the opinion of people and citizens regarding their activities, decisions, and execution of policies. Such opinions are quantified and presented as a score of popular agreement or disagreement, approval or disapproval, named as approval or favorability rating.

In order to know a reliable approval rating of some politician or a government policy, specialized polling companies carry out statistical surveys in a population sample. Although these studies are reliable, they might present a delayed snapshot of the opinions of people, which are daily changing because of the massive use of communications. As an alternative, opinion mining in Twitter seems to work well like an approval rating method, as presented in Section II-A.

In this work, we study the approval rating of the president of Peru, which is presented monthly by some polling companies. This endorsement rating reflects the citizen's satisfaction related to the work of the government and the implemented policies for the country development. These ratings have many implications: it indicates the aptitude of politicians and the impact of medium and long term polices, reveals the economic strength and politic stability, and the lack or weakens of policies. Therefore, the approval rating becomes an important indicator for decision making for external agents, foreign investors, local entrepreneurs, and Peruvian citizens.

Monthly, historical approval ratings are consolidated in chart plots by several Peruvian polling companies [21], [22], [23], [24]. These results are used for making other studies and forecasting the trend curve. Downward trends indicate bad news: a government weakness and failures in the implementation of policies. For a developing country like Peru, it means capital flight, recession, economic instability, rising unemployment, and disinvestment [25].

## III. LITERATURE REVIEW

The study of [26] concluded that there are high limitations when working with text data originated on Twitter, being the presence of colloquial lexicon, informal syntax, short structure, context-dependent and dynamics nature of messages are the major challenges for mining opinion [3]. NLP methods intend to solve that issues and discover meaning in human utterances and translation [27]. Moreover, the recent rising of deep learning methods in NLP has boost the Sentiment Analysis

field [28], with the goal to discover the meaning of an opinion, its context and sentimental charge.

As follows, we summarize the most relevant works related the topic investigated in this study:

The study of [29] compared a supervised learning model against a simple voting algorithm to classify tweets into three categories (positive, negative, and neutral). First, the tweet sentence is split into words (or token). Next, words are scored according to a lookup table of 2014 positive and 4783 negative words. Each positive word adds one to the sentence score, in contrast each negative word subtracts one to sentence score. The amount of positive words minus the amount of negative words provide the sentiment score of a tweet message. For classification, the voting algorithm just take in account the final score of the tweet: if the score is greater than zero, then the sentence is classified as positive; if the score is zero, then the sentence is negative; otherwise, the sentence is neutral. Following the same criteria, using a dataset of 1500 tweets, they trained a Naive Bayes (NB) classifier, achieving an average accuracy of 81%, against 74% using the simple voting algorithm. The major limitations of this work is that the scoring is strong dependent on the number of words in the lookup table.

Later, the work of [30] applied sentiment analysis in order to know the political opinions of citizens in the Indian electoral process of 2019. They proposed sentiment-based classification model to predict the electoral results. First, a dataset of 3896 tweets were collected from Twitter taking in account the two most popular political parties. Preprocessed messages were classified using the Long Short-Term Memory (LSTM) neural network, achieving a F1-Score of 0.74. In comparison against traditional machine learning (ML) methods, although relatively slow during inference time, LSTM outperforms such other methods.

The study of [9] collected data from Twitter aiming to predict the Congress election outcome in India by using sentiment analysis. To label tweets, they used the Valence Aware Dictionary and Estiment Reasoner (VADER) [31], and used a manual feature extraction [32] which are combined in a bag of words fashion (BoW). For classification, a set of MLs algorithms were compared: Logistic Regression, Decision Tree, XGBoost, Naive-Bayes and Linear Support Vector Machine [33]. Among them, the decision tree method predicted the winner political party with an accuracy of 86.3%.

Next, the study of [18] used Twitter data to analyze the opinion of people against policies of Donald Trump during the Covid-19 pandemic. First, tweet data was recovered by means of the Twitter service using the keyword DONALD TRUMP from February to May 2020. The study does not provide the number of collected tweets. Next, the collected tweets were labeled manually as either of positive or negative sentiment. And finally, for classification, they used two learning algorithms for comparison. The first one, the LSTM model achieved an average accuracy of 69%, whereas, the second one, the NB algorithm, 63%. Again, it is noticeable that LSTM outperforms the traditional ML methods due to its capability of automatic learning features.

Recently, in the context of the COVID-19 pandemic, the work of [10] used sentiment analysis to identify the Brazilian population's perceptions about their Public Health System (named *Sistema Unificado de Saúde* in Portuguese) by analyzing Twitter content. They collected 27500 tweets using the Twitter service with the keywords SAÚDE and SUS. Data was recovered from December 2019 to October 2020. A message is scored based on the polarity of words contained in it and receives a final score, either positive, negative, or neutral. For the whole message processing and scoring, they used a dictionary of emotion lexicons [34] and its implementation in the R language programming [35]. Note that no learning model is used. As results, the authors show word clouds comparing qualitatively the sentiments of people, before and after the pandemic.

In summary, sentiment analysis is a good choice for opinion mining because it can capture underlying characteristics of messages. Among the studies, the majority of them prefer to NN models as a classifier in opposite to ML ones, which resides on hand-crafted features. However, the complex syntax, the short structure, and the use of colloquial lexicon in most of tweets still challenges current methods [3], [28].

Furthermore, yet there is scarce proposals of sentiment analysis in other languages than English, e.g., in Spanish. To the best of our knowledge, in the context of Peru, the study of [36] is a pioneering work aiming to detect cyberbullying in tweet messages written in Spanish, we assume that other works are ongoing or not published yet.

In contrast, in this work we propose a general method for approval rating of Peruvian politicians, which is evaluated in two politic scenarios to measure its generalization capability. The model trained to predict the favorability rating of the President of the Republic of Peru is used to predict the popular support of two hot topics widely discussed in Twitter: the approval rating of the Peruvian Congress and the agreement with a new State Constitution. Our method is simple, but effective, achieving high sensitivity and specificity scores in all tested cases.

## IV. METHODS

The proposed framework for approval rating based on sentiment analysis in Twitter is shown in Fig. 1. This approach is designed to extract tweet posted by Twitter users related to the President of Peru. First, we gather data directly from the web page of Twitter. Next, data is preprocessed in order to prepare input data for the learning model. Then, the proposed model is trained in order to learn how discriminate positive from negative sentiment messages. Once trained the model, it is used as a classifier in order to make prediction of new unknown input data.

Fig. 1. The Proposed Framework.

As follows, we provide an in deep description of each module of the proposed framework:

### A. Dataset

A dataset of 1150 tweets was collected from tweet messages and discussions in Spanish between Peruvian users regarding the President of the Republic of Peru. Due the cost of the Twitter service is prohibitive of us, we used the Beautiful Soup web scrapping library for Python [37].

The data collection about the Peruvian president was conducted from August 2021 to February 2022 using the tags @PEDROCASTILLO and @PRESIDENCIENCIADELPERU, and their related interactions. From August 2021 to January 2022, 900 tweets were collected (150 tweets per month), and during February 2022, 250 messages.

For each discussion topic about the Peruvian Congress (tag @CONGRESOPERU) and the new State Constitution (tag @CONSTITUCIÓN), a short dataset of 200 tweets was recovered in Abril 2022.

The collected tweets of the Peruvian president were labeled manually according to the perceived emotional charge in two categories. Label zero (0) was assigned for approval and label one (1) for disapproval. The Table I shows some tweets and their respective label.

TABLE I. SOME TWEETS OF THE DATASET.

| Tweet | Label |
|---|---|
| This is how to govern for the people! *Así se gobierna para el pueblo!* | 0 |
| Thank you for the effort, president *Gracias por el esfuerzo presidente* | 0 |
| Get to work seriously, stupid *Ponte a trabajar en serio inepto* | 1 |
| I hope you get vacate, idiot *Ojalá te vaquen inútil* | 1 |
| Get rid him, I hate him *Sáquenlo lo odio* | 1 |

### B. Preprocessing

*1) Data Cleaning:* Raw tweet messages contain numeric digits, punctuation symbols, and special characters likewise @, #, ?, !, (, ), $ ,&. All of them must be deleted. Next stop-words (i.e., common words in a language) also must be removed [38]. We used the Natural Language Tool Kit (NLTK) library with stop-words in Spanish [39].

*2) Lematization:* Because tweets can use different ways of a word to express the same meaning, lemmatization intends to reduce the effect of inflectional and derived forms of words to their common base form. For instance, the words blood, bleed and bloody can be represented as the word blood [40].

*3) Tokenization:* During tokenization, each tweet is split into its smallest possible morpheme called word or token [41].

*4) Message Length Standardization:* After tokenization, tweets can have a variable length of words, so the idea is to standardize the length of each tweet. In our approach, we used the average length of words on tweets. This gives us $12.40\pm9.08$ of length, so we decided to fix the length of each tweet to the first 12 words. If a tweet contains words lesser than 12, the message is padded with empty words.

### C. Learning Model

The proposed learning model is based on an end-to-end trainable deep learning neural network [42]. Fig. 2 outlines the proposed model. It consists of the learnable model itself and the sentiment classifier. Considering an input data, the model processes it aiming to predict the likelihood of belonging to the approval or disapproval class.

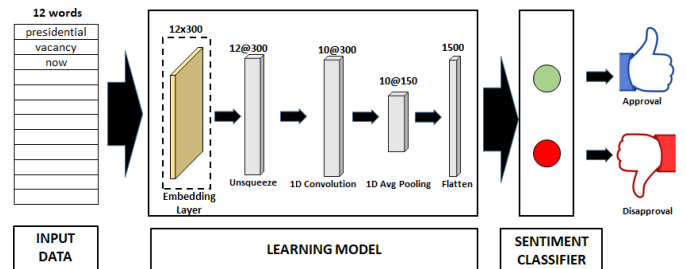

Fig. 2. The Model Architecture.

A brief description of the model is described as follows:

- Word embedding: In NLP, words must to be encoded to be processed by the model. A common encoding method is to use an embedding, which generates a representation vector for each word. Words of the same meaning or similarity will have close feature vectors in the embedding space [5].
  In this work we used the Spanish Billion Words Corpus and Embeddings (SBW). It furnishes an embedding that was pretrained on more than 1.5 billion words of the Spanish language [8]. The embedding produces a 300-dim vector for each word in the input data.

- Squeezing: The input data after embedding has a shape of $12 \times 300$. To be processed in the next layer, we reshape in order to become likewise a 300-dim sequence with a feature map of 12 filters.

- 1D-Convolution: Reshaped embedding vectors are fed to a 1D-CNN layer. The CNN has a kernel of size 3, stride 1, and padding 1. The CNN has 10 neuron filters and the Rectified Linear Unit (ReLU) is used as activation function. Also batch normalization helps us to prevent overfitting.

- Pooling: An average pooling layer, with a kernel of size 2 and stride 2, is used to down-sample the feature maps coming out from the CNN.

- Flatten: After down-sampling, feature maps are flattened and fed into a fully connected layer. The output of the flatten layer is used as feature vector and is used to perform classification.

### D. Sentiment Classifier

The sentiment classifier module implements classification. Given a feature vector, to predict either the approval or disapproval likelihood, we used a fully connected layer of two neurons with a Softmax activation function to furnish prediction (see Fig. 2).

## E. Model Training

In order to train the model in an end-to-end manner, we used the cross-entropy as loss function and the Adam optimizer. In our experiments, the embedding layer is not freezing, but to avoid overfitting we used a low learning rate (1e-5) and a short batch size (16), and the model was trained for just a few epochs (25).

## F. Model Evaluation

To assess the model performance in the dataset of the President of Peru, we split the dataset into training and test set. Tweet data collected from August to December 2021 is the training set, whereas messages from January–February 2022 is the test set.

The model performance is scored using the metrics of sensibility and specificity, being the approval rating the true positives we want to predict.

## V. Results and Discussion of Results

## A. Collected Dataset

We performed collection of tweet related to the President of Peru, from August 2021 to February 2020. Table II summarizes the number of tweets recovered by months.

TABLE II. Dataset about the President of Peru.

| Months | N° Tweets |
|---|---|
| Aug–Dec 2021 | 750 |
| Jan 2022 | 150 |
| Feb 2022 | 250 |

Fig. 3 shows the word cloud or a visual representations of words with more frequency in the collected dataset of the President of Peru.

Fig. 3. The Word Cloud about the President of Peru.

Additionally, we collected a few tweets relate the Congress and the State Constitution of Peru. Table III outlines the number of tweets by the respective topic.

TABLE III. Miscellaneous Data.

| Topic | Months | N° Tweets |
|---|---|---|
| The Congress | Apr 2022 | 200 |
| The State Constitution | Apr 2022 | 200 |

## B. Classification Performance

As exposed in Section IV-F, the trained model was assessed in the data of President collected during January and February 2022. Note that this data is totally unknown for the model. As a results, the model achieved 91.2% of sensitivity and 94.4% of specificity.

In order to provide a historical curve of trend likewise Peruvian pollsters furnish, we used the trained model and 40% of the data for each month to construct the trend curve of the approval/disapproval rating of the President of Peru. Fig. 4 shows the constructed historical curve with our predictions versus the surveys from IPSOS [21].

Fig. 4. Trend Curve of the Approval/Disapproval Rating of the President of Peru. Our Predictions vs IPSOS Surveys.

## C. Classification of Miscellaneous Political Data

In order to evaluate the agnostic ability dealing with political data, we assessed the model in two discussions that attracted the interest of the Peruvians.

1) The approval rating of the Congress of Peru due to the start of the vacancy process against the president and censorship of some ministers.
   In this case, the predicted outputs are considered as an approval/disapproval rate. Fig. 5 outlines the approval/disapproval rating of our model related the Congress of Peru against the results of two renowned pollsters, CPI [24] and IEP [23].

2) The proposal of the current government to change of the state Constitution. In this case, the predicted outputs are considered as an agreement/disagreement

rate. Fig. 6 shows the outcomes of our model against the results of CPI [24].

It is worthwhile to mention that results of the pollsters were recovered from the same period of study, April 2022, aiming to compare against our proposal.

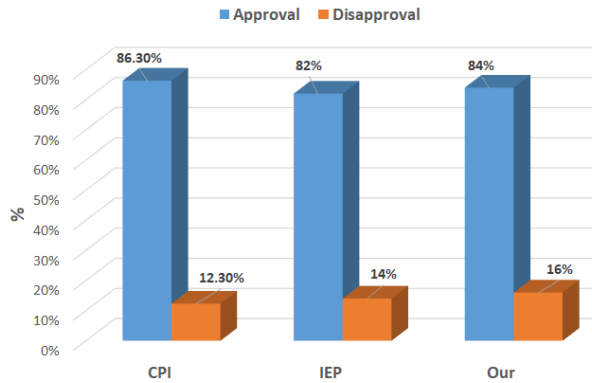

Fig. 5. Approval/Disapproval Rating of the Congress of Peru, Period April 2022.

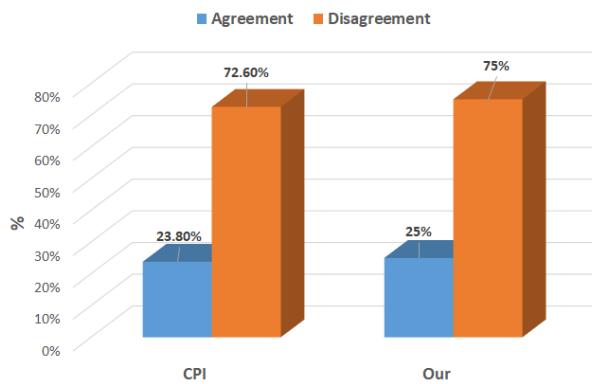

Fig. 6. Popular Agreement/Disagreement to Change the State Constitution of Peru, Period April 2022.

### D. Discussion of Results

Taking into account the first experiment to predict the approval rating of the President of Peru, the proposed model achieved high performance to classify positive and negative latent sentiments in tweet messages.

In order to gain insight whether the model is working as expected, we constructed the historical trend curve of approval rating of the president and compared it with the result of one pollster. We can conclude that our model furnishes reliable predictions (see Fig. 4).

Inspecting the model architecture, although the model can seem too simple, the CNN layer improves the input features and the average pooling gives them a degree of invariance. However, it is worthwhile to mention that the simplicity of the model is compensated with the embedding layer, which was trained in a large corpus of Spanish words [8].

Besides, after analyzing the number of words of messages with politic content, we observed that in political discussions

people prefer to use short messages, usually with harsh words or words with higher sentimental polarity.

Moreover, in order to evaluate the agnostic feasibility of the model to be applied in other politic cases, we tested it in two cases without any fine tuning. In both cases, the model was able to predict close similar results likewise two Peruvian pollsters (see Fig. 5 and Fig. 6).

### VI. CONCLUSION AND FUTURE WORK

In this work, we presented an approach to classify Twitter data in order to predict the approval rating of Peruvian politicians and the polices that they intend to implement. Our approach resides on a convolutional neural network model that is able to detect and score the sentiment polarity of tweet messages. To assess the model, we collected a new dataset of tweets about the current President of Peru and a miscellaneous data about discussions of two topics: the popularity of the Peruvian Congress and the possibility to change the current state Constitution. In all cases, the model provides results comparable to those offered by renowned Peruvian pollsters. So, our proposal is a low cost, agile, and reliable alternative against to the expensive and time-consuming traditional opinion surveys.

As future work, we intend to collect more data from other political discussions for more evaluation of the robustness of the model. Moreover, the model will be improved to take attention to syntactic order and semantic meaning.

# Construction of a Repeatable Framework for Prostate Cancer Lesion Binary Semantic Segmentation using Convolutional Neural Networks

Ian Vincent O. Mirasol, Patricia Angela R. Abu, Rosula S.J. Reyes

Department of Information
Systems and Computer Science
Ateneo de Manila University
Loyola Heights, Philippines

*Abstract*—**Prostate cancer is the 3rd most diagnosed cancer overall. Current screening methods such as the prostate-specific antigen test could result in overdiagonosis and overtreatment while other methods such as a transrectal ultrasonography are invasive. Recent medical advancements have allowed the use of multiparametric MRI — a noninvasive and reliable screening process for prostate cancer. However, assessment would still vary from different professionals introducing subjectivity. While convolutional neural network has been used in multiple studies to objectively segment prostate lesions, due to the sensitivity of datasets and varying ground-truth established used in these studies, it is not possible to reproduce and validate the results. In this study, we executed a repeatable framework for segmenting prostate cancer lesions using annotated apparent diffusion coefficient maps from the QIN-PROSTATE-Repeatability dataset — a publicly available dataset that includes multiparametric MRI images of 15 patients that are confirmed or suspected of prostate cancer with two studies each. We used a main architecture of U-Net with batch normalization tested with different encoders, varying data image augmentation combinations, and hyperparameters adopted from various published frameworks to validate which combination of parameters work best for this dataset. The best performing framework was able to achieve a Dice score of 0.47 (0.44-0.49) which is comparable to previously published studies. The results from this study can be objectively compared and improved with further studies whereas this was previously not possible.**

*Keywords*—*Convolutional neural networks; binary semantic segmentation; prostate cancer; computer vision; deep learning*

## I. Introduction

Prostate cancer (PCa) is the 3rd most diagnosed and the 8th leading cause of death among all cancers; this constitutes to a 7.3% incidence rate and 3.8% mortality rate from 2020 worldwide cancer cases [1].

While the Prostate-Specific Antigen (PSA) test remains to be an effective test at detecting prostate cancer [2], approximately 40% from this screening method were found to be an occurrence of overdiagnosis [3]. This increases the risk of overtreatment leading to unnecessary procedures which yielded conflicting results in terms of benefit [4].

Recent developments in multiparametric magnetic resonance imaging (mpMRI) have provided a reliable non-invasive screening process for detecting clinically significant cancer with great specificity [5], [6] while being non-inferior to a

systematic biopsy [7]. This allows the lesion to be classified in a more specific manner through objective metric scoring measures such as the Prostate Imaging and Reporting Archiving Data System (PI-RADS) [8]. However, the process for scoring requires a qualified professional to observe various images and manually assess the presence and severity of the lesion. It is also worth noting that due to the subjectivity of the assessment, results may vary for different professionals.

Various convolutional neural network (CNN) algorithms have allowed applications in MRI images specific to PCa through prostate organ segmentation and volume estimation, lesion detection, and lesion segmentation [9]. These studies explore the viability of creating an aid for professionals to use as basis and potentially lessen the subjective component of the assessment. But in training and comparing results, the ground-truth is set forth by the professionals' assessment which poses the problem of a standardized ground-truth.

The QIN-PROSTATE-Repeatability (QPR) Dataset [10] is a publicly available annotated dataset. This dataset includes mpMRI images of 15 patients of two studies each with confirmed or suspicion of prostate cancer. These images can be utilized as input and ground-truth.

This study aims to create a pipeline to execute the task of prostate lesion detection and segmentation from an ensemble of frameworks from recent CNN studies to be applied on the QPR dataset for validation.

## II. Statement of the Problem

Results from mpMRI images need to be assessed by a qualified professional (e.g. trained radiologist). The procedure remains to be subjective [6] and may vary from person-to-person. The Prostate Imaging and Reporting Archiving Data System (PI-RADS) provides a systemic scoring for image interpretation and lesion detection [8] but does not completely eliminate the subjectivity of human interpretation.

There have been various studies involving the implementation of CNN to prostate mpMRI images [9]. However, most of the datasets used are not publicly available. Moreover, the ground-truth for various studies involving CNN applications for PCa also varies depending on the qualified professional assigned for the assessment. This results in a lack of stan-

dardization. The results from these studies also could not be objectively compared, reproduced, nor improved.

## III. Scope and Limitations

The study focused on PCa specifically found in the peripheral zone (PZ) only. About 70% of all PCa are found to be in the PZ having the most amount of prostatic glandular tissue [11]. Patients whose lesions were not found within the PZ were not considered. For sequences and views, only the apparent diffusion coefficient (ADC) map was considered. In PI-RADS scoring for PZ PCa, ADC along with diffusion-weighted imaging (DWI) images are used as references for scoring while dynamic contrast-enhanced (DCE) images are used to distinguish between PI-RADS 3 and 4 having T2-Weighted images used as a supplementary [12]. The DICOM files acquired from the QPR dataset for this study is limited to the ADC map only as the DWI images do not contain any available annotated lesion segmentation. However, these images are closely related wherein the ADC map removes the T2-weighting aspect inherent to the DWI. T2-Weighted images were also not considered as these are used as supplementary in PZ PI-RADS scoring.

## IV. Review of Related Literature and Studies

PCa biomedical images are not only scarce and hard to obtain, but they require a lot of resources to manually annotate. While this is the avenue that most studies implement, this introduces variability among datasets. "An overview of publicly available patient-centered prostate cancer datasets" is a paper that summarizes all of publicly available patient-centered PCa datasets with the goal of providing researchers an avenue to select the appropriate dataset needed for their specific field of study [13]. Among the list of datasets within the article, under the imaging category, only the QIN-PROSTATE Repeatability (QPR) dataset had annotated images.

Data image augmentation is a technique used to expand the quantity of images by altering existing images from a dataset. This has been shown to prevent over-fitting and improve the overall accuracy while also being more advantageous to weight decay and dropout which both require fine-tuning of parameters [14]. Isensee et al. achieved the highest score among participants that utilized the U-Net architecture and 2nd place overall for the multi-class brain-tumor segmentation from MRI in the Brain Tumor Segmentation (BraTS) 2018 challenge [15] . This was achieved by using the baseline U-net model while focusing on aggressive data augmentation.

For training modern deep neural networks, it was shown that best results were consistently obtained through smaller batch sizes (2,32) [16]. This was further validated with an experiment on the effects of different batch sizes on a histopathology dataset [17]. Kandel and Castelli ran their model on both Adam and SGD optimizers with a learning rate (LR) set to $1 \times 10^{-4}$ and $1 \times 10^{-3}$. The best AUC was achieved with a batch size of 16, Adam optimizer, and LR set at $1 \times 10^{-4}$.

The U-Net architecture showcased in a paper published in 2015 by Ronneberger et al. proposed a model that can be trained with limited images offset by data augmentation [18]. It tackled the main issues presented with working with medical data such as scarcity of an annotated dataset and the importance of proximal location assessment. Advancements in CNN have allowed the option of combining U-Net with a different backbone for the encoder such as ResNet as well as the inclusion of batch normalization.

Multiple studies have applied U-Net on prostate-related tasks. Three U-Net models were applied to prostate MRI in a study by Bardis et al. in segmenting the prostate, PZ, and TZ separately [19]. The ground-truth was set by a radiologist and achieved Dice scores of 0.94, 0.91, and 0.76 for the prostate, TZ, and PZ segmentation respectively. A paper published in 2019 by Yoon et al. [20] used a CNN pipeline for segmenting the prostate organ, lesion detection, and then make a PI-RADS scoring. The study utilized U-Net for prostate organ segmentation then used R-CNN for lesion detection and segmentation. Moreover, a single board-certified radiologist was used as the ground truth for the manual lesion segmentation. The study achieved lesion segmentation with a Dice score of 0.76. The study by Sanford et al. published in 2020 was a development study that used CNN with the goal of predicting PI-RADS classification [21]. The lesions were segmented and bounded by a professional radiologist which was then the input for the CNN model. A study by Youn et al. published in 2021 [22] explored the viability of using deep learning algorithms for PI-RADS scoring. The study reaffirmed that at varying levels of experience of professional radiologists, the assessment would also vary. The study utilized a deep-learning based software called Prostate AI version 1.2.1 which is currently not available for commercial use.

Specific to lesion segmentation, Liu et al. implemented fuzzy Markov random fields and attained a Dice score of 0.62. A pathologist was used as the baseline for ground-truth and the PZ was manually outlined to be used for segmentation [23]. Kohl et al. used U-Net implemented with adversarial network and achieved a Dice score of 0.41. They used a radiologist for this study to establish their ground-truth. [24]. Dai et al. implemented Mask R-CNN and achieved a Dice score of 0.46 while using a clinician to establish their ground-truth [25]. These studies all have varying ways of establishing their ground-truth and the results show that lesion segmentation remains to be an area with promise for improvement.

## V. Methodology

### A. Image Dataset

The relevant DICOM files were acquired through the QPR dataset [10] which includes segmented mpMRI images of 15 patients with two studies per patient done two months apart. Images extracted that appear to be completely black were removed.

3D Slicer, an open source image computing platform developed for image analysis and visualization [26], was used to view the DICOM files. Within 3D Slicer, the ADC map with their corresponding segmentations were extracted. For each extracted image, the lesion segmentation was set to red within 3D Slicer. This is to maintain a high contrast of the lesion from the original grayscale image to assist in creating the mask.

Even if the patient has a confirmed lesion in the PZ, the lesion can only be seen during specific frames in the ADC sequence. Specifically, only 14.98% of the total images

have the lesion present in them. Only images with the lesion showing was used. The summary of images with lesion and the distribution from the total images can be seen in Table I.

TABLE I. PERCENT DISTRIBUTION OF IMAGES WITH LESION

| Total Images | With Lesion | Distribution |
|---|---|---|
| 434 | 65 | 14.98% |

The ADC maps are available in grayscale of dimensions 272x672 and was cropped into 256x256. Using OpenCV and HSV threshold, the grayscale images with red lesion segmentations were transformed to images with binary masking having a white mask for the lesion on top of a black background. These masks served as the ground-truth for model training.

The Albumentations library [27] was used to implement the various data augmentations. To assess the effect of varying augmentation techniques for the segmentation model, we trained the model with varying levels of augmentation. The augmentations are categorized as the Isensee et al., and extended realistic augmentations.

The following augmentations were adopted from the Isensee et al., (2018) paper:

1) Horizontal Flip - This flips the image horizontally on the y-axis. This particular augmentation is applicable for the prostate as the original MRI scans are symmetric in nature as opposed to medical images wherein regional location is critical (e.g. images with the heart on the left side of an image).

2) Rotate - This rotates the image randomly in degrees within a lower and upper threshold. The threshold was set at -45 to 45 as to maintain realistic scenarios for mpMRI prostate scans (e.g. It would be unlikely to have a scan that would be 90 degrees).

3) Random Sized Crop - This crops the image and scales it back to its original dimensions. The minimum height was set at 162 and the maximum at 192. This allowed the PZ to be captured regardless of where the cropping would occur. This would then be scaled back to 256x256.

4) Random Gamma - This applies a random gamma pixel-wise adjustment on the image. This augmentation technique is viable for the prostate mpMRI scans caused by varying equipment used by different hospitals.

5) Elastic Transform - This applies a more liberal distortion to the image. This can simulate the varying transformations that naturally occur within the prostate.

Other realistic augmentation techniques were implemented to the dataset. These are augmentations that are realistic scenarios for variations in mpMRI scans.

1) Brightness, (BC) - This alters the image's brightness and contrast. This accounts for the variation in the equipment used.

2) Blur - This blurs the input image using a median filter with a random aperture linear size. This accounts for the variation in quality of scans from different equipment.

3) Grid Distortion (GD) - Random distortions are applied per grid width and height with a maximum magnitude. This accounts for the patient's natural movement during breathing as well as expansion and contraction of body parts such as the rectum.

### B. Segmentation

Due to similarities in the dataset and problem being tackled, we chose U-Net as the main architecture for this study. The flexible architecture also allowed us to modify the encoder with ResNet. The architecture comprises of two major segments: the encoding path which consists of four down-convolutions of 2x2 max pooling and a decoding path which is a set of four 2x2 up-convolutions. Batch normalization was applied before each activation. The $\gamma$ and $\beta$ initializers were set to their default values of 1 and 0.

For the model parameters, we used an Adam optimizer with batch size set to 16 and learning rate set at $1 \times 10^{-4}$. The initial epoch was set at 300. For the image sampling, we used a train-test-validation split of 70-15-15.

To avoid overfitting the model, EarlyStopping was added to the training on the validation loss metric with a patience of 30 epochs. This meant that if validation loss did not decrease for 30 straight epochs, training will prematurely terminate and not continue to train for the remaining epochs.

A larger learning rate could possibly result in non-convergence of the model. This was mitigated by adding ReduceLROnPlataeu which decreases the learning rate if there is no improvement on the validation loss with a patience of 20 epochs. The maximum decreased learning rate was set at $1 \times 10^{-7}$ with a reduction factor of 0.1.

Dice score (F1 Score) is a segmentation performance metric that compares the similarity of the predicted mask with the ground-truth mask. This is calculated by having double the intersection of the pixels of the predicted and ground-truth mask divided by the total number of pixels of the predicted mask and the ground-truth mask as shown in (1). The lesion segmentation performance of the model was measured with the average Dice score for the test images.

$$Dice = \frac{2\,|A \cap B|}{|A| + |B|} \tag{1}$$

### VI. RESULTS AND DISCUSSION

Different encoders and model variations were applied to the dataset with Isensee augmentations applied. The results can be seen in Table II.

TABLE II. SUMMARY OF SCORES FOR DIFFERENT MODELS

| Model + Backbone | Dice |
|---|---|
| U-Net | 0.39 |
| U-Net + ResNet34 | 0.36 |
| U-Net + SE-ResNet152 | 0.30 |
| U-Net + SE-ResNet18 | 0.26 |
| U-Net + ResNet152 | 0.26 |
| U-Net + Attention | 0.06 |

The baseline U-Net still outperformed the other variations. The addition of Attention was also not beneficial to this dataset. The decrease in scores when the model gets more complicated could be attributed to the low quantity of images in the dataset. This further validated the statement from the Isensee et al. paper that the generic U-Net architecture can be competitive in segmentation given a proper framework [15].

The model was trained on all possible combinations of Isensee (base augmentation), random brightness and contrast (BC), blur, and grid distortion (GD) augmentations to the base U-Net. The effects of adding augmentations to the base U-Net can be seen in Table III.

TABLE III. SUMMARY OF SCORES FOR DIFFERENT AUGMENTATIONS

| Augmentations | Dice |
|---|---|
| Isensee | 0.392 |
| Isensee + BC | 0.411 |
| Isensee + Blur | 0.466 |
| Isensee + GD | 0.467 |
| Isensee + BC + Blur | 0.416 |
| Isensee + BC + GD | 0.411 |
| Isensee + Blur + GD | 0.256 |
| Isensee + BC + Blur + GD | 0.403 |

Adding realistic augmentations improved the overall score compared to the baseline. However, the combination of using blur and GD together did not result in an increase in score. We believe that the generated training set from the combination of blur and GD augmentations became too distant from the features that were present within the original images while the BC augmentations were not enough to significantly alter them.

The highest Dice score of 0.467 was achieved with Isensee + GD augmentations followed closely by the Isensee + blur augmentations with a Dice score of 0.466. To verify the performance of the framework with Isensee + GD and Isensee + Blur augmentations, each model was trained thrice. Each cycle had new sets of training augmentations with randomized rotations and distortion values fit within the range and tested on the same test images. Dice scores from the Isensee + GD and Isensee + blur runs can be seen in Table IV and Table V, respectively. The results show that the Isensee + GD runs were more consistent than the Isensee + blur runs and implies that the more aggressive augmentation works better for this particular dataset.

TABLE IV. COMBINATION OF ISENSEE AND GD DICE SCORE

| Dice 1 | Dice 2 | Dice 3 | Average |
|---|---|---|---|
| 0.47 | 0.44 | 0.49 | 0.47 |

TABLE V. COMBINATION OF ISENSEE AND BLUR DICE SCORE

| Dice 1 | Dice 2 | Dice 3 | Average |
|---|---|---|---|
| 0.47 | 0.37 | 0.40 | 0.41 |

The average Dice score of the Isensee + GD model was then compared to previously done studies. This can be seen in

Table VI. For this comparison, only the segmentation results that had a similar approach and methodology were considered. The result from the Liu et al. paper [23] was not considered since the their methodology included a preliminary process of manually outlining the PZ while only considering said pixels for segmentation.

TABLE VI. SUMMARY OF SCORES COMPARED TO LITERATURE

| Model | Dice |
|---|---|
| Mask R-CNN (Yoon et al., 2019) | 0.76 |
| U-Net in this study | 0.47 |
| Mask R-CNN (Dai et al., 2020) | 0.46 |
| U-Net (Kohl et al., 2017) | 0.41 |

While this comparison involved studies that were established using different ground-truths, the aim was to have a more standardized comparison with this framework with potential areas for improvement.

## VII. CONCLUSION

In this study, we provided a repeatable framework for prostate lesion segmentation that can be improved and compared with future studies. We used the ADC map and isolated the images that contained lesion as the input for the model trained using various encoders and augmentation combinations. The baseline U-Net with batch normalization trained on images augmented with a combination of Isensee (horizontal flip, random rotation, random sized crop, random gamma, elastic transform) and grid distortion augmentations with batch size of 16 and LR set at $1 \times 10^{-4}$ using Adam optimizer for Dice loss performed best and achieved an average Dice score of 0.47 (0.44-0.49). Furthermore, the QPR dataset shows promise in being a viable standardized dataset for future testing and benchmarking as shown by the comparison of results to other published studies.

## VIII. RECOMMENDATIONS FOR FUTURE WORK

Due to hardware limitations, the study only implemented a hold-out method. However, it is worth considering to implement a k-fold cross-validation technique for performance metrics evaluation and fine-tuning of parameters. Moreover, other models with different encoders could be considered. For the dataset, new augmentation techniques and various combinations may be further explored. Lastly, the use of other mpMRI views aside from the ADC map could be looked into.

*Abstract*—The contact tracing process is a mitigation and monitoring strategy that aims to capture infectious diseases to control their outbreak in a practical time. Various applications have been proposed and developed contact tracing process; most of these applications utilize the smartphone technologies to record all movements of contacts and send notifications to the expected infected ones, either high-risk or low-risk. On the other side, several challenges limit the functionality of contact tracing applications and processes; these limitations include (1) privacy concerns, (2) lack to fully identify contacts, and (3) delays in identification. In this paper, we survey the functionality of the contact tracing process, how its works, open directions and challenges, applications, and its domain of use.

*Keywords*—*Contact tracing; routes analysis; epidemic discovery; big spatial health applications*

## I. INTRODUCTION

In December 2019, the would witness an unprecedented outbreak disease struck Wuhan's city, China [1]. This mysterious disease reveals itself to the globe as Coronavirus disease 2019 (COVID-19). This contagious disease dramatically spread and affected millions of people world wide [2]. This threat leads the World Health Organization (WHO) to trigger an international emergency warning to this unprecedented virus [3]. At the time of writing this paper, WHO reported that the number of people lost their lives is over 500 thousand, and over 10 million others are still struggling and fighting for their survival. This virus is extremely infectious, where it can easily pass from person to person. Hence, to cope with the coronavirus's spread, authorities around the world implemented lockdown measures for months. However, these measurements have significantly affected global economic and social activity.

Governments started to find alternatives to ease the socio-economic catastrophes, the authorities have gradually started to partially left the lockdowns. However, they are still struggling to find efficient techniques to monitor the mobility of potentially COVID-19 infected patients and who have been in contact with a virus infected person. Since people in close contact with someone who is infected with the virus are at higher risk of becoming infected themselves, and of potentially further infecting others, closely monitoring these contacts can prevent further transmission of the virus. This process of this monitoring is known as contact tracing.

The contact tracing process is a mitigation and monitoring strategy that aims to capture infectious diseases to control their outbreak in adequate time. The contact tracing process's main objective is to prevent the onward transmission of infectious diseases by examining the infected individuals and then identifying and examining each individual's contacts. Contacts are defined as all individuals who made direct physical connections to the infected ones; thus, all next-generation suspected cases will be controlled. Various applications have been proposed and developed to serve this process, the majority of these applications utilize the smartphone technologies to record all contacts mobility and send notifications to the expected infected ones, either high-risk or low-risk. On the other side, several challenges limit the functionality of contact tracing applications and processes. These limitations include (1) privacy concerns, (2) lack to fully identify contacts, and (3) delays in identification.

In this paper, we survey the functionality of the contact tracing process, its mechanisms, open directions, challenges, applications, and its domain of use. The survey reviews an extensive collection of models adopted based on the contact tracing process output and serves this domain. Mainly, the contribution of this paper is presenting an integrated view of the contact tracing process as a whole, which will help the researchers understand the functions of the process, identify the challenges and open issues, and inspire them to develop new applications, methods, and models in this domain.

The articles mentioned in the survey have been carefully collected to reflect the impact of applying contact tracing in controlling the spread of epidemics. The main keywords in the search have been formalized to select articles that focus on the definition of contact tracing, the applications of contact tracing in epidemics, the usage of contact tracing to developing statistical models that can predict the spread of the epidemic, and the technologies of contact tracing. These keywords include contact tracing, epidemics, Covid-19, infectious diseases, and epidemic models. The targeted articles have been published between 2003 and 2020. Also, publishers with high reputation have been targeted, such as IEEE, Springer, BMC, and journals of medical internet research (JMIR).

The rest of the paper is organized as follows. Section II presents the standard definitions of contact tracing according to

different perspectives. Section III highlights the importance of contact tracing and main applications that use contact tracing. Section V tries to shed the new directions of contact tracing and the main challenges that face these directions. Section VI presents the typical models that have proposed to simulate the outbreak of epidemics and the impact contact tracing in preventing the spread of epidemics.

## II. DEFINITION OF CONTACT TRACING

This section explores several definitions of the contact tracing process and highlights the different functions that must exist in this process.

In [4], authors define the COVID-19 contact tracing as the process that controls and manages the prevention of the onward transmission of COVID-19 disease by accurately determine and evaluate individuals that had direct physical contact with COVID-19 patient during the past period.

In [5], the authors define the contact tracing process, as the strategies that ensure and confirm the monitoring and controlling of the infectious disease. In [6], [7] authors define the contact tracing process is the process of following and capturing the course of infectious disease, this process starts from investigating the diagnosed cases that confirm their infection to all other individuals that were in physical contact with the patients in the recent past. In [8], authors define contact tracing as an essential procedure needed to fight the outbreak of infectious diseases; like the COVID-19 epidemic.

In [9], the authors define the contact tracing as a process of following up with the contacts that recently reacts with infected people physically. Also, the authors considered the contact tracing process as a mitigation methodology to controls the spread of infectious diseases by identifying, examining, and taking precautions the next-generation cases in a timely fashion.

In [10], the authors define the contact tracing process as a robust disease control strategy that contains and controls the disease by preventing and reducing the disease from transmissions from individual to another. In this regard, this strategy is working by following up infected cases reported, and suspected ones, then isolate them. In addition to, tracing all contacts that come into close physical contacts with theses cases; either infected or suspected. Fig. 1 presents the contact tracing process. This process traces all contacts that deal with an infected patient. Then, the process categorizes these contacts into two categories: (1) infected and (2) not infected. After that, the infected patients are classified into two categories: (1) high-risk contacts; which are contacts that are exposed to death and need special care, and (2) low-risk contacts.

## III. IMPORTANCE AND APPLICABILITY

This section presents the importance of contact tracing in preventing the spread of epidemics and recent applications of this technique.

Authors in [11], [12], [13] explore various methods for contact tracing including pairwise-approximation and fully random simulations methods to tackle and investigate the infected and suspicious cases. Therefore, these methods start by examining the network of contacts that belongs to the

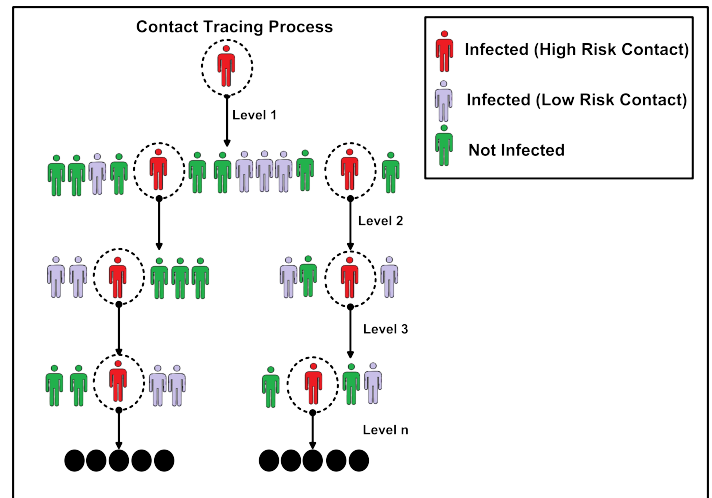

Fig. 1. Contact Tracing Process

infected and suspicious cases. Particularly, This research focus on the significance of studying well the disease-transmission pathways for each person and how to model the contact tracing approaches accurately based on disease-transmission pathways information. In the end, results show that there is a strong relationship between the accuracy of modeling the contact tracing and reproductive ratio of the disease by alert and deal with the infected and suspicious cases by either immediate treatment or isolation.

In [4], the authors highlight and investigate community surveillance roles and guidelines to reduce and prevent the spread of COVID-19 disease. Besides, the authors study how to apply the contact tracing and quarantine for COVID-19. Overall, the spread of COVID-19 disease from individual to another through nasal or oral spray or exhalation or cough of COVID-19 infectious persons. The authors mentioned the importance and criticality of contact and this for performing the quarantine in a good manner and timely fashion. Additionally, the authors classified the contacts that deal with a COVID-19 infectious human into two categories: (1) high-risk contacts, and (2) low-risk contacts. The high-risk contacts are persons that made direct physical contact with COVID-19 infected person or live with the with COVID-19 infected person in the same house. The lower cases are persons that are with COVID-19 infected persons in the same workplace or same environment or travel with the patient through any means of transportation such as; train or bus. Furthermore, the authors highlight the significance of quarantine to prevent and limit the spread of COVID-19 disease, quarantine is the process that restricts the movement of individuals that deal with COVID-19 patients in the past period. The quarantine duration of the COVID-19 identified by the World Health Organization is 28 days. Finally, the authors mentioned challenges that limit the contact tracing process in general. These challenges include: (1) the tracing difficulty of contacts who are traveled via bus or train or any other means of transportation, (2) the inability to track and remember all contacts that deal with COVID-19 patient in the last 14 days, (3) it is difficult to track and find all people that directly contact the COVID-19 patient, particularly if the patient visited wide gatherings like marriage or religious

gatherings or market, and (4) the common fear between the health care staff to trace contacts, as they are thinking they will become infected.

In [14], the authors studied the Ebola virus and concluded that the virus is transmitted from individual to another via physical interaction with the infected patients such as body fluids. Additionally, authors in [15], introduced a study that investigates the Ebola virus contact tracing process, this study aims to perform surveillance for persons that were in exposure for infected patients during 21 days. For this purpose, in [9], the authors propose and develop an Ebola transmission model that adopted contact tracing. This model investigates the perfect timing for contact tracing actions to be done. Also, the authors differentiate the contact tracing delays into three types: (1) initiation delays, (2) contact identification delays, and (3) hospitalization delays. Results showed that quick contact identification and hospitalization can lead to decreasing the spread of the epidemic to 50% compared to delayed identification. In this regard, the authors concluded that starting the contact tracing process at an early stage is a must.

In [16], [17], the authors shed light on using social networking sites (SNS) for contact tracing activities. Additionally, the authors ask the official health sectors and specialized authorities to adopt SNS for controlling and monitoring the evolution of diseases. The authors pay the attention for using SNS because SNS is considered as a significant source of data and knowledge, also the growing popularity of these sites and enriching on several easy portable devices such as; smartphones and tablets, this will provide great opportunities for health sectors to perform the contact tracing in a well-manner.

Mainly, the contact tracing process depends on studying well the contacts network of proximity interactions between persons during the Epidemic period spread. Several attempts have been done to obtain the knowledge of these physical interactions to be investigated. For example in [18], authors get a large scale Facebook data of the interaction between individuals, authors investigate this data to clarify and present the disease dynamics in the community. Additionally, in [19] authors employ wireless sensors to capture face-to-face interactions. In [20], authors describe these attempts as a costly and resources used can be not available or limited to be owned for the majority of people. For this purpose, authors a model for contact tracing based on a mobile phone, and describe the mobile phone as a powerful tool to capture communication traces for the contacts with the proximity interactions. Authors conclude that effective contact tracing can significantly reduce the impact of the Embedic outbreak. Moreover, the contact tracing becomes more effective at the beginning of the Embedic outbreak because the number of contacts that need to be traced is much less than contacts need to be traced after the Embedic evolution. Finally, the authors mentioned that the use of mobile phones to trace contacts can be a valuable option to stop the Embedic outbreak.

In [21], the authors purpose two models for reducing the spread of HIV, these models consider the stochastic screening and contact tracing strategies, these models include (1) differential infection model (DI), and (2) staged-progression model (SP). Overall, the DI model focuses on the individuals'

differences during the disease transmission, while the SP model focuses on more on the time differences for the same infected person. The authors define the stochastic screening and contact tracing as intervention strategies to fight the spread of disease transmission. In this study, the authors formulate various formulas to generate reproductive numbers and identify the equilibrium points during the embedic outbreak. Then, the results produced from either the stochastic screening or the contact tracing are compared in both models. Results showed that in the DI model, the contact tracing strategies are powerfully effective tools to determine and bound the superspreaders of the diseases, and therefore this can assist in reducing the final size of the embedic. This feedback is also consistent with the feedback provided in the following studies [22], [23], [24], [25]. On the other side, the authors highlight that in the SP model the stochastic screening is more effective and has a large effect than contact tracing in limiting and slowing the spread of the disease. Finally, the authors conclude that the effectiveness of the intervention strategies can be determined mainly by the underlying reasons for disease transmission.

In [26], [27] authors presents that due to the incubation long period of Ebola virus, which is 11 days, a massive number can come to physical contacts with infected case and the spread of the disease will grow rapidly. For this purpose, in [10], the authors propose a model that incorporates the contact tracing for prediction and monitoring the reproduction rates for Ebola infection diseases. The purposed model considers various control scenarios, to perform a perfect analysis for Ebola disease characteristics and investigates how these characteristics affect on the effectiveness of the contact tracing process to control the Ebola outbreak. These characteristics include: (1) Ebola disease characteristics, (2) surveillance protocols for infected and suspected cases, (3) reporting time of the infected cases, (4) epidemic incubation period, and (5) intervention time to handle reported cases. Additionally, the authors purpose formula to highlights the critical cases from contacts that are traced to obtain reproduction number ($R_e$) less than one. The formula is as follows: $R_e = k\frac{1-q}{q} + k_m$, where $k$ represents the count of infected contacts that determined in the second iteration per un-traced contacts identified in the first phase, $k_m$ represents the count of infected contacts that determined in the second iteration per traced contacts identified in first phase, $\frac{1-q}{q}$ is the odds that probabilities that the reported contact is not traced. To conclude, $R_e$ production number represents the observation of reported cases per number of contacts traced (observed cases/total number of contacts traced).

Table I summarizes the main papers with their purposes and description in this direction.

## IV. DOMAINS OF USE AND APPLICATIONS

This section presents the importance of contact tracing in preventing the spread of epidemics and recent applications of this technique.

To construct an effective contact tracing application that can identify contacts of infected individuals, the system should be loaded over handheld devices. Mobile phones are used by most people, so developing a mobile application for individuals will enable authorities to effectively identify contacts. Fig.

TABLE I. IMPORTANCE AND APPLICABILITY (SUMMARY)

| Paper | Rational | Information Sources | Study Selection | Keywords | Year |
|---|---|---|---|---|---|
| Contact tracing and disease control | introduced methods for contact tracing including pairwise approximation and fully random simulations methods | Sexual relationships in Manitoba, Canada that contain sexual partnerships between 82 connected individuals together with the presence of chlamydia and gonorrhea infection (A model to predict the spread) | Importance and applicability of Contact racing | tracing efficiency; transmission networks; pairwise approximations; stochastic simulation | 2003 |
| Modeling the impact of random screening and contact tracing in reducing the spread of HIV | Purposed two models for reducing the spread of HIV, these models consider the stochastic screening and contact tracing strategies, these models include (1) differential infection model (DI), and (2) staged-progression model (SP) | Synthetic dataset | Importance and applicability of Contact racing | AIDS; Mathematical modeling; Epidemic modeling; Screening; Contact tracing; Reproductive number; Endemic equilibrium; Sensitivity | 2003 |
| A high resolution human contact network for infectious disease transmission | Employed wireless sensors to capture face-to-face interactions | US 2009 absentee data because of the influenza (H1N1). The dataset covers CPIs of 94% of the entire school population, representing 655 students, 73 teachers, 55 staff, and 5 other persons, and it contains 2,148,991 unique close proximity records | Importance and applicability of Contact racing | disease dynamics; network topology; public health; human interactions | 2010 |
| Dynamics and control of diseases in networks with community structure | Investigated a large-scale Facebook data to clarify and present the disease dynamics in the community | Synthetic dataset | Importance and applicability of Contact racing | dynamics of infectious diseases spread; immunization interventions | 2010 |
| 1) Social Networking Sites as a Tool for Contact Tracing: Urge for Ethical Framework for Normative Guidance. 2) Using Social Networking Sites for Communicable Disease Control: Innovative Contact Tracing or Breach of Confidentiality? | Investigated using social networking sites (SNS) for contact tracing activities to control and monitor the evolution of diseases. | None | Importance and applicability of Contact racing | disease control and surveillance; Social media applications | 2013 |
| Modeling contact tracing in outbreaks with application to Ebola | Proposed a model that incorporates the contact tracing for prediction and monitoring the reproduction rates for Ebola infection diseases. | Data collected from the West Africa (Sierra Leone and Guinea) Ebola outbreak | Importance and applicability of Contact racing | Contact tracing; Ebola; Epidemiology; Mathematical modeling | 2015 |
| Quantifying the impact of early-stage contact tracing on controlling Ebola diffusion | Developed an Ebola transmission model that adopted contact tracing. This model investigates the perfect timing for contact tracing actions to be done | Synthetic dataset (A model to predict the spread) | Importance and applicability of Contact racing | Contact tracing; Ebola; activity-driven network; compartmental model; epidemic model | 2018 |
| Contact Tracing and Quarantine for Covid 19: Challenges in community surveillance | Highlighted and investigated community surveillance roles and 109 guidelines to reduce and prevent the spread of COVID-19 disease | None | Importance and applicability of Contact racing | Quarantine; Contact Tracing | 2020 |

2 shows an example of an effective framework that uses an application loaded over individuals' mobile phones. An individual mobile application can automatically connects with another application in case they are in a specific distance. This can identify the contacts of each individual. The application sends these data to the server to store such data. In case an individual is identified as infected with Covid-19, the contacts of this person will be notified to isolate themselves and to have medical attention. Also, the systems gives the statistics of the spread of Covid-19 for decision makers to decide whether to force quarantine, isolation, or lock-down for specific regions, identified by the application.

On 20-March-2020, the government of Singapore published an application named TraceTogether which uses Bluetooth to track and trace contacts. The TraceTogether application works when two users who use the application are nearby, and a user alerts that he is a COVID-19 patient, the application starts to notify the Ministry of Health to identify the network of contacts logged to be near to them. Additionally, the application communicates with those contacts and reports them with the proper follow-up actions [28].

In [29], the authors utilize the power of smartphone application technology and develop a novel peer-to-peer smartphone application that performs the contact tracing process effectively. The authors sheds the light on the significance of the contact tracing as it is an essential process that restricts the transmission of COVID-19 pandemic. The main objective behind this study is developing a smartphone application that performs the contact tracing and similarly preserves user privacy by not collecting any personal information or any location data. The method adopted in this study that performs contact tracing with preserving the privacy mainly depends on a novel data structure named transmission graph, which

Fig. 2. A Depiction of Contact Tracing Framework based on Real-Time Monitoring of Individuals

consists of nodes and edges, the nodes represent the contact points between the persons, while the edges represent the transmission vectors between contact points. Specifically, each contact point is represented by a node and captures the physical interaction between two or more persons at a particular time and location. Finally, the transmission graph has created a network of interactions between persons and preserves user privacy at the same time.

In [30], [6], the authors describe several procedures for performing the contact tracing process. These procedures include (1) first-order tracing, (2) single-step contact tracing, (3)

iterative contact tracing, and (3) retrospective contact tracing. The first order tracing procedure identifies the individuals that make an immediate direct physical connection with the patient, these individuals require self-isolation and specific medical care handle. Furthermore, the first order tracing procedure does not care about tracing the contacts of the contacts and leave this to happen in the next step "second-order" after the first order has been done successfully. The single-step contact tracing procedure identifies all individuals that contact with the confirmed infected person, and all these individuals are considered as infected, also their contacts are identified and the procedure continues. The Iterative contact tracing procedure, this procedure performs diagnostic tests for all individuals in an iterative way, these tests include symptom screening, and the purpose of this is to discover the infection before its occurrence. The last type is retrospective contact tracing procedure, it follows the same steps of the single-step or iterative procedures, additionally, it investigates the recent past of the infected person and operates in a reverse way to identify all individuals that the patient makes a contact with them. The retrospective contact tracing procedure aims to identify who was the infected person by the disease.

The Australian government has released an application named COVIDSafe. This application aims to control the spread of COVID-19 epidemic, by communication with the expected individuals who are exposures for the infection. the application notifies these individuals and alerts them to take all required immediate precautions [31], [32].

The following studies[5], [29], [33] summarized that the effectiveness of the contact tracing approaches must consider the following: (1) contacts identification, (2) contact notifications, (3) utilizing mobile applications technology for performing automatic contact recording of the movements and direct physical communications, and (4) narrowcast communication via messages.

During the period between 2014 and 2016, the Ebola virus disease (EVD) outbreak has a dangerous effect on the following countries in Africa; such as Liberia, Guinea, and Sierra Leone. As a result, 28,000 cases are reported as infected and above 11,000 deaths as per the study introduced in [34]. In [35], authors developed a smart-phone application named Ebola Contact Tracing application (ECT app), to monitor and trace infected individuals by Ebola in Sierra Leone. This application is integrated with an alert system to report symptomatic individuals and their districts to the response center.

This study [36], discusses how contact tracing is employed by the Liberian authorities to prevent the spread of Ebola during (2014-2015). They uses the official reports of number of cases, provided by the counties, to evaluate the efficiency of the method. Authors build a model that classified the cases into: potential cases to represent cases that had previous symptoms, recovered or died, and Positive Predictive Value (PPV) to represent traced contacts. It applies their analysis over 25,830 contact tracing records of suspected cases during the period from June 4, 2014 to July 13, 2015. These cases represent 26.7% of total EVD cases. Contact tracing showed its ability to detect 3.6% of new cases during its operational time.

Authors in [37] study the spread of the severe acute respiratory syndrome *(SARS)* in Hong Kong in 2003. The authors apply contact tracing over index-cases that have been in hospitals based on questionnaires. Nurses run these questionnaires to identify contacts of index-cases to inform them to isolate themselves and to have medical care. Also, the questionnaires were used to identify the transmission paths to index-cases. Analyzing the questionnaire results allows the authorities to cluster index-cases using multiple criteria, such as demographic (housing and working locations), age (friends and schools), and workplaces. These data allow the authorities to locate the hot-spots to quarantine them and to prevent the spread of the epidemic.

Authors provide a case study analysis for the spread of the Severe Acute Respiratory Syndrome CoronaVirus 2 (SARS-CoV-2) in Wuhan, China. The paper analyzes a dataset of patients in the Shenzhen provenance to identify the efficacy of applying the contact tracing in preventing the spread of the epidemic. The study focuses on applying the contact tracing to detect transmission paths and prevent new infections. The Shenzhen Center for Disease Control and Prevention (CDC) applies contact tracing to track the contacts of infected individuals. Results shows that the prediction of new cases based on contact tracing was very similar to those cases found through traditional surveillance and from hospital records [38].

In [39], the authors provide a study for different non-pharmaceutical interventions (NPI) to mitigate and suppress the spread of Covid-19 epidemic. They classifies the NPIs into two classes: mitigation and suppression interventions. The mitigation interventions aim to reduce the need of healthcare system by protecting people from severe infection. The mitigation interventions include: isolation, quarantine, and social distancing. The suppression aims to minimize the number of new cases and keeps that situation for a long time. Examples of the suppression interventions are: school and university closure and social distancing for long time. The authors provide a study for the impact of each NPI on the spread of Covid-19 and the impact of combining multiple interventions. The authors conduct the study over data collected from China, United Kingdom, and United States. Results show that combining multiple interventions can have a substantial impact in preventing the spread of the epidemic. These interventions affect the economy of the countries on both short and long terms, so countries should choose carefully the suitable NPIs for them.

### A. Sexual Disease Monitoring

The Human Immunodeficiency Virus (HIV) is a serious virus that damages the immune system. It damages and kills the CD4 cells, which makes the patient body vulnerable to get infected with different infections and cancers. The HIV can be transmitted thou rough body fluids, such as blood, semen, breast milk, and rectal fluids [40]. The early detection of the HIV gives a higher probability of patients to get treated.

Dennis et al. [40] propose an integration between contact tracing and phylogenetics to control the spread of HIV in North Carolina (NC). They initiate a routine public screening test for HIV. These tests allow the authorities to identify individuals with acute HIV infection (AHI) [41]. After identifying the infected individuals, they will be investigated to construct networks of suspicious individuals to identify transmission paths and warn infected contacts to get medical care. This

enables the authorities to control the outbreak of the epidemic. Contact tracing enables the authorities to construct a spatiotemporal clustering of infected individuals, which resulted into identifying the increase of AHI among Men that had sex with Men in two regions in NC.

Lin et al. [42] proposed another application of contact tracing in controlling the spread of sexual diseases. They employ contact tracing to identify infected individuals with HIV in Taizhou Prefecture, Zhejiang Province in China. They study collected the data in the period (2008–2010). Data were gathered from volunteers that were subjected to the HIV test. Individuals that have HIV-positive are subjected to surveys to construct a network about their contacts using surveys. The study enables the authorities to identify 463 new HIV-infected cases. The contact tracing starts with 398 as index-cases to construct their network using surveys. Tracking the 398 index-cases results into tracking 1,403 sexual contacts. The early identification of HIV-infected individuals enables the authorities to inform suspicious individuals to have medical care, which decrease the number of late diagnosis that may acquire immunodeficiency syndrome (AIDS).

### B. Social Networking

In [43], the authors discuss how to construct an efficient model that can simulate the dynamics of an epidemic spread in large social contact networks (SCN)s. Large SCNs need huge computation capability to run the simulation algorithms. The authors proposed applying parallel models to simulate huge SCNs to get results in an affordable time. The authors use the high performance computing clusters to run their model in parallel. Running algorithms in parallel needs the SCN to be partitioned. The main problem of SCNs is the distribution skew in these networks as there are some nodes, which are connected to multiple nodes (hubs) and normal nodes connected to a small number of nodes. To partition the hubs, the authors propose splitting the hubs (malls and metros) into fixed splits to run the algorithm over each split in parallel. Also, they propose partitioning the agents (visitors) to mimic the dynamics of the network. The authors test their method over multiple datasets and result show the efficiency of the method.

In [44] the authors propose constructing a model that can simulate the spread of an epidemic. They focus on the social networks of contacts and how can an epidemic propagate in such networks. They consider the heterogeneity of social networks and do not give the same probability to all social network members to get infected at the beginning of the epidemic. They consider the "crowding" or "protection effect" in their model. They develop an Infected-Susceptible-Infected-Recovered (ISIR) model to simulate the spread of an epidemic. Results show that only networks with multiple links have high probability to get infected. Also, they evaluate four immunization strategies and find that the high-degree set and critical set immunization strategies are the best techniques to prevent the spread of the epidemic.

Mainly, to ensure that all contact tracing applications working effectively, they must pass through four stages. Fig. 3 summarize these stages.

The next section describes the new directions of applying contact tracing and the challenges that faces these directions.

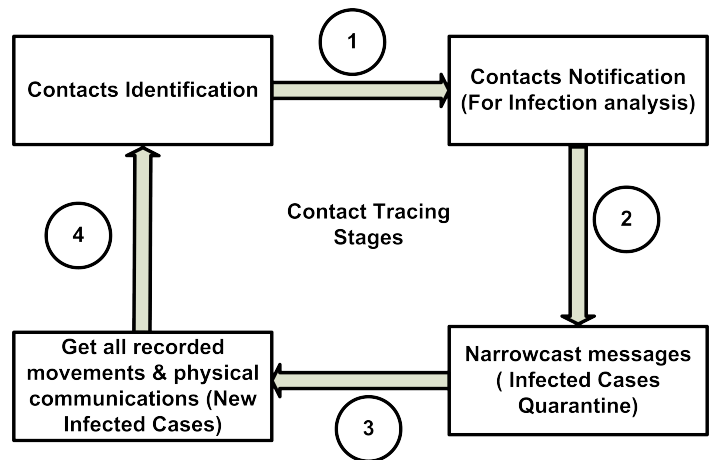

Fig. 3. Contact Tracing Stages

## V. OPEN DIRECTIONS AND CHALLENGES

This section highlights the main challenges of applying contact tracing for real-life applications.

In [8], the authors highlight the privacy concerns as the constraints that limit the functionality of contact tracing applications, and they analyze the implications of these concerns and discussed the ways of improvements. The authors summarized the privacy concerns as following: (1) protection of contacts privacy form the snoopers, (2) ensuring the privacy from contacts, and (3) ensuring the privacy from authorities.

The authors in [45], [46], [47], discussed as classified the challenges in contact tracing process as follows: (1) Inability to fully identify contacts, (2) the lack in reporting systems that adopted on papers, (3) incomplete contact lists, (4) inefficiencies in data collection, (5) transcription errors during the early-stage of the contact tracing, specifically during the contact's identification, and (6) delays in identification and isolation of the suspected individuals from these contacts.

In [48], the authors highlight some challenges that face the contact tracing process such as; the need to involve large labor to trace the contacts efficiently and accurately. For example, (1) the Canadian Health Sector opens the door for a volunteer workforce to perform the tasks of contact tracing and other relevant tasks [49], (2) In South Korea, the governments employed a huge number of medical staff and other workers at the peak of COVID-19 disease outbreak to trace contacts and controls this epidemic [50].

In [51], the authors classify the individual contact tracing methods into two categories: static and dynamic contact tracing methods. Fig. 4 shows a categorization of contact tracing devices according to contact tracing methods. The authors consider that static individual contact tracing to include: questionnaires and surveys. Although these methods have been effective in dealing with sexual diseases [52], [52], they have certain drawbacks that can be summarized into: (1) not giving an online assessment of the epidemic spread, (2) need of labor force (3) time consuming, (4) need to find contacts one by one. Online versions of these methods, such as online questionnaires and online surveys have been proposed to provide an online assessment of the spread of an epidemic [53], [54],
Fig. 4. Categorization of Devices used in Contact Tracing

person when he gets an infection until he becomes non-infectious again.

Fig. 5. Infection Progress of Covid-19

[55]. Despite of their advantages, the authors consider that the online methods still do not give a real-time information for decision makers and users sometimes fill them with incorrect information [56]. Considering the dynamic contact tracing methods, the authors focus on mobile applications, wireless sensors, and GPS [57], [58], [59], [60], [61], [62], [63]. They identify different challenges of these methods. Considering mobile applications, the battery of mobiles represent a great challenge as it has a limited life-time. The wearable sensors are expensive to track a huge number of people and participants do not like to wear them because of privacy issues. The Radio Frequency Identification Devices (RFID)s have a limited range for sending and receiving data. Even the Global Positioning Systems (GPS) devices have limitations as they are not effective to be used in closed areas, such as schools and universities [51].

## VI. Models

This section discusses how researchers can construct models that can describe the spread of epidemics and the impact of applying contact tracing in limiting the outbreak of epidemics.

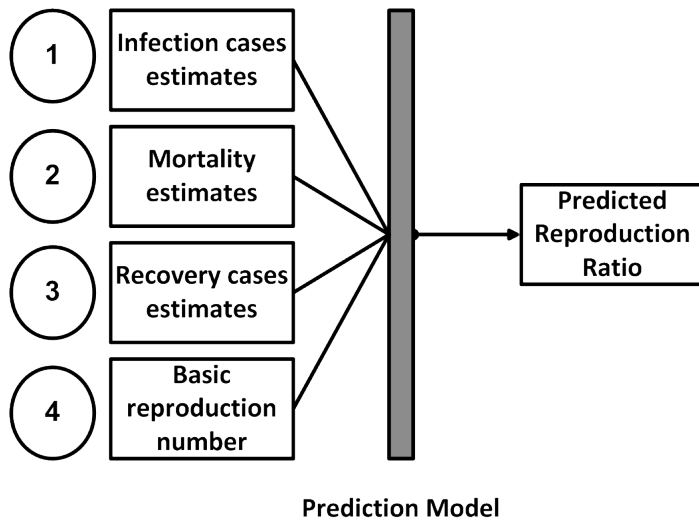
Models are developed to predict the spread of epidemics, they can be classified into two categories: deterministic and stochastic models [64]. The deterministic model is formulated as a system of differential equations, which generates the same solution each time in case the conditions and parameters' values are the same. The main advantage of deterministic models is their ability to show how the initial conditions can affect over the behavior of the model. A stochastic model can be constructed based on differential equations. It has at least one probabilistic parameter, which makes the output changes each time the model is run [64].

In [65], the authors introduce conceptual models to simulate the outbreak of COVID-19 in Wuhan, these models consider the reaction of human behaviors and actions needed from the governments. The objective of these models is to distinguish and understand the future trends of the outbreak and predict the future ratio. Finally, these models can catch the COVID-19 paths and logged all anticipated future trends of the outbreak. The authors use important information about the COVID-19 to build the model correctly. These information include incubation time, time from onset to discharge from hospital or die. Fig. 5 shows the important stages of each
In [66], the authors propose an epidemiological model that depicts reality. This objective of this model is to describe and control the evolution of the diseases and predict individuals with high-risk exposures. The authors admit that the leverage of this model lies in generating the prediction results within a short time and how this will be useful in emergency response systems.

In [67], the authors propose an epidemiological model named "Susceptible-Infectious-Recovered-Dead (SIDR)" model, this model is designed to monitor the evolution of COVID-19 epidemic. The monitoring of the COVID-19 epidemic outbreak is done by providing and predicting the following estimates: (1) estimates about infection cases, (2) estimates about mortality, (3) estimates about recovery rates, and (4) estimates about basic reproduction number. These estimates are generated daily. The objective behind this model is to expect the outbreak evolution of the COVID-19 epidemic three weeks ahead before it happens.

In [30], the authors investigate how the effectiveness of contact tracing can limit the evolution of infectious diseases. The authors investigate a contact tracing model that is appropriate for most infections. Several cases are investigated using this model and result concluded that: (1) the variability of detection time leads to an effective contact tracing, and (2) the iterative tracing can increase the effectiveness, and (3) in general, there is no specific formula to predict the proportion that will be traced.

In [68], the authors focus on constructing a stochastic network-based simulator that can predict the spread of the Covid-19 epidemic. They develop the simulator based on the data gathered from Republic of Kazakhstan, taken as case study. The simulator is based on Susceptible-Exposed-Infectious-Recovered (SEIR) model to represent the transition of individuals among different infection states. To verify the efficacy of the model, authors run the simulator over data collected form Lombardy (Italy). Different parameters have been tuned and the simulator was helpful in predicting the duration and number of infected individuals during the spread of the epidemic.

In [69], the authors develop a stochastic model based on the susceptible-infectious-removed to discuss the effect of applying contact tracing to mitigate the spread of the epidemic.


**Prediction Model**

Fig. 6. Prediction Models (Reproduction Ratio)

Basically, the output of the contact tracing process includes the following: (1) infection cases, (2) mortality cases, and (3) recovery cases. These outputs can be considered as an input for any prediction model that anticipates the reproduction ratio of the infection. Fig. 6 concludes inputs and outputs for prediction models that try to predict the production ratio of infection.

## VII. Conclusion

The contact tracing process is a mitigation and monitoring strategy that aims to capture infectious diseases to control their outbreak in adequate time. In this paper, we reviewed various applications developed contact tracing process, discussed in great detail the challenges that limit contact tracing applications, such as privacy concerns, lack of identifying contacts, and delays in identification fully. In this survey, we have shown how researchers can construct models that can describe the spread of epidemics and the impact of applying contact tracing in limiting the outbreak of epidemics. Finally, We have surveyed and listed open directions, applications, and its domain of use.

They represent the spread of the epidemic in social networks with a graph. This facilitates the task of contact tracing in identifying new suspicious individuals. The model shows the effectiveness of contact tracing in stopping the exponential growth of the epidemic, especially in medium states. Also, the model shows the effectiveness of random screening of individuals in limiting the spread of the epidemic.

In [70], the authors provide a statistical model to evaluate the severity of Covid-19 based on the data collected from Wuhan, Hubei. The data was collected from national and provincial health commissions in Wuhan. They extend their work by including the data of 37 countries to study the fatality of Covid-19 in these countries. The data has been used to provide an estimation for important characteristics of the epidemic, such as time from onset to death or to discharge from hospital, and case fatality ratio. The model applies first over the data collected from China, then the model is applied over the data gathered from other countries. Results shows that the estimations generated from model were very similar to real data collected from the authorities in China and other countries.

In [64], the authors focus on developing a stochastic susceptible-infected-recovered (SIR) model that combines contact tracing to analyze the effect of contact tracing in controlling the spread of epidemics. The methods used the tree structure to simulate the spread of the epidemic. The authors derive equations that can describe the spread of the epidemic and the effect of the intervention tools over the spread rate. These equations are then applied over non-tree contact graphs.

In [71], the authors present an analysis of different models, proposed to simulate the spread of two epidemics: SARS and Middle East Respiratory Syndrome (MERS). The authors defines and discusses the important parameters that can affect on the efficiency of the models, such as the basic reproduction number, incubation period, latent period and infectious period. Also, they extend their work to study the effect of the intervention techniques in mitigating or stopping the spread of the epidemic, such as quarantine, isolation, and contact tracing.

*Abstract*—The outbreak of COVID-19 in 2019 has brought greater international attention to emergency decision making and management. Since emergency situations are often uncertain, prevention and control are crucial. For better prevent and control, according to the characteristics of emergency incidents, the paper proposes a new form of linguistic expression trapezoidal Pythagorean fuzzy probabilistic linguistic variables to express decision-making information. Next, the paper develops the operational rules, value index and ambiguity of trapezoidal Pythagorean fuzzy probabilistic linguistic variables. Then, the new trapezoidal Pythagorean fuzzy probabilistic linguistic priority weighted averaging PROMETHEE approach is introduced to aggregate the trapezoidal Pythagorean fuzzy probabilistic linguistic information combining with preference relation. Finally, an emergency decision making case of prevention of infectious diseases analysis illustrate the necessity and effectiveness of this method, the results of comparative and experimental analyses demonstrate that the constructed new trapezoidal Pythagorean fuzzy probabilistic linguistic priority weighted averaging PROMETHEE approach owns better performances in terms of effectiveness and reasonability.

*Keywords*—*COVID-19; emergency decision model; trapezoidal Pythagorean fuzzy probabilistic linguistic variables; preference relations; PROMETHEE approach*

## I. Introduction

COVID-19 first appeared in Wuhan, China, on December 30, 2019. Due to its pandemic characteristics, long incubation period and strong transmission capacity, COVID-19 is now expanding globally, with more than 133.14 million people infected worldwide as of April 5, 2021, a lot of researchers have done a lot of research on this [1], [2], [3], [4]. This poses a great threat to people all over the world. After the COVID-19 incident happened, China and the international community have paid more attention to emergency management. Hence, how to choose an effective emergency response plan and organize it quickly to reduce casualties and property losses has been reconsidered by governments, public and scholars all over the world. But in real life, all kinds of sudden events occur frequently, and the evolution of abrupt events is often uncertain. This may lead to multiple emergency scenarios. Considering the urgency of emergencies and the complexity of the matter, the emergency command department often organizes many experts from the relevant departments, and the expert may prefer to express their opinion by linguistic terms, just like [5], [6], [7], [8]. For instance, the linguistic term "good", "bad" or "very bad" can be used to express the alternative. Due to the ambiguity and complexity of human cognition, one issue of emergency decision making is how to express the experts evaluations or preference information accurately [9], [10], [11].

In several real situations, professional judgments could not be expressed and interpreted as certain qualitative numbers; In other words, data and certain numbers are insufficient for modeling the real-world systems because of ambiguity and uncertainty in the judgment of decision-makers. In previous researches on emergency management, the linguistic term set (LTS) has been introduced into various emergency decision-making processes, like [12], [13], [14]. Whereafter, Xu et al.[9] applied the probabilistic linguistic term set(PLTS) to emergency management. But the trapezoidal Pythagorean fuzzy probabilistic linguistic term set(TrPFPLTS) has not been applied to emergency management events so far, even the application of PTS to emergency management is rare. In fact, TRPFPLTS has greater flexibility and wider applicability than other PLTS or LTS. It not only allows experts to use more than one linguistic term to express their preference, but also reflects the different probability of occurrence of all possible linguistic terms. At the same time, it is more comprehensive in the expression of fuzzy information. In this study, the paper will select the TRPFPLTS to represent the fuzzy decision information and uncertainty probability of the decision makers(DMs) for the emergency event. Take prevention and control of a local outbreak of infectious diseases as an example. When an infectious disease breaks out somewhere and its source is unknown, the emergency command department invites several experts to assess and judge the infectious ways: population density, air pollution index, number of parks and entertainment equipment,

density of restaurants, density of cultural and educational centers. In different cases, the proportion of influencing factors is different, for that reason it is very necessary to introduce TRPFPLTS to represent the real situation and the behavior of DMs.

It is unlikely that a single expert will consider all aspects of infectious disease control. Multiple attribute group decision making (MAGDM) is to find a collective solution to a decision-making problem in which a group of experts express their opinions regarding multiple alternatives. However even in a friendly environment, a lot of differences across the expert group are generated inevitably, and greatly discordant opinions are aggregated and this may lead to an intermediate opinion with which no expert totally agrees. In MAGDM, the information provided by the experts has different forms. Because of the nature of infectious diseases, it is difficult for emergency response authorities to provide an accurate assessment and determine the route of transmission among the many influencing factors. Therefore, in order to determine the cause of the outbreak of the infectious disease, we introduced a preference relationship(PR) to make a pairwise comparison of the influencing factors. Because linguistic variables are the natural expressions of DMs, researchers often use linguistic preference relations(LPR) to express DMs' subjective preferences. Herrera et al. [15], Liu et al. [16], Liu. p et al. [17] and Dong[18] respectively apply the LPR to multi-attribute group decision making(MAGDM). Due to the neglect of the probabilistic nature of linguistic terms in DMs's judgment, the linguistic preference relation has some limitations. Hence Zhang et al. [19], [20], Alonso et al. [21], Wang et al. [22] put forward different probabilistic language preference relations respectively and applied them to different fields.

It's important to find proper way to aggregate the PRs. So far, various formats of aggregation approach have been put forward to aggregate decision making preferences. Due to the increasing complexity of social problems, more and more researchers are using PROMETHEE approach to provide solutions for DMs through priority relationships, which is based on pairwise comparisons between alternatives. The PROMETHEE method is extremely useful in complex decision making processes, especially real world MAGDM problems involving human perception and subjective judgment of experts. It is worth noting that the PROMETHEE method has considerable advantages when collaboration among specialists are restricted by their distinct fields of expertise. The PROMETHEE method is a robust decision making approach since it determines the relative merits of alternatives by comparing them in pairs, rather than ranking all of them directly. This approach can avoid the round off error which may occur during data normalization. Lolli et al. [23] defined the elicitation of criteria weights in PROMETHEE based ranking methods. Gul et al. [24] propoesed a fuzzy logic based PROMETHEE method for material selection problems.

From the previous research, with the diversity, complexity of the MAGDM problem, although a lot of researches on the PRs at this stage, there are still many defects:

(1) They are limited in their depiction of each person's point of view, using only a single linguistic term to express an evaluation of an object. It can be seen that due to the limited knowledge and the complexity of reality, people often carry out the evaluation with a certain degree of uncertainty. For example, one may use "very good", "good", "somewhat good" to describe the quality of a product, rather than simply "good" or "bad".

(2) They did not fully take into account the poor structural of the information itself, and only considers the fuzziness of the MAGDM problem. Therefore, the paper have made several innovations on the basis of previous studies.

(3) When a simple aggregation operator aggregates group decision information, it retains less information and loses the original information, which seriously leads to the loss of fuzzy information.

Based on the above investigation, we've improved and expanded on previous methods. This paper makes significant contributions on the probabilistic linguistic MAGDM problems:

(1) The paper proposes a new form of linguistic expression trapezoidal Pythagorean fuzzy probabilistic linguistic variables (TrPFPLVs) and trapezoidal Pythagorean fuzzy probabilistic linguistic preference relations (TrPFPLPRs) to express decision-making information.

(2) The paper develop the operational rules, value index and ambiguity index of trapezoidal Pythagorean fuzzy probabilistic linguistic variables (TrPFPLVs).

(3) The paper introduce the new trapezoidal Pythagorean fuzzy probabilistic linguistic priority weight(TrPFPLPW) PROMETHEE approach to aggregate the trapezoidal Pythagorean fuzzy probabilistic linguistic information.

The remainder of this paper is organized as follows. Section 2 reviews the concept of linguistic term sets, probabilistic linguistic term set and probabilistic linguistic preference relationship. Section 3 proposes the TrPFPLVs and TrPFPLPRs to express the MAGDM information, and proposed the operations and operational rules of TrPFPLVs. Section 4 develops TrPFPLPWA-PROMETHEE approach to aggregate the trapezoidal Pythagorean fuzzy probabilistic linguistic information. An emergency decision making model is introduced in Section 5. Section 6 presents a case study: prevention of infectious diseases. The paper ends with some concluding remarks in Section 7.

## II. Preliminaries

This section present some basic definitions to facilitate our presentation.

### A. The Linguistic Term Sets

A linguistic value is less precise than a number, however it is closer to human cognitive process. Therefore it is used to solve uncertain problems successfully. The LTSs are used to express the DMs's opinion over the considered objects, which is initial and totally ordered. It can be defined as follows [25]:

**Definition 1.** *Suppose that* $S = \{s_i | i = -\tau, ..., -1, 0, 1, ..., \tau\}$ *be a pre-established finite and totally ordered discrete linguistic term set, where* $s_i$ *denotes the ith linguistic value of S and* $\tau$ *represents the cardinality of S.*

*In which* $s_i < s_j$ *iff* $i < j$. *Usually, in these cases, it is often required that the linguistic term set satisfies the following additional characteristics [26], [28], [27], [29]:*

(1) *There is the negation operator,* $Neg(\tilde{s}_i) = s_j$ , $j = \tau - i + 1$.
(2) *The maximum operator:* $\text{Max}(s_i, s_j) = s_i$ *if* $s_i \geq s_j$.
(3) *The minimum operator:* $\text{Min}(s_i, s_j) = s_i$ *if* $s_i \leq s_j$.

**Example 1.** *The set of nine terms S could be given as follows[30], [31]:*

$S = \{s_{-4} = extremely\ bad(EB), s_{-3} = very\ bad(VB),$
$s_{-2} = bad(B), s_{-1} = little\ bad(LB), s_0 = general(G),$
$s_1 = little\ good(LG), s_2 = good(G), s_3 = extremely$
$good(EG), s_4 = perfect(P)\},$

*B. Probabilistic Linguistic Term Sets*

In LTSs, each linguistic term value is equally important by default while ignoring the preference information in group decision making. Then Pang et al. [32] defined the PLTS to solve this problem.

**Definition 2.** *Let* $S = \{s_i | i = -\tau, ..., -1, 0, 1, ..., \tau\}$ *be a LTS, the PLTS can be defined as:*

$$L(p) = \{L^{(k)}(P^{(k)}) | L^{(k)} \in S, P^{(k)} \geq 0, k = 1, 2, ..., \#L(p),$$
(1)

*and*

$$\sum_{l=k}^{\#L(p)} P^{(k)} \leq 1\}$$
(2)

*where* $L^{(k)}(P^{(k)})$ *denotes the kth linguistic term* $L^{(k)}$ *with the probability* $P^{(k)}$, *and* $\#L(p)$ *is the number of linguistic terms in* $L(p)$. *For the PLTS* $L(p)$, *let* $p^{N(k)} = p^{(k)} / \sum_{k=1}^{\#L(p)} P^{(k)}(k = 1, 2, ..., \#L(p))$, *then get the normalized PLTS (NPLTS), denoted as* $L(p)^N = \{L^{N(k)}(p^{N(k)}) | k = 1, 2, ..., \#L(p)\}$. *The PLTS is composed of the linguistic terms and the corresponding probabilities rather than the linguistic terms only. To be concise, the elements in the PLTS, i,e.,* $L^{(k)}(p^{(k)})(k = 1, 2, ..., \#L(p))$, *are called probabilistic linguistic elements (PLEs).*

*To conduct computation, some operations are defined[32]:*

*(1)* $L(p)_1 \oplus L(p)_2 = \{L_3^{(k_3)} p_3^{(k_3)} | k_3 = 1, ..., \#L(p)_3\}$, *where* $L_3^{(k_3)} = L_1^{(k_1)} \oplus L_2^{(k_2)}$, $p_3^{(k_3)} = p_1^{(k_1)} p_2^{(k_2)}(k_1 = 1, ..., \#L(p)_1; k_2 = 1, ..., \#L(p)_2)$;

*(2)* $\lambda L(p)_1 = \{\lambda L_1^{(k_1)} p_1^{(k_1)} | k_1 = 1, ..., \#L(p)_1\}$.

*The operational laws related to the linguistic terms in PLTS satisfy[30]:*

*(1)* $s_\alpha \oplus s_\beta = s_{\alpha+\beta}$, , *where* $\lambda \in [0, 1]$;

*(2)* $neg(s_\alpha) = s_{-\alpha}$, *especially,* $neg(s_0) = s_0$.

*(3)* $\lambda s_\alpha = s_{\lambda\alpha}$

*C. Probabilistic Linguistic Preference Relations*

In many MAGDM problems, the experts use the PLTSs to express their preference degrees of one alternative over another. The preference relation with the PLTSs is called PLPR. For a finite set of alternatives $X = x_1, x_2, ..., x_n (n \geq 2)$, the PLPR is defined on the linguistic evaluation scale $S = \{s_\alpha | \alpha = -\tau, ..., -1, 0, 1, ..., \tau\}$.

**Definition 3.** *[33]. Given a PLPR* $B = (L(p)_{ij})_{n \times n} \subset X \times X$ , $L(p)_{ij}$ *indicates the preference degrees of the alternative* $x_i$ *over* $x_j$ *and* $L(p)_{ij}$ *satisfies the following conditions: (1)* $p_{ij}^{(k)} = p_{ji}^k$, $L_{ij}^{(k)} = neg(L_{ji}^{(k)}), L(p)_{ii} = \{s_0(1)\} = \{s_0\}$, $\#L(p)_{ij} = \#L(p)_{ji}$; *(2)* $L_{ij}^k p_{ij}^k \neq L_{ij}^{(k+1)} p_{ij}^{(k+1)}$ *for* $i \neq j, L_{ji}^k p_{ji}^k \geq L_{ji}^{(k+1)} p_{ji}^{(k+1)}$ *for* $i \geq j$.

## III. Trapezoidal Pythagorean Fuzzy Probabilistic Linguistic Variables and Trapezoidal Pythagorean Fuzzy Probabilistic Linguistic Preference Relations

In this part, TrPFPLVs and PPLPRs are introduced.

*A. Trapezoidal Pythagorean Fuzzy Probabilistic Linguistic Variables*

In order to describe the uncertain , complexity and poor structural probabilistic linguistic information more accurately and completely, the paper propose TrPFPLVs to express making decision information.

**Definition 4.** *Let* $\hat{t}_k = ([s_{\varphi_{\tilde{t}_k}}]; \mu_{\tilde{t}_k}(x_k), \nu_{\tilde{t}_k}(x_k); p_{\tilde{t}_k})$ *for all* $k = 1, 2, ..., n$ *be a PFPLVs, where* $s_{\varphi_{\tilde{t}_k}}$ *represents a possible value for a linguistic label, If* $s_{\varphi_{\tilde{t}_k}} = s_{(\alpha_k, \beta_k, \gamma_k, \theta_k)}$, *that is* $\hat{t}_k = ([s_{(\alpha_k, \beta_k, \gamma_k, \theta_k)}]; \mu_{\tilde{t}_k}(x_k), \nu_{\tilde{t}_k}(x_k); p_{\tilde{t}_k})$ *be the TrPFPLV. If* $s_{\varphi_{\tilde{t}_k}} = s_{(\alpha_k, \beta_k, \gamma_k, \theta_k)}$ *and* $\beta_k = \gamma_k$, *which is triangle Pythagorean fuzzy probabilistic variables(TPFPVs).* $\mu_{\tilde{t}_k}(x_k)$ *and* $\nu_{\tilde{t}_k}(x_k)$ *represent the degrees of membership and nonmembership respectively, and satisfy* $0 \leq \mu_{\tilde{t}_k}(x_k) \leq 1$ , $0 \leq \nu_{\tilde{t}_k}(x_k) \leq 1$ *and* $0 \leq \mu_{\tilde{t}_k}^2(x_k) + \nu_{\tilde{t}_k}^2(x_k) \leq 1$. $\pi_{\tilde{t}_k}^2(x_k) = 1 - \mu_{\tilde{t}_k}^2(x_k) - \nu_{\tilde{t}_k}^2(x_k)$ *is interpreted as indeterminacy degree or a hesitancy degree.* $p_{\tilde{r}_k})$ *indicates the degree of certainty of his/her preference for the decision problem.*

Such as his/her preference can be expressed as $([\hat{s}_3]; \mu_{\tilde{r}_k}(x_k), \nu_{\tilde{r}_k}(x_k); 0.5)$, it can be interpreted as he/she is 50% sure that the alternative is bad in comparison with other alternative.

if a decision maker prefers the alternative, he/she will use "positive" linguistic labels, such as "bad" or "little bad", to describe his/her degree of preference. Different "positive" linguistic labels reflect different preference degrees of the DMs. Inspired by [34], [31], the TrPFPLVs set of nine terms $T$ can be given follows:

$$\hat{T} = \{\hat{t}_1 = ([s_0, s_1, s_2, s_3]; \mu_{\tilde{t}_k}(x_k), \nu_{\tilde{t}_k}(x_k); p_{\tilde{t}_k})$$
$$= extremely\ bad(EB),$$
$$\hat{t}_2 = ([s_1, s_2, s_3, s_4]; \mu_{\tilde{t}_k}(x_k), \nu_{\tilde{t}_k}(x_k); p_{\tilde{t}_k})$$
$$= very\ bad(VB),$$
$$\hat{t}_3 = ([s_2, s_3, s_4, s_5]; \mu_{\tilde{t}_k}(x_k), \nu_{\tilde{t}_k}(x_k); p_{\tilde{t}_k})$$
$$= bad(B),$$
$$\hat{t}_4 = ([s_3, s_4, s_5, s_6]; \mu_{\tilde{t}_k}(x_k), \nu_{\tilde{t}_k}(x_k); p_{\tilde{t}_k})$$
$$= little\ bad(LB),$$
$$\hat{t}_5 = ([s_4, s_5, s_6, s_7]; \mu_{\tilde{t}_k}(x_k), \nu_{\tilde{t}_k}(x_k); p_{\tilde{t}_k})$$
$$= general(G),$$
$$\hat{t}_6 = ([s_5, s_6, s_7, s_8]; \mu_{\tilde{t}_k}(x_k), \nu_{\tilde{t}_k}(x_k); p_{\tilde{t}_k})$$
$$= little\ good(LG),$$
$$\hat{t}_7 = ([s_6, s_7, s_8, s_9]; \mu_{\tilde{t}_k}(x_k), \nu_{\tilde{t}_k}(x_k); p_{\tilde{t}_k})$$
$$= good(G),$$
$$\hat{t}_8 = ([s_7, s_7, s_9, s_9]; \mu_{\tilde{t}_k}(x_k), \nu_{\tilde{t}_k}(x_k); p_{\tilde{t}_k})$$
$$= extremely\ good(EG),$$
$$\hat{t}_9 = ([s_8, s_9, s_9, s_9]; \mu_{\tilde{t}_k}(x_k), \nu_{\tilde{t}_k}(x_k); p_{\tilde{t}_k})$$
$$= perfect(P)\}$$

Inspired by Xian's work [35], the paper further propose operational laws for TrPFPLVs to facilitate the calculation.

**Definition 5.** *Let* $\hat{T} = (\hat{t}_1, \hat{t}_2, ..., \hat{t}_n)$ *be the set of all TrPFPLVs, and* $\hat{t}_1 = ([s_{\alpha_1}, s_{\beta_1}, s_{\gamma_1}, s_{\theta_1}]; \mu_{\hat{t}_1}, \nu_{\hat{t}_1}; p_{\hat{t}_1})$, $\hat{t}_2 = ([s_{\alpha_2}, s_{\beta_2}, s_{\gamma_2}, s_{\theta_2}]; \mu_{\hat{t}_2}, \nu_{\hat{t}_2}; p_{\hat{t}_2})$, $\hat{t} = ([s_\alpha, s_\beta, s_\gamma, s_\theta]; \mu_{\hat{t}}, \nu_{\hat{t}}; p_{\hat{t}}) \in \hat{S}$. $\lambda, \lambda_1, \lambda_2 \in [0, 1]$, *their operational laws and properties are defined as follow:*

*(1)* $\hat{t}_1 \oplus \hat{t}_2 = ([s_{\alpha_1+\alpha_2}, s_{\beta_1+\beta_2}, s_{\gamma_1+\gamma_2}, s_{\theta_1+\theta_2}];$
$\sqrt{\mu_{\hat{t}_1}{}^2 + \mu_{\hat{t}_2}{}^2 - \mu_{\hat{t}_1}{}^2 \mu_{\hat{t}_2}{}^2}, \nu_{\hat{t}_1}\nu_{\hat{t}_2}; p_{\hat{t}_1}p_{\hat{t}_2});$

*(2)* $\lambda \odot \hat{t} = ([s_{\lambda\alpha}, s_{\lambda\beta}, s_{\lambda\gamma}, s_{\lambda\theta}]; \sqrt{1 - (1 - \mu_{\hat{t}}{}^2)^\lambda}, \nu_{\hat{t}}^\lambda; p_{\hat{t}});$

*(3)* $\hat{t}_1 \oplus \hat{t}_2 = \hat{t}_2 \oplus \hat{t}_1; \hat{t}_1 \otimes \hat{t}_2 = \hat{t}_2 \otimes \hat{t}_1;$

*(4)* $\lambda \odot (\hat{t}_1 \oplus \hat{t}_2) = \lambda \odot \hat{t}_1 \oplus \lambda \odot \hat{t}_2;$

*(5)* $(\lambda_1 + \lambda_2) \odot \hat{t} = \lambda_1 \odot \hat{t} \oplus \lambda_2 \odot \hat{t}.$

In order to rank alternatives, it is necessary to consider how to compare two TrPFPLVs. Pang et al. [32] defined the comparison between PLTSs, Xian et al. [35] defined the concepts of the compare the TrPFLVs, but there is some set of information can not be compared by the TrPFPVs. Consequently we put forward a method to compare multiple TrPFPVs. In order to do so, in the following, we define the score of TrPFPVs:

**Definition 6.** *Suppose Let* $\hat{t}_k = ([s_{\varphi_{\tilde{r}_k}}]; \mu_{\tilde{r}_k}(x_k), \nu_{\tilde{r}_k}(x_k); p_{\tilde{r}_k})$ *for all* $k = 1, 2, ..., n$ *be a TrPFPLVs, the value index of TrPFPVs are defined as:*

$$L_{\mu_i}(\varphi^+(A_i)) = (m_1\alpha_i + m_2\beta_i + m_3\gamma_i + m_4\theta_i)\mu_i(\varphi^+(A_i))$$
$$(3)$$
$$L_{\nu_i}(\varphi^+(A_i)) = (m_1\alpha_i + m_2\beta_i + m_3\gamma_i + m_4\theta_i)\nu_i(\varphi^+(A_i))$$
$$(4)$$
$$L_{\mu_i}(\varphi^-(A_i)) = (m_1\alpha_i + m_2\beta_i + m_3\gamma_i + m_4\theta_i)\mu_i(\varphi^-(A_i))$$
$$(5)$$

$$L_{\nu_i}(\varphi^-(A_i)) = (m_1\alpha_i + m_2\beta_i + m_3\gamma_i + m_4\theta_i)\nu_i(\varphi^-(A_i))$$
$$(6)$$
$$P_{\mu_i}(\varphi^+(A_i)) = (-m_1\alpha_i - m_2\beta_i + m_3\gamma_i + m_4\theta_i)\mu_i(\varphi^+(A_i))p(A_i)$$
$$(7)$$
$$P_{\nu_i}(\varphi^+(A_i)) = (-m_1\alpha_i - m_2\beta_i + m_3\gamma_i + m_4\theta_i)\nu_i(\varphi^+(A_i))p(A_i)$$
$$(8)$$
$$P_{\mu_i}(\varphi^-(A_i)) = (-m_1\alpha_i - m_2\beta_i + m_3\gamma_i + m_4\theta_i)\mu_i(\varphi^-(A_i))p(A_i)$$
$$(9)$$
$$P_{\nu_i}(\varphi^-(A_i)) = (-m_1\alpha_i - m_2\beta_i + m_3\gamma_i + m_4\theta_i)\nu_i(\varphi^-(A_i))p(A_i)$$
$$(10)$$

*where* $m_1, m_2, m_3, m_4 \in [0, 1]$, $m_1 + m_2 + m_3 + m_4 = 1$. *The value of* $m_1, m_2, m_3, m_4$ *is different and they depend on the degree of preference of the DMs for MAGDM problems.* $\varphi^+(A_i)$ *and* $\varphi^-(A_i)$ *are respectively trapezoidal Pythagorean fuzzy positive dominant flow and trapezoidal Pythagorean fuzzy negative dominant flow, they are introduced in Section 4, which will not be repeated here.*

On the basic of the concept of Definition 6, a method compare between two TrPFPLVs is introduced in detail.

**Definition 7.** *Let* $\hat{t}_k = ([s_\alpha, s_\beta, s_\gamma, s_\theta]; \mu_{\tilde{r}}, \nu_{\tilde{r}}; p_{\tilde{r}})$, $\hat{t}_1 = ([s_{\alpha_1}, s_{\beta_1}, s_{\gamma_1}, s_{\theta_1}]; \mu_{\tilde{r}_1}, \nu_{\tilde{r}_1}; p_{\tilde{r}_1})$, $\hat{t}_2 = ([s_{\alpha_2}, s_{\beta_2}, s_{\gamma_2}, s_{\theta_2}]; \mu_{\tilde{r}_2}, \nu_{\tilde{r}_2}; p_{\tilde{r}_2})$ *be any three TrPFPLVs.*

$$E(\varphi^+(A_i)) = \rho_i L_{\mu_i}(\varphi^+(A_i)) + (1 - \rho_i)L_{\nu_i}(\varphi^+(A_i)) \quad (11)$$

$$E(\varphi^-(A_i)) = \rho_i L_{\mu_i}(\varphi^-(A_i)) + (1 - \rho_i)L_{\nu_i}(\varphi^-(A_i)) \quad (12)$$

$$E(\varphi(A_i)) = \frac{E(\varphi^+(A_i))}{E(\varphi^+(A_i)) + E(\varphi^-(A_i))} \quad (13)$$

$$P(\varphi^+(A_i)) = \rho_i P_{\mu_i}(\varphi^+(A_i)) + (1 - \rho_i)P_{\nu_i}(\varphi^+(A_i)) \quad (14)$$

$$P(\varphi^-(A_i)) = \rho_i P_{\mu_i}(\varphi^-(A_i)) + (1 - \rho_i)P_{\nu_i}(\varphi^-(A_i)) \quad (15)$$

$$P(\varphi(A_i)) = \frac{P(\varphi^+(A_i))}{P(\varphi^+(A_i)) + P(\varphi^-(A_i))} \quad (16)$$

*Where* $\rho_i$ *is a parameter used to demonstrate the different degrees between two alternatives,* $\rho_i \in [0, 1]$. *Then the paper have*

*(1) If* $E(\varphi(A_1)) < E(\varphi(A_2))$, *then* $A_1$ *is smaller than* $A_2$, *denoted by* $A_1 < A_2$.

*(2) If* $E(\varphi(A_1)) = E(\varphi(A_2))$, *then:*

*(a)If* $P(\varphi(A_1)) < P(\varphi(A_2))$, *then* $A_1$ *is smaller than* $A_2$, *denoted by* $A_1 < A_2$.

*(b) If* $P(\varphi(A_1)) = P(\varphi(A_2))$, *then* $A_1$ *and* $A_2$ *represent the same information, denoted by* $A_1 \sim A_2$.

**Example 2.** *If* $\varphi^+(A_1) = ([s_{3.3}, s_{3.9}, s_{4.3}, s_{4.75}]; 0.8329, 0.1000; 0.0039)$, $\varphi^-(A_1) = ([s_{1.5}, s_{2.05}, s_{2.65}, s_{3.25}]; 0.8944, 0.1861; 0.0059)$, $\varphi^+(A_2) = ([s_{2.35}, s_{2.85}, s_{3.4}, s_{3.95}]; 0.8456, 0.1414; 0.0020)$, $\varphi^-(A_2) = ([s_{2.45}, s_{3.05}, s_{3.55}, s_{4.1}]; 0.8372, 0.1414; 0.0013)$, *be four TrPFPLVs, Though Definition 6, we can get*

$L_{\mu_1}(\varphi^+(A_1)) = 3.2418$, $L_{\nu_1}(\varphi^+(A_1)) = 0.4108$, $L_{\mu_1}(\varphi^-(A_1)) = 2.1093$, $L_{\nu_1}(\varphi^-(A_1)) = 0.4389$,

$L_{\mu_2}(\varphi^+(A_2)) = 2.6495$, $L_{\nu_2}(\varphi^+(A_2)) = 0.4430$, $L_{\mu_2}(\varphi^-(A_2)) = 2.7557$, $L_{\nu_2}(\varphi^-(A_2)) = 0.4654$,

*Then though Definition 7, we can get $E(\varphi^+(A_1)) = 0.9770$ , $E(\varphi^-(A_1)) = 0.7730$*

*$E(\varphi^+(A_2)) = 0.8843$ , $E(\varphi^-(A_2)) = 0.9235$,*

*$E(\varphi(A_1)) = 0.5583$ and $E(\varphi(A_2)) = 0.4892$, we can clearly see that $0.5583 > 0.4892$, that is to say $E(\varphi(A_1)) > E(\varphi(A_2))$.*

### B. Trapezoidal Pythagorean Fuzzy Probabilistic Linguistic Preference Relations

In the actual decision-making process, the DMs usually need to express their preference information through pairwise comparison. Because of the ambiguity of information and the incomplete understanding of the preference degree between any pair of alternatives, the DMs can not give the exact membership degree of the preference information. On the basis of Zhang et al. [33], the paper defined the trapezoidal Pythagorean fuzzy probabilistic linguistic preference relations(TrPFPLPRs).

**Definition 8.** *A Trapezoidal Pythagorean fuzzy probabilistic linguistic preference relations (TrPFPLPRs) on the set $X = x_1, x_2, \ldots, x_n$ is represented by a matrix $\tilde{R} = (\tilde{r}_{ij})_{n \times n}$, where $\hat{t}_k = \tilde{r}_{ij} = ([s_{\varphi_{\tilde{r}_{ij}}}]; \mu_{\tilde{r}_{ij}}(x_{ij}), \nu_{\tilde{r}_{ij}}(x_{ij}); p_{\tilde{r}_{ij}})$ for all $i, j, k = 1, 2, \ldots, n$, where $\mu_{\tilde{r}_{ij}}(x_{ij})$ denotes the degree to which the object $x_i$ is preferred to the object $x_j$, $\nu_{\tilde{r}_{ij}}(x_{ij})$ indicates the degree to which the object $x_i$ is not preferred to the object $x_j$, and $\pi_{\tilde{r}_{ij}}(x_{ij}) = 1 - \mu_{\tilde{r}_{ij}}^2(x_{ij}) - \nu_{\tilde{r}_{ij}}^2(x_{ij})$ is interpreted as indeterminacy degree or a hesitancy degree, where $s_{\varphi_{\tilde{r}_{ij}}}$ represents a possible value for a linguistic label, if a decision maker prefers A to B, he/she will use "positive" linguistic labels, such as "good" or "little good", to express his/her preference. Different "positive" linguistic labels reflect different preference degrees of the DMs. $p_{\tilde{r}_{ij}}$ represents the credibility of $s_{\varphi_{\tilde{r}_{ij}}}$ given by the experts when evaluating alternatives and $s_{\varphi_{\tilde{r}_{ij}}} = s_{(\alpha_i, \beta_i, \gamma_i, \theta_i)}$ .*

*For convenience, let $\hat{t}_k = \tilde{r}_{ij} = <[s_{\varphi_{\tilde{r}_{ij}}}]; \mu_{ij}, \nu_{ij}; p_{ij}>$ is TrPFPLVs, with the conditions:*

$$\begin{cases} S = \{s_{\varphi_{\tilde{r}_{ij}}} | \varphi_{\tilde{r}_{ij}} = -\tau, \ldots, -1, 0, 1, \ldots, \tau\} \\ \mu_{ij}, \nu_{ij} \in [0,1], \mu_{ji}, \nu_{ji} \in [0,1], \mu_{ij} = \nu_{ji}, \mu_{ii} = \nu_{ii} = \sqrt{0.5}, \\ \pi_{ij}^2 = 1 - \mu_{ij}^2 - \nu_{ij}^2 \\ p_{ij} \in [0,1], p_{ij} = p_{ji} \end{cases} \quad (17)$$

*where the for all $i, j = 1, 2, \ldots, n$. Specially, the TrPF-PLPR, in which each TrPFPLTS is normalized, is called the normalized TrPFPLPR (NTrPFPLPR), denoted as $\tilde{R}^N = (\tilde{r}_{ij}^N)_{n \times n}$.*

**Remark 1.**

*(1) If neglect the linguistic $s_{\varphi_{\tilde{r}_{ij}}}$ and $p_{\tilde{r}_{ij}}$, that is $\tilde{R} = (\tilde{r}_{ij})_{n \times n} = (\hat{t}_k)_{n \times n} = (\mu_{\tilde{r}_{ij}}(x_{ij}), \nu_{\tilde{r}_{ij}}(x_{ij}))_{n \times n}$, we can get trapezoidal Pythagorean fuzzy preference relations (TrPFPRs).*

*(2) If $0 \le \mu_{\tilde{r}_{ij}}(x_{ij}) + \nu_{\tilde{r}_{ij}}(x_{ij}) \le 1$, we can get trapezoidal fuzzy probabilistic linguistic preference relations (TrFPLPRs).*

*(3) If neglect the linguistic $s_{\varphi_{\tilde{r}_{ij}}}$ and $p_{\tilde{r}_{ij}}$ , $0 \le \mu_{\tilde{r}_{ij}}(x_{ij}) + \nu_{\tilde{r}_{ij}}(x_{ij}) \le 1$ , we can get intuitionistic fuzzy preference relations (IFPRs).*

*(4) If neglect the probabilistic linguistic term set $p_{\tilde{r}_{ij}}$, we can get trapezoidal Pythagorean fuzzy linguistic preference relations (TrPFLPRs).*

## IV. TRAPEZOIDAL PYTHAGOREAN FUZZY PROBABILISTIC LINGUISTIC PRIORITY WEIGHTED AVERAGING PROMETHEE APPROACH

In this part, we propose trapezoidal Pythagorean fuzzy probabilistic linguistic priority weighted averaging PROMETHEE (TrPFPLPWA-PROMETHEE) approach. In dealing with trapezoidal Pythagorean fuzzy probabilistic linguistic making decision problems, it is not enough for traditional aggregation approach to consider only the fuzziness of preference, but it is very important to consider the fuzzy weight among attributes for poor structural making decision problems, so that we develop the TrPFPLPWA-PROMETHEE approach.

### A. Trapezoidal Pythagorean Fuzzy Probabilistic Linguistic Priority Weighted Averaging PROMETHEE

The PROMETHEE method is a classic method to deal with making decision problems. The PROMETHEE method is a sorting method based on levels above relationships. By defining the priority function, it can judge the degree of superiority between alternative according to the difference between the attribute values of each alternative. The value of the priority function is $0 \sim 1$, the smaller the function value is, the smaller the priority degree between the two schemes under the same attribute, and the larger the function value is, the greater the priority degree between the two schemes under the same attribute. It not only considers the fuzzy preference among alternatives, but also considers the weight among attributes. At present, many scholars have done a lot of research on the PROMETHEE, for instance, Le Teno et al.[36]. Therefore in this part, we develop the TrPFPLPWA-PROMETHEE approach.

**Definition 9.** *Let $\hat{t}_k = \tilde{r}_{ij} = ([s_{\varphi_{\tilde{r}_{ij}}}]; \mu_{\tilde{r}_{ij}}(x_{ij}), \nu_{\tilde{r}_{ij}}(x_{ij}); p_{\tilde{r}_{ij}})$ for all $i, j, k = 1, 2, \ldots, n$, then we can get TrPFPLPWA-PROMETHEE approach:*

$$\varphi^+(A_i) = \frac{1}{m-1} \oplus_{k=1, k \ne i}^m r(A_i, A_k) = \frac{1}{m-1} \oplus_{k=1, k \ne i}^m r_{ik} \quad (18)$$

$$\varphi^-(A_i) = \frac{1}{m-1} \oplus_{k=1, k \ne i}^m r(A_k, A_i) = \frac{1}{m-1} \oplus_{k=1, k \ne i}^m r_{ki} \quad (19)$$

*where*

smaller the possibility that other alternatives are better than $A_i$ is. Thus, $\varphi^+(A_i)$ and $\varphi^-(A_i)$ can be used to determine the level between alternatives, $p_i$ and $p_j$ can be interpreted as he/she is $p_i$ or $p_j$ sure that the alternative is bad in comparison with other alternative.

**Theorem 1.** *Let* $\hat{t}_k = \tilde{r}_{ij} = ([s_{\varphi_{\tilde{r}_{ij}}}]; \mu_{\tilde{r}_{ij}}(x_{ij}), \nu_{\tilde{r}_{ij}}(x_{ij}); p_{\tilde{r}_{ij}}) \in \hat{T}(i, j, k = 1, 2, ..., n)$ *be a collection of TrPFPLVs , the trapezoidal Pythagorean fuzzy positive dominant flow and trapezoidal Pythagorean fuzzy negative dominant flow are also TrPFPLV by Definition 9.*

$$\varphi^+(A_i) = \frac{1}{m-1} \oplus_{k=1,k\neq i}^m r(A_i, A_k) \tag{21}$$

$$\varphi^-(A_i) = \frac{1}{m-1} \oplus_{k=1,k\neq i}^m r(A_k, A_i) \tag{22}$$

*where* $r(A_i, A_k) = \left\{ [s_{\sum_{i=1}^n \omega_j \alpha_i}, s_{\sum_{i=1}^n \omega_j \beta_i}, s_{\sum_{i=1}^n \omega_j \gamma_i}, s_{\sum_{i=1}^n \omega_j \theta_i}]; \right.$

$$\left. \sqrt{1 - \prod_{j=1}^n (1 - \mu_{ik}^{2(j)})^{w_j}}, \prod_{j=1}^n \nu_{ik}^{w_j(j)}; p_i^{(j)} p_k^{(j)} \right\} \tag{23}$$

$r(A_k, A_i) = \left\{ [s_{\sum_{i=1}^n \omega_j \alpha_k}, s_{\sum_{i=1}^n \omega_j \beta_k}, s_{\sum_{i=1}^n \omega_j \gamma_k}, s_{\sum_{i=1}^n \omega_j \theta_k}]; \right.$

$$\left. \sqrt{1 - \prod_{j=1}^n (1 - \mu_{ki}^{2(j)})^{w_j}}, \prod_{j=1}^n \nu_{ki}^{w_j(j)}; p_k^{(j)} p_i^{(j)} \right\} \tag{24}$$

**Proof 1.** *According to Definition 5, we can get first result. In the next, we only prove the above formula by using mathematical induction on* $n$.

*For* $n = 2$, *since* $\hat{t}_1 = ([s_{\alpha_1}, s_{\beta_1}, s_{\gamma_1}, s_{\theta_1}]; \mu_{\hat{t}_1}, \nu_{\hat{t}_1}), \hat{t}_2 = ([s_{\alpha_2}, s_{\beta_2}, s_{\gamma_2}, s_{\theta_2}]; \mu_{\hat{t}_2}, \nu_{\hat{t}_2}),$

*then*

$\oplus_{k=1,k\neq i}^m r(A_1, A_2) = \omega_1 \odot \hat{s}_1 + \omega_2 \odot \hat{s}_2 = ([s_{\omega_1\alpha_1+\omega_2\alpha_2}, s_{\omega_1\beta_1+\omega_2\beta_2}, s_{\omega_1\gamma_1+\omega_2\gamma_2}, s_{\omega_1\theta_1+\varpi_2\theta_2}];$
$\sqrt{1 - (1 - \mu_1^2)^{\omega_1}(1 - \mu_2^2)^{\omega_2}}, \nu_1^{\omega_1}\nu_2^{\omega_2})$

*Suppose that, if Eq 20-23 holds for* $n = k, k \in N$, *that is*

$\oplus_{i=1}^k \omega_i \odot \hat{t}_i = ([s_{\sum_{i=1}^k \omega_i \alpha_i}, s_{\sum_{i=1}^k \omega_i \beta_i}, s_{\sum_{i=1}^k \omega_i \gamma_i}, s_{\sum_{i=1}^k \omega_i \theta_i}];$
$\sqrt{1 - \prod_{i=1}^k (1 - \mu_{\hat{t}_i}^2)^{\omega_i}}, \prod_{i=1}^k \nu_{\hat{t}_i}^{\omega_i}).$

*Then, according to the operational laws of Definition 5, when* $n = k + 1$, *we have*

$$\omega_1 \odot \hat{t}_1 \oplus \omega_2 \odot \hat{t}_2 \oplus ... \oplus \omega_k \odot \hat{t}_k \oplus \omega_{k+1} \odot \hat{t}_{k+1}$$
$$= ([s_{\sum_{i=1}^{k} \omega_i \alpha_i}, s_{\sum_{i=1}^{k} \omega_i \beta_i}, s_{\sum_{i=1}^{k} \omega_i \gamma_i}, s_{\sum_{i=1}^{k} \omega_i \theta_i}];$$
$$\sqrt{1 - \prod_{i=1}^{k}(1 - \mu_{\hat{t}_i}{}^2)^{\omega_i}}, \prod_{i=1}^{k} \nu_{\hat{t}_i}{}^{\omega_i})$$
$$\oplus ([s_{\omega_{k+1}\alpha_{k+1}}, s_{\omega_{k+1}\beta_{k+1}}, s_{\omega_{k+1}\gamma_{k+1}}, s_{\omega_{k+1}\theta_{k+1}}],$$
$$\sqrt{1 - (1 - \mu_{k+1}^2)^{\omega_{k+1}}}, \nu_{k+1}{}^{\omega_{k+1}})$$
$$= ([s_{\sum_{i=1}^{k+1} \omega_i \alpha_i}, s_{\sum_{i=1}^{k+1} \omega_i \beta_i}, s_{\sum_{i=1}^{k+1} \omega_i \gamma_i}, s_{\sum_{i=1}^{k+1} \omega_i \theta_i}];$$
$$\sqrt{1 - \prod_{i=1}^{k+1}(1 - \mu_{\hat{t}_i}{}^2)^{\omega_i}}, \prod_{i=1}^{k+1} \nu_{\hat{t}_i}{}^{\omega_i}).$$

*We can see $\oplus_{k=1,k \neq i}^m r(A_i, A_k)$ is still a TrPFPLV, because*

$$\varphi^+(A_i) = \frac{1}{m-1} \oplus_{k=1,k \neq i}^m r(A_i, A_k)$$

$$\varphi^-(A_i) = \frac{1}{m-1} \oplus_{k=1,k \neq i}^m r(A_k, A_i)$$

*Then the aggregating value by TrPFPLPWA-PROMETHEE approach $\varphi^+(A_i)$ and $\varphi^-(A_i)$ is still a TrPFPLV.*

**Theorem 2.** *(Commutativity) $(\hat{t}_1^*, \hat{t}_2^*, ..., \hat{t}_n^*)$ is any permutation of the TrPFPLVs vector $(\hat{t}_1, \hat{t}_2, ..., \hat{t}_n)$, then $TrPFPLPWA - PROMETHEE(\hat{t}_1^*, \hat{t}_2^*, ..., \hat{t}_n^*) =$*

$$TrPFPLPWA - PROMETHEE(\hat{t}_1, \hat{t}_2, ..., \hat{t}_n) \quad (25)$$

**Proof 2.** *Let*

$$TrPFPLPWA - PROMETHEE(\hat{t}_1^*, \hat{t}_2^*, ..., \hat{t}_n^*) = \frac{1}{m-1} \oplus_{i=1}^n \omega_i \odot \hat{t}_i^*$$

$$TrPFPLPWA - PROMETHEE(\hat{t}_1, \hat{t}_2, ..., \hat{t}_n) = \frac{1}{m-1} \oplus_{i=1}^n \omega_i \odot \hat{t}_i$$

*Since $(\hat{t}_1^*, \hat{t}_2^*, ..., \hat{t}_n^*)$ is any permutation of $(\hat{t}_1, \hat{t}_2, ..., \hat{t}_n)$, then we have $\hat{t}_i^* = \hat{t}_i$ for all $i(i = 1, 2, ..., n)$. Consequently*

$$TrPFPLPWA - PROMETHEE(\hat{t}_1^*, \hat{t}_2^*, ..., \hat{t}_n^*)$$
$$= TrPFPLPWA - PROMETHEE(\hat{t}_1, \hat{t}_2, ..., \hat{t}_n)$$

**Theorem 3.** *(Idempotency) If $\hat{t}_i, \hat{t} \in \hat{T}$, and $\hat{t}_i = \hat{t}$ for all $i(i = 1, 2, ..., n)$, where $\hat{t} = ([s_\alpha, s_\beta, s_\gamma, s_\theta]; \sqrt{1 - (1 - \mu_{\hat{t}}^2)}, \nu_{\hat{t}})$, then*

$$TrPFPLPWA - PROMETHEE(\hat{t}_1, \hat{t}_2, ..., \hat{t}_n) = \frac{1}{m-1} \odot \hat{t}$$

**Proof 3.** *Since $\hat{t}_i = \hat{t}$ for all $i(i = 1, 2, ..., n)$, let*

$$TrPFPLPWA - PROMETHEE(\hat{t}_1, \hat{t}_2, ..., \hat{t}_n) = \frac{1}{m-1} \odot \omega_1 \odot \hat{t}_1 \otimes \omega_2 \odot \hat{t}_2 \otimes ... \otimes \omega_n \odot \hat{t}_n$$
$$= \frac{1}{m-1} \odot \omega_1 \odot \hat{t} \otimes \omega_2 \odot \hat{t} \otimes ... \otimes \omega_n \odot \hat{t}$$
$$= \frac{1}{m-1} \odot (\omega_1 + \omega_2 + ... + \omega_n) \odot \hat{t}.$$

*According to and $\sum_{i=1}^n \omega_i = 1$, we have $(\omega_1 + \omega_2 + ... + \omega_n) \odot \hat{t}$*
$$= ([s_{\sum_{i=1}^n \omega_i \alpha}, s_{\sum_{i=1}^n \omega_i \beta}, s_{\sum_{i=1}^n \omega_i \gamma}, s_{\sum_{i=1}^n \omega_i \theta}]; \sqrt{1 - \prod_{i=1}^n (1 - \nu_{\hat{t}})^{\omega_i}}, \prod_{i=1}^n \nu_{\hat{t}}^{\omega_i})$$
$$= ([s_\alpha, s_\beta, s_\gamma, s_\theta]; \sqrt{1 - (1 - \mu_{\hat{t}})^{\sum_{i=1}^n \omega_i}}, \nu_{\hat{t}}^{\sum_{i=1}^n \omega_i})$$
$$= ([s_\alpha, s_\beta, s_\gamma, s_\theta]; \sqrt{1 - (1 - \mu_{\hat{t}}^2)}, \nu_{\hat{t}})$$
$$= \hat{t}.$$

*Hence, $TrPFPLPWA - PROMETHEE(\mu_1, s_1, ..., \mu_n, s) = \frac{1}{m-1} \odot \hat{t}$.*

$$TrPFPLPWA - PROMETHEE(\hat{t}_1, ..., \hat{t}_n)$$

$$< TrPFPLPWA - PROMETHEE(\hat{t}_1^*, ..., \hat{t}_n^*) \quad (26)$$

**Proof 4.** *Let $TrPFPLPWA - PROMETHEE(\hat{t}_1^*, ..., \hat{t}_n^*) = \frac{1}{m-1} \oplus_{i=1}^n \omega_i \odot \hat{t}_i^*$ $= \frac{1}{m-1} \odot \hat{t}_a^*$ $TrPFPLPWA - PROMETHEE(\hat{t}_1, ..., \hat{t}_n) = \frac{1}{m-1} \oplus_{i=1}^n \omega_i \odot \hat{t}_i = \frac{1}{m-1} \odot \hat{t}_a$ Since $\hat{t}_i < \hat{t}_i^*$ for all $i (i = 1, 2, ..., n)$, it follows that $\hat{t}_a < \hat{t}_a^*, i = 1, 2, ..., n$. Then $TrPFPLPWA - PROMETHEE(\hat{t}_1, ..., \hat{t}_n) < TrPFPLPWA - PROMETHEE(\hat{t}_1^*, ..., \hat{t}_n^*)$.*

**Theorem 5.** *(Boundedness) Let $\hat{t}_m = \min_i(\hat{t}_1, \hat{t}_2, ..., \hat{t}_n), \hat{t}_M = \max_i(\hat{t}_1, \hat{t}_2, ..., \hat{t}_n)$, then*

$$\frac{1}{m-1} \odot \hat{t}_m \leq TrPFPLPW - PROMETHEE(\hat{t}_1, ..., \hat{t}_n)$$

$$\leq \frac{1}{m-1} \odot \hat{t}_M \quad (27)$$

**Proof 5.** *Since $\hat{t}_m \leq \hat{t}_i \leq \hat{t}_M$ for all $i = (i = 1, 2, ..., n)$ and $\sum_{i=1}^n \omega_i = 1$, according to Theorem 1-4, we have*

$TrPFPLPWA - PROMETHEE(\hat{t}_1, ..., \hat{t}_n) = \frac{1}{m-1} \odot \oplus_{i=1}^n \omega_i \odot \hat{t}_i$

$\geq \frac{1}{m-1} \odot \omega_1 \odot \hat{t}_m \oplus \omega_2 \odot \hat{t}_m \oplus ... \oplus \omega_n \odot \hat{t}_m = \frac{1}{m-1} \odot (\sum_{i=1}^n \omega_i) \odot \hat{t}_m$

$= \frac{1}{m-1} \odot (\omega_1 + \omega_2 + ... + \omega_n) \hat{t}_m$

$= \frac{1}{m-1} \odot \hat{t}_m.$

$TrPFPLPWA - PROMETHEE(\hat{t}_1, ..., \hat{t}_n) = \frac{1}{m-1} \odot \oplus_{i=1}^n \omega_i \odot \hat{t}_i$

$\leq \frac{1}{m-1} \odot \omega_1 \odot \hat{t}_M \oplus \omega_2 \odot \hat{t}_M \oplus ... \oplus \omega_n \odot \hat{t}_M =$

$\frac{1}{m-1} \odot (\sum_{i=1}^n \omega_i) \odot \hat{t}_M$

$= \frac{1}{m-1} \odot (\omega_1 + \omega_2 + ... + \omega_n) \hat{t}_m$

$= \frac{1}{m-1} \odot \hat{t}_M.$

*Consequently $\frac{1}{m-1} \odot \hat{t}_m \leq TrPFPLPWA - PROMETHEE(\hat{t}_1, ..., \hat{t}_n) \leq \frac{1}{m-1} \odot \hat{t}_M$.*

**Remark 2.** *Let $(\hat{t}_1, \hat{t}_2, ..., \hat{t}_n)$ be a collection of the TrPFPLVs and $W = (\omega_1, \omega_2, ..., \omega_n)^T$ be the weighting vector of the TrPFPLPWA-PROMETHEE with $\omega_i \in [0, 1], \sum_{i=1}^n \omega_i = 1$. Thus,*

*(1) If $W = (\omega_1, \omega_2, ..., \omega_n)^T = (\frac{1}{n}, \frac{1}{n}, ..., \frac{1}{n})^T$, then we get the TrPFPLPA-PROMETHEE approach as follows: $TrPFPLPA - PROMETHEE(\hat{t}_1, ..., \hat{t}_n) = \frac{1}{m-1} \oplus_{i=1}^n \frac{1}{n} \odot \hat{t}_i$*

$= \frac{1}{m-1} \odot ([s_{\frac{1}{n}\sum_{i=1}^n \alpha_i}, s_{\frac{1}{n}\sum_{i=1}^n \beta_i}, s_{\frac{1}{n}\sum_{i=1}^n \gamma_i}, s_{\frac{1}{n}\sum_{i=1}^n \theta_i}],$

$\sqrt{1 - [\prod_{i=1}^n (1 - \mu_{\hat{t}_i}^2)]^{\frac{1}{n}}}, (\sum_{i=1}^n \nu_{\hat{t}_i})^{\frac{1}{n}}).$

*(2) If $W = (\omega_1, \omega_2, ..., \omega_n) = (1, 0, ..., 0)^T$, then $TrPFPLPA - PROMETHEE(\hat{t}_1, ..., \hat{t}_n) = \frac{1}{m-1} \odot \max_i \hat{t}_i$.*

*(3) If $W = (\omega_1, \omega_2, ..., \omega_n) = (0, 0, ..., 1)^T$, then $TrPFPLPA - PROMETHEE(\hat{t}_1, ..., \hat{t}_n) = \frac{1}{m-1} \odot \min_i \hat{t}_i$.*

*(4) If $\omega_i = 1, \omega_j = 0, i \neq j$, then $TrPFPLPA - PROMETHEE(\hat{t}_1, ..., \hat{t}_n) = \frac{1}{m-1} \odot \hat{t}_{a_i}$, where $\hat{t}_{a_i}$ is the ith largest of $\mu_{\hat{t}_i}$.*

**Remark 3.** *Let $\hat{t}_k = \tilde{r}_{ij} = ([s_{\varphi_{\tilde{r}_{ij}}}]; \mu_{\tilde{t}_{ij}}(x_{ij}), \nu_{\tilde{t}_{ij}}(x_{ij}); p_{\tilde{t}_{ij}})$ be TrPFPLSs, if $0 \leq \mu_{\hat{t}}(x_i) + \nu_{\hat{t}}(x_i) \leq 1$, we can get TrIFPLSs.*

**Remark 4.** *Let $\hat{s} = ([s_{\alpha_i}, s_{\beta_i}, s_{\gamma_i}, s_{\theta_i}]; \mu_{\hat{t}_i}, \nu_{\hat{t}_i})$ be the TrPFLV, if $s_{\beta_i} = s_{\gamma_i}$, we have triangle Pythagorean fuzzy probabilistic linguistic variables (TPFPLVs).*

**Remark 5.** *If $\hat{t}_k = \tilde{r}_{ij} = ([s_{\varphi_{\tilde{t}_{ij}}}]; \mu_{\tilde{t}_{ij}}(x_{ij}), \nu_{\tilde{t}_{ij}}(x_{ij}))$ be*

*TrPFLSs, we have trapezoidal Pythagorean fuzzy linguistic variables (TrPFLVs).*

**Remark 6.** *If* $\hat{t}_k = \tilde{r}_{ij} = (\mu_{\tilde{r}_{ij}}(x_{ij}), \nu_{\tilde{r}_{ij}}(x_{ij}); p_{\tilde{r}_{ij}})$ *be PFPLSs, we have Pythagorean fuzzy probabilistic linguistic variables(PFPLVs).*

**Remark 7.** *If* $\hat{t}_k = \tilde{r}_{ij} = ([s_{\varphi_{\tilde{r}_{ij}}}]; p_{\tilde{r}_{ij}})$ *is a linguistic sets (LSs), if* $s_{\varphi_{\tilde{r}_{ij}}} = s_{\alpha_i}, s_{\beta_i}, s_{\gamma_i}, s_{\theta_i}$; *we have trapezoidal probabilistic linguistic sets (TrPLSs).*

## V. An Emergency Decision making Model in the Poor Structural's Trapezoidal Pythagorean Fuzzy Probabilistic Linguistic Environment

**Step 1.** In an emergency decision making problem , there are $l$ alternatives $X = x_1, x_2, ..., x_l$ and $q$ attributes $A = A_1, A_2, ..., A_q$, whose weight vector is $W = (\omega_1, \omega_2, ..., \omega_q)$ be the set of attributes, where the $\sum_{i=1}^{q} \omega_i = 1$. Let $E = e_1, e_2, ..., e_m$ be the set of decision makers.

$$R^{(z)} = \begin{bmatrix} \hat{r}_{11}^{(z)} & \hat{r}_{12}^{(z)} & ...... & \hat{r}_{1q}^{(z)} \\ \hat{r}_{21}^{(z)} & \hat{r}_{22}^{(z)} & ...... & \hat{r}_{2q}^{(z)} \\ . & . & ...... & . \\ . & . & ...... & . \\ . & . & ...... & . \\ \hat{r}_{l1}^{(z)} & \hat{r}_{l2}^{(z)} & ...... & \hat{r}_{lq}^{(z)} \end{bmatrix}$$

where $\hat{r}_{ij}^{(z)} = ([s_\alpha.s_\beta, s_\gamma, s_\theta]; \mu_{\hat{t}_{ij}}, \nu_{\hat{t}_{ij}}; p_{ij})$ be a TrPFPLV, and $\mu_{\tilde{r}_{ij}}, \nu_{\tilde{s}_{ij}}, p_{ij} \in [0,1], 0 \le (\mu_{\tilde{t}_{ij}})^2 + (\nu_{\tilde{t}_{ij}})^2 \le 1$. $\hat{r}_{ij}^{(z)} = ([s_\alpha.s_\beta, s_\gamma, s_\theta]; \mu_{\hat{r}_{ij}}, \nu_{\hat{r}_{ij}}; p_{ij})$ represents expert z's preference for attribute $x_i$ in attribute $x_j$.

**Step 2.** By formula (19): $r(A_k, A_i) = \oplus_{j=1}^{n}(w_j \oplus r_{ik}^{(j)}) = \left\{ [s_{\sum_{i=1}^{n} \omega_j \alpha_i}, s_{\sum_{i=1}^{n} \omega_j \beta_i}, s_{\sum_{i=1}^{n} \omega_j \gamma_i}, s_{\sum_{i=1}^{n} \omega_j \theta_i}]; \sqrt{1 - \prod_{j=1}^{n}(1 - \mu_{ik}^{2(j)})^{w_j}}, \prod_{j=1}^{n} \nu_{ik}^{w_j(j)}; p_i^{(j)} p_k^{(j)} \right\}$ to obtain the collective overall preference TrPFPLV and construct the TrPFPLPR matrices of the attributes $T^{(z)} = (\hat{t}_{ij}^{(z)})_{l \times l}$:

$$T^{(z)} = \begin{bmatrix} \hat{t}_{11}^{(z)} & \hat{t}_{12}^{(z)} & ...... & \hat{t}_{1l}^{(z)} \\ \hat{t}_{21}^{(z)} & \hat{t}_{22}^{(z)} & ...... & \hat{t}_{2l}^{(z)} \\ . & . & ...... & . \\ . & . & ...... & . \\ . & . & ...... & . \\ \hat{t}_{l1}^{(z)} & \hat{t}_{l2}^{(z)} & ...... & \hat{t}_{ll}^{(z)} \end{bmatrix}$$

where $\hat{t}_{pn}^{(z)} = ([s_\alpha.s_\beta, s_\gamma, s_\theta]; \mu_{\hat{r}_{pn}}, \nu_{\hat{r}_{pn}}; p_{pn})$ be a TrPFPLV, and $\hat{t}_{pn}^{(z)}$ represents the degree to which attribute $A_p$ is superior to attribute $A_n$

**Step 3.** By Definition 9, further calculate trapezoidal Pythagorean fuzzy positive dominant flow and trapezoidal Pythagorean fuzzy negative dominant flow.

$$\varphi^+(A_i) = \frac{1}{m-1} \oplus_{k=1,k\neq i}^{m} r(A_i, A_k) = \frac{1}{m-1} \oplus_{k=1,k\neq i}^{m} r_{ik}$$

$$\varphi^-(A_i) = \frac{1}{m-1} \oplus_{k=1,k\neq i}^{m} r(A_k, A_i) = \frac{1}{m-1} \oplus_{k=1,k\neq i}^{m} r_{ki}$$

**Step 4.** Calculate $L_{\mu_i}(\varphi^+(A_i))$, $L_{\nu_i}(\varphi^+(A_i))$, $L_{\mu_i}(\varphi^-(A_i))$, $L_{\nu_i}(\varphi^-(A_i))$ by Definition 6.

**Step 5.** Calculate$E(\varphi^+(A_i))$ and $E(\varphi^-(A_i))$ by Definition 7.

**Step 6.** Finally, we can calculate $E(\varphi(A_i))$ to obtain the ranking results by Definition 7.

## VI. Case Study: Application to Prevention of Infectious Diseases

In this section , we apply the above method to an application in emergency decision support for the prevention of infectious diseases to illustrate the proposed method, and supplies some discussions about the results. In late December 2019, the outbreak of COVID-19 in Wuhan, China, brought global attention to infectious diseases. An epidemic of infectious diseases appears somewhere and is difficult to control. To address the problem, the local health organization invited five experts($e_1, e_2, e_3, e_4$) to make decisions on population density($A_1$), air pollution index($A_2$), number of parks and entertainment equipment($A_3$), density of restaurants($A_4$), density of cultural and educational centers($A_5$) in a certain area to prevent and control the spread the disease.

**Step 1.** The experts made a decision based on the factors that might affect the infectious disease and established a decision matrix, as shown in Table I to Table III:

**Step 2.** Constructing the matrix by formula (7), and supposed $\omega_1 = (0.2)$, $\omega_2 = (0.2)$, $\omega_3 = (0.2)$, $\omega_4 = (0.2)$, $\omega_5 = (0.2)$, the decision matrix of the attributes which is shown in Tables IV, V and VI:

**Step 3.** Calculate trapezoidal Pythagorean fuzzy positive dominant flow and trapezoidal Pythagorean fuzzy negative dominant flow:

$\varphi^+(A_1) = \frac{1}{m-1} \oplus_{k=1,k\neq i}^{m} r(A_1, A_k) = \frac{1}{m-1} \oplus_{k=1,k\neq i}^{m} r_{1k}$
$= \frac{1}{5-1} * \{([s_{3.6}, s_{4.2}, s_{4.6}, s_{5.2}]; 0.8072, 0.1800; 0.3360) \oplus ([s_{3.6}, s_{4.2}, s_{4.6}, s_5]; 0.8589, 0.0480; 0.0.5040)$
$\oplus ([s_{1.6}, s_{2.2}, s_{2.8}, s_{3.4}]; 0.8932, 0.1920; 0.0800) \oplus ([s_{4.4}, s_5, s_{5.2}, s_{5.4}]; 0.7314, 0.0840; 0.2880)\}$
$= ([s_{3.3}, s_{3.9}, s_{4.3}, s_{4.75}]; 0.8329, 0.1000; 0.0039)$

$\varphi^-(A_1) = \frac{1}{m-1} \oplus_{k=1,k\neq i}^{m} r(A_k, A_1) = \frac{1}{m-1} \oplus_{k=1,k\neq i}^{m} r_{k1}$
$= \frac{1}{5-1} * \{([s_{1.2}, s_{1.8}, s_{2.4}, s_3]; 0.8887, 0.3360; 0.5040) \oplus ([s_{1.2}, s_{1.8}, s_{2.4}, s_3]; 0.9360, 0.1960; 0.5040)$
$\oplus ([s_{3.2}, s_{3.6}, s_{4.2}, s_{4.8}]; 0.8075, 0.0420; 0.0800) \oplus ([s_{0.4}, s_1, s_{1.6}, s_{2.2}]; 0.9101, 0.4320; 0.2880)\}$
$= ([s_{1.5}, s_{2.05}, s_{2.65}, s_{3.25}]; 0.8944, 0.1861; 0.0059)$

Similarly, we can get

$\varphi^+(A_2) == ([s_{2.35}, s_{2.85}, s_{3.4}, s_{3.95}]; 0.8456, 0.1414; 0.0020)$

$\varphi^-(A_2) == ([s_{2.45}, s_{3.05}, s_{3.55}, s_{4.1}], 0.8372, 0.1414; 0.0013)$

$\varphi^+(A_3) = ([s_{2.4}, s_{2.95}, s_{3.5}, s_{4.05}]; 0.8981, 0.1000; 0.0223)$

$\varphi^-(A_3) = ([s_{2.4}, s_{2.9}, s_{3.45}, s_4], 0.8099, 0.1000; 0.0223)$

$$\varphi^+(A_4) = ([s_2, s_{2.5}, s_{3.1}, s_{3.86}]; 0.6424, 0.1000; 0.0002)$$

$$\varphi^-(A_4) = ([s_{2.8}, s_{3.25}, s_{3.85}, s_{4.45}], 0.8196, 0.1000; 0.0003)$$

$$\varphi^+(A_5) = ([s_{1.95}, s_{2.45}, s_{3.05}, s_{3.65}]; 0.8456, 0.1189; 0.0030)$$

$$\varphi^-(A_5) = ([s_{2.8}, s_{3.25}, s_{3.85}, s_{4.45}], 0.8456, 0.1000; 0.0003)$$

Hence, the trapezoidal Pythagorean fuzzy dominant flow can be shown in Table VII.

**Step 4.** Calculate $L_{\mu_i}(\varphi^+(A_i))$, $L_{\nu_i}(\varphi^+(A_i))$, $L_{\mu_i}(\varphi^-(A_i))$, $L_{\nu_i}(\varphi^-(A_i))$ by Definition 6, which is shown in Table VIII.

**Step 5.** Calculate $E(\varphi^+(A_i))$ and $E(\varphi^-(A_i))$ by Definition 9.

Therefore, Value index of $A_i$ is shown in Table IX.

**Step 6.** Finally, we can calculate $E(\varphi(A_i))$ to obtain the ranking results by Definition 9.

Obviously, from Table X, the ranking order is shown as

$$A_3 > A_1 > A_2 > A_5 > A_4$$

We can see that the third influencing -number of parks and entertainment equipment-is the biggest for infectious diseases. the second is the effect of population density. Thus it can be seen that the prevention and control of infectious diseases should be prioritized from the park recreation facilities. Under certain control, then start from the population mobility, because of the high population density.

To illustrate the rationality of our proposed approach in dealing with emergent decision problems, some comparative analysis is performed for the above example if we use the aggregate method shown in Table XI.

The results calculated by different methods are shown in the Fig. 1.

Fig. 1. Ranking Results

We can obtain $A_1 > A_3 > A_2 > A_5 > A_4$ by TrPFLECOWA and $A_3 > A_1 > A_2 > A_5 > A_4$ by TrPFLECOWMD. It can be seen from the results that the influencing factors $A_1$, $A_3$ of infectious diseases have different order. The reason is that some information is lost in the fuzzy linguistic environment due to indeterminacy, the relationship between influencing factors is ignored, and the occurrence probability of each influencing factor is not considered in the emergency situation. It is difficult for experts to make reasonable evaluation when making uncertain decisions in emergency situations, hence it is very important to introduce probability language in the poor structural's emergency decisions. Compared with other decision making methods, this paper proposed method has the following advantages:

(1) The TrPFPLVs can describe the fuzzy probability language and its probability, and it is reasonable to make decision in the uncertain environment of emergency.

(2) The TrPFPLPWA-PROMETHEE approach mainly considers the deviation measure between alternatives or attributes, hence it can deal with the decision information with incomplete structure. It is more malleable and applicable in the poor structural's emergency decisions.

## VII. CONCLUSION

The existing methods are limited and defective in terms of tackling MAGDM problems with TrPFPLVs. In addition, the researches on the aggregate operator for TrPFPLV are blank. The aim of this paper is to solve these problems. The case analysis show that the new decision-making approach can not only derive the ideal alternative efficiently, but conquer demerits of the existing methods. The contributions of this paper are summarized in the following:

(1) Compared with trapezoidal Pythagorean fuzzy linguistic variables in [37], [38], [39], [40], [41], a finer variable has been introduced to deal with complex decision-making environment, a new form of linguistic expression trapezoidal Pythagorean fuzzy probabilistic linguistic variables (TrPFPLVs) have been presented to express decision-making information.

(2) Compared with fuzzy linguistic weight averaging operator in [30], [31], [37], [35] , a more complete operator has been introduced to aggregate the trapezoidal Pythagorean fuzzy probabilistic linguistic information, which is the new trapezoidal Pythagorean fuzzy probabilistic linguistic priority weight averaging (TrPFPLPWA) PROMETHEE approach.

(3) Relying on trapezoidal Pythagorean fuzzy probabilistic linguistic variables, this paper develop the operational rules, value index and ambiguity index of trapezoidal Pythagorean fuzzy probabilistic linguistic variables (TrPFPLVs).

In future studies, the TrPFPLPWA-PROMETHEE approach shall further combine with different decision-making models and extend the applications of the proposed method to other domains.

## ETHICAL STATEMENT

### AUTHORSHIP CONTRIBUTIONS

(1) This paper propose a new form of linguistic expression trapezoidal Pythagorean fuzzy probabilistic linguistic variables (TrPFPLVs) and trapezoidal Pythagorean fuzzy probabilistic linguistic preference relations (TrPFPLPRs) to express decision-making information.

(2) This paper develop the operational rules,value index and ambiguity index of trapezoidal Pythagorean fuzzy probabilistic linguistic variables (TrPFPLVs).

(3) This paper introduce the new trapezoidal Pythagorean fuzzy probabilistic linguistic priority weight(TrPFPLPW) PROMETHEE approach to aggregate the trapezoidal Pythagorean fuzzy probabilistic linguistic information.

# Analysis of the Influence of De-hazing Methods on Vehicle Detection in Aerial Images

Khang Nguyen, Phuc Nguyen, Doanh C. Bui, Minh Tran, Nguyen D. Vo
University of Information Technology, Ho Chi Minh City, Vietnam
Vietnam National University, Ho Chi Minh City, Vietnam

*Abstract*—In recent years, object detection from space in adverse weather, incredibly foggy, has been challenging. In this study, we conduct an empirical experiment using two de-hazing methods: DW-GAN and Two-Branch, for removing fog, then evaluate the detection performance of six advanced object detectors belonging to four main categories: two-stage, one-stage, anchor-free and end-to-end in original and de-hazed aerial images to find the best suitable solution for vehicle detection in foggy weather. We use the UIT-DroneFog dataset, a challenging dataset that includes a lot of small, dense objects captured in various altitudes, as the benchmark to evaluate the effectiveness of approaches. After experiments, we observe that each de-hazing method has different impacts on six experimental detectors.

*Keywords*—*Foggy weather; vehicle detection; DWGAN; two-branch; YOLOv3; sparse R-CNN; deformable deter; cascade R-CNN; crossDet; adverse weather*

## I. INTRODUCTION

Nowadays, with the significant development of information and communication technology, especially the surging growth of the deep learning era, vehicles detection and surveillance have become extremely important and necessary. Along with that development, the prevalence of UAVs (Unmanned Aerial Vehicles) makes vehicle surveillance extremely simple and effective. Traffic surveillance from aerial images is a particular interest to researchers because it serves many essential different purposes, such as being used in the military or monitoring traffic conditions, urban management, or simply helping us know where to park in the parking lot. Compared to detecting ground view vehicles, detecting vehicles from the aerial image is more complicated and challenging due to multiple frames, various backgrounds, small objects appearing with a variety of shapes. In addition, there is a critical factor that directly affects the model's performance: the weather.

Recently, by applying deep convolution neural network CNN [1], a significant number of studies have been done to tackle this problem, such as the proposal of the Double focal loss convolutional neural network framework (DFL-CNN) model [2] with the combination of feature CNN and the focal loss function [3] or [4] carried out experiments on YOLO [5] for vehicle detection based on aerial images datasets COWC [6], VEDAI [7] and DOTA [8]. These articles have one thing in common: they were all experimented with in clear-weather conditions and achieved excellent results.

However, in reality, the weather conditions are constantly changing (rain, snow, smog, night, thunderstorms, fog, etc.), which significantly affects the accuracy and learning ability of the models.

We choose the scope of our research to detect vehicles from aerial images under foggy weather. We choose the fog scene because it is often seen in the early morning. Sometimes, the appearance of dense fog may seriously affect the ability to monitor the traffic situation. Prior studies such as SFA-Net [9] used to detect objects in the rain or solve the problem of semantic foggy scene understanding (SFSU) by de-fogging of convolutional neural networks [10].

In this study, we focus on investigating advanced object detection methods Cascade R-CNN [11], Casdou [12], YOLO-v3 [13], CrossDet [14], Deformable DETR [15], Sparse R-CNN [16] for object detection in foggy conditions that limit visibility. At the same time, the evaluation of visibility improvement through 2 de-fogging (Image Dehazing) methods, which are DW GAN [17] and Two-branch Dehazing [18], also implemented on the UIT-DroneFog [12].

We summarize our contributions in this paper as:

- Using image dehazing methods to filter foggy images from the challenging dataset UIT-DroneFog.

- Experimenting with one-stage, two-stage, and the latest end-to-end deep learning methods on dehazed datasets.

- Providing in-depth evaluation of dehazing methods on experimental deep learning models to choose the best models.

The rest of the paper is: Section II is Related work; Section III is Experimental Methods; Section IV is Experimental Results; and finally, Section V is Conclusion and Future Work.

## II. RELATED WORK

Object detection in the foggy condition in particular and in adverse weather conditions has been addressed in two directions: domain adaption and condition-based object detection. In domain adaptation approaches, many studies proposed to improve the more robust detector based on Faster R-CNN [19], [20], [21] to help it be adapted with other domains of images, which could be different from the original dataset. These domain-adapted detectors were trained on the source dataset, which might include images with normal, original conditions. Then, the detectors were then evaluated the performance on images with foggy, rainy or other adverse weather conditions. The characteristic of this approach was focusing on the model's architecture and did not affect the images. On the other hand, condition-based approaches tended to propose the specific detectors in concrete contexts [22], [23]. Therefore, these

detectors include processing modules such as rainy and foggy removal to transform condition-adverse images into normal images. Then the transformed images were then used for training and testing.

### A. Domain Adaptation in Adverse Weather

The author in [19] tackled the adaptive domain problem by focusing on two levels: the image-level shift and the instance-level shift. The image-level shift could be described as style, illumination, etc., while the instance-level shift was object appearance and size. Based on Faster R-CNN, the authors designed H-divergence theory-based adaption module on image-level shift and instance-level shift to decrease domain discrepancy. In detail, a domain classifier was built and trained in an adversarial training manner at each level. Those two classifiers then incorporated a consistency regularizer to train a domain-invariant Regional Proposal Network in Faster R-CNN, which then could be adapted with other domains of images. The authors used the Cityscapes dataset as one of the experimental datasets. They trained on the normal version of Cityscapes and evaluated on its foggy version. Experiments proved that the performance increased by combining the proposed adaption module.

The author in [20] proposed a robust Faster R-CNN and the Noisy Labeling strategy for domain adaptation. In detail, the authors split the pipeline into three phases. In the first phase, the Faster R-CNN was trained on the source dataset then used as the base detector. Next, the authors used the base detector to obtain noisy bounding boxes. At the same time, all ground-truth instances in the source dataset were also extracted. After that, noisy bounding boxes and all extracted ground-truth boxes were fit into a classification module. The classification module would be trained on the exact ground-truth boxes from the source dataset and refine the class categories of the noisy boxes. Finally, the upgrade version of Faster R-CNN was trained on both datasets: the source dataset with human-annotated ground-truth boxes and the target dataset with annotations refined via a classification module. The proposed approach was evaluated by training on the Cityscapes and evaluating on Foggy Cityscapes dataset. Through experiments, the authors proved that using the Noisy Labeling strategy and their improved Faster R-CNN could help achieve better results than normal training, original Faster R-CNN, and other approaches 36.45% AP. Notably, this result was 7.07% lower than the result obtained via training Faster R-CNN on the Foggy Cityscapes Dataset.

The author in [21] defined a novel prior-adversarial loss function that utilized the additional knowledge from images in foggy, rainy images to correlate the amount of degradation directly. In detail, the proposed loss was used to train a prior estimation network to predict condition-specific prior from features map and minimize the weather information present in the features. This approach helped the main detection network features become invariant, decreasing the effects of adverse weather such as foggy or rainy. Furthermore, to avoid distortions caused by weather-based degradation, the authors proposed a set of residual feature recovery blocks in the detection network for de-distorting features leading to better performance. The proposed method was evaluated by training Cityscapes and evaluating on Foggy-Cityscapes dataset, the

highest result was 39.3%, which extremely outperformed the previous approaches.

### B. Condition-based Object Detection Methods

To handle the problem of vehicles in foggy images that are difficult to recognize, [22] proposed a feature recovery module, which was considered as a restoration subnet and integrated with the main backbone of the detection model. The feature recovery (FR) module was designed by sharing feature extraction layers with the backbone. So, this proposed module learned to restore the clean image from the foggy image via the MSE loss in the training time. Notably, the aim was not fitting the restored image to the detection model. They trained the external FR module to help improve the weights in the main backbone, which helped enhance the quality of the features extracted from foggy images. The proposed approach was evaluated on the FOD and Foggy Driving dataset, proving the effectiveness of other detection methods.

The author in [23] proposed an encoder-decoder U-shaped network with residual connection from one layer to another for fog removal. Then, the authors employed the PP-YOLO [24] detection model for training object detection. The authors also created a dataset of foggy images by synthesizing them based on the existing dataset. Their ablation studies proved that the detection performance increased when including the proposed fog removal module.

The author in [12] proposed a synthesized foggy dataset named UIT-DroneFog based on a normal-weather dataset. Then, they experimented with the existing detectors on the new dataset to observe the performance. In their study, no fog removal techniques were recommended or used, but the authors proposed the combination of Double Heads and Cascade R-CNN, which achieved better results compared to the other methods.

### C. Discussion

The adaptive domain approaches encourage object detectors to operate well on cross-domain datasets, which is suitable if we can not collect the images belonging to the domain we expect. Furthermore, adaptive object detectors also help us not to retrain the model for the new domain dataset, which is time-consuming. However, adaptive detectors still have limitations because they can not perform well as their counterparts trained and evaluated on the same domain data. Therefore, we suppose that if we have the images belonging to the domain data we need, it is unnecessary to employ adaptive detectors. So, in this study, we focus on exploring the performance of normal two-stage, one-stage and end-to-end object detection methods combined with de-hazing methods on the foggy dataset.

## III. EXPERIMENTAL METHODS

### A. Object Detectors

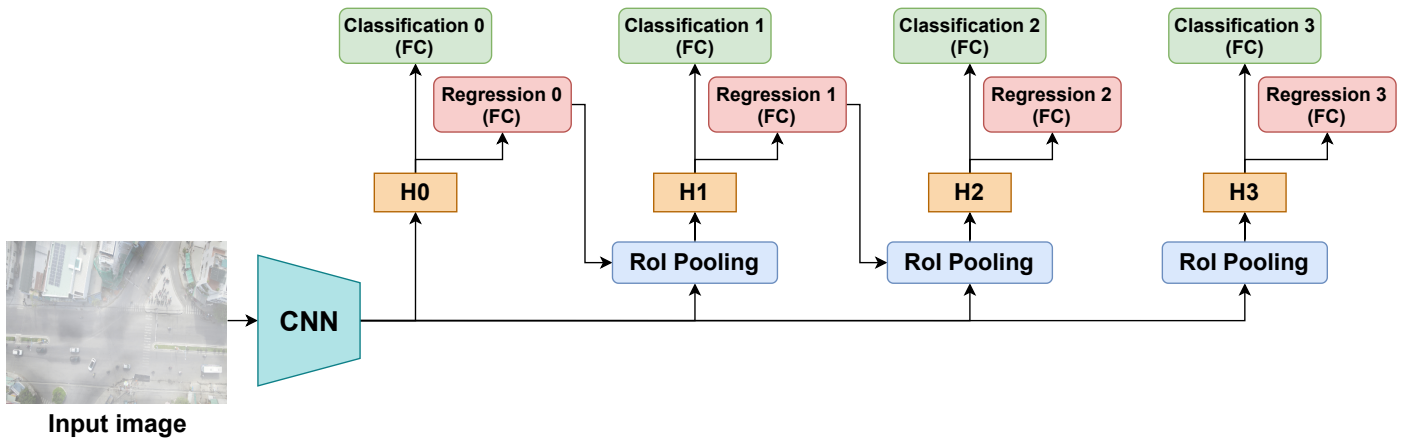
Object Detection is a complex, challenging problem in computer vision used to localize and classify objects based on images and videos. With the surging growth of Deep Learning in recent years, feature extraction from data is straightforward to implement and time-efficient, leading to the emergence


Fig. 1. Illustration of Two-Stage Cascade R-CNN Object Detection Method

of intensive studies of Object Detection. In addition to improvements in classification, researchers conduct many in-depth studies in localization to reduce computational costs and memory to make the model work more efficiently. Therefore, the research on the following detection frameworks happens to meet nowadays's needs: Two-stage, One-stage, Anchor-free and End-to-end object detection.

*1) Two-Stage Detectors:* The framework is also known as the region-based framework. Region proposals generated from input images pass through CNN where features are extracted. Then, based on the extracted features, category-specific classifiers are used to classify labels for the region proposals. There are many well-established two-stage methods that we are going to carry out the experiment on, like Cascade RCNN and Casdou.

**Cascade R-CNN.** In 2018, [11] proposed the high-quality detection model Cascade R-CNN. Multi-stage object detection architecture with set detectors trained in turn with the current detector's output as the input to the next detector used to solve not only the mismatch in quality between the output and the detector but also the overfitting problem caused by the sensitive IoU threshold(when the IoU is large). However, creating a high-quality detector is not simply increasing the IoU during the training phase. As we increase the IoU threshold, it also means that a significant decrease is witnessed in the number of active training samples. Different heads in the architecture designed for a particular IoU threshold, from small to large, are used at different stages (H1, H2, H3). Cascade regression is a resampling process, providing positive samples for further processing stages:

$$f(x,b) = f_T \circ f_{T-1} \circ ... \circ f_1(x,b)$$

$T$: total number of refining bounding box stages. Each $f_T$ regressor in the cascade optimized for the respective distribution $b_T$. Fig. 1 illustrates the architecture of Cascade R-CNN.

**CasDou (Cascade R-CNN and DoubleHead).** In the year 2021, [12] proposed Casdou with the combination of Cascade R-CNN, Double Heads [25], and Focal Loss [3]. The method tested on the high-quality aerial foggy outdoor vehicle dataset UIT-DroneFog achieved 34.70% on the mAP score. The author

used the Cascade R-CNN backbone instead of the Faster R-CNN because it helps the model attain high-quality detection with structural cascade regression. What's more, the Double Heads detector can be flexibly attached to various models to achieve higher detection results. In addition, based on their analysis and assumption, the author uses Focal Loss to help the model converge and have a more apparent distinction between class objects than Cross-Entropy Loss. Focal Loss is defined as follows:

$$L_{FL}(p_T) = -\alpha(1 - p_T)^\gamma log(p_T)$$

With $(\alpha)$ is the balanced form of the Focal Loss function, and $(\gamma)$ is used to calculate the modulating factor.

Fig. 2 illustrates the architecture of CasDou.

*2) One-Stage Detector:* Although achieving high accuracy, the two-stage methods are computationally expensive and have high resources-consumption. One-stage method - the YOLO was born for incredible processing speed while maintaining high accuracy to achieve real-time object detection. One-stage architecture directly predicts class probabilities and regress bounding-box offset values with a single feed-forward CNN network instead of heavily depending on generated region proposals.

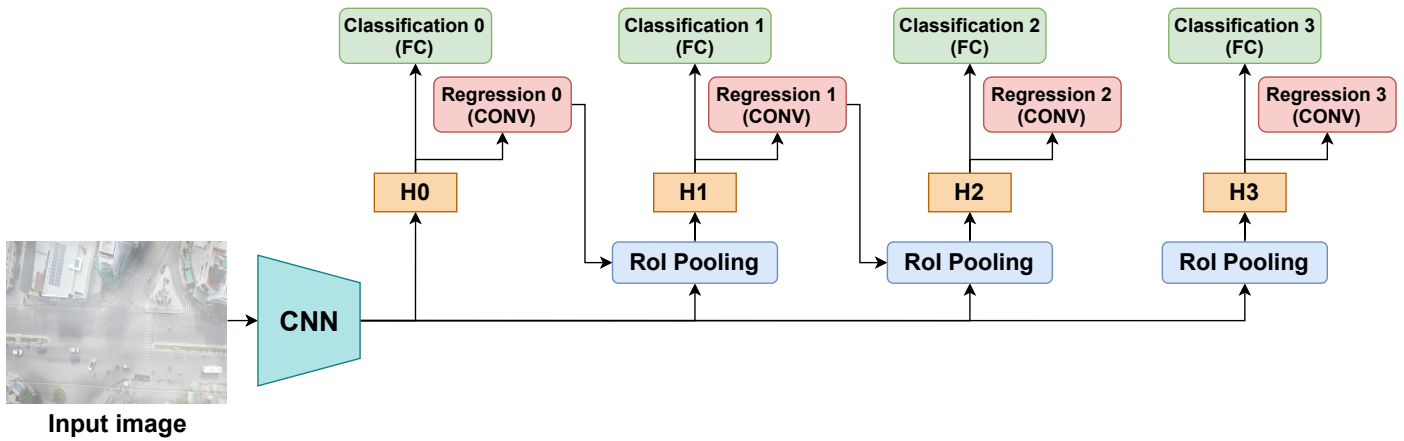
**YOLO-v3. (You Only Look Once v3)** YOLO-v3 was proposed by [13] with the help to improve the accuracy of the object detection problem while keeping the interference time at the appropriate speed. YOLOv3 uses Darknet-53 (ImageNet [26] Trained Network) and Residual Network (ResNet)[27] consisting of 53 convolutional layers built with consecutive convolutional 3x3, and 1x1 layers, followed by ResNet connection skips to activate propagating through deeper layers without diminishing the gradient. Finally, the average pooling layer, 1000 fully connected layers, and Softmax activation function are added to perform classification. With this robust structure, DarkNet-53 has a much higher speed than other platforms like ResNet-101 or ResNet-152. Initially, the image is passed through a block of convolutional layers to extract features. Then, it is divided into a grid of size S × S. When the image is divided into a grid, each cell in the image is responsible for detecting the object whose center locates on that cell. After selecting the anchor box, the model uses the


Fig. 2. Illustration of Two-Stage CasDou Object Detection Method

Direct Position Prediction formula to regress the size of the true bounding box. The model then predicts the bounding box's label using Multiple Classification. The illustration of the YOLOv3 method is shown in Fig. 3.

*3) Anchor-Free Detector:* Anchor-free detectors find the object without the preset anchors. It helps the model become less dependent on anchor-related hyperparameters and generalize more easily. CrossDet stands out to be the effective anchor-free detector that considers continuous object information and reduces noise interference.

**CrossDet.** CrossDet was proposed by [14] in 2021. Instead of using anchor-based methods and point-based methods that are inclined to produce noise feature output, the author proposed the CrossDet helping extract the information continuously and accurately. CrossDet-an anchor-free detector using a set of cross lines to represent objects consists of two main phases: (1) Generating the coarse crossline representation (2) Refining the crossline representation based on the extracted features on the horizontal and vertical lines. Based on trained cross lines features, feature maps $I \in R^{C \times W \times H}$ generated from backbone FPN are processed to crossline extract module (CEM). CEM is then trained to extract horizontal and vertical features. The model uses decoupled regression mechanism to optimize cross lines growth along with vertical or horizontal features. CrossDet yields the results on the two data VOC2007 [28] and MS-COCO [29], with the results, are 52.8 and 48.4 respectively on the AP score. Fig. 4 shows the architecture of CrossDet method.

*4) End-to-End Detectors:* The End-to-end approach aims to build a complex deep learning model, removing hand-designed components like pre-processing (anchor generation) and post-processing (Non-maximum suppression) and integrating them into a single model. Today's famous End-to-end methods are Deformable DETR or Sparse R-CNN. They work on sparse candidates which are progressively processed and refined through various stages.

**Deformable DETR.** In 2021, [15] proposed the Deformable DETR method as an improved version of the prior DETR [30]. However, achieving results as high as Faster R-CNN, DETR witnesses slow convergences and problems in detecting small objects due to the limitation of the attention mechanism in the Transformer. The Deformable DETR is a combination of a Deformable convolution [31] and a Transformer [32]. It combines the effectiveness of the sparse spatial sampling of Deformable convolution and the relation modeling capability of Transformers. From there, it was formed into a Deformable attention module to focus on the part of "sampling spatial" as a pre-filter to focus on prominent areas instead of every location on the feature maps. Moreover, thanks to the fast convergence and flexibility of Deformable DETR, the authors also experimented with some methods to optimize the predict bounding box on the MS COCO dataset such as iterative bounding box refinement mechanism on region proposals proposed by the model. Experiments show that Deformable DETR converges faster and gives more accurate results than DETR with x10 fewer training epochs. Fig. 5 shows the architecture of Deformable DETR method.

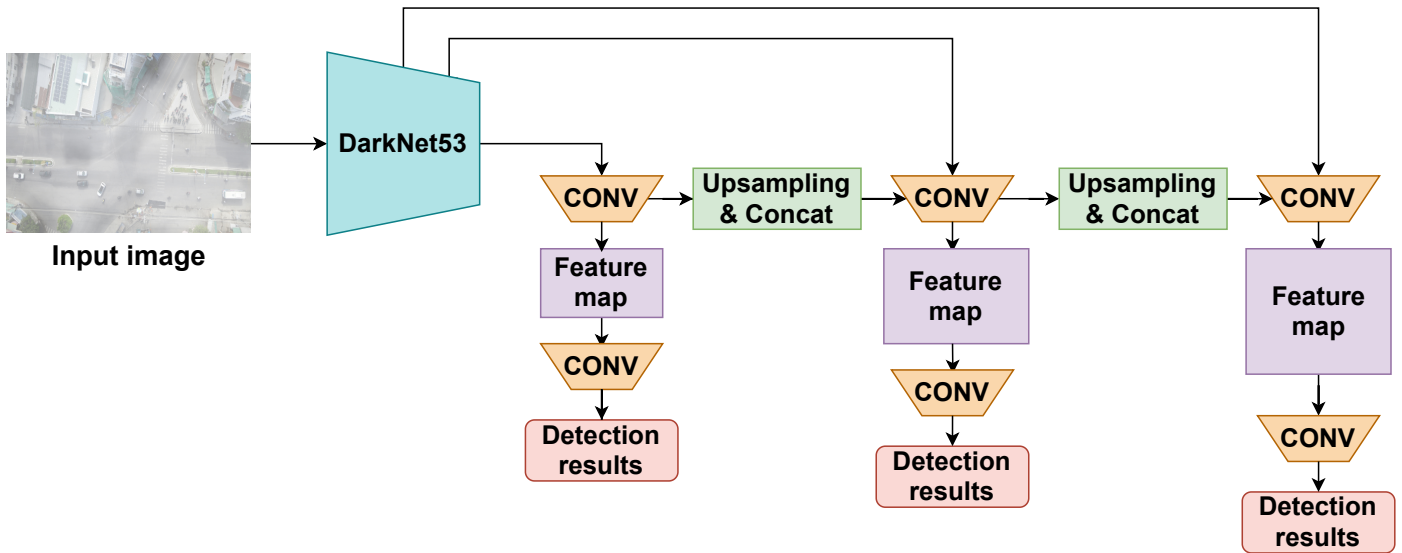
**Sparse R-CNN.** In 2021, the Sparse R-CNN method, proposed by [16], is a sparse object detection method. Sparse R-CNN is an End-to-End object detection method because it eliminates the post-processing mechanism of non-maximum suppression, which is different from prior R-CNN models. Object detection methods such as the Dense method in the YOLO family where locations of anchor boxes densely cover spatial positions, scales, and aspect ratios in a single-shot way. A typical Dense-to-sparse approach is Faster R-CNN, which uses RPN [33] to derive region proposals from the dense region of candidates and refine those bounding boxes and class-specific features. The sparse method applied by Sparse R-CNN replaces RPN with a set of learnable region proposals and proposal features. Input is an image with a set of region proposals and proposal features that are randomly initialized and optimized with other parameters in the whole network. Features are extracted and fed into the backbone along with region proposals and proposal features, eventually generating outputs classification and localization. Sparse R-CNN shows its accuracy, run-time and convergence in training on the challenging COCO dataset, yielding a 45.0 AP score at 22 fps using the ResNet-50 FPN backbone. Fig. 6 shows the architecture of Sparse R-CNN object detection method.


Fig. 3. Illustration of One-Stage YOLOv3 Object Detection Method

Fig. 4. Illustration of Anchor-Free CrossDet Object Detection Method

## B. Image Dehazing Methods

*1) DW GAN (Discrete Wavelet Transform GAN):* DW-GAN was proposed by [17] in 2021. This method was designed to tackle two problems that some existing CNN-based dehazing methods have when working with non-homogeneous cases. These problems are the loss of texture details when images are being dehazed due to the complicated haze distribution and over-fitting problems because of the lack of training data. The architecture of this method is a novel two-branch generative adversarial network. For the first branch, called the DWT branch, they proposed the idea of directly embedding the frequency domain knowledge into the dehazing network by utilizing wavelet transform. Therefore more high-frequency knowledge in the feature map can be retained. In terms of the knowledge adaptation branch, the Res2Net was employed with the pre-trained ImageNet weights as initialization in order to prevent overfitting and improve the generalization ability of the network. Finally, they add a basic $7 \times 7$ convolution layer as a fusion operation to map the features from two branches to clear images. Furthermore, they also introduced the final loss blend function shown in Equation 1. ($L_1$) is L1 loss, ($L_{SSIM}$) denotes MS-SSIM [34] loss ,($L_{perceptual}$) represents

perceptual loss [35] and, for the adversarial loss ($L_{adv}$), the discriminator in [36] is employed.

$$\mathcal{L}_{total} = L_1 + \alpha L_{SSIM} + \beta L_{perceptual} + \gamma_4 L_{adv} \quad (1)$$

Where ($\alpha$) = 0.2, ($\beta$) = 0.001 and ($\gamma$) = 0.005 are the hyper-parameters weighting for each loss functions.

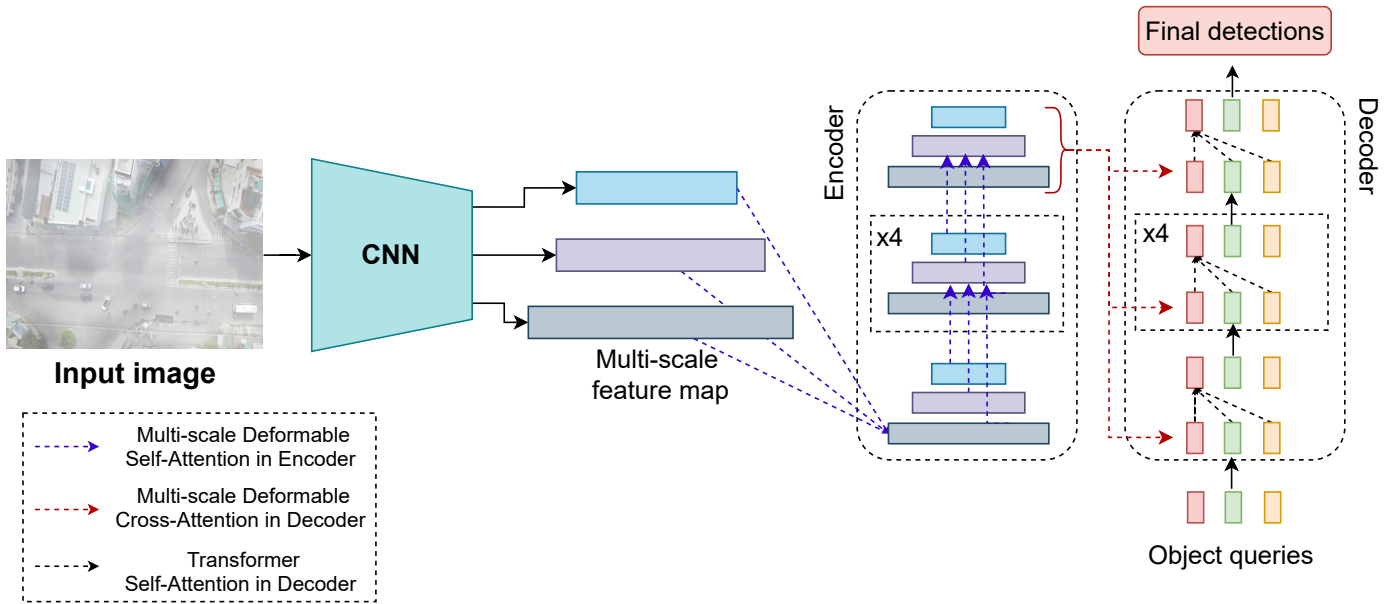
*2) Two-Branch Dehazing:* [18] proposed another two-branch neural network for non-homogeneous dehazing via ensemble learning. The authors found that a carefully built CNN frequently fails on a non-homogeneous dehazing dataset introduced by NITRE challenges [37] even though it performs well on large-scaled dehazing bench-marks. Therefore, they introduced a two-branch neural network to deal with the afore-mentioned problems separately, followed by a learnable fusion tail to map their different features. The first branch, the transfer learning sub-net, is based on an ImageNet pre-trained Res2Net. This branch extracts robust global representations from input images with pre-trained weights and then helps the network address the problem of lacking training data. In the second


Fig. 5. Illustration of End-to-End Deformable DETR Object Detection Method

Fig. 6. Illustration of End-to-End Sparse R-CNN Object Detection Method

branch, [18] used residual channel attention network to design the current data fitting sub-net. This branch has five residual groups; each has ten residual blocks. However, the second branch always maintains the input image's original resolution and avoids using any downsampling operation. Finally, a fusion layer generates the entire network's final output. The fusion layer, in particular, takes the concatenation of features from the branches and maps them to clear outputs. Besides, they also applied the adversarial loss with the discriminator in [36] because of its effectiveness in helping restore photo-realistic photos [38], especially for a small-scaled dataset.

## IV. Experimental Results

### A. Benchmark Suite

In this study, the UIT-DroneFog dataset, which was created by [12], was employed to evaluate the performances of detectors in foggy aerial images. This dataset consists of 15,370 foggy aerial images captured by drones with about 0.6 million bounding boxes of various means of transportation and pedestrians. This dataset has four classes: Pedestrian, Motor,

Car, and Bus. We also used the default subsets provided by the authors, which include: Training set (8,580 images), Validation set (1,061 images), and Testing set (5,729 images). The numbers of each class are shown in Fig. 7.

There are several reasons why we choose this dataset. Firstly, the images in this dataset are of high quality, which helps the detectors work more efficiently. Secondly, the context of these images is diverse and especially, there is an imbalance in this dataset with a vast majority of motor objects. This can be a tough challenge for our detectors.

Example images of this dataset are shown in Fig. 8.

### B. Experimental Settings

The experimental processes were conducted on a GeForce RTX 2080 Ti GPU with 11018 MiB memory. We trained the models by employing the MMDetection framework V2.10.0[39]. For each model, we used the highest mAP score configuration, provided on the MMDetection GitHub website[1]

---
[1]https://github.com/open-mmlab/mmdetection

Fig. 7. Statistics of UIT-DroneFog Dataset.

or author's GitHub. We conducted every training process on a single GeForce RTX 2080 Ti GPU.

To evaluate the detectors, we used the best weights of each model on the validation set to predict and report the results on the testing set via the mAP measure to evaluate the performance of models, which is the same as the object detection contest on the MS COCO dataset. The AP score was calculated for 10 IoU varied from 50% to 95% with steps of 5%. Besides, the results of two specified values of 50% and 75% were also reported.

### C. Experimental Results

The experimental results are reported in Table I, Table II, Table III. In Table I, we report the performance of five experimental object detectors on original foggy images. Overall, CasDou - a two-stage method - shows the best performance (34.7% AP) while YOLOv3 performs the worst. These results reflect the characteristic of two-stage and one-stage detectors correctly: two-stage methods often perform better than one-stage methods about accuracy. However, Deformable DETR, an end-to-end detector, has the highest results on Pedestrian and Motor class objects, which are 0.5% and 2.8% higher than CasDou. Moreover, Deformable DETR is exceptionally competitive with CasDou about AP score (33.7% AP compared to 34.7% AP), proving that end-to-end detectors that may have higher FPS can perform as well as two-stage detectors.

In Table II, we report the results of five object detectors but use DW-GAN to de-haze images before training. In general, there is a variation in the order of accuracy between the methods. Cascade R-CNN, again a two-stage method, becomes the detector that shows the best performance among the experimented detectors, but the AP score is not higher than CasDou trained on original foggy images. However, Cascade R-CNN trained on images de-hazed by DW-GAN has a noticeable improvement than its counterpart trained on synthetic hazy images (+1.3% AP, +2.5% AP@50, +1.9% AP@75). Furthermore, DW-GAN also helps YOLOv3 and Sparse R-CNN enhance the AP score compared to their results in Table I (+1.4% AP and +0.3% AP, respectively). Therefore, de-hazing images using DW-GAN significantly and positively affect the performance of five object detectors.

Table III reports the results using Two-Branch as the de-hazing method. It can be seen that this de-hazing method can not help object detectors improve the results compared to their counterparts trained on original hazy images. However, the accuracy between the methods is the same as Table I: CasDou shows the best performance (33.1% AP) and YOLOv3 performs the worst (20.4% AP); CasDou also indicates the best AP on Car and Bus classes (57.4% AP and 40.1% AP) while Deformable DETR shows the best AP on Pedestrian and Motor (2.7% AP and 35.8% AP). Notably, the CrossDet detector using the Two-Branch de-hazing method shows a slight improvement compared to its results in Table I (+0.5% AP, +0.3% AP@50, +1.3% AP@75).

Through three experimental results, we can notice that two-stage methods, especially CasDou and Cascade R-CNN, have the ability to perform better than one-stage and end-to-end detectors on both original and dehazed datasets. Besides, from these experiments, it can be seen that resurfacing objects from hazy aerial images by dehazing them is a tough challenge and not always effective due to color deviation and the loss of information compared to haze-free images. In fact, the Two-branch dehazing method significantly reduces the detection results of CasDou's detection result (−1.6% AP), while the DW-GAN is proved to be more effective when helping Cascade R-CNN improve its detection results were improved. This could be explained by the fact that DW-GAN has higher results than Two-branch dehazing when both of these two methods use the same dataset [37]. In addition, although the AP result is not so high, the DETR shows that this method can outperform all other methods by a large margin when detecting small objects, which are Pedestrian and Motor, on all three datasets (shown in Fig. 9. This means that although the small objects are blurred by fog, this method learns the features of this kind of object better. On the other hand, when detecting objects in big sizes such as Bus and Car - many times bigger than Motor and Pedestrian, a two-stage method will be an appropriate choice because the AP scores of Car and Bus detected by two-stage methods in three report tables always ranks top. Fig. 10 and Fig. 11 show the detection results of CasDou and Cascade R-CNN methods with and without using de-hazing techniques.

## V. Conclusion

This study has provided experimental results and a thorough analysis of condition-based approaches to the problem of vehicle detection on aerial images in foggy weather. In short, we evaluate the effectiveness of advanced object detectors on aerial images with and without foggy removal. DW-GAN and Two-Branch are used for de-hazing. CasDou achieves the highest performance among experiments when the AP is recorded at 34.7% on original images. Experimental results also show that detectors trained on de-hazed methods can not achieve the best results. Still, with some detectors such as YOLOv3, CrossDet, Sparse R-CNN, foggy removal help them slightly improve the detection performance compared to their counterparts trained on original images. As we reported, the approaches using a GAN-based model to remove foggy images somehow can not achieve the results of using original images. Therefore, in the future, we plan to conduct more experiments on other recent GAN-based methods to explore their effectiveness in de-hazing. Besides, we also plan to

Fig. 8. Example Images of UIT-DroneFog Dataset.

# Designing a Mobile Application using Augmented Reality: The Case of Children with Learning Disabilities

Misael Lazo-Amado, Leoncio Cueva-Ruiz, Laberiano Andrade-Arenas
Facultad de Ciencias e Ingeniería
Universidad de Ciencias y Humanidades, Lima, Peru

*Abstract*—The learning disorder has several difficulties to learn correctly; in many cases they have more stress because they do not understand the subjects proposed by the teacher. The aim of the research is to propose an innovative plan to design a mobile application for the treatment of learning disabilities using augmented reality in primary education. In this way, we used a methodology called Design Thinking that has five phases, empathize, define, devise, prototype and testing, which facilitates us in identifying the problems for itself to have solutions to these problems. For the prototype we used tools such as Marvel App, which is responsible for the layout of the mobile application. TinkerCad allows us to design the 3D model of the educational games and finally App Augmented Class to create the augmented reality model. The results obtained were through a survey about the prototype; identifying the acceptance about the prototype by parents for the usefulness of this idea for their children with learning disabilities, with 76% that the prototype is ideal for children. In addition, the prototype was validated by five experts, resulting in 85.4% acceptance. As a conclusion of the research is the achievement of a good design for a solution to the problems of children with learning disabilities to have a better understanding and to be free from stress.

*Keywords—App augmented class; design thinking; marvel App; learning disorder; TinkerCad*

## I. INTRODUCTION

The learning disorder makes it difficult for the child to learn these causes correctly. These are presented worldwide, as there are various problems of language, comprehension or dyscalculia. In Jordan, it indicates that their primary school students have a lack of attention to classes, as they have a bad use of the internet, causing them to be completely distracted and prevent them from developing in their student process [1]. COVID-19 also had an impact on primary education, students were studying from home, avoiding the physical approach; they had no control over their virtual classes and were easily distracted by video games [2]. In the United States, multilingual children in most American schools are found to have language and learning disabilities [3].

In rural areas of Latin America there are difficulties in children's learning. In this way they obtain a low level in their subjects, as they do not have any learning method [4].By the end of 2021, students in Latin America will be affected by the COVID-19 pandemic, making a rapid shift from face-to-face to digital learning [5]. Brazil has 55 million people living in extreme poverty and has pre-school boys with illiteracy problems [6]. This developing, resource-poor

country also analyses that 21 families believe that difficulties in learning development stem from poor social interactions, peer relationships, stress levels and communication [7].

In Peru, there were educational problems in the teaching of children during the COVID-19 pandemic [8]. They had student delays because virtual classes were not proposed. When these methods were declared, in Ayacucho and indigenous populations, they did not have these materials to carry out their classes at a distance, and also because of poor learning, the children had various problems of learning disorders [9] [10]. In this way, many children, especially in rural areas of Peru, have problems learning mathematics [11]. This also increases the level of stress, as they do not have the strategic methods for the child to be able to understand these subjects in an easy and simple way [12]. Also, dyscalculia which is a learning disorder can cause many problems at primary level and many mistakes in performing logical operations, lack of attention and concentration makes children unable to perform these functions [13] .

According to these problems at international and national level, we can see the importance of having new innovative and strategic models for students at primary level to have ease in their understanding so that they can improve these learning disorders and prepare themselves to not have any difficulties in their future life. With the proposed design for the solution of the problems of children with learning problems is helping parents where their children have these difficulties. So also with the teachers since in this way the learning of the students will be much better.

The objective proposed in this project is to develop a strategic and innovative model to solve these problems, designing a mobile application for the treatment of learning disorders, using augmented reality in primary education. Cognitive games were used to improve student learning. The structure of the paper is as follows: in Section II the literature review is explained, in Section III the methodology to be developed, in Section IV the results of our work, in Section V the discussions, in Section VI the conclusions and finally in Section VII the future work.

## II. LITERATURE REVIEW

Augmented reality in education allows us to do didactic work as well as help us to discover new skills in children. It also implements an analysis of the impact of augmented reality in education, which indicates that teachers enable children to learn quickly and relieve their stress with the help of

augmented reality [14]. Similarly, this research analyses by Likert scale that students have more problems in the subject of geometry, and also evaluates a development of augmented reality to improve learning, indicating that 92.50% are satisfied with the use of technology and it is suitable for use in Indonesian schools [15].

In the same way, it indicates that augmented reality is used to enjoy and live a better educational experience. Therefore, the use of augmented reality was developed for the teaching of mathematics, helping to obtain a better visualisation and understanding in secondary school students. This was developed with Unity and was accompanied by the Vuforia software development kit in order to develop the augmented reality application. At the end they obtained as a result, a mobile application with augmented reality accessible to all devices that are installed in each classroom to improve the understanding of students in an easy and simple way [16].

At Sebelas Maret University, form-based tests were used with students and teachers to indicate problems in their programming education. A multimedia with augmented reality was also developed to improve critical thinking, resulting in a better understanding of basic and advanced programming [17].Something similar happens in this case, on the subject of biological education that develops an augmented reality application with Unity 3D for the training of its medical and veterinary students. Students indicate that augmented reality technology enhances their learning by demonstrating that virtual technology is a great support in their practices in human and animal anatomy [18].

On the other hand, he designed a mobile application with augmented reality, indicated that it will be the future of education. With the use of the Assembly application, he proposes that primary education can improve their learning in their computer, tablet and mobile assembly laboratories. This is done virtually, as during this pandemic, health restrictions prevented students from having contact with other people, which affected their face-to-face teaching. As a result, a survey of students showed that augmented reality design would be of great help in their laboratories [19].Similarly, in this research, it helps students to develop their knowledge in chemistry with intuitive games to learn science-related topics. This is done by combining three-dimensional objects from the virtual world to a real one, 87.90% of Indonesian students validate their improvement in their understanding of chemistry [20].

In the same way, in the business field, a mobile application is designed with the use of augmented reality to provide a multimedia marketing method with augmented reality. As a result, it was possible to improve advertising and impact users with the use of these technologies [21].This research also used Unity with the c# programming language, Blender 3D to develop a catalogue list application for the purchase of food and beverages with augmented reality. As a result, it improved the visualisation of customers observing in detail the quality of the product, gaining confidence in their purchase [22]. Finally, this article proposes to improve communications in companies, implementing an augmented reality design in animated infographics to improve their presentations, using Unity 3D to optimise communications processes resulting in the interest of new clients for their future projects [23].

The augmented reality identified by different authors in the fields of education, medicine, security, business among others, indicate the improvements that people can have when interacting with technologies. In this way, it provides ease of understanding, thus releasing stress, containing best practices in its development, so that its usefulness should be considered in problem solving. These aspects facilitate augmented reality solutions for children with learning disabilities. In this way, we will make a model for children, aiming to improve concentration in an efficient way in their cognitive development.

## III. Methodology

For the development of the methodology we will use Design Thinking which will be divided into five phases (Empathise, Define, Ideate, Prototype and Test), as well as explaining the survey tools and the design of the prototype that was used.

### A. Design Thinking

This methodology is focused on presenting creative solutions, generating ideas to improve society, and the methodology is of great interest to professionals because of their ability to adapt their innovative ideas [24]. The processes of Design Thinking are shown in Fig. 1. They are used to improve business environments by complementing the help of users in identifying their problems and thus solving them [25] .

1) Parent survey: A survey of parents about learning difficulties was formulated at the beginning.
2) Do children have learning difficulties ? In this first conditional we asked if they found the problems, if it was confirmed we took it into account and proceeded to the next step, if not we went back to the survey.
3) Identification of learning difficulties: In this process the children's learning problems were identified.
4) Solutions for learning disorders: In this process the identified problems are proposed to be solved.
5) Definition of the ideas of the prototype: Based on the proposed ideas, the final prototype is defined.
6) Surveys about the prototype: A survey about the prototype was formulated to parents for acceptance and development.
7) Is it an ideal prototype for children? In this second conditional it was asked if it is the ideal prototype, if it is ideal it is taken into account and if it is not, the new prototype is implemented again.
8) Innovation accepted: Finally, the prototype defined by the parents was accepted.

*1) Empathise:* In this first stage, it is focused on observing the needs of the users continuously through the use of interviews and surveys giving the facility to gain a better understanding of their needs [26] .

*2) Define:* In this second stage, the focus is on defining the user problems that are in the empathise phase so that the innovation team must consider the biggest problem impacted by the users [27].

*3) Ideate:* This is the third stage, which is responsible for generating innovative ideas for the problems of the defined stage, allowing the team to name the best solution [28].
Fig. 1. Process Design Thinking.

*4) Prototype:* The fourth stage, prototyping, is responsible for designing the innovative solutions chosen by the working team in such a way that it uses prototyping tools [29]. Fig. 2 will show the procedure for the development of the mobile prototype with Marvel App, accompanied by a 3D modelling with TinkerCad and finally show the augmented reality with App Augmented Class.

*a) Tinkercad:* Tinkercad is a free tool that is used in education to design 3D objects online, its designs are made in an intuitive and easy to use way [30].

*b) MarvelAPP:* MarvelApp is a tool for the design of prototypes, with simple steps for its use, as well as limited templates for the user [31].

*c) App Augmented Class:* This application is used to design augmented reality models, it is free to use and can be downloaded from the Play Store [32].

1) Mobile prototyping with Marvel Apps: The start of this process is to make the mobile prototype to get the idea of the app's functions.
2) Make the 3D modelling with TinkerCAD: The second process was done using 3D models in TinkerCad in order to design the dynamic games for augmented reality.
3) Export the 3D model as an .OBJ file: The third process is to export the 3D models in a file called .OBJ.
4) Open the Augmented Class App : The fourth process will open the mobile application called the Augmented Class App to make the augmented reality model.
5) Import the 3D model from an .OBJ file : In the fifth process, the 3D modelling in the OBJ file was imported into the Augmented Class App application.
6) Realisation of the augmented reality: In the last process the augmented reality was realised by displaying the 3D model in the Augmented Class App.

*5) Test:* This is the last stage which involves surveying users about the solution and prototyping so that they give the go-ahead for development [33].

## IV. RESULTS

This section shows the results of the proposed methodology and the validation of the prototype by the experts. We will also

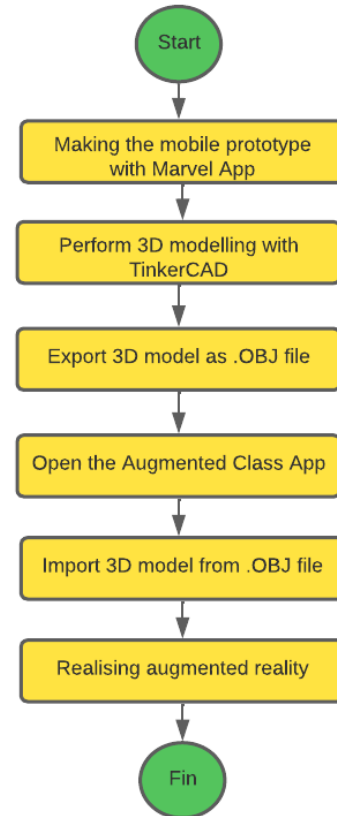

Fig. 2. The Process of Making an Augmented Reality Model.

tell the advantages, disadvantages and comparison of Design Thinking.

### A. Result of the Empathise Stage

Table I contains the questions (Q1 to Q6) for the survey of primary school children, asking about grade, gender, district, learning difficulty, learning stress and type of learning disability.

TABLE I. PRIMARY CHILDREN SURVEY

| Questions | |
|---|---|
| **ID** | **Questions** |
| Q1 | Primary Child's Grade |
| Q2 | Sex ? |
| Q3 | In which district of Lima are you located? |
| Q4 | Learning Difficulty? |
| Q5 | Stress when studying? |
| Q6 | What type of learning disability does the child have? |

### B. Result of the Define Stage

Table II indicates the 70 questionnaire responses (R1 to R6) from the first stage of Table I for parents. They are also responsible for identifying their children's learning problems at school.

TABLE II. PARENTS' RESPONSE TO THEIR CHILDREN

| | Answers |
|---|---|
| ID | Answers |
| R1 | First Grade 8.6%, Second Grade 24.3%, Third Grade 38.6%, Fourth Grade 14.3%, Fifth Grade 5.7%, Sixth Grade 8.6%. |
| R2 | Female 40% Male 60% |
| R3 | Puente Piedra 8.6%,Los Olivos 27.1%,Carabayllo 28.6%,San Martín de Porres 15.7%,Comas 17.1%,Rimac 2.9% |
| R4 | Yes 85.7% , No 14.3% |
| R5 | Yes 81.4% , No 18.6% |
| R6 | Dyslexia 15.7%,Dyscalculia 54.3%,Dysgraphia 21.4%,Dysphasia 8.6%. |

*a) R1:* According to the 70 responses, this indicates the number of pupils surveyed in primary school, Grade 1 has 8.6%, Grade 2 has 24.3%, Grade 3 has 38.6%, Grade 4 has 14.3%, Grade 5 has 5.7% and Grade 6 has 8.6%.

*b) R2:* It indicates that in the survey 60% are male students and 40% are female students.

*c) R3:* The students from Lima-Peru with the highest percentage are from the district of Carabayllo with 28.6%, Los Olivos 27.1%, Comas 17.1%, San Martín de Porres 15.7%, Puente Piedra 8.6%, Rímac 2.9%.

*d) R4:* 85.7% of students in primary education have learning difficulties and the other 14.3% have no learning difficulties.

*e) R5:* 81.4% of students in primary education have increased stress in their studies and the other 18.6% have no stress.

*f) R6:* This indicates that the students surveyed have different learning disorders and that the greatest impact of the students is Dyscalculia with 54.3%, Dysgraphia 21.4%, Dyslexia 15.7% and Dysphasia 8.6%.

### C. Result of the Ideate Stage

Table III indicates the solutions (S1 to S3) proposed by the innovation team. Giving an estimated score for the choice of the best idea and completing its development in the next phase.

TABLE III. SCORING IDEAS

| Punctuation of the Ideas | | |
|---|---|---|
| Solutions | Innovation Team | Total |
| S1 | Making a mobile application with augmented reality | 58 points . |
| S2 | To realise a website for your learning development | 34 points . |
| S3 | Implementing new learning methods in classrooms | 20 points. |

*a) S1:* The first solution will be the chosen one, as it has a high score of 58 points scored by the innovation team. This solution proposes the creation of a mobile application with augmented reality.

*b) S2:* The second solution that was not chosen but can be taken into account in future projects; it has a score of 34 points scored by the innovation team. Proposing to create a website for the development of their learning.

*c) S3:* The third solution that was not chosen but can be taken into account in future projects has a score of 20 points scored by the innovation team. Proposing to implement new learning methods in the classroom.

### D. Result of the Prototyping Stage

Fig. 3 shows the model of the mobile application so that users who have a registered account can log in. If they do not have an account, they can register correctly, and if the user forgets their password, they will have the opportunity to recover it by sending an email to change their password.

Fig. 3. Mobile System Login

Fig. 4 shows the model of the mobile prototype so that the user can request a change of password by sending an e-mail for modification. Once the user has accepted the request, a new password can be set.

Fig. 4. Password Recovery

Once logged in to the mobile application the user can choose the learning disorder problem that counts, Dyslexia, Dysgraphia, Dyscalculia and Dysphasia as shown in Fig. 5.

Fig. 6 shows the level of the game so that the child can carry out his or her treatments by showing his or her name and age. The word-forming game consists of the child with dyslexia problems observing the letters and being able to form the word.

Fig. 7 shows the level of the game for the child with his name and age with his respective Dysgraphia problem. It consists of drawing the line of the picture using a pencil; the child can also count on a stable treatment.

Fig. 8 shows the level of the game so that the child with his name and age with his respective problem Dyscalculia. It consists of performing operations, in this case subtraction, so that the child can strengthen his knowledge dynamically and select the correct option.
Fig. 5. Selection of Learning Disability

Fig. 7. Educational Game for Dysgraphia

Fig. 6. Educational Game for Dyslexia

In Fig. 9 shows the level of the game for the child with his name and age with his respective problem Dysphasia, which consists of the child speaking slowly, pronouncing each letter, with the aim of improving the form of communication .

*E. Responses from the Testing Phase*

Table IV show the questions for the parents about the final prototype that was used for the input and improvement of their children with learning disabilities. Also, this interaction will serve to know the opinion, as well as the importance of the application on their stress treatment and cognitive improvement.

Fig. 10 shows the answers to the questions in the testing phase. In Q1, 76% responded that it is the ideal prototype for the children, 76% of the respondents found it very interesting and 24% did not, in Q2 they responded that the application will help in the treatment of learning disabilities, 76% agreed and 24% disagreed, in Q3 it indicates the improvement of stress, and in Q4 it indicates that 74% of the parents are confident that it does improve stress and 30% do not, in Q4

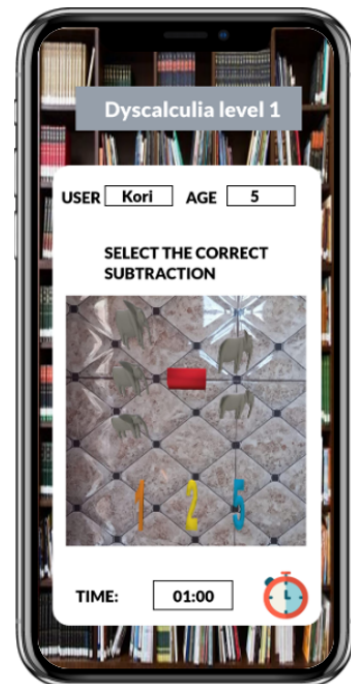

Fig. 8. Educational Game for Dyscalculia

Fig. 9. Educational Game for Dysphasia

TABLE IV. QUESTIONS FOR PARENTS ABOUT THE PROTOTYPE

| Question about the prototype with augmented reality | |
|---|---|
| ID | Questions |
| Q1 | Is the prototype ideal for your children? |
| Q2 | Do you think it will help in their treatment of children? |
| Q3 | Will this application improve children's stress? |
| Q4 | Do you recommend a family member to use this application to improve the treatment of the learning disability? |
| Q5 | Do you recommend private and public schools to implement this mobile application with augmented reality? |

it indicates that 74% of the parents are confident that it does improve stress and 30% do not, in Q4 it indicates that the application will help in the treatment of learning disabilities. Likewise, 70 per cent are confident that it does improve stress and 30 per cent are not, in Q4 it indicates that 74 per cent of parents recommend that family members or close friends use the application for the treatment of learning disorders and 26 per cent do not, and finally in Q5 they responded that 78 per cent would recommend public and public schools in Peru to implement the mobile application with augmented reality and 22 per cent responded that they would not.

### F. Expert Validation of the Prototype

This validation was carried out with 5 experts who will be in charge of scoring the four criteria (Functionality, Usability, Consistency and Integration). These validations were carried out on the final prototype, ensuring that it will be acceptable by the experts.

In Table V the scales Low, Moderate and High were considered. Low will have a range of 0% to 49% indicating that it would not be accepted, Moderate will have a range of

Fig. 10. Response from the Testing Phase

50% to 79% indicating that the prototype can be improved and High will have a range of 80% to 100% indicating that it would be an acceptable prototype.

TABLE V. LEVEL OF ACCEPTANCE

| Level | | |
|---|---|---|
| Under | Moderate | High |
| 0% - 49% | 50% - 79% | 80%- 100% |

Likewise, to find the total percentage, it was calculated as the average of the four criteria, in percentages.

Table VI shows the scores of the five selected experts, so each expert will have to score each validation from 1 to 100, and finally the result shows the level of acceptance of the prototype.

TABLE VI. QUESTIONS TO EXPERTS

| Question about the prototype with augmented reality | | | | | |
|---|---|---|---|---|---|
| Experts | Functionality | Usability | Consistency | Integration | Total | Level |
| Expert 1 | 80% | 85% | 83% | 90% | 85% | High |
| Expert 2 | 90% | 85% | 95% | 80% | 88% | High |
| Expert 3 | 73% | 89% | 85% | 90% | 82% | High |
| Expert 4 | 89% | 92% | 90% | 97% | 92% | High |
| Expert 5 | 75% | 76% | 86% | 84% | 80% | High |

Finally, Fig. 11 shows the 5 validating experts with a high level, i.e. the prototype has a level of acceptance by each expert. Expert 1 indicates a high level with 85%, expert 2 indicates a high level with 88%, expert 3 indicates a high level with 82%, expert 4 indicates a high level with 92% and expert 5 indicates a high level with 80%. The overall average is 85.4% acceptance.

### G. About the Methodology

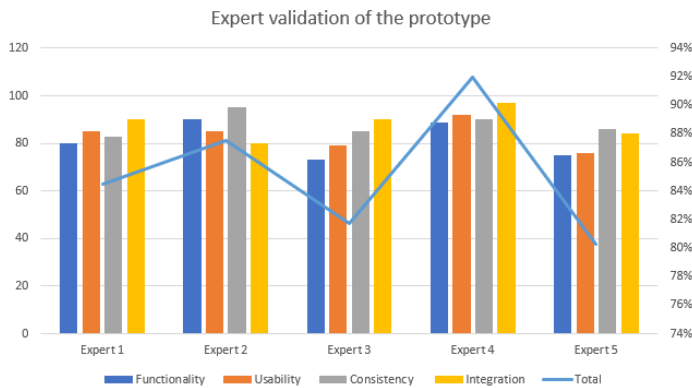
*1) Advantages:* The Design Thinking methodology was used to bring innovative ideas to meet user needs. This allowed us to have a dynamic teamwork to be able to bring new ideas to society and to improve the decision making process. This also allows us to see the creativity of the team and also the analysis that leads to the understanding of the problems towards the users.


Fig. 11. Expert Validation of the Prototype

*2) Disadvantages:* The disadvantages of the Design Thinking methodology is that it is more dedicated to the prototyping of innovative ideas and not to the development of the application. In this sense, it should be considered that this methodology can go hand in hand with another methodology for the development of the proposal.

*3) Comparison:* The 5-phase methodology helped us to speed up the process of analysis and creative ideas for prototyping. Compared to other methodologies that focus on the development of the application, these include proposing innovative plans for the contribution to society.

## V. Discussion

It is analysed that our proposal as a solution with the use of augmented reality is a good strategy, it is also integrated that the survey method that was effective for stakeholders to analyse their problems is valid for the search for solutions, this coincides with the author [15], who evaluated the problems based on surveys, proposing the use of technology to improve student learning. Similarly in the author [19], who conducted an analysis of the respondents, finding serious problems in students with learning disabilities so he proposes the use of augmented reality for computer, tablet and mobile assembly labs. In addition, the proposed design of a mobile application with augmented reality is a perfect combination as nowadays people handle their mobile devices anywhere, which results in user satisfaction. These results agree with the author [21], as he proposes a variety of mobile designs with augmented reality for advertisements in order to impact your customers with the use of technologies. In the same way, he indicates that the intuitive games with augmented reality in the [20] leads to a good result, validating an increase in learning and comprehension in his students.

## VI. Conclusion

This model of an augmented reality application is developed to improve learning disabilities. In the prototype educational games were made to have a better understanding, since the survey identified that children have problems with Dyslexia, Dyscalculia, Dysgraphia and Dysphasia. Design Thinking allows us to have a greater analysis of the problems in search of the needs of users, helping us to have a variety of creative and innovative solutions. This contribution of the design of a mobile application for the treatment of learning disorders using augmented reality in primary education would be of great help to have an adequate treatment in children with the use of technologies, allowing to improve their stress level and to have a greater understanding in their subjects. A limitation of the research that was identified was the development of mobile application and augmented reality, since the methodology used only focuses on the design of innovative prototypes for problem solving.

## VII. Future Work

It is suggested that the proposed research be considered for future work and that a virtual reality application be developed. In this way, children with learning disabilities can have a maximum technological experience. In addition, the research should be carried out in an interdisciplinary and multidisciplinary way, i.e. it is suggested that specialists in learning disabilities such as a psychologist, among others, be incorporated.

# Implementation of a Web System: Prevent Fraud Cases in Electronic Transactions

Edwin Kcomt Ponce, Katherine Escobedo Sanchez, Laberiano Andrade-Arenas

Facultad de Ciencias e Ingeniería

Universidad de Ciencias y Humanidades

Lima, Perú

*Abstract*—The purpose of this project is to prevent cases of fraud in e-commerce of purchase and sale from person to person through social networks. For the development of the research work, the Scrum methodology was used to allow the project to be carried out in an agile and flexible way, adapting to the changes that could arise along the way. The technological tools that made this project possible were SQL Server, C++, Visual Studio and Marvel app, the latter for prototype design. In addition, there was the support of an artificial intelligence software known as Optical Character Recognition that allowed the document recognition process to be completed. The social network Facebook was also relevant for the development process since the data set for the training of the system was obtained from there, guaranteeing its functionality. The results obtained benefit both parties, sellers/suppliers and consumers, reducing the impact of fraud cases and guaranteeing safer online operations. In addition, a validation was carried out by experts in the development of web applications, taking usability, feasibility, scalability, innovation, and technology as criteria. Obtaining as a result the approval in all its criteria; with the total mean value of 2.76.

*Keywords*—*Artificial intelligence; e-commerce; fraud; optical character recognition; scrum; social networks; web system*

## I. INTRODUCTION

Digital transformation has become more relevant in recent years as a result of the pandemic, although this process brings with it greater benefits and a positive impact on the development of a country, it also poses certain risks for a large number of the population. According to the World Economic Forum in a survey presented in its Global Risks Report 2021 [1], it indicates that cybersecurity flaws rank 7th out of a total of 37 risks presented. In Latin America, the growth of e-commerce due to the pandemic had an exponential increase, which meant a greater use of devices with internet access to carry out various operations such as payments or purchases of goods and services online [2]. Approximately 10 million Latinos have purchased consumer goods through electronic stores, however, one of the most relevant problems is the criminal activities carried out through computerized means as a consequence of this new normal [3].

Peru also adds to this growth, with e-commerce operations reaching an increase of 86% in June 2020 and reaching its highest point in July with 160%. This represents approximately 6 billion dollars, which covers the size of the e-commerce market as detailed in the report by the Peruvian Chamber of Electronic Commerce. However, this led to an increase in claims related to online transactions due to the few regulations and measures in this area. Let's take into account that before

the pandemic, Peru had around 65,700 businesses that sold online, but by the end of 2020 there were 263,200 businesses. We must add that this also brought with it the increase in informality in the digital sector [4].

In Peru there is a high rate of informality and this has been increasing according to the latest data provided by the National Institute of Statistics and Informatics, reaching an informality rate of approximately 75%, also affecting electronic commerce [5]. It is mainly social networks that are used for this type of informal trade, where many independent workers offer their products and services at very attractive prices. In this way they manage to capture even more the attention of the public, this activity through social networks represents an opportunity to generate income without discounts or commissions when carrying out their transactions. However, it is also an opportunity for fraudsters to carry out their criminal activities hiding behind anonymity and lack of security [6] [7]. These types of crimes are carried out through online transactions for advance payments without the guarantees or security that a platform of a formal company offers. The purchase and sale operation through social networks is based solely on trust between the seller/supplier and the customer, thus exposing themselves to being a victim of fraud [8].

Given the foregoing, the aim is to offer users the alternative of carrying out their online purchase and sale operations with greater security, thus avoiding and reducing computer fraud rates. This not only benefits the buyer but also the seller as it is an opportunity to demonstrate that their services and/or products can be requested with complete confidence. Thus, it also contributes to the security of the assets and personal assets of the citizen covered by the Law on Computer Crimes, thus being a reference to avoid fraud either by advertisements on a website or by social networks.

The objective of this research work is to implement a web system to prevent fraud in online transactions carried out by people through social networks. The platform will be available free of charge, allowing users to register and contribute by reporting fraud cases in order to expand the database, which in turn favors the system by improving its efficiency and accuracy. So that the reports by complaint are valid and avoid cases of misinformation; The user will be asked to attach the respective complaint so that their report can be considered. In this way, the aim is for users to have a system that helps them guarantee greater security in their payment transactions or online purchases for a requested product. As well as independent workers or business owners, they can avoid loss of resources and time by ensuring that their sale

is finalized and that it is not canceled at the last minute.

The article is organized as follows: in Section II the review of the literature, Section III the methodology, Section IV the case study, Section V results and discussions, Section VI the conclusions and finally Section VII future work.

## II. Literature Review

The investigation addressed the issue of fraud prevention through electronic commerce, through the development of a web system. The studies of different authors on the research topic are analyzed in order to have information on trends, limitations, among others.

According to the authors [9], their application allows identifying customers who may pose a risk of fraud for an electronic commerce, through the information of cookies or IP configured in the devices used for online transactions. Normally, fraudulent clients do not make changes to their laptop, smartphone or computer, so the application manages to keep a record and identify the devices with a history linked to these criminal acts. To achieve their objective, the developers of the project use three main components for their fraud detection system, which are PC identifier, Address identifier and Asset Classifier. These methods are based on data extraction and statistical analysis. A total of 8,020 purchase requests were analyzed, efficiently detecting suspicious transactions compared to traditional methods that use data mining, but with poor performance.

For the [10] authors, the most frequent fraud operations are carried out through the use of a credit card through e-commerce. His proposal consists of applying the Support Vector Machine (SVM) algorithm, allowing fraudulent operations to be identified and classified from safe operations. The methodology for its system includes using fingerprint scanning as a measure to reinforce security during registration and access to online operations. If a transaction is classified as fraud, the payment process will be canceled and the fraudulent user's information will be sent to the database. Finally, it can be concluded that the SVM is an efficient algorithm with an accuracy of 99.9% according to a comparison table of several models prepared by the authors. These qualities of the algorithm make an accurate classification in the process of online fraud unlike other methods.

In the work developed by [11], the authors propose a new data intelligence technique with the aim of maximizing the model in the detection of fraudulent operations, without having to depend on the data variation that may exist. As in the previous article, this project focuses on operations carried out through online payments through e-commerce. The proposed system works with the Multiple Prudential Consensus model that uses and integrates the efficiency of different classification algorithms through a double criterion, probabilistic and majority. The final algorithm is determined to classify authorized or fraudulent operations according to the previously determined model and according to the analysis of criteria elaborated. The results obtained demonstrate the effectiveness of the model, compared to other systems used to detect cases of fraud. Of a total of 492 fraud samples, the developed model was able to correctly detect 394 compared to the 349 cases that were detected by the model that ranked second. The results confirm

that the proposal stands out among many other solutions both in terms of models and classification.

The authors [12] use Blockchain-based technology which is quite secure and efficient. One of its great advantages is that once the data has been registered, it is possible to alter or delete it. In addition, it is a fairly simple technology and easy to understand. Blockchain is a chain of blocks which consists of a single registry network where information from the previous block is stored and thus passes the information to the following blocks. Based on this they decide to implement this technology to support online fraud detection and thus qualify a valid purchase. Blockchain will store verified transactions and their associated qualifications, making "verified" labels no longer necessary. It is concluded that blockchain systems are quite efficient in detecting online user fraud compared to traditional methods. In addition, the system allows better control of false accounts or information and has a reputation system to effectively reduce the number of fraudulent ratings.

In the research work developed by the authors [13], they propose a proposal based on Machine Learning in order to improve the existing fraud detection systems. They consider that there is an urgency for a better detection and prevention of cases of electronic fraud. Its model is based on the use of Machine Learning algorithms integrating big data, allowing it to predict the probability that an electronic operation is safe or fraudulent. The model was trained with a dataset composed of history of credit card transactions through electronic commerce; in order to predict any probability of fraudulent operations. Specifically, supervised learning algorithms such as Random Forest, Support Vector Machine, Gradient Boost and combinations of these were used, comparing their performance. The results obtained confirm the accuracy and precision of the proposal by combining the Gradient Boost + Logistic Regression algorithms. In addition, the model, being based on Machine Learning, has an addition that is Active Learning. This new addition allows solving data labeling problems, which means an improvement in learning for fraud detection.

After analyzing the different proposals developed by the cited authors, it is considered that the use of technologies and application of engineering is of the utmost importance to combat the growing increase in cases of computer fraud. Although most of the works focus on the use of algorithms and models for more sophisticated systems, none addresses the problem of fraud when both parties involved are natural persons. The approaches and initiatives apply to companies already established and that have the economic factor to implement the systems in their respective businesses. However, in our country there is a large percentage of independent workers who offer products through social networks. Merchants do not have their own payment system and are also responsible for making deliveries in person via delivery. For this reason, what we are looking for is to develop a web system that facilitates the safe use of this type of electronic commerce. Thus, users can make their purchases with the security of knowing if they are dealing with someone reliable for their transactions.

## III. Methodology

In the research carried out, an agile methodology was used, which allows the development team to have constant

communication and be able to carry out work efficiently, quickly adapting to the changes that may occur during the project. Next, the methodology used and the technological tools that were necessary for this project are described in detail.

### A. SCRUM Methodology

It is a methodology that offers a personalized and flexible way of working that is suitable for software development projects with a variety of requirements [14]. This iterative work model establishes the delivery of project progress incrementally, thus achieving more efficient results and greater productivity. In Fig. 1, we graphically observe the process followed by this methodology and its respective work phases.

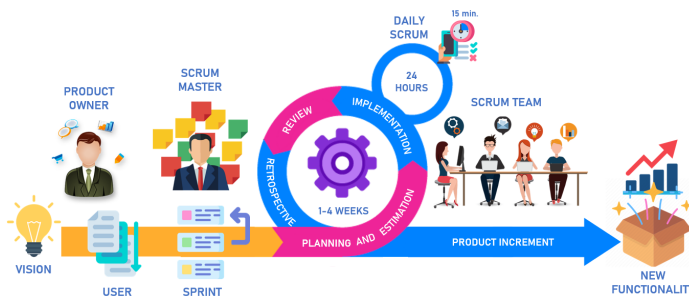

Fig. 1. Scrum Methodology Workflow.

*1) Beginning:* It is the first phase where the roles and functions of each member of the development team are identified and defined, these are assigned according to the skills and contributions of each member to the project, in the process the Scrum Master, Product Owner and the Scrum Team intervene [15]. Where the Scrum Master is mainly responsible for removing obstacles to the development of the project while the Scrum team is made up of developers, evaluators and other professionals necessary to guarantee the quality of the product.

*2) Planning and Estimation:* It is the next phase, the user stories are proposed and chosen according to the client's requirements, the product backlog is also carried out taking into account an estimation process for an adequate order of the stories. Once the requirements are organized, the sprint backlog is created. These are selected by priority and will go through the development and execution process. With the defined sprints, the team is responsible for between 1 and 4 weeks of the process to program, design and execute the sprint after the product increment is finished, the team continues with the next sprint.

*3) Implementation:* It is the third phase of the Scrum workflow, the objective is to deliver each sprint of the product organized, error-free and potentially operational, and generally at the beginning of the day during this phase small meetings are held [16]. These meetings are known as Daily Scrum that can last 15 minutes where the progress of the previous day is communicated and at the same time what impediments may be occurring for the progress of the project are discussed.

*4) Review and Retrospective:* It is the fourth and final phase of the work method, once the sprint is potentially deliverable at the end, a review of said sprint is carried out with the Product Owner to show the increase in the product. The increment is inspected and its functionalities are demonstrated. Sometimes the product list must be adapted according to the possible new requirements that the Product Owner indicates [17]. After the review, we proceed with the retrospective; where the Scrum Team makes an analysis of itself with the possibility of proposing strategies to execute improvements in the way of working for the following advances.

### B. Technological Tools

For the research work, it was considered to use specialized applications and programs for this type of project with the intention of having an adequate development environment; thus achieving the correct implementation of the proposed system.

*1) SQL Server:* It is a relational database management system that uses the Transact-SQL development language. It is ideal because it allows you to store all the information you want with a wide variety of processes and with different utilities. Plus, easily integrate application data and leverage a rich set of cognitive services to power AI processes at any data scale.

*2) Visual Studio:* It is a program that provides us with an integrated development environment which facilitates the creation, design and development of web sites and applications, at the same time allowing us to work in environments that support the .NET framework. It is compatible with a wide variety of programming languages, such as C#, C++, Visual Basic, Python, Java, PHP among others.

*3) Python:* It is a high-level programming language that processes all kinds of data. Its software is free, that is, it has no cost, allowing it to be used and distributed even for commercial use. It is accessible and multiplatform, it has an extensive library, as well as a varied repertoire of frameworks, also standing out for its simplicity of syntax.

*4) Marvel App:* It is a web application to work online that allows us to make layouts and prototypes of both web pages and applications on mobile devices. The tools it makes available are sufficient to create designs that allow developers to have clear ideas of the final product.

*5) Artificial Intelligence (AI):* This technology aims to allow software to have the ability to learn based on data, which arise from patterns and opportunities provided by developers. Once the necessary data set is obtained, performance tests are carried out to measure and calculate the efficiency and accuracy of the AI software based on the number and quantity of hits and misses [18]. Deep Learning is a type of AI that uses multiple processing steps, also known as layers, to learn and then recognize data representations with multiple levels of abstraction. It is based on artificial neural networks, one of the specialties of this AI is image processing.

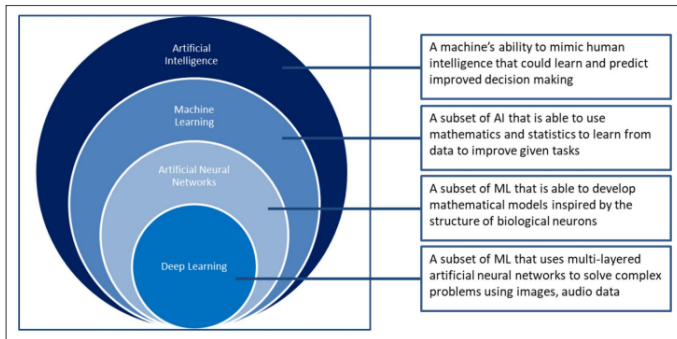
In Fig. 2, it can be seen how AI is classified, while in Fig. 3, we see the main classes of neural networks used by deep learning. For the development of this project, we worked with the Recurrent Neural Networks architecture because it was the one that best adapted to the required functionalities of the web system.


Fig. 2. Graphic that Shows how Artificial Intelligence is Classified in its Different Subfields [19].

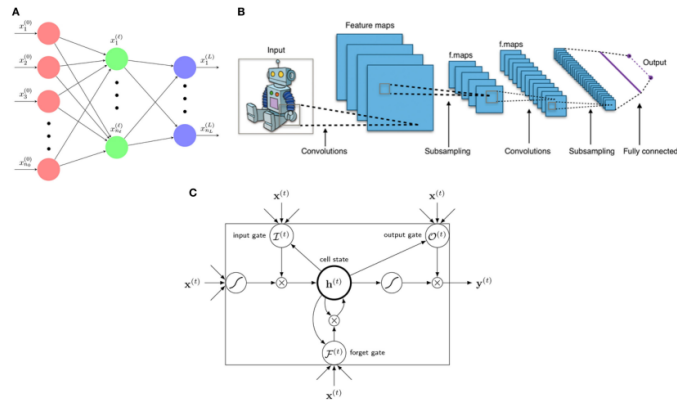

Fig. 3. The 3 Main Architectures of Deep Learning, A) Artificial Neural Network, B) Convolutional Neural Networks and C) Recurrent Neural Networks [20].

## IV. CASE STUDY

### A. Planning

With the roles already defined and assigned among the team members, the planning continues. Where we choose the user stories, these determine the desired features and functions of the web system requirements. For this project, a total of 10 user stories are proposed, in Table I you can see the description of each story, which allows us to better understand the operation of the system.

### B. Estimate

Here the user stories are organized through the product backlog, in this list certain criteria are taken into consideration so that the stories are properly ordered. The estimation process is carried out through planning poker, when putting this technique into practice the team must assign a number (Fibonacci series) to each of the user stories. The assigned numbers are chosen from lowest to highest according to the level of difficulty that the team members consider for the development of each user story.

In Table II, we can see the product backlog developed and ordered by priority, this is defined by the effort and difficulty of development as well as its relevance in the project. As a reference to choose the priority of each story, story number

TABLE I. USER HISTORY

| History No. | Description |
|---|---|
| H1 | As an administrator, I want a web platform that through its design is intuitive and friendly to be used easily. |
| H2 | As an administrator, I want the web platform to allow the user to know if a seller/supplier has a history to avoid being scammed. |
| H3 | As an administrator, I want the web platform to have a wide database to be more efficient and precise in the search for results. |
| H4 | As an administrator, I want the platform to allow users to write reviews to better understand the type of fraud that the accused uses. |
| H5 | As a user, I want to contribute by registering duly substantiated complaints to improve the prevention capacity of the web. |
| H6 | As a user, I want to be able to register on the web platform in order to be prevented from various cases of fraud. |
| H7 | As an administrator, I want the platform to have a section where information related to computer crimes is displayed to keep users informed and warned. |
| H8 | As an administrator, I want the web system to validate the attached file that will be uploaded as evidence by the user to detect if it is a police report. |
| H9 | As an administrator, I want the platform to have a section with external links to government pages to provide support and guidance to victims of fraud. |
| H10 | As administrator, I want the web platform to allow knowing a ranking of fraud complaints by number of complaints and type of fraud so that users can better and easily manage the information. |

9 has been selected as its development is considered the least difficult.

TABLE II. PRODUCT BACKLOG

| History No. | Estimate | PRIORITY | Sprint |
|---|---|---|---|
| H3 | 5 | 1 | 3 |
| H8 | 8 | 2 | 3 |
| H2 | 3 | 3 | 3 |
| H5 | 3 | 4 | 2 |
| H10 | 5 | 5 | 2 |
| H4 | 2 | 6 | 2 |
| H6 | 2 | 7 | 2 |
| H9 | 1 | 8 | 1 |
| H7 | 2 | 9 | 1 |
| H1 | 2 | 10 | 1 |

The project is divided into 3 sprints, the first sprint has a total of 5 story points, because it requires less effort. When starting with the development of the sprints, the work team begins to integrate allowing better team work as each iteration progresses. The second and third sprints receive 12 and 16 story points respectively. Likewise, the points have increased due to the time and effort required by the requirements corresponding to these sprints. At this point in the project, the team is able to communicate and organize much better, thus achieving good coordination in the development of the web system and minimizing errors. Fig. 4 graphically shows the order by effort from lowest to highest of the user stories and the sprints to which they have been assigned.

### C. Implementation and Development Stage

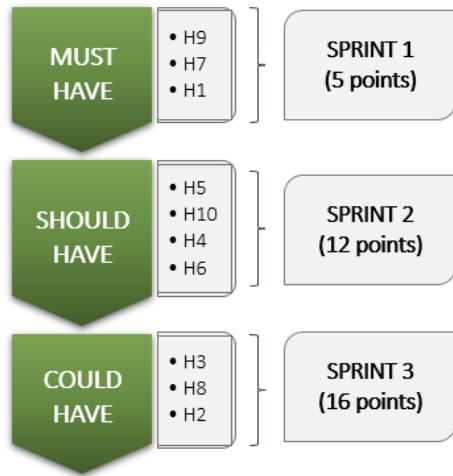
In this stage, the use of the technologies to be implemented and the procedure proposed for the web system are explained in detail.


Fig. 4. Story Points and Number of Sprints.

Fig. 5. Three Layer Architecture.

Fig. 6. Flowchart for Obtaining the Data Set.

*1) Software Development:* The web system was developed applying the use of the Model View Controller (MVC), which is a software architecture style based on three layers or levels. This type of model has proven its worth over several years and across various types of applications, a variety of programming languages, and development platforms. The model separates an application's data, user interface, and control logic into three distinct components:

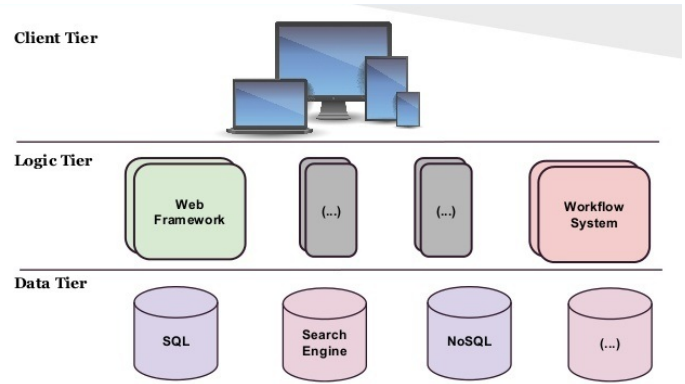
*a) Model:*
Also known as the data layer, it is where the data is located and is responsible for accessing it, it is made up of one or more database managers that perform storage. It has a representation of the data used by the system, its business logic and records of the controls and views of the system.

*b) View:*
It is the user interface also known as the presentation layer, it shows the system to the user and interacts with it through mechanisms. It also integrates and organizes the information that is sent from the model through the controller, that is, it receives the data and shows it to the user.

*c) Controller:*
Also known as the business layer or business logic because it is here where all the rules that must be met are established. It acts as an intermediary between the Model and the View, managing the flow of information between them to request the database to store or retrieve data. That is, it receives requests from the user and sends responses after the process. This is also where the programs that run are located.

In Fig. 5, we can see graphically a basic scheme of how the chosen model is structured.

*2) Data Set Preparation and Extraction:* For the present project, a set of data was needed to be used for training and testing the different functionalities that were sought to be implemented.

In Fig. 6, we observe the process to obtain the data in image format, the social network Facebook served as the basis for extracting said information. By accessing a personal account, they entered communities called groups that the social network


offers where its users can exchange or share common interests. Then we began with the search for public publications where users of the social network made reports of having been victims of fraud.

Finally, only those publications with support were considered where images of police reports were extracted to form the data set needed by the project. This meant dividing the data into two groups, allowing training and then checking the correct functioning of the web system. In this way, it was also possible to correctly identify the types of attached files in image format that are uploaded to the system by users.

*3) Optical Character Recognition (OCR):*

*a) Definition:*
It is a software that allows us to recognize text in digital documents including images, it has become a very useful tool due to its precision, speed and efficiency to classify documents and/or extract information from them [21]. For the present research work, the Optical Character Recognition software was implemented as part of the web system for the desired function of classifying the information provided by users. In Fig. 7, we can see the process and threads carried out by the software for text extraction, once the results are obtained they can have various applications as indicated in the graph.

*b) Recurrent Neural Network (RNN) and Tesseract OCR:*
From simple image classification to medical scans, speech

Fig. 7. Basic Flowchart of how OCR Works.

recognition and text-in-image recognition are among the many essential functions of deep learning. The RNN is a kind of neural network that is part of deep learning, it allows input data to flow in any direction along a time sequence through the layers that make up the network. The Long short-term memory (LSTM) is a type of RNN that has feedback connections, managing to process not only individual data but also complete sequences of data, avoiding loss of information over time [22].

For the proposed system, we worked with the Tesseract software, which is open source, which uses OCR and is complemented by LSTM to achieve a more efficient result in the field of text recognition through digital images. In addition, it has an extensive library that facilitates its training with a certain set of data. In Fig. 8, we can see the architecture of the Tesseract software in conjunction with the LSTM neural network.

Fig. 8. Tesseract Architecture where it is Noted that there are Many Revisions of Old Decisions [23].

*c) Operation:*

OCR software is normally composed of four stages that are pre-processing, segmentation, character extraction and final recognition of the text, the mentioned sequence can vary depending on the results that are desired to obtain. For the present research work, since they are simple documents and in the format of a police report, the process for text recognition did not imply difficulty.

Fig. 9 shows the operation and the stages carried out by the OCR, once it manages to recognize the text in the digital document, it can also extract said information for later use, which depends on the purpose of each system that uses this technology [25].

Fig. 9. Flowchart of the Process Performed by the OCR Software [24].

*d) Execution and Process:*

With the developed web system, the recognition software was implemented, the steps to be followed by the system as a whole were verified according to the proposal to confirm its viability and correct use. It was considered to focus a greater effort on the function of the system that requires the support of artificial intelligence because its operation is essential for the rest of the processes.

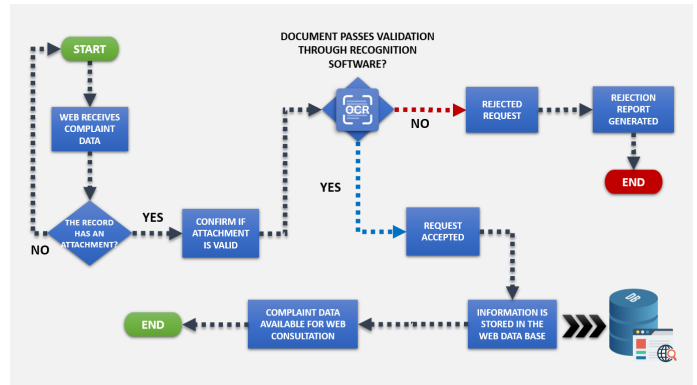


Fig. 10. Flowchart Showing Web System Working with OCR Software.

As shown in Fig. 10, the step to register a case of fraud involves attaching evidence to support it, the user through the web system must upload their respective police report in image format. Once the system receives the information of the complaint with the attached image, the recognition software will validate whether or not the image is valid by extracting the text and classifying it. If the validation result is positive, all the information entered is stored in the web system database for later use in user queries.

## V. RESULTS AND DISCUSSION

Finally, each sprint and its respective user stories are explained in detail, as well as the operation of the complete web system and we verify the importance and viability of the project through statistical data.

### A. Design and Prototypes

The prototypes were developed based on user stories, these allow us to understand graphically and in detail each function implemented in the web system, as well as its importance in this project. This section shows the main prototypes organized by sprints which make up the research work carried out.

*1) First Sprint:* This sprint mainly covers interfaces that do not require much effort and time, with a total of three deliverables. In Fig. 11, we see the prototype that represents the home page of the web system, in it the user has the option of being able to log in or register by creating an account. You can also see a brief description of the objective of the platform and at the top is the design of the created logo.

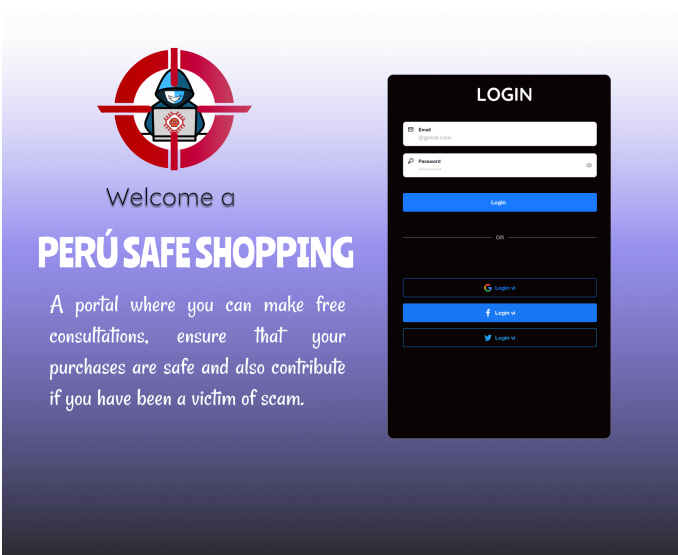

Fig. 11. Prototype based on User Story 1

In Fig. 12, we see the prototype designed for the informative section of the platform, this section includes news and advice to guide the user so that they can stay informed and prevented from the main cases of fraud and fraud at the national level.

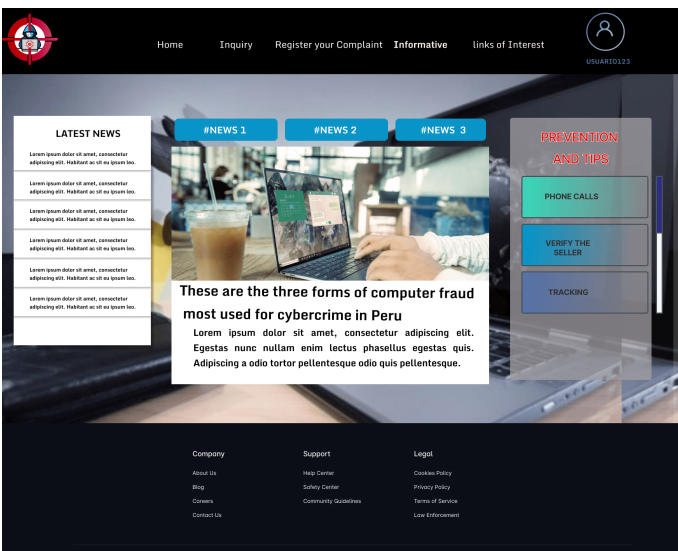

Fig. 12. Prototype based on User Story 7

*2) Second Sprint:* In this sprint, interfaces were mainly developed whose function is to show relevant information on fraud cases, which have been duly validated and stored in the system's database. In Fig. 13, the prototype shows the interface

where the user must fill out the complaint form, an important requirement in this step is to attach the document where the police complaint is certified.

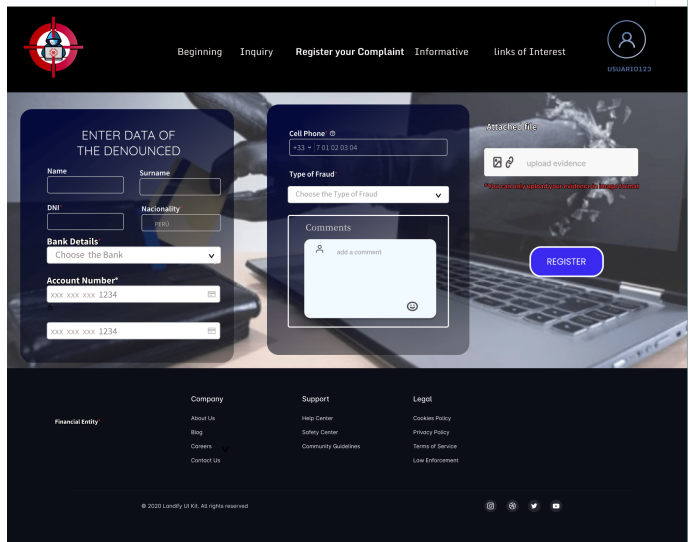

Fig. 13. Prototype based on User Story 5

The prototype in Fig. 14 shows the interface where the most reported cases of fraud can be queried, through predetermined filters such as payment method, number of reported cases and by city. In the section on the right of the interface, an easy-to-understand graph for the user is shown, where relevant information on the registered cases appears.

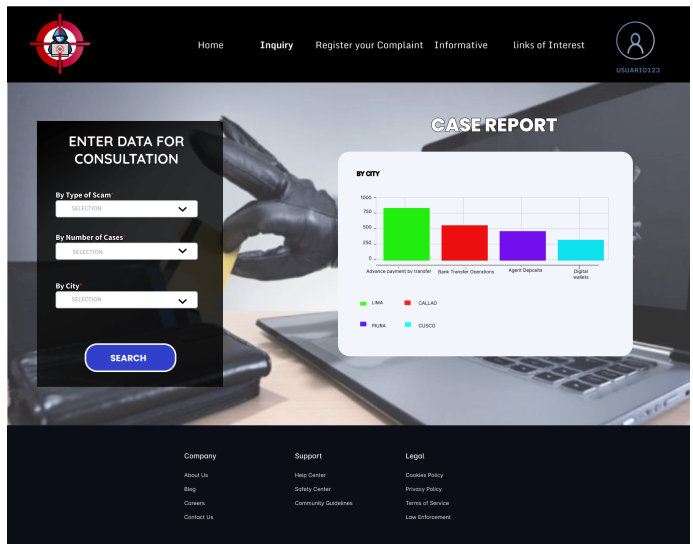

Fig. 14. Prototype based on User Story 10

In Fig. 15, we see the prototype for the user registration interface, basic data is requested for the creation of an account on the platform, also giving the alternative of being able to use a username instead of the personal name.

*3) Third Sprint:* This sprint is mostly related to internal processes and the logic of the web system, for that reason it is the sprint that requires the most time and effort in the

Fig. 15. Prototype based on User Story 6

development of the project. The database was initially filled manually in order to carry out the first tests of the system and detect possible errors.

Subsequently, the filling of the base continued, taking advantage of the learning process that the OCR software needed for optimal performance in the recognition of the entered documents. As mentioned in the Case Study section, the document in image format will allow the complaint record to be considered as valid or not.

Fig. 16 shows the interface where the user can check if a seller/supplier has been reported on the platform as a fraudster. Some of the requested data must be entered so that the system searches the database and displays the information of the accused in the section on the right.

Fig. 16. Prototype based on User Story 2

## B. Complaints Registered for Computer Crimes

Cybercrime in the current context is on the rise and the most affected are the consumers who have to deal with the loss of their property as a result of this type of crime. Although measures are being taken in the country and laws are being applied to regularize this situation, the efforts and policies applied have not worked properly or have not been sufficient. In Table III, we see a comparative table of the complaints made in the last five years in terms of computer crimes. Where computer fraud represents 78.2% of the reported cases, these cases are investigated by the High Technology Crimes Investigation Division (DIVINDAT).

TABLE III. COMPLAINTS OF COMPUTER CRIMES INVESTIGATED BY DIVINDAT

| Crime | 2015 | 2016 | 2017 | 2018 | 2019 | 2020 | Total | % |
|---|---|---|---|---|---|---|---|---|
| Computer Fraud | 414 | 610 | 1219 | 1928 | 2097 | 2615 | 9515 | 78.2 |
| Card cloning | 46 | 44 | 30 | 120 | 25 | 4 | 394 | 4 |
| Fraudulent online purchases | - | - | - | 287 | 431 | 261 | 979 | 8 |
| Unauthorized electronic and/or fund transactions and transfers | 368 | 566 | 1189 | 1521 | 1641 | 2350 | 8142 | 86 |

The crimes were classified according to the type of complaint: card cloning, fraudulent online purchases and unauthorized electronic and/or fund transactions and transfers, the latter being the one that forms part of this research work. The notorious increase in cases of this type of fraud was verified, registering a total of 8,142 complaints from 2015 to 2020. It was also identified that this type of fraud represents 86% of this type of computer crime, thus occupying the first place among the 3 types of cases [26].

## C. Informality and Social Commerce

Informality in the country remains high, according to the Institute of Statistics and Informatics (INEI) in a study carried out in 2020. With a sample of 15,224, it was confirmed that approximately 30% of them are in the category of workers. self-employed in the informal sector [12]. With these data we can have a better picture of how broad the group of independent informal workers is, even more so if we consider that 75.3% of workers are informal at the national level, as can be seen in Fig. 17.

Informality in Peru originates mostly from tax evasion and limited resources by independent workers who fail to comply with all the requirements and procedures established to formally set up a business as required by law [12]. The limitation of resources also affects the possibility of not investing in infrastructure or having your own online store. For the aforementioned reasons, informality has also moved towards electronic commerce where sellers/suppliers establish their businesses online.

They mainly carry out their commercial activities through social networks since these do not imply any type of cost, giving greater facilities to position themselves in the digital
Fig. 17. The Participation of the Formal and Informal Economically Active Employed Population (PEAO) for the Year 2020 is Shown.

market. The independent worker or business owner offers their products/services describing their characteristics through Instagram or Facebook. The purchase/sale is made directly through these platforms or transferred to WhatsApp where the date and place of delivery are agreed.

### D. Fraud and Social Networks

There are a large number of purchase and sale operations carried out through social networks such as Facebook, WhatsApp and Instagram where there are informal businesses with good intentions to comply with what is offered. But there are still risks for buyers since it is not the same to buy in a known establishment than to buy through a social network from a stranger. Fraudsters and/or computer criminals take advantage of the anonymity of social networks to commit their crimes, their way of operating involves creating false personal or business accounts as a facade. Then, through deception, they promise supposed products or services that they offer if they are previously paid in advance to cover the expenses involved in the delivery or fulfillment of what is offered.

TABLE IV. REQUESTS FOR ACTIVE JUDICIAL ASSISTANCE

| Requirements | Number |
|---|---|
| Facebook account information | 45 |
| Email account information | 18 |
| Request information from Facebook, Messenger, WhatsApp | 3 |
| Request information from Google | 2 |
| Request information from a website | 2 |
| Arrested user identity, intervention information in the Russian social network account | 1 |
| Request information from various companies that provide social networks | 1 |
| Request removal of communications and traffic information and content of a Facebook account | 1 |

According to the report on Cybercrime in Peru [26] prepared by the Public Ministry, 45% of active judicial assistance has been aimed at requesting information from Facebook accounts and 9% has involved social networks. In Table IV we can observe some of the requested requirements where requesting information from social networks for the cases in question stands out. These requests were made with the intention of helping the competent entities to clarify investigations and criminal proceedings that implicate social networks as a means of criminal acts related to computer fraud.

### E. Risk Prevention and Minimization

Through social networks, mainly through Facebook, it was found that there is an interest on the part of citizens to make public their complaints, reports or report cases where they have been victims of fraud. However, the information through this platform is not centralized or organized, which makes access to said information difficult. In addition, through social networks there are no terms and conditions that guarantee 100% secure purchase and sale transactions. For these reasons, this project seeks to organize the data and minimize the risks due to computer fraud as a result of social commerce.

Both parties, both consumers/buyers and suppliers/sellers, can benefit from this initiative. On the one hand, the consumer/buyer who makes sure that the other party involved in the transaction has not been reported for any type of fraud. And on the other hand, the supplier/seller that manages to generate greater confidence in its clients and gain a better reputational image for its business by not being reported in the base of the proposed system.

### F. Web System

The web system was designed and developed with the objective of executing a set of tasks that allow users to take preventive measures before carrying out any operation and to carry out their transactions online safely. Next, the operations of the web system are explained, grouped by their functionality, as well as the results obtained through a survey carried out on experts to validate the quality of the system.

*a) Registry Functionality:*
Made up of the User Registration and Complaint Registration sections, these have the function of allowing the entry and registration of data within the system. The first section mentioned authorizes access to the platform and the second section allows you to report cases of fraud by attaching your respective police report.

*b) Query Functionality:*
Made up of the Home, Search, Informative and Links of interest sections, these have the function of allowing the user to see information related to the topic of prevention through the different interfaces of the platform. In the particular case of the search section, it grants access to consult information on the cases reported in the system.

*c) Tesseract OCR Performance:*
The free software Tesseract with its LSTM-based OCR engine complemented the development of the system by facilitating the recognition of attachments provided by users; managing to identify and classify the documents as valid or not and confirming that they were a police report. The accuracy of the LSTM Recurrent Neural Network for text recognition in Urdu script was evidenced in the [27] investigation. This type of writing is based on an Arabic cursive style and due to its nature makes the text recognition process even more difficult.

However, in Fig. 18, the results obtained from this investigation are verified where the LSTM model achieves an accuracy of 98.38% despite the difficulty in recognizing the aforementioned writing. In the present research work, it was decided to use the Tesseract software precisely because of the good performance and precision that it has shown in

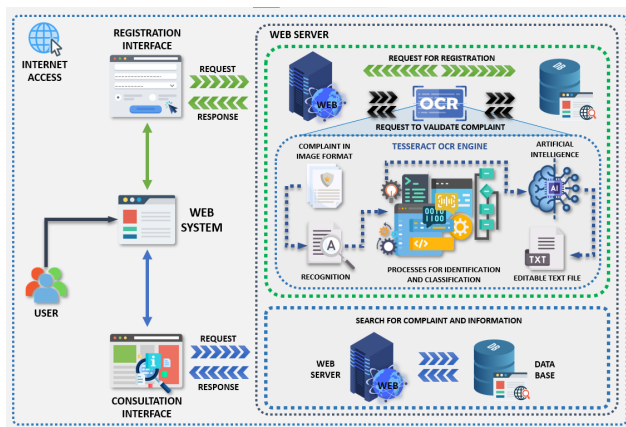
TABLE V. RESULT OF VALIDATION BY EXPERTS

| Criterion | Questions | Media | S.D |
|---|---|---|---|
| Usability | The web system runs responsively through any type of browser. | 2.87 | 0.35 |
| Usability | The web system has a friendly and easy-to-use interface for users. | 2.75 | 0.46 |
| Usability | The web system is properly organized for users to understand. | 2.87 | 0.35 |
| Usability | The design of the web system works according to a programming structure. | 3 | 0 |
| Feasibility | The web system development budget covers cloud storage. | 2.62 | 0.51 |
| Feasibility | For the development of the web system there was a certain cost or budget. | 2.50 | 0.75 |
| Feasibility | Business strategies have been designed so that the web system generates profitability. | 2.75 | 0.46 |
| Scalability | The web system is stable even with the increase in user load. | 2.62 | 0.51 |
| Scalability | The web system has a fast response time in relation to its database. | 2.87 | 0.35 |
| Scalability | System processes are well established and function properly. | 2.87 | 0.35 |
| Innovation | The web system performs quick queries regarding information on fraud complaints. | 2.87 | 0.35 |
| Innovation | The web system has been created to be able to implement more information modules on computer crimes. | 2.62 | 0.51 |
| Innovation | The web system constantly obtains knowledge and/or relevant information. | 2.75 | 0.46 |
| Technology | A transactional database was used for queries and storage of information. | 2.62 | 0.51 |
| Technology | A specialized programming language for web systems with artificial intelligence support was used. | 2.87 | 0.35 |
| Technology | A framework was used for interface design and programming of the web system that is adaptable. | 2.87 | 0.35 |
| Technology | The web system can be adapted to any type of device. | 2.75 | 0.46 |

Fig. 18. Comparison between 3 Models of Artificial Neural Networks to Recognize Text in Urdu Script [27].

Fig. 19. Web Application Architecture.

best OCR today.

*d) Validation of the Proposed Model with Experts:*
This section specifies the results obtained through a survey of 8 experts to validate the quality level of the web system. The criteria used were: Usability, Feasibility, Scalability, Innovation and Technology. The questions raised were made using the Likert scale with the answer option: 1 (very low), 2 (intermediate), 3 (very high). The questions that were applied in the validation measure the level of acceptance of the web system by experts in the development of these applications. Table V shows the result of the validation, which is divided by different criteria as well as the proposed questions and the level of quality obtained based on the calculations for the mean and standard deviation (S.D.) of each question. The calculation of the mean allowed to establish the range of the quality level, it was obtained as a result of the total mean of all the criteria of 2.76. In that sense we can say that it has been approved by the experts.


As mentioned at the beginning of this project, the use of fraud prevention systems reduces the impact of these crimes. In the research work of [28], the favorable results were confirmed with figures when implementing a web system with the same purpose. In just 1 year, the number of computer fraud cases was reduced from 30% to 28% through its proposed model, which is also supported by artificial intelligence.

On the other hand, the investigations of [9] and [10] focus on reducing cases of fraud when purchases and payments are made through electronic commerce platforms that are part of formally constituted companies. In addition [11], [12] and [13] seek to improve the existing systems of companies that have the resources to pay for more sophisticated projects. However, the works in question do not focus or have an alternative solution for cases where purchase or sale transactions are made from person to person and that is the most used type of commerce in Peru. The proposal does not seek to favor formality, on the contrary, it seeks to offer an option for safer transactions, giving these informal businesses the opportunity and time to have enough capital to later be able to go formal.

In Fig. 19, we can see graphically the architecture of the proposed web system and the aforementioned functionalities. You can also observe in detail the support given by the OCR

more complex cases to identify texts in documents with image format. In addition, the software has several advantages such as having an extensive library with features that facilitate rapid learning. It also has models for several languages, covering 116 languages including Spanish, it is even recognized among the

tool to validate the entry of a complaint into the system, which allows the automation of this process. In this way, manual reviews of the complaints were avoided, saving time, reducing possible costs, searching for quick information and improving the management of the web system.

## VI. CONCLUSION

Finally, the research work demonstrated how the proposed system contributes to the prevention of computer fraud caused by the digital informality present in social networks. The results of the project show how the system can reduce and minimize the risks of online purchase and sale transactions through advance payments which are made by bank transfers or the use of digital wallets. In this way, safer and more reliable operations are guaranteed in favor of the consumer/buyer who is the main affected in this new and growing digital commerce. The development of the web system aims to provide an easy-to-use tool, within the reach of the population and that allows them to be alert to situations of possible fraud. Reducing the impact caused by this type of computer crime until the competent entities can implement better measures to reinforce the computer security of citizens in the country.

## VII. FUTURE WORK

As future work, it is suggested to continue investigating and incorporating different disciplines such as computer security, computer risks, cryptography. Also apply another methodology that is related to risk management. At the same time, it is recommended to delve into OCR technology to take advantage of the features it offers much more and to improve the productivity of the system by automating it. Likewise, it is possible to combine specialists in the areas of computing and electronics so that together they can contribute even more to the research project.

*Abstract*—**The performance evaluation of motion planning algorithms for agricultural robotic manipulators is commonly performed via benchmarking platforms. However, creating a realistic benchmarking scene that constrains the motion planning algorithms with the characteristic of a real-work environment has always been a challenge worthy of research. In this paper, we present a lab-setup benchmarking platform to evaluate Open Motion Planning Library (OMPL) motion planners for the application of a robotic harvester of a palm-like tree using a real-time 3D occupancy grid map. First, three motion problems were defined with different levels of complexity based on a real oil palm fruit harvesting task. To achieve reliable outcomes, the benchmarking scene was modeled by converting point cloud data from a stereo-depth sensor into a 3D occupancy grid map using the Octomap algorithm. Then the benchmarking was performed, all within a real-time process. According to the results, a fair performance evaluation was achieved by modeling a realistic benchmarking scene, which can help in choosing a high-performing algorithm and efficiently conducting such harvesting tasks in real practice.**

## I. Introduction

Over the last few decades, intelligent robots for fruit harvesting have been actively developed to bridge the increasing gap between feeding a fast-growing population and limited labor resources. Moreover, the recent international travel restrictions due to the COVID-19 pandemic in 2019-2021 have exacerbated the limited labor resources issue, leading to the unavailability of seasonal migrant workers [1]. A robotic harvester can significantly boost productivity by reducing labor and production expenses, increasing yield and quality, and improving environmental management [2]. However, current harvesting robots are limited in their capabilities in motion planning, designed for specific plant structures. This limitation is due to the target crops' unstructured and dynamic nature and obstructions within their working environment [3], [4]. Environment obstructions, such as branches and leaves, reduce the performance efficiency of harvesting robotic manipulators. In addition, they are likely to collide with those obstacles when performing harvesting tasks. Therefore, establishing a benchmarking approach to accurately evaluate a collision-free motion planning algorithm for a given task is crucial to increasing the performance of robotic harvesting manipulators.

This study aimed to perform a benchmarking of different

motion planning algorithms based on real-time perception, i.e., 3D occupancy grid mapping for a robotic harvester of a palm-like tree application. In general, palm-like trees, such as oil palm, dates, and coconut trees, have unique morphological characteristics that challenge motion planning algorithms differently from other crops. The benchmarking of motion planning algorithms based on real-time 3D occupancy mapping should achieve reliable outcomes due to the actual characteristics of the working environment, which is mimicked from the real working environment into the benchmarking scene and constrains the motion planning algorithms. In this work, four motion planning algorithms from the OMPL library, namely, RRTConnect, BiTRRT, BFMT, and FMT, were benchmarked using ROS and MoveIt platform. The process outlined in this study contributes significantly to performing the motion planning benchmarking based on realistic environmental conditions. Furthermore, it can help adopt a high-performing motion planning algorithm and effectively execute such harvesting tasks in actual works.

## II. Related Work

In this section, we discuss the role of various benchmarking platforms in evaluating motion planning algorithms for different applications in the literature. In addition, a brief overview and application of 3D occupancy grid mapping in robotic real-time perception will also be presented.

### A. Motion Planning Benchmarking

Motion planning is a fundamental topic in robotics that deals with finding an optimal path that satisfies a target specification subject to constraints [5]. The issue of "which planner to choose" could be hard to answer, given the wide range of applications that robotic manipulators are used for [6]. During the last few years, several works have compared and analyzed the motion planning algorithms via benchmarking for different applications during the last few years. Iversen and Ellekilde [7] presented a benchmark for a set of motion planning algorithms based on three different scenarios for bin-picking applications. Despite longer planning time, the algorithms integrated with optimization outperformed due to faster execution. Morgan et. al [8] proposed three different robot benchmarking protocols, namely the Modified Box and Block Test (BBT), Targeted-BBT, and Standard-BBT, for assessing various aspects of the system separately and the results compared with human performance. Chatzilygeroudis et al. [9] represented a new

benchmarking protocol to evaluate algorithms for bi-manual robotic manipulation of semi-deformable objects. Therefore, the work makes the benchmark accessible to various related fields, from adaptive control and motion planning to learning the tasks through trial-and-error learning. Jedrzejczyk et al. [10] have investigated a tomato harvesting application and suggested a benchmark of optimally configured motion planners available within Robot Operating System (ROS) and MoveIt platforms. The results indicated a comparison of efficiency and repeatability of particular planners for a planning scene imitating conditions in a greenhouse or similar pick-and-place tasks. Magalhães et al. [11] suggested benchmarking path planner algorithms from Open Manipulator Planning Library (OPML) for tree pruning tasks. Thus, the results demonstrated good agreement for the BiTRRT algorithm compared with other algorithms from the OMPL library, such as BKPIECE, LBKPIECE, SBL, and others. Despite the numerous studies that benchmarked motion planning algorithms for robotic manipulators in industrial applications, few works focused on agricultural applications. Accordingly, this paper studied benchmarking motion planning algorithms for a palm-like tree harvesting application.

### B. 3D Occupancy Grid Mapping

Robotic perception is understood as a system that endows the robot with the ability to perceive, comprehend, and reason about the surrounding environment. In addition, robotic perception is crucial for a robot to make decisions, plan, and operate in real-world environments, through numerous functionalities and operations ranging from accupancy grid mapping to object detection algorithms [12]. Fryc et al. [13] proposed a robust multi-stage pipeline for efficient, collision-free brick picking given the pose of a target object. In this case, Octomap represented the realistic simulated environment as inputs to generate a set of motion plans for the robot. Terasawa et al. [14] presented a novel framework that combines a sampling-based planner and deep learning for faster motion planning, focusing on heuristics. For this purpose, the HM-TS-RRT algorithm obtained a heuristic map of the environment information from the Octomap for motion planning and generating collision-free paths within a reasonable time. Hence, the results based on HM-TS-RRT outperform the existing planners, especially in terms of the average planning time with smaller variance. Gai et al. developed a vision-based system for under-canopy navigation of agricultural robotic vehicles using a Time-of-Flight (ToF) camera [15]. A novel algorithm was used to detect parallel crop rows from occupancy grids taken under crop canopies. Therefore, the proposed system was able to map the crop rows with mean absolute errors (MAE) of 3.4 cm and 3.6 cm in corn and sorghum fields, where are provided lateral positioning data with MAE of 5.0 cm and 4.2 cm owing to the position in corn and sorghum crop rows. Chao and Chen [16] proposed a framework of visual perception, scenario mapping, and fruit modeling for robotic harvesters in orchard environments. The scenario mapping module applied the Octomap to represent the multiple classes of objects within the environment. The experiment results were shown that the localization and pose estimation of fruits, which are obtained at 0.955 and 0.923 values for the accuracy of visual perception and modeling algorithm. However, not many studies use real-time 3D occupancy grid mapping for benchmarking scenes. In

this work, we create a real-time realistic benchmarking scene based on sensor information. This approach could help the evaluation of motion planning algorithms more accurately and obtain more reliable results.

### III. METHODOLOGY

The assessment of motion planning algorithms is commonly performed using benchmarking platforms for robotic manipulators [16]. However, the outcomes can be reliable when the scene is more to reality [17]. Thus, developing methods for replicating real-work environment specifications in benchmarking scenes is crucial, e.g., the "sensed representation" of test scenes which are built from sensor information. This study established a lab-setup environment as benchmarking scene modeled by converting point cloud data from a stereo-depth camera into a 3D occupancy grid map using the Octomap algorithm [18]. The experiment was then conducted to benchmark the motion planning algorithms for the three motion problems with different levels of complexity based on the oil palmtree harvesting task. The process mentioned above, including generating the 3D occupancy grid map and the benchmarking task, was implemented sequentially. All the system components worked together simultaneously in real-time. Thus the experimental results were obtained for performance assessment of the motion planning algorithms. The overall methodology procedure for this study is indicated in Fig. 1.

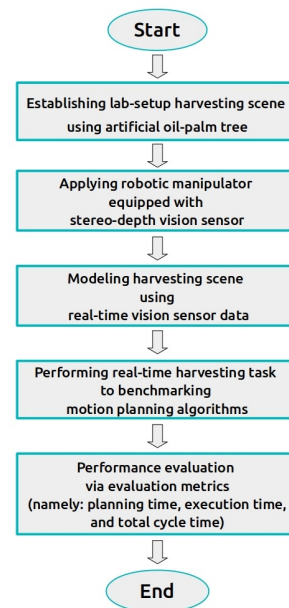

Fig. 1. Overall Methodology Procedure.

The methodology procedure of this work was performed through experimental work, as shown in Fig. 1. First, an artificial oil palm tree was utilized to establish an oil palm fruit harvesting scene. Furthermore, a robotic manipulator equipped with a stereo-depth camera (Intel RealSense D435) was used to conduct the harvesting task. The harvesting task was performed using four motion planning algorithms from the OMPL library, namely RRTConnect, BiTRRT, BFMT, and FMT. Therefore,

the experimental findings evaluated the motion planning algorithms' performance via evaluation metrics, namely planning time, execution time, and total time.

### A. Experiment Setup Environment

A laboratory-based experimental setup was established using an artificial palm-like tree and a four DoF robot manipulator to mimic the characteristic of a real oil palm tree harvesting environment, as shown in Fig. 2. In addition, a stereo-depth vision sensor was mounted on the robot manipulator's end-effector to model the working environment in the benchmarking scene.

Fig. 2. (a) Laboratory-Scale Experimental Setup with a Robot Arm Attached to a Camera and Artificial Tree (b) Real Oil Palm Tree (c) Artificial Tree.

### B. Robot Arm Kinematics

This work used an open-hardware robotic manipulator, model OpenManipulator made by Robotis, as shown in Fig. 3, to develop a generic and low-cost harvesting platform [19]. This robot platform allows the users to optimize its morphology, modify the length of the links, or design the robot for their specific purposes [20]. Furthermore, the robotic manipulator has four DoF, which, based on previous studies, met the minimum requirement in terms of degree of freedom for a palm-like tree harvesting application [21].

Fig. 3. OpenManipulator Robot Arm from Robotis.

Meanwhile, Fig. 4 illustrates the kinematics model of the robot manipulator, which was utilized to obtain the Denavit-Hartenberg parameters convention [22], as depicted in Table I. Besides, the robot manipulator was also modeled within Robot Operating System (ROS) platform using a domain-specific modeling language called Unified Robotic Description Format (URDF). The robot model was stored in a URDF file to represent the properties of the robot in the ROS Visualization (RVIZ) platform [18]. The URDF file format is based on XML language, which allows for encoding the robot's components such as links, joints, shapes, and physical appearance, as shown in Fig. 5.

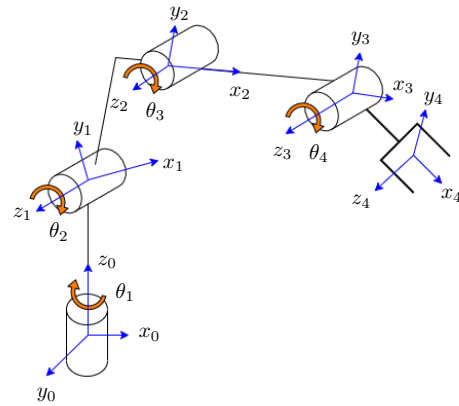

Fig. 4. Kinematic Model of Robotis OpenManipulator Robot Manipulator.

TABLE I. DH PARAMETERS FOR ROBOTIS OPENMANIPULATOR.

| Joint | $\theta_i$ (°) | $d_i$ (m) | $a_i$ (m) | $\alpha_i$ (°) |
|-------|----------------|-----------|-----------|----------------|
| 1 | $\theta_1$ | $L_1$ | 0 | 90 |
| 2 | $\theta_2 + (90° - \theta_0)$ | 0 | $L_6$ | 0 |
| 3 | $\theta_3 - (90° - \theta_0)$ | 0 | $L_4$ | 0 |
| 4 | $\theta_4$ | 0 | $L_5$ | 90 |

Fig. 5. Robotis Open-Manipulator Model in RVIZ Software based on its URDF File.

### C. Modeling the Test Scene into a 3D Occupancy Grid Map

This work used an Intel Realsense D435i stereo-depth sensor, integrated with a point cloud library (PCL), to generate point cloud data [23] to replicate a real-work environment for the test scene. The camera is equipped with two left/right image sensors, OmniVision OV2740, which can produce full-high-definition (FHD) at 60 frames per second (fps). In addition, the Octomap library was implemented to convert the point cloud data of the lab-setup environment into a 3D occupancy grid map in real-time. Fig. 6 depicts a sample of a 3D occupancy grid map of the scene, including the tree leaves, which was generated using the Octomap algorithm.
Fig. 6. A Sample of a 3D Occupancy Grid Map Including the Robot Manipulator and Artificial Oil Palm Tree.

## D. Generating the Harvesting Motion Planning Problems

In this benchmarking, three motion problems with different levels of complexity in terms of collision avoidance were defined based on a real oil palm harvesting task to measure the performance of the motion planning algorithms. Each of the motion problems contains a pair of initial and goal states. The initial robot arm's configuration and position are identical for all three motion problems. The gray-colored robot arm represents the initial state, while the orange-colored robot arm indicates the goal state, as shown in Fig. 7a, 7b, and 7c. The use of the gripper was beyond the scope of this work. Therefore, it is not included in these motion planning problems.

Fig. 7. Three Different Test Scenarios in this Work.

*1) Right-Side Fruit Bunch Problem:* The initial state of this problem is located in a less constrained space than the goal state, as illustrated in Fig. 8. The goal state is a stretched robot arm's configuration with the robot arm's end-effector approaching the right side of the fruit bunch from the bottom. Furthermore, the goal state represents the 'ready to cut' pose of the fruit bunch for the robot arm.

Fig. 8. Right Side of the Fruit Bunch Problem.

*2) Left-Side Fruit Bunch Problem:* The goal state of this problem is situated in a more constrained space than the previous motion problem due to the narrow passage that the robot arm should pass through to reach the target, as shown in Fig. 9. As in the previous motion problem, The goal state is a stretched robot arm's configuration with the robot arm's end-effector approaching the right side of the fruit bunch from the bottom. In addition, the goal state represents the 'ready to cut' pose of the fruit bunch for the robot arm.

Fig. 9. Left Side of the Fruit Bunch Problem.

*3) Left-Side Fruit Bunch to Right-Side Fruit Bunch Problem:* This motion problem defines the left side of the fruit bunch as the initial state and the right side of the fruit bunch as the goal state, as shown in Fig. 10. Furthermore, the motion path needs to be created from a highly constrained space, traveling through a narrow passage and finally reaching another highly constrained space, as illustrated in Fig. 10. Thus, a higher level of complexity in terms of obstacle avoidance is provided by this motion problem than the previous motion problems.

Fig. 10. Left Side to the Right Side of the Fruit Bunch Problem

## E. Performance Evaluation

The experiment was performed within the ROS MoveIt platform on a computer with Ubuntu 18.04.6 LTS Operating System, Intel® Core™ i7-9750H CPU, 16 GB Memory, Nvidia GeForce RTX 2060, and ROS Melodic distribution. The ROS MoveIt platform integrates a 3D occupancy grid map of the working environment with motion planning algorithms to generate feasible paths and solve motion problems for a given task.

In order to evaluate the performance of the motion planning algorithms for solving and executing the motion planning problems, three metrics, namely planning time, execution time, and total cycle time, were defined. All the metrics were analyzed individually to demonstrate the higher performance algorithm within each of them. Planning time is considered when it takes for a motion planner to find a viable path for a given motion problem. Furthermore, The time it takes for the robot arm to move from its initial state to its goal state for a given motion path is known as execution time. Finally,

the addition of planning and execution time is considered total cycle time.

The motion planning algorithms, RRTConnect, BiTRRT, BFMT, and FMT, were implemented to solve and conduct the motion problems. For each specific problem, the problem was solved and executed 10 times by each of the algorithms for 40 runs per problem. Given the three motion problems, 120 runs were performed to conduct the benchmarking task. Furthermore, each algorithm was given 5 seconds time-out to solve the respective motion problem since such harvesting applications need to be conducted quickly in real practice. The successful cycles only were used in the analysis.

## IV. RESULTS AND DISCUSSION

Fig. 11 illustrates the results of the planning time for the three motion planning problems solved by the algorithms mentioned above. In the first problem, the right-side fruit bunch, RRTConnect achieves the shortest planning time with the lowest mean of 0.11 s and also the lowest standard deviation of 0.0215 s. In contrast, FMT had the worst performance among the others. This outcome indicates that for straight forward motion planning problems, with the minimum need for curvature to avoid colliding with obstacles, RRTConnect algorithm can be considered a fast algorithm for creating motion paths.

Fig. 11. Planning Time for the Three Planning Motion Planning Problems.

In the second motion planning problem, the left-side fruit bunch, more complexity in terms of collision avoidance was provided by the motion problem to the algorithms. In this problem, RRTConnect outperformed the other algorithms again (slightly faster than BiTRRT) with the lowest mean of 0.2414 s and the lowest standard deviation of 0.0568 s. Meanwhile, in the third motion planning problem, from the left-side fruit bunch to the right-side fruit bunch, RRTConnect had the shortest mean. In contrast, BiTRRT, which had a slightly higher mean, demonstrated a lower standard deviation than RRTConnect. Again, the FMT had the longest computation time among all.

Meanwhile, Fig. 12 represents the execution time of motion planning generated by the algorithms within the three motion problems. For example, in the first problem, from the initial position to the right-side fruit bunch, RRTConnect achieved the fastest execution time with the lowest mean of 4.9455 s and the lowest standard deviation of 0.1932 s. Meanwhile, FMT was the slowest, with the highest mean and highest standard deviation with more outliers than other algorithms.

In the second problem, from the initial position to the left-side fruit bunch position, RRTConnect achieved the lowest mean of 5.257 s while obtaining the highest standard deviation

Fig. 12. Execution Time for the Three Planning Motion Planning Problems.

of 0.718 s. In contrast, FMT had the highest mean of 5.441 s and the most significant number of outliers. In the third problem, from the left side to the right side fruit bunch, the most complicated motion within this benchmarking work was provided to the motion planning algorithms. The lowest mean of 7.893 s and the highest standard deviation of 1.313 s was achieved by the BFMT. In contrast, FMT obtained the highest mean of 8.547 s but a lower standard deviation for the motions execution time.

Furthermore, Fig. 13 shows the results for the total cycle time, including motion planning times and the respective motion execution times. In the first problem, the right-side fruit brunch, RRTConnect achieved the highest performance in motion planning time and the respective execution time with the mean of 5.062 s and standard deviation of 0.1889 s. In contrast, the lowest performance was obtained by FMT with a mean of 9.702 ) and a standard deviation of 0.803 s.

Fig. 13. Total Cycle Time for the Three Planning Motion Planning Problems.

In the second problem, despite the lowest mean of 4.998 s for RRTConnect, its standard deviation is significantly higher than the second-lowest mean, which BiTRRT achieved. To this extent, BiTRRT can be considered a more consistent algorithm for such motion problems. In the third problem, where a more complicated motion problem than the first and the second one was provided, BiTRRT achieved the highest performance with the lowest mean and standard deviation of 8.689 s and 0.683 s, respectively. In contrast, FMT demonstrated the lowest performance concerning its mean of 13.305 s and a number of outliers.

Due to the smaller size of the palm-like artificial tree, which was used in our experimental setup, compared to actual palm-like trees, the Octomap resolution was increased. Thus, the generated 3D occupancy map contains all the necessary details of the artificial tree. However, the increase in resolution would result in high computational cost leading to a rise in the planning and execution time accordingly. On the other hand, with regard to the much larger size of real palm-like trees, which would result in less computational cost for generating a 3D occupancy map with lower resolution, a

considerable decrease in motion planning time and execution time is expected for real palm-like tree harvesting applications.

## V. Conclusion

In this study, a benchmarking of OMPL motion planning algorithms for a robotic harvester of a palm-like tree application was performed using the ROS and MoveIt platform. An experimental harvesting application setup was established using an artificial palm tree and a four DoF robotic manipulator equipped with a stereo-depth sensor. A 3D occupancy map was constructed using the Octomap algorithm to replicate the features and characteristics of the working environment based on the point cloud data produced by the stereo-depth sensor, which is imported into the benchmarking scene. The benchmarking was then performed within three harvesting scenarios, each including a motion planning problem with different levels of complexity, all as real-time experimental work. The motion planning performance was studied by defining three evaluation metrics: planning time, execution time, and total cycle time. RRTConnect demonstrated the highest performance in the first harvesting scenario according to the outcomes. However, for the second and third scenarios, BiTRRT outperformed the other algorithms. The work presented in this study can be extended to include methods for optimally configuring the OMPL motion planning algorithms based on the features and characteristics of a palm-like tree harvesting application to achieve the highest performance for a given motion planning algorithm.

*Abstract*—Face Recognition has progressed tremendously from its initial use of holistic learning models to using hand-crafted, shallow, and deep learning models. DeepFace, a nine-layer Deep Convolutional Neural Network (DCNN), reached near-human performance on unconstrained face recognition for the Labeled Faces in the Wild (LFW) dataset. These models performed very well on the benchmark datasets, but their performance sometimes deteriorated for real-world applications. The problem arose when there was a domain shift due to different distribution spaces of the training and testing models. Few researchers looked at Unsupervised Domain Adaptation (UDA) to find the domain-invariant feature spaces. They tried to minimize the domain discrepancy using a static loss of maximum mean discrepancy (MMD). From MMD, the researchers delved into the higher-order statistics of maximum covariance discrepancy (MCD). MMD and MCD were combined to get maximum mean and covariance discrepancy (MMCD), which captured more information than MMD alone. We use a Variational Autoencoder (VAE) with joint mean and covariance discrepancy to offer a solution for domain adaptation. The proposed MMCD-VAE model uses VAE to measure the discrepancy in the spread of variance around the mean value and uses MMCD to measure the directional discrepancy in the variance. Analysis was done using the TinyFace benchmark dataset and the Bollywood Celebrities dataset. Three objective image quality parameters, namely SSIM, pieAPP, and SIFT feature matching, demonstrate the superiority of MMCD-VAE over the conventional KL-VAE model. MMCD-VAE shows an 18 % improvement in SSIM and a remarkable improvement in the perceptual quality of the image over the conventional KL-VAE model.

*Keywords*—*Deep learning; domain adaptation; face recognition; maximum mean covariance discrepancy; transfer learning; variational autoencoders*

## I. Introduction

In the past decade, Face Recognition (FR) research has achieved high accuracy using Deep Learning (DL) approaches. It has matched that of the humans and even transcended it. Advances in DL have facilitated the growth of large training datasets required to implement DL algorithms effectively. Presently we have datasets that use large amounts of labeled data from the internet, consisting of face images in an unconstrained environment, with a marked diversity of ethnicity, gender, and age.

At times, in real-world applications, one notices a certain discrepancy. The target face image dataset is acquired in different settings compared to the source. There is a difference in the performance of a learned model on a source dataset and a target dataset. Also, in some applications, it is not possible to have large datasets from a particular domain to train a deep learning model. So can one borrow pre-trained models from similar domains? This can help to improve the learning process. However, the caveat is that the performance is boosted only for trained and tested datasets with identical data distributions.

It is interesting to understand the learning process between the deep networks and the human person in this context. The way that learning happens in deep networks and human persons is different. Humans learn from a limited set of labeled data. The other advantage humans possess is that they can generalize their learning and apply it to new conditions or situations.

The authors in [1] have shown the theoretical limitations on the performance by studying the error bounds for different source and target data distributions. The term "data shift", as first used in 2009, in [2], is the change of distribution of features [3]. The change in the distributions is referred to as covariate shift in [4]. Even a Deep CNN can experience domain shift [5]. Domain Adaptation (DA) algorithms attempt to understand these different shifts in statistical distributions for adaptation in domains.

The paper is organized as follows. Section II presents a review of domain adaptation techniques. Section III describes the metrics for measuring distribution discrepancy. Section IV focuses on the deep domain adaptation for face recognition. Section V presents the proposed MMCD-VAE latent feature extraction model. Section VI elaborates the experimental results, and finally Section VII provides the conclusion and

future work of this study.

## II. A Review of Domain Adaptation

### A. Domain Adaptation and Transfer Learning

The authors in their landmark paper [6] gave an overview of the Transfer Learning (TL) process, where they situated the DA task in the context of TL. Tasks were Inductive Transfer Learning, Transductive Transfer Learning or Unsupervised Transfer Learning based on label availability for the source and target domain. A summary is shown in Fig. 1 as in [6], which shows how DA is a subset of TL.

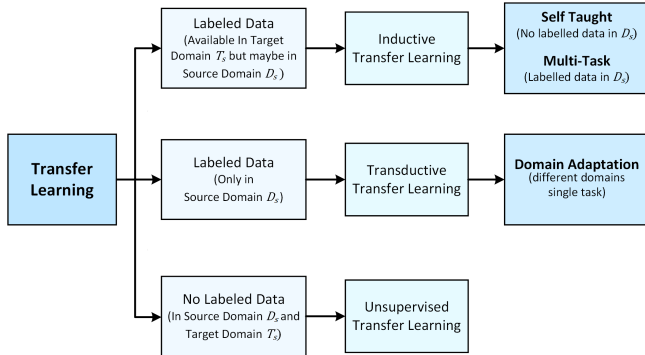

Fig. 1. The Relationship of Domain Adaptation to Transfer Learning [10].

Fig. 2. Types of Transfer Learning.

The authors in [7] define TL in terms of the domains and the given tasks. They classify TL as being homogenous when the feature space is the same and heterogeneous when the feature spaces are different, as shown in Fig. 2. They also clarify that the domain adaptation process seeks to change a source domain to match more closely with the target domain. The terms supervised or unsupervised refer to the source domain availability of labeled data. And for the target domain, as informed or uninformed. A word of caution is also given on Negative transfer when the learned information detrimentally effects the target domain.

The authors in [8] elaborate on the transfer learning categories and present about forty representative approaches to transfer learning along with experimental verification. The broad categories are shown in Fig. 3.

The notations given in [6] and [7] are used to explain the concepts of DA.

Fig. 3. Transfer Learning Categories.

Let the source domain labeled data be given by $\mathcal{D}_s = \{x_i^s, y_i^s\}_{i=1}^M$, with ith sample $x_i^s$, and label $y_i^s$. The number of source images is given by $M$.

Let target domain unlabeled data be given by $\mathcal{D}_t = \{x_i^t\}_{i-1}^N$, with ith sample $x_j^t$. The number of target images is given by $N$. The difference in data distributions as shown in Fig. 4, is given by $P(X_s, Y_s) \neq P(X_t, Y_t)$.

Fig. 4. A Simplified Transfer Learning Model for Domain Adaptation.

Many researchers have done surveys on TL [6], [7], [9], [10] [8] and DL [11], [12], [13], [14] and [15]. Beginning from Machine learning to Deep learning, the authors have methodically explained the nuanced terminology and clarified any inconsistencies in the terms that are used to explain the concepts of TL and DL.

## III. Metrics for Measuring Distribution Discrepancy

### A. Maximum Mean Discrepancy (MMD)

The distribution variations are found using metrics that measure distribution discrepancy. The ones often used are Kullback–Leibler divergence [16], the maximum mean discrepancy (MMD) [17], [18], the Bregman divergence [19], and the Wasserstein distance [20].

Among the most commonly used is MMD. It finds the measure between the mean of the two distributions into a reproducing kernel Hilbert space (RKHS). Maximum Mean Discrepancy (MMD) [17], [21], [22] is thus a distribution distance metric. The MMD [23] between two distributions $s$ and $t$, is given by

$$L_M(s,t) = \sup_{\|\phi\|_{\mathcal{H}} \leq 1} \left\| E_{\mathrm{x}^s \sim s}\left[\phi\left(\mathrm{x}^s\right)\right] - E_{\mathrm{x}^t \sim \mathrm{t}}\left[\phi\left(\mathrm{x}^t\right)\right]\right\|_{\mathcal{H}}^2 \quad (1)$$

Sup ("supremum") is the largest, least upper bound (generalizations of "max"), $E$ is the expectation of the distribution. $\phi$ maps original data to RKHS. The detailed proofs are given in [24].

*B. Maximum Covariance Discrepancy (MCD)*

The notations for MCD are taken from [24] where one can find the detailed proofs.

$$\text{MCD}[p, q, \mathcal{H}]$$
$$= \sup_{\|a\| \leq 1} \sum_{i,j \in I} a_{ij} \left( \text{cov}\left[e_i(x), e_j(x)\right] - \text{cov}\left[e_i(y), e_j(y)\right] \right)$$
$$(2)$$

where $\mathcal{H}$ is RKHS over $X$ and $\{e_i \mid i \in I\}$ is an orthogonal basis of $\mathcal{H}$, $\|a\| = \left(\sum_{i,j \in I} a_{ij}^2\right)^{1/2}$, with cov given by:
$\text{cov}\left[e_i(x), e_j(x)\right] = E_x\left[e_i(x)e_j(x)\right] - E_x\left[e_i(x)\right] E_x\left[e_j(x)\right]$.

*C. Maximum Mean and Covariance Discrepancy (MMCD)*

The authors in [24] have shown that the MMCD-based domain adaptation achieves better results for image classification. MMCD has both the first- and second-order statistical information in the RKHS. The notations for MMCD are taken from [24], where one can find detailed proofs.

$$\text{MMCD}[p, q, \mathcal{H}] = \left( \|\mu[p] - \mu[q]\|_{\mathcal{H}}^2 + \beta \|C[p] - C[q]\|_{\text{HS}}^2 \right)^{1/2}$$
$$(3)$$

where $\mu[p] = E_x[\phi(x)]$ and $\beta$, used to balance the MCD term, is a non-negative parameter, and C is a centered covariance operator. They show that MMD and MCD of MMCD measures the difference between means and covariances of the distributions with the degree d = 1 of the polynomial kernel.

## IV. Deep Domain Adaptation for Face Recognition

The authors in [25], [26], [23] discuss the approaches and challenges to deep domain adaptation in the context of face recognition which indeed is a challenging task. In real-life face recognition applications, there are domain shifts due to changing conditions, like background, location, change of pose, occlusion, illumination, and other factors.

In [25], the authors have used the TaoMM dataset created using face images of Chinese fashion models. They combined the CASIA-WebFace [27] and VGGFace-Good [28] datasets and used about 1.3 million images to train their model. They also trained the model on their TaoMM dataset. These trained models were then tested on the LFW dataset [29] which has a different distribution than the TaoMM dataset. The learned weights of labeled data are transferred to initialize the training model. They also refine all weights using face verification loss in an end-to-end framework.

Their system architecture consisted of a modified inception-v2 [30] model that enhanced training using Stochastic Gradient Descent. They used an NVIDIA GTX TITAN X GPU and pre-trained for 25 epochs that lasted 89.4 hours with a learning rate of 0.2 and decay half for every five epochs. A learning rate of 0.04 and decay half for every ten epochs was used and performed on two similar GPUs for 20 epochs that lasted 18.6 hours. The two GPUs were needed as the model was complex, and the mini-batch size was 360. Their

results are comparable to the state-of-the-art single models like DeepFace [31], DeepID [32] and BaiduFace [33].

The authors in [23] use clustering-based domain adaptation (CDA). They elaborate on how the unsupervised domain adaptation methods for object classification are not applicable to face recognition tasks. The reasons are that a larger discriminating power for the classification of faces is required, and the classes in both domains are non-overlapping. CDA generates pseudo-labels and uses cosine-similarity to form a cluster. They also use deep domain confusion network (DDC) [34] and deep adaptation networks (DAN) [35]. Here MMD estimator is integrated into the CNN error to minimize domain divergence. Thus the end classification is done based on features invariant to domain changes.

They trained the CNN with labeled source data and fine-tuned it with clustered target pseudo-labeled data, which helps determine the target data's discriminative representation. They evaluated their method on GBU [36], IJB-A/B/C [37], [38], [39] and RFW [40] datasets. The architectures that they used were VGGNet [41] and ResNet-34 [42]. Both architectures are trained on CASIA-WebFace, the former tuned using Softmax loss and later with Arcface loss [43]. They preprocessed the images of datasets by resizing, aligning and augmenting them. A Gaussian kernel is used in the MMD.

Their results outperform LRPCA-face [36], Fusion [44], VGG [44], Arcface [43] DDC [34] and DAN [35] for the GBU dataset. They remark that a uniform face-aligned algorithm can achieve good FR performance. Also, incorporating MMD helps in minimizing domain discrepancy. Similarly, better performance is obtained for IJB-A/B/C and RFW datasets. They also showed the visual representations of the learned features using t-distributed stochastic neighbor embedding (t-SNE) [45].

## V. Proposed MMCD-VAE Latent Feature Extraction Model

*A. Architectures*

*1) Deep Autoencoder (DAE):* In a Deep Autoencoder (DAE) feature selection function is carried out by an encoder. Later a decoder reconstructs the best image corresponding to the selected features. Deep CNN models are very powerful in feature extraction of the images generated from deep CNN AE. These decoders are noise-free and have competent low-dimensional feature space representation. However, only CNN-based generation requires uniform samples from all the categories.

*2) Variational Autoencoder (VAE):* Variational Autoencoder (VAE), as shown in Fig. 5 is an unsupervised probabilistic deep-neural network model consisting of an encoder-decoder pair. The encoder carries out dimension reduction and domain adaptation by having a progressively lesser number of neuronal units in a feed-forward architecture. The decoder does the reverse and brings back the compressed domain representations to their original shape by gradually increasing the number of neuronal processors. Variational autoencoders are the fabrication of a CNN Autoencoder with regularized training to avoid over-fitting. It results in a latent space favorable for the generative process. VAE is unique in the way
Fig. 5. Mapping Distribution of a Variational Autoencoder (VAE).

it uses the selected features for latent representation shared between encoder-decoder pairs.

Latent representation is nothing but the distribution of collected traits used as the communication protocol between the encoder-decoder pair. In practice, encoding and decoding distributions are parametric models. Joint optimization leading to reliable reconstruction ensures latent features contain the most salient statistical features and capture variations over main features.

The Face Recognition task falls under categorical marginal distribution. Assuming that $\phi$ and $\theta$ are parameter sets for encoder and decoder, optimized for minimum reconstruction loss, then VAE objective function can be written as:

$$
\begin{aligned}
L_{VAR\_ELBO} = \\
-\gamma D\left(q_{\varnothing}(z)\|p_{\theta}(z)\right) \\
+ E(x)E_{q_{\emptyset}(z|x)}\left[\log p_{\theta}(x\right. \\
\left.| z)\right]
\end{aligned}
\tag{4}
$$

where D is any strict divergence and $\gamma > 0$ is a scaling coefficient, E is the expectation operator, $q_\phi$ and $p_\theta$ are the distribution functions of encoder and decoder, respectively. The selection of divergence can play a crucial role. Traditionally evidence lower bound (ELBO) criterion is used in VAEs. The goal of the encoder is to obtain a simplified approximate distribution $q$ and optimize the variational parameter $\phi$ such that $q_\phi$ be as similar as possible to the true distribution of inputs. One of the approaches is to minimize Kullback-Leibler (KL) divergence. It is defined as:

$$
\text{KL}\left[q_{\phi}(w \mid D), p(w \mid D)\right] = \int q_{\phi}(w \mid D)\frac{q_{\phi}(w \mid D)}{p(w \mid D)}dw
\tag{5}
$$

where p(w | D) is the actual distribution of input samples w. Intractability due to the integration term present in equation 5, is resolved by substituting an approximation for p in terms of $q_\phi$. This substitution results in the popular Bayes by Backprop [46], a tractable objective function. ELBO suffers from uninformative latent code and variance overestimations in the feature space. Also, ELBO-VAE tends to over-fit data,

and as a result of the over-fitting, it learns a $q_\phi(z)$ whose variance tends to infinity.

*3) Proposed MMCD-VAE Model for Domain Adaptation:* The proposed MMCD-VAE Model for Domain Adaptation is shown in Fig. 6. The encoder generates the same distribution for all possible variations in a sample's inputs, which works for learning good features. Regularization is possible as the input is encoded to a distribution with some variance instead of a point. Regularization aims to have continuity and completeness in the generative process. Distributions are forced to be as close as to a standard normal distribution.

MMD evaluates the distribution as identical if and only if all their first moments are the same. Therefore, MMD divergence is a metric of differential moments of p(z) and q(z) distributions and is accomplished using the kernel embedding trick [47]. MMD prefers to maximize the mutual information between an input x and the latent representation z. Training ELBO on a dataset with complimentary samples will still try to obtain encoder $q_\phi$ and decoder $p_\theta$ as Gaussian distributions with non-zero variance. For ELBO regularization term $\gamma D(q_\phi(z) \| p_\theta(z))$ is not strong enough as against the loss function term $E(x)E_{q_\phi(z|x)}[logp_\theta(x \mid z)]$. Complimentary samples will have class means way apart, and accordingly, MMD optimization will end up by having two modes of $q_\phi$, pushed to stay far from each other. This will reduce ambiguity in reconstruction. In practice, this matters for datasets with fewer samples.

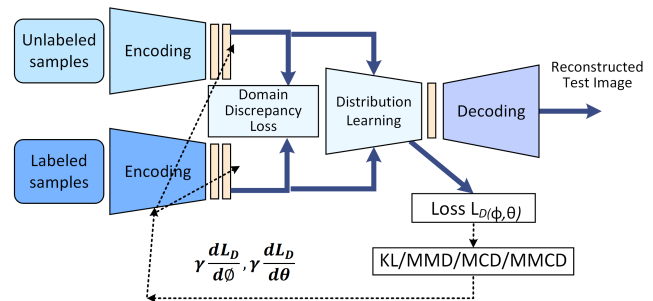

Fig. 6. Proposed MMCD-VAE Model for Domain Adaptation

The Loss function (objective function) indicates the degree to which the test image has been reconstructed and is given by:

$$
\begin{aligned}
l_i(\phi,\theta) = -E_{z \sim \theta_\phi(z|x_i)}\left[\log P_\theta\left(x_i|z\right)\right] \\
+ \text{MMCD}\left[Q_\phi\left(z|x_i\right)\|P_\theta(z)\right]
\end{aligned}
\tag{6}
$$

Given two distributions p, q in RHKS

$$
MMCD[p,q,H] = \left(\|\mu[p] - \mu[q]\|_H^2 + \beta\|C[p] - C[q]\|_H^2\right)^{1/2}
\tag{7}
$$

where $\mu[p] = E_x[\phi(x)]$ and $\beta$ is a non-negative parameter. But $C[p] = E\left[w_p w_p^\top\right] - E\left[w_p\right]E\left[w_p\right]^\top$ and $C[q] = E\left[\omega_q \omega_q^\top\right] - E\left[\omega_q\right]E\left[\omega_q\right]^\top$

---

**Algorithm 1:** The Proposed MMCD-VAE Algorithm

**Data:**
Training Dataset $= \{X_i^n\}_{j=1}^N$
Testing Dataset $= \{Y_i^n\}_{i=1}^N$
Encoder Network $= q_\phi$
Decoder Network $= p_\theta$
Batch Size $= B$
Epochs $= S$
Learning Rate $= \alpha$
**Result:**
Reconstructed Test Image

1 Initialize parameters of the Encoder and Decoder
2 **for** *epochs* = $i \leftarrow 1$ **to** $S$ *Randomly select batches of Input images from the Training dataset* **do**
3     **for** $i \leftarrow 1$ **to** $N$ $\mu_z(i), \sigma_z(i) = q_\phi(z \mid x_i)$ *Draw L samples from* $z \sim N(\mu_z(i), \sigma_z(i))$ **do**
4        **for** $j \leftarrow 1$ **to** $L$ $\mu_{\hat{x}}(i), \sigma_{\hat{x}}(i) = p_\theta(x_i \mid z)$ **do**
5        **end**
6     **end**
7     Define Objective function (L) using Log likelihood and MMCD distance
8     Update
9     $\phi = \phi_{old} + \alpha * \nabla_\phi \, ADAM(\frac{\partial L}{\partial \phi})$;
10     $\theta = \theta_{old} + \alpha * \nabla_\theta \, ADAM(\frac{\partial L}{\partial \theta})$
11 **end**
12 Return trained encoder $= q_\phi$ and trained decoder $= p_\theta$

---

$$\text{MMCD}[p, q] = \Big[ \|E[x] - E[y]\|_2^2 + \beta \big[ \big\| E\left[xx^\top\right] - E[x]E[x]^\top - \left( E\left[yy^\top\right] - E[y]E[y]^\top \right) \big\| \big]^2 \Big]^{1/2} \tag{8}$$

where $x \sim p, y \sim q$. Given limited $X$ and $Y$ sampled from $p$ and $q$ respectively there is

$MMCD[p, q] \quad : \quad \left( \|\mu_p - u_q\|_2^2 + \beta \|\Sigma_p - \Sigma_q\|_F^2 \right)^{1/2}$ where $\mu_p = \frac{1}{n} X$ is the mean vector and $\Sigma_p = \frac{1}{n} X \mu_n X^\top$ is the covariance matrix of X.

Substituting Equation (8) in (6) we get:

$$l_i(\phi, \theta) = -E_{z \sim \theta_\phi(z|x_i)} [\log P_\theta(x_i|z)] + \Big[ \|E[x] - E[y]\|_2^2 + \beta \big[ \big\| E\left[xx^\top\right] - E[x]E[x]^\top - \left( E\left[yy^\top\right] - E[y]E[y]^\top \right) \big\| \big]^2 \Big]^{1/2} \tag{9}$$

The authors in [24] have experimented with different kernel and non-kernel based cases. The kernels used were linear, polynomial, Gaussian, and Exponential. When a linear kernel is adopted, MMD, MCD, and MMCD measure the difference between the mean and covariance of the distributions, respectively.

## B. Datasets

*1) Bollywood Celebrities Dataset:* The Bollywood Celebrities dataset [48] contains the localized face of 100 Bollywood Celebrities. A class has 80 to 150 samples of size $64 \times 64$ pixels. These are in wild conditions with different orientations, illuminations, age transitions. The sample images are shown in Fig. 7. Experimentation is carried out on $64 \times 64$ size RGB images.

Fig. 7. Sample Images from Bollywood Celebrities Dataset.

*2) TinyFace Dataset:* The TinyFace dataset contains 5,139 labeled facial identities given by 169,403 native Low Resolution face images (average $20 \times 16$ pixels) designed for the 1:N recognition test. The sample images are shown in Fig. 8. These are from public web data across a large spectrum and unconstrained environment.

Fig. 8. Sample Images from TinyFace Dataset.

## C. Objective Image Quality Comparison Metrics

The quality of the images needs to be evaluated using either a subjective or objective method. The former is based on human judgment, and the latter is by explicit numerical statistical parameters.

*1) SSIM:* Traditionally the most popular metric for image quality assessment was Peak Signal to Noise Ratio (PSNR). A standard metric is Structural Similarity Index (SSIM) which measures the similarity between two images. It was developed by Wang [49], and looked at structural information changes in the images. SSIM considers three factors, loss of correlation, luminance distortion, and contrast distortion [50]. For the SSIM index, a value of 0 means no correlation between images, and 1 means the two images are the same.

*2) PieAPP:* PieAPP [51] is a perceptual image-error metric that robustly predicts visual differences like humans. It uses pairwise preference as a robust way to create large Image quality assessment (IQA) datasets and uses a new pairwise-learning framework to train an error-estimation function. A reference image and a distorted image are given as input resulting in a PieAPP value as an output. Lower the value of the PieAPP error metric better the image perceptual quality.

*3) SIFT Features:* Face recognition is challenging compared to many other object recognition tasks as face features in the two domains are often non-overlapping. Global alignment of the source and target samples is not feasible for unconstrained face images. The goal of the proposed unsupervised domain adaptation model is to discover novel domain-invariant representations using scale-invariant features transform (SIFT) [52], as a parametric evaluation entity for the domain adaptation. Some authors [53], [54] have worked using SIFT for face recognition but have not used VAE. The challenge is to maximize scale-invariant features and thus get the corresponding match.

Many domain adaptation algorithms match the distribution without understanding the goodness in preserving key spatial features. This work analyses domain adaptation by optimizing encoder and decoder parameters. We use training samples and utilize unlabeled testing samples.

## VI. RESULTS AND DISCUSSION

### A. Experimental Setup

The domain adaptation experiments were conducted on NVIDIA GeForce RTX 2070 SUPER GPU. The PC configuration consists of a Multi-core (8 total) and Hyper-threaded (16 total) 3.80 gigahertz Intel Core i7-10700K. The memory is 32 GB, and the SSD hard drive has a 1TB capacity. The software used was Python version 3.8.5 (64-bit), libraries NumPy and Matplotlib, TensorFlow, and Keras.

The Bollywood Celebrities dataset was used for training. As the images for this dataset are $64 \times 64$, the target images were resized to $64 \times 64$. 300 epochs were used to train the model.

### B. Experimental Results and Discussion

*1) Training and Testing on Bollywood Celebrities Dataset:* In [24], the authors used MMCD and compared the classification performance using two benchmark datasets PIE and Office-Caltech. Their performance was better than nearest neighbor, principal component analysis, correlation alignment transfer component analysis, geodesic flow kernel, and joint domain adaptation. We have combined MMCD with VAE and the training and testing details are mentioned below.

The MMCD-VAE model was first trained with the Bollywood Celebrities dataset for 300 epochs and then tested on different images from that dataset. The generated images for KL-VAE and MMCD-VAE models with the Training and Testing on Bollywood Celebrities dataset are shown in Fig. 9. SSIM and PieAPP error metric comparison is shown in Table I.

MMCD-VAE performs better than KL-VAE. MMCD-VAE shows an average of 20 % improvement in SSIM and a remarkable improvement in perceptual quality of the image, as seen from the PieAPP error metric, over the conventional KL-VAE model.

Fig. 10 demonstrates the SIFT features for the Bollywood Celebrities generated images. The proposed MMCD-VAE method is also applied to face images of the same class, but varying domains and generated face images are tested for

Fig. 9. Results for Bollywood Celebrities Dataset Images (a) Original (b) KL-VAE Generated Image (c) MMCD-VAE Generated Image.

TABLE I. SSIM AND PIEAPP COMPARISON FOR KL-VAE AND MMCD-VAE WITH TRAINING AND TESTING ON BOLLYWOOD CELEBRITIES DATASET

| Face Images (Bollywood Dataset) | SSIM | | PieAPP error metric | |

inter-class similarity, as shown in Fig. 11. It can be seen that MMCD-VAE generated images have comparatively more SIFT key points than conventional KL-VAE generated images. More scale-invariant features assure that the proposed MMCD-VAE can capture more information.

The reconstruction loss gives the measure of how well the test image has been reconstructed and is shown in Fig. 12. We

TABLE II. SSIM AND PIEAPP COMPARISON FOR KL-VAE AND MMCD-VAE WITH TRAINING ON BOLLYWOOD CELEBRITIES AND TESTING ON TINYFACE DATASET

| Face Images (TinyFace Dataset) | SSIM | | PieAPP error metric | |
| --- | --- | --- | --- | --- |
| | Original vs KL-VAE | Original vs MMCD-VAE | Original vs KL-VAE | Original vs MMCD-VAE |
| Face 1 | 0.472164 | 0.671485 | 1.819303 | 1.429740 |
| Face 2 | 0.527809 | 0.668509 | 3.577199 | 2.522136 |
| Face 3 | 0.559499 | 0.735055 | 1.111426 | 1.166033 |
| Face 4 | 0.477758 | 0.650393 | 2.297195 | 1.644578 |
| Face 5 | 0.529925 | 0.754939 | 1.154995 | 0.967473 |
| Face 6 | 0.377013 | 0.618141 | 4.915103 | 1.919206 |
| Face 7 | 0.508398 | 0.664005 | 1.727580 | 1.665994 |
| Face 8 | 0.530098 | 0.667237 | 3.178573 | 1.667042 |
| Average | 0.497833 | 0.678721 | 2.472672 | 1.622775 |

observe that the MMCD-VAE model training is stable like the conventional KL-VAE, and demonstrates that the MMCD-VAE reconstruction loss is a meaningful metric of progress.

*2) Training on Bollywood Celebrities Dataset and Testing on TinyFace Dataset:* In VAE networks, the latent representations correspond to different levels of abstraction mapped to multifarious face attributes. Better the hidden representations, the greater is the adaptation quality. The MMCD-VAE model trained with Bollywood Celebrities dataset for 300 epochs was tested on TinyFace data. The total dataset was not tested but only a sample was used to check the results. The MMCD-VAE model performs better than the KL-VAE model, as seen from the subjective quality of the generated face images given in Fig. 13. The TinyFace dataset images are low resolution images. Even in the case of an original blurry image, the generated image has clearer features of eyes, nose, and mouth. As seen in Fig. 14, there are more SIFT key points in MMCD-VAE than KL-VAE generated images.

SSIM and PieAPP error metric comparison is shown in Table II. MMCD-VAE performs better than KL-VAE. MMCD-VAE shows an average of 18 % improvement in SSIM and an improvement in perceptual quality of the image over the conventional KL-VAE model. In this case, the PieAPP error metric difference between KL-VAE and MMCD-VAE is smaller than the one observed with the Bollywood Celebrities dataset images as the TinyFace are low-resolution images.

## VII. CONCLUSION AND FUTURE WORK

This study reviewed the literature on domain adaptation, especially in Face Recognition. It began by looking into the challenging problem of how models trained on benchmark datasets, at times, fail in real-world scenarios. One example is test images collected from the online web. The benchmark dataset on which a model is trained is often high resolution and performs poorly for low-resolution target images. This happens because the source and target domain experience shifts due to changing conditions. Hence the need for domain adaptation and the various metrics for determining the distribution discrepancy.

Fig. 13. Results for TinyFace Dataset (a) Original Image (b) KL-VAE Generated Image (c) MMCD-VAE Generated Image.

Fig. 14. SIFT Matching Features (a)Original and KL-VAE (b)Original and MMCD-VAE.

In the experimental part, we compared the performance of the proposed MMCD-VAE model. Results are compared for sample images taken from the Bollywood Celebrities dataset and TinyFace dataset. TinyFace is a challenging dataset, because it is low-resolution and recognition performance drops with the decrease in resolution. Quantitative comparisons are shown for matching SIFT key points and SSIM. The MMCD-VAE domain adaptation method rendered images with better Objective Image Quality, as seen in the SSIM, pieApp, and SIFT key-points metrics.

The future scope is to look at detailed testing of RFW datasets to better understand how to improve face recognition across diverse races. The low-resolution surveillance face images of the QMUL-SurvFace dataset is another area to pursue further research. An emerging area of research is adversarial discriminative domain adaptation, which reduces the difference between the source and target domain distributions using adversarial learning methods.

CONFLICT OF INTEREST

The authors declare that they have no conflict of interest.

*Abstract*—**Potable or drinking water is a daily life necessity for humans. The safety of this water is a concern in many regions around the world, since polluted waters are increasing and causing the spread of disease among populations. Continuous management and evaluation of the water which is meant for drinking is very essential and must be taken seriously. Often, the quality of water is evaluated through regular laboratory testing and analysis which can be tiresome and time consuming. On the other hand, advanced technologies using big data with the help of machine learning can have better results in terms of potability evaluation. For this reason, several studies have been conducted on predicting the quality of water and the several factors and classification that affect the prediction model. In this study, a random forest model was developed using PySpark classification to predict the potability of river water by relying on ten different features: pH, hardness, presence of solids, presence of chloramines, presence of sulfate, conductivity, organic carbon, trihalomethanes, turbidity, and finally potability. In addition, The developed model was able to predict water potability classification with a 1.0 accuracy, and 1.0 F1-score.**

*Keywords*—*Big data; machine learning; classification; random forest; water quality; PySpark*

## I. INTRODUCTION

When there is no water, there's no life. Freshwater is the most essential natural resource without which life, all forms of life, would not exist. Humans of all the other living organisms rely on the water not just for drinking but also for various aspects of their lives such as bathing, cooking, and watering their agricultural fields. In fact, there's even increased demand for water due to the increase in wide spreading urbanization, the development and expansion of the economic movement, and the general rapid increase in human population [1].

However, the water quality and its safety for use for different purposes is a complex issue. The overuse of the water both underground and on the surface in addition to other factors are causing the deterioration of water quality. One of the factors that are having a significant impact on water is the global climate change since it doesn't just affect the availability of water resources but also affects their future quality. Add to that the dangerous pollution resulting from the human activities where individual humans don't only dump their waste into rivers and wells, but also large factories could pollute rivers and underground water as a result of their chemical wastes [2]. As a matter of fact, the poor-quality water is the source of many water-bourne illnesses such as diarrhea. This means that using non-clean water especially for drinking raises health issues that can be avoided but choosing the appropriate water to drink [3].

The most common estimation of water quality has been the laboratory analysis which is time-consuming, expensive, and not very practical. The laboratory analysis of water requires the collection of water samples from different areas over a period of time, then transporting these samples in suitable conditions before they can be analyzed. Of course, this method is still being applied, but with the current development of technology, these processes can be made much more efficient by applying machine learning and big data tools [4]. Machine learning ML is a method of programming software in a way that allows them to learn from historical data and adapt accordingly such that they learn, assess their performance, and improve. Machine learning algorithms are often used to detect patterns in data and the non-visible behavior of data. There are several algorithms already in ML divided into classes: unsupervised, semi-supervised, supervised, and reinforced algorithms [5].

Random Forest RF is one of the machine learning algorithms through which several decision trees are merged together to achieve more accurate results. The term random forest also corresponds to the randomness of the method where the choice of samples is random. More specifically, a number of samples are randomly chosen from the training dataset in order to form what is called the "root node" samples. Furthermore, the choice of attributes in RF is also random, where the candidate attributes are selected at random, and after that the most suitable attribute is picked to be the "split node". The RF model starts with shuffles input sample data, creates many training sets that make up the decision trees, and finally chooses the output prediction results based on the majority of votes from the collection of decision trees [6].

In this paper, PySpark for the classification is utilized to evaluate water potability using a well-known Water Quality dataset. The Random Forest Classifier was used to build a model that asses various properties, including temperature, acidity, turbidity, and hardness, to arrive at an accurate decision. The developed model is evaluated to answer the following research questions for a better understanding of the presented work.

- **RQ1:** *What factors directly affect the potability of the water?*

- **RQ2:** *Can a random forest model effectively predict the quality of water based on these factors?*

The topic of water quality assessment was chosen due to its importance, and we have selected the Random Forest model to be our predictive model for the quality of water after reviewing the literature. Through literature, it was evident that

Random Forest provides the most effective and accurate results in evaluating the quality of water.

## II. Related Work

A lot of studies discuss the quality of potable water and quality of river waters or near-shore water, and many of them also focus on finding the relationships between several factors affecting the quality of water and which of them have the greatest influence. Numerous studies applied machine learning algorithms to predict the influential factors affecting water quality, including the Random Forest algorithm.

The term water potability refers to the characteristic that the water is safe for human consumption, specifically drinking or cooking. For example, potable water must be free from micro-organisms or harmful chemicals [7]. Other factors that indicate the quality of water are shown in Fig. 1, such as the chemical pH, the clarity of the water, abundance of nutrients, presence or absence of pest animals and vegetation, etc. [8].

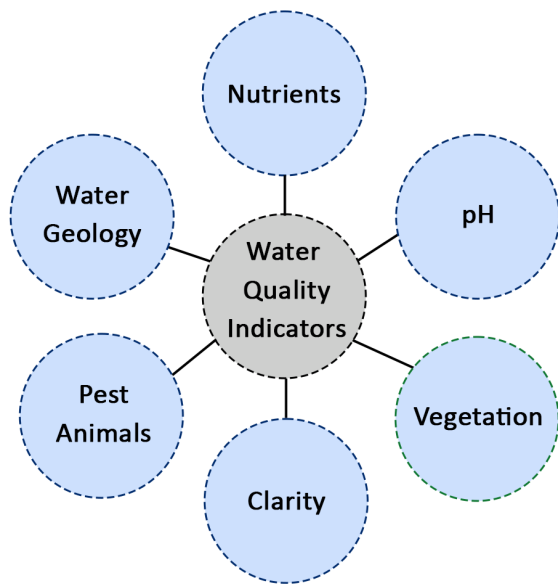

Fig. 1. Some of the Factors that Indicate Water Quality.

Back in 1960, a water quality index was created as a means to evaluate the safety of water [9]. After that period, many water assessment and quality management programs have been developed. In order to make appropriate decisions about drinkable water, one must be educated about the many factors that affect the safety of the water. Among other factors, potable water is affected by the source of origin, as well as whether it was treated before being delivered to houses, and the storage containers or water pumps and pipelines [10]. That's in addition to the factors within the water itself such as its temperature, its content of certain salts and minerals, its electrical conductivity, its pH, and other features [11]. The various water quality indicators can be divided into four classes: biological, chemical, physical, and radiological, as described in the Table I.

The aime of Xu, et al. research [12] is to design a framework for the prediction of the water quality in two

TABLE I. Classification of Water Indicators into Biological, Chemical, Physical and Radiological

| Classes of Water Quality Indicators | Examples |
| --- | --- |
| Biological | Bacteria, parasites |
| Chemical | pH, dissolved oxygen, salts |
| Physical | Temperature, electric conductivity |
| Radiological | Radioactive elements like Uranium |

regions, inland river water and nearshore water, based on different factors. The researchers were investigating the effect of several factors such as turbidity, temperature, dissolved gasses, ammonia concentrations, and dissolved solids on the total nitrogen level in the tested water. Inland water testing occurred at 2-hour intervals and total nitrogen levels were also collected at 4-hour intervals. The collected samples made a total of 1917 creating the dataset which was then subjected to normalization and correlation analysis. 90% of these data were used to train machine learning algorithms including Decision Tree, KNN, SVR, MLR, Random Forest, Ridge Regression, and GBRT. On the other hand, 10% were used to evaluate the models by comparing the predicted results of total nitrogen with the actual collected results.

This evaluation was based on correlation coefficient as well as the following metrics: Root Mean Square Error (RMSE), Mean Absolute Percentage Error, Nash–Sutcliffe efficiency coefficient, Mean Square Error, and Mean Absolute Error. The evaluation results showed that Random Forest achieves the best prediction results with 0.967 correlation coefficient and 0.509 RMSE, and that the ensemble models in general outperformed the non-ensemble models. Random Forest was also the focus when testing nearshore waters in comparison to the other ML models, where 147 new data were gathered and only three metrics were used since the acquired data differ from before (only temperature and salinity). The results of the second testing also came in favor of Random Forest compared to the other algorithms, achieving the lowest MAE and MAPE values.

In another study, Bachir Sakaa and his colleagues developed a Random Forest model as well as a Sequential Minimal Optimization-Support Vector Machine method for the determination of water quality in Saf-Saf river [13]. The researchers chose to collect the data from 35 areas in wet and dry seasons in order to gather 70 total samples that make up their dataset. The dataset was divided into training and testing subsets made up of 80% and 20% of data respectively. It was decided that the two models will be evaluated according to the root mean square error (RMSE), relative absolute error, mean absolute error, and root relative square error. In addition to these values, sensitivity analysis was carried out to assess how the independent variables (factors) are affecting the dependent variable (water quality). In order to determine the effector factors, a method called recursive feature elimination-linear "RFEL" was used where 15 different features were selected including suspended solids, ammonium, chemical, and biochemical oxygen demand, temperature, oxygen saturation, conductivity, and pH. Upon analyzing the results, it was evident that the results greatly differ in the upstream river area compared to the downstream river area. The same was noticed between data from wet seasons vs. dry seasons. RFEL was also used to determine a subset of combinations of some features

to notice their effects as a group. In this regard, for Random Forest the third created combination scored the best values (RMSE=5.17 and correlation R2=0.82) whereas for SMO-SVM the fourth input was better than the rest (RMSE=7.43 and R2=0.71). When comparing the overall performance of RF compare to SMO-SVM, it was concluded that they have similar results even though the error metrics show the superiority of RF.

RF was also employed in another study to predict the concentration of dissolved oxygen in the water of Potomac River [14]. More specifically, the purpose of the study was to determine the most important factors influencing the concentration of oxygen and to evaluate the efficiency of the Random Forest model in predicting the latter with respect to a varying combination of factors. Dissolved oxygen data were collected from a publicly available water quality database by the USGS. The variables chosen in this study are the gauge height, water temperature, turbidity, water pH, instantaneous discharge, and specific conductance. As a method of data preparation and pre-processing, a noise removal process was done by eliminating the individual predictor with its respective co-measured factors in order to avoid missing data. The Kolmogorov-Smirnov test was used to check the normality of each predictor variable, and also Box-Cox transform was used on the datasets. Furthermore, the water temperature was transformed into the Kelvin metric, and the data were standardized with the Z-score technique. After pre-processing, the data were divided 80-20 for training and testing respectively and the performance of two models: RF and MLR was evaluated through RMSE and R2 values. The correlation matrix revealed a significantly strong correlation with water temperature, and a significantly weak correlation with water salinity. There is also a strong multi-collinearity in the data due to correlation between the multiple variables. In conclusion, temperature, pH, and salinity were able to explain 98.7% of the data variance.

## III. Method

The main purpose of this study is to be able to assess the quality of rivers' water and whether it is drinkable or not based on a machine learning technique, namely Random Forest.

Quite literally, the random forest is a large collection of several decision trees that are used in unity, where the group of decisions can be collected to come up with one decision as an output. This happens after each decision tree dictates a specific class as its prediction result, and the class that collects the most votes from the tree ensemble is finally chosen as an output of the model. Fig. 2 shows a simple example of how a random forest chooses a prediction based on the collective results from each decision tree.

Machine learning is the automated data analysis process. Instead of being conventionally performed by a data scientist, nowadays, machines can replace manual analysis while using the same math and statistical techniques. The main difference though is that in machine learning, the techniques are integrated into algorithms that are capable of learning and improving themselves on their own. Machine learning has become the key to facilitating artificial intelligence (AI), where automated decisions can replace human decisions. And even though data science, machine learning, and artificial

Fig. 2. Example of Decision Making using Random Forest Model by Tony [15].

intelligence are puzzle pieces in the same field, yet each has its own applications and its own meaning.

Machine learning approaches in general can be divided into supervised and unsupervised machine learning. In the unsupervised models such as Principle Component Analysis of K-mean clustering, the algorithm finds hidden patterns within the data without them being labeled. On the other hand, supervised machine learning like Decision Tree or Random Forest, operates on previously labeled data and it is their objective to perform classification predictions based on how they were trained with the respective labels [16].

In machine learning, often several steps are done in sequence starting with data pre-processing, extraction of features, fitting of the model, and finally the evaluation of the performance of the developed model. These steps require a lot of transformation for data, which can be easily done by the machine learning pipeline to keep everything in order. The role of a pipeline is to keep the data flowing properly and that the transformations are adequately done to make sure that the result reached is accurate and without error.

Machine learning is one of the very effective methods by which Big Data can be processed, visualized, and interpreted [17], [18]. In this study, for the execution of our model, we relied on the Spark framework since spark is capable of performing large processing tasks quickly and allows the distribution of tasks over several computers for processing [19]. More specifically, PySpark was utilized as it allows the use of Python as a programming language. In Apache Spark, machine learning algorithms can be employed through Spark MLlib which we also relied on.

The ML pipeline requires a chain of command where the stages are assigned and it can run smoothly on Spark.

The stages involved within a pipeline can be transformers or estimators that have different functions. The function of a transformer is to convert one type of data frame into another type of data frame which can be done through updating the categorical values within one column into numeric values, or through user-defined logic to map the data in the column to other values. On the other hand, an estimator is capable of developing a model based on a fit method. Here, for instance, the Random Forest classifier is an estimator.

There are several steps to be done for the completion of the study. These involve exploring the data after acquiring the dataset, preparing the data, and performing correlation analysis. After that, model design and testing are followed by model assessment or evaluation, see Fig. 3.

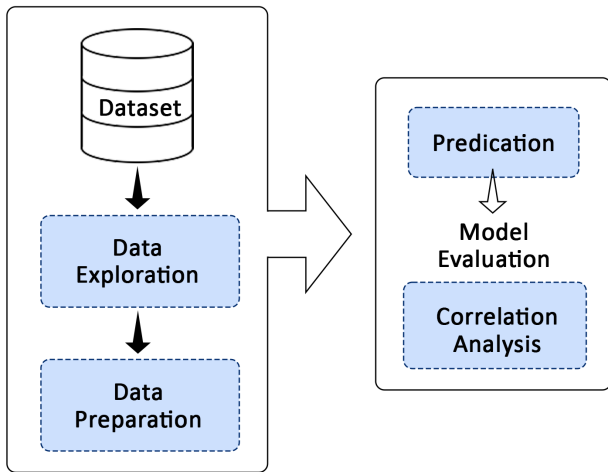

Fig. 3. Flowchart Explaining the Steps Followed in this Study: Data Exploration and Preparation, Correlation Analysis, Model Design and Evaluation.

## IV. Data

The chosen dataset comprises a total of ten features that will be used to predict the quality of water and whether it is good for drinking or not. Fig. 4 shows the ten values that describe the quality of the water, which are: pH, hardness, presence of solids presence of chloramines, presence of sulfate, conductivity, organic carbon, trihalomethanes, turbidity, and finally potability. The corresponding definitions and values of these features are described below.

**pH.** The pH metric is an evaluation of the concentration of hydrogen ions within a solution, and it allows the differentiation between acid media, basic media, and neutral media as water [20]. The pH recommended by the world health organization determines that the pH of drinkable water must range between 6.52 and 6.83.

**Hardness.** Hardness is the resultant of both magnesium and calcium salts that deposit from the geologic surrounding of running water [21]. The period of time in which the water is in contact with hardness-producing material determines how much hardness there is in raw water [22].

**Total Dissolved Solids.** Dissolved solids in water refer to the salts that can be present including potassium, magnesium, calcium, bicarbonates, sodium, chlorides, etc. [23]. The presence of these dissolved solids in water leads to changing its flavor in addition to affecting its safety [24]. The ideal concentration for TDS is 500 mg/l and should not go above 1000 mg/l for drinking water.

**Chloramines.** Chloramine alongside chlorine is often used for the treatment of water and disinfecting it from bacteria and other microorganisms [25], [26]. For safety, the amount of chloramine in drinkable water should not exceed 4 mg per liter.

**Sulfate.** Sulfates are natural elements present in the soil, minerals, food, groundwater, plants, and rocks. Yet they are heavily used in the chemical industry. The sulfate concentration in freshwater should be between 3 and 30 mg per liter [27].

**Conductivity.** Electric conductivity is a measure of conducting electricity through water. Pure water does not conduct electricity, rather it is considered an insulator [28]. However, ionic water has an increased electric conductivity as a result of the ionic compounds in it [29]. The safe electric conductivity level should be less than 400 $\mu S/cm$.

**Organic Carbon.** Total organic Carbon TOC resembles the total quantity of carbon from organic matter within the water [30]. This organic carbon can originate from either the decay of natural organic matter or from an unnatural synthetic source. The normal values of organic carbon should be less than 2 mg per liter for drinkable water, and less than 4 mg per liter for the water to be treated.

**Trihalomethanes.** Trihalomethanes are referred to as THMs in short, and these are molecules abundant in the case of chlorine treatment of water [31]. The factors that affect the amount of THMs are the temperature of treated water, the required chlorine concentration, and the level of organic matter within the water [32]. In order for water to be drinkable, the THM value must be below 80 ppm.

**Turbidity.** Turbidity is a description of the state of water and whether solids are suspended in it or not [33]. The turbidity of water can be calculated by the light emitting characteristics of water, which represents the quality of waste discharge in regard to the colloidal matter. The turbidity value recommended by the World Health Organization is turbidity=5.00 NTU.

**Potability.** Potability is a term given to describe whether the water is safe for human consumption or drinking or not [34]. In fact, it should also be considered if the same water is good for watering plants. If the given value=1 then the water is potable or drinkable, whereas value=0 means the water is not suitable for consumption.

### A. Data Exploration and Preparation

As part of data pre-processing, the data were converted into float after being in a string. In addition, the data that were in repetition were deleted, so only the necessary data were kept, see Fig. 5.

Initially, we will check whether there are NULL values or not. This is important to ensure that the algorithm can run smoothly without any missing data since null values indicate

Fig. 4. The Ten Feature for Assessing the Potability of Water.

Fig. 5. The Value of Necessary Data Needed for our Model.

missing data. Furthermore, the algorithm can obtain more accurate results when the null values are replaced. As can be seen in the image below, pH, Sulfate, and Trihalomethanes have NULL values. As a solution, the null values are usually replaced by the average or mean of the specific category. After that the information in the dataset is checked again.

The mean value is calculated by measuring the sum of the available values divided by the total number of values in the categories. This mean calculation is used to handle the missing data relative to NULL values, see Fig. 6.

Fig. 6. The Sum of the Available Values for Water Potability in the Dataset: 0 Water is not Potable, 1 Water is Potable.

The value of feature probability density is also measured

for each feature. This function describes the probability of a certain feature falling between a range of values. It is also described as density as it shows the mass distribution of said feature over the total scale. Continuous variables or features would produce a curvature shape, either described as a normal distribution or non-normal distribution. In Fig. 7, the distribution probability of all ten features is shown (as continuous bar graphs mixed into a curve).

## V. RESULT

At the beginning of the study, we presented the first research question **RQ1:** *What factors directly affect the potability of the water?* To which the answer can be deduced from the correlation analysis. The correlation is done using the heat map function of seaborn, see Fig. 8. This function shows the degree that which two factors affect each other. The correlation matrix below shows that each feature is only strongly correlated with itself (scoring +1). On the other hand, when seeing the correlation between the features with potability, no strong correlations exist. Yet there exists a weak correlation between two of the factors: pH and hardness (0.08). This analysis means that the dimensions can't be reduced in this study due to the absence of correlations between the variables. Further, the data are divided into independent and dependent features. All are independent features except Potability because Potability is our dependent feature.

Answering the second research question **RQ2:** *Can a random forest model effectively predict the quality of water based on these factors?* The dataset was divided into 80% training, and 20% testing on a Random Forest Classifier model (Fig. 9). At first, the model was trained, then it was fed the testing dataset to observe and assess the predictions. The answer to our second research question can be found by evaluating the model through numbers. The most commonly used metrics for model evaluation are accuracy, precision, recall, and f1-score.

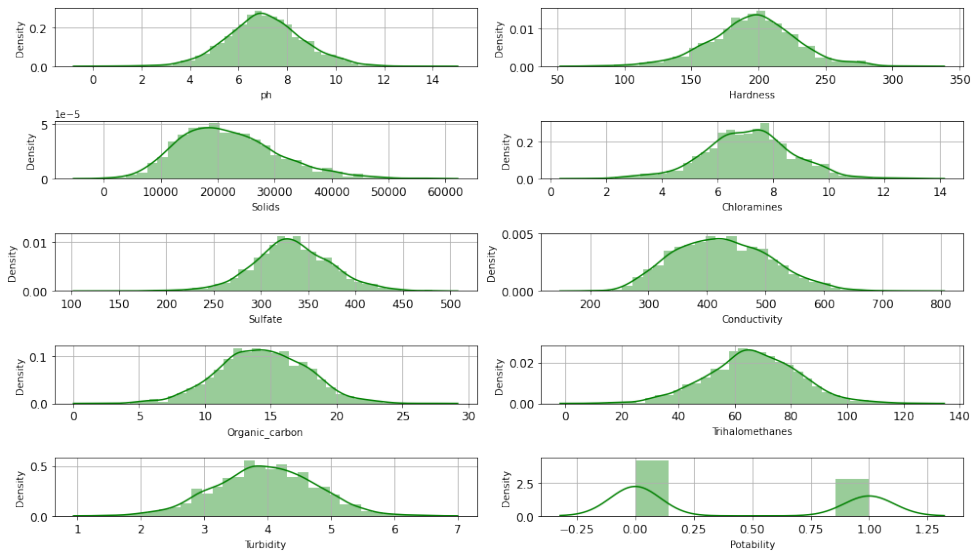
The accuracy is the measurement of how close the predicted value is to the actual value, whereas the precision is the measure of how much the model can produce a repeated prediction value. The recall shows how much the model is good at identifying true positives. Based on both precision and recall, the F1-score value is calculated, and the greater the value the better. The results obtained by our Random Forest model can be summed up in Table II. These results show good performance by our Random Forest model, and they are very satisfactory.


Fig. 7. Feature Probability Distribution as Calculated for each Feature.

Fig. 8. Correlation Matrix Showing no Correlations between the Different Variables.

TABLE II. MODEL PERFORMANCE EVALUATION BASED ON ACCURACY, RECALL, PRECISION, AND f1-SCORE

| Test accuracy | 1.0 |
|---|---|
| Test recall | 1.0 |
| Test F1-score | 1.0 |
| Test Precision | 1.0 |

## VI. DISCUSSION

In this study, water quality prediction model was designed using machine learning classification in form of random forest classifier in predicting the water potability. Various variables are considered to perform a variety of calculations related to the water quality. These included pH, hardness, presence of solids, presence of chloramines, presence of sulfate, conductivity, organic carbon, trihalomethanes, turbidity. The results of the study revealed that different machine learning models performed differently when it came to predicting water potability. In order to compare our model with previous work presented by Xu, et al. [12] and Devi [35], we used RMSE (Root Mean Square Error) as metrics to evaluate the accuracy of random forest model in each study with ours. We can visually compare the accuracy of these models using Fig. 10.

One of the main advantages of ensemble learning is its ability to improve the system's overall performance. In addition, random forest methods can also reduce the likelihood of overfitting due to their random nature.. After successfully completing the water random forest prediction task, we then used remote sensing bands to perform water quality prediction. The previous variables were used as targets, while the independent variables were used as the distribution of the data. Through the use of the Jupyter platform, we were able to perform an inverted analysis of the data to fit the water quality prediction model. As it can be seen, our model provide a better performance score.

## VII. Conclusion

The safety of our drinking water is a very essential matter, which should be monitored and managed effectively due to its importance. The quality of water that we used for drinking or cooking has a direct effect on our own health, which is why having perfectly safe water is not only a right for humans but also extremely critical. Several protocols and assessment criteria were developed to keep an eye on the safety and potability of water of different origins (underground, surface, inshore waters, etc.).

Using machine learning and PySpark classification for collection, storage, and analysis of water samples is a much more effective and efficient method for water quality evaluation than regular laboratory tests. This motivated us to create a machine learning model based on the Random Forest algorithm to evaluate the quality of river water based on 10 distinctive features: pH, hardness, presence of solids, presence of chloramines, presence of sulfate, conductivity, organic carbon, trihalomethanes, turbidity, and finally potability. The obtained results show that the developed RF model is capable of predicting whether the collected water sample is potable or not with a 100% accuracy and 1.0 F1-score.

The water quality prediction model that we designed can be used in the field of water quality monitoring. In the future, it can be used to provide an online tool that allows users to monitor the water quality of their local waterways. This method can be used to collect the necessary data using sensors to perform the prediction. The next step in the development of the water quality prediction model will be to collect the stream data necessary to perform the prediction. This method will be carried out through a dynamic update of the model.

# Virtual Reality Platform for Sustainable Road Education among Users of Urban Mobility in Cuenca, Ecuador

Gabriel A. León-Paredes[1], Omar G. Bravo-Quezada[1], Erwin J. Sacoto-Cabrera[1], Wilson F. Calle-Siavichay[1]
Ledys L. Jiménez-González[2], and Juan Aguirre-Benalcazar[3]
Universidad Politécnica Salesiana, Cuenca - Ecuador[1]
Instituto Tecnológico Sudamericano, Cuenca - Ecuador[2]
Empresa Pública Municipal de Movilidad, Tránsito y Transporte de Cuenca, Cuenca - Ecuador[3]

*Abstract*—A traffic accident is an event generated in an unforeseen way that is beyond the control of the people involved, which can produce bodily, functional, or organic injuries, leading to death or disability in the worst cases. According to the *Empresa Pública Municipal de Movilidad, Tránsito y Transporte de Cuenca* (EMOV-EP), the total accidents recorded in 2021 were, 24.97% due to ignoring traffic signs, 21.11% due to not paying attention to traffic, and 16.94% due to driving under the influence of alcohol. The EMOV-EP, is the responsible for the regulation of human mobility. Thus, the EMOV-EP in conjunction with the *Universidad Politécnica Salesiana* (UPS) have introduced the next research question: How can a road safety education strategy, supported by Information and Communication Technologies (ICTs), can be developed to contribute to the improvement of the behavior of citizens to increase their knowledge of the traffic laws and regulations, and thus reduce the number of accidents in the city of Cuenca? Furthermore, in this paper we present the development of a Virtual Reality (VR) platform designed for road safety education. The platform is composed of a Web system, and 4 VR systems (games) that have been designed for 4 common causes of accidents respectively (drunk drivers, high-speed drivers, cyclists riding in bicycle lanes, and users of the tram transport system), using a serious games approach and the Oculus Rift/Quest technology. We have found that more than 80% of users have had a very good experience of playing and learning through the VR systems. Hence, this virtual reality platform constitutes a technological proposal with social impact because it creates an entertainment environment that can raise awareness among citizens, thereby strengthening road safety education and reducing the number of accidents in the city of Cuenca.

*Keywords*—*Virtual reality; road safety education; virtual scenarios; serious games; educational experience*

## I. Introduction

Traffic education is a widely topic addressed worldwide but is not well understood. It refers to demographic elements, educational levels and even individual and collective identities. As it directly concerns road safety and the coexistence of actors, it requires a set of coresponsibilities in addition to the establishment, knowledge and socialization of rules of conduct among both pedestrians and drivers [1].

Currently, road safety education is considered a general problem whose responsibility falls to an entire society [2]. Its objective is increasing the awareness of citizens for the development of reasonable road behavior, but it is fundamentally responsible for the knowledge of the laws and regulations

in force regarding public use and road safety. In this sense, road safety includes the absence of danger and risks from the existence of regulatory mechanisms in the context of traffic, which translate to the prevention of accidents [3].

Therefore, a traffic accident is an event generated in an unforeseen way that is beyond the control of the people involved, which can produce bodily, functional or organic injuries, leading to death or disability in the worst cases [4]. Since the end of the twentieth century, the Pan American Health Organization (PAHO) has shown that traffic accidents are among the main causes of injuries (serious or minor), disabilities and death in both developed and underdeveloped countries [5] [6]. Currently, they have become a kind of epidemic worldwide that has cost the lives of more than 1.24 million people—a public health problem for the World Health Organization (WHO) due to the high percentage of mortality among young people aged 15 to 29 years; indeed, by the year 2030, traffic accidents will be one of the five leading causes of death worldwide [5] [7].

In the context of Latin America and the Caribbean, the figures are alarming; even though the percentage of traffic accidents is well below that of developed countries, the rate of injuries and deaths due to road accidents is comparable to the levels in the United States and Canada. Specifically, countries with lower incomes have higher fatality rates in traffic accidents, 90 percent of which stand out as among pedestrians and cyclists, corresponding to the most underdeveloped countries. Hence, the PAHO has expressed the need not only for a continuous and systematic evaluation of road safety worldwide but also joint efforts involving different sectors of society to address road safety in a comprehensive manner through road safety education.

Ecuador is among the ten countries with the highest mortality rate in traffic accidents, despite being among the 5 countries on the continent with the lowest rate of registered vehicles [8]. Regarding the traffic accidents that occur daily in Ecuador, they are generally caused by citizens who take improper actions in their driving; pedestrians also regularly ignore current traffic and transportation laws, causing road accidents in which about half of the fatalities are pedestrians themselves [9]. On the other hand, the expansion of the means of transport for the mobilization of citizens in large masses has been a topic of high demand in most cities of Ecuador

due to the population growth that has been recorded in recent decades. In the city of Cuenca, the capital of the province of Azuay, located in the Andean highlands in the south of the country, which has been declared a Cultural Heritage of Humanity by UNESCO, the "*Tranvía 4 Ríos de Cuenca*" project has been carried out a public transport alternative. Its planning and construction began in 2012, and its commercial operation began on September 25, 2020 following a long and complex construction process, and many economic and technical problems that had been overcome [10].

Currently, the tram for the city of Cuenca is in full operation, and the contribution of this service has been noted to a large extent. However, there is a process requiring adaptation and education for mobility users to learn to coexist with this new means of transport. In addition to the accidents related to other means of internal transportation, there have been a variety of accidents involving this means of transport that have generated a notable increase in the accident rate [11]. According to an interview with officials at the *Empresa Pública Municipal de Movilidad, Tránsito y Transporte de Cuenca* (EMOV-EP), amid the increase in traffic accidents in the city, in recent years, multiple strategies have been created to increase the awareness of citizens of the rules and mechanisms for accident prevention [12]. However, these entail the necessary intervention of all agents and social sectors related to mobility, i.e., without excluding the academy as a fundamental element for intervening in this problem with research, all training proposals and road safety education strategies. Their purpose is to educate the public in the options for avoiding and preventing traffic accidents. All of their aspects should therefore be taken into account to reduce the high accident rates that have been shown in the previous research carried out by the authors of this scientific article [7].

Accordingly, the following question arises: How can a road safety education strategy, supported by information and communication technologies (ICTs), be developed to contribute to the improvement of the behavior of citizens to increase their proper use of traffic routes and thus reduce the number accidents?

To address this question, a joint work by the EMOV-EP, Universidad Politécnica Salesiana (UPS), and UPS's Cloud Computing, Smart Cities & High Performance Computing Research Group (GIPH4C), has proposed creating a Virtual Reality (VR) platform for sustainable road safety education in the city of Cuenca. The novelty of the proposal is mainly the possibility of reducing traffic accidents within the city through an educational technological platform that recreates environments similar to those of the city, providing an alternative with a novel approach to society that is completely different from previously developed VR platforms.

The use of VR as a learning technology allows the visualization of educational scenarios in all areas from a three-dimensional perspective. Computer-generated scenarios transform educational concepts via a new rapid sensory perception of individuals. The results obtained in the test phase of this project show a high index of motivation toward road safety education; users become the new protagonists for their own education, a fundamental requirement of the concept of gamification that has been introduced in the educational field of so-called Serious Games (SGs). Similarly, the potential of virtual reality is confirmed by the serious games perspective in the adaptive learning process and through its contribution to the development of a more responsible road culture through games [13].

From a theoretical point of view, the importance of the use of this technology is demonstrated by not only the interaction that a user has with it but also this technology's ability to activate all the human senses—especially touch, vision and hearing—whereby learning becomes more productive [14]. Hence, the proposal to use virtual reality technology for road training and awareness comprises a great milestone in the environment of road safety education.

Below, the main theoretical and empirical works related to the use of information and communication technologies for road safety education are presented. Next, we describe the development phases of the development of the virtual reality platform based on serious games for sustainable traffic education among mobility users in the city of Cuenca, Ecuador. In addition, the article presents the results from the test phase, which was carried out in conjunction with the EMOV-EP. Finally, we present the conclusions of the study and some recommendations for the platform's implementation.

## II. BACKGROUND

According to research at the *Universidad de Guayaquil*, since traffic accidents in Ecuador are one of the main causes of death in the population, especially among children and adolescents, road safety education should be considered a national problem that all social actors are directly responsible for [2]. Some of the main causes of traffic accidents are the recklessness of pedestrians and drivers, ignorance of current regulations, and so-called road complexity factors. Accordingly, the development of a virtual teaching-learning platform with 3D animation has been proposed as a strategy for increasing the awareness of citizens through education in road behavior rules. This proposal was initially limited to the training of high school students. Also, does not contemplate real spaces for the simulation of accidents, nor strategies of continuity and permanent implementation of the strategy. As for the techniques used for the development of the platform, it is not detailed in depth.

Similarly, the *Universidad Espiritu Santo* of Ecuador has proposed the development of an interactive T-Learning application [15] for road safety education. The platform is based on the ISDBT-Tb digital TV standards that allow the dissemination of road safety issues. Despite being a novel proposal for the education of road culture among citizens, its implementation as a strategy for reducing traffic accidents is based on the establishment of alliances between public and private television operators and educational institutions to provide generalized training throughout the country. This proposal is limited to the use of tools offered by the internet, which, although it has the capacity to generate changes in the behavior of citizens, does not offer the possibility of interacting face to face, and the research does not delve into the mechanisms for the update of the contents.

In correspondence with [3] the results of the study places Ecuador as one of the Latin American countries with the highest rate of traffic accidents. Among the causes of this

situation, the increase in the number of automobiles and the lack of knowledge about road safety by pedestrians and drivers stand out. Also, after analyzing the public policies and mechanisms established to reduce accident levels, the authors maintain that these have been ineffective because they focus mainly on the imposition of sanctions, without considering that the traffic accidents are a consequence of the lack of road education. In this sense, they warn about the need to overcome coercive policies. Despite the fact that the study assumed the city of Guayaquil as the field of action, the analysis of the results obtained after the application of theoretical and empirical methods allows the researchers to conclude that all of Ecuador requires educational programs based on accident prevention.

On the other hand, the *Instituto Tecnológico Bolivariano* in the city of Guayaquil, Ecuador, has proposed to use social marketing to increase the awareness of road safety among university technology students [16]. This research is a response to national statistics that show a lack of education in this area drives its accident rates and that young people are one of the groups with the greatest tendency to suffer irreparable consequences. According to this study, the main causes of road accidents are drivers' alcohol consumption, reckless actions, speeding, ignoring and disrespecting traffic signs and using cell phones. The proposed marketing strategy thus focuses on awareness-raising actions that are disseminated through social networks, cell phones and other personal channels to allow users to understand that road safety education is a way of life. The research establishes novel actions based on the promotion of road education, however, it is only aimed at technology students and does not present alternatives for the use of advanced information and communication technologies as part of the strategy.

This literature review of related works shows that most of the research and proposals from higher education institutions for the road training of citizens have been developed in the city of Guayaquil. However, statistical sources show that there has been a growing and accelerating accident rate in the city of Cuenca in recent years. The largest number of traffic accidents that occur in Cuenca are a consequence of the active or passive ignorance of the citizenry of the traffic and transportation laws and regulations that are in force in Ecuador. Such accidents are produced by the recklessness and speeding of drivers of light and heavy vehicles among other factors. Although in recent years higher fines have been established and a series of radar sites have been placed on both high- and low-speed roads with the purpose of warning citizens about the established speed limits, there is no evidence of a reduction in the number of accidents; on the contrary, they have increased. As a result, the city of Cuenca continues to experience a climate of road insecurity involving large numbers of accidents and deaths from various causes [17].

Notably, regarding the causes of road accidents in Cuenca, although Ecuador is not in the top 10 countries that consume the most liquor, driving under the influence of alcohol has become a highly recidivist factor in the city of Cuenca, causing countless traffic accidents; thus, the EMOV-EP considers alcohol consumption a necessary factor in its relevant analyses [18]. In addition to vehicle drivers, a fundamental component in road education and culture is obviously pedestrians, whose behavior directly affects the processes of the regularization of daily mobility. For example, it has been empirically observed that in areas of large agglomeration in the city, especially the most commercial and concurrent sectors such as the main markets [19], passers-by do not respect traffic signals at all, crossing through prohibited crossings such as pedestrian crossings and tram lines without being aware of the consequences that these actions may have for their physical well-being and that of the rest of the citizens who use public highways.

In addition, the city of Cuenca has a high rate of traffic accidents involving two-wheeled vehicles. The vast majority of these accidents are related to the lack of respect for traffic signs by cyclists, motorcyclists and/or pedestrians [20].This situation results in accidents that put people's lives at risk; due to their recurrence, a decline in road safety is generated that affects all citizens as well as the foreigners who throughout the year come to know and enjoy Cuenca. In this point it should be mentioned that, this capital of the province of Azuay in the Ecuadorian mountain range has been recognized by UNESCO as a cultural heritage of humanity due to its culture and the natural and architectural beauty that represent it.

Moreover, notably, according to the high figures from the EMOV-EP regarding the total accidents recorded in 2021, 24.97% were due to ignoring traffic signs, 21.11% were due to not paying attention to traffic, and 16.94% were due to driving under the influence of alcohol. These data coincide with the previously cited research. Collectively, such data show that in accidents where material losses are relatively high, injuries or human losses are also unfortunately present, thereby positioning this issue as of the utmost most importance—one that must be resolved in the medium and short term [7] .

Therefore, the EMOV-EP, as the body responsible for the regulation of human mobility in the city, in conjunction with the education system, promoted a series of road safety education campaigns to reach the greatest number of people in Cuenca's population. It thus allied with the *Universidad Politécnica Salesiana*, specifically with the research group GIPH4C, to create a greater number of frequent traffic drills throughout the city to involve the citizenship in these without people knowing that they have been drilled as such. However, due to its infeasibility, this option has been discarded; it was deemed economically in sustainable due to the numerous logistics involved. Specifically, it was found that emergency calls to 911 would cease to be important while the drill was implemented and thus the time allotted should not exceed 15 minutes to create spaces where citizens could intervene. Hence, such education implies assuming the costs that these drills represent and considering the logistics that all these processes entail; these are too high and numerous for the drills to be viable factors in producing the benefits that were the goals of this proposal.

Thus, based on an analysis of human mobility in the city of Cuenca and their joint discussion of alternatives for its regulation, the EMOV-EP and *Universidad Politécnica Salesiana*, through the research group GIPH4C, have proposed the following objective: to intervene through virtual reality technology via a virtual platform that allows creating environments similar to the environments of the city, creating the most appropriate alternative to try to resolve all the problems that have been discussed.

Furthermore, the antecedents analyzed in the first part of this research allow us to maintain that until now, the impact of platforms based on virtual reality on road training in Ecuador has been unknown. However, these new technological trends have been implemented in educational environments in general, such as virtual laboratories and learning based on serious games, with excellent results. The novelty of this proposal is thus the implementation of virtual reality technology with serious games in the field of road safety education to generate processes and new information and communication tools in regard to the road education of citizens in general [21].

That is, this paper entails the creation of a virtual reality system based on serious games for the training and awareness of citizens regarding aspects of road safety education.

Virtual reality is the simulation of a certain environment in which users are immersed and have the actual sensation of being there. Although its origins date to the 1960s, the costs of the equipment necessary for its operation have long been one of the main barriers to its distribution. However, the emergence of more affordable virtual reality hardware for games and entertainment has promoted a resurgence of virtual reality in recent years [22], sparking great interest in the field of education, especially concerning the imminent need to incorporate new technologies to improve teaching-learning processes [23] [24].

Thus, we analyze VR's properties of presence and immersion, which are considered key factors to strengthen learning. Presence allows the user to have the perception of being and existing in the virtual environment, while immersion entails the veracity that technology can evoke. However, for a true immersion of the user in the virtual environment, an additional factor is needed: interactivity. Since games are the most natural means for interactivity to be achieved, this is where SGs—those activities whose approach is innovative because they are designed for entertainment purposes but can also be used to educate or train users in certain areas—are salient [23] [25].

In the framework of this research project proposal, through the virtual platform, specific environments of the city of Cuenca are rendered in 3D within a virtual reality scenario to present the experience and various causes of a traffic accident to a user. The development of each scenario involves the use of virtual reality glasses with Oculus Rift/Quest technology [26] to overcome difficulties in the game while promoting learning through these experiences.

## III. Methodology

The development of the project was structured into three stages based on the organization of serious games. The actions included in each of the stages are as follows:

1) **Living the Experience:** In this first stage, The player experiences a traffic accident in the first and/or third person, where emotions play a very important role. The idea is for people to reflect on what has happened. Thus, an introductory scenario is presented that allows them to understand the history of and know the causes that trigger the accident, generating greater awareness in each of the participants.

2) **Learning:** The accident that was experienced in the previous stage is repeated, but now a bank of questions is presented whenever a traffic violation occurs in the animation. At this stage, it is possible to measure the concentration of people while educating them about the violations presented. The responses to the questions are saved and then used to analyze the process later. To obtain a final score, a virtual driver's license is presented where a total of 30 points is accumulated. Each time a question is answered incorrectly, the score is reduced, depending on the violation committed. Thus, when the score is zero or the question bank segment has ended, feedback is presented on the questions that have been poorly answered.

3) **Free will:** In this stage, the player has the freedom to move around and interact with different objects that make up the virtual reality scenario without any restriction. The decisions that the players make during this stage experience, directly influence their final result. In theory, with the learning obtained in the previous stages, the participant at this time should make the appropriate decisions to avoid the same traffic accident in order not to repeat the game. Hence, the system successfully fosters their participation.
The "*Tranvía Cuatro Rios de Cuenca*" scenario has a more informative purpose than simply recreation or gaming *per se*. Therefore, in the third phase, the player has the possibility of approaching two different stops or tram stations, and overcoming various obstacles of daily life, such as pedestrian crossings, traffic signals, or traffic lights, with the aim of traveling to where a ticketing and ticket validation machine is located and interacting with it. Similarly, the players can recharge their balance and buy tickets for their subsequent boarding of the tram system. In this case, if a player commits an offense, a representative fine is given to train him or her in the proper use of the actual system by reducing inconveniences in its use. This is because the fine for not paying for this service has a current value of USD $ 120.00.

Notably, prior to the development of the three above mentioned stages, the identification of the places in the city, where the greatest number of problems arise was based on the agglomeration of pedestrians and traffic accidents. The sites with the highest recurrence were selected for the development of the virtual environments, as detailed in Table I:

TABLE I. Places Chosen for the Development of Virtual Environments

| No. | Location | Problem found / Chosen scenario |
|-----|----------|--------------------------------|
| 1 | Ave. *Huayna Capac* between *Calle Bolívar* and *Calle Larga* | Driving a vehicle under the influence of alcohol. |
| 2 | Ave. *Américas* entrance to *Quinta Chica* and *Hospital del Río*. | Driving vehicles at high speeds. |
| 3 | Ave. *Fray V. Solano* between *Los tres puentes* sector and *Virgen de Bronce* Church | Users of bicycles and cycle paths. |
| 4 | Ave. *Américas, Feria Libre - El Arenal* sector | Users of the tramway system. |

Once the sectors to be displayed in the platform were selected, a photographic survey was performed. The use of the Street View tools of Google Maps and Sketchup allowed the development of all the 3D virtual scenarios. Subsequently, the information obtained was exported to the Unity 3D tool; by manipulating lighting, shadows and other factors, the desired images of the scenarios for the game experiences were obtained. Below, these images are presented in Fig. 1, 2, 3, and 4.

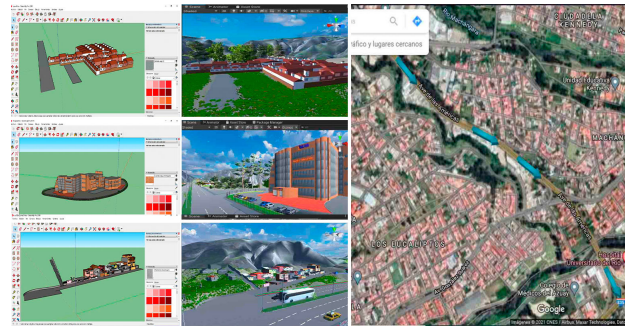

Fig. 4. Avenue of the *Americas* Scenario.

Fig. 1. *El Arenal* Virtual Scenario.

After developing the scenarios in a three-dimensional way with the tools described before, the next step was to establish all these places using Sketchup, Make Human, Adobe Fuze, Mixamo, and Blender, obtaining additional predesigned images from 3D Wearehouse. Humanoid characters and vehicles, which were positioned in various spaces within each scenario, were also created with their respective animations to approach the reality of each sector, as shown in Fig. 5, 6, and 7.

Fig. 2. *Los Tres Puentes* Sector and *Virgen de Bronce* Church Virtual Scenario.

Fig. 5. Diversity of Vehicles Designed in the Local Context.

Fig. 6. Various Objects are Designed Similarly to the Originals.

Fig. 3. *Huayna Cápac* Avenue Scenario.

An important factor throughout the research process and the development of the virtual reality proposal was the possibility of maintaining the effective representation of each place. Hence, common characters and vehicles to the city of Cuenca were included in the setting, such as the "*Cholita cuencana*" from Cuenca, a typical character of the city, visualized in Fig. 8.
Fig. 7. Design of Varied Characters.

Fig. 8. Design of a "*Cholita Cuencana*" in 3D to be Included in the Scenarios.

To maintain the same criteria, street vendors were also included (see Fig. 9), as well as characters who are commonly found in different parts of the city and security personnel, such as police, citizen guards, traffic agents, and civilians.

Fig. 9. Design of Street Vendors in the City in 3D.

After creating these scenarios according to their local context, we designed a script in which the traffic accident that occurs in each sector is narrated, necessitating our investigation of the different accidents that usually occur in real life. This information was obtained from various local media, such as the *El Tiempo*[1], and *El Mercurio*[2] newspapers, the social

networks of public security companies, such as *ECU-911*[3], and news websites. This information allowed us to determine the problems to be addressed in the scenarios and to identify the infractions that should be implemented in the context of serious games.

To better understand all the procedures that are carried out after traffic accidents and the reactions they generate among pedestrians and other security entities, the research team participated in drills conducted by the EMOV-EP during 2020. Through the observation of these drills, the different attitudes of people toward an accident involving a driver under the influence of alcohol and a cyclist on a cycle track were observed and recorded, as shown in Fig. 10. In this way, relevant conclusions were obtained to more realistically depict the specific scenario that we developed and presented.

Fig. 10. Simulation of Transit Accident Held in the City of Cuenca. *Where Members of the EMOV-EP and UPS Participate.*

Furthermore, the EMOV-EP constantly interacts with citizenship to transmit knowledge and education on road issues; these interactions became opportunities for the socialization of the research project (see Fig. 11). In these spaces, it was possible to present the serious game proposal to the public, interact with users and obtain useful feedback for the enrichment of the proposal and assure a better actual user experience, i.e., for users to effectively learn about the proper use of roads and the consequences of poor decision-making when driving a vehicle or traveling on the streets and avenues of the city.

Fig. 11. Socialization of the System with Citizens.

Another important component within the proposal concerns the mechanisms for evaluating learning among the platform's users. Therefore, a web platform has been developed. This platform allows the visualization of the reference question bank for each scenario and ensures that these are modified

[2]https://www.elmercurio.com.ec

[3]https://twitter.com/ecu911austro?lang=es

according to any needs or changes that occur, especially regarding cases of the application of fines.

In a complementary manner, the platform generates the data and statistics recorded by the entire system in graphical format. Through these data, it is possible to detect what questions are the most familiar to users and, in turn, the scenarios where the population has more difficulties or ignores more traffic laws (see Fig. 12 and 13).

Fig. 12. Visualization of the Web Platform: Main Page.

Fig. 13. Visualization of the Web Platform: Statistical Results.

Moreover, the storage system of the question bank is two MySQL databases, one local and one at the cloud level. Both databases maintain a master-master relationship. However, during the socialization of the project, it was observed that on some occasions, it is possible that there is no internet connection. Hence, the backup of the generated records must be stored on the local disk, but when there is a connection, they are uploaded to the cloud. To perform this procedure in the cloud, it is necessary to be connected to the internet through a static IP address that is assigned within the facilities of the EMOV-EP, guaranteeing the required information security.

## IV. Results

### A. Hardware and Software

To provide a greater understanding of the results of this project, developed jointly between the EMOV-EP, the *Univer-*

*sidad Politécnica Salesiana* and the UPS's GIPH4C research group, we provide the following basic characteristics of the necessary computer and the installation of the platform for use: computer with Windows 10 or higher operating system; video card Nvidia GTX1060/GTX 1660 or equivalent of AMD - Ryzen 2600/3600 or Intel i5 8600 or equivalent; Memory of 16 GB of DDR3 or DDR4 RAM; and, solid-state hard drive of at least 512 GB and a mechanical hard drive of at least 1 TB.

Nevertheless, in terms of performance and functionality, a certain latency has been observed in the fluidity and execution of the developed scenarios. Among the most important causes for this delay that we have detected are the following:

- **Lighting:** Lighting is an important factor when using many system resources since it visually depends on how much coloring and how many objects (including the addition of shadows) are added to each figure in the virtual scenarios.

- **Vertices and Groups of Objects and Rendering:** A surplus of groups and vertices to present very detailed objects causes the rendering to become slow when interpreting many points and details. It is thus advisable to make them more simple without too many details to improve the speeds of the processes.

- **Colliders:** It is better to generate these with fewer vertices and avoid their use; otherwise, it is necessary to include Mesh Colliders.

- **Occlusion:** How and when both objects and animations are visualized play a very important role in performance because they cause slowness and latency within the execution. It is advisable to use the parameter called Occlusion Map, since it gives different qualities in the rendering of the same object; the further away it is, the less its quality and thus fewer resources are used. In contrast, as you approach it, its quality and detail increase, using more resources in less time. This same parameter, due to the unified visual field of the camera, allows a rendering of a scene to be fixed as the viewer views it. Specifically, what the visual field of the camera captures is what is rendered and animated—such rendering and animation stops once the object or fraction of the scene with respect to the visual field of the scene is outside the camera's focus.

- **Scripts:** Script optimization is important for making the project work correctly because if there are infinite or constant loops, these will generate resource consumption.

- **Animations:** Within the animations, a factor to account for is the generation of the exoskeleton of the character to be animated. The greater the number of bones generated, the more fluid the animation will be and, in turn, the more graphic resources will be consumed. Hence, it is recommended that if a character does not perform movements that require complete control of all his or her joints, only a basic exoskeleton (control of head, neck, back and extremities) is rendered. Similarly, if the character does not

perform movements in terms of facial expressions, it is unnecessary to generate them, as these increase the weight of an animation due to unused resources.

Regarding the process of executing the scenarios in the computer, when executing the four scenarios at the same time, the consumption of video resources, RAM and cache memory of the computer is extensive; they are working at their maximum capacity, which causes an increase in hardware temperatures. In many cases, the programs can become "frozen"; therefore, they should be executed one scenario at a time, because a computer can only connect to a single Oculus device. By having only one scenario thus executed, everything functions without problems. A quick and timely solution, however, would be to expand the capacity of the computer's video card and RAM.

### B. The Use of the System by Users

Due to the ongoing COVID-19 pandemic, declared worldwide by WHO [27] in late 2019, the socialization phase of the research project was reduced. However, given the obligation to understand the acceptance (or not) of the virtual platform by its end users, a group of 30 people was randomly chosen. The platform was presented to them and they experienced all four virtual scenarios. This entire validation process was carried out under strict biosafety measures. Once the presentation was completed, the group responded to a survey that was formulated to obtain feedback on the proposal via their comments and suggestions. Some of the most important questions and its answers of the survey are presented in Table II, which concern the user's level of knowledge generated by a traffic accident scenario, perception of virtual reality, identification of the sector of the city and evaluation of the experience of learning through play.

It is important to note at this point that the limitations presented in the validation phase of the proposal did not affect the process of verifying the usefulness and operation of the platform. Indeed, the answers to the questions for all four scenarios were favorable. As shown in Table II, an average of more than 60 percent of the people surveyed rated them with the highest score. Notably, moreover, the contributions, observations and suggestions from those who interacted with the platform, in addition to the recommendations of the specialized staff at the EMOV-EP, will be considered in the construction of the next stages of improvement and implementation of the virtual platform project.

### V. Discussion

The literature review on the use of information and communication technologies to promote road education, previously detailed shows on one hand a growing concern about the accelerated increase in the rate of traffic accidents in Ecuador. On the other hand, it is also notorious the emergence of proposals from higher education institutions in order to promote actions that lead to the training of citizens in terms of knowledge, respect, and compliance with current laws and regulations on the matter.

Therefore, in the following paragraphs, we discuss the meeting points and differences between this proposed and the main related works addressed.

Research work in [1] contributes to our paper from the theoretical point of view which exposes the aspects related to road education, its relationship with road safety, and the necessary participation of the different actors of society; in the generation of articulated actions, from the roles and responsibilities of each instance. As for the work proposal mentioned above, it is restricted to the exposition of government actions implemented in Guadalajara-Mexico for the education of adults in respect of traffic laws. As a result, the authors proposes the implementation of a road education subject as an elective course at the *Universidad de Jalisco*. Finally, the work does not detail in depth the methodology used to generate the proposals. Likewise, it is limited to adult education, which greatly differentiates it from the proposal for the use of serious games in our research, which can be aimed at children, youth, and adults.

In the local context, another similar study is presented by [2], which concur with the gathering of its empirical information and the results of our paper regarding to the high accident rate in several cities of Ecuador. However, the study is limited to the city of Guayaquil. Similarly, our research coincides with the consideration of road education in Ecuador as a national problem, which makes it necessary to generate joint and multidisciplinary actions to reduce what they define as a technological scourge. Regarding the methodology, they are based on a training process through interactive websites with 3D animations but are only aimed at young high school students. Last, the study does not expose the methodology for the development of the applications used. Nor does it detail the results obtained in the implementation of the proposal.

In the same way, the authors in [3] agree with our study regarding the approach of traffic accidents in Ecuador as a public health problem, due to their accelerated growth in the last two years. However, among the causes of this growth, the authors point out the lack of government commitment to complement effective politics in the mobility area. Whereas, in our proposal, we have recognized mechanisms for road education in the city of Cuenca in which we have involved public and private, social, academic, and governmental actors. Also, the analyzed research is limited to proposing the development of road safety educational projects in the field of educational institutions. However, the components of the training or techniques and instruments for its application are not exposed. As result, the identification of accident statistics in the city of Guayaquil stands out, in addition to the characterization of the training undertaken by the educational units in road education.

Moreover, the authors in [16], address the city of Guayaquil as a field of action and they have the same point of view as previous and our investigations in considering that traffic accidents constitute one of the main causes of death in Ecuador, mainly for young people. Another point of agreement between the investigations has to do with affirming that the lack of road education is a fundamental factor in accident rates. In relation to the research proposal, revolves around marketing strategies and is addressed only to students of Technological Institutes. In the results, the research coincides with the data obtained in our paper by pointing out recklessness, disrespect for traffic signs, alcohol consumption, and the use of cell phones while driving as causes of main accidents.

TABLE II. COMMON QUESTIONS AN ITS ANSWERS FOR EACH SCENARIO USED FOR THE VALIDATION AND ACCEPTANCE OF THE PROJECT

| Scenarios | Questions | | | | |
|---|---|---|---|---|---|
| | *Question 1* *How much did you correctly appreciate and understand the theme of the accident presented in each scenario?* *On a range from 1 to 3, where 1 is Nothing and 3 is Everything.* | | | | |
| | Option 1 | | Option 2 | | Option 3 |
| *Driving a vehicle under the influence of alcohol* | 0 | | 0 | | 30 |
| *Driving vehicles at high speeds* | 0 | | 0 | | 30 |
| *Users of bicycles and cycle paths* | 1 | | 3 | | 26 |
| *Users of the tramway system* | 0 | | 8 | | 22 |
| | *Question 2* *How did you find the Virtual Reality experience?* *On a range from 1 to 5 (1 as very bad and 5 as very good)* | | | | |
| | Option 1 | Option 2 | Option 3 | Option 4 | Option 5 |
| *Driving a vehicle under the influence of alcohol* | 0 | 0 | 1 | 7 | 22 |
| *Driving vehicles at high speeds* | 0 | 0 | 1 | 4 | 25 |
| *Users of bicycles and cycle paths* | 0 | 0 | 7 | 10 | 13 |
| *Users of the tramway system* | 0 | 0 | 6 | 9 | 15 |
| | *Question 3* *Were you able to identify the sector of the city where you were?* | | | | |
| | Option Yes | | | Option No | |
| *Driving a vehicle under the influence of alcohol* | 29 | | | 1 | |
| *Driving vehicles at high speeds* | 29 | | | 1 | |
| *Users of bicycles and cycle paths* | 22 | | | 8 | |
| *Users of the tramway system* | 22 | | | 8 | |
| | *Question 4* *How would you rate the experience of playing and learning through these virtual means?* *On a range from 1 to 5 (1 as very bad and 5 as very good)* | | | | |
| | Option 1 | Option 2 | Option 3 | Option 4 | Option 5 |
| *Driving a vehicle under the influence of alcohol* | 0 | 0 | 0 | 3 | 27 |
| *Driving vehicles at high speeds* | 0 | 0 | 0 | 2 | 28 |
| *Users of bicycles and cycle paths* | 0 | 0 | 3 | 6 | 21 |
| *Users of the tramway system* | 0 | 0 | 0 | 7 | 23 |

## VI. CONCLUSION

The use of ICTs to promote road education in Ecuador evidences the development of several research papers in which traffic accidents and their consequences are considered a public health problem that cannot be addressed only by establishing public policies, but with the cooperation of different sectors of society (public and private). The research papers studied are limited to the analysis of the causes and not the presentation of innovative proposals that go beyond the traditional methods of training in road culture. Similarly, the bibliographic review found a diversity of research applied in Ecuador, however, most are developed in the context of the city of Guayaquil, and for the city of Cuenca, there is no evidence of research proposals of great impact for reduce the number of accidents through road education.

The development of road education proposals based on virtual reality with a focus on serious games is currently a highly relevant topic. Through our review of the theoretical and empirical background of this research, it is evident that first, traffic accidents have become one of the main causes of death not only in Ecuador but also globally. Second, the growing number of accidents in the city of Cuenca, Ecuador is mainly generated by high speed, driving under the influence of alcohol, recklessness of drivers and pedestrians, and ignorance of traffic rules and signals. Accordingly, the need to articulate interinstitutional efforts is evident, a prerequisite to generating proposals that mediated by new information and communication technology, can contribute to the formation of a road culture in the city of Cuenca.

The social impact of the project developed jointly by the EMOV-EP and the GIPH4C, made up of professor-researchers from *Universidad Politécnica Salesiana*, derives from the cre-ation of a 3D virtual platform based on entertainment through the simulation of environments. Its purpose is to train, educate and raise awareness among citizens about the proper use of roads for the prevention of the traffic accidents that according to official statistics typically result in irremediable situations. Hence, it is proposed that through the use of new technologies for learning and the serious games approach, citizens will understand and learn about traffic education in the city of Cuenca.

For the structuring of this 3D virtual platform of traffic education, the sites in the city of Cuenca where there is a greater occurrence of accidents due to pedestrian agglomer-ations or traffic incidents were identified. In each of these scenarios, the various situations that lead to accidents or fines for failing to comply with traffic regulations were simulated. The virtual environments also included the "*Tranvía Cuatro Rios de Cuenca*", a means of mass transportation that has been operational since 2020. Given the novelty of the service it provides, citizens remain unaware of the rules for its proper use and do not grasp that the failure to comply with them carries fines and other penalties.

The validation of the virtual platform for road safety education with an Social Group focus was carried out through tests performed on citizens. A group of 30 randomly selected people experienced the 4 virtual environments, witnessing common situations related to mobility within the city. Once their simulation was complete, these users of the platform answered a series of questions about its operation, composition and usefulness. The results of the survey show that 91 percent of people fully understood the context presented in each sce-nario. After the survey, the personnel in charge of the EMOV-EP asked a question about road safety that was addressed in the

scenarios presented and obtained 100 percent correct answers. Thus, this project clearly has great educational, technological and innovation potential; it can therefore be implemented as an education and road awareness strategy in the city of Cuenca.

The results obtained in this first phase of the project are considered theoretical and empirical background for the continuity of this and other research that aims to promote road culture through the use of immersive technology as an education tool.

# An E2ED-based Approach to Custom Robot Navigation and Localization

Andrés Moreno, Daniel Páez, Fredy Martínez
Universidad Distrital
Francisco José de Caldas
Bogotá D.C., Colombia

*Abstract*—Simultaneous mapping and localization or SLAM is a basic strategy used with robots and autonomous vehicles to identify unknown environments. It is of great attention in robotics due to its importance in the development of motion planning schemes in unknown and dynamic environments, which are close to the real cases of application of a robot. This is why, in parallel with research, they are also important in specialized training processes in robotics. However, access to robotic platforms and laboratories is often complex and costly, with high demands on time and resources, particularly for small research centers. A more efficient and affordable approach to working with autonomous algorithms and motion planning schemes is often the use of the ROS-Gazebo simulator, which allows high integration with customized non-commercial robots, and the possibility of an end-to-end design (E2ED) solution. This research addresses this approach as a training and research strategy with our ARMOS TurtleBot robotic platform, creating an environment for working with navigation algorithms, in localization, mapping, and path planning tasks. This paper shows the integration of ROS into the ARMOS TurtleBot project, and the design of several subsystems based on ROS to improve the interaction in the development of service robot tasks. The project's source code is available to the research community.

*Keywords*—*End-to-End design; localization; navigation; path planning; robotics; SLAM*

## I. INTRODUCTION

Robotics is a field of research in constant growth, the need for support, cost reduction, safety, and reliability drives the development and study of problems related to its application in real tasks. There are major unsolved problems that hinder its wide use in applications such as service robotics (the area closest to our research), in general, related to interaction, autonomy, safety, and reliability [1]. Many research centers around the world are actively working in these niches, but in many cases, access to robotic platforms and specialized laboratories is restricted for reasons of cost, availability, and resources related to this activity. A working scheme of good acceptance in the scientific community is the use of high-performance simulators, which can replicate very faithfully the behavior of a robot, one of the most popular platforms today in this regard is ROS OS (Robotic Operating System).

The operating system has more than 10 years of growth and interaction in robotic programming, and its particular details such as interoperability and open source generation provide services comparable to those of an operating system, such as hardware abstraction, low-level device control, inter-process message passing and packet management [2]. Though is not

an operating system, it provides the same services to its users as an operating system does.

In today's social development, the implementation of mobile robots for problem-solving in industrial and non-industrial environments is of great relevance [3]. Applications in rural or agricultural areas, as well as those involving direct interaction with humans [4], [5], are of great current interest. In this respect, mobile robotic platforms have been proposed that can be used in a greenhouse to transport vegetables [6], [7], in some cases with safe interaction systems with humans. Another study proposes the control and tracking of trajectories based on simulations and experiments in real-time on the ROS platform, where the objective is to validate the effectiveness of the proposed control algorithm and compare it with a modified hybrid PID dynamic controller with feedback [8]. In these cases, ROS was fundamental in the design and performance evaluation stages. As for the concrete problem of mapping and navigation, whether in the land, water, or air vehicles, ROS allows SLAM simulation in the working environment, thus reconstructing the map and dynamically planning a trajectory to the target destination [9], [10].

The use of this type of software tool becomes essential when control schemes integrate a large variety of sensors [11]. Not only does it facilitate the preliminary performance evaluation of the scheme (reducing costs and implementation time), but it also speeds up the overall implementation time of the schemes. In assistive robotics, this is key, as new interaction schemes and control algorithms are continually being developed and need to be evaluated quickly [12]. These applications involve both the interaction problem and the navigation problem, which in many cases involve complex control algorithms, whose performance and coordination must be evaluated before implementation on real platforms [13], [14]. The emulation under ideal conditions, therefore, allows having an additional design tool that guarantees time and design reduction throughout the whole process [15].

Our research project is part of a macro project aimed at the development of robotic solutions for assistance tasks, particularly in applications related to the care of people (elderly and children). In previous years, we have developed a modular mobile platform with load capacity for integration with a manipulator robot (industrial application) and/or an anthropomorphic robot for services [16], [17]. Previous prototypes of this robot had been integrated with ROS to provide ease of handling and simulation of behaviors [18], [19]. At the time, the use of the platform with ROS in structured motion planning applications was justified due to the simplification

in the integration of navigation algorithms. This project seeks the same benefit in a more complex robot, which additionally requires greater availability of access for members of the research group. However, the application of ROS in more complex robot also opened the door to new problems [20].

Similar projects to the one proposed in this research have been previously developed on other platforms [21]. ROS is commonly used to facilitate the design, analysis, and tuning of control algorithms by taking advantage of its modularity and master-slave scheme of work. Our work differs from some of them, such as [22], [23], in the sense that it prefers coding in an open environment with Python support, unlike MatLab, which conforms to a closed platform with expensive licensing. Still, as in its previous uses, it allows the easy use of simulators such as Gazebo. We did not solve all the issues mentioned above, but we did accomplish our goal: We programmed robots using the ROS framework.

## II. Problem Statement

The ARMOS TurtleBot robot is a robotic platform designed and implemented by the ARMOS research group to develop assistance tasks and human support (service robot) (Fig. 1). Although it was conceived as a mobile platform for other systems, it has load restrictions (maximum value defined as 10 kg), and movement restrictions derived from its structure and motors. It has four 9 V DC motors with geared motors, driving a caterpillar on a differential structure. Each of the motors has a starting torque of 9.5 kg, no-load speed of 150 RPM (revolutions per minute), starting current of 4.5 A, and nominal working current of 1.2 A (200 mA no-load). These motors have a Hall sensor for shaft position estimation.

Fig. 1. ARMOS TurtleBot Robot.

The working model of the motors is in pairs, i.e., the same control signal activates simultaneously the two motors on the right side, and another signal activates simultaneously the two motors on the left side. This scheme improves the robot's total torque while also simplifying its model and control scheme without sacrificing displacement capacity.

The structure is composed of an aluminum base, a material chosen for its lightweight, which reduces the total weight of the platform. Object detection is done through sensors around the robot. The robot has nine SHARP GP2Y0A21YK IR infrared sensors, which are distributed throughout the robot structure. Other peripherals included in the robot are:

- Four contact buttons, that function as impact detectors.
- A TCS3200 color sensor located at the bottom of the robot.
- An inductive sensor LJ12A3-4-Z/BY located in the lower part of the robot to detect metallic elements.

For the control system, two STM32L432KCU6 microcontrollers are used to process sensor and actuator signals, and a Raspberry Pi 4 card is used as the control unit, which will also have the ROS OS operating system.

The ARMOS TurtleBot robot was designed with diversity and a wide variety of peripherals capable of interacting and communicating with each other through the master-slave level configuration. In addition, it allows the simple integration of new peripherals with a LiDAR sensor. The initial tasks of the robot contemplate navigation problems in dynamic and unknown environments, the reason why in this project we intend to implement ROS in the platform and evaluate its performance in basic navigation tasks that contemplate the use of these peripherals in a real environment.

## III. Methods

The ARMOS TurtleBot vehicle platform can be analyzed by separating it into two sections. The first one is composed of position sensors. These are in charge of identifying bodies or objects close to the trajectory performed by the robot. Additionally, the drives of these devices prevent damage to the robot's electronic circuits (Fig. 2).

Fig. 2. Proximity Sensor Connection.

The second section is composed of proximity sensors. The main purpose of these devices is to specify the characteristics of the materials that are in the path (floor) and that could

modify their behavior according to the programmed task. There is the detection of metallic materials, and the characterization of materials according to their color (Fig. 3).

Fig. 3. Connection of Color and Inductive Sensors.

To integrate ROS into the robotic platform we have sought to replicate its structure within the software. All the physical components, considering their specific capabilities, as well as the communication, signal collection, and handling capabilities, have been programmatically replicated on ROS. The correct description of the robot requires a correct description of each peripheral, which was linked to specific laboratory tests. In this way the robot architecture was developed, starting from its control unit, the Raspberry Pi 4 board, which is responsible for managing all the information. Fig. 4 shows the complete architecture of the main systems and subsystems involved in the robotic platform.

The first step is to establish serial communication with the devices or peripherals of the ARMOS TurtleBot platform. To start the interaction with the ROS OS framework, the following command is entered in a Raspberry Pi 4 terminal (on the robot):

```
$ roscore
```

In this way, the operating system starts the communication. The initial part corresponds to the user generated to work on this terminal (pi@raspberrypi:). Thus, if the connection is successful, the system responds as shown in Fig. 5.

This corresponds to the workspace and communication verification process of the master node in ROS OS. At this moment is when the communication or start of the ROS OS system is successfully obtained. The next step is to continue with the opening of the workspace defined for the nodes and commands that are entered, this can be done through the command line as follows.

```
$ cd ~/catking_ws/ &&source devel\setup.bash
$ cd rosrun rosserial_server serial_node _port:=dev/ttyACM0
```

The command line corresponding to rosserial is the one that indicates the communication through language or programs generated through Arduino IDE 18.2, which is the version implemented for the project.

The next step consists of the communication of the peripherals or sensors, both position, and proximity. For this mobile application, the programming is done under the C++ language, where it should be noted the confirmation of one of the main objectives of the ROS OS system, the recycling of code and interoperability between the various programming options available at the moment.

For the inductive sensor LJ12A3-4-Z/BY whose function, as detailed above, is to enable the robot to determine the existence (detection) of metallic material on the surface on which the ARMOS TurtleBot robot is moving (floor), the corresponding command line is as follows:

```
$ rostopic echo inductive_sensor
```

The metal detection and the message received by ROS OS are shown in Fig. 6.

The contact sensor or pushbutton has the objective of detecting contact with an object, which should produce a change in the speed and direction of the robot according to the navigation strategy. The command line to control this sensor is as follows:

```
$ rostopic echo switch_limit
```

The response or communication by ROS OS in case of contact detection is shown in Fig. 7.

The proximity sensor used is the Sharp GP2Y0A21YK IR. There are a total of nine of these sensors, which are in charge of establishing the distances to obstacles or objects around the robot. Their signal is visualized through a graph generated by the operating system, the tool is called rqt_plot. The following are the lines of code and their corresponding response for three sensors (Fig. 8 and 9).

```
$ rqt_plot / sensor3/range: /sensor4/range: /sensor5/range
```

The last sensor coupled to the system is the TC3200 color sensor. The color identification method consists of 64 photodiodes equally distributed in four colors (red, green, blue, and white). Its operating principle is based on the conversion of signals (electronic circuit) from current to frequency, where a specific frequency is assigned to the detected color, thus with the constant determination of three frequencies (red, green, and blue) and the determination of the frequency range during the three readings, the conditions to be programmed in the control unit are obtained. The frequency ranges are specified in Table I.

TABLE I. FREQUENCY RANGE FOR COLOR DETERMINATION BY THE SENSOR

| Colors according to frequency range | | | |
|---|---|---|---|
| Red | R<50 | V>90 | A>90 |
| Blue | R>85 | V>80 | A<50 |
| Green | R>90 | V<120 | A>58 |

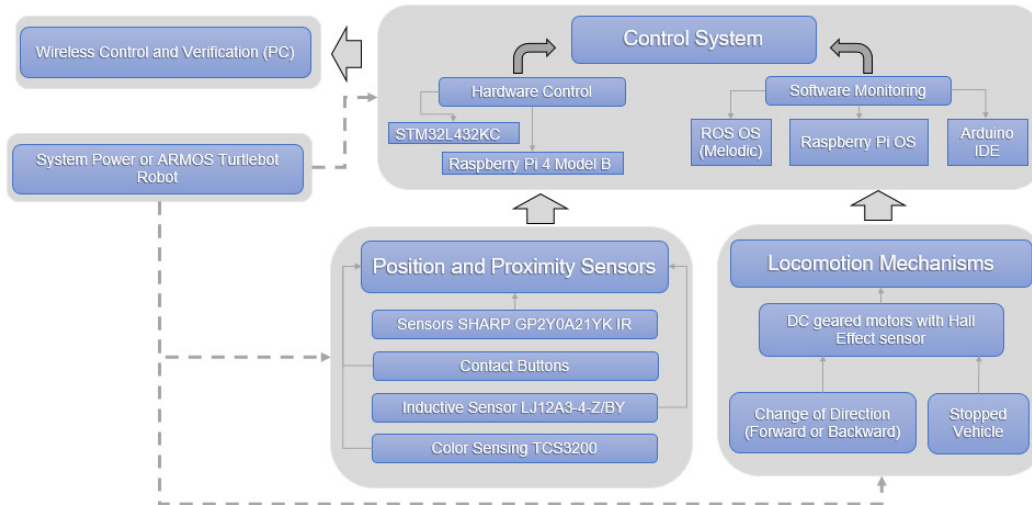
In the robot, the color sensor is managed by a STM32L432KCU6 microcontroller. This microcontroller establishes the communication with ROS OS. To query the


Fig. 4. Control Scheme: Hardware and Software.

Fig. 5. Roscore Start.

Fig. 6. Metal Detection Report from the Inductive Sensor.

reading, a message is sent from ROS similar to the one shown below.

```
$ rostopic echo color_sensor
```

Actuator management is also configured from ROS. The monitoring and instructions of the DC motors, as well as the Hall effect sensors coupled to each of them, can also be easily managed from this environment. These sensors prove to be an essential tool that allows the feedback of the movement of each motor, thus reducing errors in autonomous navigation tasks in real environments. Three basic commands were designed for its operation: go forward, stop and reverse. These commands are translated into specific movements performed by each of the motors, and controller through Hall effect sensors. The instruction for their execution is as follows:

```
$ rostopic pub forward std_msgs/empty
```

## IV. RESULTS AND DISCUSSION

To evaluate the performance of the system, a test environment was built to assess the behavior of each of the robot's sensors, as well as its actuators and communication characteristics. The following is a brief description of this test environment, as well as the expected interaction with the ARMOS Turtlebot robot, its displacement parameters, and the defined trajectory path.

The scenario where the peripheral integration tests are performed on the ARMOS Turtlebot robot has a flat surface (Fig. 10). In the center of the area, there is a box composed of different materials with characteristics recognizable by the devices embedded in the robot. The navigation of the robot was programmed with restrictions on its displacement, to evaluate the interaction of sensors and actuators in the ROS OS operating system. The navigation conditions for the execution of the experiment are detailed below.

The displacement of the robot starts with the control signal generated from the control unit installed on the robot

Fig. 7. Impact Report from the Contact Sensor.

Fig. 8. IR Sensors Report.

itself. From there, the ROS connection is established with the peripherals as described above. As soon as the communication is established and the work folder is opened, the trajectory is started with the instruction from the corresponding command line. At this point, the ROS connection has been established between the control unit and other peripherals.

The specific mechanism to intervene during the whole test is the caterpillar wheels equipped with geared motors and coupled to Hall effect sensors. These devices are used to

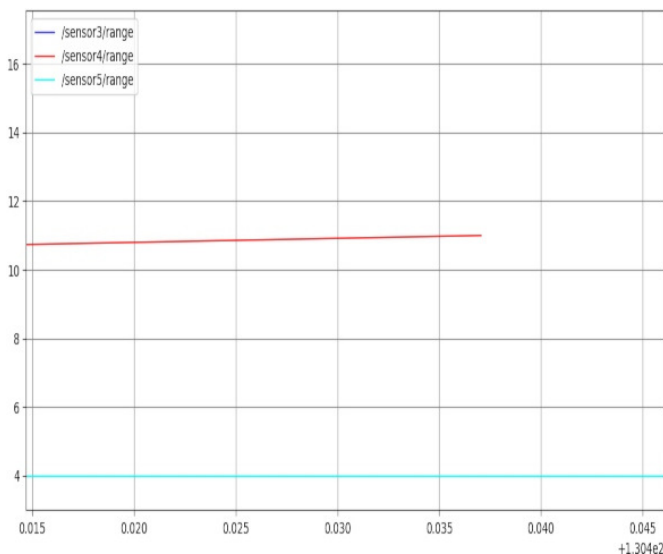

Fig. 9. Distance Curves Reported by the IR Sensor

Fig. 10. Test Environment Setup.

move the robot to carry out the trajectory. The path is defined on a surface adapted with characteristic colored materials, recognizable by the TC3200 color sensor. The first zone corresponds to the blue material, the sensor acquires this information and transmits it directly to ROS OS, which is in charge of processing the data and sending a color detection message. In this case, the text specifying the color of the detected object is displayed on the terminal.

Sharp GP2Y0A21YK IR infrared proximity sensors have a maximum detection range of 80 cm. For the proposed test application, this detection is conditioned to a maximum of 20 to 25 cm, and the control is done graphically in real-time through the rqt_plot tool of ROS OS, making the recognition of object or obstacle and its distance. Once this condition is met, the programmed instruction is the change of direction, and to perform this action by the robot, a rotation is performed on its axis (right) which occurs whenever the motors on each side rotate at the same speed and in opposite directions (one side of the robot moves forward and the other backward).

Starting up in the new direction, the surface on which it is running is colored green, which is detected by the TC3200 color sensor. Thereupon the system and its programming will issue a message on the terminal indicating that the second green area has been detected. While the vehicle is running, a green-colored area is detected by the TC3200 color sensor.

When a metallic material is detected, it is time for the intervention of the inductive sensor LJ12A3-4-Z/BY, which causes two different interactions in the programming and control of the robot. The first consists of the ROS instruction that indicates the detection of metal, performing a change of direction or rotation on the axis. Additionally, the data of the metal material is sent so that a message is transmitted to the terminal indicating the detection of this element.

It changes direction in a 90-degree turn with a new rotation on its axis in relation to its previous position. The robot is moving over a third displacement zone, this time in red. As before, this information is reflected through ROS OS using a message indicating the detection of a colored area.

The test or experiment ends with the intervention of the contact sensors that aim to detect the impact of an obstacle on the robot. These are activated when changing state (bi-valued sensor), which complements the reading of the distance sensor formed by the nine infrared sensors IR Sharp GP2Y0A21YK, or even substitute it when the obstacle is below the line of sensing of the infrared. The action defined at this point is that the robot stops immediately.

This navigation circuit was developed by the robot multiple times to verify the consistency of operation and results. One of these tests can be seen in the following link (Fig. 11).

https://youtu.be/uh5wzhIwi6g

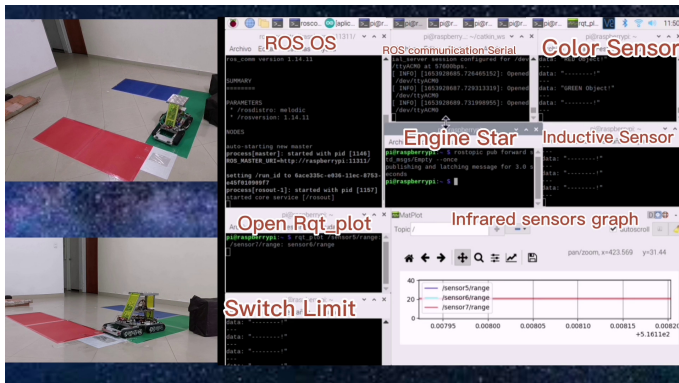

Fig. 11. ROS-Controlled Robot Performance Test.

Communication between ROS OS and the sensors allows it to know where they are and allows for these devices to communicate between them automatically, as a message that is generated by one device will be transmitted automatically to all other devices. When running all the peripherals and devices associated with the robot, it is evident that the communication between ROS OS and these works correctly because there are no crashes or failures when all these devices are communicating at the same time in the system. This feature guarantees the robustness of the system and allows for validating it for evaluation tests of more complex navigation algorithms.

The inductive sensor detects the metal correctly, and the message display transmitted by ROS OS through the terminal shows the warning message approximately one second after the sensor detected the metal surface. In the case of the contact sensor, it was triggered immediately when the robot had a collision with the obstacle that was not detected by the IR ranger sensors located at the front of the robot. The warning message displayed by the ROS system was almost instantaneous when the collision occurred (about a 120 ms delay).

As for the motors, when the command was executed in ROS OS on the terminal to move the wheels of the robot and produce forward motion, it was evident in all tests that there was a delay in the response of the motors of approximately three seconds after the command was executed. The same was true for moving the wheels backward or for stopping the movement of the motors completely. After almost three seconds of waiting to start or stop the movement, the motors responded appropriately.

The most important sensor in the reactive control tasks is the ranger IR sensor. Each sensor in the system was individually tested for interaction with ROS OS. The object detection tests were verified in the rqt_plot tool that is integrated in ROS OS, which allows to view two-dimensional plots. In this tool, a distance vs. time graph is displayed, where a continuous line appears referring to the distance in cm, in which the ranger sensor is detecting an obstacle. The individual tests showed that the sensors detected the objects acceptably with an error of approximately one to two centimeters. Back in the test application, where the sensors were acting in conjunction with the other devices on the robot, it was found that the reading accuracy error increased to almost three centimeters for some sensors. When trying to visualize the nine signals detected by each of the sensors in the rqt_plot tool, the operating system of the raspberry pi generated delay in the response and sometimes even total crash of the system. So to avoid this problem, it was decided to visualize in the rqt_plot tool only some of the IR, but to use all of them for mapping tasks. In the tests, the response of the three ranger sensors located at the front of the robot is visualized. The ranger sensors were programmed to detect objects within a range of 0.2 to 0.25 m, and then instantly generate action on the robot's motors. Furthermore, when they detected an object in this distance range, the motors reacted within two to three seconds after the sensor had detected the object.

The color sensor was evaluated individually with ROS OS before being incorporated with the other devices and sensors on the robot. The ROS readings were accurate over the three colors that the sensor measures. When the sensor was incorporated into the test task, the color readings began to differ significantly from the previous ones, resulting in erroneous readings in the application. The possible interference of communication delays on the performance of this sensor is evaluated in this case.

In this study, the results of implementing ROS as a handling strategy for the ARMOS TurtleBot robot were achieved and shown. The strategies used can be generalized and further investigated on this platform as well as on other custom robotic platforms not initially designed with ROS in mind. This work can be further enhanced with the use of navigation algorithms and optimization techniques that reflect the comparative performance of each case. This study shows that ROS can be used as a suitable programming environment for a robot and should be the one platform from which further work is don

## V. Conclusion

The constant innovation in design, programming, and control in mobile robotics leads to the generation of a wide variety of algorithms, compromising the understanding and suitability of robotic applications as a whole. A design methodology already proven and widely studied is the versatility offered by the ROS OS operating system in the different stages of the development of control schemes for robots. This tool combines the ease of code recycling and the interaction and communication of different types of programming languages. This paper presents and explains the integration of the ROS OS (Melodic) operating system on the ARMOS TurtleBot mobile robot and its peripherals. The platform is designed to perform navigation tasks or activities, thus obtaining synchronization, data transfer, and information management in real-time on surfaces with suitable characteristics to be detected by the different devices that make up the robot. The proposed purpose corresponds to the integration of the devices that make possible the displacement and recognition of the robot in a given environment. The systems involved according to the architecture are Raspberry Pi OS, ROS OS (Melodic), and some microcontrollers as embedded systems that directly manipulate sensors and motors, with this architecture the compatibility and possibility of integration of peripherals are confirmed. The simultaneous interaction of the proximity peripherals and position sensors through the ROS OS operating system is visualized through windows or terminals utilizing messages or interactively in 2D graphics, confirming the interoperability and real-time control of the environment surrounding the robot when it performs navigation tasks. The presence of windows and graphic interfaces for its control demonstrates the possibility of remote real-time observation and monitoring, providing immediate feedback about the robot's environment. No communication problems are detected that could prevent its use as a general strategy in the development of navigation algorithms. On the contrary, the possibility of integrating additional peripherals such as a LiDAR sensor or a digital camera onboard is observed.

# Identifying Community-Supported Technologies and Software Developments Concepts by K-means Clustering

Farag Almansoury, Segla Kpodjedo, Ghizlane El Boussaidi

Department of Software Engineering and Information Technology, École de Technologie Supérieure(ETS)

University of Quebec, Montreal, QC, Canada

*Abstract*—Working on technologies that have community support is one of the most important factors in software development. Software developers often face difficulties during software development, and community support from other software developers help them significantly. This paper presents an approach based on K-mean clustering technique to identify the level of community support for software technologies and development concepts using Stack Overflow discussion forums. To test the approach, a case study was performed by gathering data from SO and preparing a dataset that contains over a million of Java developers' questions. Then, K-mean clustering was applied to identify the community support levels. The goal is to find the best features that group community-supported software technologies and development concepts and identify the number of groups to determine the community support levels. Statistical error, clustering and classification evaluation metrics were applied. The results indicate that the best features to formulate community supported technologies and development concept levels are Failure Rate and Wait Time. The results show that the approach identifies two groups of community supported and development concept levels based on the best silhouette index value of 97%. According to the results the majority of Java technologies and development concepts are labeled with less community supported technologies and development concepts (Cluster 2). Random Forest classifier was applied to indirectly evaluate the approach to detect the identified community support class. The result shows that RF classifier presents a good performance and shows high accuracy value of 99.49% which indicates that the identified groups improve the performance of the classifier. The approach can be utilized to assist software developers and researchers in utilizing the SO platform in developing SO-based recommendation systems.

## I. INTRODUCTION

Developing a software from scratch with standard libraries is no longer a viable option for most meaningful software projects. Thus, some of the key decisions for a software project are about which technology to turn to, or which APIs or projects to depend on. Choosing the right technology is very important as it can significantly impact a project's quality and velocity. Depending on the particularities of their projects, software developers may have to sift through a wide range of rapidly evolving technologies (be it frameworks or libraries) across various platforms (PC, Mobile, Web). To inform their decision, they try to get guidance from online articles or blogs about which technologies are the best. For example, a developer may be looking for an IDE for his project and

end up on a website or a forum post about the "10 Best IDE Software"[1]. These online resources, though valuable, often provide opinion-driven commentary, sometimes informed by the experience of a single writer or blogger. Moreover, they run the risk of being outdated, given the fast pace of many technologies. For up-to-date, interactive discussions, developers sometimes turn to Stack Overflow (SO), the leading Q&A website for software development. However, their questions about API or technology recommendations are systematically dismissed as seeking opinions[2], which is explicitly banned by Stack Overflow. For example, "What IDE to use for Python?"[3], "What good, C++ programming IDE is available for Linux?"[4], "What is the best IDE for PHP?"[5], and "What programming language to create and format book?"[6]

Community-supported technologies used among software developers are important and help speed up software productivity. For this reason, we have turned to SO since it contains big data from software developers' discussions. SO has more than 20,000,000 questions related to different topics dealing with developers' issues in different domains and platforms. Hence, it become a target to developers since it enables them to find solutions for their problems. SO has also been utilized by researchers to carry out their studies [1], [2], [3], [4], [5]. Software developers and researchers are trying to find a mechanism to organize the data to facilitate and speed up the search processes and find the appropriate answers to the questions raised [6]. Thus, we turned to SO to identify which technologies and software development concepts have community support.

This study aims to provide an approach that help software developers and the software engineering research community to identify the technologies and development concepts that have the most and least community support by leveraging SO and the unsupervised machine learning technique k-means clustering. The study aims to answer the two following questions:

---

[1]https://websitesetup.org/best-ide-software/

[2]There are good reasons to ban opinion and recommendation-seeking questions on a Q&A forum as they may devolve into never-ending discussions or be fodder for bitter arguments about which technologies are the best. Moreover, entities behind those technologies may participate and recommend their own products.

[3]https://stackoverflow.com/questions/81584

[4]https://stackoverflow.com/questions/24109

[5]https://stackoverflow.com/questions/116292

[6]https://stackoverflow.com/questions/68275077

**RQ1:** What are the features that identify clusters of technologies and software development concepts that have community support?

**RQ2:** What is the clusters quality and if the identified clusters consistent to increase the ability to differentiate between community-supported technologies and development concepts?

To gain more insight into the potential application of the approach, it has been applied to all Java-related postings on SO from 2014 to 2021 and studied the distribution of technologies and development concepts among community support levels. We chose to concentrate on Java ecosystem to demonstrate that the technique is applicable. If the approach is effective, it is simpler to generalise it to a wider range of domains and technologies than to determine that a technique designed for multiple domains at once would not work. Java ecosystem was utilized as a case study since Java is one of the programming language that is gaining the most traction among software developers on SO.

To apply the approach and analyze data, we turned to the most useful and popular library for machine learning in Python Scikit-learn [7] and the full-featured AI and ML integrated tool that supports multiple scripting languages and is easy to work with huge datasets Tableau [8]. Scikit-learn ML is a high-level API built on data frames and datasets that allows pipelines and is easier to build. Tableau features an analytics pane with drag-and-drop machine learning that allows us to forecast future outcomes based on historical data, discover future trends for your data using multiple models, or understand the relationships between data points using clustering. Cluster validity technique for the k-means clustering algorithm had already been proposed in the literature, thus, statistical error techniques the sum of squares within each cluster (WSS) and the sum of squares between clusters (BSS) in addition to and silhouette index were used.

The paper's primary contributions can be summarised as follows:

- The novel approach introduced in this paper can be used as a decision support based on K-Mean Clustering, for community-supported techniques and development concepts detection.

- We built a clustering model to identify community-supported software technologies and development concepts level of community support based on new features namely Failure rate (FR) and wait time (WT).

The rest of the paper is organized as follows: Section II introduces the theoretical background. Section III reviews the literature related to the study. Section IV outlines the approach overview and its application on Java ecosystem. Section V evaluates the approach based on clustering evaluation techniques. Section VI provides results and discussion. Section VII provides concluding remarks. Finally, Section VIII provides the future work.

## II. THEORETICAL BACKGROUND

### A. Stack Overflow and its Tagging System

**"Stack Overflow (SO)** is a question and answer website for amateur programmers and professionals programmers"[7]. It is a privately owned website that was established in 2008 by Atwood and Spolsky. Users are encouraged to participate as they can earn points towards their reputation and other privileges (e.g. editing), for being actively involved on the site. Users can vote for questions and answers, both upvotes (positive feedback) and down votes (negative feedback) are allowed. The number of the upvotes minus the number of downvotes represent the score. It is the largest Software development Q&A community, according to the SO Annual developer survey 2019[8] which reported that SO had 80 million visit, of which 25% are developer professionals and university students, and more than 80% rely on SO for educational purposes and also 65% of Stack Overflow's professional developers contribute to open source projects.

***Tagging System:*** According to Stack Overflow's tagging system, a question must have between one and five tags. A tag is a single word or compound words (for example, WebGL, vertex-shader, respectively) that define the technical term at the centre of the question [9] (see Fig. 1 for an example). Tags on Stack Overflow include a broad variety of technical terminology [10], [11], from definitions to programming languages, IDE, frameworks, libraries/tools/, and individual APIs (at class or module level). Researchers frequently use these tags as a starting point for investigating the issues addressed on SO.

### B. Clustering

Clustering is the breaking down of a set of data or objects into a number of clusters. Each cluster consists of a group of similar facts that behave identically. Clustering is equivalent to classification, except that the classes in clusters are not defined and determined in advance, and data grouping is performed with no supervision [12], [13]. Different techniques used for clustering include partitioning based, hierarchical, density and grid [14]. K-means [15], which is the most basic and widely used partitioning procedure among scientific clustering algorithms [16], [17] was utilized.

### C. Classification

Classification is an important aspect of data mining as a technique for forecast modelling. Simply put, classification is the process of breaking down data into dependent or independent categories [18]. Based on previous decisions, classification is utilised to make some future decisions. Different techniques used for classification include Random Forest, support vector machine, decision tree learning, neural networks, nearest neighbour, and Naves Bayes method [19]. In the experiment, the Random Forest classifier was employed.

## III. RELATED WORK

In recent years, Stack Overflow questions and answers have been the topic of extensive research. One of the goals of

---

[7]https://stackoverflow.com
[8]https://insights.stackoverflow.com/survey/2019

Fig. 1. Post Example ob Satck Overflow.

these studies is to track developers' interest in various topics and how it evolves over time, as well as their relationship to current technology trends[10], [20]. The majority of research also emphasizes how challenging it is to maintain the quality of SO Q&A [11].

Stack Overflow has received a lot of attention from the research community in the recent years. The rapid increase in the number of studies are a result of two main reasons: 1) the influx of new technologies that generated discussions on Q&A forums/websites; and 2) the increased use of these technologies by software developers due to their capability of solving problems, knowledge sharing, and learning.

The popularity of SO and its sheer volume of questions and answers have made it a platform of interest for research on specific areas such as mobile development [1], web development [21], [22], [3],web 3d [23], security [24], [4], [25]. In [21], for instance, used data from Stack Overflow to obtain a better understanding of the challenges faced by web developers. Their results show there was an increase in the number of questions related to web-development, concurrently with a downtrend for cross-browser related posts. In particular, [21] used data from SO to get a better understanding of the challenges faced by web developers. It extracted questions tagged with JavaScript, HTML5, CSS and found that cross browser issues were trending down. Another study in [22] investigated web developers' concerns pertaining to Web APIs. It found that "known issue/bug" is a dominant topic of discussion, and observed that discussions are majoritarily (three times out of four) about occasional concerns that disappear quickly, which would suggest that "*Web API providers tend to timely address most problems encountered by client developers*". Finally, [3] focused on popularity and difficulty of issues related to the web frameworks Laravel and Django and found that half the issues are shared by both, with installation being a popular but difficult issue for both. The study by [9] reported that the key technologies that the question is about can typically be deduced from the question tags. These research studies are the basis for the approach, which uses Stack Overflow's crowd sourced expertise to answer information needs in technology community support inquiries.

## IV. The Approach Overview and its Application on Java Ecosystem

The aim of this research consists of two parts, the first part is to what extent we can leverage K-means clustering to distinguish and group the community-supported technologies and development concepts based on the stack overflow platform to identify Which features contribute significantly to the the clusters formation. The second goal is to examine to which extent is the discovered community supported level consistent enough to increase the ability to distinguish between community-supported technologies and development concepts? it can be used as a detection tool based on machine learning classifier model. Fig. 2 introduces the approach that starts from select targeted technologies to identify the community supported technologies and development concepts. Then data from the questions tagged with the targeted technologies was extracted after the topics based on tags co-occurrence with the target technologies were grouped. We then identified the most important features to be used as an input to the model. Later, the K-mean Clustering algorithm was applied and the model was evaluated to check the quality of the resulting clusters based on the classification and evaluation-clustering quality techniques. In the next section, we demonstrated the approach on 1297109 Java questions asked by Java developers as a case study to examine it.

Fig. 2. An Approach to Identify Community Supported Techniques and Development Concepts.

| Data set info | Items | Description |
|---|---|---|
| Java Questions | 1297109 | All questions related to the java ecosystem on SO from 2015 to 2021 |
| All paired tags (Topics) | 980 | All co-occurrence topics with java questions related to software technologies and development concepts |
| paired tags >=30 Questions | 794 | All co-occurrence topics with java questions that have at least 30 questions as threshold related to software technologies and development concepts |

| Features and metrics | Description |
|---|---|
| Questions | The number count of the questions related to tag x. |
| Tag Name | keywords provided for the questions by developers that define the technical term at the center of the question. |
| Views | Number of views for the question, extracted by metadata ViewCount attribute of the post. |
| Score | Number of upvotes minus number of downvotes, extracted by metadata upvotes and downvotes attributes of the post. |
| Favorite | Number of Favorites For the question, extracted by metadata Favorites Count attribute of the post. |
| Comment | Number of comments For the question, extracted by metadata CommentCount attribute of the post. |
| Answers | Number of answers For the question, extracted by metadata AnswerCount attribute of the post. |
| Failure rate (FR) | The percentage of questions that do not have an accepted answer. |
| Wait Time (WT) | The median time for satisfactory answers (in these cases where the question got an answer that its asker accepted). |

stock market, and many more, have made extensive use of cluster analysis.

In this paper k-means clustering was performed. The K-Means algorithm is an unsupervised learning approach for classifying/grouping objects based on their features. The technique splits the data into k clusters for a specified number of clusters k. Each cluster has a centre (centroid), which is defined as the mean value of all its points. K-means locates cluster centres iteratively by minimising the distance between individual cluster points and the cluster centre. K-means requires the specification of cluster centers from the outset. The method begins with a single cluster and selects a variable whose mean is used as a threshold for splitting the data in half. The centroids of these two components are then utilized to initialize k-means in order to optimize the two clusters' membership. Following that, one of the two clusters is chosen for splitting and a variable within it is picked whose mean is utilized as a threshold for splitting the cluster in half. K-means is then used to partition the data into three clusters, each of which is initialized with the centroids of the two split clusters and the remaining cluster's centroid. This procedure is repeated until a predetermined number of clusters has been attained [29], [30].

To compute the k-means clustering for each k. Assume a given a sample dataset $T = \{T_w | w = 1, 2, 3, \ldots, n\}$. Each sample data in T contains f features of continuous data, denoted by $f1, f2, f3 \ldots, fn$. The algorithmic approach used in K-Means is as follows: To begin, k initial clustering centres are chosen at random from $T$, denoted by $Ci(1 < i < k)$. The Euclidean distance between $Ci$ and the sample data is then calculated and divided by $Ci$ in $T$, and find the sample data closest to $Ci$. The sample data is then assigned to the

### A. Data Extraction and Preparation

In this step, data preparation refers to reprocessing the dataset for the modelling phase. We present a dataset obtained by analyzing 1297109 questions from the SO platform. The data set used in this study includes all Java discussions on SO. Over 782 topics of the million questions found, are unique to Java ecosystem. Since we are interested in identifying community-supported technologies and development concepts of the java ecosystem, hence tags with more than 30 questions were included. Table I shows data set information. Table II present the list of features to be used during clustering should be revised.

### B. K-mean Clustering to Identify Supporting Level

Clustering analysis is a well-known concept in the field of data mining [26].Clustering is a popular method for grouping data based on shared patterns or similarities. Numerous applications [27], [28], including science, technology, biology, social science economics, medicine, smart farming, geospatial,

Fig. 3. Covariance Heatmap.

cluster corresponding to $Ci$, and the average of the sample data in each cluster is recalculated as the new clustering centre. Repeat these steps until the Cluster centre no longer changes or the maximum number of iterations is reached. The Euclidean distance computation formula is as follows:

$$d\left(t, C_i\right) = \sqrt{\sum_{i=1}^{n}\left(t_j - C_{ij}\right)^2} \qquad (1)$$

Note: T is the sample data, $Ci$ is the ith cluster center, n is the number of features, $tj$ and $Cji$, are the jth attribute values of $T$ and $Ci$ respectively. The result of clustering can be judged by the sum of square error of the data set. The formula for calculating the sum of squares of errors is as follows:

$$SSE = \sum_{i=1}^{n} \sum_{n \in Ci} |(t, Ci_i)|^2 \qquad (2)$$

Before applying k-means clustering, the scale and variance of the features, as well as the multi-linearity between the features must be examined as significant correlations between features may lead to erroneous conclusions by overemphasizing one or more underlying components.Pearson correlations between features were calculated, and it was determined that the current data set has a multilinearity effect. A 2D correlation matrix was shown in Fig. 3 to show the relationships between the features.

K-means cluster analysis was carried and the number of clusters was chosen as two. the number of software technologies and development concepts are 353 for the most community supported ones (Cluster1) and 441 of software technologies and development concepts. The distance between

the centers of the clusters was determined to FR be 49.45% and 62.79%for of the clusters1 and cluster2, respectively. where the WT the centers are 89.44 minutes and 365.77 minutes for Clusters 1and 2, respectively. After deciding on the number of clusters, some tests must be carried out to check stability, the relative size of the clusters, and external validity.

## V. CLUSTER EVALUATION

A good clustering algorithm should achieve high similarity between the data points within the same cluster. To assess cluster quality: The criteria for determining the appropriate number of clusters were as follows: two strategies were employed to assess the quality of the clustering based on criteria for determining the appropriate number of clusters, including Cohesion and Separation metrics, classification and Silhouette index.

### A. Cluster Cohesion and Separation

Separation and Cohesion are internal metrics. Cluster Separation quantifies how distinct or well-separated one cluster is from others. Whereas Cluster Cohesion measures the degree to which objects inside a cluster are connected. Separation is calculated by the sum of squares between clusters (BSS). Cohesion is measured by the sum of squares within each cluster (WSS). We can therefore take WSS to be the measure of density and BSS to be the measure of separation. For clustering to be effective, a lower WSS and a larger BSS [31] are required.

### B. Silhouette Index

The silhouette index [32] is used to study validity of the separation distance between the generated clusters. It is one of the most well-known techniques for clustering validation [33], [34], [35].It shows the closeness of points in one cluster is to points in nearby clusters and thus provides a visual way to examine factors such as cluster number. The range of this metric is [-1, 1]. Silhouette coefficients of near +1 (as these values are known) suggest that the sample is far distant from the surrounding clusters. A value of 0 denotes that the sample is on or very near the decision boundary between two neighbouring clusters. However, negative values suggest that the samples might be assigned to the incorrect cluster [36], [37]. This is how the silhouette index is computed:

d(i; j) represents the distance between cluster Ci data points and j. We read a(i) as an indication of how well I is allocated to its own cluster (the smaller the value, the better the assignment).

$$a\left(i\right) = \frac{1}{|c_i| - 1} \sum_{j \in C_i i} d_{i \neq i}\left(i, j\right) \qquad (3)$$

Then, we present the mean dissimilarity b(i) of point i to a cluster Ck as the average distance between i and all Ck points (where $Ck \neq Ci$). For each data point, $i \in Ci$.

$$b\left(i\right) = mink \neq i \frac{1}{|c_k|} \sum_{j \in C} d_k\left(i, j\right) \qquad (4)$$

The value of silhouette of one data point i is defined as follows:

$$S(i) = \frac{b(i) - a(i)}{\max\{a(i), b(i)\}}, jf\, |c_i| > 1 \qquad (5)$$

Consequently, the s(i) present in the dataset is a measure of the clustering accuracy of the data.

*1) Evaluation by Classification :* Clustering is performed on unlabeled data to label each cluster. After data has been clustered into groups, a classification technique can be employed. When each cluster's classification model is built separately, there's a good probability of getting better results in terms of accuracy.

Classification based on the clustering process can be indirectly used to evaluate the quality of the clustering process. The evaluation uses the set of Java technologies and development concepts to train model that automates the classification of java technologies and development concepts topics using the supervised machine learning algorithms Random Forest (RF) [38]. RF was chosen since it has been effectively used in many research-related tasks. As a result, the RF approach will be utilised in this study to classify and discriminate between supported and less supported java technologies and development concepts.

## VI. RESULTS AND DISCUSSION

In this section reports results of the clustering formulation based on test analysis of variance (ANOVA) and the quality of clustering using the statistical error and silhouette score techniques. Additionally, the clustering assessed indirectly by a classification technique, namely, RF.

### A. Features to Formulate K-mean Clustering

Fig. 4 shows the result of k-mean clustering. It is important to note that before the application of cluster analysis, the scale and variance of the variables and multilinearity among the variables should be checked. According to the results, the calculated Pearson correlations between the features proved that multilinearity effect exists in the current data set. The correlation matrix is presented in Table III.

The results show that there are features that significantly contribute to the formation of the clusters.The failure rate and Wait time features were found to be the best features that formulate the community support technologies and development concepts clustering. The ANOVA results depicted in Tables X and V and the model Summary diagnostics as shown in Table III and VIII demonstrate the features that significantly contribute to the formation of the clusters. In Table III when clustering model was fed with all features (Views,Score,Favorite,Comment,Answers,FR and WT) there was a high correlation with these features and the clustering model. We further found that Within-group Sum of Squares (WSS) is higher than Between-group Sum of Squares(BSS). As mentioned before that WSS means the sum of distances between the points and the corresponding centroids for each cluster and BSS means the sum of distances between the centroids and the total sample mean multiplied by the number

TABLE III. INPUTS FOR CLUSTERING AND DIAGNOSTICS BASED ON FR AND WT

| Inputs for Clustering | |
|---|---|
| Features | Sum of FR |
| | Sum of WT |
| Summary Diagnostics | |
| Number of Clusters: | 2 |
| Number of Points | 794 |
| Between-group Sum of Squares | 10.039 |
| Within-group Sum of Squares | 9.3994 |
| Total Sum of Squares | 19.438 |

TABLE IV. THE AVERAGE VALUE WITHIN EACH CLUSTER BASE ON FR AND WT

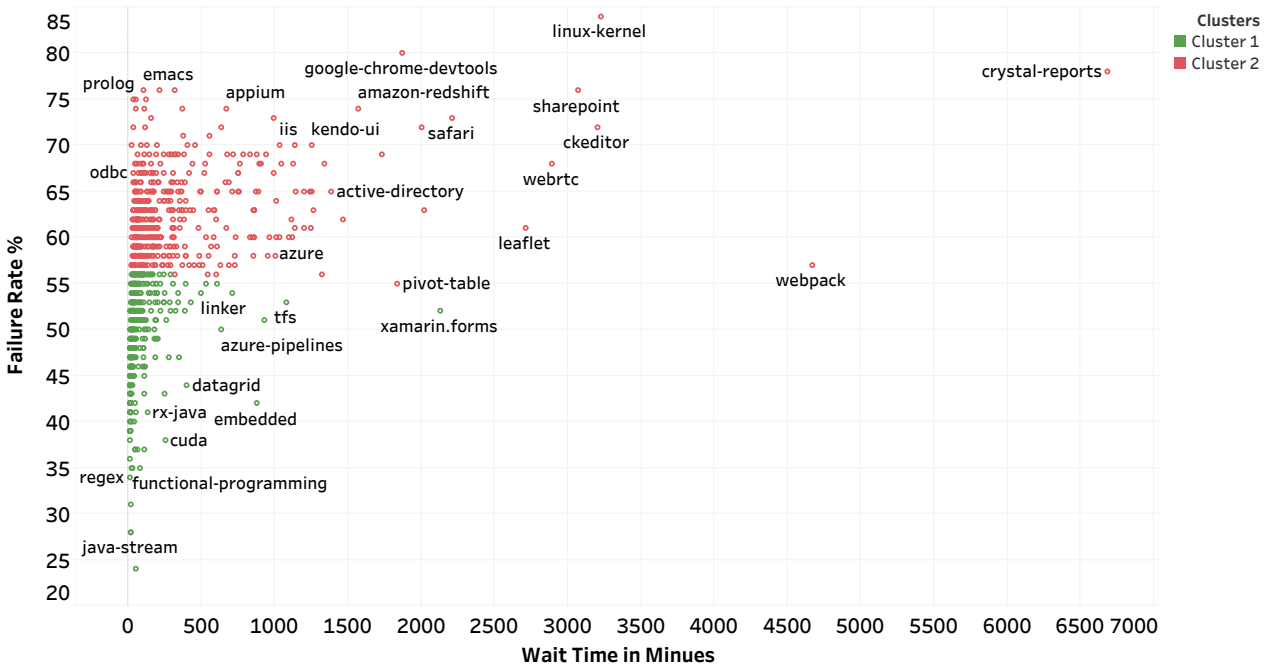
| Centers | Cluster1 | Cluster 2 |
|---|---|---|
| Number of Items | 353 | 441 |
| Sum of FR | 49.45 | 62.798 |
| Sum of WT | 89.446 | 365.77 |

of points within each cluster. After performing the experiments by inserting the features into the model, the best results were obtained only when using the two features FR and WT after achieving a value of WSS lower than BSS as shown in Tables III and VIII. It is also noted that the Table VIII has a value of WSS greater than BSS, and this indicates that the features that achieve the best results for the k-mean clustering formation to determine the levels of community supported technologies and development concepts are FR and WT. Cluster 1 represents the best community supported technologies and development concepts for java developers. Whereas Cluster 2 represents the less community supported technologies and development concepts for java developers. Table IV shows that 44% of the technologies and development concepts in cluster 1 are more supported than the items in cluster 2 that comprises 55.5% of the Java technology and development concepts. The majority of the technologies and development concepts in cluster 2 have less wait time and failure rate. the result help developers gain insights about the community supported technologies and development concepts.

### B. Assets the Quality of K-means Clustering

Extra evaluation technique was used to examine the cohesiveness of the quality matrices that is computed using the findings of the average global silhouette. Fig. 5 illustrates a silhouette curve for estimating the ideal number of clusters, gauging each cluster's quality cohesiveness. Fig. 5 reveals that the average silhouette score is (97%). This is a reasonable value because the clustering is predicated on the silhouette index, which is already high. The result shows that the two group clustering is an optimal number, thus the resulted clustering can be used as a new feature as an input of the classification models.

TABLE V. ANOVA ANALYSIS OF K-MEANS CLUSTER ANALYSIS BASED ON FR AND WT

| Variable | F-statistic | p-value | Model Sum of Squares | Error Sum of Squares |
|---|---|---|---|---|
| FR | 498.6 | 0.0 | 9.703 | 15.41 |
| WT | 66.05 | 1.67E-15 | 0.3357 | 4.026 |


z

## C. Experimental Setup Using the RF classification

The RF model was run based on the most commonly-used method to explore hyper-parameter configuration space called Grid search (GS) [39] to tune the model to fit the best result that is provided by the respective implementation of python. GS operates by calculating the Cartesian product of a finite set of user-specified values.The code developed by [40] was used, which implements hyper-parameter optimization for machine learning algorithms, the values for the parameters of the RF ML algorithm considered in this paper are summarized in Table VI.

TABLE VI. RF CONFIGURATION HYPER-PARAMETER SPACE.

| Hyper-parameter | Type | Search Space | best values |
|---|---|---|---|
| n_estimators | Discrete | [10,100] | 20 |
| max_depth | Discrete | [5,50] | 15 |
| min_samples_leaf | Discrete | [1,11] | 1 |
| criterion | Categorical | gini, entropy | gini |

This study will employ a different metric of evaluation to assess this RF algorithm. These metrics are calculated based on four primary areas. In a supervised classification issue, a true output and a predicted or model-generated output exist. Therefore, each data point's result will be categorised as one of the following:

- True Positive (TP): both the label and the prediction are positive.

- True Negative (TN): both the label and the prediction are negative.

- False Positive (FP): describes a situation in which the label is negative but the prediction is positive.

- False negative (FN): although the label is positive, the prediction is negative.

These four categories are the foundation of the majority of classification evaluation metrics. Performance parameters were used to evaluate the model: Accuracy, precision, recall and F-measure.

- Accuracy: It represents the proportion of correctly classified supported technologies and development concepts. It is technically defined as:

$$Accuracy = \frac{TP + TN}{(TP + FN) + (FN + TN)} \quad (6)$$

- Precision: It is the proportion of correctly identified supported technologies and development concepts relative to the total number of supported technologies and development concepts in a X class. The range of values is from 0 (poor precision) to 1 (high precision). The weighted average precision is determined as the mean of Precision of the true class and false class in relation to the number of tags predicted for each class. It is described as:

$$Precision = \frac{TP}{TP + FP} \quad (7)$$

- Recall: It is the proportion of successfully classified tags relative to the number of observed true instances.

The values vary from 0 (poor recall) and 1 (high recall). The weighted average recall is derived as the mean of recall of the true class and recall of the false class, weighted by the number of tags tagged with each class.

$$Recall = \frac{TP}{TP + FN} \quad (8)$$

- F1-Measure: It denotes a performance indicator that considers both the precision and recall of the classification obtained. The formula is as follows:

$$F - Measure = \frac{2 * recall * precision}{recall + \ precision} \quad (9)$$

- Area under ROC-Curve (AUC): It's a measure of the classifier's predictive strength, essentially telling us how well the model can distinguish between classes. AUC of 1 shows the best performance, while 0.5 indicates that the performance is comparable to that of a random classifier.

The dataset was divided into a training set and a testing set. In the training phase, cross validation is used 80% of the time, and 20% of the time in the testing phase. Cross-validation of 20% is used to test the model. RF algorithm was found to be achieving an average accuracy score of 99.49%. Table VII summarizes the results of the RF classifier based on these results, the configurations are shown in Table VI

TABLE VII. DETAILED ACCURACY BY CLASS

| | Precision | Recall | F-Measure | ROC Area | Class |
|---|---|---|---|---|---|
| | 0,994 | 0,994 | 0,994 | 0,999 | Cluster 1 |
| | 0,995 | 0,995 | 0,995 | 0,999 | Cluster 2 |
| Weighted Avg. | 0,995 | 0,995 | 0,995 | 0,999 | |

## VII. CONCLUSION

In this paper, we introduced an approach based on K-mean clustering techniques to identify the level of community supported software technologies and development concepts leveraging software developer's discussions on SO. The approach is based on tags explicitly assigned to questions. we identified how community supported and development concepts of java technologies based on java developers questions on SO. First, we created data set and used it to automate the clustering of software technologies and development concepts. In the

first approach, we identified which feature can formulate clustering the community supported and development concepts. We implemented correlation analysis, ANOAVA and diagnosis the K-mean model to get the best features to formulate the levels of groups of community supported and development concepts. we found that features that formulate the two clusters to determine the community supported software technologies and development concepts levels are failure rate, that is the percentage of its questions that do not have an accepted answer, and its median wait time, that is the median time to get accepted answers;are the best features. We found that the majority of Java technologies and development concepts are labeled with cluster 1 most community supported technologies and development concepts and cluster 2 less community supported technologies and development concepts.The approach was evaluated in two steps. The quality of clustering shows that the best value is 97%, the higher the silhouette index value, the more effective the construction of clusters. To assess the approach, the identified technologies and development concept groups were added as new features to the dataset and then RF was applied. The evaluation with the java data set showed that the approach outperforms the RF with an average precision and recall of 0.995 and 0.995, respectively.

## VIII. FUTURE WORK

In the future, we are planning to apply and compare the classification of results based on different types of clustering algorithms to choose the right supported technologies. Also building detailed user interface development to maximize the benefits of a decision support system (DSS) in the software development sector.

# On the Role of Text Preprocessing in BERT Embedding-based DNNs for Classifying Informal Texts

Aliyah Kurniasih
Department of Computer Science
University of Nusa Mandiri
Jakarta, Indonesia

Lindung Parningotan Manik
Research Center for Data and Information Sciences
National Research and Innovation Agency
Cibinong, Indonesia

*Abstract*—Due to highly unstructured and noisy data, analyzing society reports in written texts is very challenging. Classifying informal text data is still considered a difficult task in natural language processing since the texts could contain abbreviated words, repeating characters, typos, slang, et cetera. Therefore, text preprocessing is commonly performed to remove the noises and make the texts more structured. However, we argued that most tasks of preprocessing are no longer required if suitable word embeddings approach and deep neural network (DNN) architecture are correctly chosen. This study investigated the effects of text preprocessing in fine-tuning a pre-trained Bidirectional Encoder Representations from Transformers (BERT) model using various DNN architectures such as multilayer perceptron (MLP), long short-term memory (LSTM), bidirectional long-short term memory (Bi-LSTM), convolutional neural network (CNN), and gated recurrent unit (GRU). Various experiments were conducted using numerous learning rates and batch sizes. As a result, text preprocessing had insignificant effects on most models such as LSTM, Bi-LSTM, and CNN. Moreover, the combination of BERT embeddings and CNN produced the best classification performance.

*Keywords*—*Natural language processing; bert embeddings; deep neural network; text preprocessing*

## I. Introduction

Societies often generate informal texts in the form of complaints, aspirations, and ideas. Therefore, it is crucial to follow up on most of the reports received by the various applications to increase service quality. However, the fluid, social, and dynamic written language that continues to develop becomes a challenge in natural language processing (NLP) research field. Furthermore, other challenges in text data such as typos, slang words, and informal vocabularies, followed by various hashtags and emoticons, remain to continue.

In order to overcome these problems, text preprocessing is performed to manage text data before building an NLP model using machine learning. For example, removing hashtags, URLs, stopwords, punctuations, @annotation, ASCII, and duplicate characters in a word is common in text mining [1]. Furthermore, tokenization, case-folding, stemming, and lemmatization were also performed preprocessing texts [2]. These steps are important in conventional machine learning since preprocessing can decrease vocabulary size by removing unhelpful parts of data or noise [3]. Thus, it can reduce the

text data size and enhance the effectiveness and efficiency of the machine learning algorithms.

However, these approaches could be problematic. Some preprocessing steps could make semantic meaning between tokens or words in sentences disappear. For example, removing some stopwords could affect the contexts and generate ambiguous results. Sometimes, emoticons and hashtags could be helpful when analyzing emotions or sentiments within texts. Moreover, mistakes could be made if done manually or even automatically. To the best of our knowledge, no stemmer has 100% accuracy. Thus, in addition to losing the meaning, over stemming and under stemming could occur.

There are several techniques for extracting text features. Within text mining, feature extraction means converting texts to vectors. In conventional machine learning, the Bag-of-Word (BOW) method and Term Frequency-Inverse Document Frequency (TF-IDF) are commonly used [4]. The deficiency of these approaches is that they do not capture the position in the text, co-occurrences in different documents, and the semantics. Some of these problems were solved with word embeddings, which are learned text representations in which words with related meanings are represented similarly. It is considered one of the breakthroughs in deep learning. Studies in [5], [6], [7] suggested the Word2Vec approach to extract text features, while others suggested Glove [8]. Nevertheless, both approaches are context-independent, and they could not catch all semantic information such as Out-Of-Vocabulary (OOV) and some opposite word pairs.

Now-a-days, the NLP model that could perfectly capture almost all semantic contextual meanings is the Bidirectional Encoder from Transformers (BERT) [9]. It takes a sequence (typically a sentence) as input rather than a single word to generate contextual embeddings. Before BERT can build word embeddings, the context provided by surrounding words has to be shown. Word2Vec generates only one vector representation for each word. If there are any different word meanings, they are combined into one single vector. Meanwhile, BERT generates different vectors of a single word in different contexts. It is a leap in text mining techniques where pre-trained models are utilized in transfer learning with Transformers network [10]. Some pre-trained BERT models are already available in some languages other than English, such as AnchiBERT for ancient Chinese language [11], PhoBERT for Vietnamese [12], and

IndoBERT for the Indonesian language [13], [14].

In previous studies, BERT has been applied in text classification and generated passably result [15], [16], [17], [18], [19]. With many noises in the data, such as slang words, non-standard abbreviations, and typos, experiments conducted in [20] to analyze the sentiments of flood disaster-related texts using a pre-trained BERT model showed promising results. The study claimed that the noises had great effects on accuracy. However, the authors did not experiment with text preprocessing to prove that claim. We hypothesized that choosing the suitable word embeddings approach and DNN architecture makes most text preprocessing steps no longer required.

The contribution of this study is twofold. First, we investigated the effect of text preprocessing in the BERT embedding-based deep neural networks (DNNs) when classifying informal texts. While NLP studies suggested that text preprocessing was required most of the time, we argued that these tasks do not affect classification performance nowadays. Second, we also aimed to find and propose DNN architecture with the best classification performance in fine-tuning BERT embeddings. Therefore, we conducted experiments with or without most text preprocessing tasks using five DNN architectures, including long short-term memory (LSTM), bidirectional long short-term memory (Bi-LSTM), convolutional neural network (CNN), multi-layer perceptron (MLP), and gated recurrent unit (GRU). In addition, each model was also tuned with various optimization methods and hyperparameters, such as learning rate and batch size.

The remainder of this paper is organized as follows. First, Section II presents the dataset and research methods. Then, the results and discussions are explained in Section III and Section IV, respectively. Finally, conclusions and future research recommendations are provided in Section V.

## II. Materials and Methods

The research method in this study is shown in Fig. 1. First, we collected a dataset in the Indonesian language from society reports taken from a Citizen Relation Management (CRM) application in the Water Resources Agency of Jakarta, Indonesia. There were 3,217 instances obtained from 1 January to 31 July 2021. Initially, the CRM administration staff performed the manual classifications of the text reports into five handling categories, namely flood mitigation, waterways, drain closure, infiltration well, and others. The distribution of data is displayed in Table I.

TABLE I. Number of Labeled Data

| Category | Amount of Data |
|---|---|
| Flood mitigation | 1360 |
| Waterways | 1071 |
| Others | 423 |
| Drain closure | 343 |
| Infiltration well | 20 |

We performed text preprocessing semi-automatically before conducting one of our sequences of experiments. Correcting abbreviated vocabulary, removing repeated syllable alphabet, repairing typos, and formalizing slang words to standard words based on Indonesian dictionary rules were done manually. Meanwhile, case-folding and removing numbers, mentions, hashtags, as well as emoticons were performed automatically.

The IndoBERT model released by IndoNLU [13] was used to create the BERT embeddings of the dataset. The model was pre-trained using Masked Language Modelling (MLM) and Next Sentence Prediction (NSP), consisting of 124.5M parameters in the base architecture. A text data collection which consists of 4 billion words called Indo4B with a size of 23.43 GB, was used to train the model.

Furthermore, we divided the dataset into 70% training data, 15% validation data, and 15% test data. Training data used to build model, validation data used to test the trained networks to validate model, and testing data used to test model that was built. Validation and test data used were not part of training data to produce an objective evaluation result. Moreover, five DNN architectures were trained. The LSTM, Bi-LSTM, CNN, MLP, and GRU were chosen since they performed well in previous studies [1], [8], [21].

TABLE II. Hyperparameters of DNN Algorithms

| Parameter | Parameter Value |
|---|---|
| IndoBERT | Indobenchmark/indobert-base-p1 |
| Max length | 512 |
| Neuron | 1024, 512, 256 |
| Batch size | 16, 32 |
| Dropout | 0.2 |
| Activation function | ReLu |
| Output function | Softmax |
| Loss function | Categorical_crossentropy |
| Epoch | 20 |
| Number of layer | 1-5 |
| Type of layer | LSTM, BiLSTM, CNN, GRU, MLP |
| Optimization | Adam |
| Learning rate | $5 \times 10^{-5}$, $3 \times 10^{-5}$, $2 \times 10^{-5}$ |

TABLE III. Models' Architecture

| Architecture | Layer |
|---|---|
| MLP | One input layer, three dense layer (neuron 1024, 512, 256), dropout layer (0.2), one output layer |
| LSTM | One input layer, one lstm layer (1024), two dense layer (512, 256), dropout layer (0.2), one output layer |
| BiLSTM | One input layer, one bi-lstm layer (1024), two dense layer (512, 256), dropout layer (0.2), one output layer |
| CNN | One input layer, one convolutional layer (1024), one pooling layer, two dense layer (512, 256), dropout layer (0.2), one output layer |
| GRU | One input layer, one gru layer (1024), two dense layer (512, 256), dropout layer (0.2), one output layer |

Hyperparameter values such as maximum length, the number of neurons, learning rates, batch sizes, and epochs were determined based on previously conducted research related to BERT fine-tuning [15]. Moreover, the ReLu activation function was used on the hidden layer and the Softmax activation function on the output layer. The categorical cross-entropy was used as a loss function since target label classification has more than two classes. The dropout value was set to 0.2 used on the last hidden layer before the output layer to regularize the model to decrease overfitting from happening on the model.

Each model was built and experimented with a variation
Fig. 1. Research Method.

amount of batch size of 16 as well as 32, learning rates of $5 \times 10^{-5}$, $3 \times 10^{-5}$, $2 \times 10^{-5}$, and an epoch of 20. Moreover, Adam is used to optimizing the model since it is the best adaptive optimizer in most cases. The summary of the hyperparameter values is shown in Table II. Meanwhile, all DNN architectures were composed of one input layer, one output layer, and at least one hidden layer. The detail of the five architectures and the used parameters on the layers is represented in Table III.

Standard performance metrics, such as $TP$ (True Positive), $TN$ (True Negative), $FP$ (False Positive), and $FN$ (False Negative), were used as primary building blocks to evaluate classification models. A $TP$ is measured when the model predicts the positive class correctly. A $TN$, on the other hand, is a result in which the model correctly classifies the negative class. Conversely, a $FP$ occurs when the model predicts the positive class inaccurately. Meanwhile, a $FN$ is an outcome in which the model classifies the negative class inaccurately.

Furthermore, other classification metrics, such as accuracy, F1-score, precision, and recall, were used to evaluate the models' performances. The accuracy, calculated using Equation 1, is the ratio of the number of correct predictions divided by the total number of input samples. Meanwhile, recall, calculated using Equation 2, measures the model's ability to detect positive samples. On the other hand, precision, calculated using Equation 3, measures the model's accuracy in classifying a sample as positive. Lastly, F1-score, which summarizes a model's predictive performance by combining two previously opposing variables — precision and recall, is calculated using Equation 4. F1-score could be considered the best metric in this study since the dataset has an uneven class distribution.

Fig. 2. Representation of BERT Embeddings and CNN.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \qquad (1)$$

$$Recall = \frac{TP}{TP + FN} \qquad (2)$$

$$Precision = \frac{TP}{TP + FP} \qquad (3)$$

$$F1 - score = \frac{2 \times precision \times recall}{precision + recall} \qquad (4)$$

Finally, the performance results of DNN models with and without text processing were compared to see if there is a significant difference between both approaches using a statistical t-Test, Paired Two Sample for Means. The test statistic is calculated using Equation 5 where $\bar{d}$ is the sample mean of the differences, $s$ is the sample standard deviation of the differences, $n$ is the sample size, and $t$ is the Student t quantile with n-1 degrees of freedom used to define the p-value. In statistical significance testing, it is the likelihood of receiving a test statistic at least as extreme as the observed one, assuming that the null hypothesis is true. The null hypothesis is rejected when the p-value is smaller than the predetermined significance level, suggesting that the observed result would be highly implausible under the null hypothesis.

$$t = \frac{\bar{d}}{s/\sqrt{n}} \qquad (5)$$

## III. Results

Some of the results of text data after processing with and without text preprocessing used in building models are shown in Table IV. The performance results of various experiments without text preprocessing are shown in Table V, where the highest values are printed bold. The fine-tuned DNN architecture with IndoBERT base model to text data of society reports without text preprocessing produced the best accuracy and precision using the CNN algorithm model architecture with a learning rate of $3\mathrm{x}10^{-5}$ and a batch size of 16. The best accuracy and precision obtained were 83.85% and 88.76%, respectively. However, the best result on F1-score and recall was achieved using a learning rate of $5\mathrm{x}10^{-5}$ and a batch size of 16. The best F1-score and recall yielded 85.44% and 83.95%, respectively.

Meanwhile, the performance results of various experiments with text preprocessing are represented in Table VI, where the best values are boldly printed. The fine-tuned deep learning model with text preprocessing obtained the best accuracy, F1-score, and recall using the CNN algorithm with a learning rate of $5\mathrm{x}10^{-5}$ and batch size of 16. The best accuracy, F1-score, and recall yielded 84.47%, 85.92%, and 85.54%, respectively. However, the best precision of 87.37% was produced using a learning rate of $2\mathrm{x}10^{-5}$ and a batch size of 32.

From the two tables, it can be seen that the CNN algorithm produced the best performances compared to other algorithms. CNN even produced better results using text preprocessing. With a learning rate of $5\mathrm{x}10^{-5}$ and a batch size of 16, the

accuracy, F1-score, precision, and recall were improved by 1.45%, 0.48%, 0.06%, and 1.59%, respectively. However, these values indicated that the text preprocessing made minimal performance improvements.

Moreover, in order to make statistical comparisons of performance results of fine-tuned DNN model between with and without text preprocessing, the t-Test was performed. The statistic test can determine whether the differences between two approaches are significant. If the p-value is less than a significant level, the null hypothesis, which states no significant differences between the models, is rejected. The results are shown in Table VII, where p-values less than a significant level of 0.05, which indicated significant differences, are printed bold. It can be seen that text preprocessing had no significant effect on most architectures, such as in CNN, LSTM, and Bi-LSTM. Meanwhile, the text preprocessing significantly affected the performances of GRU as well as the accuracy and the precision of MLP but not the F1-score.

## IV. Discussion

The result of insignificant performance differences between DNN architectures with and without text preprocessing is in line with the study conducted by [22]. It performed various experiments with three preprocessing tasks: lowercasing, lemmatizing, and multiword grouping. It concluded that simple tokenization was generally adequate in DNN architectures, particularly CNN. Furthermore, the simple preprocessing worked equally or better than more complex techniques in most cases, except for domain-specific texts, such as in the medical field, where apparent differences were needed to classify cardiovascular disease.

We proved that the study conducted by [20] claimed that removing noises in the text data would significantly improve the accuracy of a pre-trained BERT model could be gone wrong. Instead, a BERT model applied to heavily cleaned text data could make things worse because the contextual information would be lost. This finding is supported by a study conducted by [23] when profiling authors from their writings. When no preprocessing method was used, the study found that BERT best predicted an author's gender. In the best scenario, the model was 86.67% accurate in estimating the writers' gender.

One possible reason for the excellent performance of the model without text preprocessing in this study was the suitable choice of the word embeddings approach. The IndoBERT was trained on an extensive Indonesian text dataset that includes formal and slang language, such as tweets. The results could differ if the pre-trained BERT models were trained using Wikipedia corpus only, like the BERT-Base multilingual pre-trained model [16]. A study conducted in [19] showed that preprocessing steps and further preprocessing processes were needed when using BERT multilingual pre-trained model to improve the classification performance of a DNN. The more data BERT pre-train, the less the negative impact of misspellings and slang words would be because the model has more examples of typos, abbreviated vocabularies, orthographic errors, et cetera.

Furthermore, CNN managed to perform best when utilizing the BERT embeddings compared to the other DNN architec-

tures. It could be because the CNN algorithm might extract local and global features very well from the vectors using the convolutional, the pooling, and the fully connected (dense) layers, which can maintain semantic context meaning on text data. This finding supports studies on sentiment analysis of a commodity review and stance detection for credibility analysis of information on social media conducted by [24], [25]. These studies showed that BERT embeddings and CNN obtained better results than single CNN that ignores relation contextual semantics on text.

BERT's input embeddings are composed of three different embeddings: Token Embeddings, Segment Embeddings, and Position Embeddings. Before being passed to the Token Embeddings layer, the input text is tokenized using a method called WordPiece tokenization. It is a data-driven tokenization strategy that balances vocabulary size and OOV words. Extra tokens are also added to the beginning and the end, namely the classification token ([CLS]) and the NSP token ([SEP]). These tokens have two functions: one serves as a representation input for classification tasks, and the other is to split a pair of input texts. Then, the sentence number is converted into a vector in Segment Embeddings. Meanwhile, the Position Embeddings create a vector for the word's position within the sentence. Finally, the three embeddings are summed up to generate a single shape representation passed to BERT's encoder layer [9]. Our proposed architecture is shown in Fig. 2.

## V. CONCLUSION

This study showed that most text preprocessing tasks such as formalizing slang, fixing typos, case-folding, et cetera were not absolute things to do with transfer learning if the word embeddings method and DNN architecture were chosen correctly. There were insignificant differences between models with or without text preprocessing on most DNN architectures such as LSTM, Bi-LSTM, and CNN when utilizing BERT embeddings. Furthermore, combining BERT embeddings and CNN produced the best classification performance. Rather than wasting time preprocessing text data, researchers should focus on finding a suitable word embeddings approach and DNN architecture. Future studies should investigate the significance of each text preprocessing step since there were significant differences in performance results between the model with and without text preprocessing using GRU and MLP.

# VIHS with ROTR Technique for Enhanced Light-Weighted Cryptographic System

Sanjeev Kumar A N, Ramesh Naik B

Dept. of Computer Science and Engineering

GITAM School of Technology

GITAM Deemed to be University

Bengaluru, India

*Abstract*—Developing a bypass parallel processing block is one of the emerging and exciting research areas in the system encrypt/decrypt application areas. A Partial Pseudo-Random-based Hashing VIHS is the most suitable methodology for designing the system to encrypt/solve a block in cryptography. For this purpose, various VIHS and register techniques have been developed to process the storage system data. But, it is limited by the problems of reduced efficiency, increased computational complexity, high area consumption, and cost consumption. Thus, this research intends to develop a novel dynamic system register with hashing with optimal Hash Signature design to process the system's encryption /decrypt data. The main intention of this paper is to analyze the transfer characteristics of the current based on the pseudo-differential pair for a proficient system detection. Then, a system window can be created and adjusted to obtain an optimized power flow with less data loss sensitivity. The major stages involved in the proposed block design are register, partition design, and VIHS design. The dynamic system register is designed at first for getting a fast decision and to enable a low input-referred offset value. Then, the partition is formed concerning the output of the register, and the VIHS is used to produce the high proportional logical work. During performance evaluation, various measures have been utilized to analyze the performance of the proposed dynamic system register-based hashing with optimal Hash Signature design. In addition to that, the estimated results are compared with the proposed technique to prove its efficiency.

*Keywords*—*Cryptography – partial pseudo-random based hashing technique; logical to sequential VIHS; system encrypts/decrypt data; dynamic system register; bypass parallel processing*

## I. INTRODUCTION

Internet of Things (IoT) [1] [2] is one of the most widely used networking paradigms for establishing reliable and secured data transmission, which contains different intelligent devices that help exchange the data across the network in a secure way. Especially in the medical healthcare systems, the patients' information must be protected and secured against unauthenticated access, which guarantees the security and authenticity of the networking system. The Electrocardiogram (ECG) signals [3] [4] are mainly used to monitor the patient's health information, which providing security to this type is also one of the crucial factors. For this purpose, various techniques [5] [6] have been developed to secure the patients' medical healthcare information. Hence, disparate security frameworks and architectures have been deployed in the proposed work. This paper mainly focuses on developing the lightweight data security model for the medical ECG signal transmission system incorporated with the IoT network.

For this purpose, the Viterbi Integrated Hash Signature (VIHS) based architecture of the ECC encryption method is implemented. Here, the random keys have been generated based on the integrated architecture of Hashed signature technique. It is mainly used to reduce the complexity of the model with an enhanced working speed of the algorithm. The reduction of iteration count can reduce the size of architecture, resulting in a lightweight encryption system. Novel lightweight data encryption with an optimal key generation system is proposed for the IoT Network transmission system to overwhelm these problems. This can be achieved by extracting the signal peaks using the Viterbi algorithm to select the best value for random key generation and the fast switching process. This can be processed by referring to the parameters of distance and the phase angle-based reference properties. This will collect information about the pattern of the signature and the size of critical formation in the batch mode of the process to retrieve the topology in parallel [7] [8]. In the encryption process, a light-weighted cryptographic system by using the ROTR Messaging technique. The proposed encryption process reduces the buffer size and reduces the power consumption due to the optimal key size of the cryptographic technique. We developed the VIHS algorithm and integrated it with ROTR in the ECC encryption method. The random critical formation is referred to from the look-up table of the ECC model, and this can generate the public and private keys for the encryption process [9]. The algorithm's implementation is in progress to enhance the performance of the encryption system [10] compared to the other traditional encryption model.

The primary objectives behind this research work are as follows:

1) To develop the lightweight security model for processing the medical ECG signals in the IoT framework.

2) To ensure the system's increased security and reduced complexity, the Viterbi Integrated Hash Signature (VIHS) verification scheme is utilized.

3) The Randomized Off-the Record (ROTR) based messaging technique is employed to reduce thOff-the-Recordand power consumption of signal transmission yet.

4) To validate the proposed security framework's performance, various evaluation indicators such as error rate, throughput, transmission delay, and key selection time have been used.

The rest of the sections present in the paper are struc-

turalized as follows: Section II discusses some of the existing security techniques used for securing the ECG signals with their advantages and disadvantages. Section III presents a detailed description of the proposed methodology with its flow illustration. The performance and comparative results of both existing and proposed techniques are validated using Section IVs performance measures. Finally, the overall paper is concluded with its future work in Section V.

## II. LITERATURE SURVEY

This section presents the literature review of various existing techniques used for ensuring the security of ECG signal processing and transmission systems. Also, it discusses the advantages and disadvantages of each method based on its operating principles.

Wang *et al.* [11] employed a logistic mapping-based encryption model for improving the security of WBAN. The main intention of this paper was to ensure the security and computing ability of biomedical sensors with restricted user access by using the quantized logistic mapping-based encryption technique. Here, the different types of parameters such as Power Spectral Entropy (PSD) and Peak-to-Average Power Ratio (PAPR) have been utilized to evaluate the performance of the suggested mechanism. Moreover, the Lyapunov factor has been considered in this work for analyzing the chaotic characteristics with respect to the random property of the system. In addition to that the normalized spectral entropy was computed based on the parameters of pseudo-random sequence, power spectrum, total power, sequence spectral entropy, and normalization of entropy. At last, binary quantization was also applied for increasing the retention accuracy of the overall security system. The major drawback of this work was, it has an increased complexity in designing algorithms that limits the performance of the entire system. Hameed *et al.* [12] implemented the lossless compression mechanism with Huffman coding scheme for ensuring the security of broadcast transmission in WBAN. It comprises the stages of estimating the buffer blocks, compression, and encryption, which helps to establish the secured transmission in the network. Also, this work intends to obtain the quality control compressed data by employing the cipher block-based chaining encryption algorithm. During the block creation, the QRS complex has been estimated for detecting the peak count of the signal. Consequently, the bandpass filtering technique was applied to eliminate the noisy contents based on the integer coefficients. The advantage of this work was, it efficiently reduced the error rate between the signals by estimating their similarity with high reliability.

Janveja *et al.* [13] designed an efficient AES algorithm for securely transmitting the ECG signals by deploying the modified folded architecture. Here, the key description module has been additionally incorporated with the standard AES technique with reduced functional units. Djelouat *et al.* [14] utilized a lightweight encryption scheme for developing the secured health monitoring architecture. The main considerations of this work were as follows: to obtain the reduced load on data transmission, and to establish the secured data transmission with increased reliability. For this purpose, the Compressing Sensing (CS) platform has been incorporated

with this framework, which helps to perform remote monitoring in a secure way. The benefits of this framework were low transmission power, low coherence, reduced complexity in designing, and simple acquisition. Qiu *et al.* [15] suggested the selective encryption mechanism with the supervised machine learning technique for increasing the security of data privacy and effectiveness in BSNs. Here, the wavelet-based transformation technique has been utilized for compressing the sensor information efficiently. Moreover, the SVM-based machine learning classification technique was employed to classify the disease based on the frequency bands.

Mathivanan *et al.* [16] employed a QR code-based encryption algorithm for processing the ECG signals with increased security. The main factors of this paper were to obtain an increased embedding capacity and ensured security for the complete data retrieval. Moreover, the quick response code has been utilized in this work for storing the hidden information for ensuring data security. The advantages of this paper were better error correction, maximum storage efficiency, and increased data retrieval capacity. Hameed *et al.* [17] recommended an AES-based encryption algorithm for ensuring the properties of authentication, confidentiality, and integrity of the ECG signal transmission system. Here, the encryption and decryption processes were carried out based on the Electronic Code Book (ECB). Yet, the major disadvantages of using AES techniques were increased computational overhead and complexity in handling. Awasarmol *et al.* [18] utilized the DWT technique with the scrambling matrix formation approach for transmitting the ECG signals in a secured way. The main intention of this paper was to extract the secret message with the help of DWT mechanism and to eliminate the noisy contents by using the band pass filtering technique. The stages involved in this work were signal decomposition, de-noising, DWT based feature extraction, scrambling matrix formation, encryption, and decryption. The merits of this work were reduced computational time, complexity and increased accuracy.

Hameed *et al.* [19] utilized a lossless compression mechanism incorporated with the hybrid cryptography technique for securing the ECG signal processing systems. This incorporated the functionalities of Huffman coding scheme with the AES encryption mechanism for enabling a lossless data compression. Also, the Diffie-Hellman based key exchange mechanism was utilized to ensure the increased security of signal transmission. However, it requires more time for signal compression and transmission, which degrades the entire performance of the system. Shaikh *et al.* [20] employed an improved data encryption algorithm for establishing the secured ECG signal transmission. In which, the homomorphic encryption mechanism was utilized to encrypt the ECG signals of patients with ensured reliability and confidentiality. Still, this work limits with the issue of increased information that reduces the performance of this security system. Karthikeyan *et al.* [21] recommended the Secure Force (SF) based cryptographic technique for improving the security of WBANs. Here, the DWT and Daubechies wavelet-based feature extraction techniques have been utilized for signal decomposition and noise removal, because the performance of the signal processing system was highly dependent on the quality of signals. The main factor of this work was to utilize the simple cryptographic technique with reduced complexity, low power consumption, and computational devices.

Premkumar *et al.* [22] recommended an enhanced encryption approach with a scrambling matrix construction technique for hiding the confidential information of patients. Also, the deterministic algorithm named, Pseudo-random binary sequence generation algorithm was employed in this work for ensuring the security of the private healthcare information system. Then, the Elliptic Curve Cryptography (ECC) technique was applied for encrypting and decrypting the user data with ensured confidentiality and reliability. L.Zheng *et al.* [23], a detailed study has been conducted on various data encryption mechanisms used for securing the internet of medical things application system. Here, the performance of standard DES and ECC techniques has been validated based on the terms of accuracy, time consumption, and stability. From this paper, it is studied that the desired properties of security and efficiency could be addressed by the cryptographic techniques for guaranteeing the secured communication of the signal processing system.

Sivasangari *et al.* [24] suggested the lightweight selective encryption mechanism for guaranteeing the confidentiality and authenticity of the users' data. The main consideration of this paper was to minimize the computational overhead of the WBSN by optimizing the energy level of nodes. Also, it aims to improve the security of the system by establishing the three-layered communication in the network. Yet, it has the limitations of requiring more time consumption, and reduced performance outcomes.

From this review, it is observed that the existing security approaches are mainly focusing on establishing reliable signal transmission by incorporating the functions of standard cryptographic mechanisms. However, it faces the major challenges of increased complexity in designing the algorithms, requires more time consumption for transmission, increased loss of information, and reduced accuracy. In order to solve these problems, this research work intends to develop a novel algorithm for securing the ECG signal processing system. The major key points that are observed from these existing methods are to provide a secure data transmission system for the medical ECG signal and its data. For that, these algorithms are consumed more bit size to generate the key-value due to the precision of signal amplitude and its parameters. This leads to an increase in the energy consumption of the overall system and reduces the transmission rate. Further to improve the security service, the key size is increased to the corresponding size of data and its length. This becomes the motivation of the proposed work to implement the lightweight cryptographic system for ECG signals. According to this, the key pattern generation and the encryption model are enhanced for the high precision of amplitude and improve the Quality of Service (QoS).

Security is a core quality of an IoMT system and is linked to certain security aspects frequently required for allowing Trust and Privacy qualities in a system. IoMT Security focuses on securing connected devices and protecting data and networks on the Internet of Medical Things. Further IoMT devices are more prone to attack from the attackers. We proposed a new method of mechanism to protect the data from the IoMT devices.

## III. PROPOSED METHOD

This section presents the overall description of the proposed bypass parallel processing optimal Hash Signature-partition design with its clear illustration. The main aim of this work is to develop an optimal Hash Signature VIHS with a new register design for storing data in the system and validate the data with a reduced error rate compared to another application process. In this, the peak value of ECG signal was extracted for the reference to generate the random key value. Here, this implementation reduces the amount of data required to be stored in various stages, and the amount of time essential for processing. According to that, an appropriate low-power hardware architecture has been designed to implement a real-time high performance and low-cost optimal Hash Signature block with the proposed decoder algorithm. This block design is highly more suitable for mobile applications. In which, the distinct data can be simulated based on the random data generation, where the sampling rate of 360Hz is relevant to clock frequency. The overall block representation of the proposed architectural design of VIHS hashing in the cryptography is represented in Fig. 1.

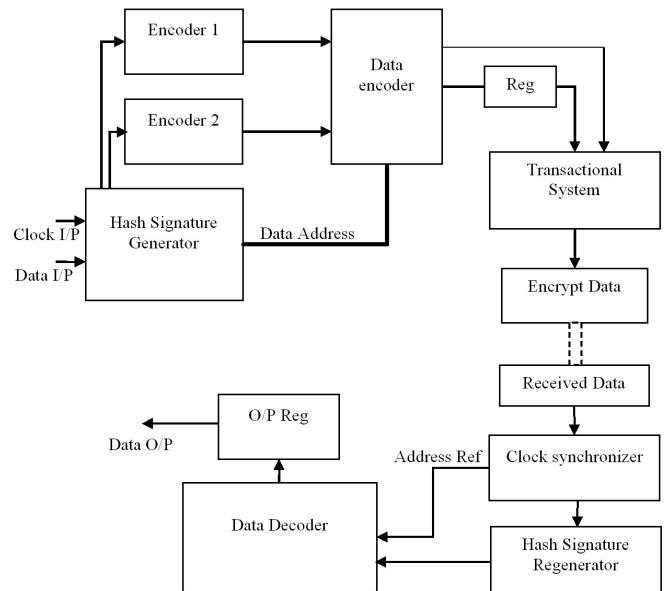

Fig. 1. Block Diagram of Proposed Hashing Technique of ECG Cryptography.

In this figure, the architecture represents the flow architecture of input ECG data and the block design of the encryption and decryption flow line. The block architecture represents the binary transmission of data to the encryption module to retrieve the hash signature and to form the encoded data. Initially, the input data are passed in bit sequence in accordance with the clock pulse that are synchronized with the encoders. Here, the Hash signature generator is to generate the random address and the key patterns based on the VIHS model. This transmit to the encoder block to encode the block that are indexed with the address of data. From that, the data got encoded and passed to the transactional system to transmit data through transmission channel. In the decryption process, the clock synchronizer predicts the data sequence and the

address of it. This provide the reference to Hash Signature Regenerator. The main parameters that are considered for the lightweight architecture of ECG signal secure transmission were the number of bit size, key initialization and the random integer number generation, energy parameter of the overall system, and the Quality of Service (QoS). From this, the data was decoded and reconstructed to the actual ECG signal pattern. The major stages comprise of the proposed register design are as follows:

1)  VIHS design
2)  Hashing Model.
3)  Data Transfer Architecture

### A. VIHS Design

The register used in this block design is one of the essential component in electronic block after each Hash Signature connected with the latches. Typically, it is a major building block for most of the applications, in which the logical information has to be recovered from the sequential data specifically in optimal XORs. Moreover, this register is more suitable for the logic blocks, where the latch provides the large and fast output data. Then, its waveform and amplitude are independent of input data. Generally, two types of registers have been used named as static and dynamic, in which each gate output is connected with flags through a decrypt line path by the static registers. Similar to that, the dynamic registers could rely on the temporary storage of data values on the binaries of high sensitive block nodes. Moreover, the static registers are more suitable medium speed applications, and the dynamic registers are more suitable for high sensitive block nodes. But, it is highly sensitive to noise, in which varying sampling rates can be used for different applications. When compared to the static registers, the dynamic registers gained a significant attraction in medium to high-speed applications. Furthermore, it is energy efficient owing to the non-consumption of static current contrast. Fig.2. shows the schematic representation of the Hash Signature and register allocation flow with corresponding output units. In this, the arrangement of XOR and the Registers was formed to extract the Hash Key pattern. The dotted block indicates the Optimal placement using VIHS for the single-bit pattern. This it will be arranged as the sequential order to construct the 'N' number of bit size for the input signal amplitude. The final output data was arranged in the output register to get the 'OUTr'. It comprises the following stages: pre-amplifier, track and latch, where the pre-amplifier is larger than the input data and is not large sufficient to drive the logical block. Then, a track and latch stages are used to amplify the data to logic with the use of positive feedback loop. The major benefits behind this register design are high input sensitive, no static power consumption, full swing outcome, and fast decision rate.

### B. Hashing Model

The proposed hashing with optimal Hash Signature design is fully based on the binary search algorithm, where the partition is a kind of logical controller block that has responsibility to run the binary search procedure. Also, the output of hashing with optimal Hash Signature can be determined with the respect to the register output. So, it has the momentous effect on improving the overall performance of

optimal Hash Signature design. This register contains N bit optimal Hash Signature, which contains three possibilities for each bit that is either 0 or 1. At first, the MSB can be set as 1 and other bits can be reset by 0, and the logical word is converted with respect to the sequential value via the VIHS unit. Then, the output of sequential data can be inserted to the input of register, and is compared with the sampled input. Based on this outcome, the partition controller can estimate the value of MSB, where if the input is higher than the VIHS output the value of MSB can be set as 1; else, set as 0. During the last cycle, the converted logical word is stored, and N+1 clock cycles could be performed for conversion. Moreover, the partition can be designed with the use of register and the controlling block for encoding the Key to cryptography, and the conversion process can be continued only when the Hash Signature input is low. Fig. 3 shows the schematic representation of the hashing with optimal Hash Signature logic. In that, the (a) shows the block architecture for encryption process and the (b) represents for the decryption flow. The registers and the indexing block are used to find the encoded data samples that are passed through shift registers and count the repeated pattern of data samples. While at the decryption stage, the synchronizer detect the data samples with the clock pulses to reconstruct the data from the decryption block. The major building blocks of this block are dynamic latched register and inverters. The Algorithm I represents the steps for proposed hashing model for random Key generation.

---

Let the input binary bits for the system stream can be represent as $I_n$. For the random Key generation, the Key should be regenerative based on the input matrix. Select a random number between 0 to 'p' as 'A' from sender and 'B' from receiver.

This cross computing generates the random Key for the system storage which can be represent as $R_V$. The reverse process can regenerate the random Key to encrypt the data from Key location in cryptography.

## C. Data Transfer Architecture

Typically, the VIHS is a kind of device that is mainly used to convert the logical input data into an sequential output data. Then, its result is highly proportional to the logical value, in which the conversion tool can be acts as an interface between the logical and sequential blocks. Moreover, it serves a feedback data to correct the errors and estimates the reference data sequence during the process of conversion. During the design of VIHS, the values of supporting blocks should be determined based on the manual estimation process. Then, it can be adjusted further during the time of simulation, where some of the parameters can be considered with respect to the AMS technology. The architecture process can be defined according to the AMS technology as follows:

1. Arrangement of Hash Signature blocks.

2. Combination of Registers and Hash Signature.

Fig. 4. State Flow for VIHS Generator.

The schematic illustration of VIHS design is depicted in Fig. 4. which comprises three stages. These are all combined with the architecture of XOR and the Register block arrangement. The state flow starts from the idle state of overall design. In this, the CNOI represents the count of number of Instant from the input ECG data samples. This was passed to the XOR combination flow and the flag CNOI are updated each time with respect to the data flow line. The decision was taken that according to the satisfactory level of encryption model and it flow in loop of updating CNOI to make the data pattern in random manner. This was also updated as the edge count that indicates the amount of loop that is running for the data

encryption. Then this was encoded by the indexing method and get the encrypted and encoded data samples.

## IV. RESULTS AND DISCUSSION

Since findings suggest that IoT security requires substantial improvement before it is suitable for wide consumer acceptance. There are still many security issues. The most prominent were computation capability, memory, and time issues, and a lack of management mechanisms. Computation capability is critical within the Internet of Medical Things since the devices utilized frequently capture private, sensitive data, such as health information.

The simulation and Key implementation results have been validated for the proposed bypass parallel processing hashing with an optimal Hash Signature model with the output waveforms in the MATLAB 2011b platform. The data samples that are used for the testing of the proposed model was Physionet MITDB database. In that, the ECG signals are pre-processed and saved it in the '.mat' file format. In that file, ECG Data is a structure array with two fields: Data and Labels. Data is a 162x65536 matrix. This indicates there are 162 number of data samples present in the matrix. This time length are represented in terms of time samples with the size of 65536 measured for the length of 1 hour. Moreover, the results are compared with the state-of-the-art models by using the measures of frequency, Gates utilization count, power, area, sampling rate and propagation delay.

TABLE I. BIT SIZE COMPARISON FOR VIHS MODEL

| Methods | Message count | Bit size |
|---|---|---|
| Mutual authentication | 2 | 1184 bits |
| Efficient authenticated key for TMIS | 2 | 1184 bits |
| Enhanced TMIS | 2 | 1344 bits |
| Burrows–Abadi–Needham logic | 3 | 1600 bits |
| TMISs | 3 | 1280 bits |
| MQTT protocol | 2 | 800 bits |
| Proposed | 2 | 763 bits |

Table I evaluates the comparison of the existing random number generation block in the hashing Memory design and proposed technique of VIHS in Cryptography with respect to the measures of components size based on the number of 2-input Hash Signature's, 3-Input Hash Signature's and the number of Flip-Flops that are referred from the paper [25]. For this analysis, some of the existing hashing with optimal Hash Signature designs have been considered. These results stated that the proposed dynamic system register-based hashing with optimal Hash Signature provides the better size in components, when compared to the existing model of VIHS.

TABLE II. COMPARISON OF TIME TAKEN FOR ENCRYPTION AND DECRYPTION (MS)

| Methods | Time taken (ms) |
|---|---|
| Mutual authentication | 13.38 ms |
| Efficient authenticated key for TMIS | 13.4 ms |
| Enhanced TMIS | 15.6 ms |
| Burrows–Abadi–Needham logic | 11.17 ms |
| TMISs | 8.9 ms |
| MQTT protocol | 8.9 ms |
| Proposed | 7.4 ms |

Fig. 6. Throughput (Gbps).

Table II compares the values of area consumption in the unit of (µm2) in the existing [25] and proposed hashing with optimal Hash Signature methodologies. For the proposed work, the power consumption is reduced to the range of 25%. From the evaluation, it is evident that the proposed hashing with optimal Hash Signature could efficiently reduce the power and area consumption when compared to the existing technique of the VIHS model. Then, its corresponding graphical illustration of the area consumption is shown in Fig. 6 and Fig. 7 shows the comparison chart of FFs, LUT, and Slices utilization count for the existing [26] and proposed design of the VIHS generator.

Table III illustrates the utilization count of throughput and delay rate of the existing and proposed VIHS technique. The corresponding graphical illustrations of these measures are represented in Fig. 5 and Fig. 6. From the analysis, it is proved that the proposed hashing with optimal Hash Signature provides better results, when compared to the other register techniques.

TABLE IV. DELAY RATE (NS) AND THROUGHPUT (GBPS) COMPARISON TABLE

| Methods | Delay (ns) | Frequency (MHz) | Throughput (Gbps) |
|---|---|---|---|
| Behavioral CAG | 3.503 | 285.47 | 9.135 |
| Primitive Instantiation | 2.67 | 374.53 | 11.99 |
| Proposed | 2.31 | 432.9004 | 12.34 |

TABLE III. COMPARISON TABLE OF MESSAGE COUNT AND BIT SIZE FOR THE VIHS KEY GENERATOR

| Methods | Message count | Bit size |
|---|---|---|
| Dey and Hossain scheme | 5 | 1312 bits |
| ECC-CoAP | 4 | 1024 bits |
| Proposed | 4 | 926 bits |

Fig. 7. Frequency (MHz).

Table IV and Fig. 7 shows the delay (ns) along with the frequency (MHz) and the throughput (Gbps) of various existing referred from [26] and the proposed technique of VIHS. In that comparison, the propagation delay is reduced to 2.31 ns by the proposed hashing with optimal Hash Signature design. These results stated that the proposed register could efficiently reduce the delay, when compared to the other techniques. Based on the overall analysis, it is evident that the proposed dynamic system register based hashing with optimal Hash Signature is more suitable and efficient for processing the system encrypt/decrypt applications.

Fig. 5. Delay (ns).

## V. Conclusion

In this paper, we presented a new register design with hashing with optimal Hash Signature for processing the system encrypt/decrypt data. The main aim behind this work is to encrypt/decrypt data in the system with a reduced amount of error rate. This designing methodology will reduce the amount of data required to be stored in various stages, and the time required for processing the data. Moreover, the proposed dynamic system register adopts the current controller, which generates both the polarity outputs and bypass trigger data during the same conversion. Here, a pseudo-differential pair is constructed to simulate the transfer characteristics. In this design, the charging speed can be adjusted with the process variation, component mismatch, and parasitics along the paths. After that the reference data sequence and binaries data sequences can be modified with respect to the bypass window size. In addition to that the bypass window size and speed of the register have been analyzed for architecture power-saving application area. The hashing with optimal Hash Signature provides low data sequence sensitivity, increased efficiency, and low power consumption. The VIHS could provide a residual data sequence with respect to the linear feedback of the conversion data. During the experimental evaluation, there are metrics have been validated to analyze the performance of the proposed register design. From the results, it is proved that the proposed technique provides better results when compared to the traditional techniques.

Future enhancement, this type of security system for medical applications is integrated with a new register design structure for the logical functionalities to generate the random number formation for a real-time application. This will improve the time complexity and the space complexities of the overall system.

*Abstract*—The palm tree is considered one of the most durable trees , and it occupies an advanced position as one of the most famous and most important trees that are planted in different regions around the world, which enter into many uses and have a number of benefits. In the recent years , date palms have been exposed to a large number of diseases. These diseases differ in their symptoms and causes, and sometimes overlap, making the diagnosing process with the naked eye difficult, even by an expert in this field. This paper proposes a CNN-model to detect and classify four common diseases threatening palms today, Bacterial leaf blight, Brown spots, Leaf smut, white scale in addition to healthy leaves. The proposed CNN structure includes four convolutional layers for feature extraction followed by a fully connected layer for classification. For performance evaluation, we investigate the performance of the proposed model and compare to other CNN- structures, VGG-16 and MobileNet, using four evaluation metrics: Accuracy, Precision, Recall and F1 Score. Our proposed model achieves 99.10% accuracy rate while VGG-16 and MobileNet achieve 99.35% and 99.56% accuracy rates, respectively. In general, the performance of our model and other models are very close with a minor advantage to MobileNet over others. In contrast, our model characterized by simplicity and shows low computational training time comparing to others.

*Keywords—Palm trees diseases; convolutional neural networks; mobileNet; VGG-16*

## I. Introduction

The date palm is considered one of the most important fruit trees in the Arab and Islamic world, as Arab countries account for 71% of its trees in the world, and 81% of the total global production, while this percentage rises to 99% (103.95 million trees) of the number of trees. The world's date palm, amounting to 105 million, when combining the Arab and Islamic worlds, according to the Food and Agriculture Organization of the United Nations. According to the latest statistics adopted in the world, including the statistic conducted by the Egyptian Embassy in Brazil in 1990 as shown in table I, it was found that the palm tree is one of the main agricultural products produced by the Arab countries and is considered a major element in supporting the macro economy in these countries, so it is very important to pay attention to the quality and quantity of production Palm trees, but

unfortunately, the quality, quality and quantity of palm trees are greatly threatened with confinement due to the common palm diseases these days, where in general palm trees are threatened by 4 main types of diseases, which are, Bacterial leaf blight, Brown spots, Leaf smut, white scale, the nature and symptoms of these diseases are different in their form, in the area of their appearance and distribution on palm trees, so it is very important to reveal modern techniques that contribute greatly to discovering them before they cause tremendous pressure on the quality and quantity of palm trees produced.

Symptoms of leaf smut Small irregular brown to black spots occurred on the upper and bottom surfaces of rachis and fronds, ranging in size from 3 to 7 mm [1]. Bacterial Leaf blight symptoms were elongated brown to black patches that grew in size and spread across a considerable region, creating cankers on the midrib [1].

Brown spot disease is characterized by the appearance of non-specific dark spots, and as the infection progresses, the center of the spot turns to a pale color, but the edges remain brown to gray. The spots appear on the leaves, thorns, and the middle vein (the leaves). The size of the spots ranges from one to several centimeters, but their size and color may vary according to the fungus that causes them..Another serious risk is a lethal pest called white scale .White palm Scale is a species of armoured scale insect. This means that they produce a hard outer coating that covers the body, which protects them from pathogens. They're also well protected from topical pesticides. White Scale insects attack palm by sucking the sap through a fine, thin feeding-tubes. Infestations rarely kill plants but can impact vigour [2]. The methods usually used by farmers depend mainly on observing the affected foliage with the naked eye by experts. Unfortunately, this method is not effective because of the distance of the palm tree from the ground and at the same time due to the somewhat similarity between the symptoms of the four palm diseases mentioned previously. In addition to that, the manual examination of palm leaves is time-consuming, especially in the case of large farms. In this paper, a CNN-based model is proposed to detect four of the most frequent palm illnesses is suggested. These illnesses are, Bacterial leaf blight, brown spots, Leaf smut, white scale. The proposed model model characterized by simplicity( easy

to train) and the efficiency comparing to the sate of the art techniques. Our model achieves 99.10% average accuracy rate to detect Bacterial leaf blight, brown spots, Leaf smut, white scale diseases and healthy leaves. 56

The remainder of this paper is organized as follows: Section II presents a summary of related work. Section III illustrates System architectures including our proposed model in details. The next section presents the experimental results of our model and compare it with other models. Finally, the conclusion in addition to the feature work are given in Section V.

## II. RELATED WORK

This section shows the previous studies that dealt with the problem of palm tree diseases. In [1], The researchers used various classifiers to detect the three most frequent palm illnesses today: leaf spot, blight, and red palm weevil. CNN was used to distinguish between Leaf Spots and Blight Spots illnesses, and SVM was used to distinguish between the Red Palm Weevil pest and the Leaf Spots sickness. The Kaggle dataset (about 90k photos) was utilized as-is, resulting in a 65 percent accuracy for the first CNN model. The data set was split into two parts: 70% for training and 30% for testing. The accuracy ratio success rates for the CNN and SVM algorithms were 97.9% and 92.8%, respectively.

In [3], the illnesses in tomato fruit were detected using multiple classifiers, the first of which was CNN and LVQ. Leaf blight, bacterial spot, late blight, sitoria leaf spot, and yellow curved leaf disease are among the illnesses he classified. The dataset utilized in this experiment was divided into 400 photos to train the model and 100 images to assess the quality and efficiency of the model, which had a size of 512 x 512 and an accuracy of 86%. The only difficulty this study faces is the degree of symptom similarity among the illnesses that affect tomato fruit.

Jiang et al. [4] proposed a system to identify apple leaf illnesses using deep learning algorithms. To identify and categorize alternate leaf spot, brown spot, mosaic, spot Gray, rust, and eventually brown apple leaf disease, the proposed system employed a new CNN based technique called INAR-SSD based on a framework called Caffe on the GPU platform. Set of data The data utilized is made up of 26377 photos that were separated into two groups: one for training the model and the other for verifying the model. The model speed was 23.13 frames per second, and the accuracy of the findings was 78.80 percent mAP.

The proposed work by [5] investigated the ability to identify chimera and anthracnose infections in palm trees. The detection procedure began with the use of a digital camera to capture photographs of the damaged palm trees, which were then subjected to a series of image processing processes following segmentation using the k-mean method. The Gray Correlation Matrix was created by applying the characteristics extraction phase on the segmented pictures using gyro compatibles (GLCM). The accuracy of the findings proved the effectiveness of the support vector machine (SVM) in such circumstances, with Chimera having a 97 percent accuracy and anthracnose having a 95 percent accuracy.

In [6], The authors used a program called Therma CAM Researcher to analyze pictures collected with an uncooled infrared thermal camera linked to a microbolometer sensor in this work. To obtain credible maps of leaf temperature, this software was enhanced with local climatic variables and leaf emission. Each experiment had 4-5 duplicates of control trees and 8-10 replicates of infected trees in each group. The Crop Water Stress Index (CWSI) was produced, and the damaged trees were identified with up to 75% accuracy using this value. In[7], The authors of this article wanted to see if they could tell the difference between healthy palm trees and palm trees afflicted with the red palm weevil by using water stress and temperature rates. Aerial photos were taken using an uncooled infrared thermal camera and a microbolometer connected to begin the procedure. The palm canopy was separated from the soil using a set of image processing techniques, and the watershed method was used to build the palm canopy diagram using the photos. This study yielded no numerical data, however it did show that various palm plants had variable water stress levels.

## III. SYSTEM ARCHITECTURE

### A. Data Preprocessing

Since the resolution and size of acquired 2D images are usually inconsistent, using them directly as training data is not applicable. In addition, using very high resolution images is time-consuming and may lead to high computational cost. Therefor, all images are resized to 60 x 60 resolution. Furthermore, The correlation between data within the image can slow down the learning process. To address this, we apply image whitening [8] based on Zero Component Analysis (ZCA) to reduce the correlation between data and make key features such as edges and curvatures more prominent, and thus easy to detect by CNN. To achieve that the pixel values in each image is normalized to be between 0 and 1 as the following:

$$\hat{X} = X/255 \tag{1}$$

, where $X$ and $\hat{X}$ are the image before and after normalization, receptively. After that the image is mean normalized by defining the mean value along each feature dimension (pixel position) of training images and then subtracted from the image as the following:

$$\bar{X} = \hat{X} - \mu \tag{2}$$

, where $\mu$ represents the mean vector across all the features of $\hat{X}$ while $\bar{X}$ represents the mean normalized image. Finally, the whitened image $X_{ZCA}$ is defined based on Singular Value
Fig. 1. An Overview of a Convolutional Neural Network (CNN) Architecture [21].

Fig. 2. The Architecture of Proposed CNN.

Decomposition (SVD) of the covariance matrix of $\bar{X}$ as the following

$$X_{ZCA} = U.diag(1/\sqrt{diag(S) + \varepsilon}\,).U^T.\bar{X} \qquad (3)$$

The function $diag(.)$ returns the diagonal matrix of the input matrix. The variable $U$ and $S$ represent the Eigen vector and Eigen value of the SVD of covariance matrix while the hyper-parameter $\varepsilon$ represents whitening coefficient.

*B. Convolutional Neural Networks*

The Convolutional Neural Network CNN [9], [10] is a deep learning model capable to achieve both feature coding (feature extraction) and classification in a single coherent architecture. In contrast, traditional neural networks are limited for classification task and require well-defined feature (engineered features) to achieve high performance [11], [12]. In general, CNNs are widely applied in many computer vision applications such as face recognition [13], object detection [14], Natural language processing [15], medical image analysis and others [16]. Fig. 1. shows the basic architecture of the CNN which involves three different set of layers, namely, 'Input Layer', 'Feature Learning Layers' and 'Classification Layers'. The first set is a single layer, includes the input image (usually colored image). The second set is a sequence of successive Convolution and Pooling layers which resulting in extracted features. The last set usually involves fully connected layers to achieve classification tasks. The main advantage of CNN is the ability to define local features such as horizontal edges through convolution layers by maintaining the same structure of the input image whilst using a small number of parameters. For example, regardless of the size of the input image, the number of parameters depends on the size and the number of filters (e.g., 10 filters of [3 x 3] size).

In the resents years, numerous attempts have been made to enhance CNN's initial design (by Lecun et al. [9]) in order to achieve better performance. A popular examples of CNN architecture are AlexNet [17], VGG-16 [18], ResNet [19] and MobileNet [20]. In this work, a simple CNN architecture is firstly proposed for the problem of Palm Trees Diseases classification and then the performance of our CNN is compared to two well-known CNN structures: "VGG-16" and "MobileNet".

*1) Proposed CNN:* In this section, we introduce a simple CNN architecture for efficient learning especially with limited training data size. The proposed architecture includes four convolutional layers followed by fully connected layer and softmax as output layer as shown in Fig. 2.

The input layer includes the input image with dimensions [60, 60,3] where the first two represent the width and the height of the image while the last value represents the number of channels (three channels for red, green and blue). The first convolutional layer includes 32 filters of each [3 x 3] size, followed by a maxpool of 3x3. In the next three convolutional layers, 64 filters [3 x 3] are used for the second layer, while 28 and 256 filters are used for the third and forth layers, respectively. Each of these convolutional layers is followed by a maxpool of 2x2. Finally, a flatten process is applied, resulting in a layer with 25600 features, fully connected to a dense layer with activation function "softmax".

*2) VGG-16:* VGG-16 was originally proposed by Simonyan and Zisserman [18] in 2014. The basic idea behind VGG-16 is to increase the depth of the network by adding more convolutional layers while using very small [3 x 3] convolution filters in all layers. Fig. 3 shows the The architecture of VGG-16.

Fig. 3. The Architecture of VGG-16.

During the training phase, the only preprocessing step is to subtract the mean RGB value (calculated over the training set) from each pixel. After that, the image is passed through a set of convolutional layers with small filters ([3 x 3] size). To preserve the spatial resolution the same after the convolution, the stride and the spatial padding are both set to one pixel. Some of the convolutional layers are followed by a max-pooling layer, so a total of five max-pooling layers are applied in the whole network.

*3) MobileNets:* MobileNet is deep learning model, proposed by Howard et al. [20] of Google Research team. This
Fig. 4. (a): Standard Convolution Filters. (b): Depthwise Convolutional Filters. (c): Pointwise Convolutional Filters [20].

model was presented to effectively maximize the performance of CNN under limited resources which is ideal for mobile and embedded vision applications. MobileNets is characterized by light weight and hyper-parameters (small number of required wights comparing to other CNN models), which allows to trade-off between latency and accuracy. To achieve that, the standard convolution filters [Fig. 4(a)] replaced by two layers: depthwise convolution [Fig. 4(b)] and and pointwise convolution [Fig. 4(a)].

The computational cost $C$ of the standard convolutional layer can be represented as:

$$C = F \cdot F \cdot M \cdot N \cdot H \cdot W \tag{4}$$

In contrast, MobileNets is capable to reduce the computational cost as:

$$C = F \cdot F \cdot M \cdot H \cdot W + M \cdot N \cdot H \cdot W \tag{5}$$

which includes the cost of the depthwise convolution plus the cost of the pointwise convolution. By comparing the ratio between Eq. 4 and 5 based on [3 x 3] depthwise separable convolutions, MobileNets can achieve 8 to 9 times less computational cost than standard convolutions [20].

## IV. EXPERIMENTAL RESULTS

In this section, the performance of the proposed CNN model, in addition to VGG 16 and MobileNet, are evaluated by combining two datasets, 'Date Palm' [22] and 'Leaf_Disease_3' [23].

### A. Dataset

Table II gives a summary of each dataset. In our experiments, Date Palm [22] and Leaf_disease_3 [23] datasets are combined to build a new dataset (DP-disease dataset). In more details, Date Palm dataset includes two types of diseases: Brown Spots with 470 samples and White Scale with 958 samples. In addition to that, the dataset also includes 1013 samples of Healthy leaves. In contrast, Leaf_disease_3 dataset

TABLE II. THE CHARACTERISTIC OF APPLIED DATASETS

| Dataset type | Total images | Training images | Testing images |
|---|---|---|---|
| Date Palm | 2631 | Not partitioned | Not partitioned |
| Leaf_disease_3 | 102360 | 82200 | 20160 |
| Combined dataset (DP-disease dataset) | 4471 | 4023 | 448 |

Fig. 5. Samples from: (a) Leaf Smut Disease and (b) Bacterial Leaf Blight Disease.

includes three different types of diseases: Bacterial Leaf Blight, Brown Spot and Leaf Smut. The dataset is partitioned into training and testing sets where 82,200 samples are used for training and 27,360 samples are used for testing. The number of samples for each disease is 27,360 in the training set and 9120 in the testing set. By combining samples from both datasets, it allows use to include more diseases (four different disease) in addition to the healthy case. As a result, the classification task in all experiments embeds five classes: 1) Bacterial Leaf Blight, 2) Leaf Smut, 3) Brown Spots, 4) White Scale and 5) Healthy leaves.

Fig. 5(a) shows samples from Bacterial Leaf Blight disease where 1,013 images with dimension 3081 x 897 are included in our experiments. Fig. 5(b) shows samples from Leaf Smut disease where 827 images with dimension 510 x 383 are included in our experiments.

Samples from Brown Spots disease and White Scale disease are shown in Fig. 6(a) and (b) where 470 images and 958 images are used in our experiments for Brown spots disease and White scale disease, respectively. For the case of healthy leaves, Fig. 6(c) shows sample of Healthy leaves where 1,203 images are included in our experiments.

### B. Experiment Configurations

In our experiments, 4023 samples from different type of diseases were used to train each CNN model while 448 samples from different type of diseases were used to test the performance of each CNN model. The size of input images are unified in all experiments to be 60 x 60 x 3, where the first two dimensions represent the width and height while the last

Recall and F1 Score. The Accuracy of each CNN model at each type of disease is defined as the following:

$$Accuracy = \frac{TP + TN}{T} \qquad (6)$$

, where $TP$ and $TN$ represent number of True Positive and True Negative classifications, respectively, while $T$ represents the total number of samples. Table VI reports the performance of each model based on accuracy. We can notice that MobileNet achieved 99.56% accuracy rate in average which is the best performance. In contrast, our model and VGG16 achieved 99.10% and 99.35% accuracy rate, respectively. It is clear that the performance of the three models are relatively very close with slight variations less than 0.5% .

The Precision of each CNN model at each type of disease is defined as the following:

$$Precision = \frac{TP}{TP + FP} \qquad (7)$$

TABLE VI. THE PERFORMANCE OF EACH MODEL BASED ON ACCURACY

| Diseases | Our model | MobileNet model | Vgg16 model |
|---|---|---|---|
| Brown Spots | 99.55% | 100.00% | 100.00% |
| white Scale | 99.35% | 99.75% | 99.35% |
| Bacterial Leaf Blight | 98.79% | 98.98% | 98.99% |
| Leaf Smut | 99.20% | 98.88% | 99.5% |
| Healthy | 98.90% | 99.90% | 98.90% |
| **Average** | **99.10%** | **99.56%** | **99.35%** |

TABLE VII. THE PERFORMANCE OF EACH MODEL BASED ON RECALL

| Diseases | Our model | MobileNet model | Vgg16 model |
|---|---|---|---|
| Brown Spots | 100.00% | 100.00% | 100.00% |
| white Scale | 98.55% | 98.55% | 99.75% |
| Bacterial Leaf Blight | 96.27% | 96.20% | 97.27% |
| Leaf Smut | 98.73% | 98.73% | 98.86% |
| Healthy | 99.15% | 99.67% | 99.55% |
| **Average** | **98.54%** | **98.63%** | **99.08%** |

, where $TP$ and $FP$ represent number of True Positive and False Positive classifications, respectively. Table VII reports the performance of each model based on Recall. The highest average precision rate is $99.08\%$ reported by MobileNet, followed by VGG16( $98.63\%$) and our model ($98.54\%$). It is clear that the performance of the three models are relatively very close with slight variations less than $1\%$.

The performance of each CNN model based Recall and $F_1 Score$ are defined as the following:

$$Recall = \frac{TP}{TP+FN}$$

(8)

$$F_1 Score = 2 \times \frac{Precision \times Recall}{Precision + Recall}$$

, where $TP$ and $FN$ represent number of True Positive and False Negative classifications, respectively. Table VIII and IX report the performance of each model based on precision and $F_1 Score$, receptively. The reported results show that the performance of the three models in both measures are very close with variations less than $1\%$.

From the previous reported results, the performance of VGG16 and MobileNet in addition to the proposed model very close with a slight advantage to MobileNet over others. We believe that VGG16 can achieve better performance with huge training data. However, in several applications, huge training

TABLE VIII. THE PERFORMANCE OF EACH MODEL BASED ON PRECISION

| Diseases | Our model | MobileNet model | Vgg16 model |
|---|---|---|---|
| Brown Spots | 100.00% | 100.00% | 100.00% |
| white Scale | 98.55% | 99.75% | 98.75% |

Fig. 7. Avg Training Time per Epoch for each Model.

data is not always available. In contrast, MobileNet and our model showed more capability to deal with limited resources such as training data and training time. Fig. 7 shows the average training time of each model. Note that our model achieved the lowest average training time of $20.048$s/epoch while MobileNet achieved $343.85$s/epoch average training time followed by VGG16 with a huge rise ($2559$s/epoch). Thus, the proposed model is capable compromise between the performance (high) and the complexity (simple structure with low training time).

## V. CONCLUSION

This paper presented an efficient CNN-model for detecting and classifying palm tree frequent diseases, including Bacterial leaf blight, Brown spots, Leaf smut and white scale. The proposed model consists of three stages. Firstly, data preprocessing was applied on all images by normalizing them using Whitening Transform to reduce the correlation among data within the image. The second stage included four convolutional layers with max pooling to extract distinctive features. Finally, the classification stage was defined using fully connected layer with softmax to detect the type of palm disease. Furthermore, this work investigated the performance of two will-known CNN- models, namely MobileNet and VGG-16, for classifying palm tree diseases. To evaluate the performance of proposed CNN-model and other models, a new dataset (DP-disease dataset) was built by combining data samples from Date Palm and Leaf_disease_3 datasets. This combination allowed us to detect four deferent diseases in addition to healthy cases. A set evaluation metrics was then applied to evaluate the performance of each model including accuracy, Precision, recall and F1 score. Our experimental results showed that the performance of the three models were very close. However, our model characterized by simplicity and low computational training cost ($20.048$s/epoch ) comparing to others ($343.85$s/epoch and $2559$s/epoch for MobileNet and VGG-16, respectively).

Future avenues of work include integrating the proposed model with object segmentation methods such R-CNN for accurately identifying the affected parts of palm trees.

*Abstract*—**Advances in the field of Neural Networks, especially Graph Neural Networks (GNNs) has helped in many fields, mainly in the areas of Chemistry and Biology where recognizing and utilising hidden patterns is of much importance. In Graph Neural Networks, the input graph structures are exploited by using the dependencies formed by the nodes. The data can also be transformed in the form of graphs which can then be used in such models. In this paper, a method is proposed to make appropriate transformations and then to use the structure to predict diseases. Current models in disease prediction do not fully use the temporal features that are associated with diseases, such as the order of the occurrence of symptoms and their significance. In the proposed work, the presented model takes into account the temporal features of a disease and represents it in terms of a graph to fully utilize the power of Graph Neural Networks and Spatial-Temporal models which take into consideration of the underlying structure that change over time. The model can be efficiently used to predict the most likely disease given a set of symptoms as input. The model exhibits the best algorithm based on its accuracy. The accuracy of the algorithm is determined by the performance on the given dataset. The proposed model is compared with the existing baseline models and proves to be outstanding and more promising in the disease prediction.**

*Keywords*—*Spatial temporal graph convolution network; disease prediction; graph neural network; graph convolutional network; deep learning; knowledge graph*

## I. INTRODUCTION

In recent times, Machine Learning has become very popular in the field of Medical Sciences, especially when it comes to detecting patterns that are associated with health and diseases. Disease prediction is one of the most sought after applications here, and the reason for that is the patterns that are associated with each disease, be it physical illness or mental well-being. Diseases are often associated and known for the symptoms that occur when a person is infected, therefore a study of the underlying structure of the symptoms, their behaviour, etc. is important for predicting them. These underlying structures usually have a temporal nature to them as the symptoms don't occur all at once, but they do in more or less sequential order.

It is common to see the use of ML models such as Naive-Bayes, Decision Trees and other classifiers to be used in these scenarios. The most common source for obtaining information about symptoms is by referring to Electronic Health Records (EHRs). Often these are used to extract features for input. In [1], the authors make a heart disease prediction model using ML techniques. They utilize features such as Age, Sex, Pain levels, etc of patients as input. In [2], it was found that most people tackled this problem using Support Vector Machines (SVM) and Naive-Bayes models. However, this did not prove to be efficient when dealing with huge volumes of Electronic Medical Records (EMRs) data without processing it and simply feeding it to these models, nor can these models take advantage of the temporal structure of the symptoms. To overcome this many researchers have started utilising Deep Learning, as a neural network can detect and represent the hidden and latent features more efficiently. In [3], the authors proposed a graph convolution network with mutual attention networks, to learn from EMR's directly and diagnose the patient. The author obtained an accuracy of 63.46% from the MIMIC-III dataset [4], which was better compared to all the other models in the paper like Convolutional Neural Networks (CNN), Graph Convolutional Network(GCN), etc. The authors in [5] use an Artificial Neural Network (ANN) to develop a model for Parkinson's disease and boast almost perfect accuracy. A method proposed in [6] uses Cascading Neural Networks in order to detect Melanoma, a form of skin cancer. In [7], the authors have developed a model called InceptionGCN for disease prediction and tested it out on various datasets. Thus it can be concluded that neural networks, especially Graph Neural Networks play an important role in the new and upcoming models of disease predictions.

However, most of the above-mentioned papers fail to utilise the temporal features of the symptoms that are associated with the diseases. Some papers [8],[9] make use of GNNs tailored for this specific purpose especially in [9],[10] where the authors use patient data to first construct a dependency of the patient with symptoms on each visit and a final diagnosis and then model a graph from which is fed to the network proposed by them. This model could achieve an accuracy of a little over 85% at the most favourable conditions.

So while the use of spatial-temporal networks is not new to this problem, a new architecture that models symptoms of a patient into a graph is quite novel. This paper proposes a method to model the input data by changing the underlying structure of the graph at each timestep, so as to utilise the temporal features of the input. Knowledge graph for diseases by [11] is utilized for proposed architecture. In this, the authors employ probabilistic models such as logistic regression, naive Bayes classifier, to derive features of various diseases from many EHRs. The authors feature a knowledge graph built on these features and so in the presented work a knowledge graph

based Spatial-Temporal GCN is proposed.

The major contributions of the paper are:

- A temporal approach to predicting diseases in order to make the models more robust and potentially exploiting such dependencies to enhance the quality of the proposed model.

- Graph Convolutional Network(GCN) model is proposed which exploits the spatial dependencies of the input first then uses these to explore the temporal dependencies of the input. This will help to understand how the symptoms relate to each other at each timestep and how that underlying relationship changes. The model will exploit this to predict and classify diseases.

- A graph model of the input data in the form of diseases and the symptoms that occur alongside proposed as well. Each symptom is associated with a probability which indicates how likely the symptom is to occur (as compared to all other symptoms for the same disease). Data is convert into a graph.

## II. Related Works

Disease prediction has been difficult with a lack of patient history and noisy data. The work tries to overcome the difficulties and improve efficiency by using knowledge graphs obtained from medical ontology. Further, mechanism is also discussed to predict diseases using symptoms via a spatial-temporal Graph Convolutional Network.

Xuedong Li et al. [12] takes an innovative approach to overcome the lack of medical history by using medical knowledge. The lack of medical history of patients owing to the nature of rare medical diseases makes it a challenging process even for machine learning approaches to recognize the diseases. They have developed a text classification algorithm to create a bag of knowledge terms from the medical ontology to develop a knowledge graph that can be leveraged for the disease classification task. It works efficiently even if the knowledge graph of medical history is incomplete. The limitation of this approach is that the dataset being used is extremely imbalanced.

Rotmensch, M., Halpern, Y. et al. [9] has directed a review observational investigation utilizing recently gathered information from Electronic Medical Records (EMR) in order to develop a knowledge graph that relates indications to sicknesses and assessed competitor knowledge graphs against physically curated knowledge graph given by (Google well being knowledge graph, or GHKG) and also the expert opinion of physicians. However, the purpose of the knowledge graph was to test how efficiently a given algorithm could recover unknown causal relationships between the diseases and their symptoms. A drawback is that any approach that infers causal relations from observational data has major limitations inherently. The algorithms should be seen as a method of providing casual relations between the entities.

Zhenchao Sun, Hongzhi Yin et al. have introduced an innovative model [13] using GNNs for disease prediction. It uses multiple knowledge bases in order to obtain sufficient

EMR data to learn highly representative node embeddings of medical concepts graph and the patient record graph (which include entities such as, the patients, diseases and symptoms), and are thus constructed from the medical knowledge base and EMRs. This results in accurate disease prediction for new patients under sparse data in an inductive manner.

Li, Y., Qian, B et al. have proposed GNDP, a disease prediction model which is based on a graph convolutional network. It exploits the spatial structure of the EHR data and the temporal dependencies of the entities to predict the patient's future diagnosis which is similar to [8,10]. Sun, Z., Dong, W. et al. propose a Reinforcement Learning mechanism that would take random walks over the knowledge graph with respect to the patient's symptoms and then propose the most likely disease. The authors have manually constructed the knowledge graph using the Mimic-III PLAGH dataset. A single knowledge graph has been made for all diseases. It is limited in terms of accuracy, as accuracy could be improved by using efficient methods. GNN models can be considered as the structure of the data is a graph and the performance can be improved using GNN algorithms.

Yuan, Q., Chen, J., et al. have constructed an elaborate GCN model [3] in which they have extracted symptoms from a given diagnosis in the form of a string. Then they embed the diseases first in the D-D GCN layer and attach symptoms (features) to the diseases in the next D-F GCN layer. Less important features have been pruned from the knowledge graph in this model. Finally, these features are given to a convolutional network modelled using attention, so that the most important disease corresponding to the symptoms is obtained. The accuracy obtained is only 63%. The limitation is that the model is not interpretable and complex to understand. Potential change or simplification of algorithms can lead to better accuracy. It only considers the features extracted from diagnosis and not the temporal relations between the features.

## III. Methodology

In this section, the proposed architecture of spatial-temporal graph convolutional networks(STGCN) in elaborately discussed. STGCN is made up of spatial-temporal convolutional blocks that are arranged in a "sequential" structure with one sequential convolution layer and one spatial graph convolution layer, as shown in Fig. 1. The following sections go over the specifics of each module.

### A. Data Collection and Preparation

One authentic medical dataset is experimented on to evaluate the proposed model. knowledge graph from electronic medical records [3], a public accessible benchmark dataset for diseases knowledge graphs with high-quality knowledge bases linking diseases and symptoms derived from the EMRs. These electronic records represent medical concepts collected from over 270,000 patient visits to the Emergency Department at Beth Israel Deaconess Medical Center (BIDMC), thus the knowledge graphs was automatically constructed using maximum likelihood estimation of three probabilistic models.

From the learned parameters, a graph of disease-symptom connections was elicited, and the developed knowledge graphs were assessed and approved, with consent, against Google's
Fig. 1. Example of the Anemia Disease Dynamic Knowledge Graph that Generated in Preprocessing of the Dataset. a) Knowledge Graph at T = 0    b) Knowledge Graph at T = 3    c) Knowledge Graph at T = n, where n is Length of Disease Trajectory

manually built knowledge graph and master doctor suppositions. The graph records all 156 diseases and 491 symptoms, all edges between diseases and symptoms, and the significance scores given to each edge.

Temporal patterns in patient disease trajectories are either disregarded or only taken into account by assessing the temporal directionality of identified co-morbidity pairs [14], [15], [16], Which concludes naturally patients undergo different symptoms at different time instances on disease trajectories (stages of the disease). In this experiment, the temporal pattern for each disease as the preliminary basis of a disease prediction model is utilized.

Provided in Table I are the sample dataset values which includes a given disease and its symptoms along with the probability of a given symptom occurring. In Table II, important statistics of the dataset itself are given.

TABLE I. SAMPLE DATASET

| Diseases | Symptoms |
| --- | --- |
| abscess | $pain(0.318), fever(0.119), ..$ |
| anemia | $lethargy(0.096), weakness(0.087), ..$ |
| common cold | $chills(0.083), sorethroat(0.075), ..$ |

Before applying the STGCN model to knowledge graphs extracted from electronic medical records [11], the existing knowledge graph must go through a series of steps to create a dynamic graph structure by leveraging temporal features for each disease knowledge graph.

As the dataset is not available with time element related with disease symptoms, a suitable time feature is created for the knowledge graph collected from electronic medical records [11]. This was done by generating all possible permutations of order symptoms that will occur in the patient's disease trajectories.

Then using the importance scores associated with each edge of symptoms, the top ten symptoms were selected with the highest probability of occurrence inpatient disease trajectories for all possible permutations. Since the disease prediction

is a multi-class classification task, more than one data point is needed on each class but dataset have only one data point on each class. To overcome this top k permutations were selected with the highest importance scores associated with each edge of symptoms.

Fig. 2. Graph-Structured Disease Data. Each $d_t$ Indicates a Frame of Current Disease Trajectory at Time Step t, which is Recorded in a Graph Structured Data Matrix.

To generate different graphs for each time instance with available data, by introducing a new initial node with the label as patient and linking new edges between each symptom node and patient node for each disease trajectory growth as shown in the figure.

This results in T unique graphs with the temporal patterns for each disease, where T represents the length of the disease trajectory. Nodal features of each node as initialized with a unique label code of symptoms and each edge weight of each edge assigned based on the importance score of symptoms associated with it.

After preprocessing the knowledge graph extracted from electronic medical records [11], 'n' disease classes of 'k' top permutations were generated with the highest importance scores associated with each edge of symptoms and each permutation contains 'T' unique dynamic graphs with the temporal patterns for each disease. The dimension of each dynamic graph data will be [Number of disease classes 'x' number to permutations 'x' length of disease trajectory].

STGCN disease prediction was a spatial-temporal graph

classification task, hence the final dataset will contain, Adjacency matrix with the shape of (length of disease trajectory x number of nodes x number of nodes), Nodal features (length of disease trajectory x number of nodes), graph label (1 x 1).

TABLE II. IMPORTANT STATISTICS OF THE FINAL DATASET

| Features | |
|---|---|
| Size of the Dataset | 2000 |
| Unique Diseases | 100 |
| Features per Disease | 10 |
| Unique Symptoms | 308 |

## IV. PROPOSED MODEL

In this section, the proposed architecture of Spatial-Temporal Graph Convolutional Networks (STGCN) is discussed in more detail. STGCN is made up of spatial-temporal convolutional blocks that are arranged in a "sequential" structure with one sequential convolution layer and one spatial graph convolution layer, as illustrated in Fig. 2. Each module's specifics are as follows.

Fig. 1 depicts an overview of knowledge-based STGCN and Fig. 2 depicts the convolution process. When importing disease data into STGCN in temporal graph format. Two convolution layers comprise the STGCN unit shown below. By broadcasting the features of each node along with the graph edge via the property of graph convolution, the first layer performs spatial graph convolutional operation parallelly on each dynamic graph of a different time instance, then node features vectors containing the aggregation label information of their neighbours can be extracted [17]. The next layer employs the temporal layer to capture the temporal relations of the resultant feature vectors of each entity in the graph.

The entire architecture of the model is depicted via Fig. 3 and Fig. 4. In the former it can be observed how samples of different timestamps are given as input to the network and how they are processed in the spatial layer, while in the latter the input obtained is processed by the temporal layer and the fully connected layer to lastly obtain the output.

A global attention pooling layer [18] is used after the STGCN unit and the output is reshaped in order to achieve proper feature dimension before the output is given to the Fully Connected unit. This unit consists of two linear layers. The first linear layer has an input channel of 55 and an out channel size of 128. The output of the first linear layer was passed through the batch normalization layer, activation function and dropout layer (p=0.3). The following second linear layer has an input channel of 128 and an output channel of n, where n is the number of diseases. Finally, a Softmax layer is applied to predict the final output which is then used for classification. This model is capable of being trained in an end-to-end scenario and the configuration is unified.

### A. Spatial Graph Convolution Layer

The spatial graph convolution layer performs the first convolution operation on incoming data. Using the adjacency matrix A and the nodes feature vector F as inputs, the following function defined by [17] can perform an effective and effective convolution operation. Adjacency matrix A was converted into Edge Index $E_i$ and Edge weight $E_w$ for simplicity.

$$X' = (D'^{-1/2} A' D'^{-1/2}) \cdot X \qquad (1)$$

Where A' = A + I denoted the adjacency matrix with inserted self-loop and $D'_{ii} = \sum A'_{ij}$ its diagonal degree matrix. The adjacency matrix can include other values than 1 representing edge weights via optional edge weight $E_w$ tensor.

Its nodes wise formulation is given by:

$$X'_i = \sum_{j \in N(v) \bigcup i} \left( \frac{e_{i,j}}{\sqrt{d'_j \cdot d'_i}} \cdot X_j \right) \qquad (2)$$

with $d'_i = 1 + \sum_{j \in N(i)} e_{i,j}$ denoted the edge weight from the source node j to target node i.

In this experiment, the temporal patterns for each disease knowledge graph simulate changing nodal features and adjacency matrix for each time instance by creating dynamic graph data for each disease. To perform spatial convolution operations for each time instance. The knowledge graph data is passed to T parallel spatial convolution layers, where T represents the length of disease trajectory (the number of time instances recorded in the disease knowledge graph).

A tensor of $(Nf, Ei, Ew)$ can be used to represent the input feature of a spatial graph convolutional layer, where $Nf$ represents node features (symptom labels) of the dynamic disease knowledge graph, $Ei$ represents the edge index of the dynamic graph data, and $Ew$ represents the edge weight of the dynamic graph data. A new tensor with the shape of (output Channel, Number of nodes, dimension of node features) is generated by using the Conv2D layer which is the standard 2D convolution layer. This is implemented using [1,1] kernel size and (4,4) stride as features on the input tensor, which is obtained by multiplying the input matrix with learnable weight matrix W and adding the bias b. The graph convolution is the result of the product of the normalised adjacency matrix A' and the new tensor's $2^{nd}$ dimension. Finally, a tensor with the dimensions (output Channel, Number of Nodes, Node Features Dimension) can be created.

$$F_{spatial} = GCN(F_{in}) = A' \times F'_{in} \qquad (3)$$

$$F'_{in} = \sum F_{in} \cdot W + b \qquad (4)$$

### B. Temporal Convolutional Layer

The dynamic disease graph's temporal aspect is created by stacking the output of the spatial convolutional layer and generating a feature matrix. The temporal axis is well-ordered, with the duration of the disease trajectory limitation, allowing for a straightforward convolutional process to extract temporal information.

The input feature matrix $Fspatial$ is implemented as a tensor with the dimensions (T, Number of nodes, spatial Output

Fig. 3. F Includes the Input Node Feature for given Graph, A Indicates the Adjacency Matrix in Time Order, $E_i$ Signifies Edge Index Matrix in Time Order, $E_w$ Means Edge Weight in Time Order. $F_{spatial}$ is the Final Feature Vector which is Obtained as the Output.

Fig. 4. The $F_{spatial}$ Denotes the Output Features of Spatial Convolutional Layer in Time Order, $F_{temporal}$ Denotes the Output Features of Temporal Convolutional Layer, Y' Denotes the Predicted Disease Class.

channel), where T is the length of the illness trajectory. The temporal kernel size is a parameter that controls how many timestamps are included in the disease graph sequence. The temporal convolutional layer's output channel dimension was determined by parameter $\gamma$ [19].

$$Output\ channel = (Input\ Channel - y) + 1 \quad (5)$$

Thus, inspired by [20], [21], the temporal convolution operation can be defined as

$$F_{temporal} = TCN(F_{spatial}) = \sum_{i=0}^{\gamma-1} F_{spatial} \cdot W + b \quad (6)$$

## V. RESULT

### A. Objective Function

Cross-entropy loss is used as the objective function because disease prediction is a multi-class classification task. Using cross-entropy loss, the loss is quantified between the ground truth class d and the model output y', represented by the following formula:

$$loss(y', d) = \frac{1}{n} \sum d^T \cdot log(y') + (1-d)^T \cdot log(1-y') \quad (7)$$

where n is the total number of category classes.

### B. Implementation Details

All the mentioned approaches are implemented using Py-Torch 1.9.0, PyTorch-Geometric, PyTorch Geometric Temporal. All training processes are refined through Nvidia T4 GPU of 8.1 TFLOPS Performance and CUDA 11.1 with Intel(R) Xeon(R) processor. The dataset is then divided into various proportions to assess the performance of the model. It is haphazardly separated into training, validation, testing set in a 0.70 : 0.15: 0.15.

### C. Baseline Methods

A comparison is established with the models given below in Table 3, but since the other models work on different datasets a direct comparison cannot be made. However their performance is highlighted with respect to the proposed model in terms of their accuracy, precision, recall, etc.. These models are:

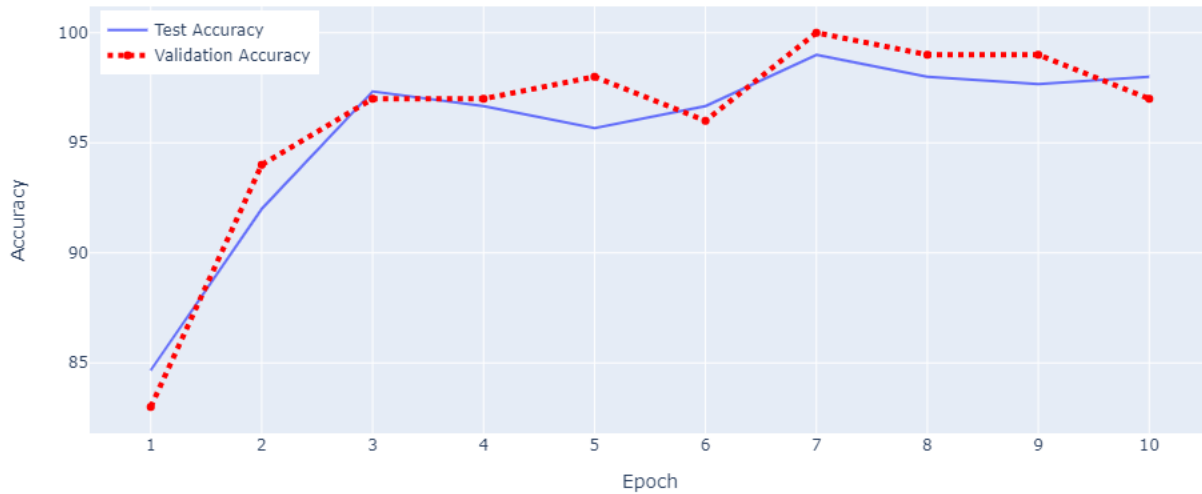
- Graph Neural Disease Prediction model is proposed in [9] which also implements STGCN blocks on patient data for prediction.


Fig. 5. Validation Accuracy and Test Accuracy Score for each Epoch

TABLE III. COMPARISON WITH OTHER DISEASE PREDICTION MODELS (CONSIDER METRIC AS ACCURACY IF NOT MENTIONED OTHERWISE)

| Sr No. | Model | Dataset used | Number of Classes | Performance Metrics |
|---|---|---|---|---|
| **1** | **Proposed** | **EMR [11]** | **100** | **98.00%** |
| 2 | DP-GNN [13] | Proprietary EMR | 71 | Recall - 75.70% Precision - 22.40% |
| 3 | Inception GCN [7] | TADPOLE [22] | 1 | 83.40% |
| 2*4 | 2*RPL [23] | PLAGH [24] | 2*65 | AUC - 74.30% |
| | | MIMIC [4] | | AUC - 63.9% |
| 2*5 | 2*GNDP [9] | MIMIC [4] | 171 | 86.29% |
| | | EHR Database | 154 | 87.49% |
| 2*6 | 2*LPNL [25] | TADPOLE [22] | 2*1 | 91.85% |
| | | UKBB | | 63.91% |
| 7 | HRP [26] | NHANES [27] | 13 | 85.50% |
| 8 | GMAN [3] | MIMIC [4] | 50 | Recall - 62.13% Precision - 63.46% |

- This is a GNN model for disease prediction proposed in [13] (DP-GNN). The authors map a graph of symptoms linked to the diseases and then use Graph Neural Networks to test their model.

- The model InceptionGCN is proposed in [7]. The author's utilise GCN layers in their model, however it is used to predict only one class of brain disease.

- The model proposed in [23] utilises Reinforcement Path Learning (RPL) over knowledge graph to predict diseases.

- This model, [25] makes use of simple Multilayer Perceptrons and Latent patient Network (LPNL) in order to predict diseases.

- The model given in [26] describes a method for representing symptoms in the form of knowledge graphs for health risk prediction (HRP).

- Graph Mutual Attention Network (GMAN) - This model [3] makes use of attention layers over graph convolution layers for disease prediction.

### D. Evaluation Results

The model is trained to differentiate among 100 unique diseases by using 308 unique symptoms. Using LabelEncoder each disease is given a unique label id from 1-100, similarly the symptoms are labelled. For batching, 10 dynamic knowledge graphs are used per batch, and the $spatial_\gamma$ and $temporal_\gamma$ is set to 6. Thus, the channel size and the temporal size will be 5.

After preprocessing, the data set is stratified based on diseases label, and then passed to the Spatial layer. The input here is of the size [10x10x11x5] (which is [batchsize x features x nodes x channel size]), the output of which is passed to the Temporal Layer which is of the size [10x10x11x5], where LeakyReLU is used as the threshold function (with a negative slope of 0.01). This is then passed through Global Pooling Layer where the output dimensions are [10x5x11x1] (which is [batch size x temporal size of features x nodes x new aggregated channel size]) and is then concatenated to shape [10x55].

The completely linked layer receives the output from here.

The first layer, which is a Linear layer, has an input of [10x55] and an output of [10x128]. This is normalised using the received output via a BatchNorm1D layer and then ReLU is used as the threshold function. Then a dropout layer is initialised, with a probability of 0.3, before passing it to the final Linear Layer which has an input of [10x128] and output of [10x100]. Then finally, ReLU is used as the threshold function so that whichever node has the highest value will be the predicted label, and hence the predicted disease.

The model was trained for 10 epochs, in which the validation accuracy obtained is 98.00%, and the test accuracy is 98.66% for $\gamma = 6$.

This accuracy indicates that there is a lot of merit in using temporal dependencies for disease prediction, especially by using the proposed method. This model can be also used practically in clinical sciences as a robust healthcare artificial intelligence system.

In Fig. 5, the validation accuracy and the test accuracy is plotted with respect to each epoch. It can be observed that there is an increasing trend and the model achieves high accuracy in a few epochs only.

### E. Comparison with Baseline Models

A comparison is established with the given models in Table III, and their features are highlighted, namely the dataset they use, number of classes that were utilised and the accuracy (or the precision, recall, Area Under the Curve [AUC]) of their models.

The GNDP model [9] has been tested on the MIMIC-III dataset [4], so a direct comparison cannot be made, but the paper also makes use of Spatial Temporal Blocks to construct their architecture. In their network, they implement 5 STGCN units, pool the outputs at specific blocks, and then finally pass the output to the fully connected layer. Compared to that, the model only makes use of one STGCN unit before passing the output to the fully connected layer. It is also important to mention here that in GNDP, the input is processed differently from how the model processes the input, and hence the simplicity. GNDP model achieves a maximum accuracy of 86.29% on MIMIC.

## VI. CONCLUSION

This paper proposes a novel deep learning framework STGCN for disease prediction, integrating graph convolution through Spatio-temporal convolutional blocks. GNDP solves the constraints of earlier techniques by using GNNs to learn spatial and temporal patterns from patients' sequential graph data, in which medical ontology knowledge and EMR information travel down distinct channels at different levels. The proposed model beats other state-of-the-art methods on datasets, demonstrating that it has a lot of potential in spatial-temporal structures.

These features are quite promising and practical for scholarly development. Moreover, the proposed framework can be applied to more general Spatio-temporal structured sequence prediction scenarios, such as evolving drug linkage, and preference prediction in diagnosis systems, etc.

## VII. FUTURE WORK

In this paper, a template and a model is proposed that works well on that template, however the major challenge that was encountered was the absence of medical datasets in the structured format that is proposed. More work can be done to devise a model which converts EMR or EHR reports into a graph structure that [11] utilises and thus the temporal nature associated can be better exploited.

There is also a need of further structured data for disease prediction uses. The model can be better trained and would definitely give us more accuracy if the temporal as well as the sequential dependencies of the symptoms could be better utilised. For example, a fever is associated with a cold, which is associated with cough. These semantics and dependencies give the symptoms a structure which can be then utilised by the STGCN model directly.

Furthermore, methods could be devised to convert popular EMR databases such as [4] can be converted to the format that is proposed in order to establish better comparisons. This is challenging due to varied nature of each database to store information, and the diverse nature of writing reports.

# Password Systems: Problems and Solutions

Lanfranco Lopriore

Dipartimento di Ingegneria dell'Informazione
Università di Pisa
via G. Caruso 16, 56126 Pisa, Italy

*Abstract*—**In a security environment featuring subjects and objects, we consider an alternative to the classical password paradigm. In this alternative, a key includes a password, an object identifier, and an authorization. A master password is associated with each object. A key is valid if the password in that key descends from the master password by using a validity relation expressed in terms of a symmetric-key algorithm. We analyse a number of security problems. For each problem, a solution is presented and discussed. In certain cases, extensions to the original key paradigm are introduced. The problems considered include the revocation of access authorizations; bounded keys expressing limitations on the number of iterated utilizations of the same key to access the corresponding object; repositories, which are objects aimed at storing keys, possibly organized into hierarchical structures; and the merging of two keys into a single key featuring a composite authorization that includes the access rights in the two keys.**

*Keywords*—*Access authorization; key; password; revocation; security*

## I. Introduction

We will refer to the classical security paradigm featuring active entities, called *subjects*, that generate access attempts to passive entities, called *objects* [15], [16], [20], [24], [29]. A subject can be a process, or the activity generated by the occurrence of an event, e.g. a hardware interrupt. Objects are typed. The definition of the type of a given object includes the specification of a set of values, and a set of operations that act on these values. For each operation, the type definition specifies the *access authorization*, i.e. the set of access rights, that is necessary to execute this operation successfully.

In an environment featuring subjects and objects, a basic problem is to allow subjects to certify permission to access objects, i.e. the subject should possess the corresponding access authorization [6]. A classical solution is based on the association of a number of *passwords* with each object, one password for each significant access authorization [4], [13]. In this solution, a subject that holds a password for a given object, and is aimed at executing a given operation on that object, presents the password to the object. If the password is valid, and the access authorization associated with the password includes the required access rights, then the execution of the operation is permitted.

Password proliferation is an inherent problem in password systems. Let us refer to an object type defining four access rights, for instance. In this type, up to fifteen passwords are necessary, if all access right combinations are meaningful. Significant memory requirements follow from the necessity to store these passwords within the internal representation of each object. Alternatively, we can associate a password with each

access right. This solution reduces the memory requirements, but is prone to significant complications of the whole password management process. For instance, a subject that should be granted a full access authorization that includes all the access rights for a given object must possess all the passwords defined for that object. The arguments of an operation requiring several access rights must include as many passwords. A subject that is aimed at passing an access authorization to a recipient must transmit one password for each access right in the authorization.

In a different approach, we associate a *master password* with each object. This password is generated at random when the object is created. Master passwords should be large and sparse, according to the overall security requirements of the system. A subject certifies its own right to access an object whose identifier is $id$ by presenting a *key $K$* referencing this object. The key has the form $K = (psw, id, au)$, where $au$ specifies an access authorization, and $psw$ is a password. The key is valid if the password is valid, i.e. if $psw = E_{mp}(id \,||\, au)$, where the $||$ symbol denotes a concatenation. In this *validity relation*, $E$ denotes a symmetric-key algorithm, the *password cipher*, which is universally known. The password is valid if it is the result of the application of the password cipher to the concatenation of the identifier and the authorization. The encryption key is the master password of the object identified by $id$. If the password is valid, possession of the key grants access to the object, to carry out those operations that are authorized by the access rights in $au$, according to the specification of the object type. The $au$ field features one bit for each access right. If a given bit is asserted, the authorization includes the corresponding access right. Thus, for instance, an $au$ field of all 1's corresponds to a full access authorization including all the access rights. A subject certifies possession of a full access authorization for the given object by a single key, i.e. key $(psw, id, 11\ldots1)$.

In this approach, a single password, the master password, needs to be stored into the internal representation of each object, and a single key is necessary in each operation to certify possession of the access authorization required by that operation. A subject that holds an access authorization expressed in terms of a given key can transmit this authorization to a recipient by copying the key to the recipient.

The rest of this paper presents the background, first (Section II). Afterwards, with reference to a key-based method of password specification and storage, a collection of significant problems is analysed, which are connected with password utilization and management. The problems considered include the revocation of access authorizations (Section III); bounded keys aimed at forcing upper limits to the number of successful

key utilizations (Section IV); key repositories, which are containers for collections of keys that can be connected to form a hierarchy (Section V); and a mechanism to merge two or more keys into a single key including all the access rights in the respective authorizations (Section VI). For each problem, we present a solution in terms of the corresponding password treatment approach. Extensions to the key format are introduced.

## II. Background

*Password capabilities* are a well-known implementation of the password concept, which was introduced in Section I [5], [9], [10], [14], [21]. Several computing systems implementing an object referencing approach based on password capabilities were designed and actually implemented in the past. Examples are Annex [19], Walnut [4], Mungi [9], Opal [5], and the Password Capability System [1]. In a password capability environment, a set of passwords is associated with each given object, one password for each significant access authorization. A password capability is a pair $(psw, id)$ where $psw$ is a password, and $id$ is an object identifier. A subject that possesses a given password capability can access the named object to carry out those operations which are made possible by the access rights in the authorization associated with the password. If passwords are sparse, large, and generated at random, it is virtually impossible for an attacker to generate a valid password capability from scratch. It follows that password capabilities can be freely mixed in memory with ordinary information items. In this respect, password capabilities are an important improvement over the capability concept [12]. In a classical capability environment, the specification of the access authorization is part of the capability [7], [17], [22]. Consequently, capabilities should be segregated, into reserved memory regions [11], or by taking advantage of memory tagging techniques [2], [3], [18], [28].

Password capabilities suffer from the password proliferation problem. For a type defining several access rights, many passwords should be stored into the internal representation of an object of that type, one password for each meaningful access authorization. Negative effects follow in terms of complicated password management and high memory costs for password storage, especially for forms of fine-grained object access security featuring small-sized objects.

Consider a subject that holds a password capability including the password for a given access authorization. The subject may transfer the authorization to a recipient by passing the password capability to the recipient. In turn, the recipient can transmit the authorization further, by new actions of a password capability copy. Now suppose that the original subject is aimed at revoking the grant from the recipients. If the subject owns the object, it can modify the password. This form of revocation extends automatically to all subjects that hold a password capability expressed in terms of that password. However, we cannot reduce the authorization by eliminating a subset of the access rights associated with the password, and we cannot limit the revocation to a specific subset of the subjects.

Of course, after changing a password, the object owner can proceed to a new distribution of password capabilities with the new password to selected recipients. The whole process is

much more complicated than implied by the desired effect. This is especially the case for those subjects that received the password capability through intermediate recipients, which may well be unwilling, or even unable, to cooperate in the new distribution. In fact, one of the main advantage of password capability systems is simplicity in access right transmission between subject. This simplicity should be also preserved for revocation.

No bound exists on the transmission ability of a subject that holds a given password capability. In fact, the subject is free to pass the password capability to an unlimited number of recipients. In turn, each recipient can transmit the password capability further. In the original definition of the password capability concept, no mechanism is provided to limit this form of password capability proliferation.

The password capability format does not include an authorization field. It follows that we cannot argue the authorization granted by a given password capability by inspection of the password capability itself. In fact, in the original password capability paradigm, the association between a password for a given object and the authorization granted by that password is part of the internal representation of the object. An *ad-hoc* operation would be necessary to convert passwords into the corresponding authorizations.

## III. Revocation

At the security system level, the key-based approach introduced in Section I is supported by a collection of system primitives for object and key management (Fig. 1). A first example is $K \leftarrow new(T, arg_0, arg_1, \dots)$. In the execution of this primitive, the constructor of type $T$ is used to create a new object of this type, according to the specifications of the type. Arguments $arg_0, arg_1, \dots$ are transmitted to the constructor. The primitive returns a key referencing the new object, with a full access authorization that includes all access rights. Primitive $delete(K)$ uses the destructor of the type of the object referenced by key $K$ to delete this object. The execution terminates correctly only if $K$ specifies an access authorization that includes access right OWN. Primitive $exec(K, op, arg_0, arg_1, \dots)$ executes operation $op$ on the object referenced by key $K$. Arguments $arg_0, arg_1, \dots$ are transmitted to $op$. The execution terminates correctly only is $K$ specifies an access authorization that includes all the access rights required by $op$. Finally, let $K_0 = (psw_0, id, au_0)$ be a key, and $msk$ be a mask having the same size as an authorization. Primitive $K_1 \leftarrow reduce(K_0, msk)$ returns a key $K_1 = (psw_1, id, au_1)$ referencing the same object as key $K_0$, with the reduced authorization $au_1$ that results from relation $au_1 = au_0 \ \& \ msk$, i.e. the bitwise AND of authorization $au_0$ and mask $msk$. The execution of this primitive uses the validity relation and the master password of the object identified by $id$ to evaluate the new password $psw_1$.

One of the main advantages of a password-based environment is simplicity in access right distribution. Consider a subject that holds the password corresponding to a given authorization. The subject can grant this authorization to one or more recipients by simply distributing a copy of the password to these recipients. In turn, each recipient can grant the authorization to additional subjects, by further password copy

$K \leftarrow new(T, arg_0, arg_1, \dots)$
Uses the constructor of type $T$ to create a new object of this type. Arguments $arg_0, arg_1, \dots$ are transmitted to the constructor. Returns a key referencing the new object, with a full access authorization that includes all access rights.

$delete(K)$
Uses the destructor of the type of the object referenced by key $K$ to delete this object. $K$ should specify access right OWN.

$exec(K, op, arg_0, arg_1, \dots)$
Executes operation $op$ on the object referenced by key $K$. Arguments $arg_0, arg_1, \dots$ are transmitted to $op$. $K$ should specify all the access rights required by $op$.

$K_1 \leftarrow reduce(K_0, msk)$
Returns a key $K_1 = (psw_1, id, au_1)$ referencing the same object as key $K_0 = (psw_0, id, au_0)$, where $au_1 = au_0 \ \& \ msk$, the $\&$ symbol denotes a bitwise AND, and mask $msk$ has the same size as an authorization.

Fig. 1. Primitives for Object and Key Management.

Fig. 2. An Access Authorization Field Featuring Four Instances of $n$ Access Rights.

*instances* of the same access right. Fig. 2 considers an example of an access authorization field featuring four instances of $n$ access rights. For the $i$-th access right in the authorization, these instances are named $au_{i,0}$ to $au_{i,3}$. If bit $au_{i,j}$ is asserted, then the access authorization includes instance $j$ of access right $i$. The internal representation of each object is modified to contain an authorization *mask*, which applies to all keys referencing that object. The structure of the mask is similar to that of an authorization field. If $mask_{i,j}$ is cleared, then $au_{i,j}$ is revoked.

When a subject generates an access attempt to a given object, the key presented by the subject is considered to certify the access. The access is permitted if, for each access right required by the access, at least one instance is asserted in the authorization field of the key, and this instance is not revoked by the corresponding mask bits. Conversely, the object access is negated if all instances of one or more of the required access rights are cleared, or are revoked by the mask. Let *eff* denote the *effective* authorization resulting from the bitwise AND of the authorization field and the mask; thus we have $eff = au \ \& \ mask$. The $i$-th access right is granted by the key if at least one instance of this access right is asserted in *eff*, that is, for $m$ instances, $eff_{i,0} \lor eff_{i,1} \lor \cdots \lor eff_{i,m} = 1$. In the mask, the bits corresponding to instance 0 are always asserted for all access rights. It follows that, in a key, an access right in instance 0 is never revoked.

The primitives to create and access objects, introduced previously and illustrated in Fig. 1, should be modified to deal with effective authorizations. When primitive *new* is issued to create a new object, the mask of that object is set to all 1's, to validate all access right instances. The key returned by *new* features an access authorization that includes all access rights in all instances. The execution of primitive $delete(K)$ terminates successfully only if the effective authorization granted by key $K$ includes access right OWN. In the execution of primitive $exec(K, op, arg_0, arg_1, \dots)$, the effective authorization should include the access rights required by the operation specified by argument *op*.

The mask of a given object can be modified by issuing primitive $mask(K, msk)$. Argument $K$ is a key referencing the object, argument $msk$ is the new mask, which should specify all 1's for instance 0. The execution accesses the internal representation of the object to modify the mask. The operation terminates successfully only if key $K$ specifies all access rights in instance 0.

### B. Categories

In a different approach to access right revocation, we extend the key format to include the specification of a *category*. A key assumes the form $K = (psw, id, t, au)$, where the $t$ field specifies the category. Each category has a *degree*. The degree of a given category expresses a limitation on the access rights granted by every key in that category.

actions. We will now consider the case that the original subject modifies its own intention, and is aimed at revoking the grants from the recipients. Revocation is especially useful to comply with the *principle of least privilege*: at any given time, each subject should possess only those access privileges that are necessary at that time for its legitimate purposes [23], [25]–[27].

Of course, by changing the password associated with a given authorization we obtain a form of revocation that includes only this authorization. The revocation involves all the subjects that received the authorization in the form of that password. Restricting revocation to a subset of these recipient subjects is a problem that is hard to solve. We can modify the password, and then proceed to a distribution of the new password to the desired recipients. However, consider the case of a recipient that was reached by means of two or more distribution steps through intermediate subjects. Collaboration will be necessary in the new distribution, but these intermediate subjects may well be unwilling, or even unable, to cooperate.

In our key-based environment, consider a subject that holds a key for a given object, and distributes a copy of this key to one or more recipients. A form of total revocation that involves all access authorizations can be obtained at little effort by a system primitive having the form $K_1 \leftarrow mpReplace(K)$. The execution of this primitive modifies the master password of the object referenced by key $K$, whose authorization should specify all access rights. The primitive returns a key $K_1$ defined in terms of the new master password and including all access rights. After the execution of this primitive, all keys generated by using the old master password are revoked; it will no longer possible to use these keys for successful object accesses. However, it is impossible to take advantage of an approach of this type to implement forms of revocation that involve only a subset of the recipients, or only a subset of the access rights. We will now introduce more flexible approaches to the solution of the revocation problem.

### A. Instances

A first approach is based on a different form of the access authorization field. In *au*, we associate more than a single bit with each access right. This means that we can have several
---

$changeDegree(K, t, d)$
Assigns degree $d$ to category $t$ of the object referenced by key $K$, which should specify category 0.

$K_1 \leftarrow changeCategory(K, t)$
Returns a new key in category $t$ for the object referenced by key $K$, with the same access authorization. $K$ should specify category 0.

---

Fig. 3. Primitives for Category Management.

Let us refer to an object type featuring $n$ access rights. As seen in Section I, authorization field $au$ is encoded in $n$ bits, one bit for each access right. If a given bit is asserted, the corresponding access right is part of the authorization. The internal representation of each object is modified to include a *category table* featuring an entry for each category. The entry for a given category contains the degree of that category. A degree is encoded in $n$ bits. For a given key, the *effective* authorization results from the bitwise AND of the $au$ field and the degree of the category specified by the $t$ field. It follows that a degree of all 1's for a given category implies that all the access rights in the authorization of a key in that category are effective. Conversely, a degree of all 0's means that all these access rights are revoked.

In an extended key environment featuring categories, the primitives for object management, introduced previously and illustrated in Fig. 1, should be modified to deal with degrees. Primitive *new* assigns degree 0 to all categories, and returns a key featuring category 0. This category is special in that its degree always is all 1's, and cannot be changed. The execution of primitives *delete* and *exec* considers the effective access authorization granted by key $K$, as follows from the compound effect of the authorization field and the degree of the category specified by the key.

Category management is supported by two primitives (Fig. 3). Primitive $changeDegree(K, t, d)$ makes it possible to modify category degrees. Its execution assigns degree $d$ to category $t$ of the object referenced by key $K$. The execution is successful only if $K$ specifies category 0. Primitive $K_1 \leftarrow changeCategory(K, t)$ returns a new key in category $t$ for the object referenced by key $K$, with the same access authorization. The execution is successful only if $K$ specifies category 0.

### C. Comparison

Let us refer to the classical properties of an access right revocation system [8]. In the approach based on access right instances, revocation is *partial*, that is, we can revoke any desired subset of the access rights. To this aim, we clear the mask bits corresponding to these access rights in all instances. Revocation is *selective*, that is, we can revoke an access right from a subset of the recipients of that access right. To this aim, we clear the mask bits of the instances specified by the keys held by these recipients. Revocation is *independent*, that is, keys received from different distributors can be revoked independently of each other, if these keys specify different instances of the same access rights. Revocation is *transitive*, that is, it propagates to all copies of the same key, independently of the path followed by the copy to reach its recipient; and in fact, a key copy cannot be distinguished from the original.

Revocation is *temporal*, as it can be reversed through the same mechanism, i.e. the mask, by setting the mask bits that were cleared for revocation.

In the category-based approach, we can obtain a partial revocation by clearing the bits of the degree field corresponding to the access rights to be revoked from the category. Selective revocation is intrinsic in the category model, and will be simply obtained by clearing the degree of selected categories. Independent revocation can be obtained at little effort for keys belonging to different categories, by modifying the degree of only those categories that are involved in the revocation; the other degrees will be left unaltered. Transitive revocation is implicit in the key model. Finally, temporality can be obtained by simply setting the bits of the degree that were cleared for revocation to reverse the effects of the revocation.

Instances imply no modification of the key format. In fact, instances need to be introduced only in those object types for which an option for revocation is necessary. In these types, the access authorization field will be extended to include several bits for each access rights. The size of the extension will be decided on a type basis. In fact, we can have different numbers of instances for different types. Conversely, in the category based approach, the key format should be extended to include the category field. This modification applies to all types. The number of categories is fixed for all types, and is determined by the size of the category field.

The memory costs of instances are connected with mask storage and the size of the access authorization field, which is increased to include several bits for each access rights. For four access rights and four instances of each access right, a two-byte access right field and a two-byte mask will be necessary. These memory costs are to be paid only for those object types for which revocation is necessary. On the other hand, a four-bit category field is sufficient to implement up to 16 categories. The memory costs for storage of the category table in the internal representation of each object are quite limited. Let us refer to an object type defining four access right, for instance. In a situation of this type, for 16 categories, a 64-bit word will be sufficient.

## IV. BOUNDED KEYS

The password paradigm, as is implemented by the key construct, implies no limitation on iterated utilizations of the same given key to access the corresponding object. We will now present an extension of the key concept aimed at forcing an upper bound to the number of successful applications of the same key.

We modify the key format by introducing a new field, the *bound field* $b$. In the new format, a *bounded key* $B$ is a quadruple $B = (psw, id, au, b)$ (Table I). The validity relation is modified to take the bound field into account. The key is valid if $psw = E_{mp}(id \parallel au \parallel b)$, where $mp$ is the master password of the object identified by $id$, $au$ is the authorization granted by the key, and $b$ identifies the bound. A *bound table* is associated with each object. The bound table features an entry for each bound. The entry for a given bound contains the *extent* of that bound. The extent is the total number of times that bounded keys in that bound can be successfully used to access the object (if the extent is 0, these keys can no longer

TABLE I. BOUNDED KEY FORMAT

| |
|---|
| $B = (psw, id, au, b)$: bounded key |
| $psw = E_{mp}(id \;\|\; au \;\|\; b)$: validity relation |
| $psw$: password |
| $id$: object identifier |
| $au$: access authorization |
| $b$: bound |
| $E$: password cipher |
| $mp$: master password |

be used). If the bound is 0, then the key is a *primary key* that has no bound, and can be used for an unlimited number of accesses to the object.

The bound table of a given object will be stored as part of the internal representation of the object. The memory requirements for storage of the bound table are determined by the number of bounds and the maximum extent permitted for each bound. For instance, a bound field of three bits allows for up to 7 bounds (bound 0 being reserved to specify a primary key). If an extent is encoded in 16 bits, for each bound we can have up to 65,535 executions of the *exec* primitive using a bounded key in that bound. In a configuration of this type, the whole bound table can be contained in two 64-bit words.

### A. Primitives

The primitives for object management, introduced in Section III and illustrated in Fig. 1, should be modified to deal with bounds and extents. Primitive $B \leftarrow new(T, arg_0, arg_1 \dots)$ uses arguments $arg_0, arg_1, \dots$ in the constructor of type $T$ to create a new object of this type, and returns a primary key for that object, which includes all acces rights. The extents of the bounds of the object are all equal to 0. This means that the object can only be accessed by using the primary key, until one or more bounds are *recharged* to specify new extents (see below). Primitive $delete(B)$ uses the destructor of the type of the object referenced by bounded key $B$ to delete the object. $B$ should be a primary key, and should include an access authorization that specifies access right OWN. Primitive $exec(B, op, arg_0, arg_1, \dots)$ uses arguments $arg_0, arg_1, \dots$ to execute operation $op$ on the object identified by $id$. The execution is successful if $B$ specifies an access authorization that includes all the access rights required by $op$. $B$ should be a primary key, or the extent of the bound of $B$ should be greater than 0. If this is the case, the extent is decremented by 1.

The primitives for bound management are summarized in Fig. 4. Primitive $e \leftarrow extent(B, b)$ returns the extent $e$ of the bound $b$ of the object referenced by bounded key $B$, which should be a primary key. Primitive $recharge(B, b, e)$ increments the extent of the bound $b$ of the object referenced by bounded key $B$ by quantity $e$. $B$ should be a primary key. Primitive $B_1 \leftarrow newBound(B_0, b)$ returns a bounded key $B_1$ referencing the same object as bounded key $B_0$, with the same access authorization and bound $b$. $B_0$ should be a primary key.

## V. REPOSITORIES

The *Repository* data type allows us to define objects aimed at key storage [15]. A name is associated with each key in a

---

|---|
| $e \leftarrow extent(B, b)$ |
| Returns the extent $e$ of the bound $b$ of the object referenced by bounded key $B$, which should be a primary key. |
| $recharge(B, b, e)$ |
| Increments the extent of the bound $b$ of the object referenced by bounded key $B$ by quantity $e$. $B$ should be a primary key. |
| $B_1 \leftarrow newBound(B_0, b)$ |
| Returns a bounded key $B_1$ referencing the same object as bounded key $B_0$, with the same access authorization and bound $b$. $B_0$ should be a primary key. |

Fig. 4. Primitives for Bound Management.

TABLE II. ACCESS RIGHTS IN THE *Repository* TYPE.

| Access right | Operation |
|---|---|
| GET | *read* |
| PUT | *write* |
| INSPECT | *list* |
| OWN | *delete* |

repository. The name is unique within the repository, that is, it will never be the case that two keys in a given repository are associated with the same name (on the other hand, the same key name can be freely used in different repositories).

Table II enumerates the access rights that are included in the definition of the *Repository* type. For each access right, the table shows the operation whose execution is made possible by that access right. For a given repository, access right GET makes it possible to read those keys in the repository whose names are known. Access right PUT makes it possible to insert keys into the repository. Access right INSPECT allows us to read the names of the keys in the repository. Access right OWN allows us to delete the repository.

Fig. 5 presents the operations defined by the *Repository* type, and gives short indications of the effects of the execution of each of them. Primitive $K \leftarrow new(Repository)$ uses the constructor of the type to create a new, empty repository, and return a key referencing that repository, with a full access authorization that includes all the access rights. Primitive $delete(K)$ uses the destructor to delete the repository referenced by key $K$. This key should specify access right OWN.

The other operations of the *Repository* type are implemented taking advantage of primitive *exec*. A first example is $K_1 \leftarrow exec(K_0, read, nm)$. The execution of this operation accesses the repository referenced by key $K_0$ to return the key named $nm$ in that repository. The execution is successful if $K_0$ specifies access right GET. Operation $exec(K_0, write, nm, K_1)$ adds key $K_1$ to the repository referenced by key $K_0$, and associates name $nm$ to $K_1$. $K_0$ should specify access right PUT. Operation $lst \leftarrow exec(K, list)$ returns a list of the names of the keys contained in the repository referenced by key $K$. This key should specify access right INSPECT.

### A. Hierarchies

The *Repository* object type makes it possible to organize keys into hierarchies. In an organization of this type, each repository can include keys for other repositories at a lower

---

$K \leftarrow new(Repository)$
Uses the constructor of the *Repository* type to create a new, empty repository. Returns a key referencing that repository, with an access authorization that includes all access rights.

$delete(K)$
Uses the destructor of the *Repository* type to delete the repository referenced by key $K$, which should specify access rigth OWN

$K_1 \leftarrow exec(K_0, read, nm)$
Returns the key named $nm$ taken from the repository referenced by key $K_0$, which should specifies access right GET.

$exec(K_0, write, nm, K_1)$
Adds key $K_1$ to the repository referenced by key $K_0$, and associates name $nm$ to $K_1$. $K_0$ should specify access right PUT.

$lst \leftarrow exec(K, list)$
Returns a list of the names of the keys stored in the repository referenced by key $K$, which should specify access right INSPECT.

---

Fig. 5. Operations of the *Repository* Type.

hierarchical level. Each repository can also include keys for objects of any other type, which represent the leaves of the hierarchy. In a given repository, the name associated with each key identifies the object referenced by that key.

A subject that knows the name of a key in a given repository, and possesses a key for that repository with access right GET, can access the repository to read the key. If the subject does not know the key name, it can use the *list* operation, but an action of this type requires access right INSPECT for the repository.

### B. Access Right Amplification

The *read* operation implements a form of access right amplification, whereby a subject that possesses access right GET for a given repository can read the keys in that repository independently of the access rights specified by these keys. For instance, consider the case of a repository $R_0$ that includes a key $K$ referencing another repository $R_1$, and $K$ specifies all access rights. A subject that possesses a key for $R_0$ featuring a single access right, GET, can read $K$ from $R_0$. In this way, the subject acquires a full access authorization for $R_1$, which is an amplification of the authorization that the subject holds for $R_0$.

## VI. MERGING KEYS

Let us refer to a subject $S$ that holds two keys that reference the same object, say $K_0 = (psw_0, id, au_0)$ and $K_1 = (psw_1, id, au_1)$, where $id$ is the object identifier. Let us suppose that the type of the object includes an operation $op$ whose execution requires both the access rights in $au_0$ and the access rights in $au_1$. Primitive $exec(K, op, arg_0, arg_1, \dots)$ features a single key, whose authorization field should include all the required access rights. It follows that subject $S$ is not in the position to execute $op$, unless the two keys $K_0$ and $K_1$ are merged to form a single key including the union of the access rights in the authorizations. To this aim, primitive $K \leftarrow merge(K_0, K_1)$ can be provided. The execution of this operation returns a key $K = (psw, id, au)$ for the object identified by $id$. $K$ features an authorization $au$ that includes the union of the access rights in $au_0$ and $au_1$.

It should be noted that *merge* implement a form of access right amplification. In the example above, by using *merge*, subject $S$ amplifies its own execution ability to include operation $op$, which would be negated in the absence of *merge*. In fact, the decision to include *merge* in the set of primitives of the security system is a design choice. If this form of access right amplification should be permitted, *merge* will be made available.

In a more flexible approach, an *ad-hoc* access right, the JOIN access right, will be required in all the keys involved in an access right merging activity. In this case, in the example above, a successful execution of primitive *merge* will be possible only if both keys $K_0$ and $K_1$ include JOIN in the respective authorizations.

Primitive *merge* also supports a form of cooperation between subjects. Consider two subjects $S_0$ and $S_1$ that hold keys $K_0$ and $K_1$, respectively. These subjects cannot execute an operation requiring the union of the access rights in $au_0$ and $au_1$, unless they agree to merge the two keys.

## VII. CONCLUSION

With reference to a security system featuring subjects and objects, we have considered a paradigm of object access, which is an alternative to classical password-based environments. Our paradigm takes advantage of keys. In particular:

- The key definition includes a password, an object identifier, and an authorization.

- A master password is associated with each object. A key is valid if the password descends from the master password by using a validity relation expressed in terms of a symmetric-key algorithm.

We analysed a number of security problems, which include:

- The revocation of access authorizations.

- Bounded keys expressing limitations on the number of iterated utilizations of the same key to access the corresponding object.

- Repositories, which are objects aimed at storing keys, possibly organized into hierarchical structures whereby each repository may include keys for other repositories at a lower hierarchical level.

- The merging of two keys into a single key featuring a composite authorization that includes all the access rights in the two authorizations.

For each problem, we have proposed a solution expressed in terms of a key treatment approach. Extensions to the original key format have been introduced and discussed.
