Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

CONTENTS

Real-Time Wildfire Detection and Alerting with a Novel Machine Learning Approach

A New Systematic Approach of Using Convolutional Neural Network (CNN) to Achieve Higher Accuracy in Automation

Audrey Zhang[1]
Mountain View High School
Mountain View, California, USA

Albert S. Zhang[2]
Amazon
Seattle, Washington, USA

***Abstract*—Up until the end of July 2022, there have been over 38k wildfires in the US alone, decimating over 5.6 million acres. Wildfires significantly contribute to carbon emission, which is the root cause of global warming. Research has shown that artificial intelligence already plays a very important role in wildfire management, from detection to remediation. In this investigation a novel machine learning approach has been defined for spot wildfire detection in real time with high accuracy. The research compared and examined two different Convolutional Neural Network (CNN) approaches. The first approach; a novel machine learning method, a model server framework is used to serve convolutional neural network models trained for daytime and nighttime to validate and feed wildfire images sorted by different times of day. In the second approach that has been covered by existing research, one big CNN model is described as training all wildfire images regardless of daytime or nighttime. With the first approach, a higher detection precision of 98% has been achieved, which is almost 8% higher than the result from the second approach. The novel machine learning approach can be integrated with social media channels and available forest response systems via API's for alerting to create an automated wildfire detection system in real time. This research result can be extended by fine tuning the CNN network model to build wildfire detection systems for different regions and locations. With the rapid development of network coverage such as Starlink and drone surveillance, real time image capturing can be combined with this research to fight the increasing risk of wildfires with real time wildfires detection and alerting in automation.**

Keywords*—*Wildfire detection; CNN (convolutional neural network); machine learning; image processing; model server framework

I. Introduction

The frequency of wildfires is increasing globally, with wildfires occurring this year in unprecedented locations, such as Europe and Yellowstone and Yosemite in the United States. Wildfires cause great property damage and result in numerous injuries and deaths each year. In 2021, there was a record breaking 58,985 wildfires, which ravaged a total of 7.1 million acres [1]. Compared to the 18,229 wildfires and 1.3 million acres lost in 1983 [1], the year when official record-keeping began, this is a sizable increase of 223% [3]. In 2020, California wildfires emitted more than 91 million metric tons of CO_2, that is about 25% of the state's annual fossil fuel emissions and this percentage is forecasted to keep increasing over the next few years [4].

Although wildfires can occur naturally and do provide some beneficial effects like soil nourishment, they need to be controlled in order to mitigate the high levels of CO_2 emission and prevent property loss and casualties. The earlier wildfires can be detected, the better the chance of reducing CO_2 emissions, property damages and life casualties. Fig. 1 breaks down the causes of wildfires [5].

Evidently, from Fig. 1 at least 69% of wildfires stem from human causes, and according to the U.S. Department of Interior, the actual percentage is even closer to 85%. Establishing an automatic wildfire detection and prevention system should be a focal point in reducing the volume of wildfires in the future. With the continuous construction of power lines across the world, a lot of drone investments should be made for surveillance purposes in order to reduce the possibility of man-induced wildfires [7].

To further understand the factors and variables that should be considered for early wildfire detection, In this research paper the top 20 largest California wildfires were examined from information on Inciweb [8], the government's incident information system that displays all present and past cases of wildfires [9]. Wildfires can happen anytime and there is a clear increase in nighttime wildfire intensity due to global warming. Globally, night wildfires have become 7.2% more intense from 2003 to 2020 [10].

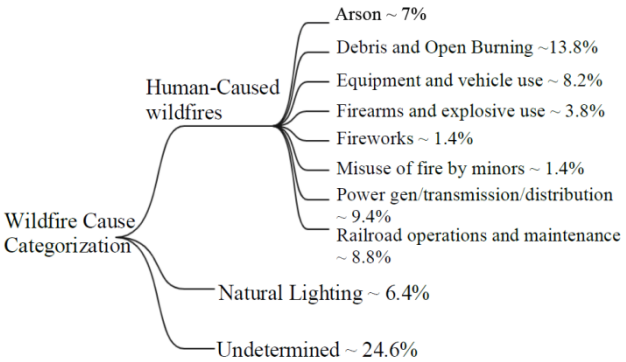

Fig. 1. The Classification of the Causes of Wildfires [5][6].

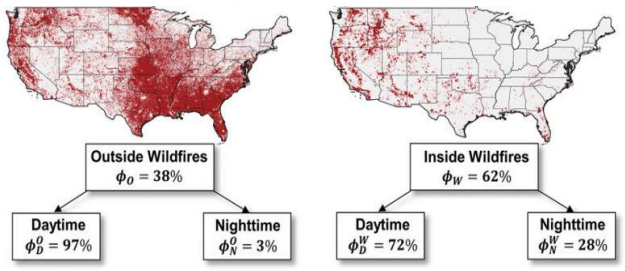

Fig. 2. Moderate Resolution Imaging Spectroradiometer (MODIS) Detected Across the US from 2003 to 2020. Left Represents Outside Wildfires, and Right Represents Inside Wildfires [11].

From the above Fig. 2, ϕ_N and ϕ_D represent the proportion of total fire radiative power detected at nighttime and that detected at daytime respectively. Fig. 2 shows that the increase in nighttime fire activity across the US has been outpacing its daytime counterpart's [11]. So in this research, the images captured at nighttime and the importance of the corresponding network model were important aspects of the research.

The early detection of wildfires is essential to controlling wildfires expeditiously. Academia and industry have come together to solve this increasingly urgent and important problem. Companies, namely soar.earth and pano.ai etc., use the latest technologies such as real time satellite imagery, drone surveillance, and remote network connectivity with Starlink to perform real time image and video capturing, which is a much more accessible and immediate way to detect wildfires. Currently, wildfire spot detection and response times take too long, and in many cases, even a few seconds are important and precious to contain wildfire damages. An automated wildfire detection and alerting system is needed to notify response systems and the public in real time to provide better containment and prevention measures.

This research concluded the convolutional neural network (CNN) paired with the AI model server framework can rapidly and successfully identify wildfires with high accuracy, even source images from daytime versus those from nighttime carry significantly different characteristics. Additionally, the learning models can be extended to different locations and regions with model fine tuning.

II. Background Study

Over the years, many research efforts have delved into the application of artificial intelligence, particularly the use of image recognition and deep learning techniques, to the field of early stage wildfire detection and management. University of California San Diego's WIFIRE center [12] and Piyush and a group of scientists published a review of ML applications to six problem domains: (i) fire detection and mapping; (*ii*) fire weather and climate change; (*iii*) fire occurrence, susceptibility and risk; (*iv*) fire behavior prediction; (*v*) fire effects (*vi*) fire management [2].

Other researchers have explored using classification machine learning models with color features combined with texture classification on superpixel regions of still images [13]. The algorithm uses an RGB color model to detect the color of the fire [13]. Researchers have employed Artificial Neural Networks (ANNs) for fire detection [14] and extended ANNs to wireless sensor networks to create a fire detection system [15]. Various ML methods used in fire detection systems include Support Vector Machines (SVM) to automatically detect wildfires from video frames [16], Genetic Algorithm (GA) for multi-objective optimization of a LiDAR-based fire detection system [17], Bayesian Network (BN) in a vision-based early fire detection system [18], Adaptive Neuro Fuzzy Inference System (NFIS) [19], and K-means Clustering (KM) and fuzzy logic [20].

In the last few years, Academia and industry have come together to find solutions with wildfire detection. Researchers and scientists have found that approaches based on deep convolutional neural networks (CNN) tend to yield the best results for wildfire detection [21]. Tao proposed training CNN models end to end, from raw pixel values to image classifier outputs, and Sharma recommended using imbalanced datasets as inputs to these networks to simulate real life scenarios [22]. In 2019, an adaptive pooling approach of conventional image processing techniques and convolutional neural networks provided even higher accuracy and reliability [23]. Recently a group of researchers at Shanghai University have used CNN and satellite images for wildfires detection [24].

From the above research papers the following conclusions can be drawn:

1) So far, all investigations are based on smoke detection. However, smoke detection using wildfire images taken during the night is not effective, especially with smaller datasets. There has been no research thus far in creating separate learning models for nighttime and daytime wildfires.

2) The wildfire images from nighttime carry large variations in color, texture and shapes. No research papers have talked about those significant variations against smoke based detection.

3) How a CNN Network model can be generic and flexible across various locations and regions for wildfires detection.

4) A self-learning and automated process is imperative to detect wildfires very early.

In this research paper, a novel systematic approach for automatically detecting wildfires and alerting response systems were proposed and implemented with the following three major advances:

1) Google Cloud Platform (GCP) was used in this research to build Convolutional Neural Network (CNN) learning models for daytime and nighttime wildfires.

2) A modern model server architecture to serve the models with input images to achieve high accuracy regardless the time of those images were taken.

3) To make this work more generic so that it can be leveraged at different locations, Convolutional Neural Network Fine tuning is explored to adapt and enhance the network models to have the same high accuracy across locations.

III. Research Methodology

A. Data and Data Preparation

For this research project, a combination of several different sources of wildfire image data were used. The images are taken from Kaggle, open source projects, and Google images. Most of the images have been properly labeled with wildfire and non-wildfire, but a few are unlabeled, so a few of hours work were spent on manually labeling those images for the purposes of this research. In real life, it is worth noting that image labeling can be achieved by crowdsourcing and having data sourcing companies, such as keymakr.ai, scale.ai, etc, provide us with lots of labeled data. The images were split into daytime and nighttime to build two separate learning models with the same setup. The number of images in the training, validation, and test sets used for the wildfire smoke detection model can be seen in Table I. The following pre-processing steps were performed:

1) Combine all images into one big data set.

2) Filter out images of wildfires in black and white and those with questionable smoke and flare.

3) Classify images into daytime and nighttime wildfire sets

4) Ensure all images are properly labeled, especially for the training and test datasets

TABLE I. Total Dataset Split Train, Validation and Test

Model	***# Fires Daytime***	***# Not Fires Daytime***	***# Fire Nighttime***	***# Not Fire Nighttime***	***# Images***
Train	823	1180	760	820	3.6K
Validation	224	380	212	390	1.2K
Test	212	412	198	320	1.1K
Omitted	32	45	63	66	206
Total	591	2717	733	2096	6.1K

Then the following transformations were performed during data loading to improve the performance of the models. The images were resized and cropped to the empirically determined size of 1040 × 1856 pixels to improve training and inference speed. This operation also enables us to evenly divide the image into overlapping 224 × 224 tiles. Finally, normalization of the images to 0.5 mean and 0.5 standard deviation was conducted, as expected by the deep learning package used (pytorch vision).

B. Implementation of CNN and Alerting Mechanism

Pytorch was used as the underlying framework for the Convolutional Neural Network in this research. Fig. 3 illustrates the overall architecture. Using the Fast R-CNN package, based on the idea of running the CNN just once per image and then finding a way to share that computation across ~1000 proposals, each wildfire image was fed once to the underlying CNN and then selective search was run as usual to generate region proposals. Then, each proposal is projected onto the feature maps generated by the CNN. Fast R-CNN offers an exponential increase in terms of speed [25] over traditional CNN's.

In this research, a model server framework was used. Currently, there are multiple implementations of model server for serving purposes, but the original idea of a low latency and high throughput model server came from the research from UC Berkeley Rise Lab Clipper framework [26]. As of now in the market, there are multiple implementations of model server for serving purposes. TorchServe was used as the implementation framework and combined the API from sunrise-sunset.org [27] to get the trigger point for model serving. Fig. 3 illustrates the model server architecture.

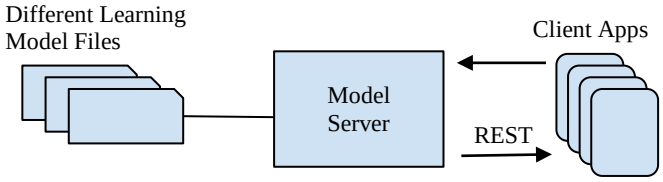

Fig. 3. The Illustration of Model Server Architecture.

The characteristics for wildfires detection in daytime and nighttime can be very different. In the daytime, early detection is heavily based on smoke, so fog, mist, etc. are the primary factors that affect the model's accuracy. At night, early detection focuses more on glares, so lights, fog, etc. are the main factors that could skew accuracy. It is important to treat them differently. After the pre-processing described in section A was completed, three models were trained - (i) one big model with the datasets from both daytime and nighttime combined, (ii) one model for just daytime, and (iii) one model for just nighttime. The models for daytime and nighttime together were aggregated by using the model server framework for the result. The comparison of the results from one big model vs the aggregation of daytime model and nighttime model is discussed in section C. Fig. 4 illustrates the overall systematic approach.

After developing a highly accurate spot wildfire detection system, an alerting and notification mechanism can be established. The higher the detection accuracy is, the lower is the count of false positive alerts. In this investigation, the alerting system was divided into two parts - 1) social channels (Twitter, Facebook, Instagram, etc.) with different social handlers, and 2) SMS text or automated phone calls to police and fire departments - to alert responders to act fast.

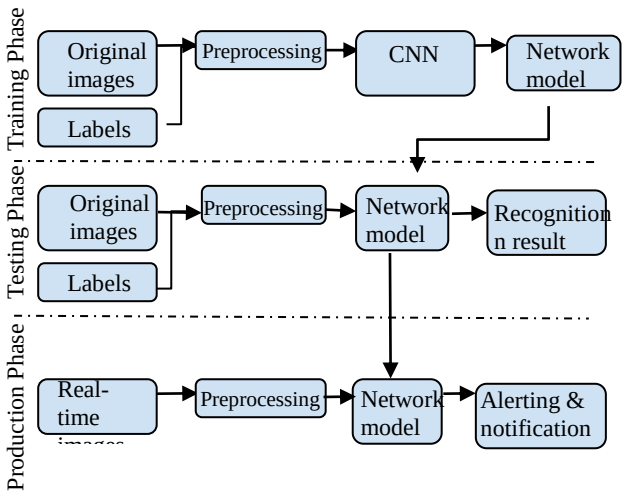

Fig. 4. The Overall Systematic Approach.

To elaborate on the first part, a social handler responsible for monitoring over a specific area can publish wildfire hazard alerts to the people subscribed to it across various social media platforms. This can be very effective in informing people who live around that specific area to prepare themselves for immediate evacuation upon the start of a wildfire. To expand on the second point, cloud services like Twilio can be leveraged to send SMS messages to a given area code for wildfire notifications.

C. Key Metrics and Results

True positive (TP), false positives (FP), true negatives (TN), and false negatives (FN) are calculated between the model predictions and the ground truth labels. For all the experiments, the following two key metrics were used typically for binary classification problems.

- *Precision* - Degree of exactness of the model in identifying only relevant objects.

  It is the ratio of TPs over all detections made by the model, namely: $Precision = \frac{TP}{TP+FP} = \frac{TP}{all\ detections}$

- *Recall* - Measure of the ability of the model to detect all ground-truths instances.

  It is the ratio of TPs over all the ground-truths, namely:

  $Recall = \frac{TP}{TP+FN} = \frac{TP}{all\ ground-truth}$

- Accuracy - Measure the fraction of all instances that are correctly categorized; it is the ratio of the number of correct classifications to the total number of correct or incorrect classifications

  $Accuracy = \frac{TP+TN}{TP+FN+FP+TN} = \frac{TP+TN}{all\ instances}$

A model is said to be a good model if it has high precision and high recall. A perfect model has zero FNs and zero FPs (that is, precision=1 and recall=1). However, it usually is not feasible to attain a perfect model.

In this research, after the model server was employed, the accuracies were calculated by the means of the daytime and nighttime models. Table II shows the comparison of precision, recall and accuracy from different models and approaches at stage training and validation.

TABLE II. RESULTS OF PRECISION, RECALL AND ACCURACY.

Model	***P (%)***	***R (%)***	***A (%)***
Train big model	90.3	71.1	87.5
Train nighttime	97.6	74.3	91.2
Train daytime	98.5	74.7	91.8
Validation big model	89.5	68.3	83.7
Validation nighttime	97.2	73.3	89.7
Validation daytime	98.1	73.9	90.6
Validation with model server	97.9	73.6	89.5

From Table II, it shows that the approach with the model server framework to serve the network models from daytime and nighttime has much higher precision and accuracy of 97.8% and 89.5% vs. one model approach of 89.5% and 83.7% respectively at image validation. Clearly the approach with the model server architecture offers much higher precision and accuracy.

D. Alerting and Notification

In this investigation, a test dataset was used to trigger the process of posting tweets to Twitter. When a test image was fed to the network model, if it is classified as fire, the Twitter API is triggered to generate a message that will be broadcasted to all the subscribers of a Twitter handler automatically in real time. The same mechanism can be implemented to send SMS messages or even automated phone calls.

E. Additional Observations and Future Plans

The results in this research show that spot wildfire can be detected with high precision and accuracy based on the AI Convolutional Neural Network (CNN) learning model with live data stream from monitoring stations, drones or satellites. The cost perspective of the approach from a commercialization perspective will not be discussed in this paper. The computing power for digesting live data and powering the AI model in addition to data storage has a significant cost impact. Soon, real time image capturing will not be an issue in feeding data through a pipeline. Potential edging computing or embedded systems with the AI learning models can be used or deployed to reduce the costs for spot wildfires detection. At the same time, alerting and notification to the public and officials can be established in an automated way. In this research the sunset and sunrise API [27] was used to invoke different models, this may not always be accurate. Wildfire characteristics at dawn and dusk time may get blue, but with more training data, classification accuracies at dawn or dusk will surely increase.

In the future, it would be interesting to do an investigation on the impact of time series images to the complexity of the

network models. Since real life images would be captured via forest monitoring high towers, drones or satellites, by nature they are time series images, this may make the network models even less complex and higher accuracy, but more research and validation are needed. The impact for the time series images to the learning correlations needs further investigation.

In this paper, the dataset used is not very big, the more data that is fed into the CNN, the more powerful the model could become when it gets trained. It would also be an interesting research topic to find a way to automate continuous improvement mechanisms for fine tuning CNN models so that learning models can be generic enough across different locations and regions. Finally, the model server architecture can be further refined and used for different segmentation of conditions with more drastic differences in order to make detection even more robust.

IV. Conclusion

In this research, a novel machine learning convolutional neural network (CNN) with a combination of model server was used to aggregate models for daytime and nighttime to have a higher accuracy. The model server serving different models with different time ranges (approach 1) vs. one big model that did not distinguish daytime and nighttime (approach 2) was compared for accuracy and feasibility. With approach 1, a higher precision of ~98% was achieved vs. approach 2 of ~90%, and with a shorter training time. Approach 1 carries more implementation complexity. This research result shows that wildfires detection accuracy can be improved significantly by considering different models for images from different time intervals and combining them using a model server architecture.

In this research, an alerting and notification system is discussed and can be built to integrate with social media and wildfire responding systems to automate the entire detection and alerting process to have wildfires under control to save lives and reduce property damages.

This investigation is based on the datasets that were collected from the Internet (Kaggle, Google Images and GitHub). In real life, real time videos/images capturing will be more accessible with the development of satellite monitoring, drones and many cases of monitoring towers set up. Those datasets would be more time series and unbalanced data with less variation. The datasets used in this research carry more variations of wildfire scenarios for training the models. A preprocessing with the data sets collected was performed before image feeding to the training process of CNN. With the real life time series images, the preprocessing also could be simplified. The models trained can be used at various places across the globe with CNN fine tuning for spot wildfire detection.

Lastly, the key in wildfire detection, prediction and prevention is to achieve automation, once network models are trained and deployed in the cloud, they can be continuously refined automatically. Live data from real time capturing from various tools can be fed to the models for wildfires detection without much human intervention. A process, feeding of the live data, refining the model and automatically redeploying the model in the cloud will greatly help our societies to fight the increasing risks of wildfires across the globe, and also will help to reduce the carbon emissions resulting from wildfires.

Severely Degraded Underwater Image Enhancement with a Wavelet-based Network

Shunsuke Takao, Tsukasa Kita, Taketsugu Hirabayashi

Department of Infrastructure
Digital Transformation Engineering,
Yokosuka, Japan

***Abstract*—Underwater images are important in marine science and ocean engineering fields owing to giving color information, low cost, and compact. Yet obtained underwater images are often degraded and restoring and enhancing wavelength selective signal attenuation of underwater images depending on complex underwater physical process is essential in practical application. While recently developed deep learning is a promising choice, constructing sufficiently large dataset covering whole real images is challenging, peculiar to underwater image processing. In order to supplement relatively small dataset, previous studies alternatively construct an artificial underwater image dataset based on a physical model or Generative Adversarial Network. Also, incorporating traditional signal processing methods into the network architecture has shown promising success, though enhancement of severely degraded underwater images remains to be a big issue. In this paper, we tackle underwater image enhancement based on an encoder-decoder based deep learning model incorporating discrete wavelet transform and whitening and coloring transform. We also construct a severely degraded real underwater image dataset. The presented model shows excellent results both qualitatively and quantitatively in the artificial and real image dataset. Constructed dataset is available at https://github.com/tkswalk/2022-IJACSA.**

***Keywords*—Underwater image enhancement; deep learning; discrete wavelet transform; whitening and coloring transform**

I. Introduction

Underwater optical images are essential in sensing vast ocean environment. Optical cameras beneficially capture high resolution color information, as well as relatively low cost and compact compared to other acoustic devices. While underwater optical images are essential especially in tasks requiring color information, such as ocean monitoring, maintenance of port facilities, and resource development, serious image degradation is obstacle in efficient utilization. Specifically, wavelength selective color distortion which displays blueish, greenish, and yellowish appearances, or decreased contrast caused by complex underwater physical process worsens the visibility of an underwater image [1], [2], as shown in the upper part of Fig. 1.

To overcome the low visibility of underwater images and expand the scope of application, underwater image enhancement methods based on deep learning have rapidly improved by refining model architecture and training dataset. In underwater image enhancement, deep learning models are mainly trained by mapping degraded images to the corresponding clear images. However, collecting clear and degraded real underwater image pairs is high cost or inherently difficult especially in turbid water in a coastal region. Alternatively, artificial underwater image datasets constructed with a simplified physical model or Generative Adversarial Network (GAN) are employed for training, yet their effectiveness are limited because real underwater images depend on complex physical process and many physical parameters like water body or ambient light and may be apart from artificial images [3], [4]. Subsequently, an artificial underwater image dataset based on the revised underwater image formation model [4] is recently proposed which more reflects real underwater environment [5].

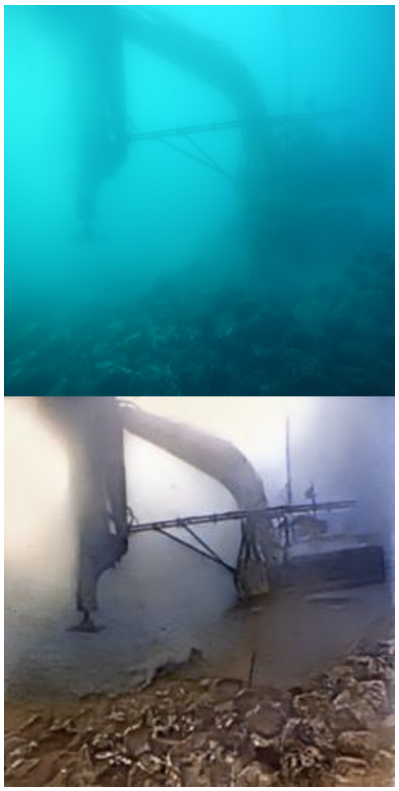

Fig. 1. An Example of a Severely Degraded Underwater Image (Above) and an Enhanced Result by our Model (Below).

Under the constraint of limited amount of data, incorporating traditional signal processing methods into the network architecture is also effective in underwater image enhancement. While the shallow CNN based model incorporating white balance, histogram equalization, and gamma correction has

shown measurable success, enhancement of severely degraded underwater images remains to be a challenging issue [6].

In this paper, we tackle severely degraded underwater image enhancement with an encoder-decoder based network combining discrete wavelet transform and whitening and coloring transform (WCT). The high frequency components of an input image is structurally extracted with discrete wavelet transform in the encoder part, and is preserved by passing them to the decoder part, thereby obtaining a sharp output. Also, as underwater images are quite diverse and display various tones of color and degrees of blurriness, input image features are whitened and mapped to style image features with WCT to stabilize training. The presented model is trained with the recently proposed physically revised artificial underwater image dataset [5] and an elaborated loss function. Also, we present a seriously degraded real underwater image dataset taken in Okinawa, Japan. The constructed dataset includes blueish and greenish images of divers, an underwater construction machine, and rubble mounds of port structures. Our underwater image enhancement model is evaluated with the artificial image dataset and the constructed real image dataset, showing fine results both qualitatively and quantitatively. Our main contributions are summarized as follows:

- We present an underwater image enhancement model combining discrete wavelet transform and whitening and coloring transform.
- We construct a real underwater image dataset including severely degraded blueish or greenish underwater images.
- The presented model successfully removes overall blueish tones of seriously degraded underwater images, mainly outperforming state-of-the-art underwater image enhancement methods both in real and artificial datasets.

II. Related Work

A. Previous Underwater Image Enhancement Methods

Supervised underwater image enhancement models based on Convolutional Neural Network (CNN), Generative Adversarial Network (GAN), and recently appeared Vision Transformer (ViT), have rapidly improved. As models mainly learn pixel transformation tasks, skip connection is often employed not to apart from the original input image. Also, encoder-decoder process is adopted to mitigate the input noise. To be specific, UWCNN is a densely connected CNN model where an input is injected to the different layers with no pooling layers or batch normalization steps [7]. FUnIE-GAN is a fully convolutional conditional GAN model. The generator has five encoder-decoder pairs with several skip connections to enable real time inference [8]. The above two models are either trained with an artificial underwater image dataset. Recently proposed ViT based model is also equipped with several skip connections to stabilize training. To cope with wavelength selective and spatially variant signal attenuation of underwater images, channel-wise attention and spatial-wise attention are incorporated into the architecture [9]. As the difficulty of covering whole real underwater images, incorporating traditional signal processing methods to the network process is effective in underwater image processing. For example, Water-Net is a simple CNN based network which fuses the results of white balance, gamma correction, and histogram equalization [6]. First, three results of each signal processing methods and the original input are fed to the network to predict the three fusion coefficient maps. The predicted three coefficient maps are multiplied by the enhanced results which are obtained by passing through the three independent feature transformation units to reduce the artifacts introduced from the signal processing methods. The refined output is finally obtained by fusing the above three results. Also, discrete wavelet transform is employed to preserve fine image structure [10], [11]. Other than learning based methods, many unsupervised underwater image enhancement methods assume physical model and correct color distortion by imposing white balance, which often requires the estimation of ambient light or average color [12], [13].

B. Previous Underwater Image Datasets

As obtaining sufficient real underwater image pairs is challenging, construction of the dataset itself is important in underwater image processing. Based on a simplified underwater image formation model, [7] constructed an artificially deteriorated underwater image dataset to which visually matches real underwater images by setting the attenuation coefficient to a constant and neglecting other related physical parameters. More recently, based on the revised underwater image formation model [4], an artificial underwater image dataset is proposed which clearly takes into account the dependency of water types, lightning conditions, and camera sensors. The constructed dataset is implied to be more real compared to the previous one [5]. GAN-based approaches generate artificial underwater images by converting initially clear underwater images to degraded ones to cheat the classifier. The model is trained with an unpaired dataset by minimizing Cycle-Consistency loss [8], [14]. Other than artificial underwater images, clearly enhanced real underwater images are collected among results of many conventional enhancement methods by scoring human ranking by hand. This approach is expected to reflect human perceptions, yet is laborious and the sample size is limited to at most a few thousand [6], [9].

III. Methodology

Presented underwater image enhancement model is based on a simple encoder-decoder network architecture with several skip connections, similar to well known U-Net in image segmentation task [15], as shown in Fig. 2. Pooling and upsampling layers are respectively replaced with discrete wavelet transform and inverse discrete wavelet transform to maintain structural information. Whitening and Coloring Transform (WCT) mainly employed in style transfer task is also incorporated into the model to mitigate covariate shift between training data distribution and test data distribution. Brief introduction of discrete wavelet transform and WCT is described followed by the details of model architecture.

A. Signal Reconstruction with Wavelet Transform

The power of discrete wavelet transform (DWT) especially using Haar wavelet is shown in style transfer and inverse problems by generalizing conventional pooling operations

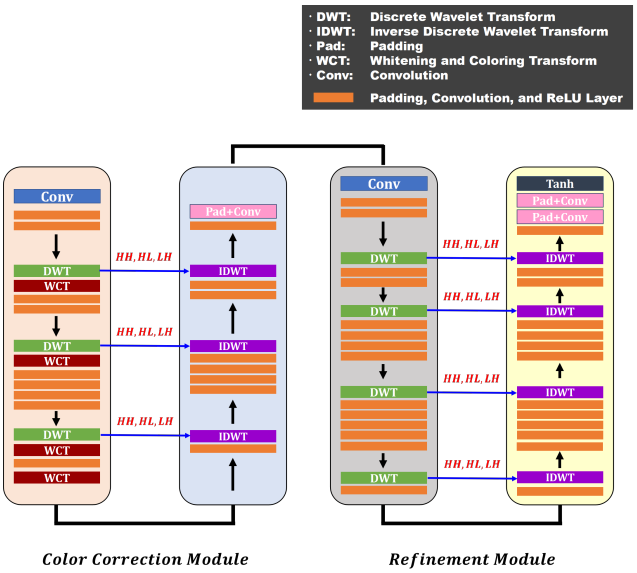

Fig. 2. An Overview of the Model Architecture. An Input Image goes through Several Convolution, Padding, and ReLU Layers Followed by WCT Layers in the Color Correction Module. High Frequency Components, HH, HL, LH, Extracted with Discrete Wavelet Transform in the Encoder are Passed to the Decoder to Preserve Detailed Signal. Compared to Color Correction Module, the Refinement Module is Simply Implemented by Removing the WCT Layers and Adding Several Convolutional Layers to Mitigate Noise.

like average pooling or max pooling, which simply subsamples and summarizes the neighboring pixel information [16], [11], [17]. Haar wavelet operation consists of four kernels, $\{LL^T, LH^T, HL^T, HH^T\}$, where L and H are respectively defined as $L^T := \frac{1}{\sqrt{2}}[1 \quad 1], H^T := \frac{1}{\sqrt{2}}[-1 \quad 1]$. Frequency information is efficiently retained and extracted with L and H, and low frequency signal is captured by L while high frequency signal is captured by H. Inverse discrete wavelet transform (IDWT) is the mirror operation of discrete wavelet transform and is employed for structural reconstruction in the decoder part with minimal noise amplification.

B. Whitening and Coloring Transform (WCT)

The aim of WCT in style transfer is to obtain a stylized image preserving content features [18]. After feature extraction with a pre-trained network, covariance matrix of high dimensional feature maps f_c of content image is first made to be an identity matrix (whitening), followd by singular value decomposition. The whitened content feature $\hat{f}_c$ is then projected onto the eigenspace of the style feature f_s (coloring), described as following procedure:

1) Whitening: Obtain whitened feature $\hat{f}_c = E_c D_c^{-\frac{1}{2}} E_c^T f_c$
2) Coloring: Obtain colored feature $\hat{f}_{cs} = E_s D_s^{\frac{1}{2}} E_s^T \hat{f}_c$

where E_c and D_c are respectively an orthogonal matrix of eigenvectors and a diagonal matrix of the covariance matrix of f_c, and E_s and D_s are that of f_s. Here, $f_c f_c^T = E_c D_c E_c^T$ is satisfied. Colored feature $\hat{f}_{cs}$ satisfies $\hat{f}_{cs}\hat{f}_{cs}^T = f_s f_s^T$, preserving higher order feature correlation which reflects style information. As underwater image distribution is complex and various,

Fig. 3. Our Model Recovers the Severely Degraded Artificial Underwater Image Better (Right) Compared with the Baseline (Left).

TABLE I. PSNR AND SSIM OF OUR MODEL AND BASELINE PER 10 WATER TYPES.

WCT is incorporated in our model to mitigate the covariate shift between training data and testing data.

C. Network Architecture

The network architecture shown in Fig. 2 is a simple encoder-decoder based model with several skip connections and no pooling layers. In order to preserve detailed image signal, high frequency components extracted with discrete wavelet transform in the encoder part, $\{LH^T, HL^T, HH^T\}$, are passed to the inverse discrete wavelet transform in the decoder part. WCT is incorporated in the color correction module to normalize feature maps.

Input images are first passed through a convolutional layer followed by several convolution, padding, and ReLU activation layers in the color correction module. Then, encoded features go through the discrete wavelet transform layer and low frequency component, LL^T, is processed with WCT and subsequent deeper layers. The remaining high frequency components, LH^T, HL^T, HH^T, are skipped to the decoder part to preserve detailed signal. The encoded features and the passed high frequency components are up-sampled with inverse discrete wavelet transform followed by several convolution, padding, and ReLU activation layers. The subsequent refinement module is similar to the color correction module, but WCT is removed and several convolution, padding, and ReLU activation layers and the last layers of padding, convolution, and hyperbolic tangent activation layer are added to mitigate input noise. Such repeated structure is designed to extract local image structure. Kernel size and stride of all convolutional layers are set to 3 and 1, respectively. We use pre-trained model on photo-realistic style transfer method [11], denoted as baseline, to normalize the complex input distribution caused by the complicated real underwater environment. Our model is similar to [11], but one DWT and IDWT layers, a few convolution, padding, and ReLU activation layers, and the last layers of padding, convolution, and hyperbolic tangent activation layer are added. Here, Fig. 3 shows that

Fig. 4. We Collect Real Underwater Images around Rubble Mounds of Port Structures taken in Okinawa, Japan. The Collected Underwater Images are Significantly Degraded, Showing Blueish or Greenish Appearances.

our model recovers the severely degraded artificial underwater image better (right) compared with the baseline (left). As for quantitative metric, Peak Signal to Noise Ratio (PSNR) and Structural Similarity Index Measure (SSIM), full reference metrics of image quality which reflects human perception, are computed. PSNR and SSIM of our method and the baseline per 10 water types classified by [19], are shown in Table I. Scores of PSNR and SSIM are improved approximately 1 and 0.3, respectively, compared to the baseline in all water types.

D. Loss Function

We combine three loss terms, reconstruction loss L_{rec}, Laplacian pyramid Lap1 loss L_{lap}, and luminance loss L_{lum} between a correct image I_c and an estimated image I_e for training our network, defined as follows:

$$Loss = \alpha L_{rec} + \beta L_{lap} + \lambda L_{lum} \tag{1}$$

where α, β, and λ are hyper parameters.

Reconstruction loss L_{rec} means the pixel wise l1 distance between I_c and I_e, denoted as follows:

$$L_{rec}(I_c, I_e) = |I_c - I_e|_1 \tag{2}$$

Laplacian pyramid Lap1 loss L_{lap} measures differences between I_c and I_e in Laplacian pyramid representation to take into account various frequency components and get a structural image [20], [21], defined as:

$$L_{lap}(I_c, I_e) = \sum_{i}^{2^{2i}} |L^i(I_c) - L^i(I_e)|_1 \tag{3}$$

Here, $L_i(I)$ means the i-th level of the Laplacian pyramid representation of an image I [22].

Also, we propose luminance loss L_{lum}. The luminance loss measures pixel wise difference between I_c and I_e of their luminance components after transforming to YCbCr color space, described as follows:

$$L_{lum} = |Y(I_c) - Y(I_e)|_1 \tag{4}$$

where luminance component Y can be defined as:

$$Y = 0.299R + 0.587G + 0.114B$$

Here, R, G, and B mean the red, green and blue channels of the original image, respectively. The luminance loss is proposed to facilitate training, as luminance components are less susceptible to color tones of an underwater image.

IV. Experiments

A. Construction of Real Underwater Image Dataset

We collected real underwater images around rubble mounds of port structures in Okinawa, Japan. The constructed dataset contains significantly degraded underwater images of an underwater construction machine, a diver, and rubble mounds, which are taken with GoPro HERO4. As shown in Fig. 4, the underwater images are directly taken by a diver or a camera mounted with the upper part of the construction machine, showing blueish or greenish appearances. The constructed dataset is available at https://github.com/tkswalk/2022-IJACSA.

B. Experimental Setting

We train the model with a recently proposed artificial underwater image dataset [5] based on the revised underwater image formation model which more reflects real underwater environment. The model clearly considers the dependencies of related physical parameters, such as water types, lightning conditions, and camera sensors [4]. In the dataset, wavelength data of 10 water types classified by [19], two camera sensors, and the three light spectrum data are employed, namely 60 kinds of artificial images are generated per one image. Clear indoor RGB-D images from NYU Depth Dataset V2 [23] containing depth information are transformed based on the underwater physical model, resulting in 86940 image pairs in total [4], [5]. Among the 1449 original images from NYU Depth Dataset V2, first 1000 images are used for the training data, next 300 images are used for the validation data, and the last 149 images are used for the test data.

A degraded input image is first resized to 256 $\times$ 256 resolutions and mapped to an enhanced image. The coefficients of the loss function, α, β, and λ, are respectively set to 1, 10, 1. Adam optimizer [24] is adopted and the learning rate is set to 0.0001. The training epoch is 80 and the model is implemented with PyTorch and GeForce RTX 2080 Ti GPU.

C. Results and Discussions of Artificial Underwater Images

We qualitatively and quantitatively compare the restoration results with available state-of-the-art underwater image enhancement methods. As shown in Fig. 5, FUnIE-GAN (4th row) [8], UWCNN [7] (7th row), Water-Net [6] (8th row), and U-Transformer [9] (9th row) are evaluated for the deep learning based approaches, while results of retinex-based theory (5th row, denoted as Retinex) [13] and underwater dark channel prior (6th row, denoted as UDCP) [12] are also compared for the unsupervised methods. The first row of Fig. 5 shows the

TABLE II. RESULTS OF PSNR PER 10 WATER TYPES

Ours	0.702	0.686	0.684	0.608	0.649	0.7	0.652	0.662	0.626	0.629

employed test data of indoor images from [23], and they are artificially converted based on a underwater image formation model, as shown in the second row. PSNR and SSIM, full reference metrics measuring the image quality, are calculated for the quantitative evaluation.

The artificial underwater image dataset contains various colors and degrees of degradation which reflects water types or lightning conditions [5]. In qualitative evaluation in Fig. 5, many restoration results are not sufficiently well recovered because of the severe image degradation of an input. While our model relatively well restored blueish, greenish, and yellowish artificial underwater images (3rd row), previous methods hardly improve the visibility (4th [8], 6th [12], and 7th row [7]) or insufficiently output whitish images (5th [13], 8th [6], and 9th row [9]). Also, PSNR and SSIM per 10 water types classified by [19] are respectively shown in Table II and Table III. Our model achieves better performance compared to other methods in 9 out of 10 water types. While our model mainly outperforms other methods in almost all water types, output images are sometimes decolored as shown in the 4th column of the 3rd row.

D. Results and Discussions of Real Underwater Images

Next, we proceed to restoration results of real underwater images, as shown in the 1st row of Fig. 6. Real underwater images of 1st to 3rd column come from the constructed dataset collected in Okinawa, Japan, and the remains come from [6] which contains severely degraded underwater images. Our model (2nd row) restores significantly degraded blueish (1st, 2nd, 3rd, 6th column), greenish (4th column), and yellowish (5th column) underwater images. The output images contain less overall blueish tones compared to results of other methods. Among the results of previous methods, Water-Net [6] (7th row) combining white balance, gamma correction, and histogram equalization, are better also in the yellowish and greenish inputs, yet failed to restore the severely degraded input (1st column). The performance of Water-Net is mainly dominated by the signal processing results as Water-Net fuses outputs of them. FUnIE-GAN [8] (3rd row), GAN based model, hardly improves the visibility and adds grid artifact in severely degraded inputs. UWCNN [7] (6th row), CNN based model, introduces color bias as shown in the 4th and 5th column. Vision transformer based U-Transformer

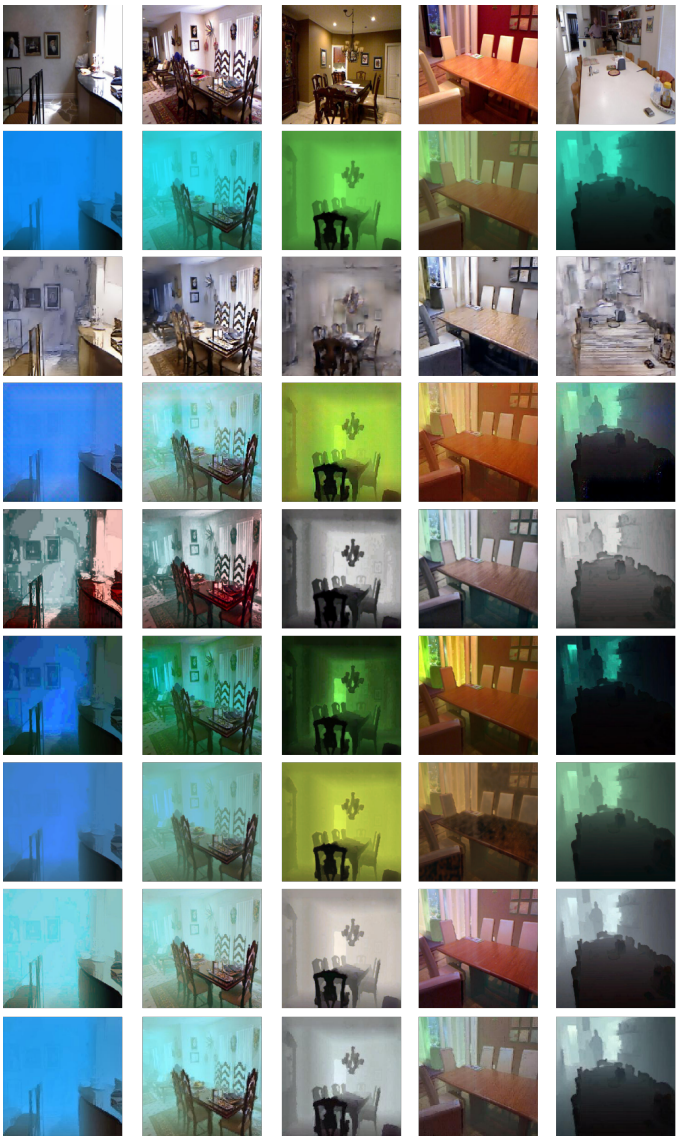

Fig. 5. Restoration Results of Artificial Underwater Images. 1st Row Shows Original Indoor Images, 2nd Row Shows Transformed Input Images, 3rd Row Shows Results of Proposed Model, 4th Row Shows FUnIE-GAN [8]. 5th Row Shows Retinex [13], 6th Row Shows UDCP [12], 7th Row Shows UWCNN [7], 8th Row Shows Water-Net [6], and 9th Row Shows U-Transformer [9].

[9] (8th row) failed to recover greenish and yellowish inputs, respectively shown in the 4th and 5th column. Among the non-learning based methods, Retinex [13] (4th row) corrects a greenish image (4th column), yet also adds reddish color bias in other images (2nd, 3rd, and 6th column). UDCP [12] (5th row), statistical method, hardly improves the overall visibility. As no ground truth is available in real underwater images, PSNR and SSIM are not computed. As real underwater images are tremendously diverse, many supervised models fail to enhance severely degraded underwater images. Among results of previous methods, better results are obtained with Water-Net [6]. Compared to Water-Net trained with a dataset less than 1000 real underwater images, our training dataset is about 100 times larger than that of Water-Net. Also, large amount of severely degraded underwater images are included [5], thus

perceptually better results are tend to be obtained with our model, as shown in the 1st column of Fig. 6.

E. Ablation Study of Loss Function

Ablation study of loss function in Eq. (1) is shown in this section. PSNR and SSIM scores per 10 water types are computed in Table IV. Results of employing only reconstruction loss L_{rec} are denoted as $L1$, plus luminance loss L_{lum} are denoted as $L1 + lum$, and all loss are denoted as ALL. Each loss functions contribute the scores in almost all water types. While proposed luminance loss L_{lum} in Eq. (4) improves less, we observe that the luminance loss stabilizes the training, as it doesn't depend on input color.

TABLE IV. Ablation Study of Proposed Loss Function

Water-type		I	IA	IB	II	III	1C	3C	5C	7C	9C
PSNR	L1	16.37	16.081	16.269	14.832	15.485	16.659	15.62	15.873	15.174	15.265
	L1+lum	16.392	16.1	16.251	14.877	15.551	16.651	15.665	15.857	15.24	15.318
	ALL	16.61	16.316	16.568	15.124	15.8	16.987	15.94	16.214	15.485	15.559
SSIM	L1	0.694	0.675	0.672	0.591	0.633	0.689	0.635	0.646	0.607	0.609
	L1+lum	0.695	0.677	0.673	0.593	0.635	0.69	0.637	0.647	0.609	0.611
	ALL	0.702	0.686	0.684	0.608	0.649	0.7	0.652	0.662	0.626	0.629

V. Conclusion

This study tackles significantly degraded underwater image enhancement with a deep learning model incorporating discrete wavelet transform and whitening and coloring transform. The presented model is trained with the elaborated loss function and recently proposed physically revised artificial underwater image dataset. We also construct real underwater image dataset taken near the rubble mounds of port structures. The dataset characteristically includes severely degraded blueish or greenish underwater images. The presented model outperforms previous state-of-the-art underwater image enhancement models in 9 out of 10 water types in the evaluation employing an artificial underwater image dataset. Also, our model successfully removes blueish tints from real underwater images, showing splendid results qualitatively and quantitatively.

***Abstract*—An adaptive e-learning scenario not only allows people to remain motivated and engaged in the learning process, but it also helps them expand their awareness of the courses they are interested in. e-Learning systems in recent years had to adjust with the advancement of the educational situation. Therefore many recommender systems have been presented to design and provide educational resources. However, some of the major aspects of the learning process have not been explored quite enough; for example, the adaptation to each learner. In learning, and in a precise way in the context of the lifelong learning process, adaptability is necessary to provide adequate learning resources and learning paths that suit the learners' characteristics, skills, etc. e-Learning systems should allow the learner to benefit the most from the presented learning resources content taking into account her/his learning experience. The most relevant resources should be recommended matching her/his profile and knowledge background not forgetting the learning goals she/he would like to achieve and the spare time she/he has in order to adjust the learning session with her/his goals whether it is to acquire or reinforce a certain skill. This paper proposes a personalized e-learning system that recommends learning paths adapted to the users profile.**

***Keywords*—e-Learning; adaptive learning; recommendation system; ontology**

I. Introduction

With the broad coverage of the internet, access to learning content through the web has become increasingly easy. A variety of educational systems such as MOOCs[1] [1] have emerged, with an essential mission that is provide educational content, to learners willing to learn; yet the diversity of people implies that each learner has her/his own particular preferences, knowledge and competencies. In that perspective adaptability was a major and essential criteria to add to e-learning systems providing learning resources, to make learning content suitable to learners. This adaptation takes a process that is established in many levels. At the cognitive model level as Ruiz et al. [2] propose, it have to go through the following steps:

- to classify the user by choosing a suitable learning style;
- to present adaptation to system by developing good techniques then conceive that adaptation to suits the user's preferences;
- choosing the right technologies and realization of that adaptation on a computer.

Brusilovsky and Millan [3] on the other hand put focus on the user modeling inside an adaptive system where the user information are a distinctive aspect to consider when the system intervene. The interaction of the user should be noticed with attention, when she/he searches, navigates; but also her/his interest, knowledge, background, learning style, goals, etc. The priority should be given to the content suitable to what user interest in the most. User modeling featured-based or stereotype-based [3] should either way take into consideration the personal information of the individual. A definition of adaptation is the reconfiguration of entities in order to adjust them to a certain request. It can be categorised as the following according to [4]:

- *Machine Centred:* In this case, the learning process is guided by a series of actions from user and analyzed by her/him.
- *User Centred:* The learning resources (lessons) are personalized by learners themselves as stats [4].

Underneath these categories we find several kinds of adaptation [3], [4]. We mention:

- *Adaptation of Content/Adaptive Evaluation:* The content of activities and resources are faced to dynamic change.
- *Adaptation of Visual Presentation:* It represents mainly the components of an interface and their properties, how and where they are displayed.
- *Adaptation of Learning Process:* The learning process is dynamically modified to the manner in which the courses contents are provided in suitable ways.
- *Adaptive Information Filtering:* The system takes care of suitable information retrieval in order to give relevant results to user.
- *Adaptive User Grouping:* This allows a distant learners to collaborate and provide assistance in achieving specific tasks.

However we could not talk about adaptation in a system without mentioning personalization which according to [5] is included into a simple mechanism that need specific technologies to ensure accurate results. Adaptation inside a system

[1]Massive Open Online Courses

takes multiple parameters. The most important one, and regardless the technique used, is the user profile and information; taking into consideration that the user interest and motivation are what will keep her/him continue learning. Therefore well modeling her/his profile is essential. This profile is a personification of different features of user. We note this profile can be built from two types. The first one constitutes a general profile not specific to any user characteristic. The second one is the developed version of the former. After extracting the user information, a personalized profile is created to represent her/him. This study provides a critical overview of previous research related to adaptive recommender systems in e-learning field. Mainly we seek to answer the following research questions:

- What aspect of adaptation should be enhanced and why?
- How is adaptation implemented in recommendation systems?
- How to enhance it?

This paper is organised as follow: Section II will outline similar research work papers. Then in Section III we will underline common techniques and methods used for adaption in adaptive e-learning systems. Section IV presents a comparison about different adaptive systems. Their advantages and drawbacks are highlighted. Section V details our proposition, then in Section VI, we make a position from the current research tendency in e-learning adaptive recommender systems and their techniques, which further consolidates our proposition in the previous section. Finally, Section VII concludes this paper and presents some perspectives.

II. Adaptive E-Learning Systems

Many studies have been conducted in the field of adaptive e-learning systems. In this section, we present an overview of the research papers selected from the literature review. We mention most relative ones from 2017 to 2021. This selection was based on the relevance and the level of the adaptability in e-learning systems in terms of adaptive information filtering, adaptive user profile and adaptive users group. The process of selection was made as follows: among many articles found in Google scholar, ResearchGate[2], DBLP[3] while searching for keywords such as "adaptation in e-learning systems", "recommendation techniques", "adaptative systems", etc. 26 papers were selected based on their relevance, their accuracy, and the number of citations in others research works. Of these 26 articles, we have selected seven (7) to be mentioned, based on the year of publication and direct projection of their content on our research.

Almmouhamadi et al [6] present a survey on the rising techniques of adaptation in educational adaptive systems. They emphasize the two most used techniques of data mining in AI: (i) the predictive which is a prediction of the next tag in general. By selecting a predictor variable or group of variables, these techniques are applied to extract single or multiple variables with predicted values; it is about predicting a missing or unknown item of a dataset, and ii) the descriptive (clustering) one which is based on grouping similar objects. The primary uses of clustering are to segment or categorize (e.g., sorting customer data by age, occupation, and residence) or to extract knowledge in an effort to find subsets of data that are challenging to categorize. This method is about determining a class for an element in a dataset. For instance, we can think of prediction as anticipating the appropriate course of treatment for a certain disease in a specific individual. Whereas the grouping of patients based on their medical records can be considered classification.[4]

George and Lal [7] show how ontology-based recommender systems became an emergent research way in the e-learning field. Those systems address most of issues found in e-learning recommender systems. Giving personalized recommendations to learners is one of the practical applications of employing ontology-based recommender systems. Based on the learner's interests, goals, etc., the recommendations that are given to them become precisely relevant. As a result, the learner is encouraged to finish what she/he started. They illustrated their point of view after a study on research papers published during the last decade concerning the recommender systems in e-learning. They present extraction and modeling techniques used and compare existing recommender systems in e-learning in the scope of these techniques. From another perspective Eke et al. [8] focused on user profiling methods, and the challenges such as multi-dimensional representation, privacy of user's information, cold start problem for new users, temporal behaviour of individuals, limitation of interest, etc. They also discuss the most relevant solution for those challenges such as ontology representation and general purpose profile, and so on.

In [9], Nabizadeh et al. outline the personalization methods and illustrate the challenges facing those methods, and how to improve the existing personalization techniques. Zaoudi et al. [10] present a critical research paper on existing approaches used in learning scenarios and adaptive e-learning situations.

Then Javed et al. [11] present review of a widely used methods in recommender systems, context-based and content-based, and a hybrid method combining multiple methods in order to benefit of the advantage of each method to cover the disadvantages of each one. Just recently, Raj and Ranumol [12] provide a review of research papers on a period of time from 2015 to 2020, with critical study of adaptive recommender systems proposed comparing on one hand methods used in those systems, from the hybrid methods, content or agent-based, semantic web based, etc. On the other hand, they are also comparing the attributes such as the user content rating, learning style, knowledge level, etc.

Table I summarises our comparison of recent research works, which we analyse in Section IV.

III. Recommendation Techniques

Adaptive recommendation systems can be divided into knowledge-based, content-based, user-based or based on hybrid approaches. They can be categorised according to what the adaptation is based on and on the recommendation techniques

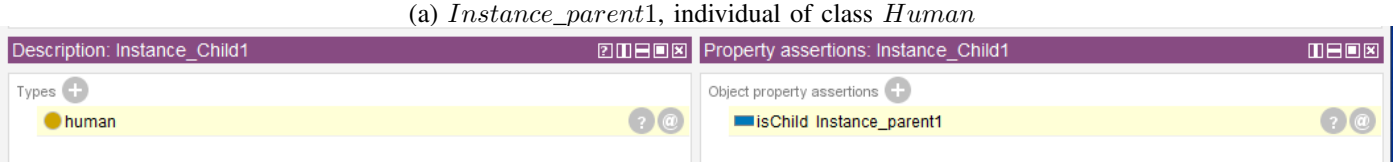
(a) $Instance\_parent1$, individual of class $Human$



(b) After inferences

Fig. 1. Example of Inferred Knowledge by the OWL Reasoner HermiT.

used. Following those used techniques the adaptation can be based on:

- *User's Profile:* this method takes into account the characteristics of the user defined by her/his intrinsic characteristics, her/his preferences for the presentation of pedagogical resources to be recommended (text, audio, video, etc.), and the experience of other users with similar profiles. To do this, several techniques have been implemented to model user profile. This allows a learner model to be designed which, according to [13], is the representation of specific characteristics of a learner that may be relevant for a personalized interaction. Managing users' profile allows the user learning style to be predicted. Most of them are based on the widely used learning model "*The Felder and Silverman Learning style Model*" (FSLSM) [14]. It is worth noting that the learner model is not intended to be a representation of the learner's mental state but rather of the learner's characteristics such as personal information (age, gender, country, native language, etc.), cognitive traits, knowledge and skill levels, preferred learning styles, and personal preferences, such as cultural background, format of learning resources (text, audio, video, etc.), preferred language, etc. Munassar and Ali [15] and Aissaoui and Oughdir [16] propose a framework based on user profile modeling using ontologies, which represent the terminology (TBox) and assertions (ABox) such as instances of concept. From a knowledge base, a reasoner checks the consistency of the model and infer new knowledge depending of description logic level used [17].
  For example, let us an ontology O (for didactic purposes):
  $Human(Instance\_parent1)$
  $isParent(Instance\_parent1, Instance\_Child1)$
  $Human.isChild \equiv Human.isParent^{-}$
  We can see below in Fig. 1 how the reasoner HermiT[5] inferred new knowledge.
  Fig. 1(a) shows an individual $Instance\_parent1$ of a class $Human$ with a role (i.e. Object Property assertion in the editor Protégé[6]) $isParent$, which is the inverse role of $isChild$.
  Fig. 1(b) displays, after starting the reasoner HermiT, new knowledge that has been inferred about $Instance\_Child1$ which belongs to class (noted *type* in Fig. 1) $Human$, represented in description logic by $Human(Instance\_Child1)$ and the new object property assertion $isChild(Instance\_Child1, Instance\_parent1)$.
- *Knowledge-Based:* this approach with slight similarity with the user profile based approach, in representing knowledge. It helps making recommendation by extracting information. In general, a reasoning system is behind that decision making, after having well represented knowledge.
  item *Content-Based:* which is based on the content of the started themes. The evaluation of the content is done in an explicit way by the attribution of notes directly to the documents which represent the contents of the topics, or in an implicit way when the system estimates through user interactions the degree of relevance of a document [18].
- *Collaborative Filtering:* which is a widely used method that consists in projecting the preferences of an individual to a group of similar users. In other words, the recommendation is made on the basis of what our neighbors (users with similar profiles) have appreciated [19];
- *Social-Based:* basically these methods can be used to enhance an already existing system, by using social network to create similar groups [20]. One might assume that users who are friends on social networks can have a common interest, or even one user can be interested in a resources because her/his friends were or are interested in taking it. It would be interesting to detect the influencers. User activity on social-media also in recent years formed a good source for recommendation, the time she/he spends watching a video can give an idea on languages she/he understands, and the subjects that interest her/him. Furthermore the content she/he likes and comments or shares also are considerable source. Her/his geolocation history can also be known through her/his publications and the location she/he visits. A variety of information can be extracted through social networks.

TABLE I. COMPARISON OF ADAPTIVE RECOMMENDER SYSTEMS IN E-LEARNING

Reference	KB	CB	UB	MU
Sarwar et al. [22]	X	-	X	hybrid techniques + ontologies
Agbonifo et al. [23]	-	X	X	collaborative filtrage + ontologies
Vagale et al. [24]	-	X	X	extraction form user model
Boussakssou et al. [25]	X	X	-	Q-learning
Shi et l. [26]	X	X	-	A designed knowledge graph +Bloom's taxonomy
Azzi et al. [27]	X	X	-	Automatic prediction of Learning style + Fuzzy C-means
El Fazazi et al. [28]	X	X	X	MAS+Q-Learning algorithm

- *Hybrid Methods:* they combine two or more approaches of the previous types of recommendation techniques [21]. For example, it can be based on user characteristics by modeling the learner's profile in the first step and, in the second step, recommending resources adaptively with respect to the profile. Usually the combination of these techniques aims to overcome the drawbacks such as the sparsity issue which is due to lack of user rating. Users are reluctant to give feedback on items they have tested. In addition to the sparcity, we mention the cold start problem faced by new users or new item. This issue shows up, when there is not a review/ratings of an item, making it unrecommendable despite its importance and relevancy. The same applies on new users. The difficulty of making recommendations based on a user's profile increases for new users with new profiles.
  Hybride methodes benefits of the advantages of each techniques used. However, some limitations still persist and even new challenges appear in hybrid approaches.

IV. COMPARISON OF ADAPTIVE RECOMMENDER SYSTEM

In this section, we compare adaptive recommender systems proposed firstly in terms of adaptability techniques used: Knowledge-based (KB), Content-Based (CB), User-based (UB) and Method-Used (MU);

and secondly in terms of adaptation itself, based on the two types mentioned in above Section I

Table I gathers recently proposed adaptive e-learning systems using different methods. We notice that [22], [23] are generally using ontology to model content or user profile in their work along side with machine learning techniques, whereas [26], [24], [25] used knowledge designed graphs to represent the user model, or Q-learning [29] with machine learning techniques.

On the other hand, Azzi et al. [27] are more focused on users learning style. They proposes an approach that predicts the user learning style and stores then the collected data. We notice that most of the adaptation techniques used belong to two main ranges, to ontology for modeling and representation, and to machine learning methods. Also other researches tend to combine two at least methods in order to develop an hybrid technique.

These systems mainly evaluate the user performance and make recommendation based on collective preferences like Agbonifo and Akinsete [23] in their work experiments. This method is not the most efficient way due to the lack of specification in those rating (based on what and by who).

Content modeling of learning objects also is another part that should be considered as important as the profile modeling. Moreover it is worth noting the low number of pedagogical resources used in evaluation when seeking for users ratings about a course.

On the other hand the hybrid techniques implemented in those systems whom the semantic part for modeling content and profiles candidate them to be technically efficient as they are using latest technologies tendencies.

Table II gathers previously mentioned systems and lists the types of adaptation presented in the proposed work. We notice that only Boussakssou et al. [25] integrate an adaptation based on user action in their proposed work. Whereas [22], [24] described a group based adaptation and then a content adaptation in [24]. In [28] along with [24] propose an adaptation model that assures course adaptation. This adaptation relies on certain characteristics of the user such as background Knowledge and learning style using Q-learning in El Fazazi et al.s' works [28].

These comparison criteria are selected on the basis of the definition and the different types of adaptation mentioned above.

V. METHODOLOGY

Following our findings on the advantages and disadvantages of current adaptive recommendar systems, we propose a new architecture for piloting and customizing adaptive learning paths, while taking into account the users' profile, the training domain and the available educational resources, and adding synchronization in the collaborative mode between learners wishing to work in collaboration. This system is based on ontologies and a multi-agent system responsible of managing events that occur inside the system. Reasoning on ontologies allows to make tacit information explicit. Among other things, this allows for a better personalization of learning paths. On the other hand, multi-agent systems have shown their great capacity to orchestrate in real time a set of agents.

A. Adaptive and Collaborative Learning Piloting Architecture

This architecture is composed of a multi-agent system (MAS), which contains an agent manager representing the entry point of the main MAPE-K loop of the platform (cf. Fig. 2). This Agent analyzes the requests, processes them and manages the communication between the recommendation agents (RA), responsible for managing the creation of learning paths and the recommendation of educational resources.

TABLE II. COMPARISON IN TERM OF ADAPTATION

Azzi et al. [27]	-	-
El Fazazi et al. [28]	-	X

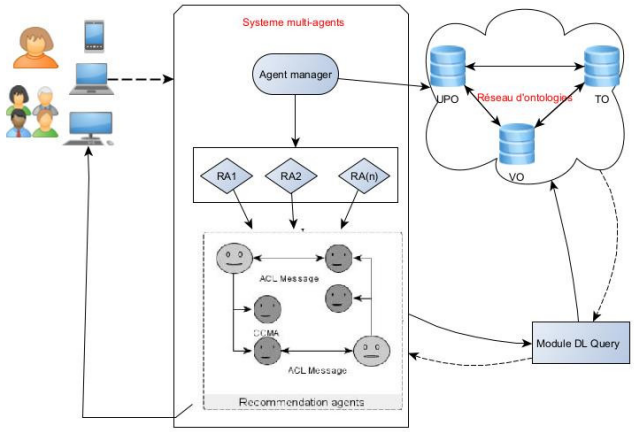

Fig. 2. SPACe-L Architecture.

B. Knowledge Base

The core of the platform is its knowledge representation by a network of ontologies describing three ontological models representing users profiles, training domains and video resources. This modularity is intended to facilitate the interoperability with other ontologies in the respect of the FAIR principles[7]. For example, the user representation (cf. Fig. 3) allows from the ontology FOAF data to be integrated. For the training domain, we can integrate ontologies describing competences like the ontology *COMP2* proposed by G. Paquette [30].

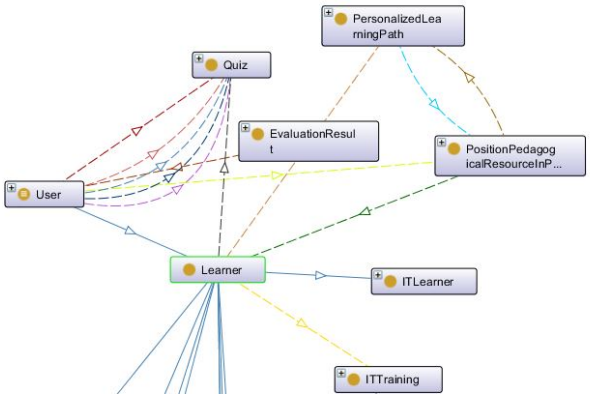

Fig. 3. Partial View of User Profile Ontology (UPO).

The partial view of UPO shown in Fig. 3 contains the personal information and preferences of the users. It mainly describes learners, their specific information, their initial or acquired skills and the personalized learning paths already completed or ongoing.

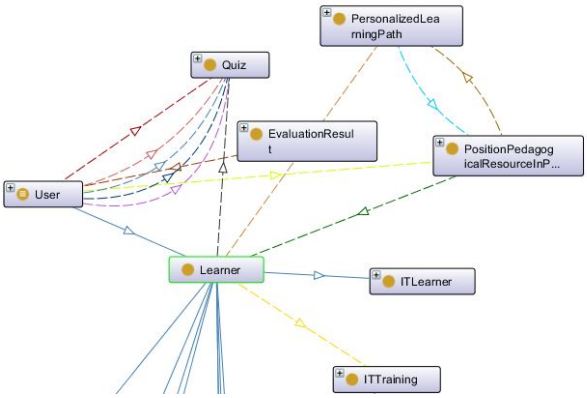

Fig. 4. Partial View of Training Ontology (TO).

The ontology of the training domains (TO) describes the competences to be acquired, the learning objects and the pedagogical resources that can be used in the different pedagogical units (Fig. 4).

C. Multi-Agent System

The multi-agent system (MAS) manages the events that occur in the system, under the supervision of the *Agent manager* who analyzes the requests received and manages the situation according to its nature. It plays a double role according to the learning situation, either individual through a recommendation agent, or collaborative. It then manages a network of recommendation agents for the synchronization of learners. The recommendation agent (RA) is associated to one user or group of users in collaborative situation. The recommendation agent will take care of the generation of the personalized path in the form of a graph by associating relevant pedagogical resources to each node of the graph.

The graph generation is done according to the user profile and the recommendation of the pedagogical resources according to several criteria including the learners' preferences, the duration of the session, but also the qualitative evaluations of the other learners, trainers or experts. The objective here is to maximize a fitness function (cf. Equation 1) which allows to dynamically generate a personalized learning path according to:

$$F = \sum_{i=1}^{n} W_i C_i \quad (1)$$

[7]https://www.go-fair.org/fair-principles/

Where W_i is the weight that defines the importance of C_i and n is the number of selected criteria of a pedagogical resource.

VI. Discussion

Based on the observation form the study done in this paper, it is obvious that adaptation in a recommender systems is essential in order to provide the learner what suits her/him. Therefore, machine learning, ontological and hybrid techniques have been applied in different propositions. We mention in particular the machine learning collaborative filtering technique for its frequent use in those systems. It is reasonable to understand it is widely implicated in most of adaptive e-learning systems since it is a new form of the most traditional method of recommendation (recommendation based on personal user experience). In addition, collaborative filtering system features include recommending an item by classing a list of object based on whether it might be interesting to the user. They include also predicting for a specific item and its rating by a user [31].

It is required, however, to pay attention to some of the challenges that can and have arisen; such as users rating to a certain pedagogical object (courses, learning object, learning path, pedagogical resources, etc.). The integrity of that rating cannot be measured in reality, without exposing publicly the interest of the user or her/his personal information, that leads to another privacy problem. In addition to these problems, we include the unequal number of users and votes on object. George and Lal [7] have pointed out in their research works that the number of users is higher than the number of votes.

Content-based method relies on the interaction of the user and data collection after. Therefore item description is as much as important as the user behaviour, seeing that the recommendation is established based on that. The steps of content-based recommendation techniques are as follows: (i) at the start, item description is stored after analyse, to determine the preferences of a user regarding this item for future use; (ii) then a comparison mechanism is done between user profiles and attributes of these items to sort only related items with similarities with that profile. That said, it still represents multiple drawbacks. Let us mentioning user preferences and interest that change and that affect directly the recommendation. Another issue is the privacy previously mentioned of the user. In order for these methods to have accurate recommendation a large and precise amount of information must be extracted, and that might expose the user privacy policy. Synonymy is also another issue represented by the fact that some of items can have very close description but they still different, which lead to erroneous recommendation [32].

Thus, Semantic Web is a research field existing since the late 90s, especially ontologies, which is promising due to its ability of sharing, reusing and inferring knowledge including through Linked Open Data (LOD), and its level of interoperability. Moreover, it is a good candidate to the FAIR principles (Findable, Accessible, Interoperable, Reusable) [33], [34]. They have also managed to address most of these problems. There is no uniform model for the learner profile or structured material in e-learning, which makes ontology even more relevant [7]. In addition, e-learning requirement can be satisfied by multiple uses of semantic web. This latter one is *Non-linear* as it allows user to describe the situation that she/he is currently in; for example the purpose of her/his learning, and the knowledge acquired. The Semantic Web is also *interactive* that agent can use commonly agreed service language, enabling collaboration between them. Despite the learning resources being distributed on the web, they are linked to one or more commonly accepted ontologies in the scope of semantic web (cf. LOD). Learning materials are distributed on the web, but they are linked to commonly agreed ontologie(s). This allows to build a course that is unique to the user by using semantic querying to find relevant subjects of interest [35]. Application of semantic web can create a responsive learning environment, a personalized learning materials where user only receives what suits her/him, and as much as decentralise content possible.

VII. Conclusions and Future Works

Adaptation in e-learning systems represents a trending research area. In this paper, we presented different adaptive e-learning systems representative of different categories. Several methods were experimented and compared, yet the existing methods have both benefits and drawbacks. The conflict of which one is more effective is still. Mainly the adaptation inside an e-learning environment is user centered even though many researches use the content-based method. Others tend to predict the learning style of the learner, or extract knowledge from user interaction and navigation history; while others lean to use techniques like collaborative filtering and machine learning methods. Except for the fact that user profile modeling remains the main axis to highly adapt content and the learner's need and interest. This being said modeling user is not an easy task to achieve, nor extraction her information by tracing her interactions through the web. Modeling user profile extends representing her interests, competences, expectations of the course and goals. It might reach her mental state at the learning session and after. We highlighted that modelling these new criteria implies a high complexity level in the adaptive process inside an e-learning system. That said the Semantic Web in a side is one sophisticated way to model a profile through the use of ontology. This research field can be highly explored and be employed to improve the current state of adaptive e-learning systems, especially the collaborative learning type which represents an important type of learning and increase learners motivation to reach new competences or reinforce competences.

However some of the relevant questions in that regard still exist such as how can the recommendation systems be improved? And in a more specific manner how is the adequate learning path recommended? How can one be sure we are actually getting the right pedagogical resources? All these questions concerns individual learning situations, it remains those regarding the collaborative situation mentioned earlier, how will the synchronisation between learner be established? Even if established how will the adaptation be maintained? How can we keep learners interested and motivated to finish the training and benefit it the most? How can we integrate citizen science in the scope of collaborative learning? These research questions are important to analyse and to focus on. In this paper we proposed a recommendation system based

on Semantic Web for knowledge representation and multi-agent system that manages the different events in the system. It seems to us that is a good way to answer of the above questions. However there are still several points to improve in order to obtain an advanced adaptive system. starting with enriching our ontology network with ontologies coming from some standards or norms of the educational sciences, and on other side improving response times for learning path and learning resource recommendations during users synchronization from what it concerns the multi-agent system performance.

A Comparative Research on Usability and User Experience of User Interface Design Software

Junfeng Wang*, Zhiyu Xu, Xi Wang, Jingjing Lu
College of Design and Innovation, Shenzhen Technology University, Shenzhen, China

***Abstract*—With the development of science and technology, people increasingly rely on intelligent interactive products, thus promoting the vigorous development of the user interface industry. Software with high usability and user experience can improve users' effectiveness and satisfaction, as well as the user viscosity. Taking three design software: Sketch, Adobe XD, and Figma, which is most frequently used by design industry practitioners and students, as research cases, this study compared and discussed the impact of interaction design and interface layout on the usability and user experience combining with subjective experiment methods, scale scoring, user testing and retrospective think-aloud interview, as well as objective experiment method, eye tracking. It is found that the overall usability and user experience of Figma is the best, Adobe XD is the second, and Sketch is the worst. The main reason for this result is that the three software have different degrees of issues in interface layout, information quality, and interaction logic. Based on the results, the optimization suggestions for the usability and user experience of user interface design software are proposed from three perspectives: interface design, information quality and interaction design.**

***Keywords*—Usability; user experience; interaction design; UI design software; eye tracking**

I. Introduction

With the rapid development of the Internet industry and the widespread use of new media, user interface (UI) design emerged, and corresponding tools and software also developed, as well as the application and design of software interfaces have been achieving greater improvement. UI design software play a significant role in the design and development of applications. However, there are few studies focusing on the usability and user experience of UI design software, which does not match the use of such software in the field of UI design [1]. In order to better understand the factors that affect the usability and user experience of this software and to enhance its interaction performance, research on UI design software is necessary. This research compares the overall usability and user experience of Sketch, Adobe XD, and Figma using one objective indicator: eye-movement data, as well as three subjective indicators: scale scores, behavior index and user interviews. It also analyzes the design factors that affect these two aspects. This research contributes to uncovering factors that affect the usability and user experience of UI design software and provides references for optimizing the design and development of such software.

The rest of this paper is divided into 6 sections. The current application of usability and user experience evaluation system in interactive interfaces is discussed Section II. Section III compares the interface layout and interaction design of the research cases. Section IV discusses the preparations for the research. The results from the two dimensions of usability and user experience are analyzed in Section V. Section VI proposes optimization suggestions. And the general conclusion is given in Section VII.

II. Literature Review

Currently, the main observed aspects for assessing the quality of software products are usability and user experience. Usability focuses on system quality and user performance during use, while user experience focuses on the overall satisfaction of users with the system. To analyze and redesign the physical human-computer interface, Ma J et al [2] adopted a subjective and objective multidimensional usability evaluation method. Interaction Experience (IX), a higher-level concept integrating the concepts of usability, user experience as well as accessibility, was proposed by Juergen et al [3] to explore the problems in user-system interaction more precisely.

Vision also is the primary modality for users to interact with the human-computer interface, and related researches show that the fixation metrics [4], saccade metrics [5] and pupil metrics [6] are relative to users' perceived cognitive difficulty and information capturing efficiency. Therefore, combining eye-tracking as an objective physiological assessment method can evaluate the interface quality of software more effectively [7].

For the shopping website pages with different interface layouts and interaction design, Liu C et al [8] acquired the user's subjective perceived usability from the four dimensions of standardization, ease of learning, navigation and attractiveness by questionnaires and interviews. Combined with the eye movement data, they established a relationship model for the perceived usability level of the shopping website pages. Lu C et al [9] used objective eye movement index and behavior index, with subjective scores of four usability indicators, including information clarity, interface comfort, overall satisfaction and performance support, to evaluate the human-machine interaction interfaces with different interface layouts. Pan F [10] proposed an interface usability evaluation model based on eye movement experiment and system usability scale, and conducted quantitative and qualitative analysis on the usability of the ticket purchase website with different information design. Wang Y et al [11] explored the interface layout factors affecting the user experience by making news website pages with different interface layouts as

independent variables, user satisfaction and eye movement index as dependent variables.

The majority of the existing researches focuses on the usability or user experience of information and human-machine interaction interfaces. Most of them explore the user experience from the five dimensions of presentation, framework, structure, scope and strategy, or the three dimensions of instinct, behavior and reflection [12-14]. And the usability is mostly evaluated in terms of ease of learning, effectiveness, satisfaction, efficiency, ease of use [15-17].

Interface design, as one of the most important elements of the software, is influenced by many factors [18]. The interface layout, information design and interaction design are the most significant factors in interface design that can directly affect the usability and user experience. Therefore, this research selects three UI design software with high usage and representative as cases, taking the three significant factors as the entry point to consider their impact on user experience and usability.

III. Comparison of the Interface Layout and Interaction Design

A questionnaire on the use of UI design software was conducted before the experiment, and the usage rate of each common UI design software is shown in Fig. 1. Sketch, Adobe XD and Figma are the three UI design software used most frequently by design industry practitioners and students. The experiment uses the three software as the case study. Interface design is one of the most essential components of software design since the interface is the most direct interaction object for users when using software, and its efficacy and experience have a significant impact on users' intention to use and purchase. Therefore, this research focuses on the core characteristics of interface design: layout and interaction, to compare the similarities and differences of the three software and analyze their impact on usability and user experience.

A. Comparison of Interface Layout

Sketch, Adobe XD, and Figma all adopt the same interface layout, which is shown in Fig. 2. The interface is divided into four areas: the top bar, the left and right sidebars, and the canvas. However, the three software differ in the internal structure of each area, mainly in the following aspects.

The quantity and placement of functions in the top bar vary among the three software, as illustrated in Fig. 3. Both Sketch and Figma include toolbars in the top bar. However, Sketch's top bar contains all tools that users will utilize during the design process, without clear divisions. The top bars of Figma and Adobe XD, on the other hand, are clearly divided into three sections with different functions.

Fig. 4 depicts the layout of the left sidebar in Sketch and Figma. In Sketch and Figma, the left sidebar is the layer list, while in Adobe XD, the left sidebar contains the toolbar and layer list. The property inspector appears on the right sidebar in Sketch, Adobe XD, and Figma, and the interior layout is highly consistent. As for the canvas, there is no distinction among the three software.

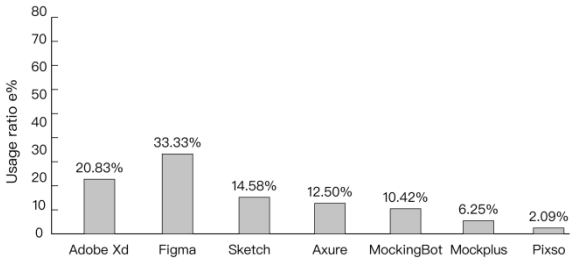

Fig. 1. Usage Rate of UI Design Software.

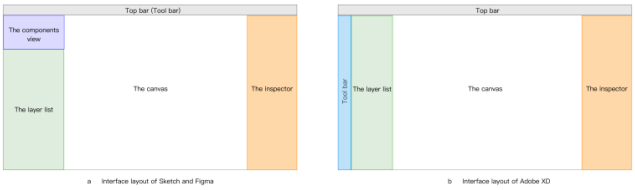

Fig. 2. Interface Layout Comparison.

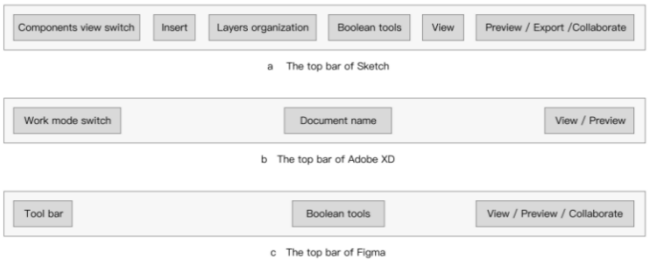

Fig. 3. Comparison of Top Bar Layout.

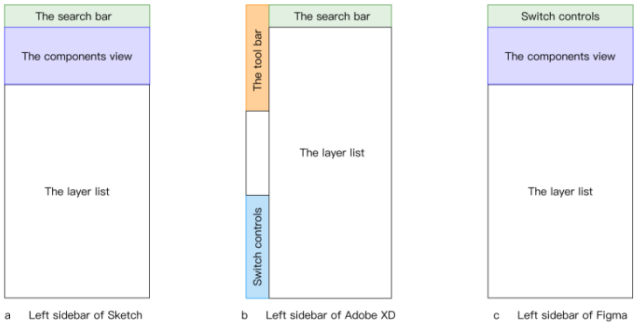

Fig. 4. Comparison of Left Sidebar Layout.

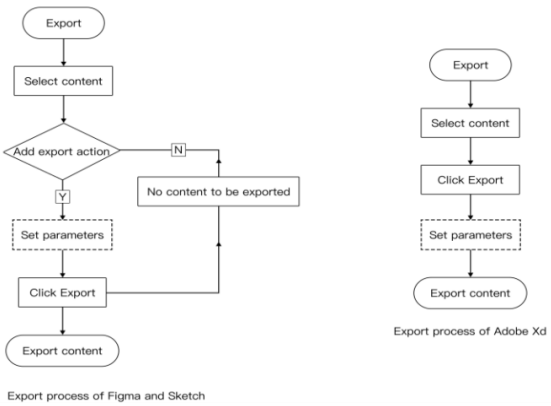

Fig. 5. Comparison of Export Process.

B. Comparison of Interaction Design

In addition to the interface layout, there are some differences and commonalities in the interaction design of the three software. Most of the common functions of the three software interact in the same way, for example, users all add or delete element properties by clicking the Add or Delete controls.

The menu levels of the three software differ. Some functions in Sketch require users to jump to the second level submenu, whereas users only need go to the submenu when using Adobe XD and Figma, and the overall interaction path is shorter. There are also variances in editing property parameters. Figma only shows the parameters frequently edited, with the remainder hidden in the corresponding submenu, while Adobe XD and Sketch show all the parameters in the first level panel of the property inspector.

As demonstrated in Fig. 5, the interaction of export is distinct. When exporting in Adobe XD, users simply select the needed content in the canvas and click Export. In addition, users can choose the content to be exported and set the parameters in the Export dialog. In Sketch and Figma, users must first select the content, then add export action and set the parameters in the property inspector, finally click Export. If users click Export without making the content exportable, the system will notify users that no content is selected or that all frames will be exported by default. This process is more time-consuming than the previous one

IV. Experiment

A. Subjects

Depending on the level of skill, users can be classified as novices, intermediates, and experts. The majority of users are intermediate users, and their amount and frequency of use are consistent. Therefore, the research should primarily focus on intermediate users, and collect their opinions as well as related data on software [19]. The subjects have to be students or practitioners of design industry with at least 6 months of experience in UI design or other related software. Nielsen's research on the number of usability test subjects serves as a basis for the experiment [20]. 17 university students were recruited to participate in this experiment. All subjects were between the ages of 19 and 25, with 9 males and 8 females.

B. Task for Experiment

The key functions of the UI design software were summarized and analyzed before the experiment. A series of interactive tasks covering functions that users use frequently in their daily work were set by combining the results of the UI design software usage questionnaire, and the tasks are shown in Table I.

This experiment chose Sketch 80.1 Chinese version, Adobe XD 45.1.62.364 version, and Figma Chinese v.99.0 as case study, which were the latest versions at the time the experiment was conducted. During the experiment, the three software were run on an iMac computer which has a 27-inch display, and all the subjects were required to finish tasks assigned by the experimenter on this computer.

TABLE I. Experimental Tasks

Task sequence	Task
Task 1	Import [01.jpg] [02.jpg] [03.jpg] into the canvas, and resize them to 200px* 150px
Task 2	Make [Figure1.jpg] [Figure2.jpg] [Figure3.jpg] vertically centered and aligned, keeping their spacing at 30px
Task 3	Add a diameter of 100px circle without fill, whose stroke style is dash and the color number is [666666], thickness of 2; endpoints for round, the dash of 5, gap of 8, transparency of 40%
Task 4	Create the circle drawn in Task 4 as a component and name it [circle].
Task 5	Add the text "Usability Test", with a font size of 14, a font weight of Medium Bold, and a font of Pingfang-SC; set its line height to 18 and the text box to auto width, and adjust the transparency to 50%.
Task 6	Add the component [Shopping Cart] to Frame 1 and detach it from the component.
Task 7	Add the drop shadow effect to [Shopping Cart], set the x-direction parameter to 4, the y-direction to 8, the blur to 8, and the transparency to 3%.
Task 8	Export Frame 1 as 2x size png file to the desktop and name it [test number - name].
Task 9	Save the document to the desktop and rename it to [Test-Number].

C. Evaluation Index System

Combining the definitions of usability and user experience in ISO 9241-11-2018[21], the three dimensions of usability and the primary factors affecting user experience are utilized as the basis for evaluation. The usability and user experience evaluation system based on eye-tracking technology, evaluation scales, retrospective thinking aloud interview, and user testing is constructed from both objective and subjective perspectives, as shown in Fig. 6. By analyzing the subjective and objective data, the elements influencing the usability and user experience of UI design software are summarized [22].

In this experiment, the user testing is a usability evaluation method that collects feedback data on user behavior and satisfaction indicators when using a specific human-machine interface. User testing mainly defines usability problems by observing the process of completing a series of prescribed tasks under a specific scenario and by asking the subjects to record the real usage. In this experiment, the usability evaluation of the software was conducted by testing users, observing and recording the number of failures and the completion time when performing tasks with each of the three software, also using the retrospective thinking aloud interview to obtain participants' experience with the software.

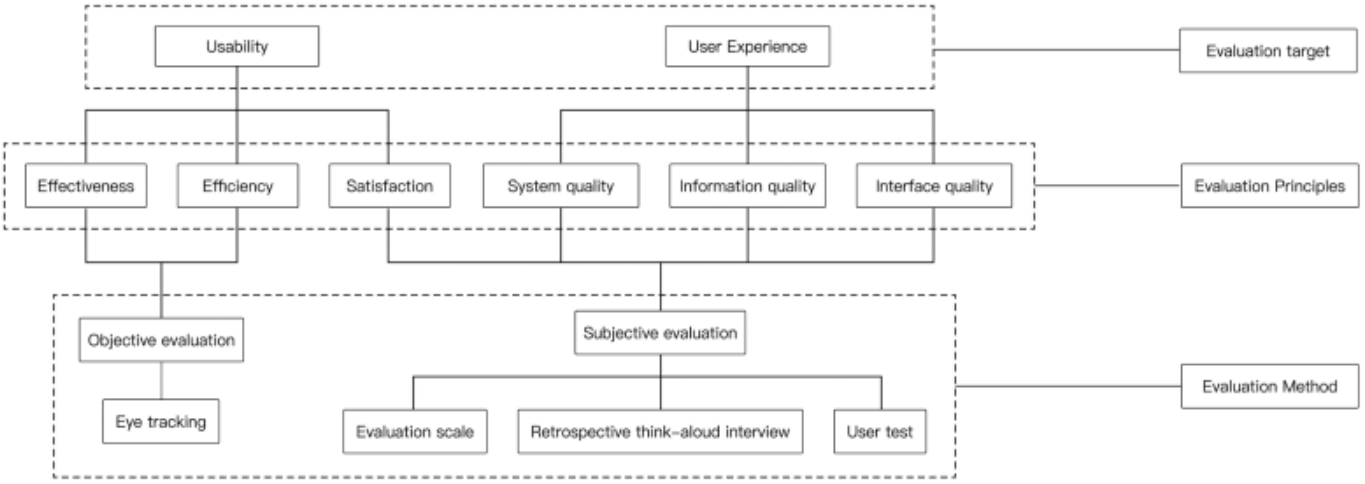

Fig. 6. Usability and User Experience Evaluation System.

The evaluation scales consist of Post-Study System Usability Questionnaire (PSSUQ) and After-Scenario Questionnaire (ASQ). PSSUQ takes information quality, and interface quality as the main evaluation indicators. ASQ quantifies satisfaction by rating the system's support in performing tasks, time spent, and support information. The two questionnaires both adopt a 7-point Likert scale, with 1 indicating "strongly disagree" and 7 indicating "strongly agree", and a higher score on this scale means better usability or satisfaction of the system.

Eye tracking is a common data collection method in usability testing. Based on the usability and user experience evaluation standards, the indicators of task completion time, number of task failures, and total fixation duration in the area of interest (AOI), as well as the heat and gaze plot maps are selected for analysis. The number of failures and task completion time are crucial indicators to evaluate effectiveness and efficiency of the software. The total gaze duration in the area of interest can quantify the difficulty of the object the user is viewing, i.e., the effectiveness of the system's information. The heat map and gaze track map are common visualization forms of eye-tracking data, which mainly demonstrate the user's attention to information and visual search path.

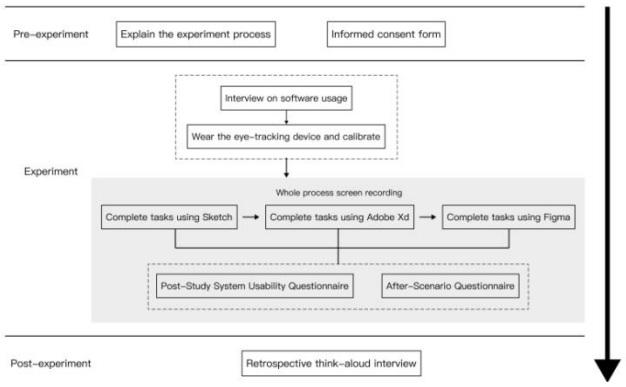

Fig. 7. Experimental Process.

D. Experimental Process

Each subject was given the same task to complete using the three software. Due to the high similarity between the interfaces of Sketch and Figma, the order of subjects using the software was specified as Sketch, Adobe XD, and Figma to prevent learning effects. Only one individual was tested in each experiment in a quiet and bright environment. The procedure of the experiment is shown in Fig. 7.

V. Results

The collected data were assessed for variance chi-square using IBM SPSS.25.0. One-way analysis of variance was used for data with chi-squared variance, while data without chi-squared variance were assessed nonparametrically using the Kruskal-Wallis method. In this experiment, all statistical results were evaluated with the 95% confidence interval. The mean was expressed as "m", while the significance was “p”.

A. Difference in Usability

There are some variances in the degree of support for UI design among the three software, according to the data collected from the experiments.

1) Overall evaluation. The statistical results do not show significant differences when subjects rated the three software overall on the usability scale ($p=0.209>0.05$), but in the post-test interview, nearly 58% of subjects indicated that the overall usability of Figma was significantly better than that of Adobe XD and Sketch. Thus the usability of Figma can be considered higher than Adobe XD and Sketch

2) Effectiveness evaluation. The difficulty of acquiring valid information in an area and the attractiveness of the target to the subject are proportional to the duration of fixation in AOI [23]. Table II shows the duration of fixation in AOI during the completion of tasks using the three software, revealing that the three software do not show significant differences in Task 2, Task 4, and Task 6 ($p_2 = 0.425 > 0.05$, $p_4 = 0.398 > 0.05$, and $p_6 = 0.974 > 0.05$), while the statistics for the other six tasks reveal significant differences.

Furthermore, there are significant differences in the total duration of fixation in AOI ($p = 0.001 < 0.05$). Table III shows the average times of failures while subjects conducting tasks. According to the post-hoc test, the difference between the times of failures using Sketch and Adobe XD is significant ($p=0.038<0.05$). Combining the interface design analysis of the three software, it is found that some ancillary information or icon meaning of Sketch is unclear, which results in subjects spending longer time focusing on the area and increases the difficulty in acquiring valid information compared to Adobe XD and Figma, as confirmed by the post-test retrospective thinking aloud interview. In conclusion, the effectiveness of the three software shows significant differences, and the subjects have difficulty extracting the target information using Sketch, indicating that Sketch has the lowest effectiveness, while the difference in effectiveness between Adobe XD and Figma is not significant.

3) Efficiency evaluation. Table IV depicts results of the average completion time of each task and its one-way ANOVA test. The time of task failed was not included in the statistics [24]. In Table IV, there is no significant difference in the completion time of Task 2, Task 4, Task 5, and Task 6 among the three software, while the total task completion time of Sketch is significantly longer than that of Adobe XD and Figma ($p=0.00<0.05$). The heat map and gaze plot map of Task 3, Task 8 and Task 9, in which subjects performed poorer during the experiment, were selected for comprehensive analysis. Hotspots of different colors can visually reflect the subjects' attention to information and the distribution of gaze points: the longer fixation in red areas, whereas the shorter fixation in green areas [25].

TABLE II. COMPARISON OF DIFFERENCES IN DURATION OF FIXATION IN AOI

Variables	Duration of fixation in AOI (s)			Degree of freedom	Significance
	Sketch	Adobe XD	Figma		
Task 1	111.76	68.08	56.50	2	0.002
Task 2	81.04	56.60	87.52	2	0.425
Task 3	136.48	60.16	64.16	2	0.000
Task 4	53.92	85.81	76.89	2	0.398
Task 5	97.95	66.15	82.00	2	0.036
Task 6	65.31	61.61	61.96	2	0.974
Task 7	98.46	45.75	31.54	2	0.001
Task 8	120.09	45.96	89.48	2	0.013
Task 9	119.47	22.96	45.96	2	0.000
Total duration of fixation	884.48	513.08	576.02	2	0.001

TABLE III. COMPARISON OF DIFFERENCES IN THE TIMES OF TASK FAILURES

Variables	**Times of task failures**			**Degree of freedom**	**Significance**
	Sketch	Adobe XD	Figma		
Times of task failures	1.21	0.21	0.79	2	0.038

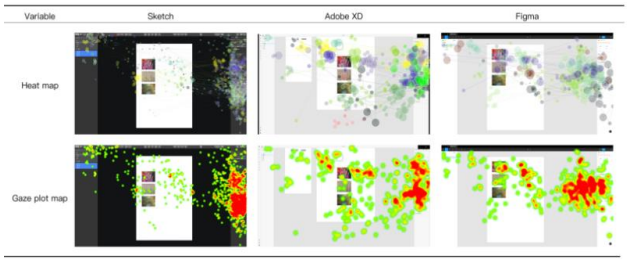

Fig. 8. Eye-movement Diagram when Completing Task 3.

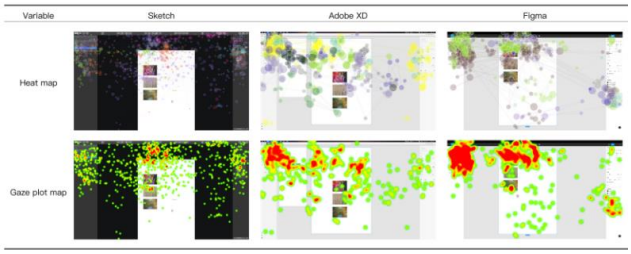

Fig. 9. Eye-movement Diagram when Completing Task 8.

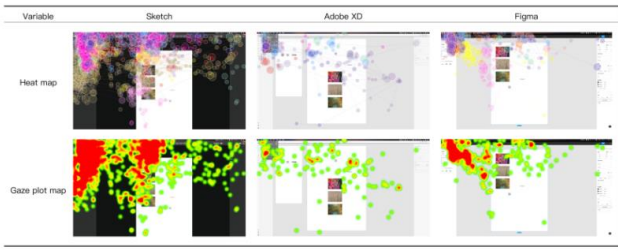

Fig. 10. Eye-movement Diagram when Completing Task 9.

Task 3: Add and edit a shape. In this task, the subjects were required to add a new shape and adjust the parameters of its properties. Fig. 8 shows the specific eye movement map, where hotspots are distributed in Sketch's interface the most widely and the gaze points are the most intensive. Combined with Table II, Table IV and the post-test interview, it is found that Add Layers function of Sketch is hidden in Insert submenu in the top bar, which varies from most of subjects' usage habits. Therefore, subjects were unable to find the required functions quickly. The more amount of eye-track crossings and the longer length of adjacent trajectory segments in Sketch, indicates that subjects' eyes constantly shifted red between the top bar and the canvas, their viewpoints were also more dispersed when using Sketch. In Sketch and Figma, the hotspots area in the right column are larger, which shows that subjects spent more time in this area. In conjunction with the subjects' performance, it reveals that the layout of information in Property Inspector of Sketch and Figma is more compact than Adobe XD, which increases the cognitive burden and leads to lower efficiency of capturing information and completing the task when using the above two software.

Task 8: Export the frame and set the relative parameters. Table IV shows that subjects spent the longest time using Sketch to complete this task and the shortest time using Adobe XD. The specific eye-movement performance is shown in Fig. 9. The subjects' eyes mostly focused on the target function

area when using Adobe XD, and most of them had shorter eye-movement trajectories and fewer red hotspot areas, indicating that their sight did not stay in a specific area for long. Combined with the subjects' performance, it can be seen that since the Export button of Adobe XD is in the Window menu, which is in consistent with majority of subjects' experience, and the parameter information is clear, the subjects could quickly understand the text then completed the task efficiently. The eye-tracking hotspots are dispersed throughout the interface of Sketch, and the amount of eye-tracking crossings is more than the other two software, indicating that the subjects' attention to the interface was scattered. Subjects indicated that Export button in Sketch is small and secluded, and the process is also distinct from their usage habits, making it hard to find the button quickly and requiring them to spend much time trying. Besides, subjects spent the longest total duration of fixation when using Sketch to complete Task 8 (see Table II), implying that the subjects were unable to find the target and acquire information quickly, resulting in low task completion efficiency.

Task 9: Save and rename the file. Combining the statistics in Tables II and IV, it reveals that the subjects' total fixation of duration and completion time when using Sketch are significantly longer than the other two software ($p_1=p_2=0.000<0.05$). Fig. 10 depicts the specific eye-movement diagram for this task. The subjects' eye-movement hotspots when using Sketch concentrate in the menu bar of the window and top bar. The large area of red hotspots and a host of eye-tracking crossings indicate that the subjects' sights shifted between two areas for times, moreover, the browsing speed was slower than Adobe XD and Figma. The subjects claimed in the interview that the main reason for the long time spent on this task using Sketch is that they did not realize the "Copy" meant saving the file as a new file, thus they kept searching for the "Save as" button. It can be seen that ambiguous wording increases the cognitive load of users and reduces their efficiency.

TABLE IV. COMPARISON OF DIFFERENCES IN AVERAGE TASK COMPLETION TIME

Variables	Time to complete each task (s)			Degree of freedom	Significance
	Sketch	Adobe XD	Figma		
Task 1	119.88	71.46	61.26	2	0.001
Task 2	77.52	54.64	61.80	2	0.327
Task 3	120.74	56.00	66.29	2	0.000
Task 4	48.10	78.67	60.65	2	0.273
Task 5	75.68	62.32	74.96	2	0.420
Task 6	59.98	54.80	46.88	2	0.687
Task 7	79.99	48.44	25.53	2	0.001
Task 8	68.11	47.79	38.10	2	0.022
Task 9	106.12	19.89	41.73	2	0.000
Total gaze duration	868.43	549.97	488.16	2	0.000

The analysis of the data leads to the conclusion that the subjects are the most efficient in completing tasks using Figma, followed by Adobe XD, and Sketch is the worst.

4) Satisfaction evaluation. In the post-test interview, the subjects expressed that they preferred Figma to the other software for its succinct interface, reasonable layout, the clear expression of icons, and functions in the toolbar were sorted according to the frequency and priority of use. Additionally, some common parameters are presented in the first-level interface, allowing users to shorten the interaction path and improve efficiency. The majority of subjects thought Sketch's interface was too complicated, which led to a low efficiency in searching for information, and the interaction path of some functions and the interface layout did not conform to usage habits, which hampered the efficiency. On the basis of post-test interview, the satisfaction of the three software can be ranked as Figma>Adobe XD>Sketch.

B. Difference in User Experience

As indicated in Table V, there are significant differences in the overall experience and the information quality of each software.

1) Although there is no statistically significant difference in the overall usability scores of the three software ($p=0.209>0.05$), combined with the specific difference in scores ($m_F=88.17>m_A=80.86>m_S=75.14$) and feedback from subjects in the interview, it can be concluded that there are some differences in the overall user experience among the three software. The data shows that Figma with its succinct interface, clear and organized property control panel, and low learning cost, gives subjects the better experience in UI design.

2) System quality evaluation. Comparing the scores for overall and each subscale of the system quality, it is found that the overall system quality and ($p=0.330>0.05$) do not show significant differences among the three software. Key factors determining the subjects' ratings are whether they can find needed functions quickly and edit parameters efficiently.

The results of the subjects' ratings reveal that Sketch is not very helpful in completing the tasks, primarily due to its complex interface layout, insufficient or ambiguous support information, also the interaction of adding new layers and exporting which differs from usage habits, as evidenced by observations of the experiment and subsequent interviews. While Adobe XD can improve the efficiency, most of subjects indicated that its functions were not as comprehensive as the other two, only supported basic UI design works. In conjunction with results of the scale and interviews, the ranking of system usefulness can be concluded as Figma>Adobe XD>Sketch.

3) Information quality evaluation. The subjects considered Figma to have the best information quality, followed by Adobe XD and finally Sketch. Although there is no significant difference in the overall information quality scores of the three software ($mF=32.36>mA=28.07>mS=26.50$, $p=0.097>0.05$), but in the scores of particular indicators such as information validity ($mF=5.57>mA=4.57>mS=4.14$, $p=0.012<0.05$). Also, subjects indicated that the information in Sketch was confusing and redundant resulting in capturing the needed information inefficiently.

TABLE V. COMPARISON OF POST-TEST SYSTEM USABILITY QUESTIONNAIRE SCORES

Variables		Ratings on the usability of the software			Degree of freedom	Significance
		Sketch	Adobe XD	Figma		
System Usefulness	A1 Ease of use	5.07	5.07	5.57	2	0.591
	A2 Ease of operation	4.64	5.43	5.64	2	0.164
	A3 Efficiency support degree	4.71	5.64	5.57	2	0.151
	A4 System comfort degree	4.50	5.29	5.50	2	0.185
	A5 Ease of Learning	4.71	5.21	5.43	2	0.420
	A6 Performance support	5.14	5.14	5.64	2	0.645
	Total system usefulness	28.79	31.79	33.36	2	0.330
Information Quality	A7 Information guidance	4.00	4.36	4.86	2	0.323
	A8 Fault tolerance	5.07	4.93	5.50	2	0.565
	A9 Information clarity	4.29	4.57	5.43	2	0.102
	A10 Information prominence	4.21	4.71	5.29	2	0.106
	A11 Information validity	4.14	4.57	5.57	2	0.012
	A12 Information structure clarity	4.79	4.93	5.71	2	0.203
	Total information quality	26.50	28.07	32.36	2	0.097
Interface quality	A13 Interface comfort	5.07	5.36	5.93	2	0.280
	A14 Interface preference	5.07	5.50	5.79	2	0.425
	A15 Expectation Satisfaction	4.57	4.79	5.57	2	0.203
	Total interface quality	4.57	15.64	17.29	2	0.251
	A16 Overall satisfaction	5.14	5.36	5.71	2	0.536
	Overall Usability	75.14	80.86	88.71	2	0.209

The main issue with Adobe XD is that the vital information or functions are not prominent enough in the interface, and insufficient auxiliary information to assist users.

4) Interface quality evaluation. The overall and specific indicators of the interface quality only differ in scores, but do not show significant differences. The interface quality of Figma is the best, followed by Adobe XD then Sketch ($m_F > m_A > m_S$). According to the subjects, Figma's interface is the most concise and clear, especially the property inspector, where common properties are shown in the first level panel while less frequently modified properties are collapsed in the second level panel, ensuring a concise interface and shortening the interaction path. Sketch's interface quality is poor for the layout and information architecture of some functions that does not correspond to usage habits; Adobe XD's interface is simple, but some of the frequently edited parameters are folded in the secondary panel, increasing the interaction path. Besides, some frequently used functions are secluded.

VI. DISCUSSION

Based on the results of the preceding analysis, it can be concluded that interface design, information quality, and interaction design highly affect system usability and user experience. Therefore, the designer can optimize the system from the perspective of these three dimensions.

A. Interface Design

Figma's interface is concise, and the color scheme of the interface helps users distinguish the panels clearly. The presentation of the content is clearer than the other two software, and the arrangement of functions is consistent with most users' preferences. The interface of Adobe XD is also concise, but some common tools are not sorted according to the frequency of use. Massive information is presented in Sketch's interface, and the arrangement of some function buttons does not correspond to users' behavior logic. For design software, the interface layout can affect the efficiency and user experience. Different layouts of controls have a significant impact on the eye-movement behavior, so the layout design needs to fully consider the proximity of each area [26]. The interface layout should be reasonably designed based on user's usage habits to make the information more organized [27], reducing the user's cognitive load and effectively improving the efficiency of information acquisition.

B. Information Design

The three software rated low on indicators of information guidance, information prominence, and information clarity in the after-scenario questionnaire. The main issues include unclear semantic expression of icons and some textual information, as well as insufficient auxiliary information. Therefore, when designing icons, it's crucial to ensure that icons are easily recognized and remembered by users [28], and the communication barriers between users and interface can be eliminated [29]. Simultaneously, it is vital to distinguish primary and secondary information in the interface, as well as to emphasize the main information to make it explicit, so as to improve users' cognitive efficiency. The UI design software should also increase or optimize the information that can assist users to work more efficiently. Furthermore, shared resources, such as plug-in libraries and design materials, can boost users' satisfaction.

C. Interaction Design

Efficiency and effectiveness are the main factors that influence users' perceptions of software usability and user experience. Figma outperforms Sketch and Adobe XD in both efficiency and efficacy, according to subjective evaluation and objective data analysis. In general, the interaction path in Figma is more in line with the logic of the user's behavior and functions, allowing users to adapt to the system in a short time and increase efficiency. Specifically, Figma distinguishes

information by frequency of editing, with necessary parameters and function buttons in the first level panel and unnecessary information in the second level panel, to keep operation logic clear and progressive while shortening the interaction path. Consequently when designing such software, the interaction of the system should be concise to make users feel natural and smooth during the process of operation [30]. On this basis, the interaction of the software needs be tailored to the users' preferences, the migration and reuse costs of the software should also be as low as possible.

VII. Conclusion

Three representative and widely used UI design software are chosen as research cases in view of the lack of researches related to usability and user experience of UI design software at this stage. In this paper, effectiveness, efficiency and satisfaction are selected as the evaluation criteria of usability, while system quality, information quality and interface quality are the evaluation criteria of user experience. Objective indicators, the eye movement index and behavioral index, and subjective indicators: evaluation scales, retrospective interviews, and user testing, are used to evaluate and analyze the user experience and usability of the three software. According to the results, each software has varying degrees of problems in interaction design, information quality, and interface layout. Therefore, interface layout, interaction logic, specific interaction pattern, and information visualization should be optimized based on the user's deep needs, as well as the behavior logic, cognitive load, and function logic, so that users can achieve high efficiency through a reasonable human-computer interface.

Though the experiment was designed to prevent learning effects, the results were influenced by the fact that the subjects became familiar with tasks for the same task was performed with three software during the experiment. The number of experiment sample should be expanded in future studies, while experiments should be conducted through a more rigorous form of group control to reduce the interference with the results.

***Abstract*—Searching for similar images is an important feature for image databases and decision support systems in various subject domains. However, it is essential that search results are sorted by degree of similarity in reverse order. This paper presents a comparative analysis of four existing similarity measures and experimentally tests whether they could be used to calculate similarity between images. Metrics could be evaluated by comparing their results to the cumulative human perception of similarity between the same images, obtained by real people. However, this introduces a lot of subjectivism due to non-uniform judgement and evaluation scales. The paper presents a more objective approach - checks which measure performs best in retrieving more images, containing objects of the same type. Results show all four measures could be used to calculate similarity between images, but Jaccard's index performs best in most cases, because it compares features vectors positionally and thus indirectly consider shape, position, orientation and other features.**

Keywords*—Content Based Image Retrieval (CBIR); image search and ranking; similarity measures; image databases

I. Introduction and Related Work

With the development of the Internet and information technology, it has become possible to store and process larger volumes of data, with more and more data in the form of images. This is the basis of the great interest in the approaches and algorithms for image organization, search and retrieval. Naturally, storing large volumes of images requires a new and efficient image retrieval approach. There are two main approaches to image organization and storage - text descriptions, keywords or labels (known as text-based image retrieval) [1] and content based image retrieval [2], [3]. The use of text descriptions is a slow and time consuming process (because of the need a person to describe images with text, not from a computational point of view), so algorithms for content based image retrieval are of greater scientific interest. The main characteristics used in these algorithms are color [4], [5], shape [6], texture [7], spatial features and their combinations [8]. Color is one of the most basic and at the same time distinctive features that hardly changes when you rotate, reduce or increase the size or when changing the orientation of the images. Therefore, the use of color or the color distribution in images at CBIR is the most popular approach among researchers, and yet it is not exhausted and is still subject of interest.

The typical architecture of CBIR systems consists of two main elements. The first is related to the feature extraction of the images and their storage, organization and indexing. The second concerns the assessment of the similarity between the query image and the images in the database. What similarity measures to use and how to assess their suitability for the specific application?

One of the major problems with assessing the visual similarity of images is that there is no classification to use as a criterion. Therefore, it is not possible to make an accurate assessment of the results of the application of the various methods for assessing the similarity of images. It is not possible to use user evaluation (through surveys or any other methods) as the subjective factor in the evaluation is too important and there are undoubtedly huge differences in similarity ratings made by different people, even on a small sample of images. All this requires the search for automatic and without human intervention criteria for assessing similarity.

II. Goal and Motivation

The aim of this paper is to test whether four popular similarity measures (not specially designed for image comparison) could be used to calculate similarity between images. We have tried to do it in our previous paper [9] by comparing the results of similarity measures to the cumulative human perception of similarity between the same images, obtained from an online survey. However, we encountered an enormous problem then – non-uniform judgment and evaluation scales used by the individual respondents.

The survey was designed so that a query image was shown next to a set of sample images, and users were required to specify the exact value of similarity (in their own opinion) in percentage between the query and each image within the set. Since we used nominal, rather than ordinal scale, we have got quite high non-uniformity between individual answers. For example, a respondent specified the similarity between the query and the image X is 80%. Another respondent specified 95% for the same pair of images, while a third respondent specified 40%. Averaging answers having high discrepancies as the above mentioned, could not guarantee reliability and accuracy of obtained "human perception of similarity". So the latter could not be reliably used as a reference.

To test the four similarity measures (Jaccard's index, Euclidean distance, City block distance and Chi-squared dissimilarity) and evaluate how good they are, we decided to use an alternative more objective approach. Inspired by the Top-N accuracy, we applied a similar evaluation approach. We defined a set of 200 images – 50 red roses, 50 tomatoes, 50 red apples and 50 red peppers. The colors of all images are similar – red (roses, fruits, vegetables) and green (leaves). The idea is to check which measure performs best in correct classification of retrieved items (precision) for a specific level of recall. Let's say we are looking for a rose and the system is set up to return 10 results. Then the best similarity measure will be the one that returns most roses out of these 10 results and just a few (or preferably none at all) tomatoes, apples and peppers. However, since there are 50 images of roses, we run 50 queries (every image is used as a query) and average their respective precision for the specified level of recall (top-N results).

This study is important in order to determine which of these four basic similarity measures performs best in searching for images. Results will allow to design and develop an improved universal image retrieval system that could correctly find similar images in various subject domains, or even a system that could automatically select the best similarity measure for a given subject domain by itself.

III. Experimental Environment and Evaluation

The experimental CBIR system used is described in details in [9] and [10]. Briefly, the formation of a feature vector for each image is a sequence of the following actions:

- Each image is divided into 32 by 32 blocks in both width and height dimensions (Fig. 1 to 4).
- All pixels in all the blocks are converted from RGB to one of our 64 primary colors. How these 64 colors were selected and the process of color transformation is described in our previous research [9], [10].
- The dominant color (out of 64 selected colors in our proposed and used color scheme) in each block is determined based on the number of pixels of each color. This dominant color is associated with this block, and the other colors in it are ignored.

In other words, we use just a single color code to substitute multiple pixels per block. In this way, the enormous image color content is reduced to a feature vector with 1024 (32 by 32) color codes. Results of such quantization and color substitution are showed on Fig. 1 to 4. That allows fast image processing and similarity searching. Also, it improves recall as well. The system does the same color analysis for both the image query and the image set and computes such feature vectors for each graphic file. Based on set-theoretic or algebraic methods and similarity measures such as Jaccard Index, Euclidean Distance, City Block Distance and Chi-Square Dissimilarity described in [9] we calculate the similarity factor between the query and each result. At the end, the system returns a sorted list of similar images (Fig. 9).

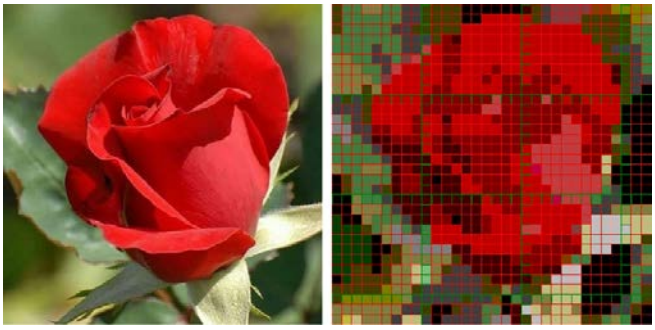

Fig. 1. Original Rose Image Processed by the Application (Left) and its Quantized Image by 32x32 Blocks with Only One Dominant Color Per each Quantization Block (Right).

Fig. 2. Original Tomato Image Processed by the Application (Left) and its Quantized Image by 32x32 Blocks with Only One Dominant Color Per each Quantization Block (Right).

Fig. 3. Original Pepper Image Processed by the Application (Left) and Its Quantized Image by 32x32 Blocks with Only One Dominant Color Per each Quantization Block (Right).

Fig. 4. Original Apple Image Processed by the Application (Left) and its Quantized Image by 32x32 Blocks with Only One Dominant Color Per each Quantization Block (Right).

A set of 200 images (as described earlier) is used in our study. They all have common visual or color characteristics, but are divided in four separate groups - roses, tomatoes, apples and peppers. The feature vectors are stored in the database and each of these 200 images is used as a query in the experiment. It is known which image is from which of the four groups and keeps track of how many images there are in the returned result in the first n similar images from the same group. The first 3, 5, 10, 15, 20, 25, 30, 35, 40, 45 and 50 results are examined and the average of the number of images returned from the same group is calculated for every query. This is repeated for each of

the similarity measures with the idea of checking the degree of accuracy/adequacy for each of the measures.

Let's take the group of images of roses for example. It is checked for each rose image, run as a query, how many of the top-N returned results are roses as well. The test is repeated for all 50 rose images and then the average precision value is determined as a proportion of the returned rose images to all returned images (e.g. top-3 results). So, if for "rose image 1" as a query, we have 3/3 returned rose images (i.e. all returned images are roses), for "rose image 2" as a query, we have 2/3 rose images (i.e. 2 images are roses indeed and the third image is another object), and for "rose 3", we have 1/3 rose images returned (i.e. 1 image of a rose and two other objects), then the average precision for top-3 results is (3 + 2 + 1) / (3 + 3 + 3) = 6 / 9 = 2 / 3.

In the experiment, this is done with 50 image queries from each of the four groups and the top-3, -5 ... results are examined. In this way, we can track how the mean precision changes for each similarity measure, based not only on individual queries, but on all 50 queries from each image group. The results are shown in Tables I, (for the set of roses, run as queries), II (for the set of apples), III (for the set of peppers) and IV (for the set of tomatoes).

TABLE I. AVERAGE RESULTS FOR EACH SIMILARITY MEASURE BASED ON ALL 50 ROSE QUERY IMAGES

TOP X RESULTS	Jaccard's index	City block distance	Euclidean distance	Chi-squared dissimilarity
TOP 3 RESULTS	2.6 / 3	2.06 / 3	2.06 / 3	1.82 / 3
TOP 5 RESULTS	4.00 / 5	3.08 / 5	3.16 / 5	2.78 / 5
TOP 10 RESULTS	7.26 / 10	5.50 / 10	5.22 / 10	4.56 / 10

TOP 25 RESULTS	10.34 / 25	10.32 / 25	9.24 / 25	9.88 / 25
TOP 30 RESULTS	11.82 / 30	11.92 / 30	10.76 / 30	11.68 / 30
TOP 35 RESULTS	13.58 / 35	13.60 / 35	12.36 / 35	13.06 / 35
TOP 40 RESULTS	15.34 / 40	14.90 / 40	13.92 / 40	14.44 / 40
TOP 45 RESULTS	16.66 / 45	16.46 / 45	15.50 / 45	15.78 / 45
TOP 50 RESULTS	18.88 / 50	17.74 / 50	16.78 / 50	16.92 / 50

Results are also presented graphically on Fig. 5 (for the set of rose query images), Fig. 6 (the set of apple query images), Fig. 7 (the set of pepper query images) and Fig. 8 (the set of tomatoes query images).

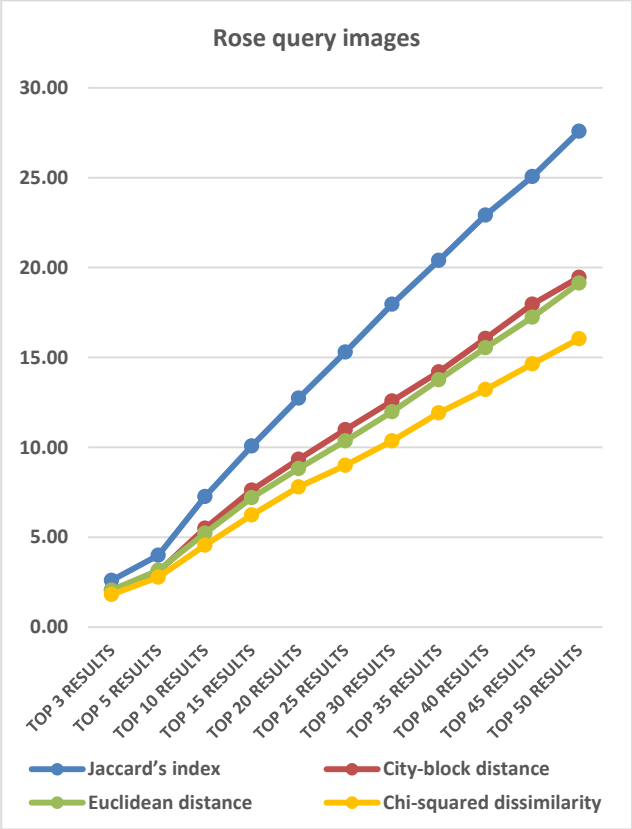

Fig. 5. Average Number of Returned Images, Containing *Roses* (y-axis), Per Similarity Measure and Number of Returned Results (x-axis).

It clearly seems that the Jaccard's index significantly outperforms (retrieves more images containing an object of the same type) all other similarity measures for the set of roses (see Fig. 5). However, this is not the case for tomatoes (Fig. 8), for example, although they have the very same colors. The in-depth analysis of the similarity measures themselves reveals the reason - the Jaccard's index calculates similarity between two images by positionally comparing the dominant colors block by block. All other described measures utilize colors globally. Taking local color distribution into account allows considering not just colors, but shapes and local details as well.

Jaccard's index performs better with roses rather than tomatoes, because the rose's flower consists of multiple individual leafs that reflect light differently and creates dark shadows between leafs (Fig. 1), while tomatoes are singular convex rounded objects (Fig. 2). So, accounting position of the shadows, the Jaccard's index can more easily and reliably guess if the red object in the center of the image is a rose or something else. However, distinguishing a convex red tomato from a convex red apple is much more difficult. That is why Jaccard's index outperforms all other similarity measures for the set of roses (due to additional surface features – shadows between leafs) and the set of peppers (due to the oblong shape), but achieves less better (but still better) results for apples, and no improvement for tomatoes image set.

Fig. 9. Example of Top-50 Similarity Results based on Rose Image Query and Jaccard's Index Sorted by Degree of Similarity in Descending Order.

IV. Conclusion

Results from the series of experiments show that:

- All described similarity measures (Jaccard's index, Euclidean distance, City block distance and Chi-squared dissimilarity) could be used to calculate similarity between images. They all provide similarity within the range of [0, 1] and allow search results to be sorted by similarity in reverse order.
- When searching by color content, and consider colors globally, then Euclidean distance, City block distance and Chi-squared dissimilarity produce commensurate results. That is clearly noticeable on Fig. 5 to 9. The main difference between these metrics is in the magnitude of the calculated value. However, the relationships between the calculated similarity factors remain the same, regardless of which one of these three similarity measure is used. It should be noted here that exactly the relationships between similarity factors, rather than the absolute values themselves, create the order of the search results.
- In contrast to all other similarity measures, Jaccard's index compare feature vectors positionally, so it takes into account not just colors, but also their spatial distribution. As a result, it indirectly considers shape, position, orientation and other features.
- When objects have specific features on their surfaces or irregular (e.g. oblong) shape, then Jaccard's index significantly outperforms other similarity measures. That is easily noticeable on Fig. 5 for the set of roses and Fig. 7 for the set of peppers.
- In general, when there is no a-priori information about the image database, the Jaccard's index seems the best single similarity measure between images. This statement is supported by the data in all tables and figures.

Automatic Detection of Roads using Aerial Photographs and Calculation of the Optimal Overflight Route for a Fixed-wing Drone

Miguel Pérez P, Holman Montiel A, Fredy Martínez S
Facultad Tecnológica, Universidad Distrital Francisco José de Caldas
Bogotá, Colombia

***Abstract*—Currently, fixed-wing drones have become indispensable tools for the surveillance of large areas of land, justified by their better cost/benefit ratio, great flight autonomy, and payload capacity. In particular, the identification of roads, traffic control, monitoring of wear on asphalt layers, risk identification, and safety improvement are applications that are being implemented in these unmanned aerial vehicles. Tracking a road requires systems capable of detecting artificial marks through images employing aerial photographs that allow the implementation of optimal overflight routes. This research work presents a solution to the problem of road tracking from aerial photographs and implements an image processing algorithm and morphological techniques that calculate and traces the ideal route for the drone to track automatically, regardless of its orientation and the type of road.**

***Keywords*—Automatic road tracking; decorrelation stretching; aerial imagery; optimal overflight route calculation; UAV**

I. Introduction

Transportation infrastructure, and in particular roads, are of vital importance for the growth and development of a country, and even more so for a country like Colombia, since 80% of the country's cargo is moved by road [1]. Surveillance of these important roads is normally done through simple methods such as cameras or with the public forces located in different segments of these roads. These methods are costly due to the many elements or people that must be available [2], [3]. Currently, the need to implement new, less expensive methods for surveillance has forced researchers to investigate systems that use fixed-wing drones for this task [4]. Such systems take advantage of the great autonomy and high payload capacity of these drones [5] for the process of monitoring and surveillance of roads. This monitoring process cannot be teleoperated due to the extension of the territories to be monitored; for this reason, research is aimed at autonomous systems that use digital image processing algorithms, obtained by the Unmanned Aerial Vehicles (UAV) themselves; to automatically detect the road and thus be able to extract elements of interest autonomously [6], [7].

Asphalt roads can be considered extraneous or artificial features that extend for many kilometers in a natural landscape [8], [9]. A process used to highlight these landmarks in an image is called decorrelation stretching (DCS) [10], [11], [12]. The DCS technique is complemented with color detection [13], [14] and image filtering [15] algorithms; which extract the violet areas corresponding to the road, leaving it in a binarized image. It should be clarified that the images used in this research are aerial photographs of roads taken by fixed-wing drone overflight; where there are great differences between them (altitude taken from the photo, direction, light conditions and brightness, topography, landscape, etc.) which demonstrates the robustness and efficiency of the developed system. Once the road is detected, the system can calculate the extreme points [16] and trace the direction of this obtaining the optimal route of overflight of the UAV [17] that allows following the road for many km.

To recapitulate, the proposed system incorporates a decorrelation stretching algorithm and filtering and color detection algorithms to automatically detect a road in an aerial image. In addition, it proposes an algorithm that allows computing the optimal overflight path of the detected road by implementing the endpoints of the detected road. These contributions are described in detail in the following sections, which are organized as follows: Sections II and III present the general definitions and methodology used respectively, and section IV presents the results obtained.

II. Methodology

This research contributes to a joint operation of decorrelation stretching algorithms (DCS), image filtering, and color detection algorithms together with image processing libraries developed entirely in MATLAB. They allow detecting and calculating a flyover route for roads using aerial images. A description of each of the elements used is presented below.

A. Decorrelation Stretching (DCS)

Decorrelation stretching is a process that improves the color differences found in an image by removing the inter-channel correlation found in the image pixels. Decorrelation stretched images provide an overview that improves spectral reflectance variations; that is, it improves color differences in images with high inter-channel correlation [11], [12].

Therefore, using DCS is useful for intensifying the color difference between roads and the surrounding landscape in an image, which facilitates the detection of roads. Fig. 1 shows an image of a road subjected to the decorrelation stretching process implemented in this research; in it, you can see the color difference between Fig. 1 (a) and (b), in addition, you can see the violet hue that takes the road to be detected.

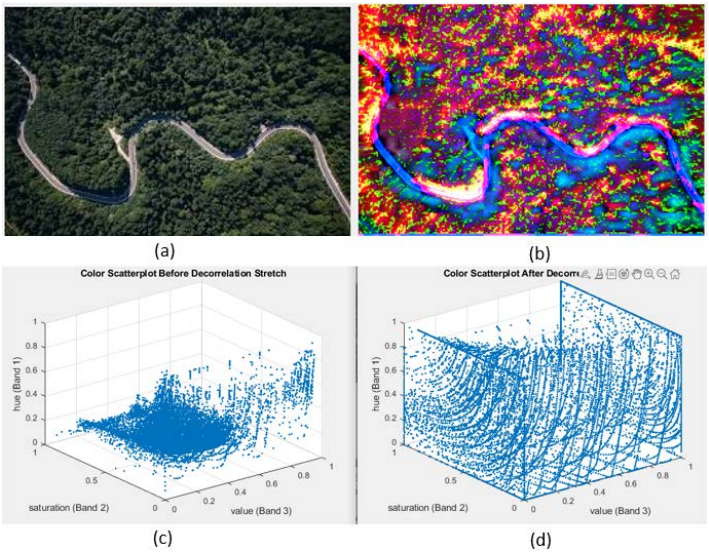

Fig. 1. (a) Aerial View of the Road from Stock Photo 2024801798 [18], (b) Image Processed by the Decorrelation Stretching Algorithm, (c) Point Spread Cloud of the Original Image, (d) Point Spread Cloud of the Resulting Image.

The decorrelation stretching is a linear operation in pixels in which the parameters depend on the values of the original image statistics and the target image and can be expressed using the following equations [19].

$$b = T * (a - m) + m\_target \quad (1)$$

a and b are vectors of n bands times 1, T is the linear transformation matrix and m contains the mean of each band in the image, m_target are vectors of n bands times 1 containing the desired output mean in each band. The linear transformation matrix T is calculated by performing a proper decomposition of the correlation matrix as follows:

$$Corr = inv(SIGMA) * Cov * inv(SIGMA) \quad (2)$$

$$S(k,k) = \frac{1}{\sqrt{LAMBDA(k,k)}} \quad (3)$$

Where $S(k,k)$ is a diagonal matrix containing the stretching factors for each band; finally, the matrix T used in (1), is calculated through:

$$T = SIGMA\_target\ V\ S\ V'\ inv(SIGMA) \quad (4)$$

Although the decorrelation stretching process is usually implemented in RGB format images [20]; the operations proposed here can be applied to any multiplane matrix. Therefore, the algorithm can be applied to images in other formats. For this research the image was processed in HSV format; since it takes advantage of the high stability of this format to the changes of brightness and luminosity in the image; which benefits the detection [21].

In Fig. 1 (c) and (d), you can see the cloud of points representing the dispersion of pixel values in both the original and the resulting image; image (c) is much less dispersed than (d); which demonstrates the color differences between the two images, eliminating the high correlation between channels.

B. Color Detection and Image Filtering Algorithm

Color detection is a technique used to separate objects containing colors of interest into the different existing color spaces; it is important to clarify that color spaces are nothing more than a representation of how machines understand the existing color in the real world [22]. An image in RGB format is made up of three matrices representing the level of red, green, and blue in the image; therefore, the combinations of these three matrices give rise to a wide range of colors ranging from black to white. A color segmentation algorithm reads the three matrices that make up the image and extracts from them the pixels containing the target color; usually, the output of this algorithm is a single plane or binarized matrix which contains in white the pixels corresponding to the target color and in black the other pixels; which are considered as the background of the image (see Algorithm1).

Algorithm 1. Color Detection

```
Start Variables;
create an array of zeros the size of the image
For a=1: up to the number of rows
For b=1: up to the number of columns
If (Image (a,b,R)> threshold)
If (Image (a,b,B)> threshold)
If (Image (a,b,G)< threshold)
transform into 1 pixel with the target color
End If
End If
End If
End For
End For
```

Algorithm 1 shows the implemented color detection; in this algorithm, it is observed that the function goes through the color image and transforms the pixels corresponding to the target color. This procedure is achieved through a function that defines the transformation threshold, see Fig. 2.

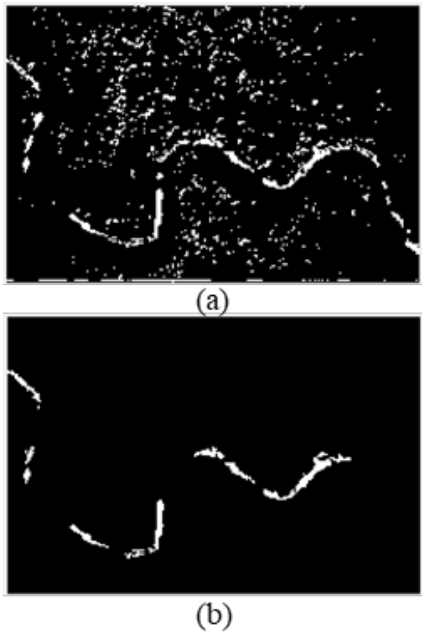

Fig. 2. (a) Binarized Image Employing the Color Detection Algorithm, (b) Filtered Image.

From Fig. 2(a) the need for the image filtering algorithm is evident. The process of image filtering is that which removes unwanted objects or noise from the original image. There are innumerable image filtering methods or functions [23]; but one of the most widely used is bwareaopen (BinaryImage, minPixels) object size filtering. This function removes objects from a binarized image that contain less than the minimum number of pixels specified by minPixels; such a filtering process finds the connected components of the binarized image and calculates the area (in pixels) for further removal. Another filter implemented is the imfill function (BW, locations), which performs a flood fill operation on the background pixels, and is used to eliminate noise in the detected objects. It should be noted that this function removes all black objects surrounded by white elements in the image. Fig. 2 (b) shows the result of the image filtering algorithms implemented in this research.

III. Implementation

The developed system is composed of two main operational blocks: the first block oversees detecting and extracting the existing roads in the processed image; this block makes use of the technique of stretching by decorrelation and conventional image filtering, see Fig. 3. The second block aims to develop an algorithm that calculates the optimal overflight route for a UAV to follow, this algorithm will be explained in full in the next section and is a creation entirely developed by the authors of this research.

A. Overflight Route Calculation for Autonomous Navigation

Calculating the overflight route that allows autonomous navigation for extended periods is essential in video surveillance systems [24] [25]; this calculation must draw a straight line between the start and end points to maximize the capabilities of the fixed-wing drone and minimize its fuel consumption. The problem is that most roads are not straight (see Fig. 4 (a)), therefore the system must calculate the orientation (horizontal, vertical, diagonal, etc.) and direction of the road to calculate an overflight route (in a straight line) that allows overflying the entire road.

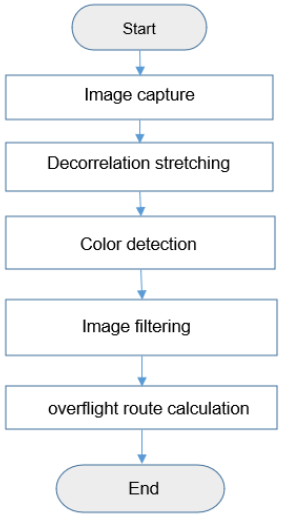

Fig. 3. Block Diagram of the Developed System.

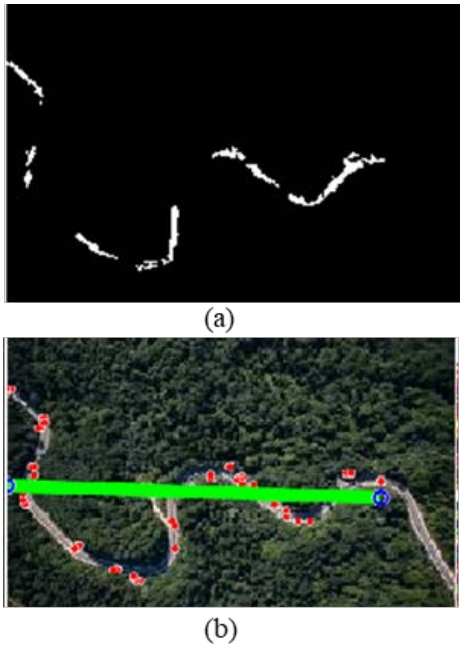

Fig. 4. (a) Road Detected by the Algorithm, (b) Automatic AUV Overflight Route Calculation.

Fig. 4(a) shows the result of the road detection algorithm. Here it can be seen that the road is not detected as a single element; but as multiple elements that are added together to give the totality of the road. These interruptions in the continuity are due to external elements that prevent its detection and with which the route calculation algorithm must deal. The proposed overflight path calculation algorithm starts by identifying the endpoints of each element, which can be seen in red in Fig. 4(b). The function in charge of calculating the endpoints by morphological processing is called

regionprops (ImageBina,'Extreme') [26]. Then the image is divided into four equal quadrants, and it is calculated which of these extreme points for each quadrant is higher, lower, left, and right than the others; which determines the orientation and direction of the road. Once these points have been calculated, the start and end point of the route is calculated as the midpoint between these points, see Algorithm 2.

Algorithm 2. Navigation route calculation

```
Start Variables;
for a=1: up to the number of items detected
calculations of the extreme points of each element
 if (the element is the highest)
                save highest_item
 else if (is the lowest)
                save lowest_item
 else if (is the most to the left)
                save left_item
 else if (it is the most to the right)
                save right_item
 end if
end for
%%% horizontal or vertical direction calculation

if (highest_item < left_item)
 fI=fminI+(fmaxI-fminI)/2  % top point
else
 fD=fminD+(fmaxD-fminD)/2 % left point
end if
if (lowest_item > right_item)
 cU=cminU+(cmaxU-cminU)/2 % down point
else
 cD=cminD+(cmaxD-cminD)/2 % right point
end if
paint line on the detected points
```

IV. Results

The algorithm was implemented on a computer with Windows 10 Pro 64bits operating system, Intel(R) Core (TM) i3-3110M CPU 2.40GHz (4 CPUs), RAM 12288MB, and MATLAB 2020b Update 5 under license from Universidad Distrital Francisco José de Caldas. The implemented system operates pixel by pixel on the input matrix. Table I shows the time report; here it can be seen that the time that contributes most to the system depends on the number of elements that were detected; since the algorithm for calculating extreme points and calculating the route must be applied individually to these elements.

The automatic road detection and overflight route calculation system was tested with different images taken by fixed-wing drone overflight. These images were taken with different cameras at different altitudes and different times of the day to demonstrate the robustness of the algorithm.

Fig. 5 shows the response of the developed system; it is observed that the system can detect and calculate the overflight path for roads going vertically, horizontally, or diagonally; demonstrates the effectiveness of the algorithm for images with different illuminations; double-lane roads, and cars. Finally, demonstrate what happens to the algorithm if it encounters intersections, elevated bridges, round-point, and other elements that are usually present on the road.

As the algorithm is designed to run on a mini pc on board the aircraft, the validation of operation was performed using different processing units. Fig. 6 shows the response time of the algorithm on different processors; it should be noted that these times were measured using the same image in which five elements were obtained after binarization.

TABLE I. System Processing Time Measurements

Time Report [seconds]		
Image size in pixels	**Number of Detected Objects**	**Time in Seconds**
33.000	3	0.2488
50.246	1	0.1113
50.246	2	0.3273
50.325	3	0.2526
50.400	1	0.0977
50.400	3	0.4041

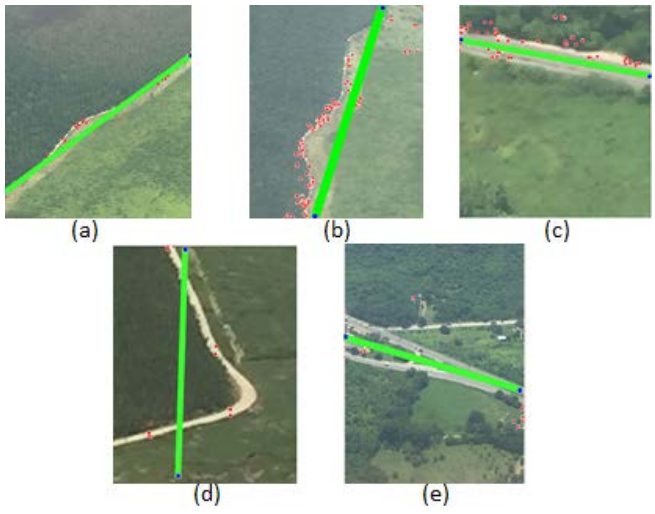

Fig. 5. Tests of the Algorithm with Photos taken from Different Environments and Altitudes.

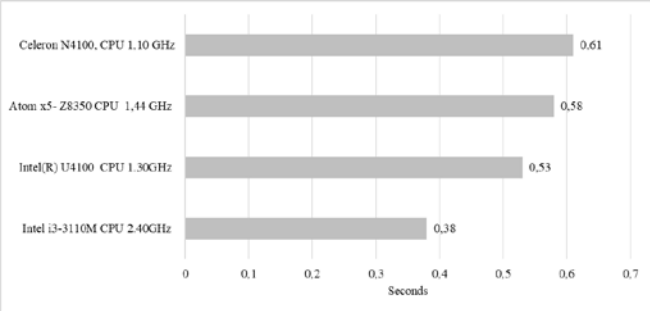

Fig. 6. Algorithm Response Time with Different Processors.

V. Conclusions and Future Work

As can be seen in Fig. 5, the performance of the system is high since it can detect the road in photos taken with different devices at different heights and with different degrees of illumination. It is important to emphasize that the overflight path calculation algorithm is a novel proposal of the researchers, this calculation is performed through the endpoints of the detected road.

Although the decorrelation stretching algorithm has been implemented to highlight the color difference in an image; its use to detect roads in aerial images is a proposal introduced in this research. This proposal demonstrates its robustness since it can separate the colors of the road and the landscape in different aerial images.

Finally, as can be seen in Fig. 5(e) the system can make a coherent decision when encountering intersections, elevated bridges, round-point, and other elements that are usually present on the road. Thus, demonstrating the high degree of stability and applicability of the proposed solution; ensuring that the road detection system can be applied in various environments since it can be functionally adapted to various road environments.

Although the algorithm was tested in a specific task, this implementation offers the possibility that it can be used in various fields of the productive sector. Since the proposed solution allows for the identification clearly and punctually of artificial long objects in a natural landscape. The next step is to complement the system with algorithms that can automatically detect anomalies (pipeline monitoring, fire outbreaks, traffic jams, suspicious vehicles, etc.) that may occur during the overflight of the drone, and thus seek to complete an autonomous aerial tracking and surveillance system.

***Abstract*—This paper studies the prediction method of regional differentiated allocation mode of energy finance based on attention mechanism and support vector machine to provide scientific guidance for the future development direction of energy finance in each region. Analysis of the key factors influencing the energy consumption, through the attention mechanism to extract the regional factors such features constitute the details of the sample set, the characteristics of the sample set after implementation of fusion and normalized processing, gain new characteristics of sample set as input to construct support vector machine forecasting model, prediction of energy consumption in each region of the output. According to the results, the differentiated allocation patterns of energy finance in each region are predicted. The results show that the prediction model of this method has high training and test prediction accuracy, and the prediction results are consistent with the actual data in historical statistics. Compared with the existing methods, the method of this study can more scientifically and effectively predict the sustainable and stable development of energy finance in various regions of the city in the future. The energy consumption of the experimental city predicted in this study in the next nine years is from high to low in the order of region C, region a and region B. from this, it is predicted that the regions A, B and C of this city in the future will be applicable to the government market dual oriented Government oriented and market-oriented energy finance allocation models. The prediction results can provide scientific guidance for the sustainable and stable development of energy finance in various regions of the city in the future.**

Keywords*—Attention mechanism; support vector machine; energy finance; differentiation configuration mode; energy consumption

I. INTRODUCTION

Energy finance refers to a cooperative model based on the energy system that uses the financial system as a driving force after the integration of energy and finance. It is a brand-new model that promotes the coordinated development of energy and finance [1]. Energy finance is mainly based on the energy industry chain. With the help of financial means, it studies the interaction between the new energy industry and the financial industry from three aspects: the initial financing, the intermediate integration of resources, and the final realization of value-added, and puts forward corresponding safeguard measures. The energy industry is usually dependent on the financial industry in its development. To obtain the highest profit and achieve the highest capital utilization rate, the financial industry also needs to rely on the assistance of the energy industry [2,3]. As the main body of energy consumption in China, the consumption of primary energy in my country has shown an increase year by year in recent years. On the premise of maintaining the sustained and stable development of our country's energy finance, the development level of energy finance is gradually improved in various regions, so that can achieve the coordinated development of energy and finance in various regions. It is necessary to configure a differentiated energy financial model that meets its development characteristics for each region of our country [4]. Therefore, it is necessary to effectively combine the respective advantages of energy and finance in each region to effectively alleviate the financial problems faced by energy development. Meanwhile, new energy financial development paths will be provided to all regions. Regarding the question of how to configure a differentiated energy finance model that applies to each region, the most important thing is to accurately predict the energy consumption of each region. Based on the prediction results, the energy financial allocation models applicable to different regions can be analyzed [5].

The attention mechanism belongs to a type of model that simulates the attention mechanism of the human brain. Its principle is to use the method of attention probability distribution calculation to highlight the effect of a certain main input on the output, and to obtain more feature detail information. When the attention mechanism is used in deep learning models, it can help improve the overall accuracy and efficiency of such models [6, 7]. Meanwhile, the combination of attention mechanisms and machine learning algorithms to solve problems in projects or life has become a development trend. Support vector machine is a relatively important prediction algorithm in machine learning. It can transform the input in the low-dimensional space into the high-dimensional space through the kernel function and slack variables, and obtain the linear sample data in the best classification method [8]. Support vector machine has the advantages of being able to find the optimal solution globally, strong learning ability, and strong pan-China ability. It can be widely used in multi-dimensional function prediction and various recognition problems [9].

*Corresponding Author.

The attention mechanism and machine learning methods are applied to study the regional differentiation of energy finance, which can realize the prediction of the regional energy financial differentiation allocation mode. However, the research should analyze the key influencing factors that affect energy consumption and extract the relevant key influencing factors on the basis of a full analysis of the regionally differentiated configuration mode of energy finance. The data under the key influencing factors are formed into a sample set, and the data of the sample set is feature-fused using the normalization method, so that can realize the establishment of the support vector machine feature model. In the entire process, key factors can be determined in terms of economic development degree, urbanization degree, energy efficiency application degree, industrial structure and demographic factors that affect energy consumption, which can realize scientific and effective forecasts. Traditional energy finance regional differentiation research is mainly to analyze the correlation between energy industry projects and energy financial derivatives in various aspects. The process of using correlation to achieve prediction requires constant adjustment of model parameters to improve the accuracy of prediction, and the process is more complicated. This paper combines the attention mechanism and support vector machine to build a scientific prediction model, which can simplify the prediction process. Through the identified key factors, the sample set is input into the support vector machine prediction model, the energy consumption prediction results of different regions are output, and the results of the model output are used to analyze the energy financial configuration modes applicable to different regions. Through the identified key factors, the sample set is input into the support vector machine prediction model, the energy consumption prediction results of different regions are output, and the results of the model output are used to analyze the energy financial configuration modes applicable to different regions.

Therefore, the purpose of this paper is to combine the attention mechanism and support vector machine to achieve a scientific and accurate prediction of the regional energy finance differential distribution mode, and can guide the development direction of Regional Energy Finance in the future according to the prediction results, promote the sustainable and stable development of Regional Energy Finance in the future, and make up for the shortcomings of existing research.

II. Related Work

The concept of energy finance appeared in the 1880s. As the traditional energy structure upgrades and the capital demand for corporate development has grown, energy finance has gradually developed. However, the issue of energy finance has become the core issue of today's world economic development. It is not only closely related to the security of the country, but also closely related to the development of society [10]. Therefore, the differential analysis of energy finance between countries or regions has gradually become one of the important research hotspots. Many relevant experts and scholars have conducted analysis and research on the differences in energy finance. Some researchers have studied the framework of regional energy finance cooperation under the new normal [11], and they theoretically explain the importance of forecasting functions to regional energy finance. Some scholars use the GABP algorithm to establish an energy financial risk early-warning model to realize the overall risk prediction of energy finance, but the accuracy of the prediction still needs to be considered [12]. Some researchers analyze the necessity of the association between early warning models and regional energy finance from a theoretical perspective [13]. In terms of the research on the regionally differentiated allocation model of energy finance, most of the existing relevant literature is theoretically analyzed. Some researchers use provincial panel data to analyze financial risks from a differentiated perspective and analyze the potential impact of regional financial risks [14]. Some researchers use the VAR model to study the regional differentiation of rural finance and analyze the correlation between influencing factors [15]. However, the current research on the difference of energy finance is still one-sided, and there are few methods to output scientific and accurate prediction results from the data accumulated in history.

The application of machine learning methods in the financial field is more common, it mainly has stock forecasting, quantitative finance, investment portfolio analysis, etc. [16]. However, there are few studies on regional financial differentiation, which mainly focus on the collection of regional financial data and regional financial risk index. A fuzzy comprehensive evaluation or analytic hierarchy process is applied to evaluate regional financial risks. The analysis of the difference is mainly based on the risk ranking by the evaluation grade [17-18]. There are also a few researchers who study the stability and differences of regional finance [19-21]. However, this type of research is also limited to the use of evaluation methods to obtain results. Few machine learning methods are applied to difference analysis, and data-driven methods are not used to output prediction results.

In summary, the machine learning method has been applied in the financial field, but the existing research on regional financial differentiation mainly focuses on the theoretical level and the correlation analysis between factors. Some studies have made key determination on the economic development degree, urbanization degree, energy efficiency application degree, industrial structure and population factors that affect energy consumption; however, the prediction of regional differentiation of energy finance by means of machine learning is still in the development stage.

Therefore, on the basis of the existing research results and after analyzing the key factors affecting energy consumption, this study uses the attention mechanism to extract the detailed features of these factors in each region, form a feature sample set, and fuse and normalize the feature sample set to obtain a brand-new feature sample set input, build a support vector machine prediction model, and realize scientific and effective research and Analysis on the basis of the existing research, provide auxiliary decision support for relevant management departments.

III. Analysis of the Differential Configuration Mode for Energy Finance Region

To achieve the coordinated development of energy and finance in various regions, it is necessary to configure

differentiated energy financial models in line with their development characteristics for different regions to achieve a more effective combination of the respective advantages of energy and finance. Its model can not only effectively alleviate the financial problems faced in energy development, but also provide brand new development paths to the financial industry in various regions [22]. Generally, the regional energy financial allocation mode can be divided into three types: government-oriented regional energy financial configuration mode, government-market dual-oriented regional energy financial configuration mode, and market-oriented regional energy financial configuration mode. The first configuration mode is suitable for areas with low energy finance levels. The second configuration mode is suitable for areas with a medium level of energy finance. The third configuration mode is suitable for areas with higher levels of energy finance [23]. Therefore, to study the energy financial allocation model applicable to each region, it is necessary to understand the energy financial level of each region. However, the level of energy finance is mainly reflected in the degree of consumption, so it is necessary to analyze the differentiated energy financial allocation models in different regions on the basis of obtaining energy consumption. Meanwhile, to obtain the energy consumption of each region, it is necessary to design an appropriate energy consumption prediction model to realize an effective prediction of the energy consumption of each region. Based on the prediction results, the energy financial level of each region is analyzed, and the differentiated configuration mode of energy finance applicable to each region is predicted. On this basis, the detailed features of such key influencing factors in each region are extracted by combining the attention mechanism. After its features are processed by feature fusion and normalization, they are used as input to the support vector machine prediction model, and the energy consumption of each area is output to realize the prediction of energy consumption in each area. Based on the prediction results, predict the differentiated allocation mode of energy finance in different regions.

A. Analysis of Key Factors Affecting Energy Consumption

The main factors that usually affect energy consumption include the level of urbanization, energy efficiency, demographic factors, industrial structure, and degree of economic development [24]. The demographic factors include two factors: population size and population structure. The degree of economic development includes factors such as the stage and scale of development. The structure of key influencing factors of energy consumption is shown in Fig. 1.

In Fig. 1, the effects of each key influencing factor on energy consumption are as follows.

1) Urbanization level factors: The difference in lifestyle between rural and urban residents has resulted in differentiated energy consumption in the two regions. Meanwhile, in the process of rural urbanization, the construction of transportation and infrastructure can also increase energy consumption. Therefore, the urbanization of the rural population has a promoting effect on energy consumption, and the proportion of the urban population can be used to measure the level of urbanization.

2) Energy efficiency factors: The improvement of energy efficiency can promote the sustainable development of energy, reduce energy waste, and effectively alleviate the contradiction between energy supply and demand, as well as achieve the purpose of saving energy and reducing emissions. The key indicator to measure energy efficiency is the value of energy consumption per unit of GDP, which is inversely proportional to energy efficiency.

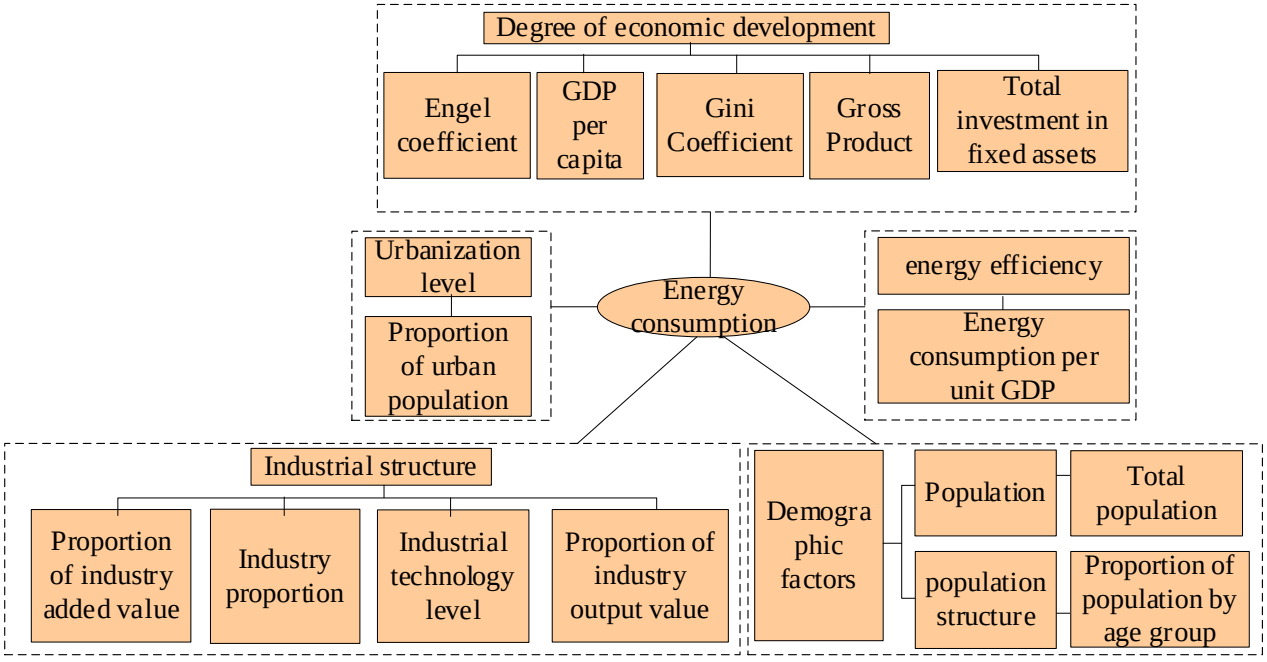

Fig. 1. Structure Diagram of Key Influencing Factors of Energy Consumption.

3) Demographic factors: With the increase in the number of people, the energy demand has gradually increased, so energy consumption has also shown an increasing trend. From the perspective of demographic structure, different age groups will lead to differences in consumption habits and lifestyles, as well as differences in energy consumption. Therefore, both population size and population structure will have an impact on energy consumption. Generally, the main indicators for measuring demographic factors are the total population, the proportion of the population of each age group, and so on.

4) Industrial structure factors: The differentiation of industrial structure has a direct impact on energy consumption, and the key energy consumption industry in my country is the secondary industry [25]. Common indicators used to measure changes in the secondary industry structure include the proportion of secondary industry's added value, the proportion of the secondary industry, the technical level of the secondary industry, and the proportion of secondary industry's output value. Therefore, the above indicators can also be used to measure the impact of changes in industrial structure on energy consumption.

5) Economic development degree factors: The increase in total energy consumption can promote the degree of economic development, and economic development will also bring about an increase in energy consumption. There is a mutually reinforcing relationship between energy consumption and economic development. Commonly used indicators to measure the degree of economic development include Engel's coefficient, GDP per capita, Gini coefficient, gross production value, and total fixed-asset investment. In which the Engel coefficient is inversely proportional to the living standards of the masses, and the Gini coefficient is directly proportional to the difference in income distribution, both of which can show the degree of economic development.

B. Feature Extraction of Key Influencing Factors for Energy Consumption based on Attention Mechanism

The attention mechanism is the process of extracting more detailed features. Its main principle is to quickly scan the overall scene of its visual interval through the human visual system, and select the key target interval from it through the brain's signal processing mechanism, and put more attention resources into this interval [26]. Feature extraction of factors affecting energy consumption is the key to energy consumption prediction. The attention mechanism can quickly extract more detailed feature information of the key influencing factors of energy consumption, which can effectively improve the accuracy and efficiency of the final energy consumption prediction in each region. The attention mechanism can search for many key-value pair mappings, and obtain the goodness of such key-value pairs. The goodness of fit is proportional to the number of allocated attention resources. The structure of the attention mechanism is shown in Fig. 2.

In Fig. 2, $L_i - W_i$ represents a key-value pair, which represents the weight of factors affecting energy consumption. The query is represented by Q, which represents energy consumption. The feature information of the key influencing factors of energy consumption extracted by the attention mechanism can be used to construct the prediction model, which can improve the prediction accuracy and efficiency of the model. The calculation process of attention is:

After calculating the goodness of fit between the energy consumption and the weight of each key influencing factor, the weights will be obtained. Here the splicing method is chosen to calculate the coincidence degree. The calculation equation is:

$$g\left(Q, L_i\right) = v_\alpha \left[Q; L_i\right] \tag{1}$$

In equation 1, the splicing coefficient is represented by v_α.

Step2: Normalization of weights. The weights obtained in step (1) are normalized by the $\mathrm{Soft\,max}$ function, and the calculation equation is:

$$\mathrm{Soft\,max}\left[g\left(Q, L_i\right)\right] = \left[\exp\left(g\left(Q, L_i\right)\right)\right] / \left[\sum_j \exp\left(g\left(Q, L_j\right)\right)\right] \tag{2}$$

Step3: Attention calculation. The weights gained by normalization of weighted and sum, and the weights acquired by factors of influencing energy consumption are used to obtain attention. The calculation equation is:

$$A\left(Q, L, W\right) = \sum_i \omega_i W_i \tag{3}$$

In equation 3, ω_i represents the normalized weight.

Based on the key influencing factors of energy consumption extracted by the attention mechanism, the detailed feature information is formed into a feature sample set. The sample set is processed accordingly and then input into the support vector machine prediction model to obtain the output of energy consumption in each region.

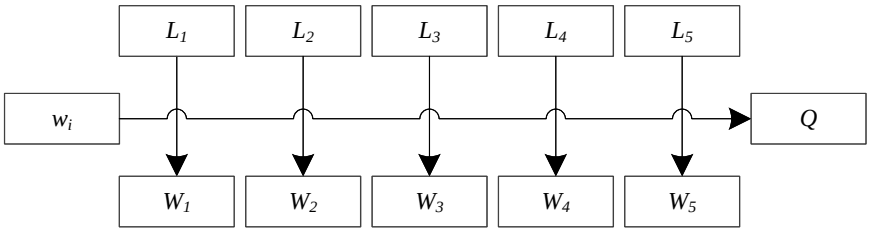

Fig. 2. Structure Diagram of Attention Mechanism.

C. Prediction of Regional Energy Consumption based on Extracted Feature Sample Sets

1) Feature fusion and normalization of the feature sample set: The feature sample set acquired by the attention mechanism can be fused to realize the complementary advantages of each factor feature in the sample set, improve the description performance of the feature, and help to further improve the prediction accuracy of the model [27]. After fusion, due to the dimensional differences of the characteristics of each factor in the feature sample set, it is easy to cause large fluctuations in the prediction results obtained by the prediction model, and the prediction performance is not stable enough. Therefore, it is necessary to further implement normalization processing on the basis of feature fusion to achieve stable prediction of the prediction model.

2) Feature fusion: Given that the features in the feature sample set obtained by the attention mechanism are the initial features, denoted by X_i *(i=1,2,...,M)*, where M represents the number of features. The features in the feature sample set after feature fusion processing are represented by X_j *(j=1,2,...,M)*. The feature fusion equation is:

$$X_j = \delta_j\left[\theta_i \times X_i\right] \tag{4}$$

In equation 4, δ_j represents the feature fusion function; the conversion function is represented by θ_i .

3) Normalization: After the fusion processing, the normalization of the feature data in the feature sample set is performed, that is, the value range of the feature data of each factor is unified to 0~1, so that can achieve the unity of dimensions and ensure the stability of the prediction results. The normalized processing equation is:

$$\tilde{x} = \left(x_i - x_{\min}\right) / \left(x_{\max} - x_{\min}\right) \tag{5}$$

In equation 5, $\tilde{x}$ represents the normalized feature sample set feature data; x_i represents the *i-th* feature data in the feature sample set after fusion processing. The highest value and the lowest value of the feature data in the feature sample set after fusion processing are represented by $x_{\max}$ and $x_{\min}$, respectively. Therefore, a new feature sample set $\tilde{X}$ composed of many normalized feature data $\tilde{x}$ can be obtained, which can be used as the input sample set of the prediction model to achieve a stable prediction of energy consumption in each region.

4) Support vector machine prediction model based on the processed feature sample set: Taking the processed new feature sample set XXX as input and the energy consumption of each area as output, a support vector machine prediction model is constructed to realize effective prediction of energy consumption in each area. The differentiated allocation mode of energy finance in each region is estimated by the prediction results.

Each feature $\tilde{X}_1, \tilde{X}_2, \cdots, \tilde{X}_M$ in the input feature sample set $\tilde{X}$ is mapped to a high-dimensional feature space ($\sigma(X_1)$, $\sigma(X_2)$,…, $\sigma(X_n)$). According to statistics, the initial nonlinear model can be changed to the linear regression model of the high-dimensional feature space. Its equation is:

$$f\left(X_j\right) = d + \lambda^T \times \sigma\left(\tilde{X}_j\right) \tag{6}$$

In equation 6, *d* and λ represent the parameters that need to be identified in the linear regression model, where the adjustable weight vector is λ, and the bias is *d*. Based on the structural risk minimization criteria, the required identification parameters are processed, and the processing formula is:

$$H\left(f\right) = \sum_{i=1}^{s} \gamma \left\|\lambda\right\|^2 + B\left(e_i\right) \tag{7}$$

In equation 7, $B\left(e_i\right)$ represents the loss function; confidence risk is represented by $\left\|\lambda\right\|^2$; $H\left(f\right)$ represents empirical risk. According to the principle of support vector machine, the solution of formula (7) is equivalent to the operation of the following optimization problem, which is:

$$\begin{cases} \min K = B\sum_{i=1}^{s}\left(\mu_i + \mu_i^*\right) + \dfrac{1}{2}\lambda^T\lambda \\ s.t.\begin{cases} y - \left(\lambda, \sigma\left(X_t'\right)\right) - d \le \mu + \mu_i^* \\ \left(\lambda, \sigma\left(X_t'\right)\right) + d - y \le \mu + \mu_i^* \\ \mu_i^*, \mu_i \ge 0 \end{cases} \end{cases} \tag{8}$$

In equation 8, the optimized parameters are represented by μ_i and μ_i^* ; *K* represents the classification hyperplane; and the parameters of the inner product function are represented by X'_t.

By converting formula (8) into a dual problem and simplifying the calculation process, the nonlinear function obtained after conversion is expressed as:

$$f\left(X\right) = \sum_{i=1}^{k}\left(c_i - c_i^*\right)G\left(X_t', X'\right) + d \tag{9}$$

In equation 9, $G\left(X_t', X'\right)$ represents the inner product function; the support vector parameters are represented by c_i and c_i^*. The radial basis function is set by the Mercer condition, which is set the inner product function, and it is expressed as:

$$G\left(X_t', X'\right) = \exp\left\{-\left(\left\|\tilde{X}_j - \tilde{X}_a\right\|^2\right) / \varphi^2\right\} \tag{10}$$

In equation 10, φ^2 represents the Mercer condition coefficient; the training feature data vector and the test feature data vector in the feature sample set are represented by $\tilde{X}_j$ and $\tilde{X}_a$, respectively.

The equation (10) is substituted into equation (9). After equivalent transformation, it is acquired as:

$$f(X)=\sum_{i=1}^{l} c_j \exp\left\{-\left(\left\|\tilde{X}_j-\tilde{X}_a\right\|^2\right)/\varphi^2\right\}+d \tag{11}$$

In equation 11, c_j represents the parameter value corresponding to the support vector; the output vector set of energy consumption in each region is represented by $f(X)$. The energy consumption prediction parameters d *and* c_j can be acquired to obtain the energy consumption output of each region. The differentiated allocation mode of energy finance applicable to each region is predicted by the energy consumption of each region.

IV. Analysis of Experimental Results

Take a city as an example, the city is divided into three regions (a~c), and the method in this paper is used to study the differentiated configuration mode of energy finance in each region. Taking the period from 2011 to 2020 as an example, the historical statistics of energy consumption and key influencing factors in each area of the experimental city during the period are used as the basis. The proportion of the urban population, energy consumption per unit GDP, total population, the proportion of secondary industry added value, gross production value and energy consumption in each region of the city can be obtained, which is as Table I.

TABLE I. Historical Statistics of Energy Consumption and Various Influencing Factors in Each Region of the Experimental City from 2011 to 2020

Number	Year	Proportion of urban population /%	Energy consumption per unit GDP /tce/ 10 thousand yuan	Total population/10 thousand people	Proportion of added value of secondary industry /%	GDP/100 million yuan	Energy consumption/10 thousand tce
a	2011	48.8	4.7×10^{-5}	60.1	45.1	208.2	98.7

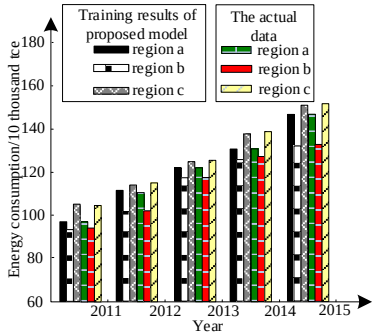
	2019	55.1	7.3×10^{-5}	65.8	44.3	246.4	180.4
	2020	56.7	8.1×10^{-5}	68	43.2	252.2	206.2
c	2011	50.6	4.9×10^{-5}	65.2	46.3	212.4	105.2
	2012	52	5.3×10^{-5}	66.7	45.5	220.6	117.3
	2013	52.8	5.5×10^{-5}	68.1	46.2	227.8	126.9
	2014	54.1	5.8×10^{-5}	69.7	44.1	236.3	138.5
	2015	55	6.2×10^{-5}	71.2	43.7	244.2	151.3
	2016	56.3	6.4×10^{-5}	72.8	47.1	251.7	162.4
	2017	57.8	6.8×10^{-5}	74.1	46.8	258.9	176.9
	2018	59.1	7.2×10^{-5}	76.3	42.1	267.3	192.6
	2019	60.5	7.7×10^{-5}	77.9	46.1	274.2	211.1
	2020	61.3	7.9×10^{-5}	79.5	45.8	285.2	226.9

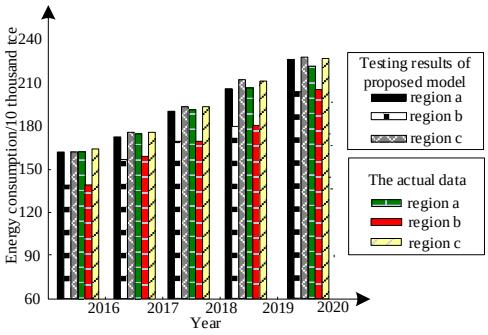
Using historical statistical data from 2011 to 2015 as the training sample set, and historical data from 2016 to 2020 as the test sample set, the prediction model of this paper is used to implement training and testing, which can obtain the training effect and testing effect, as shown in Fig. 3.

It can be seen from Fig. 3 that the training results and testing results of the prediction model of the method in this paper are in close agreement with the actual energy consumption in historical statistics, and the maximum error value does not exceed 15,000 tce. Therefore, the training effect and test effect of the prediction model in this paper are relatively ideal, and the obtained prediction results have high accuracy, which can be applied to the actual energy consumption prediction in the study of the differential configuration mode of energy finance for different regions.

This paper studies the differentiated energy financial allocation modes of the experimental cities from 2022 to 2030 in the future, and further uses the proposed prediction model to predict the energy consumption of the experimental cities from 2022 to 2030. The future energy financial differentiated allocation mode of each region is studied by the obtained prediction results. The prediction results of energy consumption in each region of the experimental city from 2022 to 2030 are shown in Fig. 4.



(a) The Training Effect of the Prediction Model for the Proposed Method by the Paper.



(b) The Testing effect of the Prediction Model for the Proposed Method by the Paper.

Fig. 3. The Training and Testing Effect of the Prediction Model in the Method of this Paper.

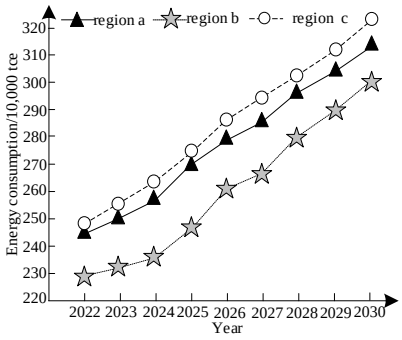


Fig. 4. The Prediction Results of Energy Consumption in each Region of the Experimental City from 2022 to 2030.

From Fig. 4, it can be concluded that the annual energy consumption of each region for the experimental city from 2022 to 2030 will show an upward trend. On the whole, energy consumption in region *c* is higher, energy consumption in the region *a* is at a medium level, and energy consumption in region *b* is the lowest. Combining this prediction result, the future energy financial level of the three regions of the experimental city is ranked *c*-*a*-*b* from high to low. Therefore, the energy financial allocation models corresponding to each region from 2022 to 2030 in the future should be: region-c-market-oriented, region-a-government-market of dual-oriented, and region-b-government-oriented. Based on the predicted different regional energy finance allocation models in the future, it can provide a clear development direction for the future development of energy finance in each area of the experimental city. It also improves the future development level of energy finance and provides help to effectively avoid bottlenecks in future development.

V. Conclusion

This paper focuses on the research on the prediction method of regional differential allocation pattern of energy finance based on attention mechanism and support vector machine. It extracts many detailed features of key influencing factors of energy consumption by using attention mechanism, and after fusing and normalizing them, the feature sample set obtained is input into the support vector machine, constructs the support vector machine prediction model, and outputs the prediction results of regional energy consumption. According to this result, the energy finance allocation mode applicable to each region is analyzed. The proposed prediction model has high training prediction accuracy and test prediction accuracy, and has a good prediction effect on the historical sample set. It can provide a scientific guidance path for the sustainable and stable development of energy finance in various regions of the city in the future.

***Abstract*—Conversational technologies are revolutionizing how organizations communicate with people, thereby raising quick responses and constant availability expectations. Students often have queries about the institutional and academic policies and procedures, academic progression, activities, and more in an academic environment. In reality, the student services team and the academic advisors are overwhelmed with several queries that they cannot provide instant responses to, resulting in dissatisfaction with services. Our study leverages Artificial Intelligence and Natural Language processing technologies to build a bilingual chatbot that interacts with students in the English and Arabic languages. The conversational agent is built in Python and designed for students to support advising-related queries. We use a purpose-built domain-specific corpus consisting of the common questions advisors receive from students and their responses as the chatbots knowledge base. The chatbot engine determines the user intent by processing the input and retrieves the most appropriate response that matches the intent with an accuracy of 80% in English and 75% in Arabic. We also evaluated the chatbot interface by conducting field experiments with students to test the accuracy of the chatbot with real-time input and test the application interface.**

Keywords*—Chatbot; conversational agent; academic advising; natural language processing; deep learning; bilingual English Arabic

I. Introduction

Conversational technologies are transforming the interaction landscape between organizations and people, causing digital communication to be propelled by technology rather than humans. A chatbot, also known as a conversational agent, is a software system that processes and simulates human conversation to provide digital assistance in real-time [1]. The constant availability of chatbots and the ability to respond immediately and communicate in a natural language have escalated their popularity across all domains [2], [3]. Chatbots are being entrusted with various tasks previously handled by human agents, such as providing customer service, healthcare advice, e-shopping, and answering queries. Organizations pervasively rely on chatbots to support customers' needs and increase customer satisfaction with services. Therefore in this digital era, chatbots have the potential to support student queries and assist in the academic advising process in the education domain.

Academic advising is an integral function of Higher Education Institutions (HEIs) and has been widely acknowledged as a principal strategy for confronting the challenges of persistence and retention [4]–[6]. While advising encompasses several tasks, one of the crucial tasks of advising is to provide students with the essential information required for navigating their academic journey successfully. This task involves a high degree of interaction between advisors and students and often leads to dissatisfaction with advising services when students cannot get timely and accurate information. The large number of students assigned to each advisor makes it impossible for the advisor to respond to all students in a satisfactory amount of time [7]. Moreover, students' expectations and information requirements for their daily tasks have intensified with today's technological advancement. Providing adequate channels for student communication is vital for their academic progression and integration with the academic environment. Therefore, a chatbot can provide numerous benefits to the students and the academic institution by providing instant responses to students, thereby enhancing student satisfaction.

This study aims at building a chatbot for the students at an academic institution in the UAE. The institution offers four undergraduate programs of study. There are nearly 3000 students of Arab origin and almost 100 faculty members employed at the institution. Each faculty member serves as an advisor to nearly 25-30 students per semester. This large ratio makes it challenging for the advisor to contribute quality time to advisees and answer all their queries or make them aware of the college policies related to registration, courses, pre-requisites, and more. A chatbot would assist in reducing the workload of the advisor so they may focus on more cognitive tasks such as creating an ideal study plan for their advisees.

Considering the aforementioned challenges of advising at the institution of study, the study aims to develop a chatbot that supports students in answering queries on college and academic-related matters and thereby improve student satisfaction with college services. The chatbot will be bilingual and provide an interface in both English and Arabic. Moreover, the chatbot will be developed using a neural network and Natural Language (NLP) technologies. Thus, our study is novel in its context with bilingual conversational support.

The rest of the paper is organized as follows. Section II provides a literature review on the background of chatbots and related studies of chatbot use in the education sector and bi-lingual chatbots. Next, Section III describes our research methodology, while Section IV presents the evaluation and results of the study. Finally, the study concludes with Section V, which summarizes the paper, significance of the study, limitations, and new directions for future research.

II. Literature Review

A. Overview of Chatbots

Chatbots, are dialog systems that mimic human conversations in text, voice, or multimodal form [1]. A chatbot, also known as a conversational agent, processes user input to discover the query's intent and respond appropriately. In the last few years, there has been a tremendous rise in chatbot applications worldwide [3]. Organizations rely on chatbots to respond to customer service queries and automate tasks [8]. Chatbots are also being used in the healthcare sector for psychiatric and medical diagnosis, raising awareness of health and safety issues [9], [10]. In the educational sector, chatbots are used for teaching and learning activities, student advising, and administrative tasks [11]. Chatbots offer a cost-effective means of delivering services to consumers eliminating repetitive and time-consuming human-agent communication, enabling them to focus on high-end complex tasks [2].

Several classifications exist in literature to categorize chatbots. A chatbot may be rule-based or driven by Artificial Intelligence (AI). A rule-based chatbot provides predefined responses based on keywords and a defined set of rules. ELIZA and PARRY were among the earliest rule-based chatbots developed in the 1960s, built using pattern recognition technology [3]. Artificial Intelligence Markup Language (AIML) [12] was used to develop the ALICE chatbot in 1995. The markup language is based on an XML structure. Chatbots developed with AIML use a rule-based approach to respond to user queries based on inputs that match a pattern.

On the other hand, an AI-driven chatbot is powered by NLP techniques to recognize the intents of the user input and generate an appropriate response based on the intent. AI-driven chatbots are technologically superior and can meet consumers' language and conversational expectations [3]. Several AI techniques have been employed in the literature to develop chatbots, such as machine learning, neural network [13], deep learning with sequence to sequence model [14], and CVAE Models [15].

Chatbots have been classified as task-oriented or non-task-oriented based on their functionality [16]. A task-oriented chatbot responds to domain-specific user queries and performs tasks such as making a reservation, placing an order, or answering queries. On the other hand, a non-task-oriented chatbot responds to open-ended queries that are not domain-specific, also called an open-domain. The main purpose of these chatbots is to act as digital assistants using an open-ended dialog. Siri and Alexa are an example of non-task-oriented virtual assistants.

Chatbots have also been classified based on their response generation method as retrieval-based and generative chatbots [17]. A retrieval-based chatbot retrieves responses from a knowledge base using machine learning algorithms, and NLP techniques process the user input, allowing users to communicate in natural language. However, the responses generated in a retrieval-based chatbot are fixed. On the other hand, a generative chatbot is trained on a conversational corpus to generate new and diverse responses that do not exist in the dataset. A limitation of the generative model is that it requires massive training data and may provide unpredictable responses not stored in the corpus.

This study uses a domain-specific knowledge base to develop a task-oriented chatbot that responds to student queries. The students ask questions in a natural language, yet the responses provided by the chatbot must be precise and accurate. Hence we use an AI-driven retrieval-based chatbot that uses NLP techniques to process user input and retrieve precise responses from a corpus of advising queries. The chatbot determines the user intent by processing the input and retrieving the response that matches the intent.

B. Chatbots in Education

Some studies used NLP techniques with a rule-based approach for developing chatbots in the educational setting to answer student queries [18], [19]. Reference [18] developed a rule-based conversational agent using PHP and NLP to respond to student queries with an accuracy of 80%. While reference [19] developed a chatbot using a social conversation dataset between students and advisors. The chatbot was developed using a frequent intent pattern by discovering rules from the dataset.

Several studies develop retrieval-based chatbots to answer student queries using AI and NLP techniques. Refrence [20] developed a chatbot based on pattern matching using AIML and Latent Semantic Analysis (LSA). The chatbot answers informational queries on college and academics. In a similar study, [21] proposed a chatbot that answers frequently asked questions. The knowledge base of the chatbot consisted of 300 questions. Both studies did not evaluate the performance of the chatbot.

Reference [22] developed an AI-driven chatbot that allows students to enquire about college admission rules and policies. The chatbot is developed using the RASA framework. The performance of the chatbot was evaluated using the confidence of the responses. However, the confidence does not indicate the accuracy of the response. Moreover, the study did not specify how they handled spelling errors in the user input.

In another study, [13] developed a chatbot using machine learning and NLP techniques that answer campus-related queries published as FAQs on the website. The study compares two chatbot models, RNN based Seq2Seq model and a semantic similarity model. The results show that the semantic similarity model performs better in cases where the dataset size is small. Furthermore, this study uses a deep learning model to process the input patterns and retrieve the most accurate response rather than constructing responses, similar to our study. However, the chatbot is developed in one language only.

Several studies have developed chatbots to answer students' admissions, policies, or academic advising queries. However, only a few have used neural networks with NLP techniques to process the user input.

C. Chatbots in Arabic and other Languages

Due to its complexity, the Arabic language is underrepresented in NLP and chatbot development and is not given enough attention by researchers. Few studies have

examined Arabic chatbots in general and education, some of which were bilingual or multilingual.

BOTTA is an Arabic Egyptian dialect female public chatbot proposed by [23] that simulates friendly conversations with users. It is a retrieval-based model designed for open domain conversations responds. Arabchat and enhanced ArabChat are conversational agents designed for students at Applied Science University in Jordan [24]. Both are interactive chatbots that use Arabic MSA textual language. The study [25] proposed a conversational social chatbot "Nabiha" for Information Technology (IT) students at King Saud University using the Saudi Arabic dialect. Nabiha is a retrieval-based chatbot that uses AIML. It serves as an academic counselor to interact with students about their courses and academic progress inquiries.

A bilingual chatbot called “Jooka” was designed by [26] to improve the admissions process at the German University in Cairo (GUC). It understands queries written in English and Arabic and responds based on the query language. Google Cloud, Translation API was used to translate Arabic to English. However, in our study we found that translation of APIs for Arabic language are still not mature and result in an unnatural response.

Reference [27] proposed a voice-interactive chatbot that adopts a multilingual interface specifically to detect and respond to exam stress of university students. The chatbot application analyzes the tone of the user's voice to determine their feelings towards their exams with an accracy of 76.5%.

Multilingual chatbots have been developed in domains other than education. For example, [28] proposed a multilingual health chatbot application that can diagnose disease based on user symptoms and supports three languages: English, Hindi, and Gujarati. Reference [29] presents a bilingual retail chatbot that can handle Filipino-Tagalog and English languages that employs k-fold cross-validation on a dataset generated using a bilingual automatic corpus engine.

Supporting users with chatbot conversations in English as well as local dialects is gaining importance and is highlighted in the literature. The above studies show that there are two ways of creating a bilingual chatbot. The first method is using translation services to perform translation between both languages while maintaining a corpus in the primary language only. And the other method is to create and maintain a two corpus files, one for each language. Our study adopts the second method as experimentation with the first method resulted in unnatural translation between English and Arabic languages.

III. Methodology

This section presents the methodology adopted for planning, designing, and developing the chatbot system. This system provides bilingual advice through a chatbot with an easy-to-use interface to communicate in either Arabic or English. Our chatbot is equipped with sufficient information to provide students with answers to their specific advising inquiries. The advice chatbot adopts a bilingual corpus as the knowledge source type used to generate responses adopting the retrieval-based model. As part of the retrieval-based model, a chatbot uses heuristics to select the most appropriate response from a predefined pool of responses. This retrieval-based model is selected due to the need for precise and accurate responses to a specific task and domain. The following sub-sections present the three phases of the methodology - data collection, building the chatbot model, and the chatbot GUI development.

A. Data Collection

The conversational data required for the chatbot was collected through interaction with students, advisors, and referrals to university policy documents. The data consists of the most commonly asked queries that advisors usually receive from students and responses to those questions. We followed four main steps in collecting the conversational data required for the chatbot. First, we identified eight primary contexts to classify each query. The context is the domain of the user’s request, such as attendance, course delivery, and more. Second, we added queries to the contents and tagged each query with a unique intent tag that identifies the main purpose of the query. Third, we created patterns for each query to depict the variety of ways the question may be presented to the chatbot. Last, we added a variety of responses for each intent to incorporate diversity in the response.

In summary, each intent reflects what students would like to accomplish when interacting with the chatbot. Table I illustrates the different contexts and the number of intents in each context. For the purpose of this study, we developed 152 English and Arabic intents, with a total of 356 patterns.

TABLE I. Distribution of Intents and Patterns

Context	Number of intents	Patterns	Description
Greeting	8	28	That greet, welcome, and thank the user
Academic Standing	22	50	Students’ academic status/probation
Registration	32	76	inquiries related to registration/ scheduling and retaking courses
Summer	6	24	Inquiries related to Summer Courses /credits
WP	26	56	Inquiries related to work placement, schedule/registering.
COVID	14	28	Inquiries related to requirements related to COVID on campus
Final Exam	20	48	Inquiries related to materials scheduling /attending / missing / to final exams
Attendance	6	12	Inquiries related to attendance
Course Delivery	18	34	Inquiries about online, Hybrid courses
	152	356	

The corpus, consisting of the conversational data, was stored in JSON format. We use two corpus files to store the English intents and the other to store the Arabic intents as the initial experiments revealed that translation services from Arabic to English and vice versa are still very weak and result in unnatural statements. For example, when translating the Arabic statement “ما هو المعدل المناسب للنجاح”, the resulting translation is “what is the appropriate rate of success,” which is

not a natural way of phrasing the statement in the English language.

The complexity and NLP challenges inherent in the Arabic language, such as dialectal differences, orthographic ambiguity, and inconsistencies, are more prevalent while translating [23]. Moreover, the existing translation functions are inaccurate and do not reflect the correct English statements.

Furthermore, using a separate Arabic corpus allows us to integrate English words that are typically used by students when they write in the Arabic language, such as “probation”, “covid,” “GPA,” and more. Also, the Arabic corpus uses Arabic words written in local dialects. Table II shows sample intents from the Arabic and English corpora, with patterns, and responses.

After building the chatbot, we conducted a pilot implementation with eight students and three faculty members to augment the corpus with additional queries. Students and advisors were asked to type questions in natural language (English and Arabic) within the contexts identified earlier. The purpose of the pilot was to re-examine the initial corpus and augment it with additional patterns in which a query may be composed by the user. Furthermore, the pilot was also meant to identify any gaps in data collection within the contexts identified. After conducting the pilot, we examined the results and added new intents or patterns to existing intents. In addition, we identified queries that were not addressed in the initial corpus development; for example, questions, such as blackboard password, arriving before the final exam, and materials needed for the final exam were not included in the initial corpus development. Therefore, the pilot implementation was crucial to extend the corpus.

B. Chatbot Modelling with Deep Learning

The chatbot model was developed in Python using a supervised deep learning algorithm. Deep learning is a subset of machine learning based on an artificial neural network, in which layers of nodes simulate the neurons of a human brain. Input neurons are interconnected with multiple hidden layers to produce output by automatically adjusting the weights of the nodes in each layer [30]. We used the keras library in Python to build our deep learning network to build two chatbot models, each trained on the English and Arabic corpus, respectively. Fig. 1 shows the steps involved in developing the English chatbot model. Similar steps were also applied for developing the Arabic chatbot model.

First, to train our chatbot model, we pre-processed the training data and encoded each intent to make it suitable for the neural network algorithm. Pre-processing is crucial to transform the corpus data in an appropriate form for the neural network algorithm. Pre-processing the data enhances the efficiency and performance of the model. The pre-processing phase includes transforming input to lower case, removing punctuations and special characters, tokenization, and vectorization of the words. We used the NLTK library in Python to perform all the pre-processing steps.

Tokenization is the process of extracting words from sentences. We tokenized all the patterns in the corpus to extract individual words. The words were then simplified to their base forms using the process of lemmatization and stemming for English and Arabic words, respectively. Lemmatization converts the words to mean their original form based on the context, while stemming reduces the words to their base by removing the last characters without preserving the meaning. We used the NLTK WordNetLemmatizer library to lemmatize the English words using the parts of speech tag. For the lack of a sound library in Python for lemmatizing Arabic words, we used the ISRIStemmer to stem the words. However, some Arabic words did not retain their meaning when stemmed, such as "يمك" does not have any meaning originally "يمكنني," also “ادة" did not preserve its meaning originally “مادة.” Table III shows input patterns in Arabic and English and the extracted words. Word extraction and reducing to its base form resulted in 247 unique words in English and 250 words in Arabic.

TABLE II. SAMPLE ARABIC AND ENGLISH INTENTS

Description	Sample Intent
Arabic intent where there is the use of a UAE dialect such as “أقدر”	{“tag”: “numberofcurses-ar,” "patterns": [" كم عدد المواد أقدر اسجل ", " كم مادة أقدر اسجل","كم مادة ممكن اسجل"], "responses": ["هذا يعتمد على مستواك الاكاديمي"], "context_set": “academic-standing”, }
Arabic intent that includes English word “Probation” and written in Arabic ” بروبيشن” and also using a dialect UAE “شتقصد” and using	{“tag”: “Probation-ar,” "patterns": [" Probation ما معنى ", "بروبيشن ما معنى تحت الاختبار","شتقصد"], "responses": ["هذا يعتمد على مستواك الاكاديمي"], "context_set": “academic-standing”, }
English intent for the registration context student clarifying of a section that is full in a course	{"tag": "sectionfull-en", "patterns": ["If all sections are full", "There are no seats available"], "responses": ["Contact your advisor to change your plan"], "context_set": "registration",}

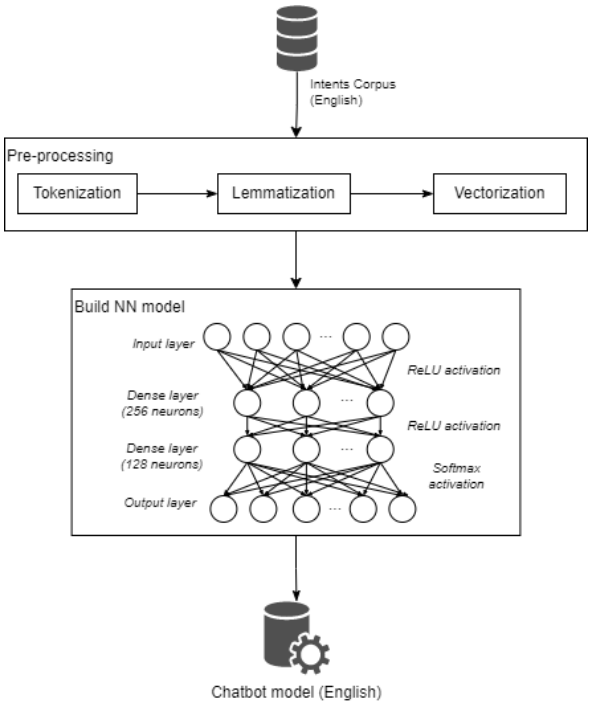

Fig. 1. English Chatbot Model Development Process.

TABLE III. SAMPLE OF LEMMATIZATION AND STEMMING OF PATTERNS

Pattern	Extracted words
‘What is going to happen if I do not raise my GPA	['what', 'be', 'go', 'to', 'happen', 'if', 'I', 'do', 'not', 'raise', 'my', 'gpa']
‘What is the time for adding and dropping courses’	['what', 'be', 'the', 'time', 'for', 'add', 'and', 'drop', 'course']
كيف يمكنني معرفة ما إذا كانت المادة عبر الإنترنت أم لا	['كيف', 'يمك', 'عرف', 'ما', 'اذا', 'كانت', 'ادة', ' "عبر", 'ترن', 'ام', 'لا]
ماذا أفعل بحضوري إذا لازم أذهب للخدمة العسكرية	['اذا', 'فعل', 'حضر', 'اذا', 'لزم', 'ذهب', 'خدم', ' "عسكر]

The next step of pre-processing is the process of vectorization. In this step, the words were converted to numerical form by creating a list of word vectors, which is a two-dimensional representation of each unique word and its frequency of occurrence. These word vectors are used as features of the neural network input layer.

After the pre-processing phase, we build two Neural Network (NN) models with deep learning for English and Arabic, respectively. The keras library in Python was used to build the NN model. The network consists of an input layer, two hidden layers, also known as the dense layers, and the output layer. The input layer comprises of all the unique features extracted from the respective corpus and has approximately 250 neurons in each model. The output layer represents the classes or the intents that should be predicted.

The first dense layer has 256 neurons, and the second has 128 neurons with a dropout rate of 0.5. The number of neurons in the layers is considered ideal since a smaller number would lead to underfitting, and a larger number would result in overfitting. Therefore, we selected the number of neurons in the dense layers between the input and output neurons. We configured the neural network with the following settings:

Optimizer – Stochastic Gradient Descent (SGD). The SGD estimates the expected risk gradient based on a single randomly selected sample instead of computing the precise value. Thus it is an optimization algorithm because the samples are randomly selected from the distribution [31].

Activation Function – Rectified Linear Unit (ReLU), was used as an activation function in the hidden layers. ReLU is a piecewise function in which if the input value is zero or less, then the output value will also be zero; otherwise, the output value will equal the input value. When data value is forced to be zero, a sparse characteristic is created, making the function fast and efficient. In addition to providing a faster computer rate, the ReLU function does not cause gradient diffusion problems, i.e., minor errors. However, because it always returns 0 for negative values, it can kill some neurons permanently and affect the final results or the output, i.e., generate exploding gradients [32].

Learning Rate – 0.01. The learning rate is a configurable hyperparameter used in training neural networks. Typically, between 0.0 and 1.0, it has a small positive value that must be carefully selected. That value determines how quickly the models are adapted to the problem. Lower learning rates result in more training cycles, and the process can get stuck, whereas larger learning rates lead to rapid changes and require fewer training cycles [33].

Classification function – Softmax. In artificial neural networks, the classification function, also known as the activation function, identifies a node's output given an input or set of inputs. The activation function allows neural networks to recognize complex relationships and patterns in data. This refers to the activated neurons features that can be retained and mapped out by nonlinear functions and employed to solve complex nonlinear problems. Furthermore, the activation function increases the neural network’s ability in which the nonlinear ability of the activation function makes the deep neural network have real artificial intelligence [32].

Epoch – 200. The epoch determines how many cycles are used to train the model. Since the dataset size is small, we set the epoch size to 200.

C. Chatbot Engine and GUI

The chatbot engine interacts with the Graphical User (GUI) to get the user query as an input and returns the most suitable response. Fig. 2 shows the architecture of our chatbot engine. There are three logical components of our chatbot engine – Natural Language Understanding (NLU), Natural Language Processing (NLP), and Natural Language Generation (NLG).

1) NLP: In this component, the user submits a query; the chatbot application first determines the language used for communication and accordingly uses the appropriate chatbot model for getting the response. The input query is first corrected for spelling mistakes using a spell check function implemented from the TextBlob Python library. In the case of Arabic input, however, there is no spell check function performed due to the complexity of the Arabic language and the inconsistency of the spellchecking function on the Arabic language, which led to many errors while applying it. This is considered a limitation of the study and a potential area for further development, research, and analysis. Also, in the NLP component, the input query is pre-processed using the same methods used in the training phase: tokenization, lemmatization/stemming, and vectorization of the words. In addition, all intents features are extracted from the input query in this component.

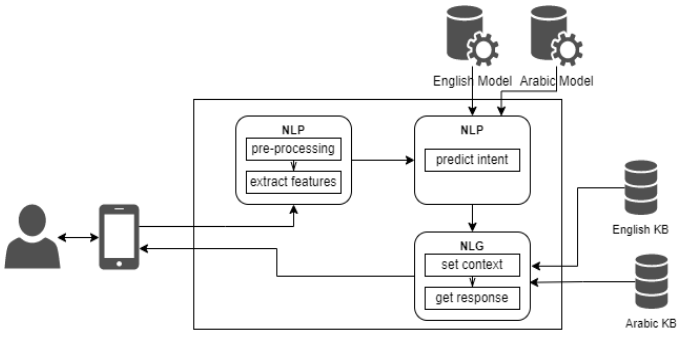

Fig. 2. Chatbot Engine.

2) NLU: This component bridges the gap between what computers understand and how people speak. The appropriate chatbot model is used for prediction by providing the word vectors to the two different models, Arabic or English, for classification. The prediction returns all the matching intents along with the probability of prediction. We set an error threshold of 25% to accept all predictions that have a probability above this threshold. Thus, in this component, if the model is not confident of the intent it detects, the user is requested to rephrase or restate their intent because of missing vocabulary.

3) NLG: In this component, the user's intent context is set based on the user query and language selected. The prediction is performed according to the training model discussed in the previous section. The function matches the intents tags and generates the response from either the Arabic or English knowledge base. If the model is unable to generate the response, a message will be displayed in English or Arabic, "contact your advisor," "اتصل بمشرفك."

The advising chatbots Graphical User Interface (GUI) was developed using Python's tkinter library. Our chatbot application employs a simple natural language user interface similar to an instant messaging application, which has a text box to type the input, a button to submit the message, and a display to show the input and response of the chat conversation. In addition, our interface consists of a language button that allows the user to toggle between the English or Arabic language mode to communicate with the chatbot. Fig. 3 shows three screenshots of an English and Arabic conversation, respectively. The screenshot (a) shows that the chatbot accepts spelling errors as the spellings are corrected in the pre-processing phase. For example, despite the spelling mistake of the word "available," the chatbot retrieves the correct response. In screenshots (b), the chatbot appends an additional message to rephrase the question when the response retrieval has a low confidence rate (below 0.75).

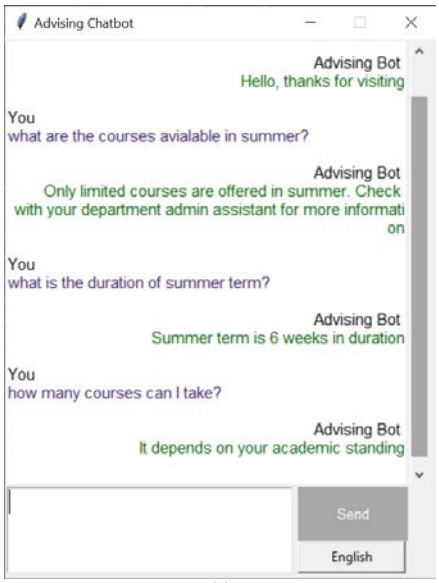
IV. Evaluation and Results

Evaluation metrics are essential to determine the machine learning algorithm's performance and assess the chatbot application. Since there are no standard evaluation methods of a chatbot application [34], the evaluation measure should be adapted to the chatbot type of service. Some studies used both automatic and human evaluations to measure the performance of chatbots [35].

Automatic evaluation measures the machine learning model's performance using known metrics such as accuracy, F1-Score, BLEU, and more, while human evaluation measures the quality of the responses using people as evaluators. Hence, human evaluation is suitable for generative chatbots that generate diverse responses, which do not exist in the corpus. However, since our chatbot is retrieval-based, we use only automatic evaluation to assess the chatbot performance.

We used two methods of evaluation. First, we used a test set consisting of queries with labeled intents, and second, we used human input to test the chatbot application and performance using ad-hoc queries. Finally, we used accuracy as a metric to evaluate the chatbot model for both methods. Accuracy measures the ratio of correct responses over the total responses that are predicted on an unlabeled set of inputs.

We developed two new test sets in the English and Arabic languages in the first evaluation method, which were not used to train the model. Each set is approximately 30% of the corpus size. The test set is populated with queries labeled with the actual intent tags. The label is hidden from the prediction algorithm when the test is performed. Table IV shows a few sample queries in English and Arabic from the test set. The queries are phrased differently than the patterns that exist in the corpus. The evaluation aims to determine the percentage of accurate responses retrieved by the chatbot. After running the prediction on the test set, predicted intents were compared to the actual intents to determine the number of correct responses. The accuracy of the English model was 80%, while the accuracy of the Arabic model was 75%.



(a)

(b)

Fig. 3. Figure 1 Screenshot of an English and Arabic Conversation.

TABLE IV. SAMPLE QUERIES FROM THE TEST SET

Query	actual_intent (label)
If I'm working do I still need to take work placement course?	wp-working-en
how long is a summer semester?	sum-duration-en
امت اضافة حذف	add-drop-ar
كيف اعرف اذا الدورة هيبرد او وجها لوجه	course-how-ar

In the second evaluation method, we involved the end-users, students, and advisors, to test the chatbot GUI application and performance of the prediction model. The objective of this evaluation was threefold, to test the chatbot interface, the effectiveness of the conversational system, and the accuracy of responses based on context.

Thirty students and three advisors evaluated the chatbot both in English and Arabic language. The participants were briefed on the context of the chatbot corpus and asked to provide random queries. The interactions were recorded in a CSV file along with the response's predicted intent, context, and confidence. When the response confidence was below 0.75, the chatbot requested the user to rephrase the question if they thought the response was not accurate. In nearly 20% of the cases, the chatbot engine could not determine the intent due to out of vocabulary words or out-of-context queries, so the standard response “Contact your advisor” was displayed. This result shows that it is essential for the chatbot corpus to be extended to include a wider domain of queries. From all the captured test inputs, we considered only the intents within the context specified to determine the accuracy of the response.

Our study does not evaluate the user satisfaction of the chatbot application. This type of study involves gathering empirical feedback from end-users from the Human-Computer Interaction perspective, which is outside the scope of our paper. However, during the testing phase of the chatbot application, several students commented that they found the chatbot useful and would prefer to use it instead of going to their advisor. In addition, they appreciated the quick response and constant availability of a chatbot application. Another observation we made from this evaluation is that students preferred to use English rather than Arabic when writing their queries as it was faster for them to type. There were several words that they did not know how to write in Arabic, such as "probation” or “covid.”.

V. CONCLUSION

In today's world, conversational agents are proving to be one of the most innovative forms of user interaction. This paper presents a new bilingual task-oriented, domain-specific Arabic English chatbot explicitly designed to advise university students to ease their academic journey. The chatbot uses NLP and neural network algorithms to retrieve English or Arabic responses. Through the bot, students may communicate and receive responses to their inquiries. Two chatbot models have been created in Python using a supervised deep learning algorithm, trained on English and Arabic corpora, respectively. An Arabic and English corpus of roughly 152 intents in both English and Arabic has been developed, with 356 patterns. In order to train the model, we pre-processed the training data and encoded each intent using the Python library so that it is suitable for the neural network algorithm. In the absence of a good library in Python for lemmatizing Arabic words, ISRIStemmer was used to stem the words. We use three logical components (NLP), (NLU), and (NLG) in our chatbot engine in order to pre-process the input query and to predict and generate a response based on the user's request. The prediction error threshold was set at 25%, and all predictions with probabilities above this threshold were accepted.

Moreover, the chatbots graphical user interface was developed using the Python tkinter library to interact with the user and display the most appropriate response. Two types of evaluations were performed to measure the performance of the system; the confidence score and another automated evaluation performed by the system users. The first provides 80% accuracy in English and 75% in Arabic. The second evaluation performed by the user also has similar results.

A. Limitations and Future Work

The bilingual chatbot system has some limitations. It was challenging to spellcheck Arabic, and many errors were produced when the results did not match the input inquiry after the check was performed. There was another issue with lemmatizing in Arabic. Some of the words did not retain their meaning, so the response was incorrect. There were also challenges with getting a response when the model confidence level was low, and the model did not understand the user's intent.

Both Arabic and English corpora should be expanded to include more vocabulary in each intent tag. Additionally, adding more intents with new context will broaden the scope of the corpora used in English and Arabic and expand advisory areas. Finally, the Arabic spellchecker needs further study and analysis to be used in the system.

Another limitation of the study is that the developed chatbot does not provide personalized assistance to students. Future work would enhance the chatbot with intelligent capabilities that allow personalized responses containing information such as students' GPA, academic standing, and courses required for graduation. Such a chatbot could assist advisors in developing study plans and communicating with the students. Another enhancement to the chatbot that can add value to the communication is to send push notifications to remind students of upcoming deadlines for registration, add and drop periods, and more.

Success Institute Chain: SIC Co., Ltd, Hakata-ku, Fukuoka City, Fukuoka, Japan[2, 3, 4, 5]

***Abstract*—A prediction method for estimation of sales based on Prophet with a consideration of nonlinear events and conditions by a modified Optuna is proposed. Linear prediction does not work for a long-term sales prediction because purchasing actions are based on essentially nonlinear customers' behavior. One of nonlinear prediction methods is the well-known Prophet. It, however, is still difficult to adjust the nonlinear parameters in the Prophet. To adjust the parameters, the Optuna is widely used. It, however, is not good enough for parameter tuning by the Optuna. Therefore, the Optuna is modified with a short-term moving mean and standard deviation of the sales for final prediction. More than that, specific event such as typhoon event is to be considered in the sales prediction. Through experiments with a real sales data, it is found the sensitivity of the parameters the upper window, lower window, event dates, etc. for the final sales and the effect of the Optuna is 11.73%. Also, it is found that the effect of the consideration of Covid-19 is about 2.4% meanwhile the effect of the proposed modified Optuna is around 3 % improvement of the prediction accuracy (from 80 % to 83 %).**

Keywords*—Prediction method; nonlinearity; prophet; optuna; typhoon event; modified optuna; mean and standard deviation adjustment

I. Introduction

Periodicity, event effects, long-term trends, and outliers are not limited to this data, but are common features of general time series data. When creating a model for future prediction, it is necessary to incorporate these features into the model well. Prophet models each of the four features and combines them to predict future values. Such a model is called a Generalized Additive Model.

Prophet is a library for time series analysis developed by Facebook's Core Data Science team in 2017[1]. Libraries are provided in both Python and R. In addition, this Prophet is embedded as a template in AutoML services such as AWS, Azure, and DataRobot for flexible modeling in future forecasting tasks[2].

There are five advantages of Prophet:

1) It can be made a model without knowledge of statistics: Simply specify the data and perform the training to complete the model.

2) Easy to incorporate domain knowledge: It can be easily put in the domain knowledge that the data analyst has.

3) No feature engineering required: Prophet training uses minimally preprocessed data. There is no need to remove trend components or convert to a moving average series.

4) There is no problem even if there are missing values: Even if there is a defect in the training data, no error will occur, and training will be performed normally. Therefore, it is not necessary to fill in the missing values in advance.

5) Easy to interpret prediction results: Prophet is a model that adds four terms. Each term represents a trend, periodicity, event effect, and error, and after prediction, the components can be extracted for each term and the obtained prediction results can be considered.

On the other hand, Optuna is a Bayesian optimization package created for optimizing hyperparameters of machine learning models[3]. It performs optimization using TPE, which is a new method among Bayesian optimizations. It can be easily used in a single process, or it can be learned in parallel on many machines. When performing parallel processing, this is achieved by creating an Optuna file on the database and referencing it from multiple machines, so it is wonderful that all machines that can access the DB can participate in learning[4].

The proposed nonlinear prediction method is based on Prophet with Optuna for parameter tuning. It is not easy to optimize the parameters in Prophet and is not ensure the best fit parameters for Prophet. In this paper, therefore, some programmatic method for the parameter optimization is proposed and effectiveness of the proposed method is validated with a nonlinear sales data.

The biggest challenge of this research work is to predict one year term of sales (annual amount of sales). Although there are many prediction methods which allow to predict one day after the current time, there is no such method which allows forecast ahead for the following 365 days with an acceptable prediction accuracy. Therefore, nonlinearity, seasonal effect, event effect, the other influencing factors have to be considered.

One of nonlinear prediction methods is the well-known Prophet. It, however, is still difficult to adjust the nonlinear parameters in the Prophet. To adjust the parameters, the Optuna is widely used. It, however, is not good enough for

[4] https://optuna.readthedocs.io/en/stable/reference/index.html

parameter tuning by the Optuna. Therefore, the Optuna is modified with a short-term moving mean and standard deviation of the sales for final prediction.

In the next section, related research works are reviewed followed by the proposed method. Then, the fact that a linear prediction method does not work for nonlinear time series of data is shown. After that, the validation of effectiveness of the proposed method is described together with effectiveness of the Optuna. Finally, conclusion and some discussions are described followed by future research work.

II. Related Research Work

There are the following related research works on prediction,

Probabilistic cellular automata-based approach for prediction of hot mudflow disaster area and volume is proposed [1]. New approach of prediction of Sidoarjo hot mudflow disaster area based on probabilistic cellular automata is also proposed [2]. On the other hand, GIS based 2D cellular automata approach for prediction of forest fire spreading is proposed [3].

Cell based GIS as cellular automata for disaster spreading prediction and required data systems is investigated [4] together with hot mudflow prediction area model and simulation based cellular automata for LUSI and plume at Sidoarjo East Jawa [5].

Comparative study between eigen space and real space-based image prediction methods by means of autoregressive model is conducted [6] together with comparative study on image prediction methods between the proposed morphing utilized method and Kalman Filtering method [7].

Prediction method for time series of imagery data in eigen space is proposed [8]. Meanwhile, image prediction method with non-linear control lines derived from Kriging method with extracted feature points based on morphing is proposed [9]. On the other hand, cell-based GIS as cellular automata for disaster spreading predictions and required data systems is proposed [10].

Prediction method of El Nino Southern Oscillation event by means of wavelet-based data compression with appropriate support length of base function is proposed [11]. On the other hand, Question Answering for collaborative learning with answer quality prediction is created [12].

Wildlife damage estimated and prediction method using blog and tweet information is proposed [13]. Prediction method for large diatom appearance with meteorological data and MODIS derived turbidity as well as chlorophyll-a in Ariake Bay area in Japan is proposed and validated [14].

Method for thermal pain level prediction with eye motion using SVM is proposed [15] together with prediction method for large diatom appearance with meteorological data and MODIS derived turbidity and chlorophyll-a in Ariake bay area in Japan [16].

Smartphone image based agricultural product quality and harvest amount prediction method is proposed [17]. Meanwhile, data retrieval method based on physical meaning and its application for prediction of linear precipitation zone with remote sensing satellite data and open data is also proposed [18].

Recursive Least Square: RLS method-based time series data prediction for many missing data is proposed [19]. Furthermore, prediction of isoflavone content in beans with Sentinel-2 optical sensor data by means of regressive analysis is proposed and conducted [20].

III. Proposed Prediction Method based on Prophet

A library often used for time series analysis using AI, especially for future prediction with the following features,

1) There is periodicity, weekly and yearly periodicity
2) There is an event effect
3) There is a long-term trend
4) There are outliers (noise)

Prophet is developed by Facebook in 2017.

The model formula of Prophet is as follows,

$$y=g(t)+s(t)+h(t)+\varepsilon_t \quad (1)$$

where *y(t)*: variable for prediction, *g(t)*: trend, *s(t)*: periodic, *h(t)*: event effect, ε_t: normal distribution of noise.

Basically, it can be used as the same as scikit-learn. Model instance creation can be done with fit flow then creation is also done with a data frame for prediction. After that, a prediction is made with the predict method.

Nonlinear for trend term: Linear by default Specify the upper limit of prediction (cap) to make it nonlinear. Fig. 1 shows the illustrative view of determination of upper limit of prediction.

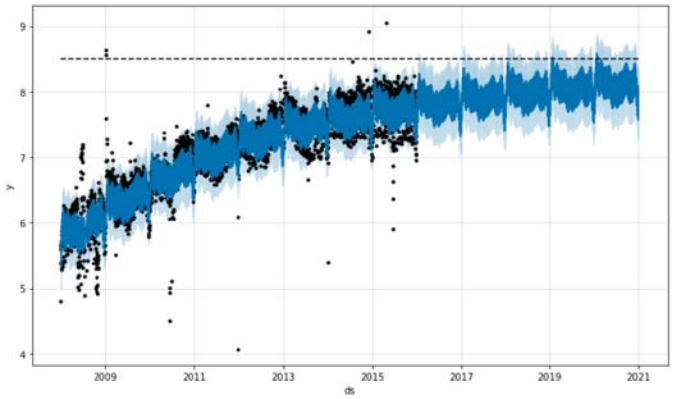

Fig. 1. Illustrative View of Determination of Upper Limit of Prediction.

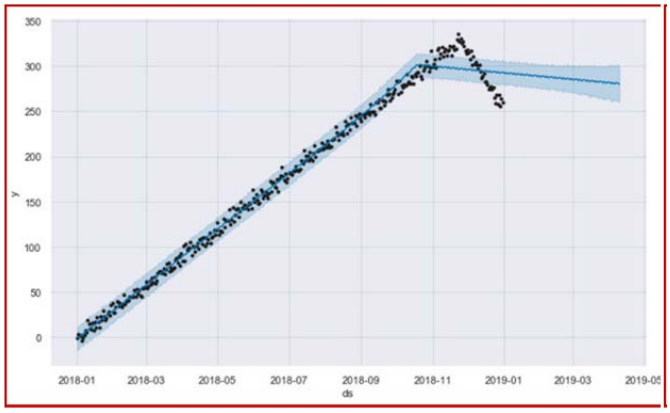
1) Changepoint-range: The default setting does not reflect the most recent change point as shown in Fig. 2 (a). The data used by Prophet to estimate the trend change point is 80% of the total by default. Resolved by setting "changepoint-range = 1". It tends to be predicted that the latest data will be overwhelmed as shown in Fig. 2 (b).



(a)Default

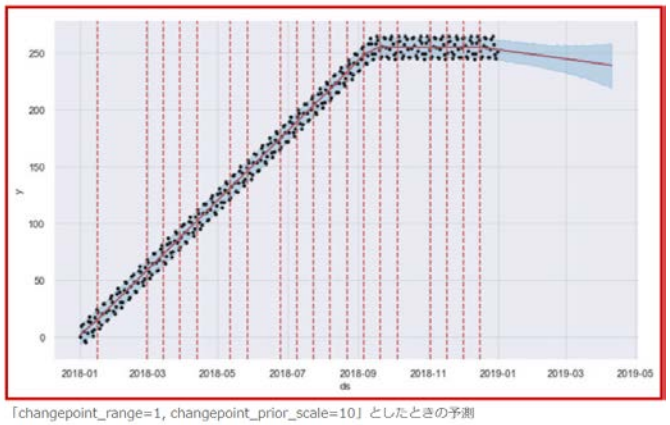
(b) Changepoint-range = 1

Fig. 2. Changepoint-Range Setting.

2) Changepoint-prior-scale: It represents the variance of the Laplace distribution, which is the prior distribution of the trend term, and the larger it is, the easier it is to detect the change point as shown in Fig. 3 (a).,

3) n-changepoints: It represents the number of change point candidates to be detected, and the larger the number, the easier it is to detect more change points as shown in Fig. 3 (b).

(a) Changepoint-Prior Scale.



(b) n-changepoints

Fig. 3. Another Parameter Setting.

Trend term g(t) is represented as equation (2) and can be determined as follows,

$$g(t) = \frac{C}{1+\exp(-k(t-m))} \quad (2)$$

where *C*: Upper limit, *k:* Growing ratio, *m*: Offset

This is the base logistic curve which is shown in Fig. 4 Phenomenon with a flow of less at the beginning then more in the middle, less again after that.

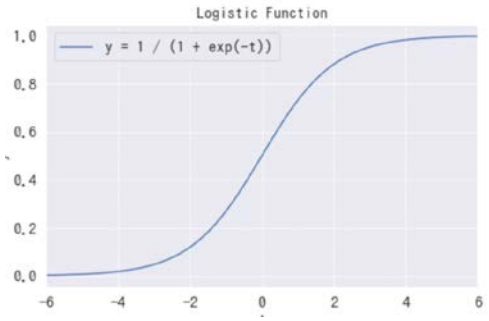


Fig. 4. Logistic Function.

Upper limit, growing ratio and offset are determined as follows,

Since *m* is an expression that directly subtracts the value of *t* as shown in Fig. 5 (c). The curve simply moves from side to side.

There are seasonal fluctuations. There is periodicity. It can be expressed like signal processing.

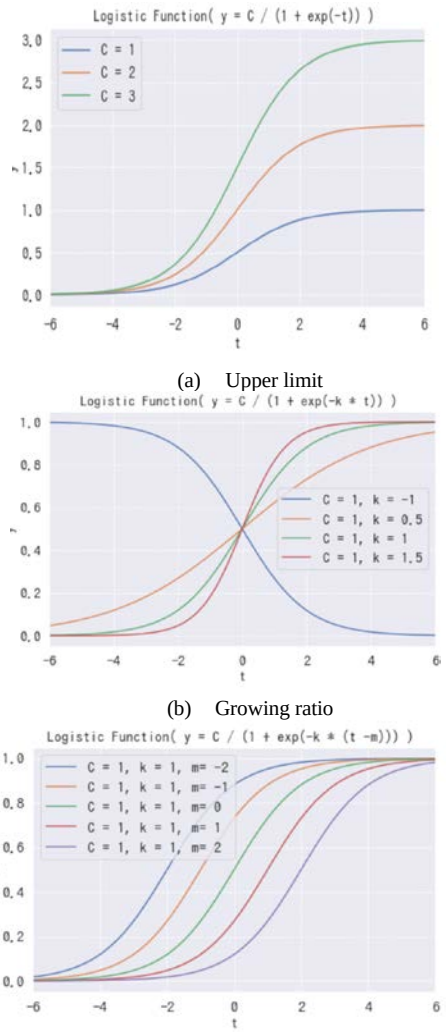
$$s(t) = \sum_{n=1}^{N}(a_n \cos\left(\frac{2\pi nt}{P}\right) + b_n \sin(\frac{2\pi nt}{P})) \quad (3)$$

Fit with N = 10 for a yearly cycle and N = 3 for a weekly cycle.

$$\beta = (a_1, b_1, \dots, a_N, b_N)^T \quad (4)$$

$$X(t) = [\cos\left(\frac{2\pi(1)t}{365.25}\right), \sin\left(\frac{2\pi(1)t}{365.25}\right), \dots, cos\left(\frac{2\pi(10)t}{365.25}\right), sin\left(\frac{2\pi(10)t}{365.25}\right)] \quad (5)$$

$$s(t) = X(t)\beta \quad (6)$$



(a) Upper limit

(b) Growing ratio

(c) Offset

Fig. 5. Determination of Upper Limit, Growing Ratio and Offset Determinations.

Event effect is defined by incorporate sudden event effects into the model *h(t)*. Prophet is designed so that the analyst can create a list of event calendars and incorporate them into the model. The coefficient parameter for each event *i* is κ_i, and the vector is represented by κ.

$$D_i = (\dots, 1975/12/25, 1976/12/25, \dots, 2020/12/25, \dots) \quad (7)$$

$$Z(t) = [1(t \in D_1), \dots, 1(t \in D_L)] \quad (8)$$

$$h(t) = Z(t)\kappa, \kappa \sim Normal(0, v^2) \quad (9)$$

Probability Density Function: PDF is defined as follows,

If you assume the distribution for each parameter, you can treat it as a state space model. In fact, in Prophet, this model formula is described in Stan and optimized by the L-BFGS method etc.

$$\beta \sim Normal(0, \sigma^2) \quad (10)$$

IV. Experiments

A. Example of Sales Prediction and Sensitivity of the Parameters

Through an adjustment of the Prophet parameters to forecast Mega-Donki Hair Salon (One of the Hair Salons in concern) sales, and then prediction of the sales. Fig. 6 shows the prediction result. In this case, the sales data of 2015 to 2020 is used for training data and also the sales data of 2021 is used for validation data.

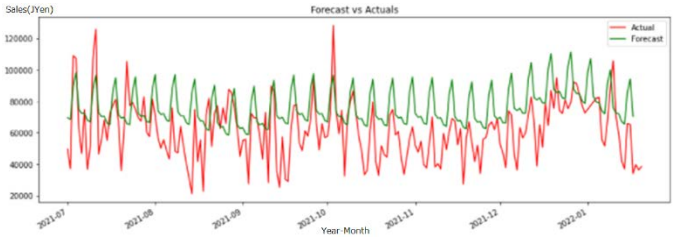


Fig. 6. Prediction of Mega-Donki Hair Salon Sales in 2021.

There is a systematic error. Also, prediction error is not so small. Therefore, some parameter adjustments are required to improve the prediction accuracy.

Optuna is a software framework for automating hyperparameter optimization. The author adjusted the parameters of Prophet using Optuna and tried to forecast the sales of the Mega-Donki Hair Salon. Parameters that can be tuned such as seasonal prior distribution, degree of influence, range of use of data used for detection of change points, influence of trends, etc. After the adjustment by Optuna, prediction result is improved as shown in Fig. 7. The total prediction error is reduced from 38.09 to 26.36. Namely, 11.73 % of improvement is confirmed.

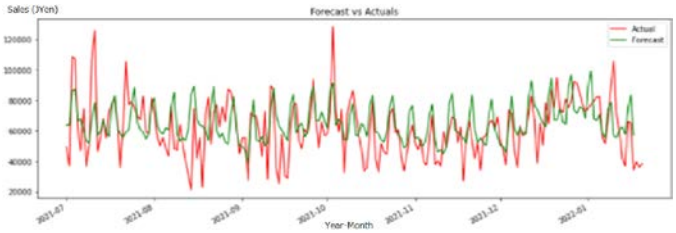

Fig. 7. Prediction of Mega-Donki Hair Salon Sales after the Parameter Adjustment with Optuna.

Tuned parameters are as follows,

1) Changepoint-range: Percentage of what range of data is used to detect the trend change point. The default is 0.8, which uses the first 80% of the data to detect the trend change point. According to the formula [0.8, 0.95] Range is reasonable

2) n-changepoints: A parameter that represents the number of candidates change points to detect. The larger the parameter, the easier it is to detect more change points. The default is 25.

3) Changepoint-prior-scale: Parameters that control the flexibility of the trend. If it is too small, the trend will be inadequate, and if it is too large, the trend will be overfitted. The default is 0.05, and the formula says that the range [0.001, 0.5] is reasonable.

4) Seasonality-prior-scale: Parameters that control seasonal flexibility. The default is 10, and the formula says that the range [0.01, 10] is reasonable.

Add-seasonality (period, Fourier-order): Not only the specified year / week / day periodicity, but also the model of any cycle can be set by the user. For each periodicity, the unit of periodicity (period), the Fourier series that is the basis of the seasonal component (Fourier-order), and the degree of influence of seasonality (prior-scale) are set. In order to be able to adjust the Fourier series and the degree of influence of each seasonality, all the prescribed seasonality is set to False, and weekly, monthly, yearly, and quarterly periodic fluctuations are added.

B. Sales Prediction Results with Parameter Setting

Data preprocessing (missing value completion) is needed. Then, consideration of event effect (entrance ceremony, graduation ceremony, pension payment date) is necessary. There is a date with zero sales. Until now, it was excluded and calculated. Therefore, complement the interpolation by the average value is needed. The average value is the day of zero. Complemented with the average value of the day of the week. With lower-window and upper-window, the range can be extended the range to which the event effect is applied to the days around the event day. Also, if Christmas is set as an event and lower window is set to -1, the event effect can be applied until Christmas Eve.

The date of the pension payment can be considered. After the 15th of even-numbered months. Also, one week defined as (7 days). Improvement of the prediction accuracy (MAPE: Mean Absolute Prediction Error) for the specific two shops: Konoha Mall Hashimoto Hair Salon (This Hair Salon is another Hair Salon in concern and has low prediction accuracy).

1) Before considering the event: MAPE= 37.8

2) After considering the entrance ceremony, graduation ceremony, and pension: MAPE=36.4

For the Hakata Station South Hair Salon (Another Hair Salon in concern) case,

1) Before considering the event: MAPE=25.5

2) After considering the entrance ceremony, graduation ceremony, and pension: MAPE=24.7

3) After considering the entrance ceremony and pension, MAPE=24.8

Sales are declining near the graduation ceremony due to learning from training data. The sales are increasing near the entrance ceremony. Also, sales increase (upside) can be dealt with relatively, but sales decrease (downside) cannot be dealt with (red ... actual green ... forecast) Hakata-eki-minami Hair Salon (another Hair Salon in concern) data as shown in Fig. 8. There are some strange prediction errors marked with blue ellipsoids. For instance, sales are gotten down on August 25 due to the typhoon #15 is hit over these areas as shown in Fig. 9. These events can be considered in the prediction by Prophet.

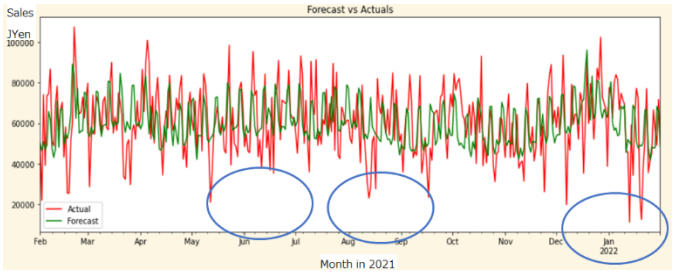

Fig. 8. Sales Prediction Result for Hakata-eki-minami Hair Salon.

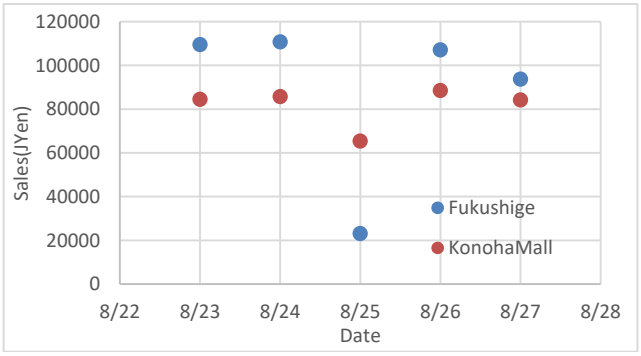

Fig. 9. Sales of the Fukushige and the Konoha-Mall Hair Salons during from Aug.22 to Aug. 28.

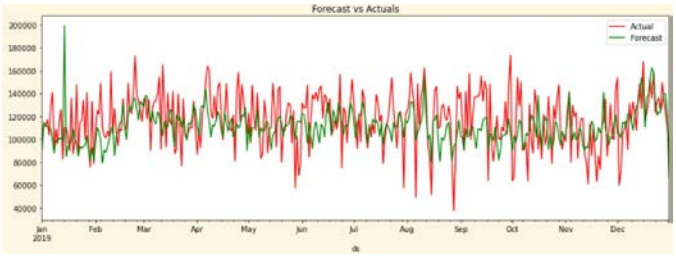
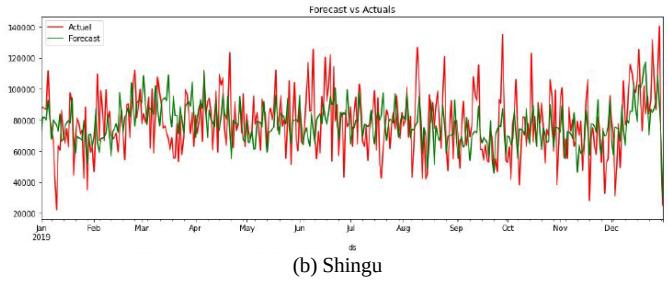
C. Influence Due to the Covid-19

The sales of the hair salon have been changed due to the Covid-19. To investigate the influence of Covid-19, the sales of the Fukushige hair salon have been predicted for one year of 2019 utilizing the nine years sales data, 2010 to 2018. The actual and the predicted sales with Prophet and the proposed modified Optuna are shown in Fig. 10(a). As the result, it is found that the MAPE is improved from 18.09 to 16.61. Also, as shown in Fig. 10(b), it is found that the actual and the predicted sales of Shingu hair salon is improved from 23.6 to 21.1.



(a) Fukusige



(b) Shingu

Fig. 10. Influence of Covid-19 on the Sales Prediction.

V. Conclusion

Through the experiments, it is found the followings,

1) Although Prophet is basically linear prediction method, it does work because it can consider trend, seasonal changes, event effect.

2) Upper window, lower window, event dates, etc. need to be entered from specialized knowledge and experience.

3) The proposed Optuna parameter tuning shows 11.73% of improvement in mean prediction error for the specific Hair Salon sales in comparison to the Prophet prediction without Optuna.

4) When the events of typhoons, heavy rain, pension payment date, entrance ceremonial date, etc. are considered in the proposed Optuna parameter tuning, then the sale prediction error is reduced.

5) The effect of the considering the entrance ceremony, graduation ceremony, and pension payment days is less than 2%.

6) Influence of Covid-19 on the sales prediction is clarified. If the influence is considered in the sales prediction processes, MAPE is improved from 8.2 to 10.6 %.

VI. Future Reaesrch Work

Further investigations are required for improvement of prediction accuracy by considering the other influencing factors such as coupon, special campaign, etc. to the sales. Weather forecast data, geolocation, population, environmental factors are other candidates of the influencing factors.

Acknowledgment

The authors would like to thank to the cooperative staff of the Success Institute Chain: SIC Holdings Co., Ltd, for their effort to conduct this research work. Also, the authors would like to thank to Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

Authors' Profile

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 77 books and published 680 journal papers as well as 550 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA http://teagis.ip.is.saga-u.ac.jp/index.ht

Encryption Algorithms Modeling in Detecting Man in the Middle Attack in Medical Organizations

Sulaiman Alnasser, Raed Alsaqour
Department of Information Technology, College of Computing and Informatics, Saudi Electronic University, Riyadh 93499, Saudi Arabia

***Abstract*—A cyberattack is a serious crime that could affect medical organizations. These attacks could affect medical organization sensitive data disclosure, loss of organization data, or the business's continuity. The Man-in-The-Middle (MITM) attack is one of the threats that could impact medical organizations. It happens when unapproved outsiders break into the traffic between two parties that think they are conversing directly. At the same time, the adversary can access, read, and change secret information. Because of that, medical organizations lose confidentiality, integrity, and availability. Data encryption is a solution that changes vital information to unreadable by unauthorized and unintended parties. It could involve protecting data with cryptography, usually by leveraging a scrambled code. Only the individuals with the decoding key can read the information. There is no full protection due to the variety of MITM attacks. Each encryption algorithm has its advantages and disadvantages, like the speed of encryption and decryption, strength of the algorithm, and the cipher type. This research investigates the MITM attacks and comprehensively compares the Rivest Shamir Adleman algorithm and the Elliptic Curve Cryptography algorithm.**

Keywords*—*Cyberattack; medical organization; man in the middle attack; encryption algorithm; rivest shamir adleman algorithm; elliptic curve cryptography algorithm

I. Introduction

In the contemporary organizational environment, governments, businesses, medical, and individuals all store data in electronic form. Electronic data storage is more effective than the previous physical storage forms since it is more compact, allows instantaneous transfer, and is easier to access information via databases [1]. Over time, the value of data increases, and organizations and individuals widely recognize stored data as among the most valuable items that must be protected against all potential threats. However, with such a notable electronic revolution, effective data storage and management face multiple new security threats that are potentially more damaging [2]. For example, electronic data has a high risk of being copied, leaving the original unaltered, or stolen, and has a high vulnerability for interceptions and alterations. Therefore, an effective data security measure must enhance secrecy, integrity, and availability. Part of the technical services crucial for optimizing data protection include data authentication and encryption [3].

A Man-in-The-Middle (MITM) attack is one of the threats that could impact medical organizations [4]. It happens when unapproved outsiders break into the traffic between two parties that think they are conversing directly. At the same time, the adversary can access, read, and change secret information. Because of that, organizations lose confidentiality, integrity, and availability. Data encryption is a powerful solution to eliminate the MITM attack [5]. It encompasses translating or encoding data into another form or a code to ensure that it is only accessible to persons with access to the secret key. It is a robust approach to protecting private information and sensitive data. It enhances communication security between different parties and servers. Encrypted data is largely depicted as ciphertext. The process is the most effective and popular information security method [6].

Data encryption is central in enhancing and maintaining the confidentiality of sensitive and private information, and the technology also increases data safety among remote workers. Therefore, it is an essential security safeguard for corporations, and in the long term, it positively impacts consumer trust and overall profitability [7].

Asymmetric encryption algorithms can be complicated, especially; most businesses and individuals rely on this type of encryption since they are strong and hard to break. Unfortunately, studies reveal that in the contemporary technology-infiltrated market setting, a wide range of cybersecurity issues and threats negatively affect entities' effective functionality [7]. However, with data encryption being done properly, for instance, by leveraging a high enough level of encryption and adequate safeguarding of the respective encryption key, the security and privacy of various features can be enhanced. This is vital in eliminating potential threats that could ultimately compromise data safety and security. Furthermore, the Internet of things (IoTs) started to become a valid solution in the medical field. Currently, many surgeries are done remotely [8]. So, strong, accurate, and speed algorithms are primary conditions that medical sectors cannot abandon.

This study presents a critical analysis of encryption. It provides cases of MITM attacks to reduce the risk of MITM attacks in corporations and urges organizations to encrypt their data. Additionally, this research aims to better understand the Rivest Shamir Adleman (RSA) and Elliptic Curve Cryptography (ECC) algorithms. Based on that, the medical organizations' systems may select the most appropriate ones for their needs. The proposed innovative method involves evaluating both algorithms using four performance measures on five distinct security level bits, as suggested by National Institute of Standards and Technology (NIST) [9]. The result will enhance the existing medical organizations' systems and

help the medical organizations' engineers to choose the optimal encryption algorithm.

The body of the article has the following structure: Section II includes the background and related work. Section III presents the research methodology. Section IV explains the results and discussion. Finally, the conclusions and possible guidelines for further work are presented in Section V.

II. Background and Related Work

A. Background

Modern society relies on communication networks and the Internet for almost every facet of everyday activities. Like online home banking, social media networks, and online shopping, most applications need cellular networks or the Internet. This is the major target of hackers since it involves transmitting sensitive information. Hackers prey on businesses and organizations, causing enormous financial damage [10]. The MITM attacks are the most effective method of controlling sensitive end-user information being sent. Therefore, it is one of the most serious risks to the security of wireless networks. A typical MITM attack scenario includes the victims, the two endpoints, and the perpetrators, a third party [11]

During a security breach, an attacker gets into a communication system and changes messages between the two endpoints. Third-party attackers can intercept, alter, replace, or alter information being carried across the communication channel between two endpoints when they conduct MITM attacks. Due to their lack of knowledge, victims feel that their communication channels are secure. Global System for Mobile (GSM), Universal Mobile Telecommunications System (UMTS), Bluetooth, and Wi-Fi are a few of the communication channels that may be used to execute such MITM attacks [11]. The hackers also compromise the data's security by targeting the actual data sent between the endpoints.

An adversary may tamper with the secrecy and integrity of communication [3]. Alternatively, an adversary may stop communication between the two parties and weaken the availability issue by intercepting, modifying, or destroying the messages. As shown in Fig. 1, the authors explain in how user one and user two do not have a trusted connection with the MITM.

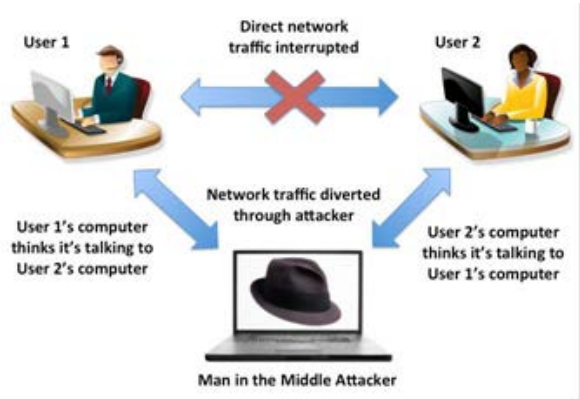

Fig. 1. Traditional MITM Attack [3].

A malicious attacker can intercept and decrypt the data passed between sensors and the Local Processing Unit (LPU) [4]. Consequently, an attacker may access confidential information and assess the recorded data to discover significant changes or clinical concerns. For example, MITM may change incorrect data and communicate normal readings to the LPU, preventing the monitoring system from sounding an alert when a patient asks for help. The author demonstrated the same malign spirit by using the Medtronic infusion pump to block it from administering insulin or overloading diabetic patients with insulin. The sensor's data is usually normal, with just a few exceptions. In [4], the authors note that the LPU analyzes the data to look for significant shifts in measurements before sounding the alert. Because the MITM cannot access personal details, the sensor merely transmits a digital signature of what it has collected. This interval between readings is preserved by the change detection mechanism in the LPU. Researchers employ Locality Sensitive Hashing (LSH) to create an irreversible information fingerprint that makes it impossible for an adversary to deduce or access confidential data.

In contrast, sending signatures rather than measurements greatly decreases the size of the data packet and, as a result, the amount of energy needed to transmit it. IMD is a trusted healthcare platform that has sensitive patient information. The authors in [11] explain that attackers can listen, change, and drop the messages when the medical unit loses authentication with the patient's IMD (Fig. 2).

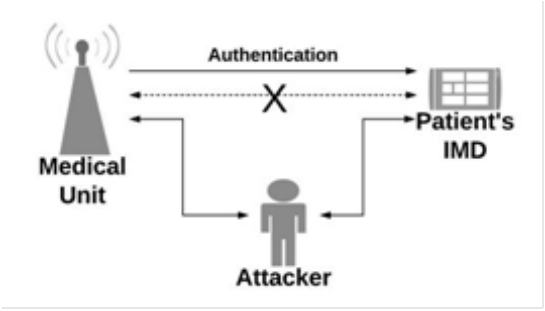

Fig. 2. Example of MITM Attacks Scheme in a Medical Unit [12].

B. Related Work

In [4], the authors reviewed aims to mitigate MITM attacks on the Internet of medical systems. Specifically, the attack happens by identifying the respective monitored individuals' healthcare emergency and replaying normal physiological data to prevent the system from raising the alarm. The authors depend on Locality Sensitive Hashing (LSH) signature as transmitted instead of physiological value. To prevent modification, replay, and black hole attacks, a Hash-Based Message Authentication Code (HMAC) is used with a key based on the Received Signal Strength Indicator (RSSI) value measured on both sensors and (Local Processing Unit) LPU. Also, propose a system that could be leveraged to prevent the devastating aftermath effects of the alarms of the remote healthcare monitoring system.

In [13], the authors proposed an efficient scheme to help design a generalized yet robust authentication protocol in medical systems. It is a countermeasure against medical

facilities' potential man-in-the-middle attacks and impersonation attacks. Specifically, the countermeasure involves mutual authentication between users, their devices, and the system's cloud server. It also involves standardizing a key agreement scheme with Elliptic Curve Cryptography (ECC). With the model in place, the authors opine that the keys are thoroughly secured, hence not copy-able; therefore, it is pivotal in enhancing security robustness.

In [14], the authors examined and proposed using a lightweight cross-layer trust computation algorithm for the MITM attacker detection, known as IC-MADS. IC-MADS are identified to have two notable contributions that the others, such as the trust-based and cryptography-based solutions, failed to possess, which relates to energy-efficient clustering and cross-layer attack detection. According to the authors, simulation results identify IC-MADS as efficient in achieving better protection against potential MIMA attacks with minimum energy consumption.

In [15], the authors have proposed a biometric-based authentication scheme that would help ensure secure access to patient's electronic health records virtually from any location. There has been a notable trend in Healthcare 4.0-based diagnostics systems globally. However, the authors often identify that patient records are continually stored in Electronic Health Records (EHR) repositories. Therefore, they use RSA encryption to protect patient data security and privacy risks. Nevertheless, results attribute the scheme as superior to the previously used state-of-the-art schemes.

In [16], the authors discussed the aspects of big data, especially in the modern-day context where it has been most impactful across industries. For example, benefits include driving health research, enhancing knowledge discovery, and improving personal health management in the healthcare domain. Primary identified big data challenges include technical challenges and privacy and security issues. The authors recommend incorporating encryption and anonymization as the best practices in enhancing big data security and privacy.

In [17], the authors identified the potential risk of the Internet of Things (IoT) era, especially with the continued advent of technology. Therefore, the security and protection of IoT depend on various factors, ranging from the producer of the device and their respective perception of device protection to the end-user and their probable awareness of the associated risks. Furthermore, in [17], the authors noted that attackers are often at an advantage concerning their inherent knowledge and technology. Therefore, despite the apparent great potential of IoT, it is faced with considerable risks that stem from insufficient protection. Therefore, advancing prevention and reactiveness is the best approach to managing the situation.

Table I shows the advantages and disadvantages of exploring related work.

TABLE I. ADVANTAGES AND DISADVANTAGES OF THE RESPECTIVE STUDIES

Related Studies	Advantages	Disadvantages
[4]	The authors successfully proposed an effective mitigation strategy to lessen the negative impact of MITM attacks on the Internet of Medical Things (IoMT). Furthermore, the approach successfully addressed critical domains, such as the privacy of the physiological data and energy consumption.	Using a classification model increases the risk of failure of the strategy.
[13]	The proposed scheme is a robust authentication protocol and can fulfill its scope within the medical infrastructure.	Mutual authentication can be disastrous, especially when parties fail to honor their pledges.
[14]	Simulation results prove that IC-MADS are integral in better protection against MITM attacks and leverage minimum overhead and energy consumption.	It is associated with a limited power rating as it is usually impossible to manufacture higher power.
[15]	The proposed biometric-based authentication method proved superior in its computational and communication costs, especially when compared to conventional schemes.	The proposed solution took more time than expected. The author suggests decreasing the encryption key.
[16]	Encryption and anonymization are unique solutions to the presenting data privacy and security challenges.	Encryption could be disadvantageous as it consumes significant resources and has issues with data compatibility.
[17]	IoT has great potential in present-day society due to increased technology and expertise. Providing certificates to identify each device will mitigate the MITM attack.	Certificates might be an insufficient solution due to the high cost. In addition, insufficient protection of the users results in increased privacy concerns.

III. RESEARCH METHODOLOGY

This chapter will debate the proposed research methodology used to achieve the research objective. Assimilation is the most popular experimentation technique in the network field. This chapter further discusses the proposed authentication scheme aimed at helping to overcome the impersonation and the MITM attacks during the user login and data storing phases, respectively. First, it introduces the authentication scheme and details how the attacks occur. It then proposes a solution for the attacks.

This research proposes a new authentication scheme for cloud computing for mobile users. The proposal is motivated by the rising levels of attacks on wireless channels. The research views that authentication and verification are critical elements that can help enhance the security channels between mobile users and cloud computing. The prosed solution in this research involves implementing two-layer security with a crucial agreement scheme. Cryptography, a well-known approach for securing communication, is proposed to be the baseline for the proposed solution.

The methodology of this research is demonstrated in Fig. 3. The figure provides an overview of the different phases of this research methodology. It begins with studying previously done literature reviews related to the research area. The focus is mainly on the literature reviews completed in recent years, whose primary study is how health care systems' phases work. After that, the focus is on the MITM attack on the health care systems. Then, the research will implement a solution that mitigates the MITM attacks. The performance of the proposed solution is then analyzed. Finally, the results are generated and discussed.

In addition, the experiment was done on a hardware server. A real server chassis model Quanta S5HF-1U was rented. To conduct the experiments, the processor is 1× AMD EPYC 7281. CPU - 16C/32T - 2.1 GHz. Storage 2 × 1 TB NVMe. 96 GB DDR4 ECC. The operating system is Ubuntu 22.04 LTS.

Furthermore, This research used python language to experiment. Python was chosen because it is a dynamically semantic, interpreted, object-oriented high-level programming language. Its high-level built-in data structures, combined with dynamic typing and binding, make it ideal for Rapid Application Development and scripting or glue language for connecting existing components.

A. Health Care System

Two phases form a basic wireless and healthcare structure. The first phase is the login phase, while the second phase is called the information storing stage. The assumption is that an impersonation attack occurs at the user-long stage. An assumption is that an attack on the man in the middle is usually in the information storing stage [13] (See Fig. 4).

The absence of authentication between a sender and receiver is one of the elements leading to an impersonation attack in a medical center. An impersonation attack involves the success of external adversaries in stealing the identity of one authorized system user or stealing a communication protocol. Therefore, an impersonation attack is bound to occur when one of the user accounts is stolen. In most instances, these attacks are usually through emails attempting to impersonate someone trustworthy. The attacks also attempt to mimic an organization to access company information and finances [18].

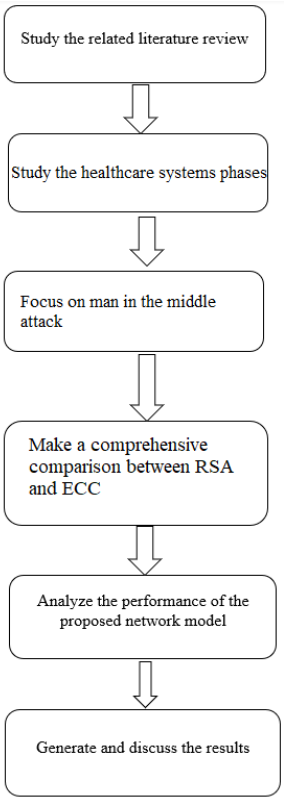

Fig. 3. Research Methodology.

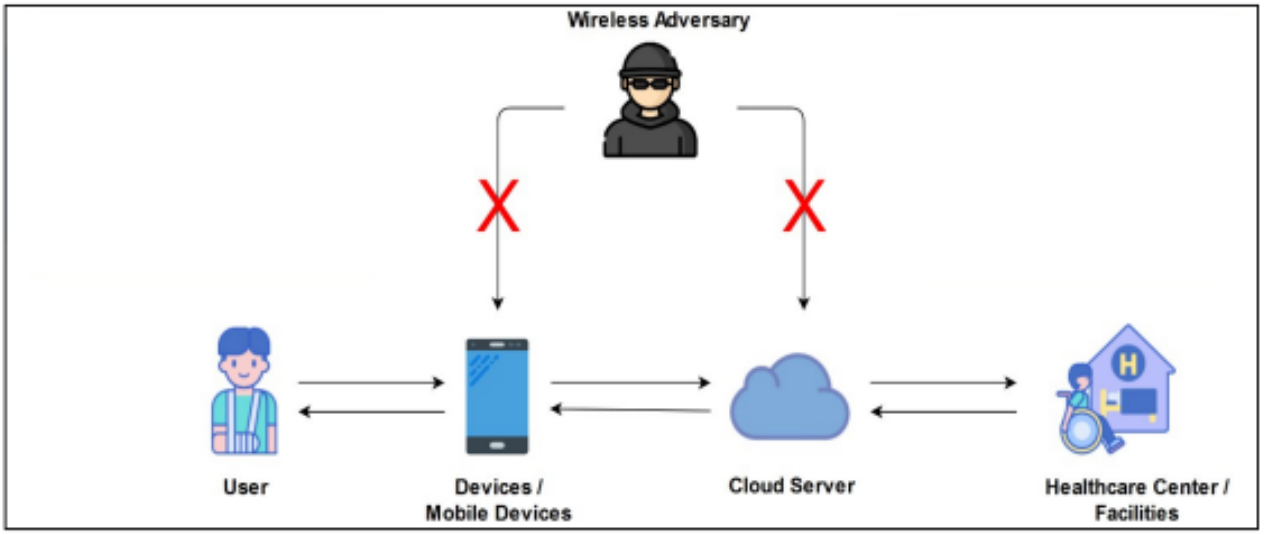

Fig. 4. Wireless Adversary Attack [13].

B. Asymmetric Keys

Asymmetric key cryptography, often known as public-key cryptography, is a type of encryption that uses asymmetric keys. In cryptography, keys are divided into two types: the first is a public key used for encryption, and the second is a private key used for decryption, as shown in Fig. 5 and Fig. 6. A certain user or device can only access the private key. Nevertheless, on the other hand, the public key is disseminated to all users and devices participating [19].

The speed and security strength are the most significant shortcomings of asymmetric ciphers; they are significantly slower than symmetric algorithms and more prone to intruder attacks, making the key exchange process more difficult. The advantage of using an asymmetric key technique is that it eliminates the need to distribute the encryption key between parties. Private keys are kept secret, and only public keys are made available to the public [19].

In addition, Digital signatures are possible with public key encryption, allowing the communication recipient to verify that the message came from the sender who specified the digital signature. With digital signatures in public-key encryption, the receiver can determine whether or not the message has been altered during transit. No changes can be made to a digitally signed communication without invalidating the signature [19].

If part A wants to communicate with part B confidentially, it should encrypt a message using B's publicly available key. Because only B has access to the associated private key, such communication can only be deciphered by B.

If part A wants to send an authenticated message to party B, as shown in Fig. 7, part A should encrypt the message using A's private key. Because this message can only be deciphered using A's public key, which may be used to verify the message's authenticity, A is indeed the message's source [20].

At the same time, public-key cryptography may support message authentication and confidentiality. For example, Fig. 8 shows how public-key cryptography ensures authentication.

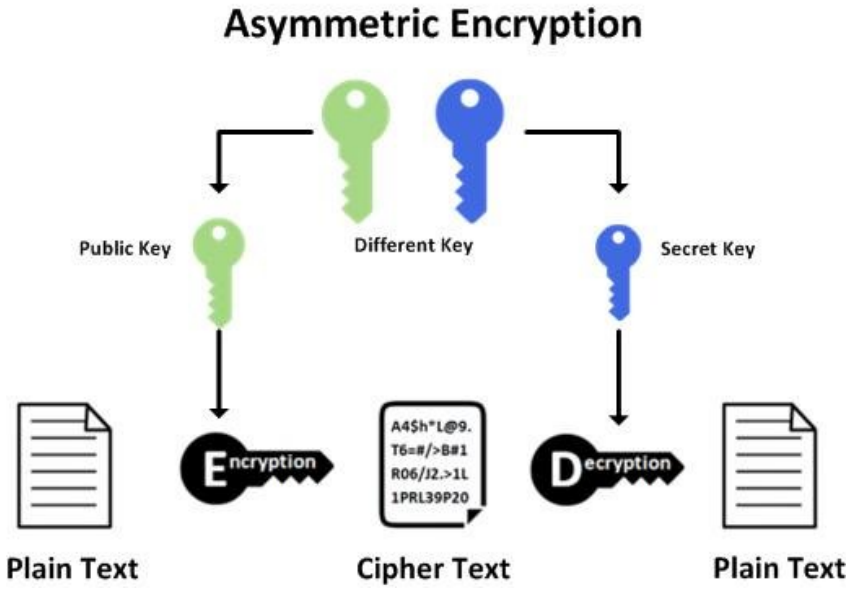

Fig. 5. Asymmetric Encryption [19].

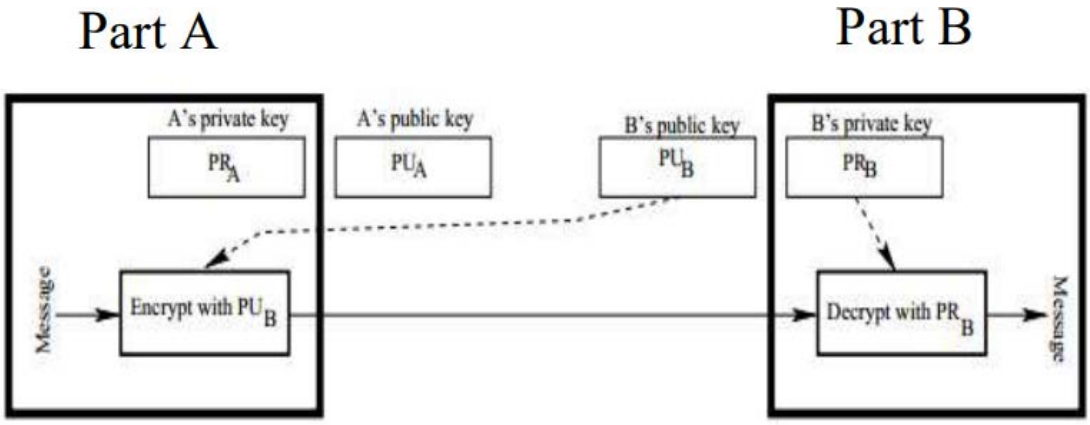

Fig. 6. Confidential Communication in Public-Key Cryptography [20].

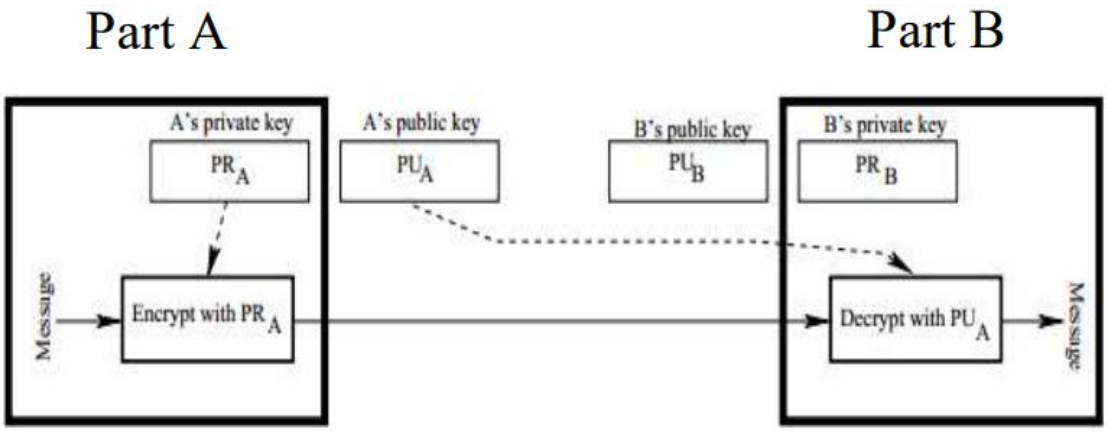

Fig. 7. Authenticated Communication in Public-Key Cryptography [20].

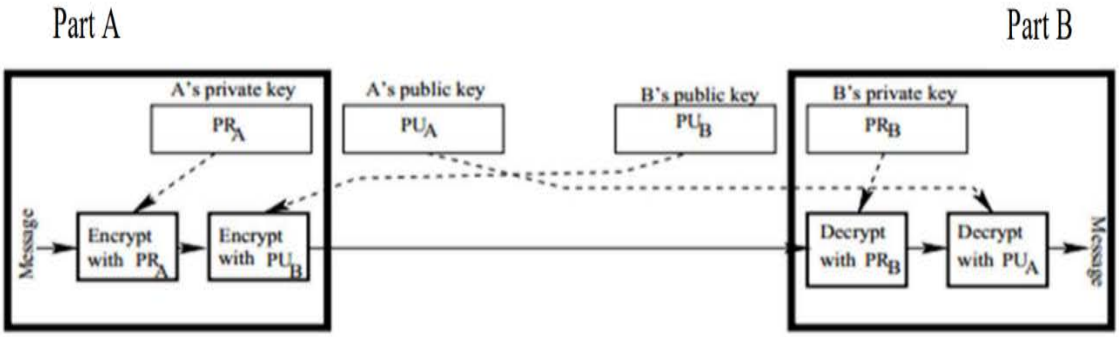

Fig. 8. Confidentiality and Authentication [20].

Fig. 8 illustrates how public-key cryptography can be used for confidentiality and authentication, including digital signatures. RSA and ECC can provide security services such as Confidentiality, Integrity, Authentication, and Authorization. Authors in [20] defined them as below as;

1) Confidentiality: Any illegal connection to the data via this security service is refused.

2) Integrity: Ensuring that messages sent to a destination have not been tampered.

3) Authentication: Any anonymous/malicious node wishes to interact with network nodes. It needs the authorized node's public key pair.

4) Authorization: This service assigns each node a unique key pair (private and public) for decryption and encryption.

C. RSA

The RSA algorithm, named after its creators, is the first method used for data encryption and digital signatures simultaneously. It is the most widely used today. The RSA algorithm's security depends on how difficult it is to decompose large integers. The public and private keys are created using two huge prime integers employed to generate the public and private keys. A rough estimate of how difficult it is to deduce the plaintext from the signal key and the ciphertext is the decomposition of the product of two large prime numbers [21].

In the Internet Key Exchange (IKE) architecture, the RSA algorithm has been proposed as a potential authentication technique. The Diffie-Hellman key exchange method is critical to the framework's security architecture. Participants interact using the Diffie-Hellman algorithm and create shared keys at the start of a key agreement session. These shared keys will be utilized for the key agreement protocol of the next steps [21].

Encrypting with private or public keys provides RSA users with many services. If the public key is used for encryption, the data must be decrypted with the private key. This is ideal for delivering sensitive data over a network or over the Internet, where the data recipient sends the data sender their public key. The data sender then encrypts the sensitive information with the recipient's public key and sends it to them. The private key owner can only decrypt the sensitive data because the public key encrypts it. Thus, even if the data is intercepted in transit, only the intended recipient can decode it. Fig. 9 explains how RSA encryption works [21].

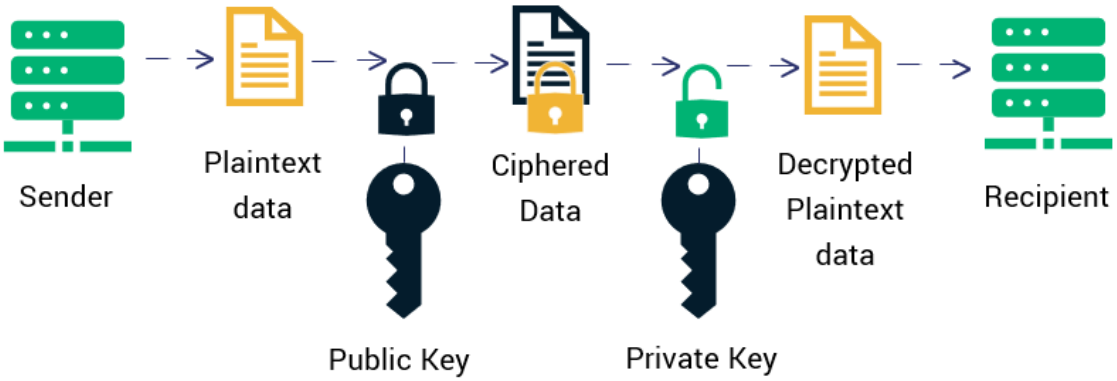

Fig. 9. How RSA Works [21].

Encrypting a message with a private key is the other asymmetric encryption method with RSA. In this case, the data sender encrypts the data with their private key and sends the encrypted data together with their public key to the data recipient. The recipient can then decrypt the data using the sender's public key, proving that the sender is whom they say they are. The data could be stolen and read in transit using this method. However, the primary purpose of encryption is to prove the sender's identity. The public key would be unable to decrypt the new message if the data was stolen and modified in route, and the recipient would be aware that the data had been altered in transit [21].

The technical aspects of RSA are based on the premise that it is simple to construct a number by multiplying two sufficiently large numbers together. Still, it is incredibly difficult to factorize that number back into the original prime numbers. For example, two numbers are used to construct the public and private keys, one of which is a product of two huge prime numbers. To calculate their value, they both use the same two prime numbers [21].

RSA is widely regarded as the first real-world asymmetric-key cryptosystem. For public-key cryptography, it becomes the de-facto standard. The integer factorization problem guarantees its safety. However, the decryption technique used by RSA is less efficient than the encrypting process. Many scholars have advocated using the Chinese Remainder Theorem (CRT) to improve the efficiency of RSA decryption. Authors in [21] suggested a CRT model improves RSA decryption time. They also advocated using a small matrix order to obtain big modulus and cryptographic keys. Larger key sizes are required for better and stronger data security, which involves higher overhead on computer systems. Small gadgets are becoming increasingly vital in today's digital world, with less memory but need security to meet market demand. RSA becomes a secondary consideration in this case.

RSA Algorithm

Key Generation
Step 1. Select p, q where p and q both are primes, $p \neq q$
Step 2. Calculate $n = pq$
Step 3. Calculate $\Phi(n) = (p-1)(q-1)$
Step 4. Select integer e $gcd(\Phi(n), e) = 1$; where $1 < e < \Phi(n)$
Step 5. Calculate d ; $d \equiv e^{-1} (mod\ \Phi(n))$
Step 6. Public key = {e, n}
Step 7. Private key = {d, n}

Encryption
Step 1. Plaintext: M<n
Step 2. Ciphertext: $C=M^e \bmod n$

Decryption
Step 1. Ciphertext: C
Step 2. Plaintext: $M=C^d \bmod n$

Each party must generate its keys to communicate safely with one another. First, the value of e in the RSA algorithm for encryption should be chosen so that gcd((n), e) equals 1. Once e has been chosen, the appropriate 'd' for decryption should be constructed by determining the inverse of 'e' mod n. During the encryption process, a sender must encrypt the message, i.e., in decimal digits, using the receiver's public key, i.e., e and n. The recipient must decrypt the ciphertext using his private key, represented by the letters d and n.

D. ECC

The ECC algorithm is public-key cryptography (PKC) with public and private keys for authentication. ECC is known as a sort of PKC built upon the algebraic structure of the elliptic curve over finite fields. The difficulty of the elliptic curve discrete logarithm problem (ECDLP) plays a major role in the security of ECC, and this problem can be resolved exponentially. Meanwhile, it has to be added that the performance of this algorithm is mainly intertwined with the efficiency of its scalar multiplication algorithm. Hamming weight of the private key is a determinant factor in algorithm efficacy regarding the scalar arithmetic level of the computation. Hamming weight measures the number of non-zero digits in a scalar representation. As the extent of Hamming's weight lowers, the speed of scalar multiplication performance rises. Accordingly, the scalar recoding method can be used to lessen the Hamming weight of the private key's scalar representation [22].

Because of its lower-key size and capacity to preserve security, ECC has gradually gained popularity over the last several years. Due to the increasing size of keys and the increasing desire for devices to remain secure, this trend will likely continue as mobile resources become more precious and the demand for devices to remain secure increases. To fully

comprehend elliptic curve cryptography, it is necessary to understand it in context. It also makes sense to use ECC to maintain high performance and security levels [22].

The ECC is becoming increasingly popular as businesses attempt to improve the online security of client data and the mobile optimization of their sites simultaneously. As the number of sites that use elliptic curve cryptography to secure data grows, the demand for brief guides to elliptic curve cryptography also grows. For the current ECC, an elliptic curve is a plane curve over a finite field composed of the points meeting the following equation: $y^2=x^3 + ax + b$. as shown in Fig. 10. It is possible to mirror any point on this elliptic curve cryptography example over the x-axis and yet have the curve retain its shape in this example. Any non-vertical line will intersect the curve three times or less if it is not vertical [22].

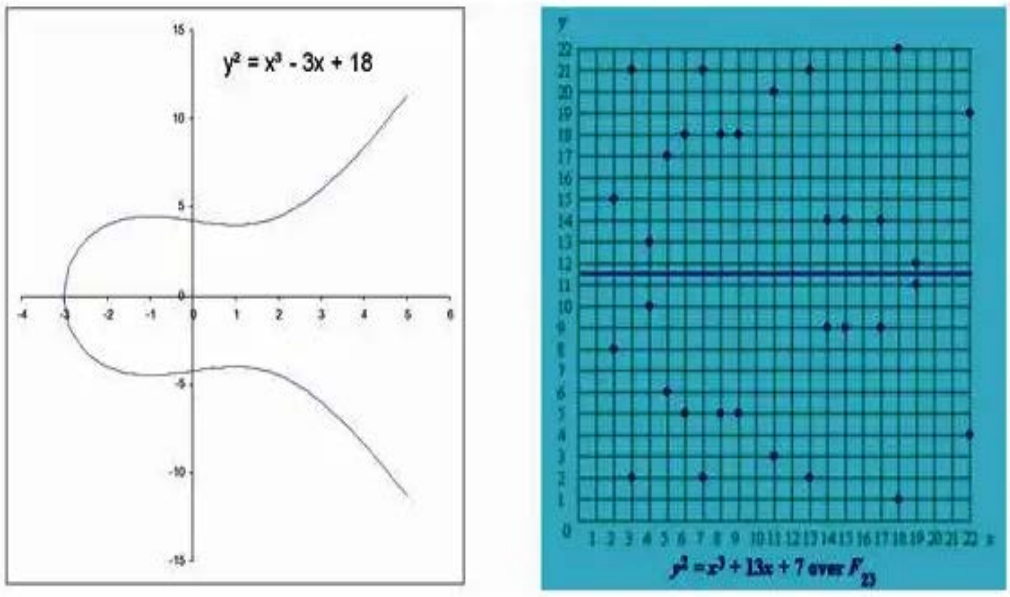

Fig. 10. 3rd-Degree Elliptic Curves [22]

Authors in [22] coined ECC as another potential asymmetric key cryptosystem in the late 1980s. This type of technology is best suited for devices with limited memory, such as Palmtops, Smartphones, and Smartcards. An ECC requires fewer or smaller parameters than RSA for encryption and decryption but with equal degrees of security.

ECC Algorithm

Global Public Elements
Step 1. $E_q(a, b)$ elliptic curve with parameters a, b, and q, where q is a prime or integer of from 2^m.
Step 2. G point on the elliptic curve whose order is large value n, where n is the mod.

User Alice Key Generation
Step 1. Select private key n_A; where $n_A < n$
Step 2. Calculate public key P_A
Step 3. $P_A = n_A G$

User Bob Key Generation
Step 1. Select private key n_B; where $n_B < n$
Step 2. Calculate public key P_B
Step 3. $P_B = n_B G$

Calculation of Secret Key by User Alice
Step 1. $K = n_A P_B$
Calculation of Secret Key by User Bob
Step I. $K = n_B P_A$

Encryption by Alice using Bob's Public Key
Step 1. Alice chooses the message P_m and a random positive integer k.
Step 2. Ciphertext: $C_m = \{ kG, P_m + kP_B \}$

Decryption by Bob using his own Private Key
Step 1. Ciphertext: C_m
Step 2. Plaintext: $P_m = P_m + kP_B - n_B (kG) = P_m + k(n_B G) - n_B (kG)$
P_m is a (x,y) point encoded with the plaintext message m in this case. Encryption and decoding take place at the P_m.

E. Performance Metrics

This section of the paper will determine the performance metrics that have been used to base our comparison of the RSA and ECC algorithms on. Performance metrics can take on various forms, but the focus is on just four types for this research.

1) Memory utilization

Memory is an integral component of the entire computer system and essentially consists of a system of devices that helps in data storage on electronic digital computers. Computer memory can either be temporary or permanent, although this depends largely on the frequency of data retrieval [23]

Memory utilization is calculated by storing the resident set size before the encryption or decryption functions. After running the encryption or decryption functions, the system time is stored in another variable. Now the difference between these two variables is memory utilization.

2) Signature generation time

When sending data, for instance, through a document, it is paramount to identify the authenticity of the senders, for optimal security and safety, for instance, against the distinct forms of cyber theft [24].

Signature generation time is calculated by storing the system time value in a variable, then running the generation function. After that, store the system time in another variable. The difference between these two variables is the signature generation time.

3) Signature verification time

The use of signature verification by algorithms means an effort to unearth the identity of the parties involved in sending and receiving messages and is integral in facilitating timely identification and aversion of potential threats that could negatively affect data security and integrity [24].

Signature verification time is calculated by storing the system time value in a variable, then running the verification function. After that, store the system time in another variable. The difference between these two variables is the signature verification time.

4) Encryption and decryption time

Encryption time is required to convert plaintext to ciphertext, while decryption time is required to convert ciphertext to plaintext [25].

Encryption and decryption time is calculated by storing the system time value in a variable before the encryption. Then, running the encryption or decryption function. After that, store the system time in another variable. Now, the difference between these two variables, encryption or decryption time

F. NIST Recommendation

The comparable key-size classes addressed in this section are based on estimations generated using currently available methodologies as of the publishing of this Recommendation. Future advancements in factoring algorithms, general discrete-logarithm assaults, elliptic-curve discrete logarithm attacks, and quantum computing may impact these equivalencies. In addition, new or improved attacks or technologies may emerge, rendering some of the current methods utterly insecure. For example, if quantum attacks become realistic, asymmetric approaches may no longer be secure. Periodic reviews will be conducted to see if the stated equivalencies need to be altered. For example, key sizes need to be increased or if the algorithms are no longer secure. Other than brute-force cryptographic attacks, strong cryptographic algorithms may be able to mitigate security vulnerabilities. For example, the algorithms may be built, so those small quantities of information about the key are unintentionally leaked. In this situation, the larger key may lower the chances of a compromised key due to the disclosed information [26]. Table II shows equivalent maximum-security strengths for the accepted algorithms and key lengths.

TABLE II. NIST RECOMMENDED SECURITY BIT LEVEL (BARKER, 2020)

Security Bit Level	RSA	ECC
80	1024	160
112	2048	224
128	3072	256
192	7680	384
256	15360	512

Security bit level is a cryptographic primitive's security level measures its strength, such as a cipher or hash function. The security level is commonly stated in bits, with n-bit security implying that breaking it would take 2n operations [26].

IV. RESEARCH RESULTS AND DISCUSSIONS

This chapter contains the analysis comparison parts of RSA and ECC algorithms based on the security bit-level suggested by NIST. Memory utilization is in bytes, signature generation time, signature verification, encryption, and decryption time are in milliseconds.

A. Memory Utilization

Based on Fig. 11 and Table. III, ECC shows better than RSA in memory utilization at all security bit levels; ECC needs less memory usage than RSA [20]. A massive spike after 192-bit level in RSA was observed. That makes RSA worst in memory handling, especially in the large keys.

TABLE III. MEMORY UTILIZATION COMPARISON BETWEEN RSA AND ECC

Security Bit Level	Memory Utilization in bytes	
	RSA	ECC
80	160	109
112	239	119
128	315	127
192	620	144
256	1777	220

B. Signature Generation Time

Fig. 12 and Table. IV show that ECC and RSA are close to each other in the signature generation time. RSA is better at 80, 112, and 128 security bit levels. In the 192-security bit-level, a small RSA latency compared to ECC was observed. Also, great latency in RSA at the 256-security level was noticed. RSA needs 3 ECC times to generate the signature [27].

TABLE IV. SIGNATURE GENERATION TIME COMPARISON BETWEEN RSA AND ECC

Security Bit Level	Signature Generation Time in Milliseconds	
	RSA	ECC
80	0.0102	0.1530
112	0.1533	0.3411
128	0.2119	0.5912
192	1.5322	1.1897
256	9.2152	3.087

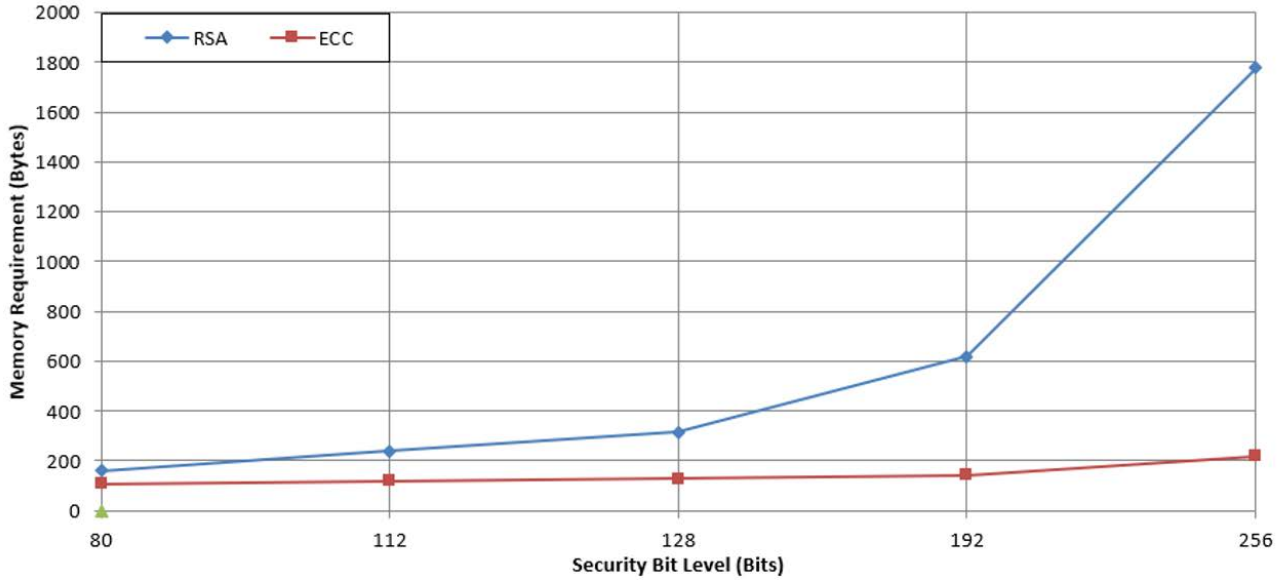

Fig. 11. Memory Utilization Comparison Graph between RSA and ECC

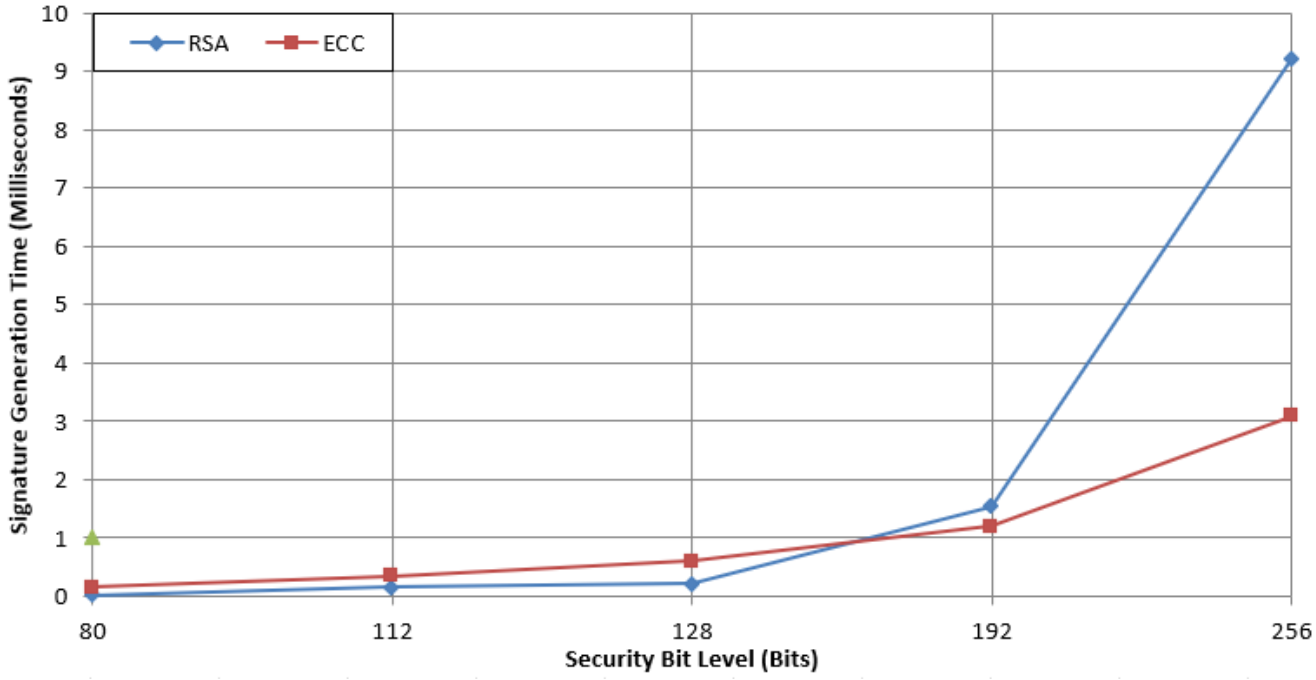

Fig. 12. Signature Generation Time Comparison Graph between RSA and ECC

C. Signature Verification Time

As shown in Fig. 13 and Table. V, RSA trumps the ECC in all security bit levels regarding signature verification. In RSA, the time required to verify a signed message is trivial for the key length employed. However, ECC is significantly slower to perform in each key range and exhibits an almost linear rise in performance with increasing the security bit level [20]. The reason because in RSA, the cost of verification can be controlled to be minimal.

TABLE V. SIGNATURE VERIFICATION COMPARISON BETWEEN RSA AND ECC

Security Bit Level	Signature Verification Time in a millisecond	
	RSA	ECC
80	0.0110	0.2310
112	0.0116	0.5231
128	0.0124	0.8622
192	0.0130	1.8100
256	0.0310	4.5410

D. Encryption and Decryption Time

Fig. 14 and Table VI show that RSA is very fast compared to ECC. in all security bit levels. Even with 256 bits, RSA needs around 1.03 seconds for encryption [28].

TABLE VI. ENCRYPTION TIME COMPARISON BETWEEN RSA AND ECC

Security Bit Level	Encryption Time in seconds	
	RSA	ECC
80	0.0306	0.4886
112	0.0310	2.2030
128	0.0360	3.8763
192	0.0489	5.2113
256	1.0310	8.5441

Fig. 15 and Table VII show a noticeable massive RSA change when the security bit level increases. Only on 80 bit of security level than RSA is better in decryption time. When the security bit level increments, a high time increment in RSA was observed. After 80 security level bit, ECC becomes better than RSA.

TABLE VII. DECRYPTION TIME COMPARISON BETWEEN RSA AND ECC

Security Bit Level	Decryption Time in seconds	
	RSA	ECC
80	0.7634	1.3376
112	2.7165	1.6012
128	7.1022	1.7770
192	14.002	2.0031
256	22.120	4.1194

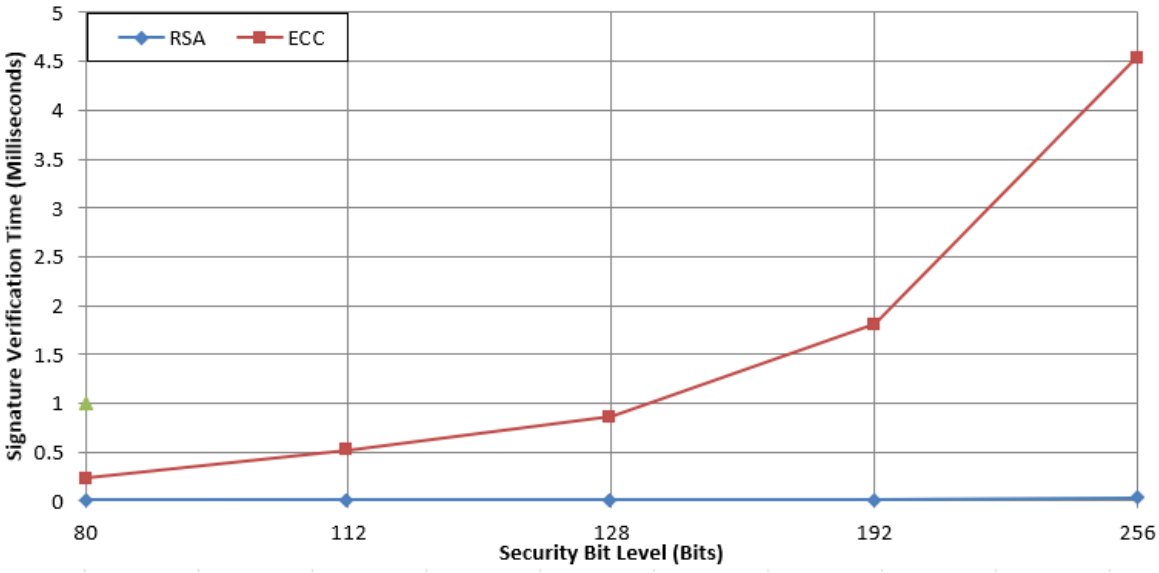

Fig. 13. Signature Verification Comparison Graph between RSA and ECC

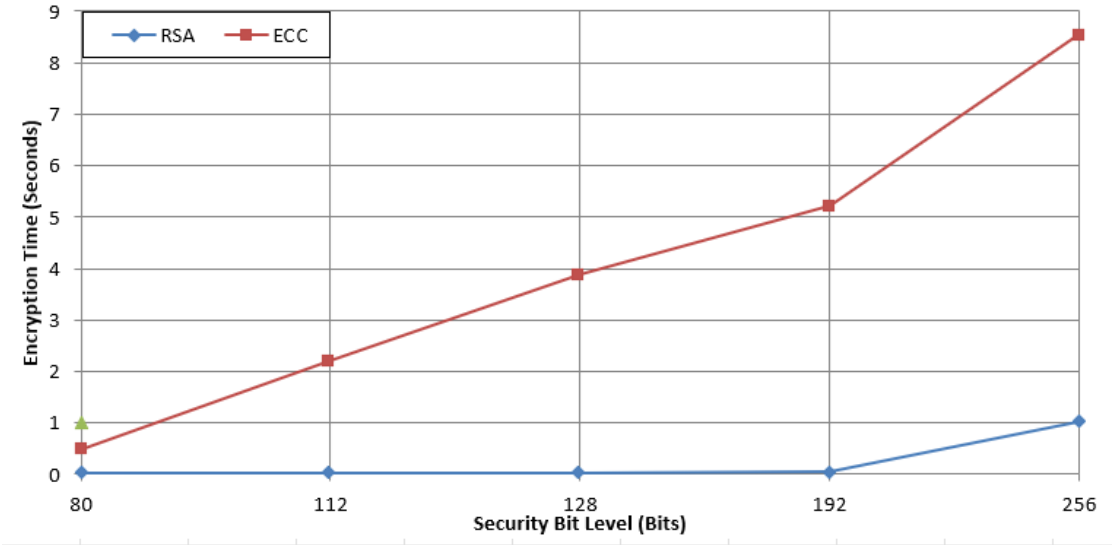

Fig. 14. Encryption Time Comparison Graph between RSA and ECC

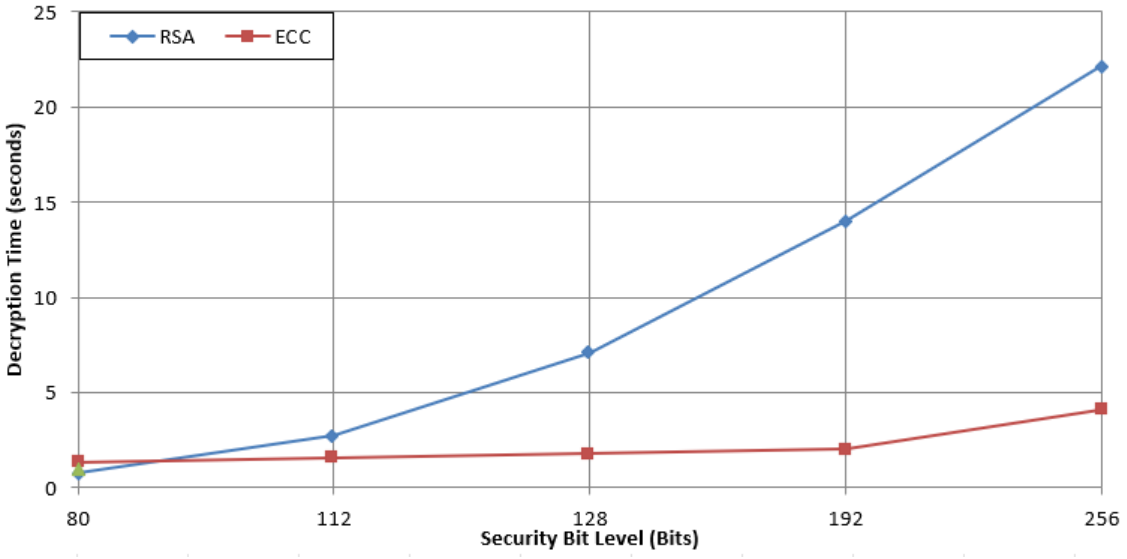

Fig. 15. Decryption Time Comparison Graph between RSA and ECC

V. Conclusion and Future Work

The majority of organizations and individuals rely on asymmetric encryption algorithms despite their complexity since they are safe and tough to break. Both RSA and ECC are instances of powerful asymmetric algorithms. This research analyzed the similarities and differences in both algorithms. Memory utilization, signature generation time, signature verification time, encryption time, and decryption time were used as performance metrics. The findings of this research show that ECC is more successful in memory use across all of the security bit-levels recommended by NIST. In addition, regarding the time required to generate signatures, RSA is more efficient than ECC when the security level is 80 or 112. On the other hand, when there is a rise in the security bit level, ECC becomes faster than RSA. When it comes to signature verification time, RSA is outstandingly fast, but ECC takes more than ten times as long as RSA, at the very least were used as a performance metric. RSA maintains its encryption time speed even when the security bit-level increases in encryption time. However, regarding decryption time, RSA becomes faster only when the security bill level increases by more than 80 security level bits. Although this experiment is done in a dedicated physical server, that service provider has limitations. One of them is in displaying the server's power consumption. That limits us from calculating the power consumption comparison between RSA and ECC in the five-bit security levels. Since electricity has become a primary factor in operational costs, adding a power-consuming as a new comparison parameter between RSA and ECC is the potential for future work.

***Abstract*—Now-a-days manufacturing processes are becoming more and more complex which constantly complicate the management of their life cycle. Although, in order to survive and maintain a good position in the competitive industrial context, industrials have understood that they must optimize the whole life cycle of their manufacturing processes. The maintenance constitutes one of the key processes indispensable to ensure the proper functioning and to optimize the lifetime of machines and production lines, and thus to optimize quality and production costs. Therefore, its automation and optimization represent until now a center of interest for researches and manufacturers, especially those related to the integration of artificial intelligence tools in the industry. In this context, several new concepts and technologies have emerged, particularly in the context of industry 4.0. One of these new concepts is digital twins, which has become a promising direction to optimize manufacturing processes lifecycle. However, the implementation of this technology faces several complex problems related to the interoperability between physical entities and their virtual counterparts, as well as to the logical reasoning between the different elements constituting the digital twin. It is in this context that an approach based on digital twins and ontologies is proposed. The originality of this paper lies in two important points: the first is the exploitation of the expressiveness and reasoning capabilities of ontologies to solve cyber-physical interoperability problems at the digital twin level, while the second is the automation of the whole maintenance process and its decision making key points using the inference potentialities of ontologies. The applicability and effectiveness of the proposed approach is validated through an industrial case of study.**

Keywords*—Maintenance systems; maintenance policy; digital twin; reasoning; ontologies; automation; cyber-physical interoperability; decision making; artificial intelligence

I. Introduction

Mastering the maintenance process of industrial systems has become a necessity for companies, in order to pursue the continuous growth of competitive markets. The achievement of this goal will allow manufacturers to optimize the productivity and quality of their production systems, and therefore gain in terms of costs, quality and delays. To this end, industrials and researchers have started to automate this key process, but until now a complete automation is not yet achieved [1]. That justifies the first objective of this paper, which is the development of a new global approach for the maintenance process automation (MMSDTO), from the data collection phase to the establishment of maintenance plans. This operation will be based on a very important artificial intelligence tool which is the Digital Twin. In fact, it will allow collecting the necessary information related to the fields, to follow the production process in real time and to locate and predict failures in the machines. However, the use of this technology requires the resolution of the cyber-physical interoperability problem, which has become the focus of many research works. Therefore, this point constitutes the second objective to be achieved through this paper. Consequently, a new concept will be integrated in the approach, namely ontologies. In fact, their expressiveness and reasoning capabilities will be exploited to preserve the semantics of the large quantities of data exchanged between the physical and virtual spaces of the Digital Twin, to overcome the problem of interoperability and also to make it able to do the logical reasoning and generate the desired results.

Thus, the first part of this paper is a literature review containing the different concepts and key points related to the work realized, notably the Digital Twin and ontologies, as well as the limitations of previous research works and the problems that need to be overcome. Then, the operating system of the newly developed MMSDTO approach will be presented and explained. The different steps of the proposed methodology will be detailed in the following sections. Finally, the approach will be applied on an industrial case study to validate its reliability and efficiency.

II. Related Work

The digital twin is a concept that has recently been the focus of several research studies [2], especially in relation to Industry 4.0 [3]. Its appearance dates back to 2003, when Michael Grieves and John Vickers participated in a conference on product life cycle management [4]. At this event, they presented the Digital Twin as a mirror space model that is used to represent physical entities in a virtual space [5]. In fact, the

Digital Twin numerically reproduces the operation and behavior [6] in real time [7] of physical elements. Therefore, several decisions will be taken in order to optimize the production system and its productivity [6]. This justifies the proposition of the digital twin's standard structure given by Michael Grieves and John Vickers. In fact, they proposed to generalize the structure (physical entity, virtual counterpart, connection between physical and virtual spaces) on digital twins [8]. Afterwards, this structure was extended, and thus, two other elements (services and digital twin data model) were added [9] to make the structure more complete and efficient. Then, this structure was projected on the production workshops by [10]. They proposed a conceptual model with four elements [11], namely:

- Physical Shop-floor: it consists of production lines, production materials and tools, products and employees [10].
- Virtual Shop-floor: it is a virtual reproduction of the functioning of the physical shop-floor and the behavior of its elements [11].
- Shop-floor Service System: it is a set of computer tools (information systems, computer aided tools, etc.) that form the services necessary to execute the commands preventing from the physical and virtual spaces [10].
- Shop-floor Digital Twin Data: data collected from physical and virtual spaces, as well as information generated from the methods of modelization, optimization and prediction of the service space are integrated [10].

The digital twins have been used in different domains such as design [12], logistics management [13], production management [14], maintenance [15], etc. Several works have focused on maintenance. The author [16] realized a literature review on the different papers produced on digital twins for maintenance. Some of these works such as [17], [18] and [19], propose the use of digital twins to do specific maintenance tasks. There are also more general approaches to predict the asset state, in order to predict accordingly the corresponding maintenance plan [20], [21], [22], etc.

By analyzing these research works, we can notice that they have two key limitations: the first one is the cyber-physical interoperability problem of digital twins. In fact, all these works propose approaches for maintenance optimization using digital twins, but they do not mention how to establish the connection between the two physical and virtual spaces of the digital twin, which is considered as a major problem to overcome. The second limitation is that none of these proposed approaches address or automate all the essential points of the maintenance process at once. It is necessary that the proposed approach be global and treat these essential points, in particular: automatic data management, real-time failure detection, prediction of future failures, automation of the maintenance policy choice, optimization of corrective and preventive maintenance, establishment of maintenance plans, automation of decision making etc.

III. The Global Proposed MMSDTO Methodology

The principal goal of this paper is to automate and optimize the maintenance management of manufacturing processes. Therefore, a structured methodology based on digital twins (DT) and ontologies is proposed. In fact, these two concepts are merged and integrated in the field of maintenance, which gives birth to MMSDTO (Maintenance Management System based on Digital Twins and Ontologies) methodology.

It is decomposed into two main phases as indicated in Fig. 1, namely: Construction phase and operation phase.

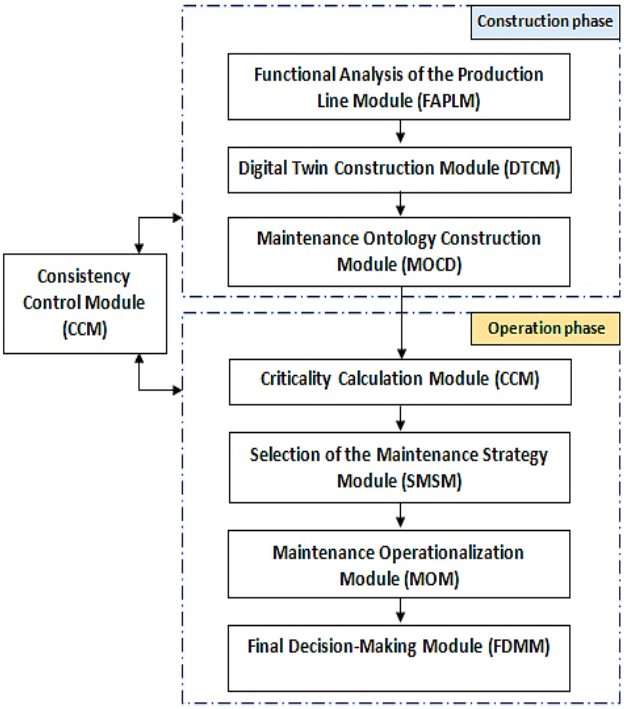

Fig. 1. The Global Proposed MMSDTO Methodology.

First, the construction phase contains three modules:

- Functional Analysis of the Production Line Module (FAPLM): the good knowledge of the production system is an essential factor to have a successful study, for this reason this first module of the construction phase represents one of the pillars of the MMSDTO methodology. Its usefulness lies in the fact that it collects all the necessary information (blocks, components and sub-components of the production lines, production parameters, etc.).
- Digital Twin construction module (DTCM): In this module, the Digital Twin will be constructed with consideration of its standard structure [9]. In fact, a virtual counterpart will be established from the physical entity studied. Moreover, the cyber-physical connection between these two spaces, serving for the transfer of the collected data, the deduced information and the necessary services for the functioning of the system, will be realized.

- Maintenance Ontology Construction Module (MOCD): Through this last module of the construction phase, the expressiveness capacity that ontologies possess will be exploited to build a maintenance ontology (DTM-Onto). The available data will be expressed in a standard language, which will allow converting them to a semantic model that will be used to achieve interoperability between the different elements of the DT.

The operation phase contains four modules:

- Criticality Calculation Module (CCM): The DTM-Onto previously constructed will be enriched by rules of computation and classification of the criticalities of the different elements of the studied system. This will be used to highlight the critical elements of the system to which priority will be given in the maintenance programs.
- Selection of the Maintenance Strategy Module (SMSM): After the analysis of the failure modes of each element as well as the evaluation of the criticality associated to each mode in the previous module, a hierarchization of the different criticality indexes is done in this module, in order to choose the adequate maintenance policy.
- Maintenance Operationalization Module (MOM): The DTMa-Onto will be enriched by other calculation rules to generate the various results and information necessary for the establishment of maintenance plans and planning.
- Final Decision-Making Module (FDMM): Based on the results obtained by the ontologies, maintenance actions must be planned. Thus, maintenance plans and planning will be realized to synthesize the work realized.
- Consistency Control Module (CCM): This module plays a key role in maintaining consistency between the modules of the two main phases of the global methodology.

These modules are executed according to a working process, as shown in Fig. 2.

The first step of the operating system of the proposed MMSDTO methodology is the functional decomposition of the studied machine in several blocks, then in several elements. This will allow to build the Digital Twin of the machine and to feed the ontology with the necessary data and inference rules. In fact, the ontology will help to solve the cyber-physical interoperability problem between the elements of the Digital Twin. In addition, it will generate several computation and classification results: criticalities of the machine elements, TBF, MTBF, Weibull parameters, etc. Finally, all these results will lead to the establishment of global maintenance plans and planning for the production equipment.

All the modules of the methodology will be detailed in the following sections.

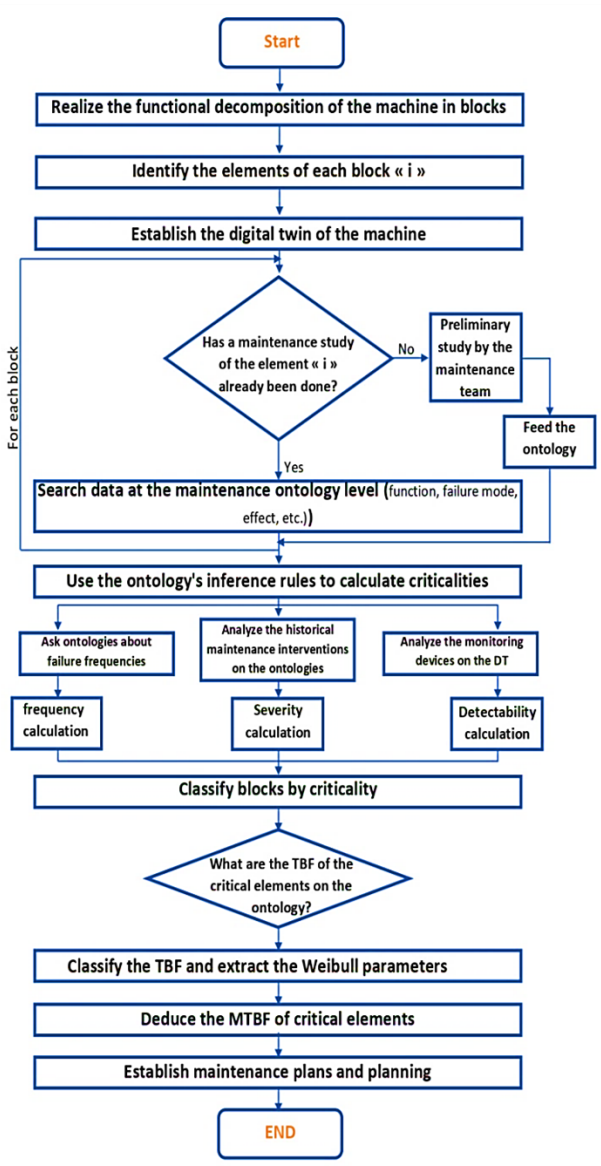

Fig. 2. The Working Process of the MMSDTO System.

IV. Functional Analysis of the Production Line Module

This module consists in identifying the components of the production system studied as well as the functions they must ensure. Therefore, it is a question of identifying the functions performed by the system and the technological solutions that achieve these functions. To do this, the following elementary phases are implemented:

- A decomposition of the system into blocks, components and sub-components in an exhaustive or limited way, up to the desired level of decomposition according to the needs and the objectives of the study.
- A description of the functions performed by each element.
- A preliminary identification of the dependencies (or cause & effect) between these functions.

V. Digital Twin Construction Module

The main objective of this module is the construction of the Digital Twin which requires the validation of the five elements of its standard structure, namely: Physical entity, virtual model, connection model, services and DT data model: [9].

Firstly, a passage from the functional decomposition of the production line module is crucial, at the level of which the latter is decomposed into several blocks, the blocks into components and the components into sub-components. In fact, this decomposition serves to simplify the virtual reproduction of the functioning of the physical entities, as well as to identify the zones that must be reinforced by sensors to achieve a perfect similarity between the physical and virtual spaces, to increase the detection of failures and to ensure a good follow-up of the production and maintenance. On the other hand, on the virtual level, the components of the manufacturing system are represented by geometrical models in CAD software. In addition, the flows (production flows, logistic flows, etc.) and the behavioral models (fatigue, elasticity, etc.) are simulated respectively on flow and behavioral modeling software.

At this stage, and to ensure a faithful exchange of data and services between the two spaces, a cyber-physical connection must be established. Normally, this connection is achieved using artificial intelligence tools and monitoring information systems [23] [24], but this still has some shortcomings in the industrial context, namely: the difficulty of preserving the semantics of the transmitted data, the inability to transfer a considerable quantity of information between the different actors of the system and the difficulty of logical reasoning. So, to overcome these problems, the concept of ontologies is integrated. This concept has already been integrated in one of our previous paper [23], through the construction of a production ontology that solves the problem of interoperability between physical entities and their virtual counterparts. In this paper, another maintenance ontology (DTMa-Onto) is added. The DTMa-Onto will be enriched with inference rules (maintenance rules, prediction rules, optimization rules, etc.), in order to be able to establish, at the end, the maintenance plans and planning.

In fact, both ontologies will be fed with the necessary data. This data will be stored in the ontologies, processed by the ontology inference processors, and transferred to the virtual space. Afterwards, new information can be generated.

This information will also be stored and processed by the ontologies. The cycle repeats itself in order to control and master the production and maintenance.

The operating system of the Digital Twin is clearly schematized in Fig. 3.

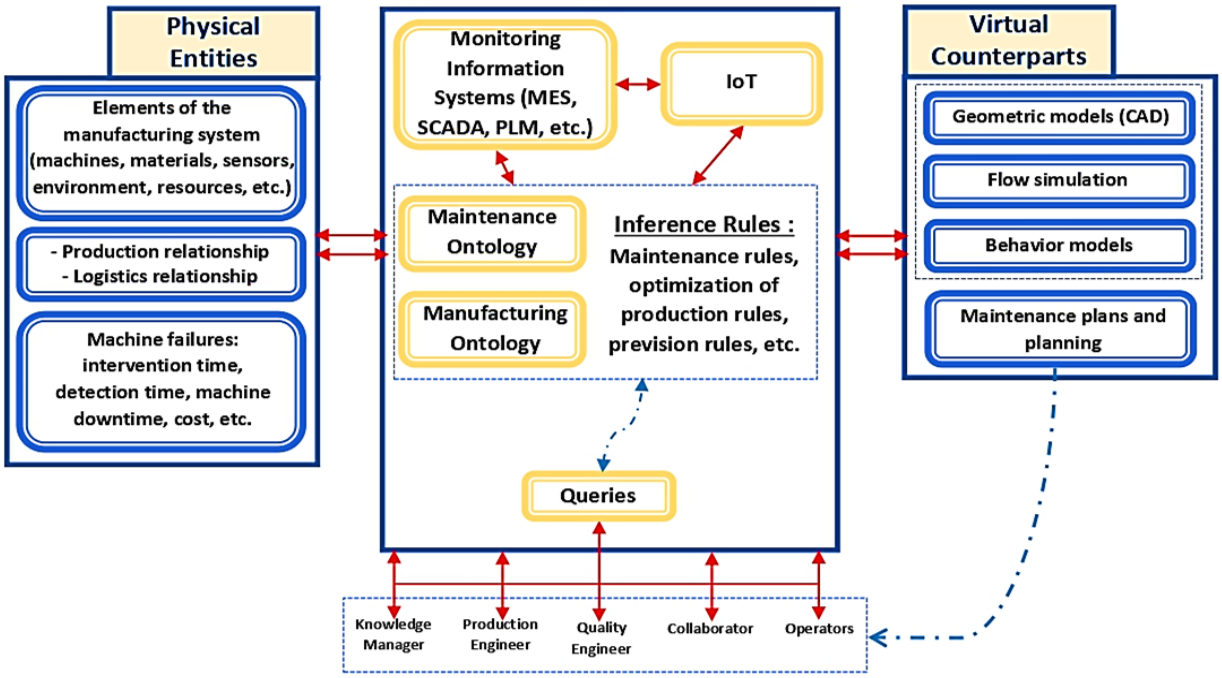

Fig. 3. The Operating System of the Digital Twin is Clearly Schematized in Figure 3.

VI. Maintenance Ontology Construction Module

This module represents the starting point for the implementation of the later phases.

At this level, a maintenance ontology (DTMa-Onto) will be constructed, as shown in Fig. 4, which will solve a large part of the problem of interoperability between the two physical and virtual spaces of the Digital Twin, due to its capacity to exchange a large quantity of data between people and/or machines, to analyze the information exchanged and to reuse it [25].

This will help to reproduce the operation of the production system digitally, as well as detect anomalies and report failures. In fact, the construction of the DTMa-Onto recognizes that it must pass through several main stages and that are realized on the editor of the ontologies Protégé.

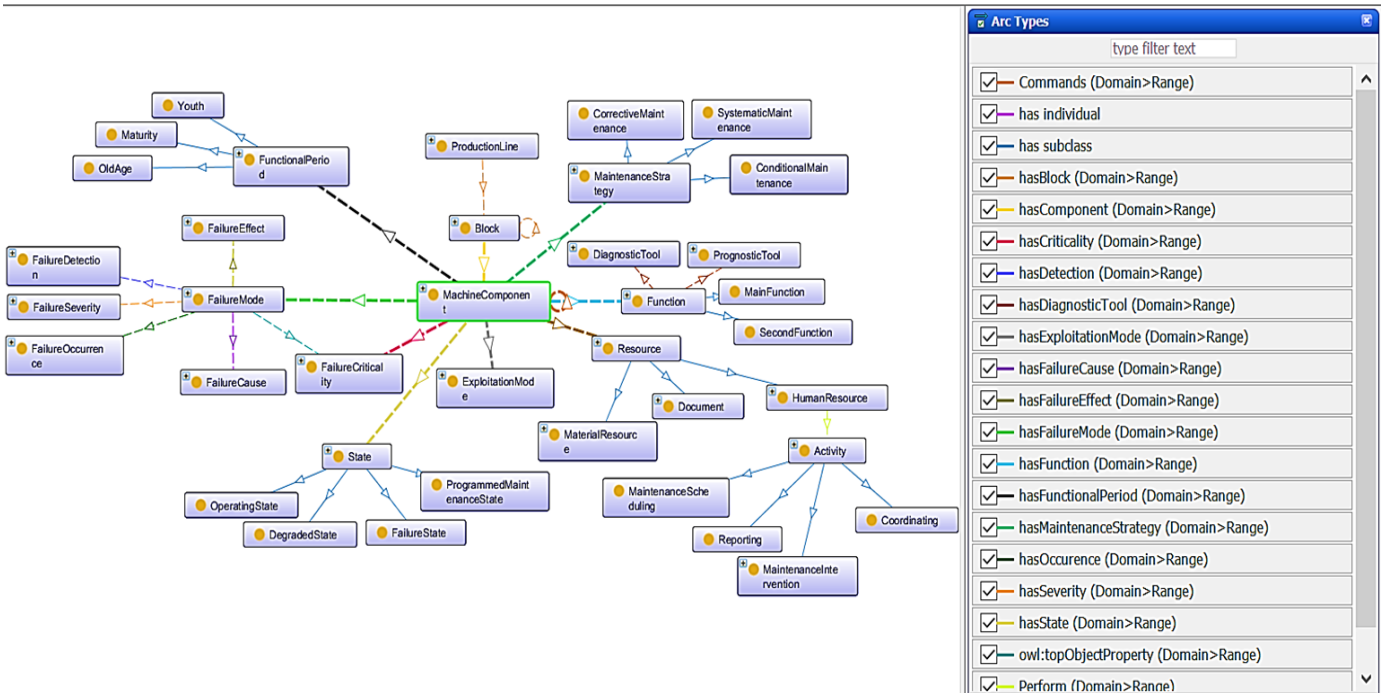

Fig. 4. The Constructed DTMa-Onto.

A. Class Definition

This phase consists in the determination of the ensemble of individuals in a specific domain. The domain considered in our case is the maintenance domain. In this way, these classes are divided into three categories:

- Classes related to the production line: they contain the different blocks, components and subcomponents of the machine, the operating mode as well as the human and material resources necessary for the operation of the production line, etc.
- Classes related to the maintenance of the production line: they comprise the failure modes, the human and material resources necessary for diagnosis and maintenance, the operating period, etc.
- Classes related to the choice of maintenance strategies: they include the different types of possible maintenance (corrective maintenance, preventive maintenance, etc.).

The whole set of classes is represented in Fig. 5.

B. Object and Data Properties Definition

First, this step consists of defining the object properties. In other words, the relationships between classes and individuals must be determined, while defining their domains, ranges and inverse properties.

Secondly, we need to specify the data properties. These relate a predicate to a single subject to an attribute data form, which can be a string, an integer, a real number, a date, etc. Fig. 6 recapitulates all the object properties and the data properties of the DTMa-Onto.

It should be noted that the implementation of all these steps leads to a hierarchy of the classes and subclasses of the production line, the maintenance of its different parts and the choice of the appropriate maintenance strategy for each situation.

The particularity of the proposed DTMa-Onto resides in the fact that it is standard and can be adapted to the maintenance of any industrial manufacturing process.

In order to evaluate the consistency of the developed ontology and to execute forward the reasoning rules, we have used the description logic reasoner Pellet [25] which is integrated in the open-source ontology editor Protégé 5.0.

In the next section, the expressiveness of the OWL ontology DTMa-Onto will be enhanced with three different categories of reasoning rules modeled with SWRL Language (Semantic Web Rule Language).

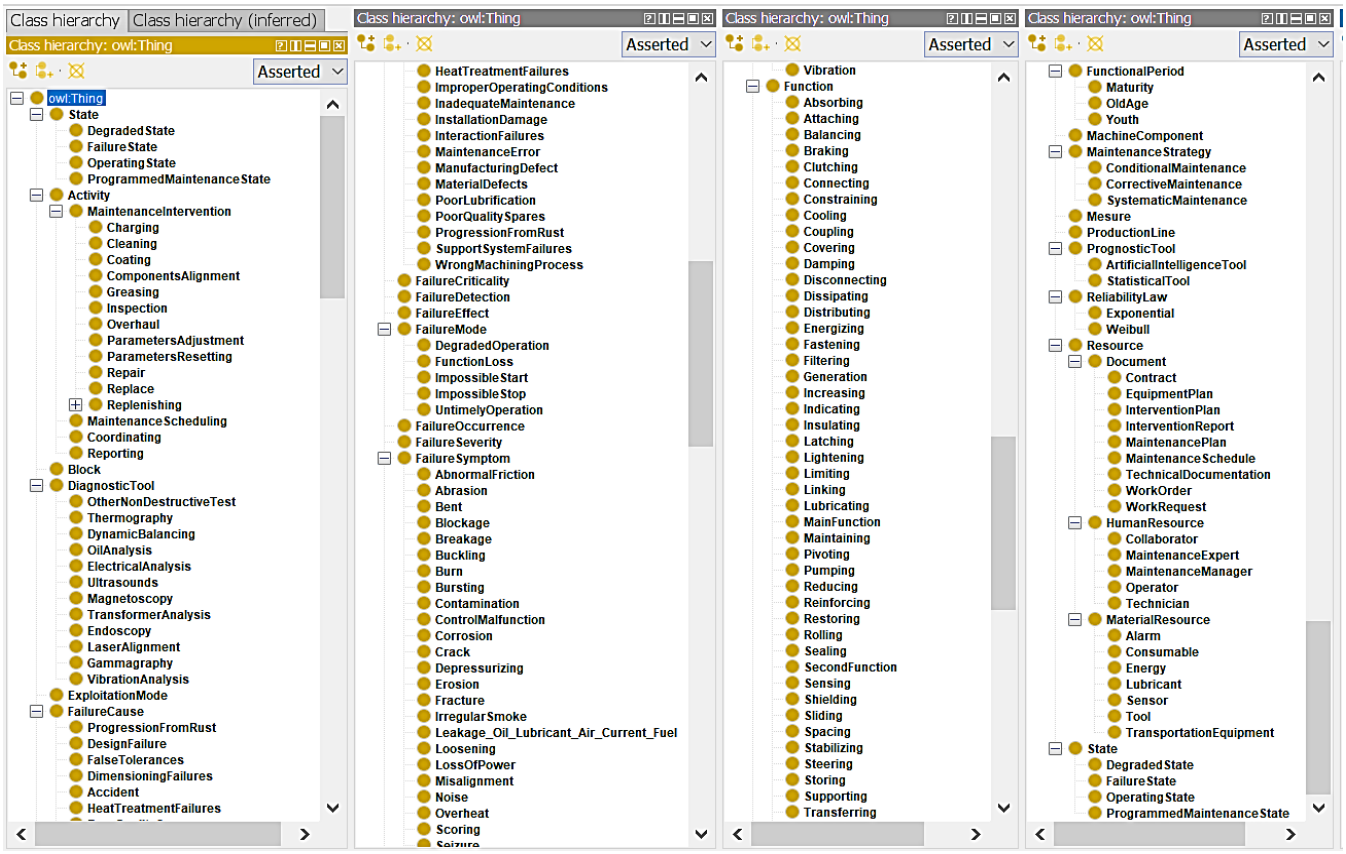

Fig. 5. All Classes of the DTMa-Onto.

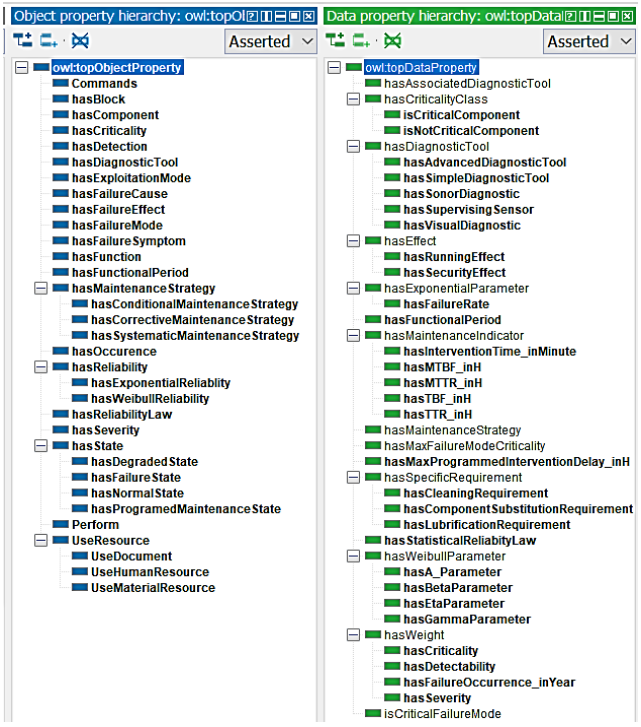

Fig. 6. Object Properties and Data Properties of the DTMa-Onto.

VII. Criticality Calculation Module

After constructing the backbone of the DTMa-Onto through the definition of classes, object properties and data properties, now it needs to be enriched with inference rules in order to perform the computation and the logical reasoning. Therefore, a first category of rules will be executed in this module, namely the rules for calculating and classifying the criticality of components. First of all, the criticality evaluation is based on the calculation and estimation of:

- The Frequency of Occurrence Index (O) (Rules R1-R4): it represents the probability that the cause of failure appears and generates the failure mode considered.
- The Severity Index (S) (Rules S1-S4): it quantifies the severity of the consequences that the failure generates.
- The Non-Detection index (D) (Rules D1-D6): it represents the probability of non-detection of the failure mode.

The criticality index (Rule C1) is calculated by multiplying the three elementary indices for each component:

$$C = O * S * D \quad (1)$$

In addition to that, the evaluation is done taking into account the current or expected state of the system, which allows to prioritize the failure modes and to identify the most critical ones to study in priority.

In addition to that, the evaluation is done taking into account the current or expected state of the system, which allows to prioritize the failure modes and to identify the most critical ones to study in priority.

As Table I shows, the calculation of these indices is formalized in the form of several rules expressed using the SWRL language.

TABLE I. RULES OF CRITICALITIES CALCULATION AND CLASSIFICATION EXPRESSED IN SWRL LANGUAGE

Criticality Rules
R1 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^hasFailureOccurrence_inYear(?M, ?o) ^ swrlb:greaterThanOrEqual(?o, 12) -> hasOccurrence(?M, 4)
R2 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^hasFailureOccurrence_inYear(?M, ?o) ^ swrlb:greaterThanOrEqual(?o, 4) ^ swrlb:lessThanorEqual(?o, 12) -> hasOccurrence(?M, 3)
R3 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^hasFailureOccurrence_inYear (?M, ?o) ^ swrlb:greaterThan(?o, 1) ^ swrlb:lessThanorEqual(?o, 4) -> hasOccurrence(?M, 2)
R4 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^hasFailureOccurrence_inYear(?M, ?o) ^ swrlb:lessThanOrEqual(?o, 1) -> hasOccurrence(?M, 1)
S1 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^hasInterventionTime_inMinute(?M, ?IT) ^ swrlb:greaterThan(?IT, 60) -> hasSeverity(?M, 4)
S2 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^hasInterventionTime_inMinute(?M, ?IT) ^swrlb:greaterThan(?IT, 20) ^ swrlb:lessThan(?IT,60) -> hasSeverity(?M, 3)
S3 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^hasInterventionTime_inMinute(?M, ?IT) ^swrlb:greaterThan(?IT, 5) ^ swrlb:lessThan(?IT, 20) -> hasSeverity(?M, 2)
S4 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^hasInterventionTime_inMinute(?M, ?IT)^swrlb:lessThan(?IT,5) -> hasSeverity(?M, 1)
D1 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^ hasSupervisingSensor(?M, 0) ^ hasVisualDiagnostic(?M, 0)^hasSonorDiagnostic(?M,0)^hasSimpleDiagnosticTool(?M,0) ^hasAdvancedDiagnosticTool(?M,0) -> hasDetectability(?M, 4)
D2 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^ hasSupervisingSensor(?M, 0) ^ hasVisualDiagnostic(?M, 0)^hasSonorDiagnostic(?M,0)^hasSimpleDiagnosticTool(?M,0) ^hasAdvancedDiagnosticTool(?M,1) -> hasDetectability(?M, 4)
D3 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^ hasSupervisingSensor(?M, 0) ^ hasVisualDiagnostic(?M, 0)^hasSonorDiagnostic(?M,0)^hasSimpleDiagnosticTool(?M,1) ^hasAdvancedDiagnosticTool(?M,0) -> hasDetectability(?M, 3)
D4 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^ hasSupervisingSensor(?M, 0) ^ hasVisualDiagnostic(?M, 0)^hasSonorDiagnostic(?M,1)^hasSimpleDiagnosticTool(?M,0) ^hasAdvancedDiagnosticTool(?M,0) -> hasDetectability(?M, 2)
D5 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^ hasSupervisingSensor(?M, 0) ^ hasVisualDiagnostic(?M, 1)^hasSonorDiagnostic(?M,0)^hasSimpleDiagnosticTool(?M,0) ^hasAdvancedDiagnosticTool(?M,0) -> hasDetectability(?M, 1)
D6 : MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^ hasSupervisingSensor(?M, 1) ^ hasVisualDiagnostic(?M, 0)^hasSonorDiagnostic(?M,0)^hasSimpleDiagnosticTool(?M,0) ^hasAdvancedDiagnosticTool(?M,0) -> hasDetectability(?M, 1)
C1: MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^ hasOccurrence(?M, ?o) ^ hasSeverity(?M, ?s) ^ hasDetectability(?M, ?d) ^ swrlb:multiply(?q, ?o, ?s, ?d) -> hasCriticality(?M, ?q)
C2: MachineComponent(?C) ^ hasMaxFailureModeCriticality(?C, ?q) ^ swrlb:greaterThanOrEqual(?q, 32) -> hasCriticalityClass(?C, "Critical")
C3: MachineComponent(?C) ^ hasMaxFailureModeCriticality(?C, ?q) ^ swrlb:lessThan(?q, 32) -> hasCriticalityClass(?C, "NotCritical")
Q1: MachineComponent(?C) ^ hasFailureMode(?C, ?M) ^ hasCriticality(?M, ?q) ^ hasCriticalityClass (?C, ?s) -> sqwrl:select (?C , ?M , ?q, ?s) ^ sqwrl:columnNames ("MachineComponent", "FailureMode", "Failure Mode Criticality", "Component Criticality Class")
Q2: MachineComponent(?C) ^ hasCriticalityClass(?C, ?s) -> sqwrl:select(?C, ?s) ^ sqwrl:columnNames("MachineComponent", "Component Criticality Class")

In fact, the Digital Twin collects the necessary data (i.e. downtime, failures appeared, failure frequency, etc.), stores them on the DTMa-Onto. In its turn, the DTMa-Onto treats this collected information, and assigns for each index an adequate value according to a rating scale (from 1 to 4) programmed by the inference rules, and then the criticality of each component is calculated. It should be noted that the values as well as the rating criteria can change from one production process to another, but the principle remains the same.

A deployment of the results of the computation is performed. The final objective is to define and launch all the necessary actions, both corrective and preventive, taking into account the priorities highlighted by the evaluation of the failures' criticality. Indeed, we proceed to a prioritization of all the failure modes according to their criticality indexes (The rules: C2, C3, Q1, Q2). The critical points of the equipment are then identified. They correspond to the failures which have a criticality higher than a threshold predefined by the maintenance team and which takes into account the expected reliability objectives as well as the studied technologies. Priority actions must also be considered for any severity or occurrence index score equal to 4, because, even if the criticality of these failures is lower than the pre-established threshold, they represent a real risk. This constraint has been taken into account in the rules.

VIII. SELECTION OF THE MAINTENANCE STRATEGY MODULE

Fig. 7 summarizes the methodology for choosing the maintenance policy proposed.

The inference rules implemented in the criticality calculation module have led to the establishment of other rules concerning the choice of the maintenance policy.

In fact, to make the analysis of the failure modes of each component and the evaluation of the criticality associated with each mode useful, it is necessary to define for each component the type of maintenance that is appropriate. To do this, the maintenance team determines a minimum criticality threshold above which the failure modes become critical, and then the corrective maintenance is replaced by the preventive one.

However, in some cases, it is difficult to control the equipment even if the criticality index exceeds the threshold set by the working group, and therefore, its maintenance remains corrective. In addition to this, the safety of the personnel and the equipment must be taken into account.

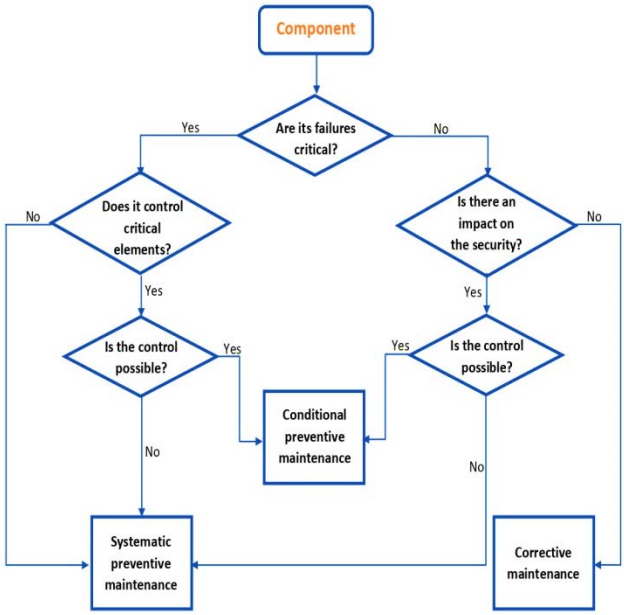

Fig. 7. The Proposed Methodology for the Maintenance Policy Selection.

This approach for selecting the maintenance strategy is programmed at the DTMa-Onto level using various rules expressed by the SWRL language. Table II groups all these rules.

TABLE II. MAINTENANCE STRATEGY RULES EXPRESSED IN SWRL LANGUAGE

Maintenance Strategy Rules
P1: MachineComponent (?C) ^ hasCriticalityClass(?C, "Critical") ^ Commands(?C, NoneComponent) -> hasMaintenanceStrategy(?C, "SystematicMaintenance")
P2: MachineComponent (?C) ^ MachineComponent (?N) ^ hasCriticalityClass(?C, "Critical") ^ Commands(?C, ?N) ^ hasCriticalityClass(?N, "NotCritical") ^ hasAssociatedDiagnosticTool(?C, 0) -> hasMaintenanceStrategy(?C, "SystematicMaintenance")
P3 : MachineComponent (?C) ^ MachineComponent (?N) ^ hasCriticalityClass(?C, "Critical") ^ Commands(?C, ?N) ^ hasCriticalityClass(?N, "NotCritical") ^ hasAssociatedDiagnosticTool(?C, 1) -> hasMaintenanceStrategy(?C, "ConditionalMaintenance")
P4: MachineComponent (?C) ^ hasCriticalityClass(?C, "NotCritical") ^ hasSecurityEffect (?C, 1) ^ hasAssociatedDiagnosticTool(?C, 1) -> hasMaintenanceStrategy(?C, "ConditionalMaintenance")
P5: MachineComponent (?C) ^ hasCriticalityClass(?C, "NotCritical") ^ hasSecurityEffect (?C, 1) ^ hasAssociatedDiagnosticTool(?C, 0) -> hasMaintenanceStrategy(?C, "SystematicMaintenance")
P6: MachineComponent (?C) ^ hasCriticalityClass(?C, "NotCritical") ^ hasSecurityEffect (?C, 0) -> hasMaintenanceStrategy(?C, "CorrectiveMaintenance")

IX. MAINTENANCE OPERATIONALIZATION MODULE

As presented in Table III, this module covers the third class of inference rules of the DTMa-Onto.

These rules are a formalization of the two statistical laws of component reliability, namely:

- The exponential law: where the failure rate is constant. It is valid in the case of electrical components and components in maturity phase.

$$R(t) = exp(-\lambda t) \quad (2)$$

With:

✓ λ is the failure rate. It represents the proportion of defective parts that we obtain during a very short time interval

- The Weibull law: It is valid in the general case and takes into account the three phases of the life cycle (Growth, maturity and decline)

$$R(t) = \exp(-(\frac{t-\gamma}{\eta})^{\beta} \quad (3)$$

With:

✓ β is the shape parameter

✓ η is the scale parameter

✓ γ is the position parameter

TABLE III. MAINTENANCE OPERATIONALIZATION RULES EXPRESSED IN SWRL LANGUAGE

Maintenance Operationalization Rules
W1: MachineComponent(?C) ^ ReliabilityLaw(?R) ^ hasReliabilityLaw (?C, ?R) ^ hasStatisticalReliabityLaw(?R, "Weibull") ^ hasBetaParameter(?R, ?b) ^ hasGammaParameter(?R, ?g) ^ hasEtaParameter(?R, ?e) ^ hasA_Parameter(?R, ?A) ^ swrlb:multiply(?t, ?A, ?e) ^ swrlb:add(?u, ?t, ?g) -> hasMTBF_inH(?C, ?u) ^ hasMaxProgrammedInterventionDelay_inH(?C, ?u)
W2: MachineComponent(?C) ^ hasFunctionalPeriod(?C, "Maturity") -> hasStatisticalReliabilityLaw(?R, "Exponential")
W3: MachineComponent(?C) ^ hasReliabilityLaw(?C, ?R) ^ hasStatisticalReliabilityLaw(?R, "Exponential") ^ hasFailureRate(?R, ?l) ^ swrlb:divide(?u, 1, ?l) -> hasMTBF_inH(?C, ?u) ^ hasMaxProgrammedInterventionDelay_inH(?C, ?u)

This module works in interaction with the numerical analysis environment and the programming language "Matlab". Indeed, using the TBF (Time between failures) extracted from the failure histories collected by the Digital Twin and stored in the DTMa-Onto, the approach developed by [26] will be applied for the estimation of the exponential and Weibull law parameters of the concerned components. These parameters will constitute the inputs for the SWRL rules of the ontology. These rules model the exponential (rules W2-W3) and Weibull (rules W1) reliability laws, and enable the calculation of MTBF (Mean time between failures) and the prediction of the next component failures, which will allow to schedule future maintenance interventions before the machine components fail. The MTBF formula is as follows:

$$R(t) = \exp(-(\frac{t-\gamma}{\eta})^{\beta}) \quad (4)$$

With:

- ✓ β is the shape parameter
- ✓ η is the scale parameter
- ✓ γ is the position parameter

X. Final Decision-Making Module

From the maintenance Operationalization module, the TBFs and MTBFs of the different critical components are calculated, and the life phase of each element is determined. Based on these calculation results obtained by the DTMa-Onto, the appropriate maintenance actions (lubrication, greasing, etc.) must be planned before the end of the TBFs. All this work gives birth to the maintenance plans and planning, which will be stored and archived at the DTMa-Onto level, in order to benefit from the experience feedback for future maintenance situations. This phase has two objectives, namely the identification and standardization of good practices and methods, as well as the transmission to the design all the experience acquired (means, processes, operating modes, etc.). The obvious goals are to capitalize successful actions and generalize them.

XI. Case of Study

The objective of this part is to validate the applicability of the proposed methodology MMSDTO, as well as its effectiveness for the resolution of maintenance problems of industrial production systems. This validation will be done through a concrete example of a company that operates in the agro alimentary industry. In fact, this company works on dairy products manufacturing (milk, yogurt, etc.), but the case study will only focus on the yogurt manufacturing and packaging process.

The first step of the process is the unrolling of the plastic, which is done by two rollers driven by a gear motor. The plastic roll is introduced in the insertion section, and in order to ensure its pecking, it passes directly into a heating system to heat its edges, due to heating resistances and temperature probes. This operation is done by a chain and serves to transmit the plastic strip during the rest of the process. Before moving to the forming block, the plastic strip passes through two ionizing dust collectors. The first one ionizes the plastic strip to prevent electrostatic sticking and to remove any foreign body. The second is a tunnel of ultraviolet lamps, which ionizes the operculum to prevent electrostatic sticking and to aspirate the existing particles. Once the plastic and the operculum are ionized, the product cups are formed using a mold and punches according to the desired specifications. The cups are then dosed with the products, which have already been prepared in the process section, using a piston dosing unit. Then the operculum is welded onto the dosed cups using a cam press and the product packs are cut out. After the product packs have been cut, they are transported to the case packer by a conveyor system to be packed in empty boxes. The last step of the packaging process is the manual pallet handling of the full boxes, and their storage in cold rooms.

The competition in the market is fierce and the interruption of production generates huge losses for the company (market shares, profits, etc.), that's why the control of the production equipment maintenance is a necessity. To this effect, the MMSDTO methodology is applied.

The first step in the approach is the functional decomposition of the production process into blocks, the blocks into components and the components into sub-components. This decomposition will be used, initially, to locate the areas of the production line that require the installation of sensors for the data transfer between the two physical and virtual spaces of the Digital Twin. Fig. 8 and 9 show, respectively, an example of the installation of the position determination sensors and an extract from the virtual part of the Digital Twin.

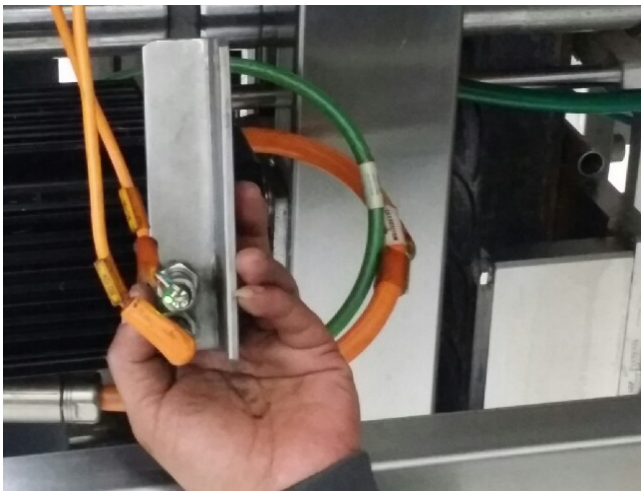

Fig. 8. Example of Sensors Installation Necessary for the Digital Twin Functioning.

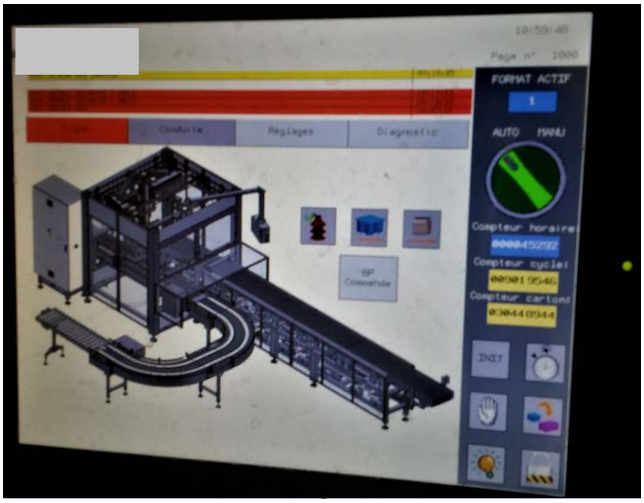

Fig. 9. An Extract from the Virtual Part of the Digital Twin.

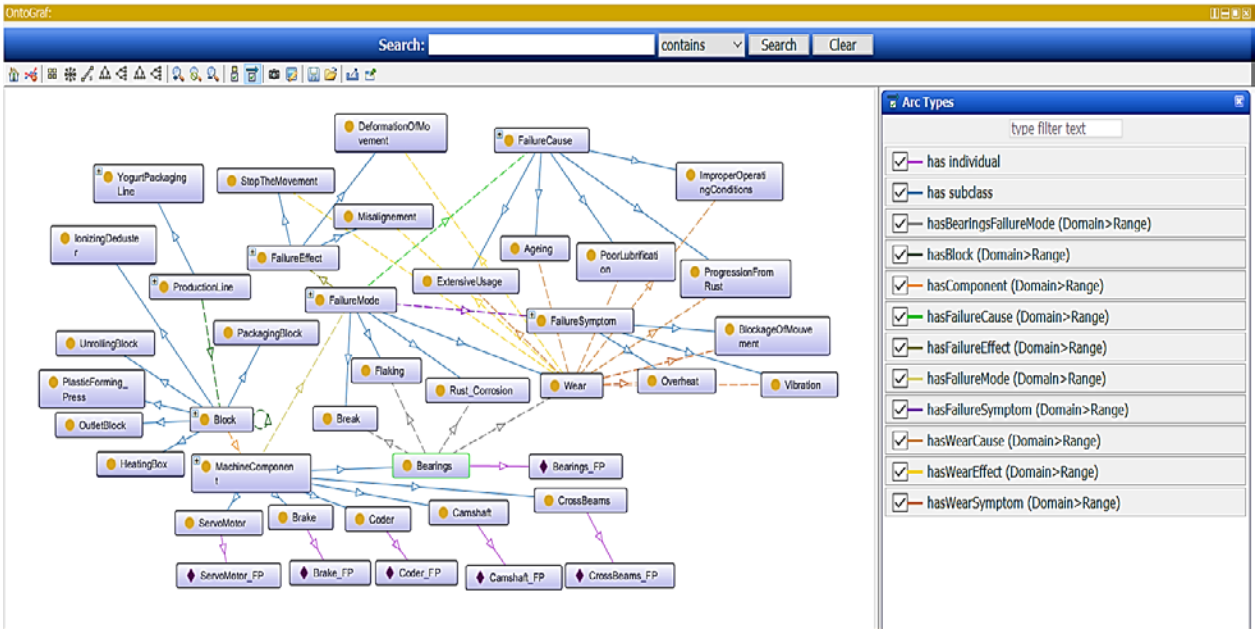

Fig. 10. The DTMa-Onto related to the Case of Study.

The second objective of this decomposition is the preliminary construction of the DTMa-Onto. Thus, the classes, the object properties and the data properties of the forming press are entered on the ontology (the work will be focused on the forming block to simplify the case of study and make it clearer). In fact, as it is represented on Fig. 10, the DTMa-Onto schematizes the different blocks of the production line, the failure modes of the different components of the forming block (the studied block), their causes, their symptoms and their effects.

Now, based on the collected data from the Digital Twin, in particular the machine downtime tracking, the DTMa-Onto, and due to its information storage and logical reasoning capabilities, assigns for each failure mode a suitable occurrence, severity and detectability value. Then, the DTMa-Onto immediately generates the results of the calculation and classification of the failure modes' criticalities, using the inference rules listed in the Table IV.

The totality of the calculation and criticality classification results of the other failure modes of the forming press components is presented in the Fig. 12.

After the classification of the failure modes by their criticality, the ontology lists all the critical elements based on the criticality threshold set by the maintenance team.

An extract of the obtained results are illustrated in the Fig. 11. These results concern the criticalities of the forming press bearings failure modes.

At this stage, the second category of inference rules, namely the rules for the maintenance policy choice, is applied. Thus, the type of maintenance for each component is determined by the DTMa-Onto.

The third category of rules, including maintenance operationalization rules, will be applied on the brake and bearings of the forming press to calculate the proper MTBFs. Fig. 14 shows the results obtained.

The Fig. 13 summarizes the results of the appropriate maintenance policy for each element. The results obtained indicate that the bearings and the brake of the forming press require a systematic preventive maintenance policy.

Finally, from all the results obtained before, it only remains to establish the general maintenance plans and planning, in order to control the maintenance process of the production line, and subsequently improve its performance.

It is necessary to note that the maintenance plans and planning are not presented in order to avoid burdening the study case with too much information and results.

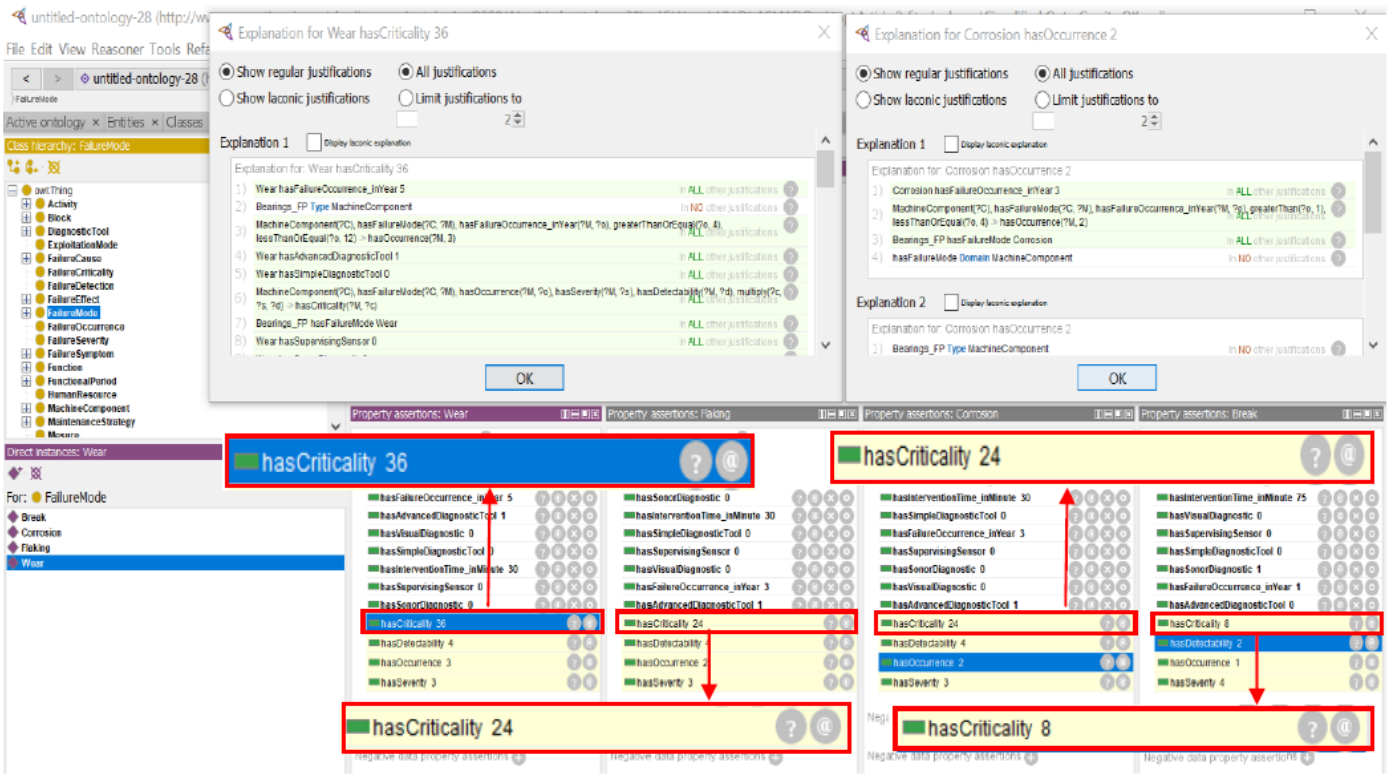

Fig. 11. An Extract of the Criticalities Calculation Results Obtained.

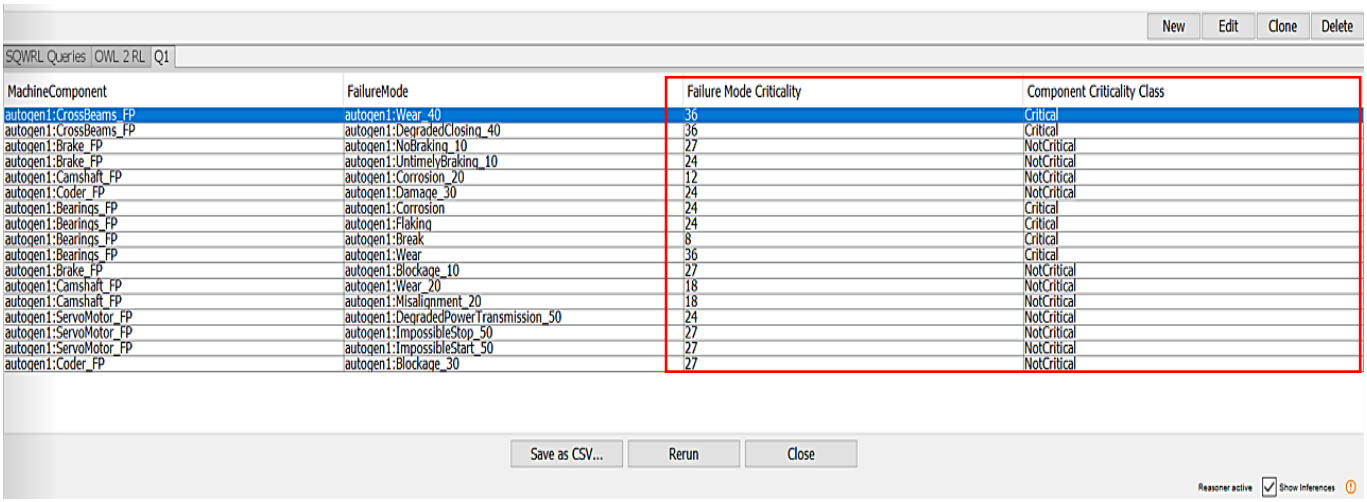

MachineComponent	FailureMode	Failure Mode Criticality	Component Criticality Class

XII. Conclusion and Perspectives

An intelligent decision making system for the automation of industrial production systems maintenance using digital twins and ontologies is developed in this paper. The integration of these two concepts in the same approach applied to the maintenance process has given birth to a hybrid system that presents new originalities.

On the first hand, the majority of research works related to digital twins propose a variety of approaches in relation to different domains and processes in general, and in relation to the maintenance process in particular, but they do not take into account the dimension of the connection between the physical and virtual spaces, which is essential for the applicability of these approaches. Thus, the resolution of this problem of cyber-physical interoperability of digital twins was the first objective to be attained through this paper. In fact, the concept of ontologies was integrated in the proposed approach. A maintenance ontology (DTMa-Onto) was constructed, and due to the expressivity capacities of ontologies, the DTMa-Onto

was employed to ensure in real time a faithful transfer of large quantities of data between the two physical and virtual spaces in order to reproduce the functioning and behavior of physical entities digitally. On the other hand, the second originality of this paper is that it proposes an automation approach for the control of the whole maintenance process, contrary to previous works which only treat some sides of the maintenance process in the same approach and cannot take the decision automatically. Indeed, the DTMa-Onto has been fed by many categories of inference rules that are used to calculate and classify criticalities and downtimes, choose the maintenance policy, propose actions to be taken, predict failures, etc. To summarize, the work realized is in the form of a structured and global methodology for the automation of the entire maintenance process, from data collection to decision making and the methodology was validated by an industrial case study.

As perspectives, it is suggested to integrate other aspects in the proposed approach (the environmental aspect, the financial aspect, etc.). It is also proposed to automate the maintenance process in another way, using other artificial intelligence tools. Another perspective is to propose other approaches for the automation of other processes (logistics, design, etc.).

An Improved Arabic Sentiment Analysis Approach using Optimized Multinomial Naïve Bayes Classifier

Ahmed Alsanad
STC's Artificial Intelligence Chair, Department of Information Systems
College of Computer and Information Sciences, King Saud University, Riyadh 11543, Saudi Arabia

***Abstract*—Arabic sentiment analysis has emerged during the last decade as a computational process on Arabic texts for extracting people's attitudes toward targeted objects or their feelings and emotions regarding targeted events. Sentiment analysis (SA) using machine learning (ML) methods has become an important research task for developing various text-based applications. Among different ML classifiers, multinomial Naïve Bayes (MNNB) classifier is widely used for documents classification due to its ability for performing statistical analysis of text contents. It significantly simplifies textual-data classification and offers an alternative to heavy ML-based semantic analysis methods. However, the MNNB classifier has a number of hyper-parameters affects the classification task of texts and controls the decision boundary of the model itself. In this paper, an optimized MNNB classifier-based approach is proposed for improving Arabic sentiment analysis. A number of experiments are conducted on large sets of Arabic tweets to evaluate the proposed approach. The optimized MNNB classifier is trained on three datasets and tested on a different separated test set to show the performance of developed approach. The experimental results on the test set revealed that the optimized MNNB classifier of proposed approach outperforms the traditional MNNB classifier and other baseline classifiers. The accuracy rate of the optimization approach is increased by 1.6% compared with using the default values of the classifier's hyper-parameters.**

Keywords*—Machine learning; Arabic sentiment analysis; optimized multinomial Naïve Bayes (MNNB) classifier; hyper-parameters optimization

I. Introduction

Recently, sentiment analysis (SA) using machine learning methods has become an important research task for developing various text-based applications [1, 2]. It is used in natural language processing (NLP), text search, and computational linguistics for extracting people's opinions or feelings about products, events, or other in one way or another [3]. The SA imposes the identification of several elements which are four elements including the entity, its aspect, the opinion holder, and its feeling and can categorize the opinions extracted into either a subjective or objective text. The subjective text can also be categorized into negative or positive feelings. Several methods have been conducted on sentiment analysis of several languages, including Arabic, and differences have been discovered, as NLP in Arabic is still in its early steps and lacks tools and resources [4]. Hence, the Arabic language still faces difficulties in NLP tasks because of its complexity, structure, and the different dialects to which it belongs. A large number of tools and methods have been used, in the literature, to perform the sentiment analysis task. Most of them are considered in English, which is the science language, these tools and methods are based on either a machine learning approach or a semantic approach [5]. The semantic approach extracts emotion words and computes their poles based on the emotion dictionary. Conversely, in a machine learning approach to building a new model, machine learning classifiers are trained on pre-labeled data after transforming into feature vectors. Finally, the new model can be applied for predicting a new category of data based on these characteristics. It should be noted that these methods can be modified to another language, such as Arabic. The Arabic language did not receive the effort that other languages did [6]. However, several studies of sentiment analysis of Arabic writing have been proposed [7]. A decade ago, Arabic sentiment analysis became one of the most common information mining forms in many fields. These analytics have contributed to achieve many benefits, such as offering brand value insights for a product or service Invite potential product customers, identify social media influencers, and detect spam. Consequently, Arabic sentiment analysis has been investigated in different contexts, and a number of techniques in several studies have been published on this topic. However, there is still a limitation in MNNB classifier, which is widely used to analyze users' sentiment from texts and classify their topics.

This study aims to develop an optimized simple ML model-based approach for improving Arabic sentiment analysis using grid search algorithm and multinomial naïve Bayes (MNNB) classifier. The approach is able to select the optimal values for alpha hyper-parameter and control the decision boundary of the classifier. Through this proposed approach, the research contributions to the field can be presented in the following points:

- Propose an improved approach for Arabic sentiment analysis using a grid search algorithm and MNNB classifier that can be able to optimize the learning process of the classifier.
- Use the grid search algorithm as a selection step to assign the optimal or near-optimal values of MNNB classifier's alpha-parameter, improving the sentiment analysis of Arabic tweets.
- Train the proposed approach on three datasets with a large number of Arabic tweets for achieving the diversity in learning the ML models.

- Evaluate and compare the performance results of the optimized model with the baseline models on the same test dataset.

The rest of the paper is structured as follows: Section II gives a detailed literature review for the study. Section III describes the research methodology. Section IV presents the experimental results with discussions and findings. Finally, the conclusions and future work are summarized in Section V.

II. Literature Review

Nowadays, the rapid development of social media makes the text messages posted by users become the largest public data source in the world. Such text messages contain an important information and a great commercial and research value. Sentiment analysis and text analytics using NLP is one of the key methods that can provide a necessary support for text analysis in the social media. Consequently, text analytics technique including sentiment analysis, entity recognition, topic modeling, and text summarization using NLP in social media has attracted widespread attention.

The social media Arabic sentiment analysis can analyze and mine the tendency and view of user expressions from his subjective text. This analyzing supports the decision making of different researchers, users, government agencies, and business organizations. In this context, the worth question of discussion is how to effectively mine these massive textual information, identify the sentiment in it, and use it reasonably and effectively. Sentiment analysis, also known as propensity analysis, is a computational study of emotions, opinions, and feelings held by people about things and their attributes [8]. Things can be services, products, individuals, organizations, questions, events, or topics. Sentiment analysis task can also be defined as the process of automatically mining attitudes, opinions, opinions, and emotions from speech, text, Weibo, and other data sources through NLP technology [9]. Text sentiment analysis is to analyze the sentiment of a paragraph of text, as the basic work of public opinion monitoring, and has a wide range of uses.

Social networks are getting more and more popular, and "opinion leaders" are getting more and more. Sites that allow users to rate product and service evaluations have sprung up, and user reviews and suggestions can be spread throughout the network. These text-type data are undoubtedly the source of the power of precision marketing. Enterprises can build their own digital image based on sentiment analysis, identify new market opportunities, do a good job of market segmentation, and then promote the successful listing of products. But grasping the value of these reviews is also a huge challenge for companies. Governments, like enterprises, need to monitor, alleviate, and lead public opinion through sentiment analysis, and eliminate social conflicts. The above is the application background of sentiment analysis. But contrary to such an important background is the weakness of the Arabic sentiment analysis system.

Common sentiment analysis is separated into dictionary-based sentiment analysis and supervised model-based analysis. Dictionary-based sentiment-analysis, as the name suggests, relies heavily on the construction of sentiment dictionaries. Ku et al. [10] and Kaji et al. [11] conducted in-depth research on the construction of sentiment dictionaries. Generally, the emotional words are first divided into positive (meaning) and negative (derogatory), and then the number of positive words and negative words of an Arabic text to be analyzed is counted. If the positive words number is greater than the negative number of words, this text belongs to the positive emotion, otherwise it belongs to the negative emotion.

Some researchers have artificially weighted sentiment dictionaries. However, no matter how it is changed, this analysis method has the following limitations: first, the accuracy is very low, which can hardly support the requirements of public opinion monitoring; second, the positive or negative tendency or weight of emotional words is manually defined, and the workload is huge and very arbitrary; in the end, this approach is almost ineffective for negative sentences and sentences reinforced by adverbs of degree, thus losing the ability to analyze the delicateness (degree) of emotions.

Social media is an online interactive platform based on online social networks and the main form of Internet users' creation and dissemination of information. Twitter and Facebook are typical examples of online social networks. The emergence of social media has epoch-making significance, so that the general public's emotions can be easily and fully expressed, spread, and influence each other. There are a large number of research problems in the field of sentiment analysis. Many of today's naming related tasks with small differences are usually included in the research field of sentiment analysis, such as opinion mining, opinion, sentiment analysis, comment mining and so on. Text sentiment analysis [12-15] aims to analyze the attitudes and sentiment of opinion expressers, that is, to analyze the subjective information in the text.

Although text sentiment analysis studies texts with a polarity have started before the year 2000, few scholars studied the sentiment from texts in the field of linguistics and NLP. This may be partly because there was no growth in digital records at that time. With the explosive growth of the Internet and social media, people can have an uninterrupted data stream and store it in digital form, which is also an important reason why sentiment analysis has maintained a consistent growth rate with the Internet in recent years. For many years, social media systems have provided users with a very convenient channel to communicate and share. The important carrier of information is text information in social media.

People are keen to be in such a free and convenient environment that is not limited by time and space. Make your own voice, express your views on everything, and establish connections between users. This user-generated content provides researchers with great convenience to track, collect, store, retrieve, and analyze people's emotional changes. Appearance has injected new vitality into sentiment analysis, and sentiment analysis has also provided a new research area for social media analysis.

As early as 1997, Tiwari et al. [16] began to try to use the conjunctions in linguistics that are binding on sentiment words to infer the opinions and attitudes of the whole article, that is, to use adjectives with known sentiments to infer The emotional

tendency of an adjective. Turney et al. [17] used the association between words and some seed words with obvious semantic tendencies and combined statistical methods to identify the propensity characteristics of words. The research term of sentiment analysis may be first proposed in the literature of Nasukawa and Yi [14] in 2003, but many related work of sentiment analysis has been started before 2003 [15-17]. Earlier related studies include interpretation of metaphors, extraction of adjectives with emotions, sentiment calculation, subjective analysis, and so on.

The existing applications and research of sentiment analysis are mainly focused on text, which has become a hot spot in the field of NLP research. Since 2002, sentiment analysis research has become very active. In addition to the large number of trending texts in social media, its extensive application scenarios have become increasingly prominent in various human activities. This is also social media sentiment analysis is different from traditional text sentiment analysis. Social sentiment-oriented text sentiment analysis is mainly based on information sharing and interactive review mechanisms. When people need to make a decision at a certain time, most people often refer to the opinions of others. This situation is not only for individuals but also for enterprises and institutions.

Because the large amount of information with user sentiment is publicly available on the Internet, companies no longer use a large number of questionnaires to collect and understand consumer opinions on their products, and the government can easily grasp the public's perspective to supervise their regions. Therefore, social media from about 2006, sentiment analysis has ushered in its prosperity. Its widespread application has given rise to a strong demand for research, and at the same time brought many unprecedented challenges. These challenges are exactly the problems that this article needs to solve.

The related research on text sentiment analysis for social media has been widely concerned by academia and industry. Researchers and institutions have invested a lot of manpower and material resources in order to use text sentiment analysis technology to obtain relevant information. At present, text sentiment analysis has been discussed in many international top conferences.

In the industrial sector, such as major e-commerce shopping websites and portals, they have applied sentiment analysis technology to user review analysis, and found problems in the product and improved them through user reviews, thereby achieving the goal of increasing product sales.

Develop a comprehensive social media analytics tool to help decision makers with external customers to understand sentiment and feedback mapped to the services/products in discussion. The data source is social media feeds such as Twitter or Facebook. The model should be an engine to analyze Saudi dialect and English using advanced NLP algorithms which can be used with any free text platforms to understand main topics and sentiment analysis.

In recent years, Arabic sentiment analysis has become a popular research topic. Using an SVM classifier, Abdul-Mageed et al. [18] investigated the effect of subjectivity and sentiment classification at the sentence level for the Modern Standard Arabic language (MSA). Shoukry and Rafea [19] used 1000 tweets to apply SVM and Nave Bayes (NB) at the sentence level for sentiment classification. For sentiment analysis, Abdulla et al. [20] compared lexicon-based and corpus-based approaches.

The lexicon construction challenges and sentence analysis were addressed by Abdulla et al. [21]. Badaro et al. [22] used an English-based relating to a WordNet and the lexicon approach to create a large Arabic sentiment lexicon. Duwairi et al. [23] used crowdsourcing to collect over 300,000 Arabic tweets and label over 25,000 of them. For Arabic sentiment classification, Al Sallab et al. [24] applied three deep learning methods. Ibrahim et al. [25] used different types of text data, such as tweets and product reviews, to show sentiment classification for Egyptian dialect. The use of pre-trained models with CNN for Arabic word representation improved sentiment analysis performance, according to Dahou et al. [26].

Researchers developed aBidirectional LSTM Network (BiLSTM) with efficient feature extraction capability in [27]. The backward and forward dependencies are used to extract information from feature sequences. For evaluating the models' performance, a number of experiments was conducted on six benchmark datasets of sentiment analysis. The results show that the proposed model outperformed the other models, including the Support Vector Machine (SVM), Random Forest (RF), and LSTM. The authors of [28] investigated various deep learning (DL) models for sentiment analysis of Arabic microblogs based on LSTM and CNN. They used datasets from continuous bag-of-words (CBOW), skip-gram (SG), ASTD, and Ar-Twitter in their experiments. The experimental results revealed that LSTM outperforms CNN. In another work, the authors [29] used NB and SVM with different schemes for weighting such as n-gram sizes and TF-IDF to analyze the Arabic sentiment. They performed the experiments on AJGT dataset and they found the best performance is for the scenario of SVM classifier. The hybrid models-based DL algorithms for sentiment classification were proposed by the authors in [30]. They compared and evaluated the hybrid model to DT, RF, CNN, and RNN-LSTM, using over one million tweets from various domains. The hybrid model performed the best, according to the results.

To predict Arabic sentiment analysis, A. M. Alayba et al. [31] used a variety of machine learning models, including NB, SVM, Ridge Classifier (RDG), LR with Stochastic Gradient Descent (SGD), and the DL models, such as CNN and other methods of feature extraction. The Arabic Health Services Dataset was used to conduct the tests. Mohamed Fawzy et al. [32] stated a diversity of deep learning network models for classifying Arabic sentiment, as well as word embedding techniques. To conduct experiments, we used RNN, CNN, and Bidirectional Multi-Layer-LSTM with various word embedding. Large-scale Arabic book reviews were used in the experiments (LABR). The results revealed that the Bidirectional Multi-Layer LSTM has a high level of precision. In [33], the authors used NB, DT, LR, SVM, and DL models on Arabic tweets dataset for Saudi dialect sentiment analysis. Deep learning and SVM classifiers outperform all others in terms of accuracy. To predict sentiment analysis, some studies

used an ensemble learning (EL) approach. To predict sentiment analysis, Al-Hashedi et al. [34] used NB, RF, voting ensemble method, SGD, and LR. The author gathered COVID-19 Arabic tweets and classified them as negative or positive. The voting classifier performs well, as evidenced by the results. Alharbi et al. [35] proposed a DeepASA architecture model that included hidden layers, as well as input and output layers. Two types of deep neural networks (LSTM and GRU), and a voting classifier were used to improve the prediction performance of the model. Large Scale Arabic Hotel Reviews (HTL), Library Book Reviews Dataset (LABR), Product Reviews (PROD), Restaurant Reviews (RES), ASTD datasets, and ArTwitter were used in the experiments. The DeepASA-based approach performs well, as evidenced by the results. On the ASTD dataset of sentiment analysis for Arabic text, Oussous et al. [36] used a voting method built on top of three classifiers: NB, SVM, and Maximum Entropy. The results show that the vote algorithm is extremely accurate.

For classifying the Arabic text sentiment, Al-Saqqa et al. [37] offered an ensemble approach combines three ML classifiers, SVM, KNN, and NB using a majority voting algorithm. The datasets such as ArTwitter, Movie reviews, and a large-scale Arabic sentiment analysis were used in this study. The results of the experiments revealed that the ensemble of classifiers outperforms individual classifiers. On the Arabic sentiment dataset, Al-Azani et al. [38] studied the performance of various ensemble learning methods to enhance the performance of single classifiers, including boosting, bagging, stacking, voting, and RF. The stacking ensemble performs well, as evidenced by the results. Other researchers used ensemble learning techniques to analyze sentiment in other languages than Arabic language. For example, Sitaula et al. [39] created the NepCOV19Tweets, a Nepali Twitter sentiment dataset that was labeled negative, neutral, and positive. The authors developed some feature extraction methods based on fastText, domain-agnostic, and domain-specific feature selection techniques. Each feature selection method was implemented using different CNN models. Then, for capturing multi-scale information in order to obtain better classification results, they proposed a CNN ensemble model. The authors suggested a multi-channel CNNs (MCNNs) classification system for classifying the tweets in NepCOV19 dataset into negative, neutral, and positive sentiment [40]. A hybrid feature extraction method has been proposed for extracting syntactic and semantic features to train their proposed MCNNs model. When compared to single methods of feature extraction, the hybrid features achieved the highest accuracy result, and the MCNNs model obtained a best performance threshold. Ahmed Mohamed [41] applied Naive Bayes and SVM algorithms for Arabic sentiment analysis and El-Masri et al. [42] presented a novel method for sentiment analysis to Arabic language tweets that uses a mix of parameters related n-grams-based features and preprocessing methods. The tool analyzes the most recent tweets about the issue to determine the polarity (positive, negative, and neutral) and then displays the findings. The results of the study demonstrated that the Naive Bayes method is the most effective in detecting topic polarity. Expert and intermediate users can choose the most effective combinations of parameters for sentiment analysis with the aid of the tool. However, the related studies have a limitation in selecting the best values to hyper parameters of Naive Bayes method.

Among different ML classifiers used in previous studies, MNNB classifier is widely used for documents classification due to its ability for performing statistical analysis of text contents. It significantly simplifies textual-data classification and offers an alternative to heavy ML-based semantic analysis methods. However, the MNNB classifier has a number of hyper-parameters affects the classification task of texts and controls the decision boundary of the model itself. In this paper, an optimized MNNB classifier-based approach is proposed for improving Arabic sentiment analysis.

III. Research Methodology

This section describes the research methodology of proposed approach for social media Arabic tweets analytics. It is based on an optimized MNNB classifier model. The steps of the research methodology are shown in Fig. 1.

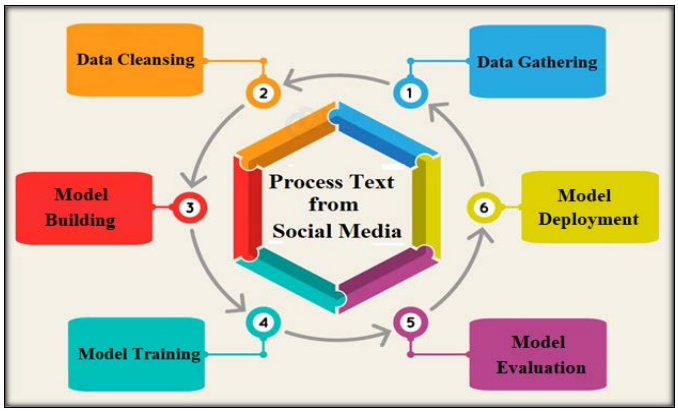

Fig. 1. Research Methodology.

A. Data Gathering

As mentioned in the scope of this research work, the model should be able to analyze Arabic sentiment from users' tweets in the highly used social networks, Twitter. The data gathered are the tweets and their retweets. Then, the data collected from the Twitter source will be stored in a dataset for training after manually labeling or for testing in the evaluation phase. Once gathering a list of Arabic topics or keywords, you can find them on Twitter and then save their related information in the storage device for further processing. The Twitter API makes it simple to search for users and returns results in JSON format. This format is easy to parse in a Python script. Dealing with social media accounts may face one complication, which is the fake accounts with similar or identical names, making them difficult to detect. Fortunately, each user object in Twitter includes a handy data field that indicates whether the account is verified, which I checked before saving the handle. The next step was to use Twitter's API to download the user's tweets and save them into a dataset once a topic or required keyword was linked to a Twitter handle.

B. Data Cleansing

It is a part of NLP since the data received contains incomplete, incorrect, inaccurate or irrelevant parts of the data records that required replacing, modifying, or deleting them.

Therefore, it will be used in the proposed methodology for English and Arabic text. It can perform the following:

- Delete the empty records.
- Delete the retweets.
- Remove the Hashtags, pictures, and links.
- Remove usernames from mentions.
- Remove English and Arabic stop words.
- Normalize the words.
- Stemming the words.

After performing the previous functions, the data will be ready to be used in the model for training and testing purposes.

C. Model Building

After data cleansing, the selection of a model is the next step in the research methodology process. Over the years, researchers and data scientists have developed a variety of models. Some are better suited to image data, while others are better suited to sequences (such as voice or text), numerical data, and text-based data. A multinomial naïve Bayes (MNNB) classifier is a simple and effective ML model to deal with text features. The MNNB classifier is often used as a starting point for sentiment analysis.

The core idea behind the MNNB technique is to use the joint probabilities of words and classes to find the probabilities of classes given to texts.

Given a vector of dependent features $(f_1, \dots, f_n)$ and the class L_k, Bayes' theorem can be expressed mathematically as:

$$P(L_k|f_1, \dots, f_n) = \frac{P(L_k)P(f_1,\dots,f_n|L_k)}{P(f_1,\dots,f_n)} \quad (1)$$

For the given class L_k and consistent with the assumptions of naïve conditional independence, each feature f_i is conditionally independent of every other feature f_j where $i \neq j$.

$$P(f_i|L_k, f_1, \dots, f_n) = P(f_i|L_k) \quad (2)$$

Thus, it can be simplified the relation to be as:

$$P(L_k|f_1, \dots, f_n) = \frac{P(L_k)\prod_{i=1}^{n} P(f_i|L_k)}{P(f_1,\dots,f_n)} \quad (3)$$

Because $P(f_1, \dots, f_n)$ is constant and if the feature values of the known variables, the following rule for classification can be employed:

$$P(L_k|f_1, \dots, f_n) \propto P(L_k)\prod_{i=1}^{n} P(f_i|L_k)$$

$$\Downarrow$$

$$\hat{y} = arg\max_k P(L_k)\prod_{i=1}^{n} P(f_i|L_k) \quad (4)$$

Log probabilities can be used to avoid underflow.

$$\hat{y} = arg\max_k(\ln P(L_k) + \sum_{i=1}^{n} \ln P(f_i|L_k)) \quad (5)$$

According to the distribution of $P(f_i|L_k)$, the assumptions made by the Naive Bayes classifier differs between them, whereas $P(L_k)$ is relatively defined as the frequency of class L_k in the training data set.

The distribution of multinomial naïve Bayes is parametrized by the vector $\theta_k = (\theta_{k1}, \dots, \theta_{kn})$ for each class L_k , where n represents the number of features (vocabulary size) and θ_{ki} denotes the probability $P(f_i|L_k)$ of feature i that appears in a sample that belongs to the class L_k.

The estimation of parameters θ_k can be obtained by a smoothed version of maximum likelihood (i.e., relative frequency counting) as follows:

$$\hat{\theta}_{ki} = \frac{N_{ki}+\alpha}{N_k+\alpha n} \quad (6)$$

Where N_{ki} represents the number of times feature i appears in class a sample k of the training dataset T. The total count of all features for class L_k is N. The smoothing parameter alpha (α) can have a value greater than zero and less than or equal 1 $0 < \alpha \leq 1$ for features, which are not present in the learning samples and to prevent from division by zero probabilities in further computations.

Setting $\alpha = 1$ is termed as Laplace smoothing, while $\alpha < 1$ is termed as Lidstone smoothing. Therefore, the final decision rule is written as:

$$\hat{y} = arg\max_k(\ln P(L_k) + \sum_{i=1}^{n} \ln \frac{N_{ki}+\alpha}{N_k+\alpha n}) \quad (7)$$

Unfortunately, the way to know what α gives the most accurate responses is through iterating over all values of α on the training set and this way is a hard problem. The optimized MNNB classifier used in this research determines the optimal value for hyper-parameters is through a grid search over possible parameter values and using cross-validation evaluation technique for each value. The flowchart of the optimization process for MNNB classifier-based proposed approach is shown in Fig. 2.

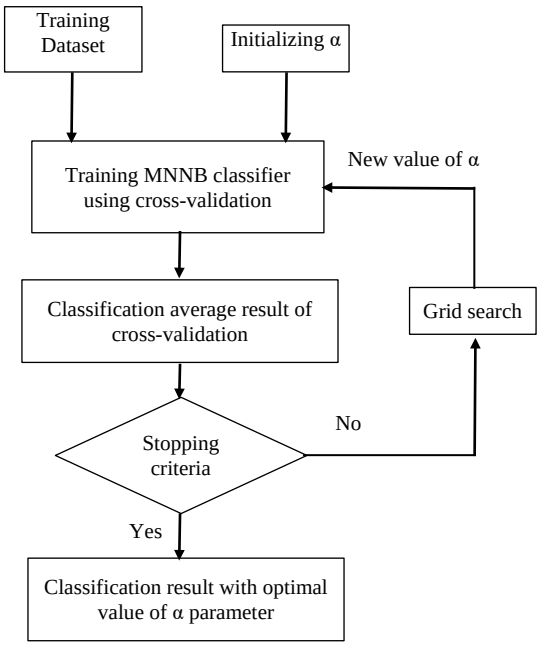

Fig. 2. Flowchart of Optimized MNNB Classifier-based Approach.

D. Model Training

The training phase is where the main process of developing the baseline and proposed models begins. Three different datasets are used for training the models of the research approach. By analyzing the characteristics of Arabic tweets, the models learn to classify their sentiments. For the MNNB classifier, the model is trained through mining the statistics from the training dataset. The utilization of frequency and likelihood tables for each feature facilitates the calculation process.

Possible feature values are grouped together in a frequency table derived from the observations. Instead of counting the number of occurrences, the likelihood table shows the probability values for each class. The multiplication and comparison operations are used to determine the class of an observation using these tables. The training process of MNNB classifier can be summarized in the following steps:

- Convert the Arabic text data into words vectors such as using TFIDF vectorizer or count vectorizer.
- Calculate the counts based on the class.
- Calculate all the likelihood probabilities.
- Calculate the prior probability.
- Calculate the posterior probability.

Feature vectors represent the frequency with which specific events were generated by a multinomial distribution. This is the most commonly used event model for Arabic text classification. This algorithm is used to solve problems with Arabic text classification. This method could be used to determine whether a tweet belongs in the ‘positive’ or ‘negative’ category, for example. It takes advantage of the current words’ frequency as a feature.

E. Model Evaluation

The model must be tested after it has been trained with train data. The goal of testing is to see how the model performs in real-world situations. During this phase, we can assess the model's accuracy. In our case, the model uses the learning from the previous phase to try to identify the type of fruit. The evaluation phase is crucial, as it allows us to see if the model achieves the goal we set for it. If the model does not perform as expected during the testing phase, the previous steps must be repeated until the required accuracy is achieved. As stated, it should not use the same data that was used in the training phase. For evaluation, it should have to use the separate data splitter from the dataset.

The only thing that classification models care about is whether or not the result is correct. When making classification predictions, such as the one we used, there are four possible outcomes. True negatives, true positives, false negatives, and false positives are the four types. On a confusion matrix, these four outcomes are plotted. After making predictions on the test data, you can create the matrix and categorize each prediction as one of the possible outcomes. The percentage of correct predictions made by the test data determines the model's accuracy. The model's accuracy can be determined by dividing the number of correct predictions by the total number of predictions. Classification models are also evaluated using other metrics such as accuracy.

F. Model Deployment

Model deployment is the integrating process of ML model in an existing construction environment to make decisions for data-driven business. It is the last step in the ML process and one of the most time consuming steps. Traditional model-building languages are frequently incompatible with an organization's IT systems, which force programmers and data scientists to spend brainpower and valuable time for rewriting them.

A model must be successfully deployed into production before it can be used for practical decision-making. If you can't rely on your model to provide practical insights, then its impact is severely limited. One of the difficult aspects of achieving value from ML is model deployment. IT teams, software developers, data scientists, and business professionals must work together to ensure that the model works reliably in the organization's production environment. This is a significant challenge due to there is frequently a mismatch between the programming-language used to create an ML model and the languages that the production system understands. Model re-coding can add weeks or months to the project timeline.

The deployment of ML models is the final step in the process. ML models are typically developed and tested using training and testing datasets in a local or offline environment. When a model is deployed, it is placed in a live environment and is exposed to new and unknown data. As the model performs the task, it was trained for working on live data, the model begins to bring to the organization a return on investment.

Containerization is becoming increasingly popular as a tool for deploying ML models. Containers are a common environment to deploy the models because they simplify updating and deploying different parts of the model. Containers are intrinsically scalable, as well as able to provide a consistent environment for the model function. Kubernetes and other open-source platforms are utilized for managing and automating the container management aspects such as scaling and scheduling.

IV. Experimental Results and Discussions

Before presenting the experimental results, this section starts by presenting the number of instances for each class in the training and test datasets. The adopted ML models are trained on three different datasets. Each dataset has a larger number of tweets as shown in Fig. 3 to 5. For the dataset 1, Fig. 3 illustrates that the number of negative instances is 976, and the positive instances is 1046, as well as the number of natural instances is 724. For the dataset 2, Fig. 4 demonstrates that the number of negative instances is 2588, and the positive instances are 1817, and the number of natural instances is 1587. Similarly, the dataset 3 contains 228 negative instances, 263 positive instances, and 192 natural instances as seen in Fig. 5. The test dataset is also used to evaluate the trained models for sentiment classification of Arabic tweets. Fig. 6 displays the number of instances in the test dataset.

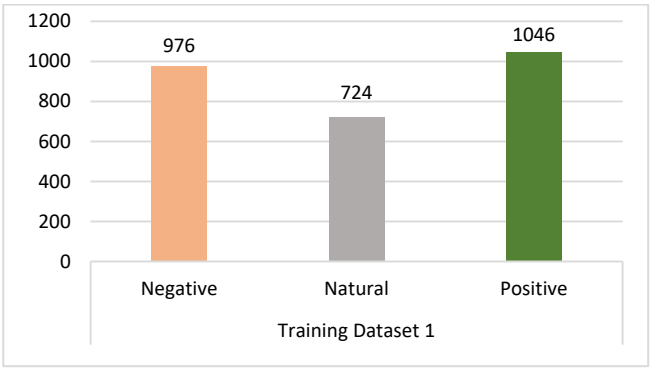

Fig. 3. Number of Instances in Training Dataset 1.

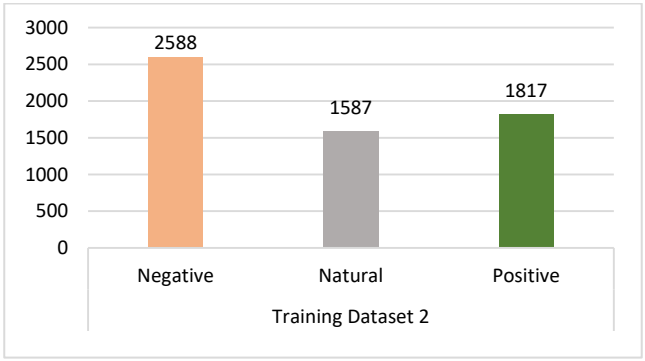

Fig. 4. Number of Instances in Training Dataset 2.

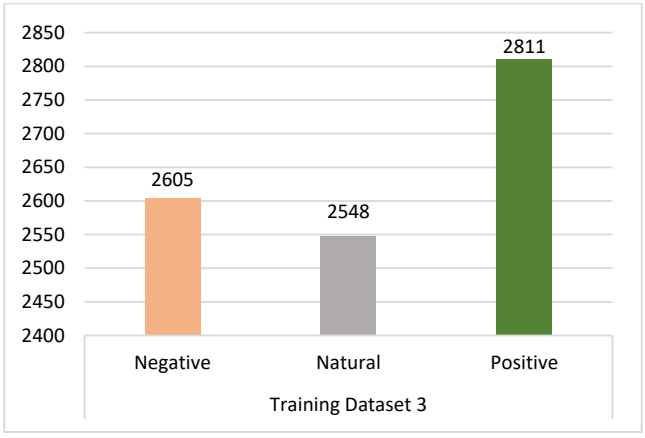

Fig. 5. Number of Instances in Training Dataset 3.

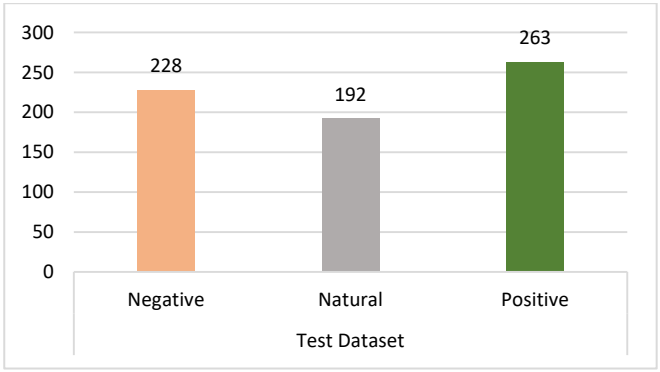

Fig. 6. Number of Instances in Test Dataset.

From Table I to Table VI, the confusion matrices of test set classification for the optimized MNNB trained on the three datasets is given using TFIDF and count vectorizers. Table VII and Table VIII show the evaluation results, which show each classifier's performance on positive, natural and negative instances, as well as their overall performance.

TABLE I. CONFUSION MATRIX OF TEST DATASET FOR THE OPTIMIZED MNNB CLASSIFIER TRAINED ON DATASET 1 AND USING TFIDF VECTORIZER

Optimized MNNB	**0.562**	**0.542**	**0.530**

From the above results, the following observations are made:

- From the three datasets used for training as shown in Fig. 3 to 5, we can see that there is a diversity in the number of instances for each class to see the effect of class size for training the models.
- From Table I to Table VI, the confusion matrices show that the number of instances, which are correctly classified for the optimized MNNB classifier is improved by selecting the optimal values of α hyper-parameter, especially on neutral and negative instances.
- As shown in Table VII and Table VIII, the optimized MNNB classifier obtains high accuracy results by using count vectorizer representation for Arabic tweets as features rather than TFIDF vectorizer.
- SVM with linear kernel works well than other models, especially using TFIDF vectorizer but not better than MNNB and optimized MNNB classifiers.
- For sentiment classification of Arabic tweets, MNNB model is preferable as a generative model. It outperforms the other baseline classifiers.

V. CONCLUSION AND FUTURE WORK

Arabic sentiment analysis using machine learning methods has become an important research task for developing various applications. In this paper, an optimized MNNB classifier-based approach is presented for improving Arabic sentiment analysis. It aims to select the optimal value of the MNNB's alpha hyper-parameter to control the decision boundary of the model itself. The sentiment classification experiments of the research are conducted using a large-scale data sets. The baseline and optimized MNNB classifiers are trained on three datasets and tested on a different separated test set to show the performance of developed approach. The experimental results on the test set revealed that the optimized MNNB classifier of proposed approach outperforms the traditional MNNB classifier and other baseline classifiers. The accuracy rate of the optimization approach is increased by 1.6% compared with using the default values of the classifier's hyper-parameters. The output from the study shows that a MNNB classifier with count vectorizer as features can achieve a high performance compared to the other baseline classifiers. Because there are a large number of Arabic tweets features that are likely to be noisy, a feature selection scheme can be investigated in future work. Previous classification studies have shown that feature selection is critical for classification task success. Another promising extension of this research would be to classify Arabic tweets on different scales instead of just positive, neutral, and negative classes. Moreover, a combination of different classifiers and deep learning methods will be explored.

ACKNOWLEDGMENT

"The author is thankful to the Deanship of Scientific Research, College of Computer and Information Sciences (CCIS) at King Saud University for funding this research."

***Abstract*—The difficulty in lecture videos is an erratic navigation in lecture video for watching only the needed portion of video content. Machine learning technologies like Optical Character Recognition and Automatic Speech Recognition allows to easily fetch the information that is hybrid text from lecture slides and audio respectively. This paper presents three main analysis for hybrid text retrieval, which is further useful for indexing the video. The experimental results indicate that the key frame extraction accuracy is 94 percent. The accuracy of the Slide-To-Text conversion achieved by this study's evaluation of the text extraction capability of Tesseract, Abbyy Finereader, Transym, and the Google Cloud Vision Optical Character Recognition is 92.0%, 90.5%, 80.8%, and 96.7% respectively. Similarly the result of title identification is about 96 percent. To extract the speech text three different APIs are used namely, Microsoft, IBM, and Google Speech-to-Text API. The performance of the transcript generator is measured using Word Error Rate, Word Recognition Rate, and Sentence Error Rate metrics. This paper found that Google Cloud Vision Optical Character Recognition and Google Speech-to-Text API have achieved best results compared to other methods. The results obtained are very good and agreeable, therefore the proposed methods can be used for automating the lecture video indexing.**

Keywords*—Automatic speech recognition; indexing; key-frames; lecture video; optical character recognition; title identification; text extraction

I. INTRODUCTION

The learning style of each individual learner has changed due to the lot of improvement in lecture videos as distance learning gives flexibility to access it independent of learner's time and place. Though the lecture recordings are convenient to learn from any place at any time there is a problem of watching only the needed topic from the long lecture recording. The focus of this paper is to generate the index points for non-linear navigation based on hybrid text. The processing of hybrid text extraction includes three analysis like "Visual screen analysis, Video OCR analysis, and Speech–to–text (STT) analysis."

Text in video pictures can be utilized as an indexing reason. Thus it is generally fair to initially identify elements from pictures. At the point when items have been effectively separated from their experiences, they likewise should be explicitly recognized. In this paper, a technique is presented that at the same time names contour and elements in binary images. There are numerous strategies that utilize certain contour highlights for ranking characters. The presented strategy marks every element utilizing a contour tracing method. A frame differencing method is used to obtain the key-frames [2]. Once the key-frames are retrieved, an OCR technique is used to extract the text from it. Current video OCR (Optical Character Recognition) methods depend on the mix of complex pre-handling methods for text extraction and conventional OCR engines. For video OCR, first video outlines must be recognized that acquire noticeable printed data; at that point, the content must be confined, the meddling background must be taken out, and mathematical changes must be applied before standard OCR engines can handle the content effectively and it is very powerful [3]. The general video OCR system comprises two fundamental advances: text detection and text recognition. Text detection measure decides the area of text inside the video picture. Microsoft Cognitive Services and Google Vision API [5] are some minimal expense answers that are presently available. The present status of technology says that recognition of object can be done using Convolutional Networks or Selective Search [7] Likewise, recognition of face is done using Fisherfaces or EigenFaces [8]. Google takes these methods and implement its AI cycles to further develop them. Google's Cloud Vision (GCV) is based on incredible PC vision models that power various Google administrations. Thus, a GCV OCR is applied to obtain sequence of strings from the key-frames.

Automatic Speech Recognition (ASR) [24] is being used in day-to-day applications. "The goal of speech recognition is to enable the humans and computers to have natural communication via speech". The accuracy of the model performance can be known with the results of transcription and segmentation obtained by the manual and automatic methods. The limitations of manual transcription such as costly, delayed performance, and error-prone when thousands of speech files are involved, lead to adaptation of automatic transcription; thus the study suggests to go for automated approach. The systems like automatic speech recognition (ASR) and text-to-speech (TTS) are performing in excess of 90% of accuracies. With AI ASR systems can result high-quality transcripts and with the usage of multi-modal data accuracy can be improved. Other than speech clarity there are many causes for the result of ASR system error rate [9] [10]. Now Google provides improved speech recognition with the usage of new technologies like "Voice Search on mobile, Voice Input, Goog411, Voice Actions, Voice Search on desktop, etc." The following are the objectives of this study:

- Retrieval of key-frames by analysing the visual screen.

- Video OCR analysis to identify title lines and extract text from lecture slides which is further helpful for creating index points.
- To extract the audio portion from the lecture videos to convert the instructor's spoken remarks into text for the purpose of creating index points.
- OCR and ASR performance is compared in order to determine which method is more effective.

II. Related Work

Effective searching and navigation of lecture video topics was especially intended for Slide Based Lecture Videos (SBLV) [11] that addresses a critical part of online talk recordings. A design for a successful Video Summarization [12] similarly as video motion rundown was proposed. A procedure for key edge removal was intended [13, 14] ward on the square based Histogram qualification and edge matching rate. Static video synopsis is perceived as a compelling style for users to rapidly peruse and understand enormous quantities of recordings [15]. Hence static video outline is considered as a clustering issue. Video skimming [16] normally viewed as a significant system for video summary. Generally, video text is installed in an exceptionally heterogeneous foundation with an incredible assortment of differences, which makes it hard to be perceived by standard OCR programming. GCV (Google cloud Vision) OCR is one of the popular API used in this case. GCV API enables the improvements of appliances that require AI help, notably for pictures comprehension [17, 18, 19]. A few examinations have successfully been made utilizing Cloud Vision API. Paper [20] efficiently executed GCV API for content-Based Image Retrieval. Mulfari carried out OCR capacity of GCV API to invent helpful innovation for humans with lack of ability, particularly for people who are evidently disabled or visually impaired. They removed text from pictures at that point express it through installed text-to-speech programming. From the study of previous works on GCV API we found that GCV API has been shown to offer one of trustworthy OCR appliance. Hence, its skill will also be examined in separating text from the talk video pictures.

For large vocabulary speech recognition, a DBN (Deep Boltzmann Machine) with a pre-trained ANN/HMM (Artificial Neural Network/Hidden Markov model) can be used. For recognizing disordered speech of the user a VIVOCA (Voice-Input Voice-Output Communication Aid) was evaluated [21], using this users can produce understandable speech from disordered speech. An Android-based application was developed for English learning using the Google Speech API, which has motivated authors to work on a speech recognition application in order to get text from the audio. The developers of the speech recognition system are expected to select Open API for the development of application speech recognition system [22]. As the study recommended to use automatic speech recognition, there is a demand for the efficiency and accuracy. Among most eminent Automatic Speech Recognition (ASR) systems, three are benchmarked on the bases of their performance namely the Google, wit, and IBM Watson [23], among these three the results of Google's ASR is better [4] [23]. The comparative study between Google Speech with Pocketsphinx shows that the background noise filtering result of Google Speech is more impressive than Pocketsphinx. According to research [1],[6], we note that the Google's Speech-to-Text outperformed other services and it has the less error rate in any case.

III. Hybrid Text Extraction from Lecture Video Images

The framework for hybrid text extraction has been shown in the Fig. 1, which includes "Visual screen analysis, Video OCR analysis, and Speech–to–text (STT) analysis." The two main parts in Lecture Video (LV) are slides (visual content) and audio (explanation of slides given by the instructor).

With the visual screen analysis we have segmented input lecture video to extract the slides from video and applied frame-differencing method to obtained key-frames. With the Video OCR analysis we have performed text detection and recognition using OCR to extract the texts from the slides. Then identified the title line from the text bounded images using geometrical information. With Speech–to–text (STT) analysis, extracting text from the audio track of the LV using ASR technology. Text from speech is one of the principle wellsprings of data in a talk video. The teacher gives detailed data about the point in the video address. The speech text is generous and unconstrained. The speech is one of the significant variables in content-based recovery of a point in a long video address.

A. Visual Screen Analysis

The main aim of this analysis is to extract key-frames from the LV. Extraction of key-frames for different sorts of video should be possible by consolidating distinctive sort of video content. Keypoint-based framework was intended to address the keyframe assurance issue with the objective that close by features can be used in picking keyframes. Usually, picked keyframes ought to be both descriptive of video content and containing least abundance. At first the long lecture video is divided into number of segments. Normally, a video holds 24 frames in a second, among them, most of the frames are repetitive. Thus, it is necessary to extract only useful frames. Generally, a video of M minutes is divided into:

$$F = M * 60 * 30 \text{frames} \quad (1)$$

where F is variety of frames created from the video at the start.

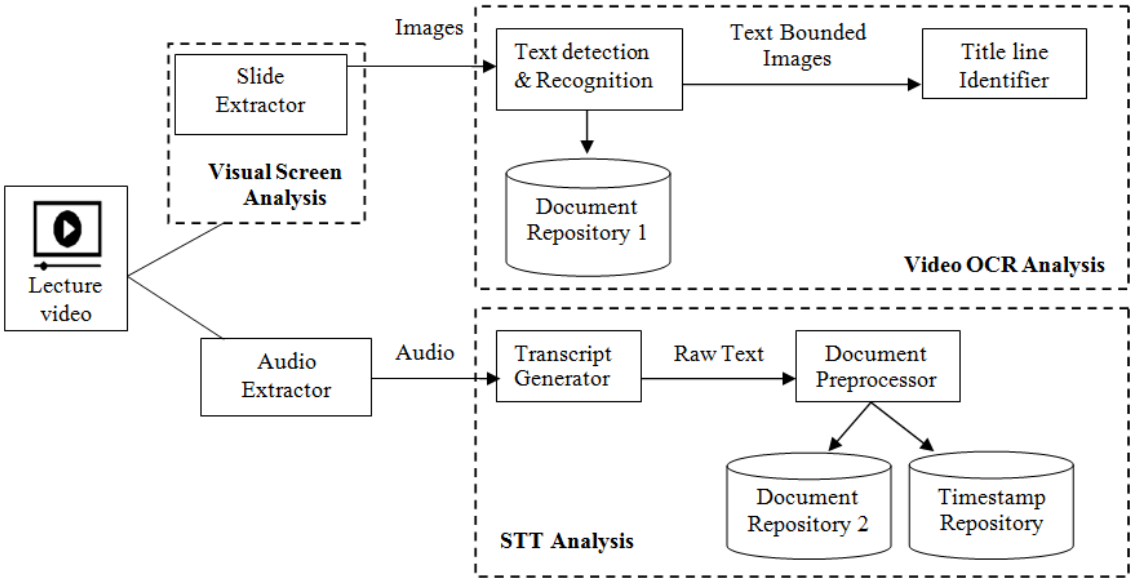

Fig. 1. Framework for Hybrid Text Extraction from Lecture Video.

In a lecture video, a topic will be deliberated for at least 10 seconds. Thus, to reduce the repetitive frames, 10 seconds delay is made in frame creation. The difference between adjacent frames is obtained to get the key-frames. The flow diagram of this procedure is shown in the Fig. 2.

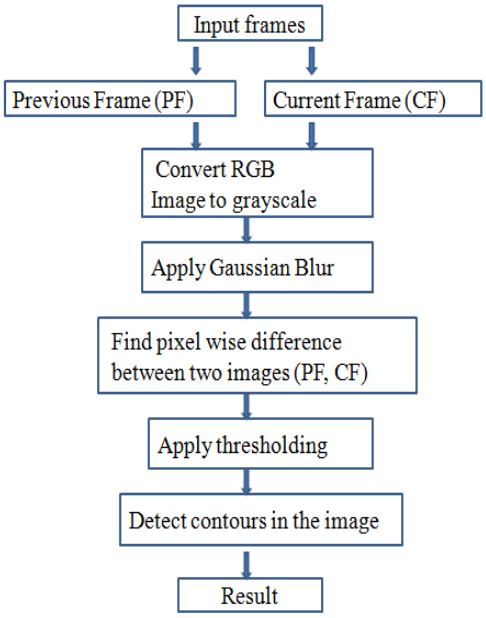

Fig. 2. Flow of Key-Frame Selection.

The method we developed for obtaining key-frames works in three stages. Initial stage is to get the difference between adjacent frames using frame-differencing method.

To compute this, frames are removed at 1 Hz from the informant video. Then compute the pixels whose difference beats the threshold value of 24. The bounding box is found for all such pixels whose change is higher than 1% of the total and analyse its size and overlay at the center of frame. A new segment is detected when the bounding box is moreover overlapping the center or is at least a third of the frame. After a time when the inter-frame difference gets steady for somewhat three seconds, a fresh key-frame is obtained as the final frame in the segment. Next, we test frames to build training sets for representing the talker/background, and slide images. Histograms are removed from the tested frames and train a SVM to discriminate slide and non-slide frames. Sample result of key-frames obtained from lecture video has been shown in the Fig. 3.

B. *Video OCR Analysis*

This section discusses two tasks.

1) Text detection and recognition: Text extraction process includes two subprocesses namely text detection and recognition which can be performed automatically by applying GCV OCR. GCV OCR is a part of GCV API. The GCV API permits developers to know the subject of a picture by enclosing wonderful AI designs in a user-friendly REST API. The Cloud Vision API rapidly groups pictures into many classes and peruses printed words contained inside pictures; it also recognizes singular items inside pictures. The Google permits the API to handle singular bits of a picture independently and return the outcome rapidly in brought together organizations.

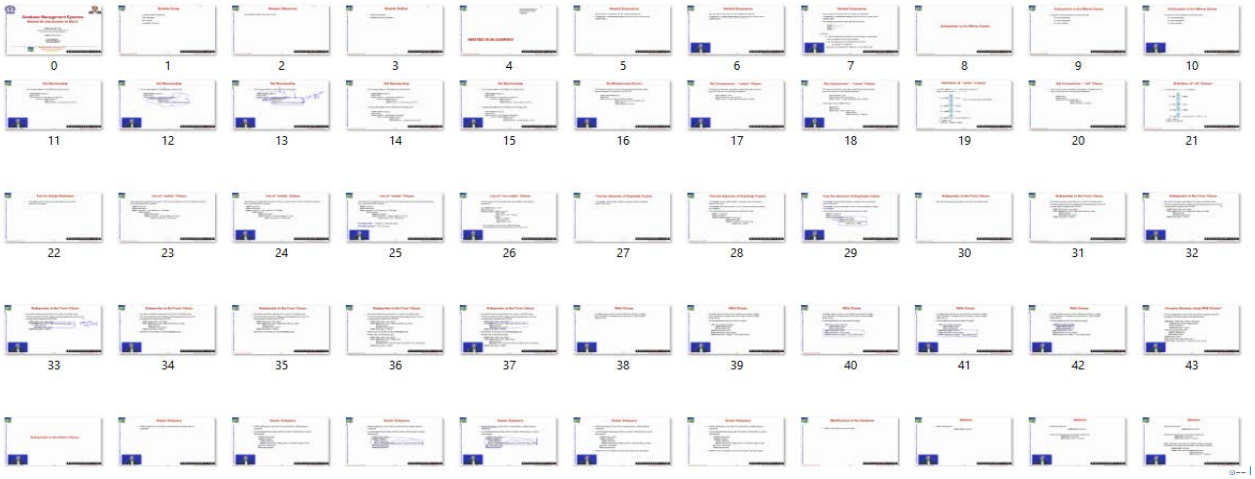

Fig. 3. Sample Result of Key-Frames.

One more asset of the GCV API is when doing a request for processing a picture; Google provides the power to imply the types of evaluation that must be on this picture. For instance, object detection, facial location, milestone recognition, and a lot more examination perform on the picture. The workflow of the Fig. 4 has been implemented using a python script.

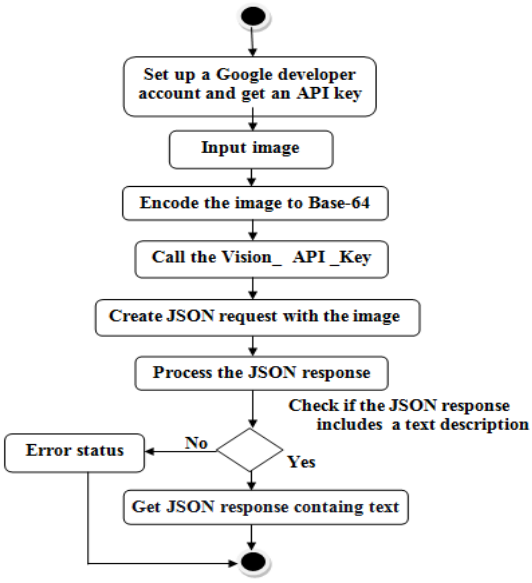

Fig. 4. Workflow of Image Text Extraction Process.

Google OCR has different advantages, here we depict the hugest advantages:

- Robust - The two capacities, serving two kinds of text records subject to the clients' choice, make the Google Vision OCR similarly more robust than single-model OCR tools.
- Language support - Google has exhorted that its OCR is appropriate to in excess of 60 languages.
- Ease of utilization - The actual model is important for the in-constructed Google
- Vision library. The function-calling technique can be utilized in various languages in an extremely clear way.
- Scalability - Google's evaluating technique promotes clients to increase the use of the API, as more use prompts a less expensive normal cost.
- Speed - Google Cloud's warehouse stage superbly goes with the API utilization. By transferring the pictures into the drive, the response or reaction time of API can be extremely quick and versatile.

a) API call: Indicate the URL to the API and include the JSON data to POST to it. We first need to set up a Google developer account and obtain an API key [7] to perform OCR using Google Cloud Vision API.

b) Request: Send a JSON request containing a base64 encoded image file. The vision API performs feature detection on an image file.

c) Response: We get a response in JSON format which includes text and bounding box containing location coordinates. Sample results of text extraction using Google Cloud Vision API is shown in Fig. 5.

2) Title Identification: For the most part, in the talk slides, the substance of title, caption, and main points has more importance than the typical slide text, as they sum up each slide. The design of text lines can mirror their diverse importance. This data is important for a talk video indexing. To recognize the potential title text lines, we apply the accompanying conditions.

a) The height of the title text line is more prominent than or equivalent to the normal height of text lines.

b) Title text line has, at any rate, three characters.

c) Horizontal start position of the text line ought to be, not exactly 50% of the frame width.

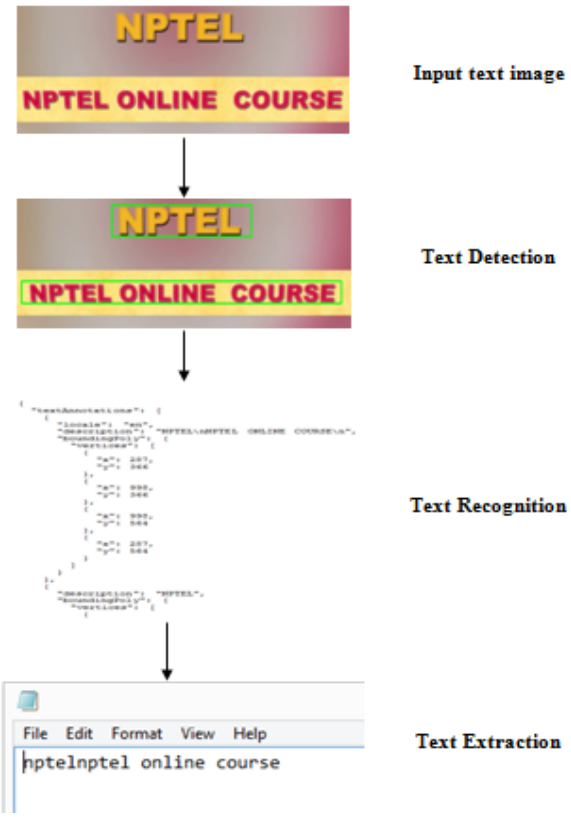

Fig. 5. Sample Result of Text Extraction from an Image.

C. Speech-to-Text (STT) Analysis

Text from speech is one of the principle wellsprings of data in a talk video. The teacher gives detailed data about the point in the video address. The speech text is generous and unconstrained. The speech is one of the significant variables in content-based recovery of a point in a long video address. Utilizing Google Speech-to-Text Programming interface as a speech recognition instrument in our trial, the speech records of talk recordings are used for indexing purposes. The speech text may differ marginally; the educator might talk some irregular substance. In any case, accepted that speech includes significant theme data and can be utilized to accomplish topic division and index point creation. Speech-to-text APIs provide lot of pros like boosting productivity and efficiency, saves time, Reliability, helps physically disabled people, etc. This API is used in several applications like Chatbots, Automated dictation, Smart assistant, Voice commanding, Transcriptions for call centers, mixed language detection, etc. Among the popular APIs like Microsoft Google Speech-To-Text, Cognitive Services, Dialogflow, IBM Watson, etc., for speech-to-text processing the Google Speech-To-Text API gives more accurate results.

3) Google Cloud Speech-to-Text API: The Google Cloud Speech API is integrated with Google Translate API and Cloud Vision API. Machine Learning is essential for the Google Cloud Stage in the development of applications that can listen, view, and comprehend its general surroundings. With this complete Google Cloud Speech API developers can easily translate an audio into text by using neural network models. This API supports 110 plus languages and variations, to help a worldwide user base. The Google Speech Programming interface, otherwise called Speech-to-Text (STT), is a modern instrument that uses Google's AI innovation to change voice over to message. Google Speech Programming interface is one of the most amazing speech recognition service [1]. This API is an automated speech recognition (ASR) API adapted with deep neural networks. It can likewise deal with noisy sound in a variety of conditions. This API result include not only text but also the timestamp corresponding to each word. The flowchart of Talk-To-Text (TTT) processing is shown in the Fig. 6.

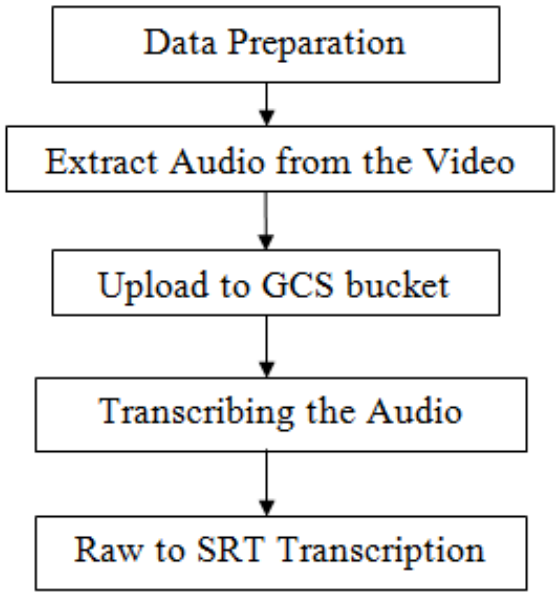

Fig. 6. Flowchart of TTT Processing.

a) Data preparation: Download lecture videos from different online courses like YouTube, NPTEL.

b) Extract audio from the video: Build the instance using Google speech-to-text API for Talk-To-Text (TTT) processing. Before doing anything, we have to install Ffmpeg to extract the audio from the lecture video. Here we are converting mp4 video file to ogg audio file. We have specified codec Opus in VoIP because of its audio compression with more quality and less delay rates. The sampling rate is set to 16000 hertz.

c) Upload to GCS bucket: We know that usually lecture video duration is longer than 60 seconds. Thus, we are requesting asynchronous speech recognition and we must store the audio file longer than 60 seconds in Google Cloud Storage bucket.

d) Transcribing the audio: The processing of audio file to obtain the transcription has been shown in the Fig. 7.

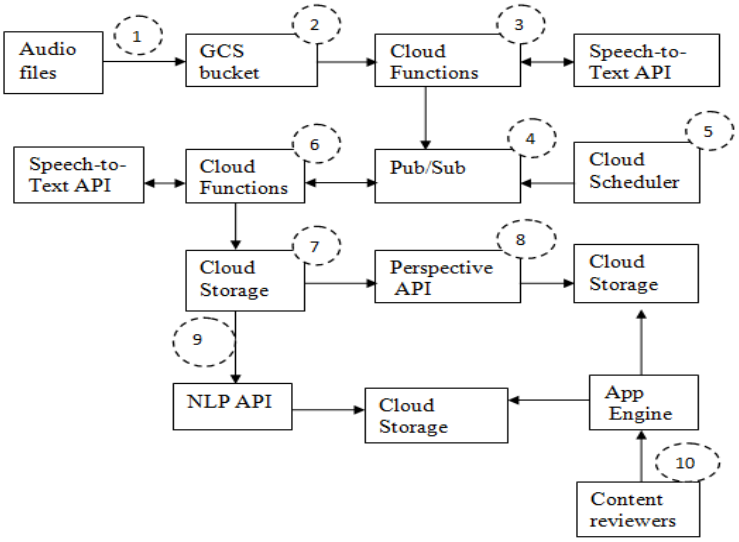

Fig. 7. Transcript Generation Process.

- Store audio file. The audio file is then stored in a Cloud Storage bucket. Before the audio file go through the remaining steps this step functions as a production bucket to maintain the files.
- Activate Cloud Function. When audio file meets the production bucket, a notification is generated. This notification triggers a Cloud Function to invoke a Speech-to-Text API.
- Invoke the Speech-to-Text API. Speech-to-Text API is invoked by Cloud Function to get a transcription of the audio file. This process is nonparallel, so a job ID is sent to the Cloud Function by Speech-to-Text API.
- Report Speech-to-Text job IDs. The audio filename and job IDs are then reported to the Pub/Sub point.
- Speech-to-Text voting. For every 10 minutes the Cloud programmer reports an announcement to a Pub/Sub point, which activates a next Cloud Function.
- Get Speech-to-Text API results. This Cloud Function extracts all announcements from the initial Pub/Sub point and pulls the filename and job IDs for every news. Each individual job status is checked by calling the Speech-to-Text API.
- In case when a job is over, the resulted transcription are registered to a next Cloud Storage bucket. Then Cloud Function moves the audio file to Cloud Storage bucket from the production Cloud Storage bucket. In case when a job is not over, a Pub/Sub announcement is added again to the Pub/Sub point. If there is no result from Speech-to-Text, the audio file is passed to a Cloud Storage error bucket. The obtained result (transcript of the audio file) is reported to a Cloud Storage bucket.
- Call Perspective API. The chance of "corruption" in the transcription is checked by calling Perspective API. Obtained results on this analysis is reported to another Cloud Storage bucket.
- Call the Cloud Natural Language API. The overall notion of the transcription is checked by calling the Natural Language API (called by fourth Cloud Function). The Cloud Function then reports the obtained results to another Cloud Storage bucket.
- Content reviewers. In the above diagram the App Engine enables user to check the outputs.

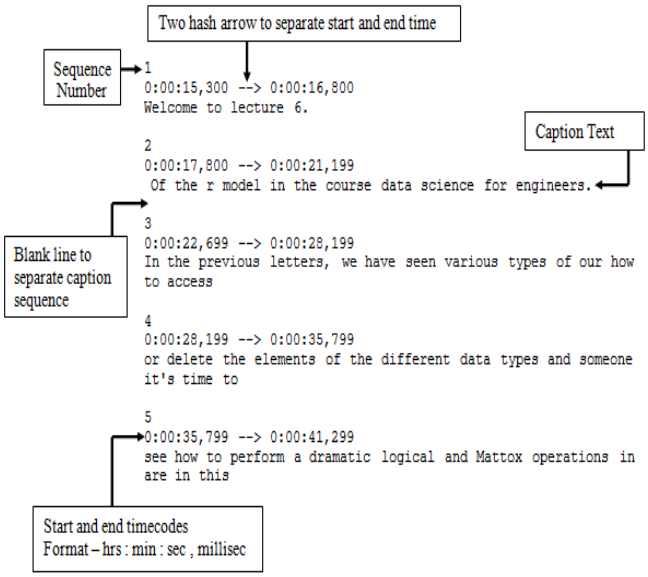

Fig. 8. SRT Formatted Text.

e) Raw to SRT Transcription: Raw text is the text obtained or collected from transcript generator before any manipulation. Thus, this text data is being send to the document pre-processor for analysing the raw text and produce resultant speech text with corresponding timestamps.

The raw text file is been formatted to SRT ("SubRip Subtitle") formatted text file because each sequence of text in .srt file has five important parts shown in the Fig. 8.

IV. Result and Discussion

The implementation is done in an Intel Core 8 CPU @ 5.0 GHz, with ubuntu operating system.

A. Keyframe Extraction

To evaluate the performance of video keyframe extraction, we randomly chose seven lectures videos like data science (DS), cryptography(crypt), cloud computing (CC), computer networks (CN), DBMS, algorithms (Alg), and machine learning (ML) from different online courses with varying layouts, font size, and styles.

TABLE I. Key-Frames

Lecture Video	Duration in minutes	Keyframes	Total slides
DS	22	38	49
ML	60	39	43
CN	23	38	42
crypt	100	75	77
DBMS	33	72	75
CC	45	51	57
Alg	109	125	147

The number of desired slides in the lecture videos are manually annotated for ground truth. Then, we applied the slide extraction algorithm to these videos. We compare the results of extracted slides with ground truth using recall and precision. The precision and recall esteem recognize bogus alert rate and missed location outline rate individually. The estimation of precision diminishes if there is over-segmentation, i.e., superfluous frames are separated. The assessment of Recall lowers if there is under- segmentation, i.e., an ideal frame stays undetected. The Table I shows the result of obtained keyframes.

The F1 score is measured as:

$$\text{F1 score} = \frac{(2 * \text{Precision} * \text{Recall})}{(\text{precision}+\text{Recall})} \quad (2)$$

Where,

$$\text{Precision} = \frac{\#\text{slides detected correctly}}{\#\text{slides detected}} \quad (3)$$

$$\text{Recall} = \frac{\#\text{slides detected correctly}}{\#\text{ground truth slides}} \quad (4)$$

Results of Precision, Recall, and F1 score obtained fromthe above formulas is 0.9, 0.98, and 0.94 respectively.

B. Slide-to-Text Conversion

With an average accuracy of 96.7 percent (Fig. 9), the text extraction results from each lecture video using the obtained key-frames showed that GCV outperformed other OCR APIs in this task. The findings are displayed in Table II. Transym's is 80.8 percent, Tesseract's is 92 percent, and Abbyy Finereader's is 90.5 percent. When the file size and resolution are taken into account, the accuracy of the GCV OCR is significantly higher than that of other methods. Additionally, low-resolution or small-size photos have the lowest accuracy. Performance is assessed using the three factors stated below.

$$Recall = \frac{Total\ Extracted\ text}{Total\ key-frames} \quad (5)$$

$$Precision = \frac{Correctly\ extracted\ text}{Total\ Extracted\ text} \quad (6)$$

$$F1 - score = equation\ (2)$$

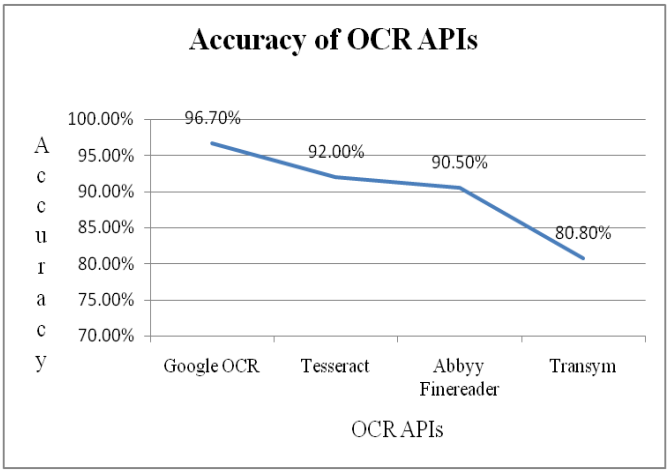

Fig. 9. Performance Comparison of Different OCR APIs.

C. Title Identification

Segmentation is done on lecture videos and taken 98 lecture slides to evaluate title identification. Then, the geometrical information of the text lines are used to identify the title line. The accuracy (Acc) of the title identification method is measured using the formula given below:

$$\text{Acc \%} = 1 - \left(\frac{\#\text{errors}}{\#\text{slides with title}}\right) * 100 \quad (7)$$

As a result, we obtained that the title line in 94 slides was identified correctly among 98 slides. The accuracy gained is 96%.

D. Transcript Generation

Three different speech to text APIs are used to perform this. The performance of each method is evaluated using the below three metrics

1) Word Error Rate (WER): It is used to test the occurrence of word errors in the obtained transcript. Levenshtein Distance is applied to find the difference between two word placements. As the word placement can have varying length, there can be substitutions (S), deletions (D), and insertions (I) to alter one word into the other. The WER can be calculated using the below equation (8).

$$\text{WER} = ((S+D+I)/N)*100 \quad (8)$$

TABLE II. RESULTS OF DIFFERENT OCR APIS

Method	Pr (%)	Re (%)	F1-Score (%)
Google OCR	97.2	94.7	**97.4**
Tesseract	88.2	89.4	88.7
Abbyy Finereader	87.8	86.8	87.2
Transym	65.6	84.2	73.7
Google OCR	94.7	97.4	**96.0**
Tesseract	86.1	92.3	89.0
Abbyy Finereader	91.4	89.7	90.5
Transym	72.7	84.6	78.1
Google OCR	97.2	97.3	**97.2**
Tesseract	88.8	94.7	91.6
Abbyy Finereader	88.2	89.4	88.7
Transym	62.5	84.2	71.7
Google OCR	97.2	97.3	**97.2**
Tesseract	91.5	94.6	93.0
Abbyy Finereader	91.3	92.0	91.6
Transym	83.3	88.0	85.5
Google OCR	98.5	98.6	**98.5**
Tesseract	92.6	94.4	93.4
Abbyy Finereader	95.5	93.0	94.2
Transym	86.1	90.2	88.1
Google OCR	98.3	96.0	**97.1**
Tesseract	93.4	90.1	91.7
Abbyy Finereader	88.6	86.2	87.3
Transym	75.6	80.3	77.8
Google OCR	89.4	98.4	**93.6**
Tesseract	96.6	96.8	96.6
Abbyy Finereader	94.1	95.2	94.6
Transym	88.8	93.6	91.1

2) Word Recognition Rate (WRR): Below equation (9) is used to calculate the WRR.

$$WRR = ((N-D-S) / N)*100 \quad (9)$$

3) Sentence Error Rate (SER): It is used to find the occurrence of errors in the sentences of the transcript. If there is a word by word match between manual transcription and recognition output, then it is taken into account as exact match. The SER accuracy is calculated using the below formula.

$$SER = \frac{\text{No.of inaccurate sentences}}{\text{Total No.of sentences}} * 100 \quad (10)$$

The results of WER, WRR, and SER obtained by three Speech-to-Text APIs is shown in Table III and it clearly shows that results of Google Speech-to-Text API is much more better than other two methods. IS stands for incorrect sentences. The comparison of three APIs (IBM, Microsoft, Google) in terms of WER, WRR, and SER is shown in Fig. 10.

TABLE III. RESULTS OF DIFFERENT SPEECH-TO-TEXT APIS

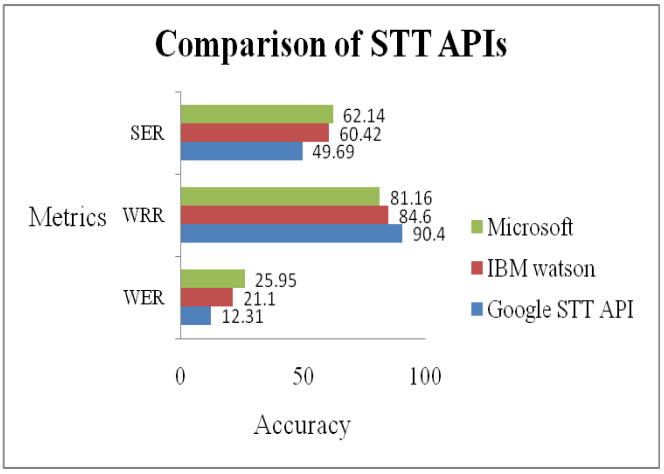

Fig. 10. Comparative Results of Three Different APIs.

V. CONCLUSION

This paper presents a whole work stream for keyframe extraction, hybrid text extraction and title identification proof. Frame differencing method is applied to accomplish superior key-frame extraction and achieved 94% of F1 score. To extract the text from key-frames four OCR methods have been proposed and found that Google cloud vision OCR is best achieving upto 97% accuracy. Google permits the API to handle singular bits of a picture independently and return the

outcome rapidly in brought together configuration. The title lines are identified using the geometrical information of the text lines and gained 96% accuracy. To extract the speech text three different APIs are used namely, Microsoft, IBM, and Google. The WER, WRR and SER are computed to measure the accuracy of these model and the achieved result of these parameters is shown in this paper. This paper founds that Google speech to text API has achieved best result in terms of WER, SER, and WRR compare to other two APIS. The outcomes acquired are really exact and very helpful.

The future work includes the implementation of an indexing algorithm for lecture videos based on obtained hybrid text.

ACKNOWLEDGMENT

We are very thankful to our parents, family, and friends for supporting to complete this work.

***Abstract*—Data security is becoming an important issue because of the vast use of the Internet and data transfer from one place to another. Security of these data is essential, especially when these data represent critical information. There are several techniques used to hide these data, such as encryption. Steganography can be utilised as an alternative to encryption because encryption is susceptible to data modification during transmission. Steganography is the hiding data on a cover multimedia such as images, audio, and video. The technique allows security for data transmission so unwanted third parties cannot notice the hidden data. The challenge of steganography is the trade-off between the hidden data's payload capacity and the system's imperceptibility and robustness. If the hidden data increases, the imperceptibility and the robustness will be decreased. This case is a big challenge in this digital world where social media, Internet, and data transfer are used hugely. Because of this, this paper proposes using a modified Least Significant Bit (LSB) method for the embedding process called Multi-Layer Least Significant Bit Exchange Method (MLLSBEM). This proposed algorithm uses the AES encryption method to encrypt the secret text and then uses Huffman coding to compress the encrypted message as pre-processing data. The proposed study seeks to strike a compromise between important issues, provide maximum payload capacity, and retain high security, imperceptibility, and reliability for secret communication Using image processing and steganography techniques. Simulation findings demonstrate that the suggested method is superior for existing PSNR, SSIM, NCC, and payload capacity investigations. The proposed method is immune to the histogram, chi-square, and HVS attacks.**

Keywords*—Information hiding; steganography; cryptography; multi-layer security; high capacity component

I. Introduction

Increasing the use of data transfer from one place to another, especially with the improvement of the Internet and online transferring tools, the concern of data privacy and security becomes an important issue [1]. Third-party attacking of data is a risk. This circumstance means that attackers can reach the sender's data in many ways leading to the possibility of malicious threats, eavesdropping, and other malicious activities [2]. Three common techniques are used in this field to ensure data security and privacy: steganography, cryptography, and the watermarking technique. These three techniques are used to ensure security in different ways [3]. In steganography, the required data, which can be called the secret data that is to be sent, is hidden within media data such as images, video, audio, and protocol. On the other hand, in cryptography, the required data to be sent is coded with a predefined code known by both the transmitter and the receiver while in watermarking, the secret data does not change, but it is carried on multimedia data, such as images, to be sent to the required receiver to ensure confidentiality [4]. Image steganography is a widely used technique because the secret data does not change as in cryptography and does not appear as in watermarking. Image steganography can hide the secret data in its original format within the image by using a stego-key at the transmitter. The same stego-key is used at the receiver to recover the hidden data from the stego-image, as shown in Fig. 1.

Image steganography system has become the most popular research area than the other types of systems because of the availability, ease to use by users, and the ability to hold a large amount of data, in addition to the difficulty of noticing the hidden data by the unwanted third party [5].

However, using image steganography nowadays, where a high volume of data exchange is required, becomes a challenge, in particular to the issue of the payload capacity. Besides this, the trade-off challenge between payload capacity, security, and visual image quality is also a critical issue. These criteria imply that when the hidden data increases, the security of the steganography technique will decline and vice versa. Accordingly, as the amount of hidden data increases, the imperceptibility will decrease as well [6].

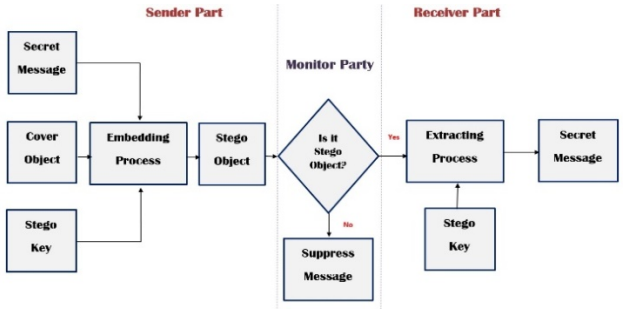

Fig. 1. The General Principle of the Image Steganography System.

Several methods and techniques have been used in the literature to overcome these challenges. The most straightforward and efficient method uses the Least Significant Bit (LSB) as an embedding technique, as in Gupta et al. [7] and Hameed et al. [8]. They propose LSB with some encryption techniques to ensure the system's security. Maurya & Gupta [9] suggested a method based on the adaptive LSB substitution steganography technique. In this method, the aim is to divide the image into two segments - non-sensitive and sensitive parts based on texture analysis. The majority of the bits in the non-sensitive area are used to hold secret messages and other bits in the sensitive area. The main advantages of this method are achieving both high payload capacity and imperceptibility.

The challenge of using LSB is the payload capacity of the system. Nowadays, most researchers, according to the best of our knowledge, use Artificial Intelligence (AI) and Deep Learning (DL) algorithms to overcome the capacity challenge. The study by [10] proposed the General Adversarial Networks (GAN) as a form of DL algorithm. GAN employs game theory to train the generative model using an adversarial method based on two networks for generator and discriminator. The data is fed into the generator model, and the result is approximately equal to the input image. The discriminator networks determine the class of the created images. Using GAN in steganography allows for increasing the payload capacity of the system, but this approach increases the complexity of the developed steganography technique. This complexity arose from the training data requirement before applying steganography to train the model. To overcome this, Volkhonskiy et al. [11, 12] proposed a Steganographic GAN (SGAN) based on DCGAN to simplify the training process as in Shi et al. [13] and [14]. They propose four fractionally convolutional layers followed by a functional layer with Hyperbolic tangent activation with base WGAN. The proposed model is based on multi-layer steganography but also depends on eavesdropping on the generator. Simulation results show that using four layers increases the receiver's prediction complexity, so Yang et al. [15] and [16] use the SGAN with three layers process. They use pixel-wise segmentation. This use reduces the complexity of the process but increases the discriminator and generator losses.

The work in [17] uses fuzzy logic to make decisions based on local statistical, texture, and brightness information-based feature vectors. The fuzzy logic can be used instead of AI algorithms to reduce the decision complexity. Simulation results show that at higher embedding rates, the approach helps to eliminate stego-image distortions. The study by [18] explained another fuzzy-based technique in which, before the real embedding process, the cover pixel selection is based on fuzzy pixel classification, and the secret message is translated to a mode of fuzzy data.

Fuzzy logic can improve stenographic techniques in various ways, especially when there is vagueness in the image textures. It benefits the system by recognising appropriate visual patterns quickly and avoiding irreversible complexities. However, adding a fuzzy process to select the embedding process affects the system's capacity.

This paper proposed a Multi-Layer Least Significant Bit Exchange Method (MLLSBEM) algorithm as an effective hiding method to embed a high volume of security data into an image without affecting the security and imperceptibility of the system. Thus, several contributions of this paper can be summarised as the following:

- This paper proposes a hiding method based on multi-layer operations, which is Advanced Encryption System (AES) technique to enhance security. Furthermore, the paper uses Huffman coding to increase the payload capacity of the hidden data.
- The propose method is based on Linear Significant Bit Exchanging Method (LSBEM) that is a simple, secure, and efficient method used with image steganography based on the resulting image quality.
- The evaluation of the proposed multi-layer algorithm is performed on grey-scale and colour images to generalise its use and efficiency.

The remaining of this paper is structured as follows: the proposed algorithm description is discussed in Section II. The overall methodology and simulation parameters are mentioned in Section III. Simulation results and discussion based on performance metrics are presented in Section IV. Finally, the conclusion and some future work discussions are mentioned in Section V.

II. The Proposed Algorithm

This newly proposed technique aims to have a stego-image like the original image with high capacity hidden data. The aim is to satisfy the imperceptibility of maintaining a high PSNR value. The proposed MLLSBEM algorithm depends on two methods: designing a new LSBEM and using Implicit Key Generation (IKG). The proposed LSBEM technique's principle is to expand the LSB substitution method to exchange the secret message bits with the cover image's pixels using the shared IKG between the sender and receiver.

Algorithm 1: The proposed hiding algorithm

If STB1 = CIPLpixel,

The BL of the pixel is set to ‘1'; otherwise, it is set to ‘0'.

If STB2 = CIPRpixel,

The BR of the pixel is set to ‘1'; otherwise, it replaces it with a ‘0'.

If either BL or BR = 0,

The next cover pixel's 2-LSBs are substituted with the previously unmatched secret bit pair (i.e., STB1 or STB2).

If BL and BR = 0,

The skipped mapped block. “there is no mapping”.

Algorithm 1 expresses the proposed algorithm to hide the secret payload in the carrier image. While Fig. 2 depicts the proposed scheme of the concealing process. As shown, the Secret Text Bits (STB) are initially grouped into two secret bit pairs, i.e. STB1 (1,0), STB2 (1,0), and STB3(1,1), as shown in Fig. 2(i). Similarly, all the cover image pixels bits are divided into pairs, as shown in Fig. 2(ii), with Left Pair called Cover Image Left Pixel (CIPLpixel) and the Right Pair called Cover

Image Right Pixel (CIPRpixel). CIPLpixel, pixel denotes the cover pixel's 7th and 8th Most Significant Bits (MSBs), while CIPRpixel denotes the 5th and 6th MSBs.

The pixel on the cover of the secret text bits pair would be mapped using CIPLpixel, and CIRpixel bits. Similarly, the 1st and 2nd LSBs of a cover pixel are represented by Right Bit (1LSBp) and Left Bit (2 LSBp), respectively, and are utilised as indicators for pixel pair mapping. In terms of indicator bits, 2LSBp, and 1LSBp, the pixel is closely related to CIPLpixel, and CIPRpixel, respectively, as shown in Fig. 2(iii).

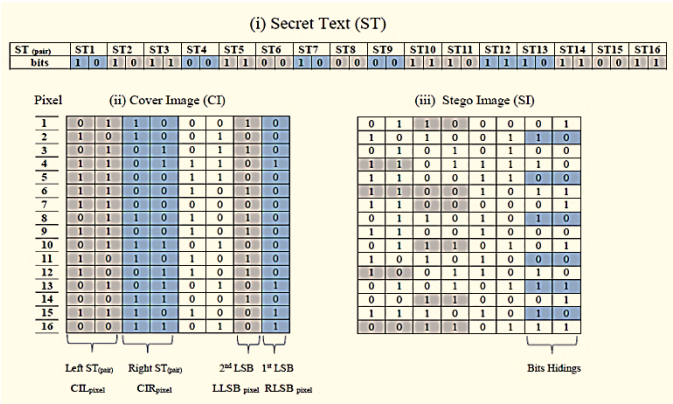

Fig. 2. The Full Scenario of the Proposed Embedding Process: (i) Secret Text Bits; (ii) Cover Image Pixels; (iii) Stego-image Pixels.

III. System Model and Methodology

Four phases describe the whole methodology of this paper, as shown in Fig. 3. These four phases are:

- Phase one: Data pre-processing. There are two stages in this phase which are (i) the secret message pre-processing and (ii) cover image preparation. In secret message processing, AES and Huffman coding are used while image normalisation is performed in the cover image preparation stage.
- Phase two: Embedding process. This phase also has two stages which are (i) LSB exchanging method and (ii) IKG, as described in Section II.
- Phase three: Evaluation process. This phase uses objectives and subjective evaluation metrics to test and evalaute the stego-image that includes the secret message. Some of the metrics used are Peak Signal-to-Noise Ratio (PSNR), Normalized Cross-Correlation (NCC), Structural Similarity Index Metric (SSIM), Mean Square Error (MSE), and payload capacity.
- Phase four: Extraction process. The objective of the extracting process is to extract the embedded data (secret bits) from the LSB pixels and simultaneously follow the procedure designed in the embedding process. Most of the information related to the extracting stage is made by the agreement between the sender and receiver parties.

The proposed methodology starts by applying data encryption using AES to convert the secret readable message to a non-readable message, raising the redundant characters, and then Huffman coding is used to reduce the size of the redundant character as much as possible. The proposed system perfectly deals with the USC-SIPI image database from the University of Southern California with different image sizes [15]. To work with this dataset, a preprocessng stage is needed to select the target pixel from the carrier image called "image normalisation process" before the embedding process. The proposed embedding algorithm (Stage 2), is applied. Then, the extraction process starts. The secret text bits are extracted by referring to the indicator bits (BLpixel or BRpixel) that the 2-LSBs substituted in each pixel. The extracting strategies are illustrated in Algorithm 2.

Algorithm 2. The proposed extracting algorithm.

First Action: If BL, the pixel is '1' and BR, the pixel is '0':
Restore CILpixel as STB1, and
Restore the 2-LSBs as STB2.

Second Action: If BL, the pixel is '0' and BR, the pixel is '1':
Restore CIRpixel as STB2, and
Restore the 2-LSBs as STB1.

Third Action: If both BLpixel, and BRpixel is '1', then
Restore STB1 from CILpixel bits, and
Restore STB2 from the CIRpixel bits.

Fourth Action: If both BLpixel, and BRpixel are '0', then
No mapping indication.

Table I shows the simulation parameters used in this paper. The image size used is 512×512 with coloured and grey-scale images type. The payload capacities are 16384, 32768, and 49152 (16 kB, 32 kB and 49 kB). The PSNR threshold is 30 dB to consider imperceptibility.

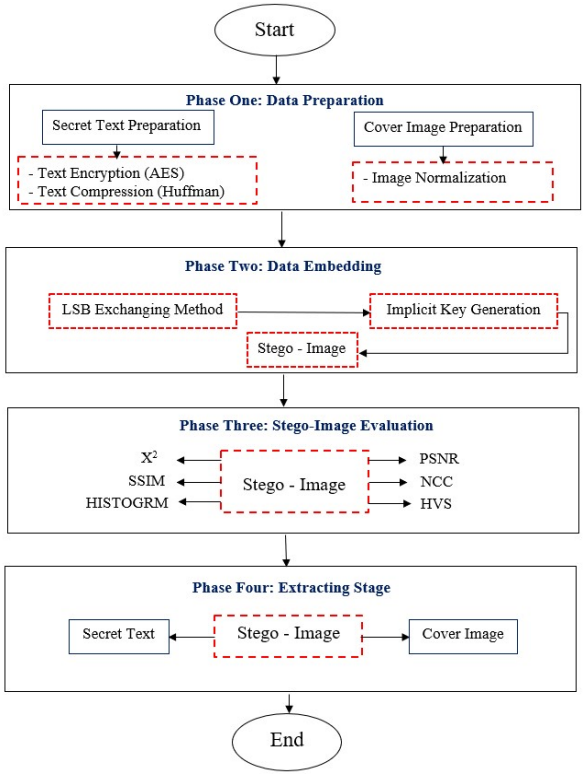

Fig. 3. The General Flowchart of the Proposed Methodology.

TABLE I. SIMULATION PARAMETERS

Simulation parameter	Values
Image size	512×512
Image format	TIFF format
Database used	USC-SIPI
Normalization	No
Payload capacity	16384, 32768, and 49152
PSNR threshold	30 dB
Coding	Huffman
Encryption	AES

IV. SIMULATION RESULTS AND DISCUSSION

In steganography, the imperceptibility and capacity of the proposed algorithm are the main concern in the simulation results. As known, there is a trade-off between capacity and imperceptibility of steganography. The proposed algorithm is evaluated based on the Embedding Capacity (EC) and three attacks system: the Human Visual System (HVS) attack, the Chi-square (χ^2)attack, and the Histogram attack. The comparison between the proposed algorithm with previously proposed methods in the literature is also presented.

The proposed algorithm uses colour and grey-scale images with different payload capacities which are 16 kB, 32 kB, and 49 kB. The 16384 bytes corresponded to 6.25%, meaning that every two pixels represented 16 bits; thus, 1/16 = 6.25% when 1 bit of two pixels was embedded. The 32768 bytes were equal to 12.5%, implying that every pixel corresponded to 8 bits, so 1/8 = 12.5% when 1 bit of one pixel was embedded. The 49152 bytes corresponded to 18.75%, signifying that every two pixels were assigned to 16 bits; accordingly, 3/16 = 18.75% when 1.5 bits of one pixel were embedded.

The PSNR threshold should be $\geqslant$ 30 dB in evaluating the imperceptibility to satisfy no HVS. In conventional image processing, the imperceptibility of the stego image is determined using the PSNR measures. By applying the PSNR measures, the fidelity of the stego image can be evaluated against the original carrier image. To ensure that the proposed system achieves the target aim, the proposed MLLSBEM is evaluated with two other embedding algorithms, the simple LSB and the embedding with pre-processing. Moreover, the proposed system is evaluated using various payload capacities: 16 kB, 32 kB, and 49 kB and three colour and grayscale images: Lena, Baboon, and Pepper. Table II presents the achievements of different embedding methods of grayscale images with 16 kB of payload capacities.

Simulation results in Table II show that the best PSNR comes from the proposed MLLSBEM because of the AES and Huffman coding compared to PSNR value of with pre-processing and simple LSB. Furthermore, the PSNR factor took the frequency of bits in the LSB of the cover image. The same conclusion comes from all the images via high PSNR value and low MSE. Fig. 4 shows the results of the proposed MLLSBEM using various payload capacities and various USC-SIPI dataset images Lina, Baboon and pepper images.

Coloured images are also used to evaluate their performance for the same payload capacities used in grey-scale images. Fig. 5 shows the PSNR values for the proposed algorithm when using coloured images. Simulation results show that the calculated PSNR values for the colour images are lower than the grey-scale images due to the representation of colour pixels with 24-bits for one pixel as opposed to only 8-bits for the grey scale. In addition, the Baboon image showed a higher PSNR value due to the different properties of this image, and also the nature of the image itself has more contrasts in the pixel value, thereby enabling the Baboon image to be more chaotic.

The proposed method used different evaluation metrics such as MSE, SSIM, and NCC to check the stego image before sending it to the authorised receiver to ensure that familiar attacks such as HVS, Chi-square and Histogram are unable to detect the secret message. Table III shows the various evaluation metrics with different amounts of embedding capacity for the standard grey-scale and coloured images.

TABLE II. THE DIFFERENT EMBEDDING METHODS OF GRAY-SCALE WITH 16 KB OF PAYLOAD CAPACITY

Image/ Dataset	PSNR evaluatiom metric		
	Simple LSB	***With Pre-processing***	***MLLSBEM (Proposed)***
Lena	65.225	71.332	78.094
Baboon	66.331	72.099	78.129
Pepper	64.997	71.009	78.1491

A. Human Visual System Attacks Analysis

In image steganography, a system can detect edges that become blurred or unclear. Consequently, the LSB can detect the HVS attack, which is still ambiguous to human sight because it is trained to recognise the known things. This simulation aims to distinguish the presence or absence of the hidden data in the stego-image. Simulation results in Fig. 6 show that the eight-bit planes HVS attack can detect only the LSBs; the rest are ignored. The embedding in the bit planes 1 and 2 appears very clear where the vertical lines refer to the frequencies in their bits, implying that hidden information is embedded in these two-pixel. This type of detection is somewhat interactive between the system and humans because the system generates the pattern, and the human eyes detect it.

Fig. 7 depicts the comparison of the proposed MLLSBEM towards HVS attack as compared to the simple LSB and with pre-processing. Observations indicate that embedding simple LSB images is ineffective because the injection of the hidden bits directly, without processing or bit position selection, makes them immediately detectable by human eyes.

Due to preparation for the usage of picture normalisation, the pattern of the first bit-plane was improved for the pre-processing procedure. Using AES encryption and Huffman coding, the proposed MLLSBEM can generate a stego-image similar to the original cover image due to the arbitrary distribution of bits and the process of preserving the original image bit values by mapping the secret bits before embedding them.

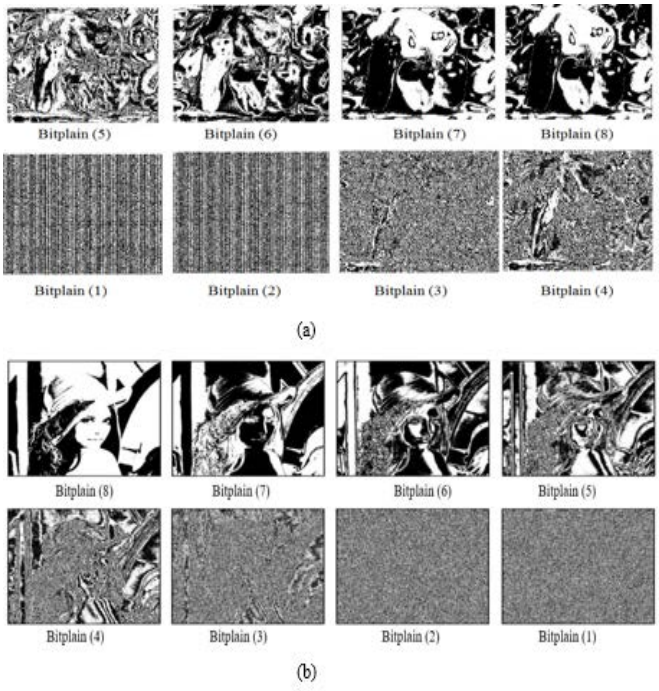

Fig. 6. The HVS Attacks with Various the Eight Bit-plains Layers. (a) Pepper Image, (b) Lena Image.

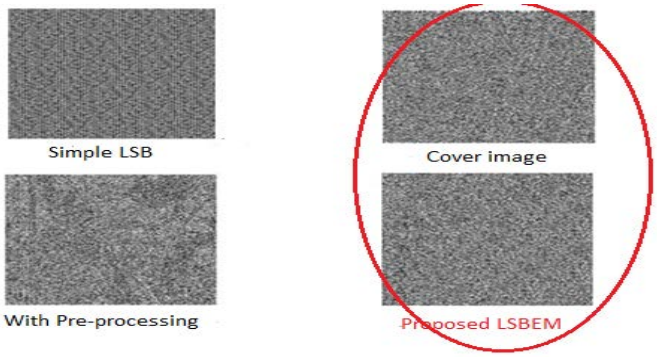

Fig. 7. The Figure shows Three Embedding Methods in Resistance against the HVS Attack on the Original Lena Image.

B. Chi-square Attack (X^2) Attack

A special attack called Chi-square (χ2) is based on the statistical analysis of the Pairs of Values (PoVs) exchanged during the secret data embedding, which is also based on the probability distribution. The (χ2) attack can find the probability of embedding the secret bits inside the stego image where the normal image follows the usual behaviour.

Fig. 8(a) shows the χ2-test for the original pepper image. In the first 10%, the probability is 0.065 because when the function checks the pixels, most of the characters in the alphabet start with the same value as the frequent bits. Thus, the test detects this frequently and suggests these pixels as the embedded data. The absence of detection for embedding in the remaining images is normal, as the original images do not have any hidden data.

Fig. 8(b) shows the χ2-test for the simple LSB that detects fifty per cent of the image as concealed data with a probability of one. In Fig. 8(c), the proposed algorithm covers the entire image with a low probability, even better than the original image. This occurs because the statistical distributions of the values in the LSB are good. After all, the segments of the secret bits are chosen carefully.

C. Histogram Attack

The histogram analysis is applied to three types of images, as shown in Fig. 9. The analysis shows that the variance between the constructed histograms is comparatively low for all tested images when using the proposed MLLSBEM method. The distortions caused by the embedding process are not noticeable to the human eye when concealing an acceptable amount of secret bit. However, when we hide more secret bits (exceeding the embedding limit), the variance between the constructed histograms is high and noticeable to the human eye. Moreover, the PSNR value becomes low.

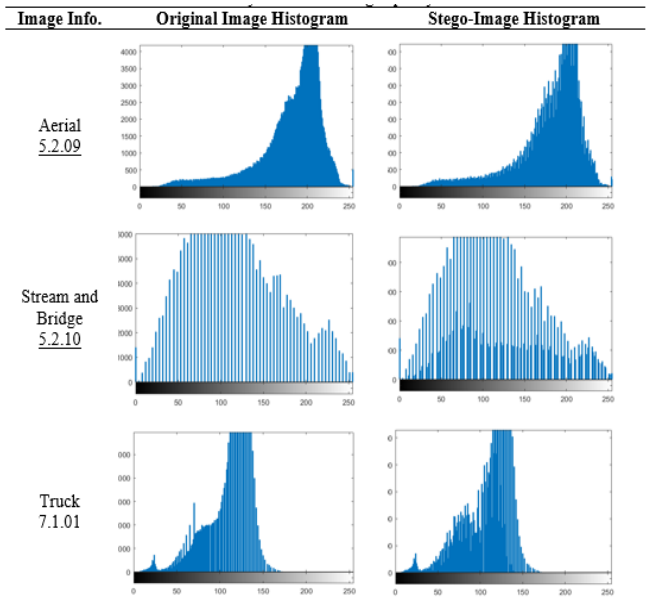

Fig. 9. Histogram Analysis of 16 kB Capacity of Grey-scale Image.

Fig. 10 shows the comparison between the stego images and the original image with different payload capacities. 18.75% embedding corresponds to 49 kB payload capacity.

Fig. 10. The Stego and Original Images' Resemblance with Different Payload Capacity.

Table IV compares the proposed algorithm's results with the previously published methods. The evaluation results of the proposed method were found to be better than those reported in the literature. This evaluation indicates that the proposed algorithm used for the pre-processing and embedding stages in the proposed scheme improve the final results. The proposed method is excellent as compared to the previous studies in terms of PSNR, SSIM, NCC, MSE for different payload capacities. In addition, the proposed method is resistant towards the histogram, chi-square, and HVS attacks.

V. CONCLUSION

We have presented a new image steganographic method using the MLLSBEM to hide the secret bits. The proposed algorithm uses pre-processing operations such as AES encryption and Huffman coding. The proposed embedding algorithm is based on the modified LSB exchanging method and IKG. Simulation results show that the proposed method is excellent as shown in the achievement of PSNR, SSIM, NCC, and payload capacity and is robust towards the histogram, chi-square, and HVS attacks. In the future, we plan to take into consideration an open challenge to achieve adaptable exchange between the cover image and secret bits. This work opens up several new avenues that are worth doing for the future. For instance, the security can be enhanced by mixing the frequency domain and spatial domain. This may achieve better results in terms of security and robustness. Also, the proposed method can be combined with the DWT and embedding may result in high coefficients based on the obtained findings. Many methods have already used high coefficients for the embedding. However, the use of LSBEM may yield better results in terms of security and imperceptibility. The most important gap in the steganography system is related to the capacity improvement of the secret message. The limitation of the secret message with PSNR makes the steganography difficult to improve. In such a scenario, it is better to handle the secret message before embedding and to make it dynamic with the embedding method. The concealed message's limitation (direct hiding) makes steganography difficult to improve. In this case, it's preferable to manipulate the secret message before embedding it by coding and compressing it, making the secret text pre-processing stage interactive with the embedding process.

Recognition of Odia Character in an Image by Dividing the Image into Four Quadrants

Aradhana Kar, Sateesh Kumar Pradhan
Department of Computer Science & Applications
Utkal University
Bhubaneswar, Odisha, India

***Abstract*—This paper deals with optical character recognition of Odia characters written in a particular font family 'AkrutiOriAshok-99' with different font sizes 18, 20, 22, 24, 26, 28, 36, 48 and 72 in Bold style. The font 'AkrutiOriAshok-99' is a font from the typing software 'Akruti'. The basic idea behind the approach followed in this paper is the character decomposition into four quadrants and then extracting features from each quadrant. The image processing techniques like converting the image to gray, resizing of image and converting gray image to binary are used in this approach. The system explained in this paper has two major parts: DictionaryBuilding and FindingMatch. For DictionaryBuilding, dictionary of images which are created either by scanning a document or a document converted to image, both written in same font family in different sizes. The features are extracted from each image in any font size in the 'Dictionary' using Preprocessing, FindPath, GettingFeaturesLeft or GettingFeaturesRight, VisitSubQuad, RemainingSubQuad, WriteToExcel and CommonFeature modules. The part FindingMatch is responsible for finding a correct match in the dictionary for the input image. For this, FeatureExtraction and Recognition modules have been used. Longest Common Subsequence (LCS) has been used for finding the common feature in DictionaryBuilding as well as finding the correct match. A total of 1800 characters, 200 characters of each font size have been tested and 98.1% of correctness has been achieved.**

***Keywords*—Odia characters; image processing; character decomposition; machine learning; optical character recognition**

I. INTRODUCTION

In present days, the textual data are either scanned or converted to image by using software to store the data in the form of image. It is required to recognise the characters present in the scanned document or document converted to image by using some algorithm. For recognition of characters in an image, efficiency in the segmentation of lines, words and characters should be achieved.

In Odia language, the alphabets are grouped into three categories: Swara Barna, Byanjana Barna and Atirikta Barna [1] (Fig.1). Only Chandra Bindu ( ), Anusara ( ) and Bisarga ( ), which are part of Byanjana Barna can be used with all the alphabets of Swara Barna, other alphabets of Byanjana Barna and all alphabets of Atirikta Barna to form words. When a Swara Barna is used with the alphabets of Byanjana Barna and Atirikta Barna, the former is used as a symbol with latter to form words. These symbols are known as Matras [2]. When a Byanjana Barna alphabet is used as a symbol with the other alphabets of Byanjana Barna, these are called Juktakhyara [2].

There are different types of software available for typing Odia language in a computer. Akruti and Microsoft Indic Language Input tool for Odia are some popularly used typing software.

This paper has concentrated on the recognition of Swara Barna, Byanjana Barna and Atirikta Barna. The alphabet is written in a document in a particular font family ***'AkrutiOriAshok-99'*** in a particular font size in bold style. The font sizes that are considered in this paper are 18, 20, 22, 24, 26, 28, 36, 48 and 72. This document is either scanned or converted to image by software. The approach described in this paper first creates a dictionary of images written in ***'AkrutiOriAshok-99'*** font family, with font sizes 18, 20, 22, 24, 26, 28, 36, 48 and 72 and in bold style. The features of these images are extracted using Preprocessing, FindPath, GettingFeaturesLeft or GettingFeaturesRight, VisitSubQuad, RemainingSubQuad modules and the extracted features are written to the excel file using WriteToExcel module. A common feature is extracted from the extracted features from the images in dictionary using CommonFeature module. For finding a correct match for the input image in the dictionary of features, FindingMatch has been used. For finding a correct match, CheckCommonFeature module of Recognition has been used. If a correct match has not been found by the CheckCommonFeature module, then MatchCommonFeature module has been used to find a correct match. If in some cases, these two modules of Recognition are unable to find a correct match, the TraceAnotherDirection module of Recognition has been used.

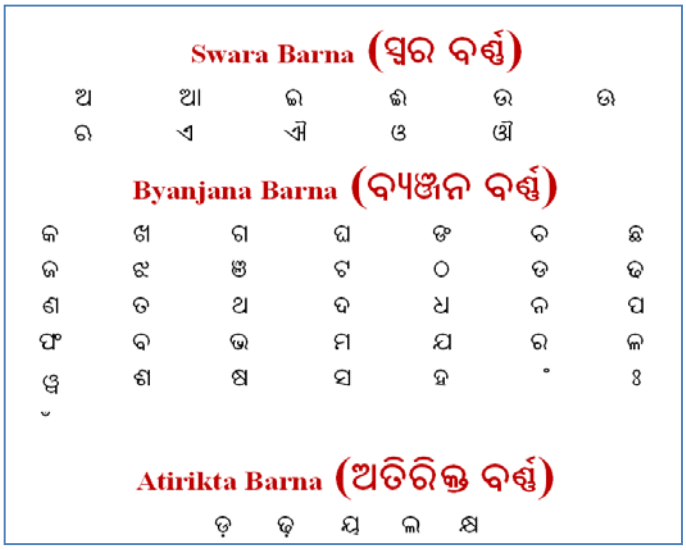

Fig. 1. Odia Alphabets.

The Preprocessing module in ***'DictionaryBuilding'*** and ***'FindingMatch'*** converts the image into gray image and then the white spaces surrounding the Odia alphabet in the gray image are removed using the Phase – 1 of RemoveNoise module of [3] (RemoveBoundarySpaces). For converting image to gray, OpenCv package of python has been used. After the elimination of white spaces from gray image, it is resized into 64 x 64 and the resultant resized image is converted to binary by using OSTU's method of thresholding [4, 5, 6]. Gray image is a type of image where intensity is stored as an 8-bit integer, hence each pixel can have intensity value ranging from 0 – 255 [7]. Binary Image is a type of image where image data is represented in terms of 0 and 1[7, 8, 9]. The basic idea for extracting features followed in this paper for DictionaryBuilding and FindingMatch is dividing the image into four quadrants and then tracing continuous path of black pixel in a particular direction in each quadrant. Experimentally, a specific direction of tracing has been agreed upon for each quadrant. The inputs to DictionaryBuilding and FindingMatch are a directory named as ***'Dictionary'*** (consists of all alphabets of Swara Barna, Byanjana Barna and Atirikta Barna of Odia language) and a directory named as ***'Input'*** (consisting of an image of Odia alphabet) respectively. The files present in ***'Dictionary'*** are accessed using os package of python [10]. The extracted features for DictionaryBuilding and FindingMatch are written in excel files, ***DictionaryFeatures.xlsx'*** and ***'InputFile.xlsx'*** respectively by using openpyxl package of python [11]. The common feature is extracted from the extracted features present in ***DictionaryFeatures.xlsx'*** by using ***Longest Common Subsequence (LCS)*** [12, 13, 14, 15, 16] and the common feature is written to the excel file, ***'CommonFeature.xlsx'*** by using openpyxl package of python. Both in DictionaryBuilding and FindingPath, Numpy package of python [17, 18] has been used for rounding off values and Matplotlib package of python [19] for sub-plotting four quadrants of the given image in one single figure (Fig. 3). Data structures like List and Dictionaries of python are used for holding multiple values. List is a data structure which behaves as a dynamic array in python and multiple values can be appended to it [20, 21]. Dictionaries consist of key values and for each key value there will be a specific value [20, 21]. The key values and values for each key value in dictionaries can be a number and can also be a string.

In other words, the proposed system concentrates on dictionary building by extracting features from the images present in ***'Dictionary'*** directory and storing the extracted features in an excel file ***'DictionaryFeatures.xlsx'***. As per the research, the same character in different font sizes results in a number of features. Therefore, it is needed to find out a common feature among all the font sizes. To achieve this ***Longest Common Subsequence (LCS)*** has been used so that there will be one common feature for a particular character. This common feature for the particular character has been stored in an excel file, ***'CommonFeature.xlsx'***. The above process is done by using phases of ***'DictionaryBuilding'***. Then feature is extracted from an input image and this feature is searched in 'CommonFeature.xlsx' by following the phases of ***'FindingMatch'*** to get a correct match. The proposed approach will help to recognise Odia characters from a scanned image or a document converted to image and these recognised characters can be written into a document and further editing can be done.

II. Related Work

The system introduced in [22], segments handwritten text into lines, from lines, words were segmented and from words characters were segmented. This system had used the water reservoir principle introduced in [23]. The input to the system was a document which was handwritten in Odia. To segment lines, the document was divided to find vertical stripes. Based on vertical projection profile and structural features of Odia characters, text lines were segmented into words. For character segmentation, at first, characters that were connected were detected. Using water-reservoir-concept touching characters of the word were then segmented. The word segmentation module was tested on 3700 words and it was noticed that the word segmentation module had an accuracy of 98.2%. The proposed technique for the isolated and connected character identification had an average accuracy of 96.7%. From the experiment it had been noticed that, in 98.6% cases, isolated characters fall into isolated group. From the experiment it had been noticed that 96.7% accuracy was obtained from two-character touching components. The accuracy of the proposed scheme on three character touching components was 95.1%.

The system introduced in [23] uses a technique for automatic segmentation of handwritten connected numerals. This system had worked on the images of French bank checks from French Company (Itesoft). Initially, the images were in gray scale (256 levels) and they had used histogram based thresholding approach to convert the gray image into binary image. Features were extracted by using the technique called water reservoir. Reservoir was obtained by the accumulation of water poured from the top or from the bottom of the numerals. Top reservoirs were formed when water was poured from the top and bottom reservoirs were formed when water was poured from the top after rotating the component by 180^{o}. Water reservoirs were the white regions of the component.

The features that were considered in the scheme were: number of reservoirs, position of reservoirs with respect to bounding box of the touching pattern, shape and size of the reservoirs, centre of gravity of the reservoirs and relative positions of the reservoirs. The segmentation result was verified manually and observed that 94.8% of the connected numerals were accurately segmented.

The system described in [24] recognises odia compound character by analysing strokes. The approach had identified 12 strokes that are enough to describe any Odia character. The input character was resized into a 60 x 60 image and then divided into nine equal halves called zones. Each zone consists of some strokes. There are nine zones and 12 strokes so; each feature vector of the character was represented in a 1 x 108. The value of similarity between strokes and zone were arranged in a vector format. Structural Similarity Index had been used as it is based on the concept that the structure of the image is independent of the illumination. The training set had been prepared from the 211 classes of Kalinga font. The system was implemented in windows machine and on MATLAB platform. The independent character recognition accuracy was achieved as 92%. The system also covers many test samples of degraded Kalinga characters. A complete OCR was also designed to work on scanned text document.

The approach described in [25] deals with handwritten Odia character recognition. This system has two level of classification. The input to the first level of classification was a cropped image. Then the input image was binarized followed by thinning. The mid value of the image was found. Then the image was divided into three equal halves row wise and two halves column wise, making it six zones. The distance between the pixel value and the centroid was calculated and this was done for all pixels for a zone and then average distance was calculated for that zone. The angle between image centroid and the pixel was calculated and this was done for each pixel in a zone. Then the average of the angles was calculated. In second-level classification, the cropped image was taken as input and it was divided into nine zones. Then the same procedure that was carried out in first-level classification was also followed in second-level classification. The first-level classification output six average distances and six average angles. The second-level classification also output nine standard deviations, nine average distances and nine average angles. Then Artificial Neural network was used for classification.

The system introduced in [26] considered each character as composition of sequence of high-level strokes and low-level strokes. They had identified low-level strokes in the system explained in [27]. In [26], they had identified forty eight visually non-redundant high-level strokes which form the maximum of a Gujarati character. Each high-level stroke is a combination of point, curves and lines. The proposed method start scanning from the center region of the character in left to right order and extract all junction points. The 3 x 3 neighbourhood of each junction point was then scanned in clockwise order to obtain the starting point of each high-level stroke. The high-level stroke ends at endpoint or until next junction point is not reached using contour tracing method. The system had used finite state machine to identify high-level stroke. For classification, the system had used Naive Bayes Classifier and Hidden Markov Model. The overall accuracy achieved using Naive Bayes Classifier and Hidden Markov Model was 93.26% and 96.87% respectively.

III. System Architecture

This approach consists of ***'DictionaryBuilding'*** and ***'FindingMatch'*** parts. The output of the above two parts are given as input to the Recognition module to find a correct match. The overall system architecture has been shown in Fig. 2

A. DictionaryBuilding

This part deals with building dictionary of features extracted from the dictionary of images of Odia alphabets which are created by scanning a document or a document converted to image by using software, both written in a font family, ***'AkrutiOriAshok-99'*** in a particular font size. The different font sizes used are 18, 20, 22, 24, 26, 28, 32, 48 and 72. For a particular font size, images of Odia alphabets of that font size are stored in a directory. Hence, nine directories are created as nine different font sizes have been used. These nine directories are stored in a directory named as ***'Dictionary'***.

The input to the ***'DictionaryBuilding'*** is the ***'Dictionary'*** directory. The directories in ***'Dictionary'*** and the image files in each directory are accessed using os package of Python. Each image file goes through ***'Feature Extraction in DictionaryBuilding'***.

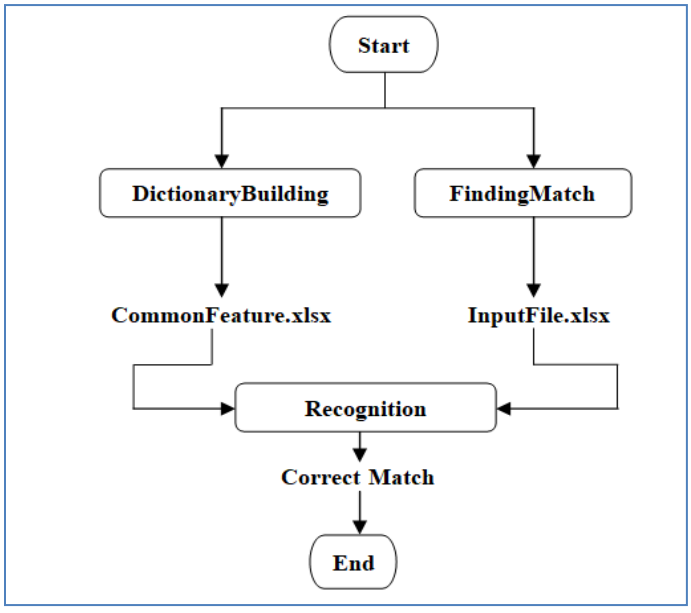

Fig. 2. System Architecture.

1) Feature Extraction in DictionaryBuilding

The ***'Dictionary'*** directory consists of nine directories, each directory dedicated to a particular font size. For example, the directory dedicated to font size 18 consists of images of each Odia alphabet written in font size 18, directory dedicated to font size 20 consist of images of each Odia alphabet written in font size 20 and so on. All the images in all these directories of ***'Dictionary'*** undergoes Preprocessing, FindPath,

GettingFeaturesRight or GettingFeaturesLeft, RemaingSubQuad, VisitSubQuad modules to extract the features of the images and these extracted features are written into an excel file using WriteToExcel Module. For each directory in the ***'Dictionary'***, a sheet is created in the excel file named as ***'DictionaryFeatures.xlsx'*** and the features are written in that sheet. The overall process of feature extraction of ***'Dictionary'*** images has been shown in Fig. 5.

a) Preprocessing Module

The input to the Preprocessing module is the directory ***'Dictionary'.***

Algorithm:

Input: Directory ***'Dictionary'***

For each image in the directories of the ***'Dictionary',*** the following steps have been followed:

1. The image is converted to gray image.
2. The white spaces that surround the text in the gray image are removed using Phase – I of RemoveNoise module of [3], that is, RemoveBoundarySpaces. This gives an image that consists of Odia alphabet only.
3. After white spaces have been removed, the image is resized into 64 x 64 by using inter-cubic interpolation.
4. The resized image consisting of Odia alphabet only is then converted into a binary image named as ***'BinaryImage'*** using OSTU's method. In ***'BinaryImage'***, the pixels that form the Odia alphabet are called black pixels and they are represented as 0 whereas the pixels that form the other areas of the ***'BinaryImage'*** are called white pixels and they are represented as 1.
5. The ***'BinaryImage'*** is divided into two equal parts, both horizontally and vertically. In this way, this image is divided into four equal quadrants. The dimension of this image is m x n (m = 64 and n = 64), where ***'m'*** is the number of rows and ***'n'*** is the number of columns. The row that equally divides the ***'BinaryImage'*** horizontally is named as ***'MidRow'*** and it is found out by using the following formula:

$$MidRow = \lceil m/2 \rceil$$

The column that equally divides the ***'BinaryImage'*** vertically is named as ***'MidCol'*** and it is found out by using the following formula:

$$MidCol = \lceil n/2 \rceil$$

6. The four quadrants are found out from the ***'BinaryImage'*** by using ***'MidRow'*** *and* ***'MidCol'***. The four quadrants 1st, 2nd, 3rd and 4th are named as B, C, D and E respectively. The four quadrants are shown in Fig. 3.

B = BinaryImage[0 : MidRow-1, 0 : MidCol-1]
C = BinaryImage[0 : MidRow-1, MidCol : n]
D = BinaryImage[MidRow : m, 0 : MidCol-1]
E = BinaryImage[MidRow : m, MidCol : n]

7. Call ***FindPath(quadNo, quadrant, DicItem, DicInnerItem, DataPath, shortName)*** for the quadrants B, C, D and E where,

quadNo is the number of quadrant among the four quadrants. Here, quadNo = 1, 2, 3, 4
quadrant can be B, C, D and E
DicItem is the ***dth*** directory in the directory ***'Dictionary'***. DicItem = 1, 2, 3, 4, 5, 6, 7, 8 and 9. For each value of DicItem, a sheet in the excel file named as ***'DictionaryFeatures.xlsx'*** is created named with the value of DicItem. For example, if DicItem = 1 then a sheet named '1' is created in the excel file.
DicInnerItem is the ***ith*** item of the ***DicItemth*** directory of ***'Dictionary'***. Each ***'DicInnerItem'*** is an image file. DicInnerItem = 1, 2, 3,....., num where ***'num'*** is the total number of image files in the ***DicItemth*** directory.
DataPath is the absolute path of the excel file, ***'DictionaryFeatures.xlsx',*** where the features are being written.
shortName is the name of the image file present in any ***DicItemth*** directory of ***'Dictionary'***.

Suppose quadNo = 1, quadrant = B, DicItem = 2, DicInnerItem = 12 then a sheet named ***'2'*** will be created in the excel file, ***'DictionaryFeatures.xlsx'*** whose path has been provided in the ***'DataPath'*** parameter, and then the extracted feature is being written in the '***12th'*** row (as DicInnerItem = 12) and ***'1st'*** column (as quadNo = 1) of the sheet. The value in the parameter ***'shortName'*** is written in the fifth column.

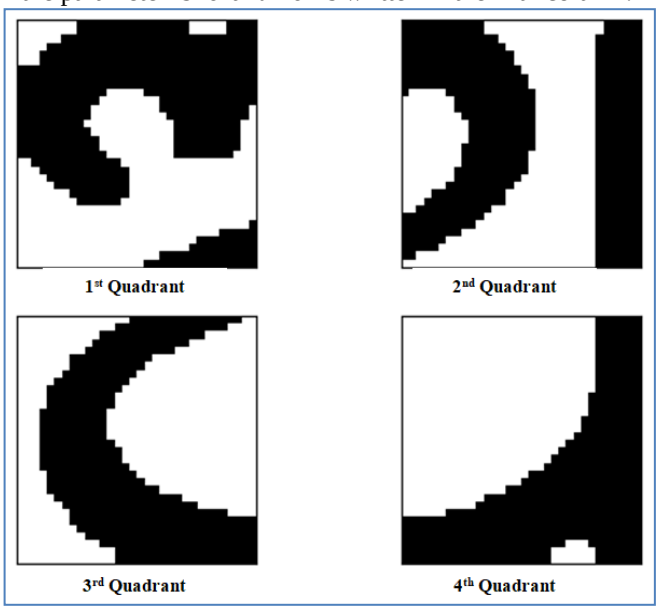

Fig. 3. An Odia Alphabet Divided into Four Quadrants.

b) FindPath Module

The steps of FindPath Module are performed for each of the quadrants B, C, D and E. The idea of this module is that the scanning of each quadrant is started from a particular corner and also scanned in a particular direction to extract the features. The scanning of Quadrant B (quadNo = 1) is started from the leftmost and bottom-most corner and when the first black pixel is found, the 'I' and 'J' (co-ordinates of the first black pixel) values are passed to GettingFeaturesRight module for scanning towards right. The scanning of Quadrant C (quadNo = 2) is started from the topmost and leftmost corner

and it is scanned towards right using GettingFeaturesRight module. The scanning of Quadrant D (quadNo = 3) is started from the bottom-most and right-most corner and it is scanned towards left using GettingFeaturesLeft module. The scanning of Quadrant E (quadNo = 4) is started from the bottom-most and left-most corner and it is scanned towards right using GettingFeaturesRight module.

row = Number of rows of quadrant

col = Number of columns of quadrant

Algorithm:

FindPath(quadNo, quadrant, DicItem, DicInnerItem, DataPath, shortName)

1. SET I = row – 1
2. SET J = 0
3. IF quadNo = 1 THEN GO TO STEP 4
4. REPEAT STEP 5 WHILE J < col
5. REPEAT STEP 6 WHILE I > 0
6. IF quadrant[I][J] = 0 THEN GO TO STEP 7
7. CALL GettingFeaturesRight(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
8. SET I = 0
9. SET J = 0
10. IF quadNo = 2 THEN GO TO STEP 11
11. REPEAT STEP 12 WHILE I < row
12. REPEAT STEP 13 WHILE J < col
13. IF quadrant[I][J] = 0 THEN GO TO STEP 14
14. CALL GettingFeaturesRight(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
15. SET I = row – 1
16. SET J = col – 1
17. IF quadNo = 3 THEN GO TO STEP 18
18. REPEAT STEP 19 WHILE I > 0
19. REPEAT STEP 20 WHILE J > 0
20. IF quadrant[I][J] = 0 THEN GO TO STEP 21
21. CALL GettingFeaturesLeft(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
22. SET I = row – 1
23. SET J = 0
24. IF quadNo = 4 THEN GO TO STEP 25
25. REPEAT STEP 26 WHILE I > 0
26. REPEAT STEP 27 WHILE J < col
27. IF quadrant[I][J] = 0 THEN GO TO STEP 28
28. CALL GettingFeaturesRight(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
29. EXIT

c) GettingFeaturesLeft Module

When the first black pixel is found in FindPath Module while scanning the quadrant from the specified corner, the coordinates of the pixel (I value and J value) are passed to this module to get a continuous trace of black pixels in the specified quadrant. This module scans the quadrant towards the left starting from the first black pixel. This module is used in quadrant D.

'quadrant', ***'quadNo'***, ***'DicItem'***, ***'DicInnerItem'***, ***'DataPath'*** and ***'shortName'*** are explained in the step 7 of preprocessing module.

'LSubQuad' will contain the final feature extracted from a particular quadrant.

'I' and ***'J'*** consists of the row and column number of the first black pixel obtained in a particular quadrant using FindPath module.

row1 = Number of rows of quadrant

col1 = Number of columns of quadrant

Algorithm:

GettingFeaturesLeft(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)

1. IF J = 0 THEN DO STEPS FROM 2 TO 5
2. LSubQuad = CALL VisitSubQuad(I, J, 0, row1, 0, col1)
3. CALL RemainingSubQuad(quadrant)
4. CALL WriteToExcel(DicItem, DicInnerItem, quadNo, LSubQuad, DataPath, shortName)
5. RETURN
6. ELSE DO STEPS 7 OR 12 OR 17 OR 22, WHICHEVER SATISFIES CONDITION FIRST
7. IF quadrant[I – 1, J - 1] = 0 THEN DO STEPS FROM 8 TO 11
8. I = I – 1
9. J = J – 1
10. LSubQuad = CALL VisitSubQuad(I, J, 0, row1, 0, col1)
11. CALL GettingFeaturesLeft(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
12. ELSE IF quadrant[I, J - 1] = 0 THEN DO STEPS FROM 13 TO 16
13. I = I
14. J = J – 1
15. LSubQuad = CALL VisitSubQuad(I, J, 0, row1, 0, col1)
16. CALL GettingFeaturesLeft (I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
17. ELSE IF quadrant[I + 1, J - 1] = 0 THEN DO STEPS FROM 18 TO 21
18. I = I + 1
19. J = J – 1
20. LSubQuad = CALL VisitSubQuad(I, J, 0, row1, 0, col1)
21. CALL GettingFeaturesLeft (I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
22. ELSE IF (quadrant[I – 1, J - 1] = 1 AND quadrant[I, J - 1] = 1 AND quadrant[I + 1, J - 1] = 1) OR (J = 0) OR (I = 0) OR (I = row1 – 1) OR (J = col1 – 1) THEN DO STEPS FROM 23 TO 25

23. CALL RemainingSubQuad(quadrant)
24. CALL WriteToExcel(DicItem, DicInnerItem, quadNo, LSubQuad, DataPath, shortName)
25. RETURN
26. EXIT

d) GettingFeaturesRight Module

The aim of this module is to get a continuous trace of black pixels scanning from left to right. When the first black pixel is found in FindPath Module while scanning the quadrant from the specific corner, the coordinates of the pixel (I value and J value) are passed to this module to get a continuous trace of black pixels in the specified quadrant. This module is used in quadrants B, C and E.

'quadrant', ***'quadNo'***, ***'DicItem'***, ***'DicInnerItem'***, ***'DataPath'*** and ***'shortName'*** are explained in the step 7 of Preprocessing module.

'LSubQuad' will contain the final feature extracted from a particular quadrant.

'I' and ***'J'*** consists of the row and column number of the first black pixel obtained in a particular quadrant using FindPath module.

row1 = Number of rows of quadrant

col1 = Number of columns of quadrant

Algorithm:

GettingFeaturesRight(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
1. IF J = col1 - 1 THEN DO STEPS FROM 2 TO 5
2. LSubQuad = CALL VisitSubQuad(I, J, 0, row1, 0, col1)
3. CALL RemainingSubQuad(quadrant)
4. CALL WriteToExcel(DicItem, DicInnerItem, quadNo, LSubQuad, DataPath, shortName)
5. RETURN
6. ELSE DO STEPS 7 OR 12 OR 17 OR 22 WHICHEVER CONDITION SATISFIES FIRST
7. IF quadrant[I – 1, J + 1] = 0 THEN DO STEPS FROM 8 TO 11
8. I = I – 1
9. J = J + 1
10. LSubQuad = CALL VisitSubQuad(I, J, 0, row1, 0, col1)
11. CALL GettingFeaturesRight(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
12. ELSE IF quadrant[I, J + 1] = 0 THEN DO STEPS FROM 13 TO 16
13. I = I
14. J = J + 1
15. LSubQuad = CALL VisitSubQuad(I, J, 0, row1, 0, col1)
16. CALL GettingFeaturesRight(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
17. ELSE IF quadrant[I + 1, J + 1] = 0 THEN DO STEPS FROM 18 TO 21
18. I = I + 1
19. J = J + 1
20. LSubQuad = CALL VisitSubQuad(I, J, 0, row1, 0, col1)
21. CALL GettingFeaturesRight(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
22. ELSE IF (quadrant[I – 1, J + 1] = 1 AND quadrant[I, J + 1] = 1 AND quadrant[I + 1, J + 1] = 1) OR (J = 0) OR (I = 0) OR (I = row1 – 1) OR (J = col1 – 1) THEN DO STEPS FROM 23 TO 25
23. CALL RemainingSubQuad(quadrant)
24. CALL WriteToExcel(DicItem, DicInnerItem, quadNo, LSubQuad, DataPath, shortName)
25. RETURN
26. EXIT

e) VisitSubQuad Module

Each of the four quadrants **B, C, D** and **E** is again divided into four sub-quadrants named as a, b, c and d. This module uses a list data structure named as ***'subQuad'*** and appends name of the sub-quadrant (***'a'*** or ***'b'*** or ***'c'*** or ***'d'***) for each black pixel found while scanning by GettingFeaturesLeft or GettingFeaturesRight module including the first black pixel found in the FindPath Module in ***'SubQuad'***. The sub-quadrants of each quadrant have been shown in Fig. 4. The value returned by this module is stored in ***'LSubQuad'*** of either GettingFeaturesLeft or GettingFeaturesRight module. The final value in ***'LsubQuad'*** is the feature extracted for a particular quadrant (***'B'*** or ***'C'*** or ***'D'*** or ***'E'***).

'srow' is the row number where the quadrant starts.

'erow' is the row number where the quadrant ends.

'scol' is the column number where the quadrant starts.

'ecol' is the column number where the quadrant ends.

$$frow = \left[\left((erow - srow)\right)/2\right]$$

$$fcol = \left[\left((ecol - scol)\right)/2\right]$$

Algorithm:

VisitSubQuad(I, J, srow, erow, scol, ecol)
1. IF (I >= srow AND I <= frow – 1) AND (J >= scol AND J <= fcol – 1) GO TO STEP 2
2. APPEND ***'a'*** in ***'subQuad'***
3. ELSE IF (I >= srow AND I <= frow – 1) AND (J >= fcol AND J <= ecol) GO TO STEP 4
4. APPEND ***'b'*** in ***'subQuad'***
5. ELSE IF (I >= frow AND I <= erow) AND (J >= fcol AND J <= ecol) GO TO STEP 6
6. APPEND ***'c'*** in ***'subQuad'***
7. ELSE IF (I >= frow AND I <= erow) AND (J >= scol AND J <= fcol - 1) GO TO STEP 8
8. APPEND ***'d'*** in ***'subQuad'***
9. RETURN ***'subQuad'***
10. EXIT

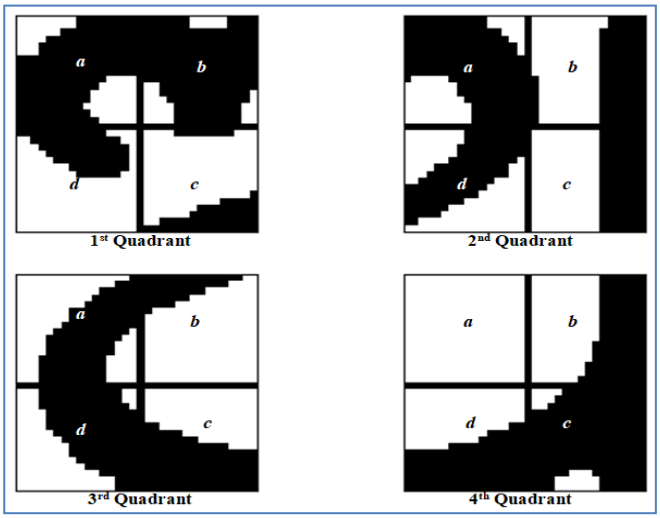

Fig. 4. Sub-Quadrants of Four Quadrants.

f) RemainingSubQuad Module

A continuous trace of black pixels is found by either GettingFeaturesLeft or GettingFeaturesRight starting from the first black pixel found in FindPath module and the name of the sub-quadrant is appended in ***'LSubQuad'***. But the continuous trace of black pixels may not have accessed some part of the quadrant (***'B'*** or ***'C'*** or ***'D'*** or ***'E'***). To ensure, all parts of the quadrant have been accessed, the remaining parts are accessed using RemainingSubQuad Module. First, this module checks if all the sub-quadrants have been accessed for the black pixels. This is done by checking the contents of the ***'LSubQuad'*** list. In other words, if a sub-quadrant does not have any black pixel then that sub-quadrant is not allowed to be present in the ***'LSubQuad'*** list. If the name of the all sub-quadrants that have black pixels have appeared at least once in ***'LSubQuad'*** then, RemainingSubQuad exits, otherwise, RemainingSubQuad is called recursively to scan the sub-quadrants until all sub-quadrants that have black pixels have been scanned and stored in the ***'LSubQuad'***.

'quadrant' consists of ***'B'***, ***'C'***, ***'D'*** and ***'E'***.

Algorithm:

RemainingSubQuad(quadrant)

1. IF ***'a'***, ***'b'***, ***'c'*** and ***'d'*** all are in ***'LSubQuad'*** THEN
2. GO TO STEP 20
3. ELSE
4. IF ***'a'*** IS NOT IN ***'LSubQuad'*** THEN DO STEP 5 TO 7
5. SCAN black pixels of quadrant from top-most and left-most corner to find the first black pixel and from there scan towards right following the similar procedure as in GettingFeaturesRight to find the continuous trace of black pixel.
6. For each black pixel in the continuous trace APPEND ***'a'*** in ***'LSubQuad'.***
7. CALL RemainingSubQuad(quadrant)
8. ELSE IF ***'b'*** IS NOT IN ***'LSubQuad'*** THEN DO STEP 9 TO 11
9. SCAN black pixels of quadrant from top-most and right-most corner to find the first black pixel and from there scan towards left following the similar procedure as in GettingFeaturesLeft to find the continuous trace of black pixel.
10. For each black pixel in the continuous trace APPEND ***'b'*** in ***'LSubQuad'.***
11. CALL RemainingSubQuad(quadrant)
12. ELSE IF ***'c'*** IS NOT IN ***'LSubQuad'*** THEN DO STEP 13 TO 15
13. SCAN black pixels of quadrant from bottom-most and right-most corner to find the first black pixel and from there scan towards left following the similar procedure as in GettingFeaturesLeft to find the continuous trace of black pixel.
14. For each black pixel in the continuous trace APPEND ***'c'*** in ***'LSubQuad'.***
15. CALL RemainingSubQuad(quadrant)
16. ELSE IF ***'d'*** IS NOT IN ***'LSubQuad'*** THEN DO STEP 17 TO 19
17. SCAN black pixels of quadrant from bottom-most and left-most corner to find the first black pixel and from there scan towards right following the similar procedure as in GettingFeaturesRight to find the continuous trace of black pixel.
18. For each black pixel in the continuous trace APPEND ***'d'*** in ***'LSubQuad'.***
19. CALL RemainingSubQuad(quadrant)
20. EXIT

g) WriteToExcel Module

When a quadrant (***'B'*** or ***'C'*** or ***'D'*** or ***'E'***) is scanned completely for tracing black pixels, all the features of the quadrant are extracted in the form of a, b, c and d and stored in ***'LSubQuad'***. The contents of the ***'LSubQuad'*** are concatenated to present the features in a string format. This string value is written in the ***'DicItemth'*** sheet, ***'DicInnerItemth'*** row and ***'quadNoth'*** column of the excel file, ***'DictionaryFeatures.xlsx'***. The path of the excel file is stored in ***'DataPath'*** parameter. The ***'shortName'*** is the file name and it is written in the fifth column and ***'DicInnerItemth'*** row of the ***'DicItemth'*** sheet of the excel file. All the extracted features are written in the excel file by using the openpyxl package of Python. This excel file contains the features of each alphabet in all font sizes (18, 20, 22, 24, 26, 28, 32, 48 and 72). For example, the alphabet ಅ in font size 18, 20, 22, 24, 26, 28, 32, 48 and 72 is written in the first row of sheet named 1, 2, 3, 4, 5, 6, 7, 8 and 9 respectively.

Algorithm:

WriteToExcel(DicItem, DicInnerItem, quadNo, LSubQuad, DataPath, shortName)

1. INITIALIZE ***'S'*** to an empty string
2. A = 0
3. REPEAT STEP 4 WHILE A < LENGTH(LSubQuad)
4. S = S + LSubQuad[A]
5. For each value of DicItem, CREATE a new sheet named with the value of the DicItem.

6. IF the current value of DicItem is same as the value in the previous iteration THEN a new sheet is not created and the feature in string format is written in the current sheet of the excel file, ***'DictionaryFeatures.xlsx'.***
7. ELSE CREATE a new sheet for writing extracted features of the alphabets of next font size in the excel file, ***'DictionaryFeatures.xlsx'***.
8. EXIT

h) CommonFeature Module

When all the features have been extracted and written in the excel file, ***'DictionaryFeatures.xlsx'*** for all alphabets in all font sizes using WriteToExcel module then, a common feature is found from all the extracted features of an alphabet in different font sizes. For this, CommonFeature module is used. This module finds the ***LCS (Longest Common Subsequence)*** of all the features of a particular alphabet in different font sizes to find the common feature. LCS is a way of finding longest common sub-sequences from a set of sequences.The common feature found using LCS is written in another excel file named as ***'CommonFeature.xlsx'*** which consists of only one sheet.

'fiQuList', ***'SeQuList'***, ***'ThQuList'*** and ***'FoQuList'*** are the lists that contains features of first quadrant (B), second quadrant (C), third quadrant (D) and fourth quadrant (E) of a particular alphabet in different font sizes respectively.

'row' is the total number of rows present in the excel file, ***'DictionaryFeatures.xlsx'*** which contains features of all alphabets in a sheet. The value of ***'row'*** is same in all sheets of the excel file, ***'DictionaryFeatures.xlsx'***.

'sheet' is the total number of sheets present in the excel file, ***'DictionaryFeatures.xlsx'*** which contains features of all alphabets in different font sizes (In this research, sheet = 9 as nine different font sizes are considered).

'Text1', ***'Text2'***, ***'Text3'*** and ***'Text4'*** are strings.

'sr' is initialized to 0.

'sh' is initialized to 0.

Algorithm:

CommonFeature()
1. REPEAT STEP 2 WHILE sr < row
2. REPEAT STEPS FROM 3 TO 6 WHILE sh < sheet
3. APPEND the feature in first column of ***'sr^{th}'*** row of ***'sh^{th}'*** sheet of ***'DictionaryFeatures.xlsx'*** in ***'fiQuList'.***
4. APPEND the feature in second column of ***'sr^{th}'*** row of ***'sh^{th}'*** sheet of ***'DictionaryFeatures.xlsx'*** in ***'SeQuList'.***
5. APPEND the feature in third column of ***'sr^{th}'*** row of ***'sh^{th}'*** sheet of ***'DictionaryFeatures.xlsx'*** in ***'ThQuList'.***
6. APPEND the feature in fourth column of ***'sr^{th}'*** row of ***'sh^{th}'*** sheet of ***'DictionaryFeatures.xlsx'*** in ***'FoQuList'.***
7. Text1 = fiQuList[0]
8. f = 0
9. REPEAT STEP 10 WHILE f < (LENGTH (fiQuList) – 1)
10. Text1 = FindLCS(Text1, fiQuList[f + 1]
11. Text2 = SeQuList[0]
12. f = 0
13. REPEAT STEP 14 WHILE f < (LENGTH (SeQuList) – 1)
14. Text2 = FindLCS(Text2, SeQuList[f + 1]
15. Text3 = ThQuList[0]
16. f = 0
17. REPEAT STEP 18 WHILE f < (LENGTH (ThQuList) – 1)
18. Text3 = FindLCS (Text3, ThQuList[f + 1])
19. Text4 = FoQuList[0]
20. f = 0
21. REPEAT STEP 22 WHILE f < (LENGTH (FoQuList) – 1)
22. Text4 = FindLCS (Text4, FoQuList[f + 1])
23. WRITE the value of ***'Text1'*** in the first column of ***'sr^{th}'*** row of the excel file, ***'CommonFeature.xlsx'***.
24. WRITE the value of ***'Text2'*** in the second column of ***'sr^{th}'*** row of the excel file, ***'CommonFeature.xlsx'***.
25. WRITE the value of ***'Text3'*** in the third column of ***'sr^{th}'*** row of the excel file, ***'CommonFeature.xlsx'***.
26. WRITE the value of ***'Text4'*** in the fourth column of ***'sr^{th}'*** row of the excel file, ***'CommonFeature.xlsx'***.
27. Clear all the lists ***'FiQuList'***, ***'SeQuList'***, ***'ThQuList'*** and ***'FoQuList'.***
28. INITIALIZE ***'Text1'***, ***'Text2'***, ***'Text3'*** and ***'Text4'*** to empty string.
29. EXIT

i) Longest Common Subsequence

This module finds and returns the LCS (Longest Common Subsequence) of ***'String1'*** and ***'String2'***. The LCS algorithm has been implemented using Dynamic Programming in this paper. If ***'String1'*** and ***'String2'*** are equal then ***'String1'*** is stored in ***'ls'*** and it is returned, otherwise the LCS of ***'String1'*** and ***'String2'*** is found out and it is stored in ***'revLs'*** and returned. The two arrays ***'LcsForm'*** and ***'b'*** are used to store the length of the LCS and the traversing direction of the LCS respectively in each column of each row. The ***'s'***, ***'u'*** and ***'l'*** denote ***'towards diagonal'***, ***'towards upper'*** and ***'towards left'*** directions respectively. After all the values of ***'LcsForm'*** and ***'b'*** are found out, both arrays are scanned from the bottom-most corner and right-most side to get the value of **I** and **J** where ***LcsForm[I][J] = MaxValue and b[I][J] = 's'*** and for each ***'s'*** in ***'b'*** array, the common item in both the strings (String1 and String2) is appended in ***'ls'***. The ***'MaxValue'*** is the maximum length of LCS in '***LcsForm'***. At last ***'ls'*** is reversed and the result is stored in ***'revLs'***.

Algorithm:

FindLCS(String1, String2)
1. IF String1 = String2 THEN DO STEP 2 TO 3
2. APPEND ***'String1'*** in the list named as ***'ls'***.
3. RETURN ***'ls'***.
4. ELSE DO FROM STEP 5 TO 37
5. m = LENGTH(String1)

6. n = LENGTH(String2)
7. INITIALIZE the array ***'LcsForm'*** with dimensions (m + 1, n + 1) to zero.
8. INITIALIZE the array ***'b'*** with dimensions (m + 1, n + 1) to zero.
9. I = 0
10. J = 0
11. REPEAT STEP 12 WHILE I < (m + 1)
12. REPEAT STEP 13 or 16 or 19 WHICEVER SATISFIES THE CONDITION FIRST WHILE J < (n + 1)
13. IF String1[I – 1] = String2[J – 1] THEN DO STEP 14 TO 15
14. LcsForm[I][J] = LcsForm[I][J] + 1
15. b[I][J] = ***'s'***
16. ELSE IF LcsForm[I – 1][J] >= LcsForm[I][J – 1] THEN DO STEP 17 TO 18
17. LcsForm[I][J] = LcsForm[I – 1][J]
18. b[I][J] = ***'u'***
19. ELSE DO STEP 20 TO 21
20. LcsForm[I][J] = LcsForm[I][J – 1]
21. b[I][J] = ***'l'***
22. Find the maximum value in the array ***'LcsForm'*** and it is stored in ***'MaxValue'***.
23. Search the array ***'LcsForm'*** from right-most side and bottom-most corner of the array and find the value of I and J in the array where LcsForm[I][J] = ***MaxValue*** and b[I][J] = ***'s'***.
24. After values of I and J are found for LcsForm[I][J] = ***MaxValue*** and b[I][J] = ***'s'***, DO STEP 25
25. REPEAT STEP 26 or 30 or 33 WHICHEVER SATISFIES THE CONDITION FIRST WHILE I > 0 AND J > 0
26. IF b[I][J] = ***'s'*** THEN DO STEP 27 TO 29
27. APPEND the value in String1[I][J] in the list ***'ls'***.
28. I = I – 1
29. J = J – 1
30. ELSE IF b[I][J] = ***'u'*** DO STEP 31 TO 32
31. I = I – 1
32. J = J
33. ELSE IF b[I][J] = ***'l'*** DO STEP 34 TO 35
34. I = I
35. J = J – 1
36. REVERSE the items of the list ***'ls'*** and store it in ***'revLs'***.
37. RETURN ***'revLs'***.
38. EXIT

Hence, the final output of the ***'DictionaryBuilding'*** is the ***'CommonFeature.xlsx'*** excel file which consists of the common feature for each alphabet extracted from features present in ***'DictionaryFeatures.xlsx'.*** For example, the final common features for the alphabet ଅ are:

1st quadrant – aaaaaaaaaaaaabbbbbbccccccccccccc

2nd quadrant – aaaaaaabbbbbccccccddddddddddddd

3rd quadrant – ccccccccccccccddddaaaabbbbbbbbbbbbaaaaaaaaa

4th quadrant - ddddddddddddddccccbbbbbbbbbb

B. FindingMatch

This part deals with finding a correct match from the dictionary of common features stored in the excel file, ***'CommonFeature.xlsx'*** when an image of Odia alphabet is provided as input. This input image is stored in a directory named as ***'Input'***. The ***'FindingMatch'*** part undergoes through two phases: ***'Feature Extraction'*** and ***'Recognition'***.

1) Feature Extraction

This phase undergoes through seven modules for extracting features from the input image present in the directory ***'Input'*** and the features are written to an excel file named as ***'InputFile.xlsx'***. The different modules are: Preprocessing, FindPath, GettingFeaturesRight or GettingFeaturesLeft, VisitSubQuad and RemainingSubQuad for extracting features from the input image and the features are written in the excel file using WriteToExcel Module. The overall process of feature extraction of Input image has been shown in Fig. 5.

a) Preprocessing Module

The steps in this module are same as described in Preprocessing module of ***'DictionaryBuilding'*** except the values passed to the parameters in FindPath module. The input to this module is the directory ***'Input'*** consisting of an image of Odia alphabet. The input image is converted to gray image. The white spaces surrounding the Odia alphabet in the gray image are removed using the Phase – 1 of RemoveNoise module of [3] (RemoveBoundarySpaces). Then the resultant image is resized into the dimension p x q (p = 64 and q = 64) where, ***'p'*** is the number of rows and ***'q'*** is the number of columns**.** Then the resized image is converted to binary image named as ***'BinayImageIn'.*** The row that equally divides the ***'BinayImageIn'*** horizontally is named as ***'MidRow'*** and it is found out by using the following formula:

$$MidRow = \lceil {}^{p}/_{2} \rceil$$

The column that equally divides the ***'BinayImageIn'*** vertically is named as ***'MidCol'*** and it is found out by using the following formula:

$$MidCol = \lceil {}^{q}/_{2} \rceil$$

The four quadrants are found out from ***'BinayImageIn'*** in the following way:

U = BinaryImageIn[0 : MidRow-1, 0 : MidCol-1]

V = BinaryImageIn[0 : MidRow-1, MidCol : n]

W = BinaryImageIn[MidRow : m, 0 : MidCol-1]

X = BinaryImageIn[MidRow : m, MidCol : n]

'U', ***'V'***, ***'W'*** and ***'X'*** are the first, second, third and fourth quadrant respectively.

Then CALL FindPath(quadNo, quadrant, DicItem, DicInnerItem, DataPath, shortName) for the quadrants U, V, W and X.

b) FindPath Module

The steps in this module are same as described in FindPath module of ***'DictionaryBuilding'*** except that the steps of FindPath Module are performed for each of the quadrants U, V, W and X. Here ***'DicItem'*** and ***'DicInnerItem'*** are constants and are set to 1 as the ***'Input'*** folder has no sub-directories and it has only one image at any given time. The ***'DataPath'*** parameter holds the absolute path of the excel file named as ***'InputFile.xlsx'*** and in this file features of all the four quadrants of the input image are being written. The features of ***'U'***, ***'V'***, ***'W'*** and ***'X'*** are written in first, second, third and fourth column of ***'InputFile.xlsx'*** respectively.

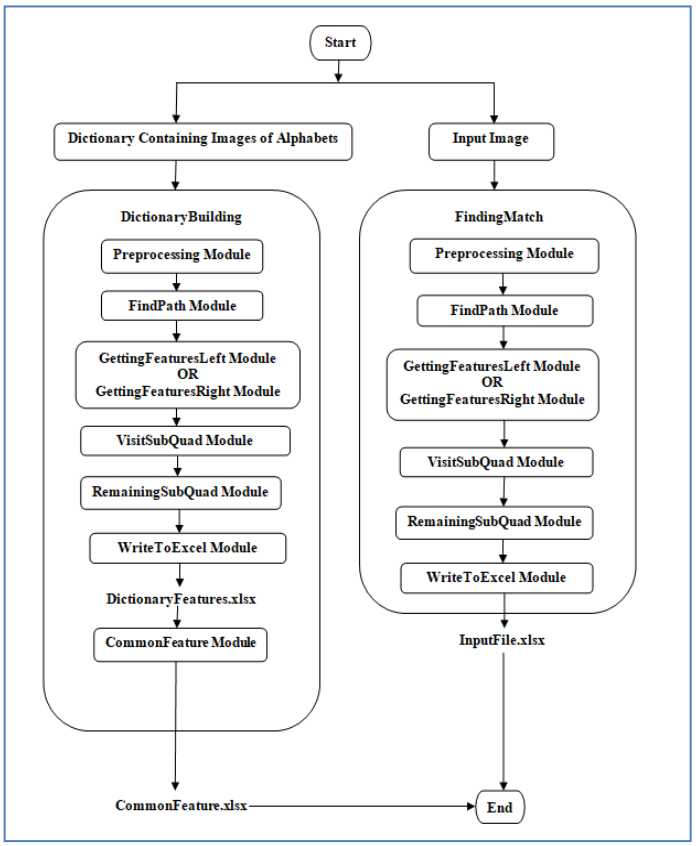

Fig. 5. Feature Extraction for Dictionary of Images and Input Image.

c) GettingFeaturesLeft Module

The steps in this module are same as described in GettingFeaturesLeft module of ***'DictionaryBuilding'*** except that the steps here are applied to W quadrant.

d) GettingFeaturesRight Module

The steps in this module are same as described in GettingFeaturesRight module of ***'DictionaryBuilding'*** except that the steps here are applied to U, V and X quadrants.

e) VisitSubQuad Module

The steps in this module are same as described in VisitSubQuad module of ***'DictionaryBuilding'*** except that the steps are applied to U, V, W and X quadrants. Similar to as explained in the VisitSubQuad module of ***'DictionaryBuilding'***, the quadrants are divided into four sub-quadrants, a, b, c and d. For each black pixel in the continuous trace, the sub-quadrant (either ***'a'*** or ***'b'*** or ***'c'*** or ***'d'***) is found out and appended in ***'subQuad'***. The value of ***'subQuad'*** is returned and set to ***'LSubQuad'*** in ***'GettingFeaturesLeft'*** or ***'GettingFeaturesRight'***, whichever has been called.

f) RemainingSubQuad Module

The steps in this module are same as described in RemainingSubQuad module of ***'DictionaryBuilding'*** except that the steps are applied to U, V, W and X quadrants. If any portions of the quadrants U, V, W and X are not covered by the continuous trace of black pixels, those remaining portions are covered by this module and the name of sub-quadrants (either ***'a'*** or ***'b'*** or ***'c'*** or ***'d'***) are appended in ***'LSubQuad'***.

g) WriteToExcel Module

The steps in this module are same as described in WriteToExcel module of ***'DictionaryBuilding'*** except that the features extracted from the quadrants U, V, W and X are written in an excel file named as ***'InputFile.xlsx'***. The absolute path of ***'InputFile.xlsx'*** is stored in the ***'DataPath'*** parameter and the file name of input image is stored in ***'shortName'***. The value in ***'shortName'*** parameter is written in the fifth column of ***'InputFile.xlsx'.*** Hence, the feature extracted from the quadrants U, V, W, X and the value in ***'shortName'*** parameter are written in the first, second, third, fourth and fifth column of the first row of the excel file, '***InputFile.xlsx'*** respectively and there is only one sheet present in the excel file as there is no sub-directories of the ***'Input'*** directory. For example, the final feature for the input image are:

1st quadrant – aaaaaaaaaaaaaaabbbbbbbbbbbbbbbbbccccccccccccccddd

2nd quadrant – aaaaaaaaaaaaabbbbbbbbcccccccddddddddddddddd

3rd quadrant – ccccccccccccccddddddaaaaaaabbbbbbbbbbbbaaaaaaaaaa

4th quadrant - ddddddddddddddccccbbbbbbbbbbb

2) Recognition

This phase undergoes through three modules: CheckCommonFeature module, MatchCommonFeature module and TraceAnotherDirection Module. The overall process of recognition has been shown in Fig. 6.

InCol: number of columns in the ***'Input.xlsx'***

ComRow: number of rows in the ***'CommonFeature.xlsx'***

'InpPat' is a list consisting of the final features of 1st, 2nd, 3rd and 4th quadrants for the ***'e^{th}'*** row of ***'Input.xlsx'.***

'QuList' is a list consisting of the final features of 1st, 2nd, 3rd and 4th quadrants for the ***'f^{th}'*** row of ***'CommonFeature.xlsx'.***

'MatchFirst' is a list consisting of the file names of the matched features obtained as the output of CheckCommonFeature module.

'MatchedRow' is a list consisting of the row numbers of the matched features in ***'CommonFeature.xlsx'.***

'MatchSecond' is a list consisting of the output of MatchCommonFeature module.

Algorithm:

2. REPEAT STEP 3 WHILE e <= InCol
3. APPEND the feature present in ***'1st'*** row and ***'eth'*** column of ***'Input.xlsx'*** in the list ***'InpPat'.***
4. SET f = 1
5. REPEAT STEPS FROM 6 TO 17 WHILE f < ComRow
6. APPEND the feature present in the ***'fth'*** row and ***'1st'*** column of ***'CommonFeature.xlsx'*** in the list ***'QuList'.***
7. APPEND the feature present in the ***'fth'*** row and ***'2nd'*** column of ***'CommonFeature.xlsx'*** in the list ***'QuList'.***
8. APPEND the feature present in the ***'fth'*** row and ***'3rd'*** column of ***'CommonFeature.xlsx'*** in the list ***'QuList'.***
9. APPEND the feature present in the ***'fth'*** row and ***'4th'*** column of ***'CommonFeature.xlsx'*** in the list ***'QuList'.***
10. ite = 1
11. REPEAT STEPS FROM 12 TO 14 WHILE ite <= LENGTH (InpPat)
12. Param1 = CALL CheckCommonFeature(InpPat[ite], QuList[ite])
13. IF Param1 = 1 THEN GO TO STEP 14
14. Param3 = Param3 + 1
15. IF Param3 = 4 THEN GO TO STEP 16
16. RETRIEVE the file name of the matched image feature present in the ***'fth'*** row and ***'5th'*** column of the ***'CommonFeature.xlsx'*** and APPEND the file name in a list named as ***'MatchFirst'*** and ***'fth'*** row number of the matched image feature in a list ***'MatchedRow'***.
17. CLEAR the list ***'QuList'***.
18. IF LENGTH(MatchFirst) > 1 THEN DO STEPS 19 TO 33
19. SET f = 1
20. REPEAT STEPS FROM 21 TO 33 WHILE f <= LENGTH (MatchFirst)
21. APPEND the feature present in the ***'(MatchedRow[f])th'*** row and ***'1st'*** column of ***'CommonFeature.xlsx'*** in the list ***'QuList'.***
22. APPEND the feature present in the ***'(MatchedRow[f])th'*** row and ***'2nd'*** column ***'CommonFeature.xlsx'*** in the list ***'QuList'.***
23. APPEND the feature present in the ***'(MatchedRow[f])th'*** row and ***'3rd'*** column ***'CommonFeature.xlsx'*** in the list ***'QuList'.***
24. APPEND the feature present in the ***'(MatchedRow[f])th'*** row and ***'4th'*** column ***'CommonFeature.xlsx'*** in the list ***'QuList'.***
25. SET ite = 1
26. REPEAT STEPS FROM 27 TO 29 WHILE ite <= LENGTH(InpPat)
27. Param2 = CALL MatchCommonFeature (InpPat[ite], QuList[ite])
28. IF Param2 = 1 THEN GO TO STEP 29
29. Param4 = Param4 + 1
30. IF Param4 = 4 THEN DO STEPS 31 TO 32
31. RETRIEVE the file name of the matched image feature present in the ***'(MatchedRow[f])th'*** row and ***'5th'*** column of the ***'CommonFeature.xlsx'*** and APPEND the file name in a list named as ***'MatchSecond'***.
32. PRINT 'MatchSecond'
33. CLEAR the list 'QuList'
34. ELSE GO TO STEP 35
35. PRINT the list 'MatchFirst'
36. EXIT

a) CheckCommonFeature Module

When feature extraction of the input image has been completed, features of all the four quadrants U, V, W and X are written in the excel file named as ***'InputFile.xlsx'***. The common feature of a particular alphabet that is extracted from all the features present in ***'DictionaryFeatures.xlsx'*** file has been written in ***'CommonFeature.xlsx'***. The common feature of first quadrant present in the first column of each row of ***'CommonFeature.xlsx'*** is searched to find whether the sequence of common feature is present in the first column of ***'InputFile.xlsx'***. The same search procedure is repeated for second, third and fourth columns of both the files, ***'CommonFeature.xlsx'*** and ***'InputFile.xlsx'.*** In other words, the second, third and fourth columns of each row of ***'CommonFeature.xlsx'*** are searched in second, third and fourth columns of ***'InputFile.xlsx'*** respectively. For this, the CheckCommonFeature(String1, String2) has been used. The presence of common features of ***'CommonFeature.xlsx'*** in the features of ***'InputFile.xlsx'*** in a continuous form or non-continuous form helps to find a correct match. If the features in the first, second, third and fourth columns of ***'InputFile.xlsx'*** are present in the first, second, third and fourth columns of ***'CommonFeature.xlsx'*** respectively in a particular row then Param1 is set to 1 otherwise it is set to 0. If Param1 = 1 then Param3 is incremented by 1. For example, if the value of Param3 is 4 after all the columns of ***'InputFile.xlsx'*** have been checked with the respective columns of ***'CommonFeature.xlsx'*** for all rows, then the file name is retrieved from the fifth column of the row that consists of matched image feature in ***'CommonFeature.xlsx'.*** The file name from fifth column of matched image feature is appended in the list ***'MatchFirst'*** and the row number of matched image feature is appended in the list ***'MatchedRow'***. In some cases, the list ***'MatchFirst'*** have more than one correct match and in these cases ***'MatchCommonFeature'*** module is called.

b) MatchCommonFeature Module

This module is used when the list ***'MatchFirst'*** (output of ***'CheckCommonFeature')*** consists of more than one match. In this module, the common features from the first, second, third and fourth columns of the each row number that is present in the list ***'MatchedRow'*** are retrieved from ***'CommonFeature.xlsx'*** and appended in the list ***'QuList'***. The features present in the first, second, third and fourth columns present in ***'InputFile.xlsx'*** are retrieved and appended in the list ***'Inpat'.*** Then the LCS (Longest Common Sequence) of the two strings, ***'Str1'*** and ***'Str2'*** is found where Str1 = QuList[ite] and Str2 = Inpat[ite], ite = 1, 2, 3, 4 and the resultant LCS is matched with ***'Str2'***. If the resultant LCS gets

a match with ***'Str2'*** then this module returns 1, otherwise 0. The return value of this module is stored in Param2. If Param2 = 1 then, Param4 is incremented by 1. This process is done for each item present in the list ***'MatchFirst'***. If Param4 = 4 for an item in ***'MatchFirst'*** then that file name is copied to the list ***'MatchSecond'***. According to the research, the ***'MatchCommonFeature'*** selects the correct match from the multiple matches in the list ***'MatchFirst'***. But if for some images, both the modules of ***'Recognition'*** result in multiple matches or no matches, then ***'TraceAnotherDirection'*** module is called.

c) TraceAnotherDirection Module

This module consists of two parts '***DictionaryAnotherWay'*** and ***'FindingMatchAnother'***. For extraction of features from the dictionary of images stored in the directory ***'Dictionary'***, the ***'DictionaryAnotherWay'*** undergoes same modules as in ***'DictionaryBuilding'***, the only difference being the direction of tracing of the continuous black pixels in the '***FindPath'*** module in ***'DictionaryBuilding'*** for the four quadrants. The modified direction of the tracing of the continuous black pixels is shown in a module named ***'FindPathAnother'***.

row = Number of rows of quadrant

col = Number of columns of quadrant

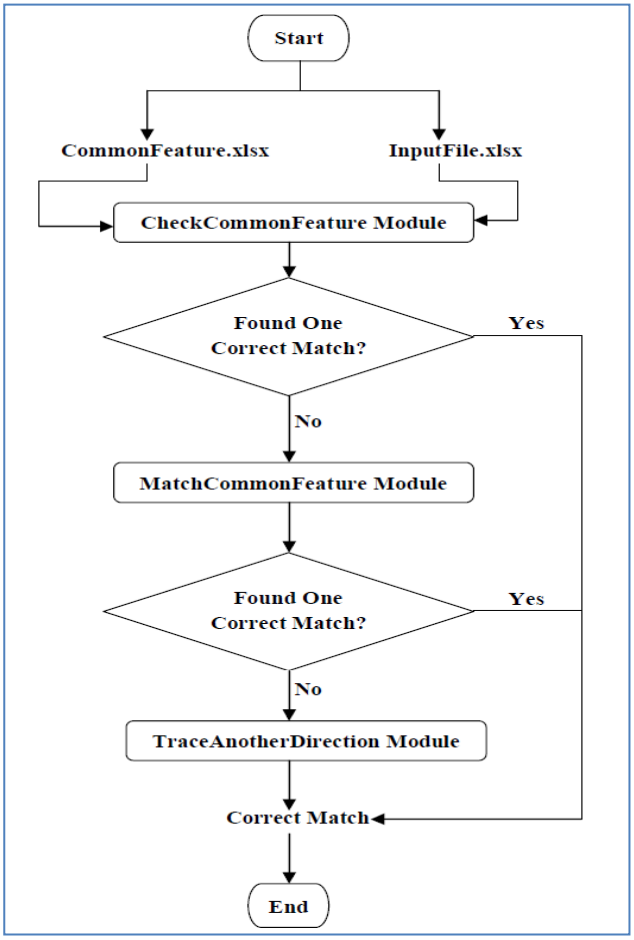

Fig. 6. Recognition of Input Image.

Algorithm:

FindPathAnother(quadNo, quadrant, DicItem, DicInnerItem, DataPath, shortName)

1. SET I = 0
2. SET J = col – 1
3. IF quadNo = 1 THEN GO TO STEP 4
4. REPEAT STEP 5 WHILE J > 0
5. REPEAT STEP 6 WHILE I < row
6. IF quadrant[I][J] = 0 THEN GO TO STEP 7
7. CALL GettingFeaturesLeft(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
8. SET I = row – 1
9. SET J = col – 1
10. IF quadNo = 2 THEN GO TO STEP 11
11. REPEAT STEP 12 WHILE I > 0
12. REPEAT STEP 13 WHILE J > 0
13. IF quadrant[I][J] = 0 THEN GO TO STEP 14
14. CALL GettingFeaturesLeft(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
15. SET I = 0
16. SET J = 0
17. IF quadNo = 3 THEN GO TO STEP 18
18. REPEAT STEP 19 WHILE I < row
19. REPEAT STEP 20 WHILE J < col
20. IF quadrant[I][J] = 0 THEN GO TO STEP 21
21. CALL GettingFeaturesRight(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
22. SET I = 0
23. SET J = col – 1
24. IF quadNo = 4 THEN GO TO STEP 25
25. REPEAT STEP 26 WHILE I < row
26. REPEAT STEP 27 WHILE J > 0
27. IF quadrant[I][J] = 0 THEN GO TO STEP 28
28. CALL GettingFeaturesLeft(I, J, quadrant, quadNo, DicItem, DicInnerItem, DataPath, shortName)
29. EXIT

'FindingMatchAnother' finds a correct match from the '***CommonFeature2.xlsx***'(output of ***'DictionaryAnotherWay').*** For Feature extraction, the input image present in the directory ***'Input'*** undergoes same modules as in ***'FindingMatch'***, except the direction of tracing of the continuous black pixels in the '***FindPath'*** module in ***'FindingMatch'*** for the four quadrants. The modified direction of the tracing of the continuous black pixels is shown in a module named ***'FindPathAnother'***. The same modules of ***'Recognition'*** are used for finding a correct match. As per the research, the ***'TraceAnotherDirection'*** gives a correct match for the input image.

IV. Results

This paper deals with recognising a printed Odia alphabet in an image which is created by scanning a document or document converted to image by using a software, both

written in a font family ***'AkritiOriAshok-99'*** in a particular font size. The font sizes that have been considered are 18, 20, 22, 24, 26, 28, 32, 48, and 72.

To achieve recognition of an Odia alphabet, the system explained in this paper is divided into two parts; one is ***'DictionaryBuilding'*** and other is ***'FindingMatch'.*** The ***'DictionaryBuilding'*** takes a directory ***'Dictionary'*** (consisting of images of Odia alphabet), undergoes through several modules to extract features from images present in ***'Dictionary'*** and the extracted features are written in an excel file, ***'DictionaryFeatures.xlsx'***. The common feature found out from the extracted features in all font sizes for each Odia alphabet (***'DictionaryFeatures.xlsx'***) is written in an excel file, ***'CommonFeature.xlsx'***. The ***'FindingMatch'*** takes an image of Odia alphabet as input and the alphabet can be in any font size of font family ***'AkrutiOriAshok-99'***; features are extracted from the input image and the extracted feature is given as input to ***'Recognition'***. The Recognition finds a correct match for the input image.

The Lenovo ideapad 310 Laptop with 64-bit Windows 10 Operating system, 4GB RAM and Intel(R) Core(TM) i5-7200U CPU @ 2.50GHz 2.70 GHz have been used for the system. The JetBrains PyCharm Community Edition 2019.1 as Integrated Development Environment (IDE) and opencv-python 4.1.1.26 libraries has been used to implement the system.

For testing, an image of Odia alphabet is given as input to the ***'FindingMatch'*** to find a correct match. Nine font sizes have been considered for this research and 200 images of Odia alphabet of each font size making a total of 1800 images are provided as input to ***'FindingMatch'*** one at a time. The percentage of correctness has been shown in Fig. 7.

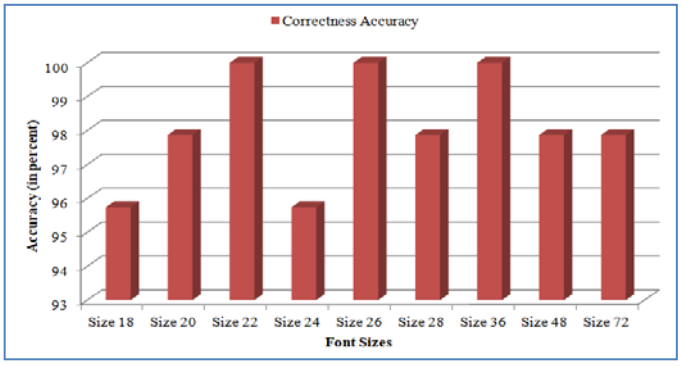

Fig. 7. Correctness Accuracy of Odia Alphabets in Different Font Sizes.

For feature extraction, [22] and [23] had used Water-Reservoir Principle to get the shapes of the characters and numerals respectively; [24] had divided the characters into nine zones and traced the shapes in each zone; [25] had found out the centroid of the character and then the angle between the centroid and the pixel to trace the shapes of the characters; and [26] had first found out some low-level strokes to detect the high-level strokes and using these strokes, the shapes of the character had been traced. The proposed approach has also traced the shapes of the characters by first dividing the character into four quadrants and then scanning each quadrant in different directions to get the features in string format. The proposed system has also been compared with the systems in [22], [23], [24], [25] and [26], and the results have been tabulated in the Table I.

TABLE I. ACCURACY COMPARISON OF PROPOSED APPROACH WITH OTHER APPROACHES

Accuracy Achieved by the Approaches in Related Work				**Accuracy Achieved by the Approach in this Paper**
Approaches	**Language**		**Accuracy**	
[22]	Handwritten Odia	Isolated Characters	98.6%	98.1%
		Two-Character Touching Components	96.7%	
		Three-Character Touching Components	95.1%	
[23]	Handwritten English Numerals		94.8%	
[24]	Printed Odia		92%	
[25]	Printed Odia		91.3%	
[26]	Printed Gujarati		96.87%	

It has also been found that alphabet Chota U (ଉ) is recognised as Bada U (ଊ) in some font sizes because they have very little difference in their structure. The system faces the same challenge for the alphabets Ra (ର) and Ru (ଋ).

V. CONCLUSION

The approach described in this paper goes through two parts. First part deals with building a dictionary and the second part deals with finding a match for the image given as input. In the first part (***'DictionaryBuilding'***), a dictionary of images consisting of alphabets in the font family ***'AkrutiOriAshok-99'*** and in different font sizes are prepared. Then features are extracted from the images and written in an excel file, ***'DictionaryFeatures.xlsx'***. LCS has been used to find the common feature from the extracted features and the common feature has been written in an excel file, ***'CommonFeature.xlsx'***. The second part deals with finding a match for the image that is given as input. In second part, features are extracted from the input image and matched with the feature present in ***'CommonFeature.xlsx'***. In some cases, if more than one match or no match is found then the four quadrants of the input image have been scanned in another direction. The overall correctness accuracy of the system has been achieved as 98.1%.

As the proposed approach recognises Chota U (ଉ) as Bada U (ଊ) and Ra (ର) as Ru (ଋ) in some font sizes, hence, further research can be done in future to eliminate this disadvantage. Elimination of this problem may increase the accuracy percentage. Moreover, research can be done to reduce the number of phases of the proposed system which may increase the efficiency of the system.

Enhancement of Design Level Class Decomposition using Evaluation Process

Bayu Priyambadha[1], Tetsuro Katayama[2]
Interdisciplinary Graduate School of Agriculture and Engineering, University of Miyazaki, Miyazaki, Japan[1, 2]
Faculty of Computer Science, Universitas Brawijaya, Malang, Jawa Timur, Indonesia[1]

***Abstract*—Refactoring on the design level artifact such as the class diagram was already done using the threshold-based agglomerative hierarchical clustering method, specifically class decomposition. The approach produced a better cluster based on the label name similarity of attribute and method. But, some problems emerge from the experiment result. The negative Silhouettes element still exist in the cluster. And, there is an unusable cluster that only consists of one attribute element. This paper has proposed the evaluation process to optimize the result of clustering. This evaluation process is an additional process that aims to move the negative Silhouettes element to the other cluster. The movement is also to get the better value of element Silhouettes value. The evaluation process can produce a better result for clusters. The clusters produced from the evaluation process have higher Silhouettes values. The average Silhouettes value is increased by about 40%. Ultimately, the result shows no unusable cluster as mentioned in the previous research.**

Keywords*—Refactoring; design level refactoring; software refactoring; class decomposition; software quality

I. Introduction

Refactoring the software design artifact is essential to maintain the design's internal structure [1]. Changes or alteration to the design artifact is easier than source code. The easiness is because of the original character of the model. The model is easy to change because the model is an abstract description of something more detailed. Refactoring at the design level means the refactoring activity is using the software design artifact as an object. The easiness of alteration and simulation of quality measurement using the specific metric is one of the benefits of refactoring software design artifacts. The software design artifact is a model bridging the requirement and implementation artifact and is the center of the software development process [2]. The changes will impact both sides, requirement and implementation artifact. In the case of software maintenance, refactoring activity is one way to decrease the maintenance cost [3], [4]. In the case of software development, the refactoring activity can be used as the evaluation process to maintain the internal quality of the design artifact before it is implemented into the source code. The design level refactoring increases the quality awareness of the design artifact as early as possible.

Shifting the object of refactoring activity to a higher level of abstraction has a specific problem. There is a limitation of information in the design artifact rather than the implementation artifact [5]. Therefore, excavation or mining and in-depth information analysis of the design artifacts are necessary [6]–[8]. Generally, the information on the design artifact is only written on the artifact. Sometimes, the information contains a hidden meaning that needs extra analysis to mean it. Natural language processing or semantic analysis is one approach that provides the functionality to gain the meaning of information [7]. Different from that, the source code level information clearly defines a specific element. The software developer can easily use it as data to analyze and measure quality, for example, the number of operand or operators in the source code to measure the complexity of the source code. The developer also can easily know the relation between attribute and method by reading the internal source code. They can figure it out by looking at the assigning value statement to the specific attribute.

Refactoring activity begins from the existence of the smell in the software artifacts. The smell is the indicator that there is something wrong in it. The quality of the artifacts decayed because of the smell. Finding the smell in the artifact is the first activity before refactoring itself. Researchers have already researched the smell detection process in the software artifacts. Smell detection mostly uses the source code as an object, known as code smell detection. Nowadays, the design of smell detection has started to emerge [9]–[11]. The terms and characteristics between code and design smells are different. The differentiation is based on the object, and the information lies in it. But, the previous research tried to use the code smell term and characteristics to find the smell in the design artifacts [8]. As a result, the Blob smell is detected using the class diagram information. Semantic analysis was used to determine the relation between class elements based on the name labels to enrich the class diagram information.

Blob smell is one of the lacks of internal structure quality indicators. It indicates the greedy process of the class. One class has a lot of process in it, whereas the other class nearby is only the data provider. The blob class monopolizes data processing provided by the nearby classes [8]. This phenomenon can happen due to software changes or the developer's lack of clean architecture theory. The clean architecture theory explains that the class must comply with the Single Responsibility Principle [12]. During the development or evolution cycle, the class has to have only one reason to change. The reason to change is related to the process or functionality of the specific class. If the class has more than one function or manipulates many operations, it will be the candidate that there is much reason to change it during the software cycle.

Furthermore, the blob class in the software system will increase the maintenance cost because it affects the class's

understandability [13]. The refactoring activity can resolve the problems of the Blob class. One of the refactoring processes to solve the blob class problem is class decomposition. Mostly, a source code became the field of the class decomposition process. Much research has been conducted using source code information on the class decomposition process. Shifting the decomposition process to the design level is interesting due to the possibility of decreasing the cost of the change, easiness of change simulation, and early quality awareness.

Class decomposition is the process of separating one class into many classes. The decomposition is based on the specific characteristics defined before the separation process. Many researchers proposed the class decomposition mechanism at the source code or design level. Most of the class decomposition mechanism approach uses the clustering process [13]–[19], in which the elements in the class are separate based on each element's closeness characteristic. This method aims to make the separation process result following the Single Responsibility Principle concept. The Threshold-based Agglomerative Hierarchical Clustering was tried to implement on both source code [19] and design level artifacts [5]. Each clustering process is based on the metrics generated from each source code and design artifacts. The design level class decomposition on the class diagram uses two metrics, syntactic (syn) and semantic (sem) [5]. Both metrics are calculated by considering syntactic and semantic closeness from the element's label name. Using the closeness of syntactic and semantic of the label name, the Threshold-based Agglomerative Hierarchical Clustering created a more compact cluster compared to the result of clustering on the source code level. The compactness of clusters was observed from the value of the Silhouettes value of every cluster. However, the decomposition results still show the elements with a negative Silhouette value. A negative Silhouette value indicates that an element's distance from the others in its cluster is large. The negative Silhouette elements are considered the worst in the relation with the concept of single responsibility principle. It is important to enhance the element placement mechanism of the negative element. Additionally, some clusters are considered unable to implement because, in case implemented as a class, it will instantiate objects that cannot interact with each other. A cluster with only one element, especially if the element includes a private modifier, is deemed worthless or useless. As a result, it is seen to be critical to incorporate the modifier aspect in the decomposition process.

The validity of the class decomposition's result is important. It is related to the class's applicability when implemented in the real case or source code. The existence of negative elements in the resulting cluster and a single private element in one cluster is a big problem for the applicability of the class. This condition requires in-depth attention, especially to validate the result of the decomposition process. The basic validation mechanism is to move the specific element from the origin cluster to the other cluster. The moving mechanism aims to put the specific element (negative element) to the other cluster to get a better Silhouette value. The other problem is the existence of the private single-member cluster. It also decreases the applicability of the class when it is implemented into the software's source code. In the previous approach, the clustering process is based on the two metrics syn and sem. The addition of other metrics is important to solve the unusable class.

This research is conducted to propose the validation mechanism to solve previous research's problems. The basic idea is to move the elements in the cluster that are not well-positioned. The new metric is proposed to increase every cluster's placement accuracy and compactness. All descriptions of the proposed algorithm of the validation mechanism and the experiment are organized as follows. Section II summarizes the state of the arts of the class decomposition approach. Then continue the description of the class usability and compactness of the class in the decomposition process in Section III. Section IV and V explain the proposed algorithm and the research scenarios. Section VI describes the result and discussion. Then the last is the conclusion and future work in Section VII.

II. Related Work

Many researchers published methods for class decomposition based on a specific type of smell. The research has two object studies, source code, and class diagram. The following section summarizes the history of research in the area of class decomposition.

A. Class Decomposition on Source Code

Bavota et al. presented a number of methods that could be used to decompose classes at the level of source code. Bavota's research history used the two-step decomposition techniques and MaxFlow-MinCut algorithms to extract classes [14]–[16]. The research involved considering both structural and semantic characteristics of the class. There are three metrics used: Structural Similarity between Methods (SSM), Call-based Interaction between Methods (CIM), and Conceptual Similarity between Methods (CSM). According to a study, transitive closure was calculated using metrics based on the values of distance between class elements. The other method uses the graph to represent the relatedness between elements and the weight to represent the closeness between elements. The transitive closure is able to split a Blob class into more than two classes, which is a significant improvement over the MaxFlow-MinCut approach. Furthermore, it can automatically determine how many classes should be extracted from a Blob.

A discussion of metric-based refactoring opportunities identification for object-oriented software systems is presented in an article by Isong Bassey et al. [20]. They conducted a thorough analysis of sixteen (16) primary studies in order to identify the state of the practice in ROI. The purpose of this article is to summarize all existing refactoring opportunities. The analysis was divided into three categories: structural, semantic, and structural and semantic. Using metrics to identify refactoring opportunities is the focus of this paper. Al Dallal's structural approach and Bavota's structural and semantic approaches previously published elsewhere are summarized in this paper.

According to Wang Ying et al., weighted clustering is automatically used to refactor software [13]. This article focuses on class-level refactoring. A network is considered to be a representation of the relationship of dependencies between

methods (as nodes). There are three matrices that illustrate the relationships between methods, (i) attribute sharing (Sharing Attribute Weight/ SAW), (ii) method invocation (Method Invocation Weight/ MIW), and (iii) functional coupling (Functional Coupling Weight/ FCW). A combination of three matrices as well as semantic similarity weights (SSW) is used to compute edge weights. Thus, the most advantageous cluster with the appropriate weight is selected. Wang compares his method with Bavota and Fokaefs. Wang's approach improves cohesion and coupling without affecting the code's behavior. Furthermore, it improves code's understandability, flexibility, reusability, and maintainability.

Mohamed Hamdi discusses the Agglomerative Hierarchical Clustering (AHC) method for class decomposition [19]. The decomposition occurs until classes have a single responsibility iteratively. One of the main challenges is terminating the decomposition process. They define the threshold concept for determining the endpoint during the decomposition process. There are six matrices: Internal Attribute Sharing (IAS), Internal Direct Call Dependency (IDC), Internal Indirect Call Dependency (IIC), Internal Method Sharing (IMS), and External Indirect Call Dependency (EIC). In this case, the weighted AHC results are more beneficial. This approach appeared to be a solution to the problem of the limited number of classes resulting from the decomposition process and the termination state.

B. Model-Driven Software Engineering

Model-Driven Software Engineering (MDSE) uses a software model as the primary artifact of software development [2]. Compared to the implementation artifact (source code), the software model is closer to the problem domain. The model transformation is the heart of the MDSE since the MDSE aims to generate the source code from the models. On the other hand, there is another approach to the development of software called Code-centric Development (CcD). A comparison study between MDSE and CcD has already been done for over a decade. From the review paper by Domingo et al., many researchers have been evaluating the benefit of the MDSE [21]. Some works said that MDSE decreases development time (up to 89%) relative to Code-centric Development (CcD). The other works suggest that the MDSE is suitable for academic exercise. Furthermore, the other works assert that MDSE is also suitable for inexperienced developers. Finally, Domingo et al., based on their review of MDSE, conclude that the MDSE is suitable for academic exercise and inexperienced developers [21].

C. Class Decomposition on Class Diagram

The class decomposition process is shifted to the design level artifact taking into account the ease of change and quality measurement. A similarity score is calculated between the class's elements (attributes and methods) used in the decomposition process based on the metrics that are derived from the information found in the class diagram. There are two approaches to determining the similarity rates between elements of a class: syntactic and semantic analysis. Thus, the two approaches evaluate the similarity of sentences based on their similarity in terms of syntax and meaning. Those metrics are syn and sem. The following formulas are defined for the metrics [5].

$$syn = \begin{cases} 1, & similar\ type > 0 \\ 0, & similar\ type \leq 0 \end{cases} \quad (1)$$

and,

$$sem = \frac{2.wi.|w_1 \cap w_2| + ws.(|s(w_1,w_2)| + |s(w_2,w_1)|)}{|w_1| + |w_2|} \quad (2)$$

where $s(w_1, w_2)$ or $s(w_2, w_1)$ is the number of words that have a synonym relationship between two labels, and $wi = 1$ and $ws = 0.75$ [22]. The closeness or similarity between class elements is calculated using the following formula.

$$Sim(e1, e2) = \frac{syn + sem}{2} \quad (3)$$

The class decomposition process uses the Threshold-based AHC that is used the similarity formula to calculate the closeness between class elements. Based on the previous decomposition result, the static and dynamic threshold AHC clusters are more compact than Hamdi's approach. The compactness of the clusters is measured using the Silhouette value. Based on the results, it is evident that there are certain advantages to be gained, but there are also some shortcomings as well. Decomposition results still show elements with negative Silhouette values. When the Silhouette value is negative, it indicates that the current element is far from the other elements in the cluster. In other words, negative Silhouette elements are considered to be the worst. Negative elements need to be improved in their movement mechanism. Moreover, some clusters are considered unable to implement because their objects may not be able to collaborate. It is considered useless to have a cluster with only one element, especially if the element has a private modifier. This is why the modifier aspect must be included in the decomposition process. Avoiding useless clusters is essential.

III. Proposed Approach

A. Scope of Study

The research focuses on our previous research results using the same dataset as the previous experiment. Two formulas will be proposed to solve the previous problems. Those formulas will be focused on overcoming the negative Silhouette and useless cluster [5] by combining Class Usability ($CUsability$) and Silhouettes value ($s(i)$). The combination of two metrics are used to evaluate the cluster after the clustering process. The whole evaluation process will be proposed as an evaluation algorithm. This study also uses classes that are not problematic to gain other insights in this study.

B. Problem Accomplishment

The previous research's result mentioned that there were two problems found. The first is the negative Silhouette element, and the second is the cluster that is predicted to be unusable. That is why the evaluation process must consider two aspects: the Silhouette value and the usability of the class

(that will be quantified in the form of a metric). The following formula calculates the Eval value ($Eval$).

$$Eval = a.s(i) + b.CUsability \quad (4)$$

$s(i)$ shows the Silhouette value, and $CUsability$shows the class usability value. a and b is the weight that describes the proportion of each value to the evaluation value. $CUsability$ has measured the usability of the class by considering the number of public methods that existed in the cluster. The class is usable if it at least consists of one public method. In other words, if the class has a public method, the class will be able to collaborate with the others (useful). The $CUsability$ is calculated using the following formula.

$$CUsability = \begin{cases} 0 & ,mpub = 0 \\ 1 & ,mpub \geq 1 \end{cases} \quad (5)$$

The $mpub$ is the number of public methods in the class candidate (in the cluster). The silhouette value is calculated using the following formula [23].

$$s(i) = \frac{b(i) - a(i)}{\max(a(i), b(i))} \quad (6)$$

Where,

- $a(i)$ = the average dissimilarity of i to all other objects of A, then,
- $d(i, K)$ = the average dissimilarity of i to all object cluster K, when $K \in Cluster\ and\ K \neq A$,
- $b(i) = MIN\big(d(i, K)\big), K \neq A$.

The proposed evaluation algorithm has the main process of selecting the negative element and then moving it to the other cluster by comparing the Eval value before and after moving. The algorithm will be appended to the previous algorithm as the evaluation process.

C. Preliminary Experiment

Before the algorithm is confirmed, a preliminary experiment is conducted to ensure the performance of the evaluation process. The preliminary experiment uses one study case from the Landfill dataset, Class Transfer (Blob class from HSQLDB). The preliminary experiment is an early evaluation of the proposed algorithm (implementation of the $Eval$ formula) that uses a combination of weights a and b. In the case of Class Transfer, using a combination of weights with the value a bigger than b in the $Eval$ formula, the process was always run because the negative element always existed. As a result, the process of evaluation is never stopped. Based on this result, it was tried to print out the difference of $Eval$ value (before and after moving) every iteration and draw it into the line graph to show the trend. Fig. 1 shows the line graph of $Eval$ value differences in the case Class Transfer using weights $a = 0.9$ and $b = 0.1$. The trend shows that the values are shifted alternately in the mid to late iterations. It seems that the specific element was moved and moved back to the same cluster because the value of Silhouettes of that particular element is always negative in both clusters (origin and destination cluster).

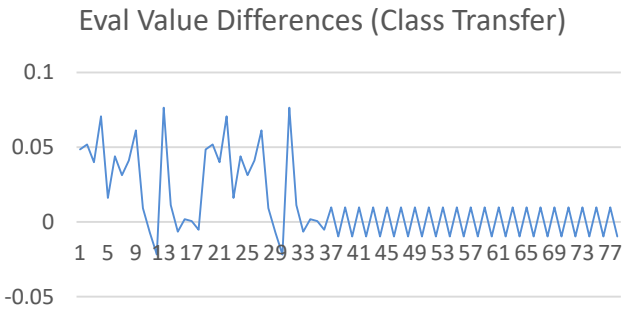

Fig. 1. Eval Value Differences of Class Transfer.

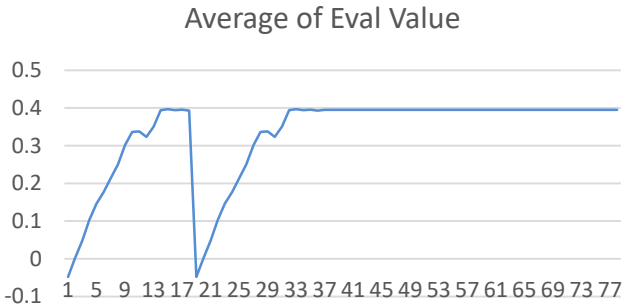

Fig. 2. The Average of Eval Value.

Fig. 1 shows the graph of the Eval value in every iteration. In the middle of the graph, Fig. 1, the data show a pattern that causes the unstoppable process. Even though it shows the pattern, the data seems unstable (continually moving from positive to negative). So, it needs to calculate to get a more stable value. Starting from iteration number 37, the Eval value between before and after moving is 0.00977 and -0.00977. Then, it tried to use the average formula to get a more stable value.

Fig. 2 shows the result after the values are averaged. The graph shows the flat value starting from iteration number 37, and it is easier to use as a termination condition for the algorithm for Class Transfer. The flat value of Class Transfer is about 0.4. The value of 0.4 cannot be used in the other study cases. It is only suitable for Class Transfer. Therefore, it is possible to be different from the other study cases. The other calculation is necessary to find a universal value to get the stopping condition.

D. Stopping Condition of Algorithm

The stopping condition in the decomposition process was the new problem that emerged in the preliminary experiment. One formula that can be used to find the pattern is by calculating the average Eval value between pre and post-movement to the other cluster. The following formula represents how the average of $Eval$ can be calculated.

$$AvgEval_n = \frac{Eval_n + Eval_{n-1}}{2} \quad (7)$$

Where,

- n is the number of decomposition iterations,
- $Eval_{n-1}$ is Eval value before moving to the other cluster,
- $Eval_n$ is Eval value after moving to the other cluster.

The $AvgEval$ for every iteration is represented in a line graph in Fig. 2. The easiest way to find the stopping condition is to calculate the differences of $AvgEval$ between two iterations using the following formula.

$$AvgDiff = AvgEval_n - AvgEval_{n-1} \quad (8)$$

Then the stop condition is represented as follows.

$$StopCondition = \begin{cases} AvgDiff = 0 & ,true \\ AvgDiff \neq 0 & ,false \end{cases} \quad (9)$$

Where,

- $AvgEval_n$ is Average Eval value from iteration number n,
- $AvgEval_{n-1}$ is Average Eval value from iteration number $n-1$.

The main idea of the stopping condition is to find zero (0) differences of $AvgEval$ between iterations. If the differences of $AvgEval$ are zero (0), then it means that there is no increment of Eval value even if the specific element is moved to the other cluster. Then the last position of the cluster will be chosen as the best solution. Fig. 3 shows the line graph of $AvgDiff$ as the representation of the differences of $AvgEval$ before and after movement.

E. Proposed Algorithm

The algorithm is proposed to answer the problems that emphasize the previous class decomposition approach. The new algorithm is the representation of an additional process on the class decomposition. The evaluation algorithm is described in Fig. 4. In the design level class decomposition research, the decomposition process is done by the Threshold-based Hierarchical Agglomerative Clustering. First, two metrics are used to calculate the closeness between elements in the class decomposition process, syn, and sem. Then, the process continues to the evaluation process. That is aim is to evaluate the placement of every element. This process is focused on the element that has the negative silhouette value. The evaluation process's main idea is to move the negative element to the other cluster to get a better silhouette value. The evaluation process is an iteration process that considers the increment of silhouette value and stopping condition that is defined in the previous section.

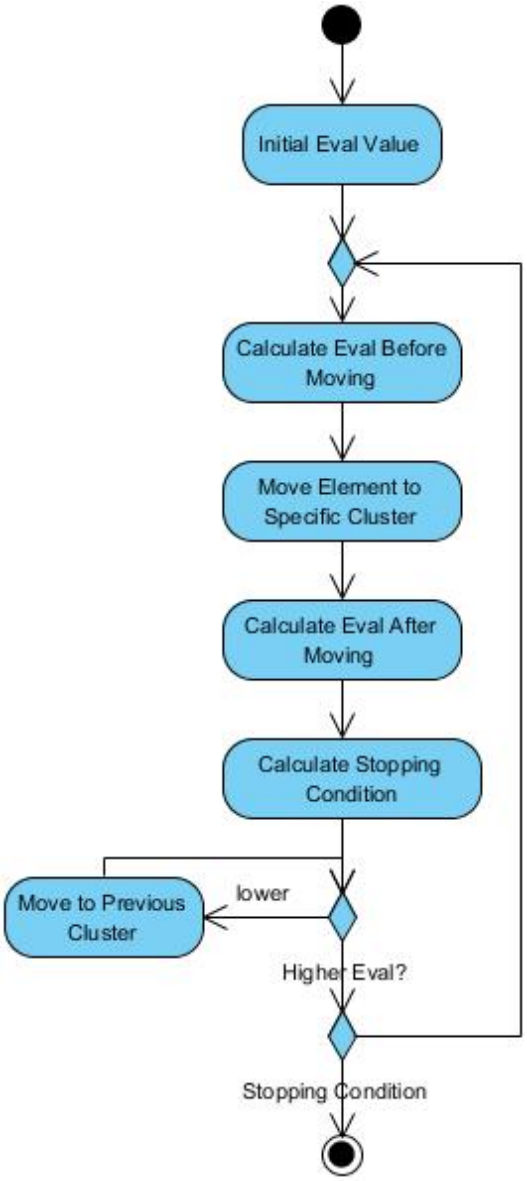

Fig. 4. The Evaluation Algorithm

IV. The Experiment Scenario

The class decomposition experiment uses ten study cases taken from the open-source Java application. The test cases are classes in several open-source Java application that is indicated as Blob smell according to the Landfill smell dataset [24]. Table I shows the list of test cases. All test cases will be decomposed using the threshold-based hierarchical agglomerative clustering and static and dynamic thresholds. Then evaluate using the proposed approach in various combinations of weights. The weights are set to start from a=0.1 and b=0.9 until a=0.9 and b=0.1, with the increment and decrement of 0.1.

The combination of weights has aimed to find the best composition of weights in the class decomposition process based on the compactness and usability of clusters.

TABLE I. List of Test Cases

V. Result and Discussion

A. Result of the Experiment

The proposed algorithm was implemented in the prototype applications. Ten study cases of the Blob class are ready to use to ensure the new approach's final result. All of the classes were decomposed using a prototype application that was already updated using a new algorithm. Every result using the static and dynamic threshold decomposition is described in the following tables (Table II for the static and Table III for the dynamic threshold).

B. Compared to the Previous Approach

In the previous paper, two study cases were used, one of which is MDIApplication class. The result of decomposition using the previous algorithm on MDIApplication (using $a = 0.5$ and $b = 0.5$) is as described in Table IV and V.

In the case of the Silhouette value, using a new approach (after adding the validation process using the $Eval$ value), the result is shown as case number 10 (Tables II and III). There are increments of Silhouettes value of both static and dynamic threshold decomposition. The static threshold increased from 0.08 to 0.274, and the dynamic threshold increased from 0.15 to 0.233. Even though the dynamic threshold has a lower Silhouettes value, the dynamic threshold produces more clusters that match the purpose of single responsibility principles. More clusters are produced using a dynamic threshold.

The other result compared to the previous approach is the useless class. The problem emerged according to the cluster that only has one element (Table V), and the element is private (cluster number 2). The element name is scrollPane which has -0.27 of Silhouette. After updating the algorithm using the evaluation process ($Eval$ value), the result of decomposition is shown as follows (Table VI). The scrollPane element is moved to cluster number five, together with the other element. No clusters are considered unusable after updating the algorithm using the evaluation process.

C. Discussion

The previous section shows the experiment result after updating the algorithm using the evaluation process. Tables II and III show the detail of every combination of weight and express every case based on the cluster, $Eval$ value, and Silhouettes value. The result is different from one case to the other. For example, six cases using the dynamic threshold AHC produced a better value of Silhouettes than the static threshold AHC. Those cases are AudioFile, Interpreter, SVGOutputFormat, Import, and RipCDDialog. The rest of the cases are better using the static threshold AHC. The Silhouettes value is used as the consideration because the cluster requirement results in the high compactness of elements based on the similarity of syntax and semantics.

Higher Silhouettes also show the similarity of the cluster's context to produce the single responsibility class. With the use of the evaluation process, the result of Silhouettes can be increased by at least 40% of Silhouettes. This result shows that the evaluation process can place the elements more precisely by considering the value of the class usability and the Silhouettes. Most of the results show that the combination of weight (a and b) that can produce the best cluster is a higher portion than b.

TABLE VII. ELEMENT'S CHARACTER OF STUDY CASES

Class	A	B	C	D
AudioFile	39	9	30	Dynamic
JDBCBench	33	21	12	Static
Interpreter	65	20	45	Dynamic
SVGOutputFormat	61	9	52	Dynamic
Transfer	80	50	30	Dynamic
Import	30	13	17	Dynamic
StringConverter	16	1	15	Static
RipCdDialog	36	15	21	Dynamic
DefaultDrawingViewTransferHandle	15	2	13	Static
MDIApplication	25	6	19	Static

A: Total element; B: Attribute Element; C: Method Element; D: Approach

TABLE VIII. CORRELATION RESULT

No.	Pair Data	*p*-value
1.	Element - Approach	0.0134
2.	Attribute Element - Approach	0.1645
3.	Method Element - Approach	0.0247

In the specific number, $a \geq 0.7$ is suitable to produce a better cluster in both static and dynamic threshold AHC. Six cases are good using a dynamic threshold, and four cases using a static threshold. This result raises curiosity about whether the class decomposition uses static or dynamic.

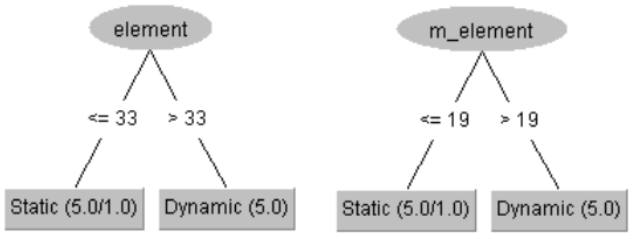

Fig. 5. The Tree Visualization of Tree-Based Classification Analysis

Based on the existing study cases in this research, every studied case is detailed into specific characteristics of class that relate to the element. For example, the number of total elements, the number of method elements, and the number of attribute elements are counted to find a correlation with the type of approach. Table VII shows the detail of the class based on the element.

The correlation between each character to the approach that is used on the class decomposition is counted using a statistical approach. There are three data pairs; the result is shown in Table VIII. Two pairs of data have significant differences. It is determined based on the result of the p-value of each pair. The total element (No. 1) and method element (No. 3) has a p-value lower than 0.05, and the attribute element (No. 2) is higher than 0.05. The total element and the number of method elements are related to the type of approach used in the class decomposition process.

The threshold number that can be used as the decision point for each total element and method element is also interesting. The data of element characteristics were analyzed using the tree-based classification method (Fig. 5). Furthermore, the total element and method element can indicate when the static or dynamic threshold should be used in the class decomposition process. The tree visualization shows the threshold number for each characteristic. The total element and method element have the threshold numbers 33 and 19. If the number of each characteristic is lower than the number, then the static threshold AHC is better and vice versa. This classification analysis result has an accuracy of about 80%.

The statistical and the threshold number analysis is only suitable for the current scope of the experiment. It needs more study cases to make the result acceptable to the larger scope of the experiment.

VI. Conclusion and Future Work

The class decomposition in the level of design is worth doing to support the concept of model-driven software engineering. The optimization of the design level Threshold-based Agglomerative Hierarchical Clustering (AHC) experiment has been done by adding an evaluation process. The evaluation process aims to move the specific element with negative Silhouettes value in every cluster to the other better cluster. The evaluation process is able to increase the average Silhouettes of the cluster compared to the previous approach. The increment of Silhouettes has averaged about up to 40%. The evaluation process is also able to solve the unusable cluster, as mentioned in the previous approach result.

This research experiment takes ten study cases from the Landfill smell dataset. All data consists of Blob smell. Most of the good result of decomposition is using the Dynamic Threshold AHC. Six study cases are good using the dynamic threshold, and four study cases are good using the static threshold. And the best result is produced by using the higher portion of Silhouettes (a) in the Eval formula.

The results were analyzed using a statistical approach to get more valuable information about the result. Three variables are related to the class: the number of total elements, method, and attribute elements. The total element and method element affect the use of the approach (static or dynamic threshold) to get a better result of decomposition. In the scope of the experiment, both the total element and method element have the threshold numbers 33 and 19. A smaller number than the threshold will use static, and a larger will use dynamic threshold.

The design-level class decomposition research is important to be continued in the future. The future plan aims to increase the optimization of the result of decomposition. In this experiment, the evaluation process is a separate process that is in sequence with the previous approach. Merging the algorithms became a consideration for future computational improvements. The increment of study cases number is worth increasing the algorithm's usability. Implementing the decomposition process at the source code level is worth doing in the future. The impact of changes in real implementation is important to study.

***Abstract*—Supply chain management seeks to solve the complex problems of transporting goods from the suppliers to the end customers. Improving the differentiation between different paths to reduce costs and time may require smart systems. This paper proposes two new algorithms for determining, with Multi-Objective Optimization, the least cost and the most appropriate path between two nodes. First: Ant colony optimization (ACO) algorithm, working alongside with Multi Objective Optimization (MOO), is adopted to determine the shortest path and time between two nodes to reach with the least cost. Multi-Objective intelligent Ant Colony (MOIAC) algorithm improves supply chain management to achieve the optimal and the most appropriate solutions. Second: Particle Swarm Optimization (PSO) algorithm, also working alongside MOO, is adopted to determine the least cost, time, and shortest path. Multi Optimization Intelligent Particle Swarm (MOIPS) algorithm improves supply chain management by determining the shortest path with the least cost. These two proposed algorithms seek the optimal solution by MOO using a JAVA Program. The experimental results show the excellence of the first algorithm in determining the optimal and the most appropriate path while getting throw risks inherent in transporting goods. It also demonstrates excellence in transporting goods in the shortest possible time and with the least cost. The second algorithm also shows excellence in transporting goods with the least possible cost via the shortest path and in the shortest time.**

Keywords*—Supply chain management; artificial intelligence; particle swarm optimization; ant colony optimization and multi-objective optimization

I. Introduction

Now-a-days, Supply Chain (SC) networks play a key role among suppliers [1] and end customers. Generally, SC networks involve variant agents such as suppliers, manufacturers, distributors, wholesalers, retailers, and customers [2], beside the interactions between them. SC is more complicated than traditional logistics as it is not limited to the transportation process among variant agents; rather, it has different phases and roles for different agents, such as what is supplied by suppliers [3-5], and what is ordered by customers. SC networks are sophisticated supplier-customer networks encompass agents, information, techniques, activities, [6], and resources. SC networks consist of: suppliers, manufacturing or production factories, stores, distribution centers [7], and customers. This network aims to achieve optimal resource choice to reduce cost and time [8]. SC networks are the main structure of the operations and the interactions among those agents, from the preliminary strategic level [9], to the final operational one. A good practiced SCM is a competitive advantage for organizations working in the field of investment and raising capital. Organizations have variant options in managing such interactions in SC (supplying with goods, assessing products, offering end products to customers) [10-13], according to time, cost, and profit. The problem is that SCM is responsible for a huge number of processes and operations such as production and procurement planning, choosing the optimal product, customer orientation, marketing, distributing products [14], and sales among others. SCM has to balance the SC and each organization's different objectives; some objectives may contradict other objectives in the same organization. So, there must be an appropriate method to coordinate between such objectives taking into consideration that the SC has variant agents in variant phases (i.e. the supplier, the distributor, the seller, and the customer). Suppliers and end customers may have different locations, a thing that may increase the cost of transporting goods in different paths [15-17], and among different nodes to reach the end customer. To achieve this balance among different objectives, companies must consider comparing and differentiating between different timings & time limits and between the added costs for the goods to determine the appropriate path, cost, [18], and timing. Generally, it is clearly noted from previous relevant works and papers that SCM has many dimensions that need to be studied simultaneously to achieve the least cost and [19], the shortest time. In this paper, however, we not only focus on the least cost and the shortest time, but we also try to determine the optimal and the best path alongside with the highest profit while preserving the quality, and improving it if possible. Moreover, this paper focuses on reducing the cost while giving attention to possible risks that may occur in the transportation process. So, we must be precise and careful in improving SCM using the two new algorithms to reach the best possible results, then comparing them to those of other algorithms. Artificial intelligence techniques can help organization improve their objectives) [20]. (the cost - the time limit - the optimal path.In this Work, we use several objectives integrated with AI techniques (i.e. PSO and ACO algorithms)[21-24]. Problem description of SCM covers a wide range of subject. Users, distance, marketing, distribution, least cost path, production and procurement in companies work independently and in parallel in the supply chain. Although each of these companies

has its own objectives and often these objectives are in contradiction with another, so there needs to be a method to achieve these different objectives. We study the problem of the least cost and the shortest time path to improve the transportation process. We propose two algorithms for determining the least cost path: the first algorithm (MOIAC) determines with ZIPF random distributions the shortest and optimal path between nodes to reach to the end customer, while the second algorithm (MOIPS) reduces time and cost in the process of transporting goods from suppliers or producers to end customers. The Main Contribution of the study can be highlighted as follows:

- Solves the problem of determining the optimal path with the least cost to reach the end customer.
- Uses (MOIAC) algorithm to reduce the cost and shrink the distance by choosing the shortest path to the end customer, seeking a balance between the nodes.
- Uses Zipf distributions along with ACO to create random distributions to determine the optimal path to transport goods to the end customer in an appropriate time.
- Uses (MOIPS) algorithm to determine the optimal path to the end customer in the shortest time.
- Apply and test the two proposed algorithms using a JAVA program to verify their superiority over other algorithms.

The rest of this paper is organized as follows. Section I is the introduction. Section II overviews the relevant previous works that addresses the SCs. Section III focuses on the main structure proposed for transporting goods from suppliers to end customers. Section IV focuses on the proposed system; (MOIPS) and (MOIAC) algorithms. Section V introduces the experimental results and compares it with results of other algorithms. Section VI shows the conclusions and recommendations for further research.

II. Related Work

E. Mastrocinque et al. proposes a technique of improving SC using the Bees algorithm with MO to reduce the cost and the time consumed. It also uses the Pareto system to determine the optimal solutions to the problem of cost and time to improve the SC. It proposes new weights in applying the algorithm and compares the proposed system with other algorithms. The results show that the proposed algorithm exceeds other algorithms in reducing the cost and time. This work recommends complicating the problem and improving the Bees algorithm by integrating other objectives in further work [25].

R. Ehtesham et al. improves the SC by integrating other environmental and economic dimensions to the MO. The main goal of this work is to achieve the highest margin of profit by transporting the largest amount of goods, while reducing environmental pollution. This problem has been solved using two algorithms with Multi-Objective Optimization to select the suppliers and to improve the SC. These proposed algorithms have been applied to Mega Motor Company to reduce the cost and time. The results show that the proposed algorithm exceeds other algorithms in reducing environment pollution. This work recommends improving the algorithm using Meta-heuristic and addressing cost and time simultaneously [26].

H. Banerjee et al. proposes a new technique that is using Pareto Optimization in the cases of the uncertainty of the preliminary assumptions. It uses Pareto Optimization with a Genetic algorithm and Mixed-Integer Linear Programming (MILP). It shows some scenarios of avoiding risks in SC systems that are affected directly by the customer's requirements. The work also improves the process of selecting the nearest suppliers to the customers to reduce the total cost and to avoid risks. This methodology proves that the experimental results are better than those of other algorithms in cases of uncertainty. The work recommends using different algorithms to improve the methodology used in the cases of uncertainty [27].

L. Martínez et al. this work proposes the technique of Meta-heuristic using Water Drop with MO to reduce the cost and the time. It depends on Pareto optimization to determine the number of optimal solutions simultaneously. The results show that the proposed algorithm exceeds other algorithms in reducing the cost and time. This work recommends improving the algorithm using the distances between nodes to determine the optimal and the shortest path [28].

S. Gupta et al. proposes a method of an optimal allocation of suppliers and resources with specific products with the help of decision makers. The work divides the decision makers into two groups: the first group is responsible for the goods transported to distributors, and the second group determines the amounts reasonably. The first group is concerned with transporting goods with least cost, while the second group is concerned with reducing delivery time also with least cost. This paper uses Fuzzy with MO to address Conflicting objectives, reaching a compromise in the process of transportation. The results show that the proposed algorithm exceeds other algorithms in achieving the optimal amounts of products in the process of making a decision. This work recommends using Meta-heuristic with Pareto optimization [29].

R. Sun et al. describes the application of Ant Colony with MO in SCM. It addresses a number of objectives such as cost, time, customer service, and flexibility with the goal of improving the SC. The work also introduces MO system to solve some problem to improve the SC. It recommends improving the algorithm and using other algorithms [30].

P. Phuc et al. focuses on the problem of directing the vehicles for logistic services. While delivering a product to the customer, the vehicle has to pass over all the nodes inherent in the network to reach every customer in their lists. The main objective of this work is to reduce the cost of traveling from one customer to another, considering that not all vehicles are similar. ACO has been used to direct vehicles and detect each vehicle's arrival time. The work recommends analyzing more optimal results by integrating MO and using AI to reach the shortest path, considering time and traffic [31].

Y. Wenfang et al. has designed a new strategy to manage the inventory of the SC, manage the marketing process, and improve companies' response speed. It also improves more than one methodology of ACO algorithm with Fuzzy. This work positively influences the efficiency of the organizations' ability to manage inventory in SC. The work recommends using AI to manage inventory to improve SC [32].

X. Zhang et al. developed ACO algorithm with MO using two different colonies to reduce the cost of the goods in the SC. The work also develops a method to determine priorities and weights, detecting the path of transporting goods and the optimal cost. The results show that the proposed system exceeds other algorithms on a large scale in smart cities. Therefore, this work recommends reducing resource consumption to the minimum, and improving the system with other algorithms that can be applied on a larger scale with addressing objectives such as cost, time, and optimal path to transport goods [33].

A. Discussion and Related Works

It is clearly noted from previous studies and articles that is relevant to this field that SCM has many dimensions that has been largely studied to achieve the least cost and the shortest time. This paper does not only focus on reducing the cost and time, but it also tries to determine the optimal and the best path taking into consideration the highest margin of profit and preserving the quality of the product and improving it without negatively affecting the customer or environment. The paper focuses on reducing the cost while giving attention to possible risks that may occur in the transportation process among nodes as presented in Table I. So, we have to be precise and careful in improving SCM using the two proposed algorithms (PSO & ACO) to reach optimal results.

III. PROPOSED ARCHITECTURE FOR SUPPLY CHAIN DESIGN CASE STUDY USING THE SWARM INTELLIGENT WITH MULTI-OBJECTIVE

Presented in Fig. 1, this section describes the proposed structure of the smart system of a SC from the supplier to the customer, where agents are referred to by nodes on the network [11]. In our model, we use a Heterogeneous system with AI techniques and MO to determine the optimal path in transporting goods to reach the end customer, considering time and cost problems. The proposed system consists of (i) suppliers (the first node, from which goods are transported via different types of vehicles and different paths to reach the next node), (ii) distributors (the second node, the wholesaler who receives goods from suppliers, classify them, then transport them to the next node), (iii) retailers (the third node, who finally hand the goods over to the next node), and (iv) end customers (the final node). This is clearly shown in the figure.

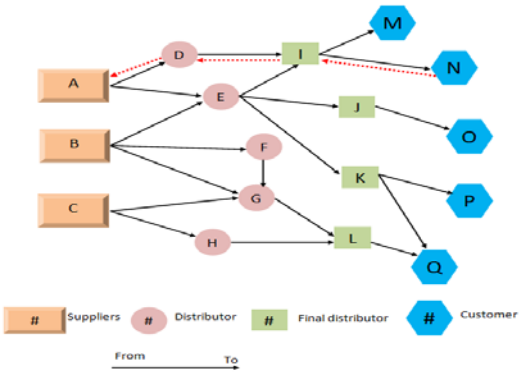

Fig. 1. Proposed Model Architecture for Supply Chain Management Systems.

Determining the location of the optimal supplier to the customers depends on the latter's needs. Choosing the optimal and the shortest path is accomplished using an AI and a number of mathematical equations concerning time, cost, and distance. When goods are to be transported from suppliers to customers, the proposed algorithm determines the optimal path. The proposed system is divided into four parts: (i) using AI techniques to choose the optimal path, (ii) using an improved ACO algorithm with MO, (iii) using a PSO algorithm with MO to improve the system, and (iv) employing the equations of cost, time, and distance among nodes to reach the destination with the least cost. Finally, the proposed system is applied using a JAVA program.

A. Multi-Objective Optimization in Supply Chain

MOO in the SC is improved using AI techniques to determine the optimal and shortest path among nodes. To accomplish such objectives in the SC, cost and transportation systems have to be improved. That is why we integrate the distance equation among nodes to determine the optimal and shortest paths among suppliers and customers [33].

1) Cost: Costs among different nodes are calculated to reach the optimal cost. Costs of transporting goods from suppliers and customers must be low for the variant means of transportation [34]. We need to consider that the system is a Heterogeneous system.

$$\mathbf{Cost}(\boldsymbol{c_i}) = \sum_{i=1}^{n}\left(\boldsymbol{cost}(\boldsymbol{c_{ij}}) * \boldsymbol{demand}(\boldsymbol{d_{ij}})\right) \quad (1)$$

$$\boldsymbol{c_{ij}} \in \{0,1\}, ij = 1,2,\dots,\text{n } Node$$

2) Distance: The minimum distance among nodes is calculated to determine the optimal and the shortest path among nodes in the system to ensure that goods are handed over to the end customers through the path with the least cost and time.

$$\boldsymbol{Min}\ \sum_{i=1}^{n}\sum_{j=1}^{n}\boldsymbol{d_{ij}x_{ij}} \quad (2)$$

S.T:

$$\sum_{\mathbf{i=1}}^{\mathbf{n}}\boldsymbol{n_i x_{i\geq k, x_i\in\{0,1\}\ (1\leq i\leq n)}} \quad (3)$$

3) Time : Time needed to move among different nodes is calculated to reach the optimal time. $LTime_i$ is the time among the nodes, while $_i$ is the time of the node. The goal is to shrink the time consumed when transporting goods among nodes.

$$\mathbf{Demand_i} = \sum_{\mathbf{j\in\{downNodei\}}}\mathbf{Demand\ j, i = 1,2,\dots\dots,nNode} \quad (4)$$

$$\mathbf{LTime_i = Time_{i,xi} + MaxUPLT_i}\ \mathbf{, i = 1,2,\dots\dots,nNode} \quad (5)$$

$$\mathbf{MaxUPLT_i = Max_{j\in\ UpNodei}}\left\{\mathbf{LTime_j}\right\}\mathbf{, i = 1,2,\dots\dots,nNode} \quad (6)$$

Equations (4) and (6) show these functions: the time needed for the SCN to accomplish the work is referred to by T, the total number of the nodes in the network is nNode, the demand quantity of node is $Demand_i$, while the time of the $node_i$ is $LTime_i$. Equation (5) shows the decision vector x with node, where the number of options available for node $_i$ is $Option_i$, and the chosen option of the corresponding node is represented by different values of dimensions. Equation (6) calculates $Demand_i$, where the set of down nodes of node $_i$ is $downNode_i$, and it is previously determined for each customer. Equation (5) calculates $LTime_i$, where the time needed of the node $_i$ to accomplish option $_{xi}$ is $Time_{i, xi}$, the maximum LTime of $upNode_i$, is $maxUpLT_i$ (the set of up nodes calculated as shown in equation (6). The typology of SCN determines the upNode and the downNode.

4) ZIPF Distribution: Zipf distributions create random distributions of goods among nodes. Goods are distributed among nodes according to the different tasks of the suppliers and the end customers [35].

$$\boldsymbol{p(f_i)} = \frac{\mathbf{1}}{\boldsymbol{i^a}} \quad (7)$$

Where i = 1, 2, …, n; and α is a factor of goods distribution, where $0 \leq \alpha < 1$.

IV. Proposed PSO and ACO-based Algorithm for the Supply Chain

A. Multi Objective with Particle Swarm Optimization

The process updates the particle velocity, position and inertia weight is presented in Table II using Eq. (8), Eq. (9) and Eq. (10) as follows [33-36]. We update the velocities for every particle as follows:

$$V_{i,j}^{k+1} = W.V_{i,j}^{k} + C_1R_1\left(pbest_{i,j}^{k} - X_{i,j}^{k}\right) + C_2R_2\left(gbest_{i,j}^{k} - X_{i.j}^{k}\right) \quad (8)$$

Where

$V_{i,j}^{k+1}$ Refers to the new velocity of a particle

$V_{i,j}^{k}$ Refers to current velocity

C_1, C_2 positive constants acceleration parameters

$pbest_{i,j}^{k}$ personal best position particle

$X_{i,j}^{k}$ position of i^{th} particle in j^{th} swarm

R_1, R_2 two random variables in the range [0,1]

$gbest_{i,j}^{k}$ global best position particle

$$\boldsymbol{X_{i,j}^{k+1} = X_{i,j}^{k} + V_{i,j}^{k+1}} \quad (9)$$

Where

$X_{i,j}^{k+1}$ new position of particle

k iteration population

$i \in 1,2,3,\dots,m$ m is the number of members in an iteration

$j \in 1,2,3,\dots,d$ d is the size of the swarm

$$\boldsymbol{w = w_{max} - \frac{w_{max}-w_{min}}{iter_{max}} * iter} \quad (10)$$

Where

w inertia weight

w_{max} initial value of inertia weight

w_{min} final value of inertia weight

$iter_{max}$ maximum number of iterations

$iter$ current iteration number

Accomplishing the mission of reaching the end nodes, the proposed algorithm is proven to choose the optimal nodes to reach the destination by testing the appropriateness of each node according to the agents in the network. The algorithm uses MOO to determine paths with the shortest distance and the least cost and time. The steps of the MOIPS Algorithm are shown in Fig. 2 and (Algorithm 1):

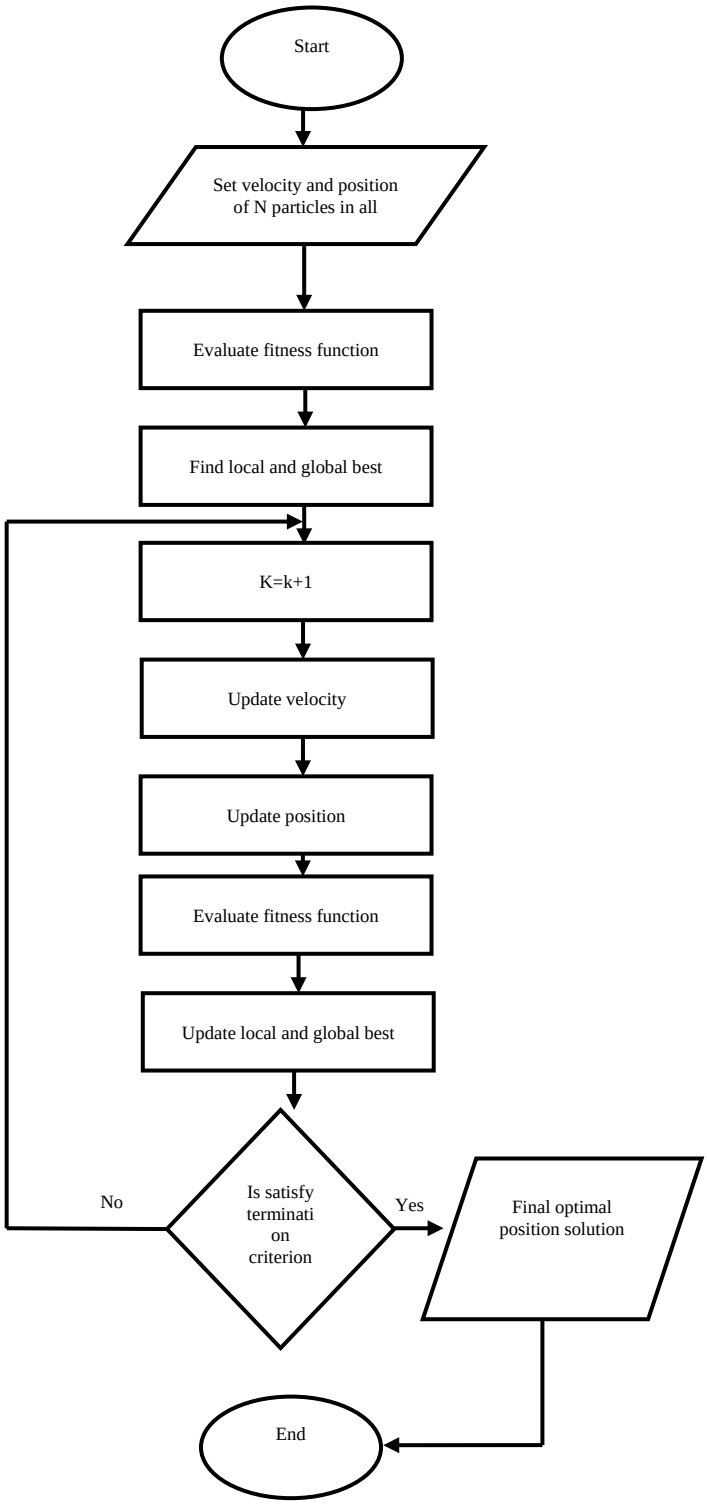

Fig. 2. Proposed Flowchart MOIPS.

Algorithm 1. The Proposed MOIPS

Input: Size α of Population
Number of Iterations
Node
Cost and Time
Distance
Output: Selected $P_{position}$ ← (Optimal $_{Best\ node}$, Optimal $_{Total\ Execution\ Time}$ and Optimal $_{Costs}$)
Initialization:
Define Values of parameters, Size of Pop, Num of Iterations and Num of Particles
Initialize set values of particle swarm (Num of Iteration)
Initialize availability and unavailability probabilities
Initialize best node according to costs and time
Repeat
Count I = 0
For j=1 to α do
For each goods in node do
Calculate fitness function
Update velocity
Update position
$P_{velocity}$ ←Random velocity()
$P_{position}$ ←Random position()
$P_{best} \leftarrow P_{position}$
If $\alpha \leq 0$ then
Exploitation
Else
Exploration
Select best node
End if
Calculate the distance of the node
Calculate the time of the node
Calculate the costs of the node
End for
End for
Until maximum number of iterations is reached, or access solution optimal
Return the optimal best node solution

TABLE II. PSO PARAMETERS

No.	Parameters	Values
1	*Number of particles*	100
2	*C1*	2
3	*C2*	2
4	*R1*	[0 - 1]
5	*R2*	[0 – 1]
6	w_{max}	0.9
7	w_{min}	0.4
8	*Number of iteration*	1000
9	*W*	1
10	*Population (swarm size k)*	50

B. Multi-objective with Ant Colony Optimization

In this section, the MOIAC algorithm is discussed. This algorithm determines the least cost path between nodes depending on time, cost, and optimal distance in order for the supplier to reach the end customer. MOIAC algorithm is applied to choose between one path or another to reach the optimal choice according to the needs of the end customers from the suppliers. MOIAC algorithm is of great benefit in reaching the shortest path with the least cost and time. Both ACO and PSO are types of swarm intelligence. The task of determining the optimal path with the least cost is NP-hard; however, it can be more useful in solving complicated problems than traditional methods as presented in Table IV [9-12]. The positions of the pheromones are calculated on different paths using FF, while moving from one node to another is calculated according to the following:

$$p_{ij} = \begin{cases} \frac{[\tau_{ij}]^{\alpha}[\eta_{ij}]^{\beta}}{\sum_{s\in k}[\tau_{is}]^{\alpha}[\eta_{ij}]^{\beta}} \\ 0 \; otherwise \;\; if \; j \in k \end{cases} \quad (11)$$

The calculation of the next node that is selected by Eq as follows:

$$\boldsymbol{i} = \begin{cases} \boldsymbol{arg\,max_{s\in k}} \{[\boldsymbol{\tau_{ij}}]^{\boldsymbol{\alpha}}[\boldsymbol{\eta_{ij}}]^{\boldsymbol{\beta}}\}, \boldsymbol{if\ q \le q_0}, \boldsymbol{if\ q > q_0} \\ \boldsymbol{j} \end{cases} \quad (12)$$

The calculation of the detection array of the ant proceeds according Eq. (13):

$$\boldsymbol{\eta_{ij}} = \frac{\mathbf{1}}{\boldsymbol{d_{ij}}} \quad (13)$$

The pheromone values on the routes are updated after every repetition. When ants reach the end of their travel path, the pheromone value is a positive constant. The updated local pheromone value can be calculated by Eq. (14) as follows.

$$\boldsymbol{\tau_{ij}} = (\mathbf{1} - \mathbf{p})\boldsymbol{\tau_{ij}} + \boldsymbol{p_{\tau 0}}, \forall(\mathbf{i},\mathbf{j}) \in \boldsymbol{t_k}, \mathbf{where}\ (\mathbf{0} < p \le 1) \quad (14)$$

After evaporation, every ant adds pheromones to the routes according to the set method, and the updated global pheromone value is calculated by Eq. (15) as follows:

$$\boldsymbol{\tau_{ij}} = (\mathbf{1} - \boldsymbol{p}) + \boldsymbol{p}.\sum_{\boldsymbol{k=1}}^{\boldsymbol{m}} \Delta_{\boldsymbol{\tau ij}} \quad (15)$$

$\Delta_{\tau ij}$: is the amount of pheromone added by ant k on their route. It can be represented Eq. (16) as follows:

$$\Delta_{\boldsymbol{\tau ij}} = \begin{cases} \frac{\mathbf{1}}{\boldsymbol{c^k}} \; \boldsymbol{if}\ \forall(\boldsymbol{i},\boldsymbol{j}) \in \; \boldsymbol{t^k} \\ \mathbf{0}\ \boldsymbol{otherwise} \end{cases} \quad (16)$$

$$\boldsymbol{p(f_i)} = \frac{\mathbf{1}}{\boldsymbol{i^a}} \quad (17)$$

Where i = 1, 2, …, n; and α is a factor determining the data access distribution, where $0 \le \alpha < 1$. As mentioned in Table III, notation of ant colony optimization.

TABLE III. NOTATION OF ANT COLONY OPTIMIZATION (ACO)

α	Pheromone trial control parameter τ_{ij}
β	Pheromone trial control parameter η_{ij}
S	Probability for slave ant $\forall s \in \{1,2,3,\dots,k\}$
K	Ants
Q	Random variable uniformly distributed in [0,1]
J	Random variable selected to the probability distribution with $(\alpha = 1)$
I	Currently node i
J	Choose go to node j
P	Evaporation rate
M	Number of ants
τ_{ij}	Pheromone density or node j (amount of pheromone between i & j)
η_{ij}	Heuristic information (importance between nodes i & j) $= 1/d_{ij}$
p_{ij}	Probability ant transits. Currently node i to node j
$p_{\tau 0}$	Initial pheromone
$\Delta_{\tau ij}$	Amount of pheromone that an ant adds to the path it has visited
c^k	The length of tour t^kWhich was built by the Ant k
t^k	Total lengths of path
t_k	Tour by ant k iteration
d_{ij}	Distance between two nodes

TABLE IV. ACO PARAMETERS

No.	Parameters	Values
1	α	1
2	β	2
3	P	0.3
4	Q	1
5	m	110
6	t_k	800
7	$p_{\tau 0}$	0.8

The algorithm determines the optimal nodes using Zipf and calculating the fitness function for each node,

ZIPF distributions are applied to create distributions to reach the optimal nodes and paths. ZIPF is a random distribution that aims to determine the optimal and shortest paths between the supplier and the customer. The function is as follows: The steps of MOIAC Algorithm that aims at improving its distributions are shown in Fig. 3 and (Algorithm 2):

Algorithm 2. The Proposed MOIAC

```
Input: Number of Ants
       Number of Iterations
       nodes
       Zipf Distribution
       Min Distance between nodes
Output: Selected Optimally Best distance (Optimal Best node
       Optimal Total Execution Time and Optimal Costs)
   Initialization:
       Define Values of parameters, Num of Iterations and Num
of Ants
       Initialize distance between nodes
       Initialize costs of nodes
       Initialize time of nodes
   Repeat
     For I=1 to (Num of ants)
         Step = step + 1
         Set all ant distribution in node
       For each node in current system
         Calculate desirability of the movement
         Calculate probability of the movement
          If q ≤ q0 then
             Exploitation
          Else
             Exploration
          End if
       End for

               Then
                Apply the global update rule
               Else if
                Apply this path
               End if
         End for
     End for
   Until max number of iterations is reached or access solution is
found
   Return the optimally best node
```

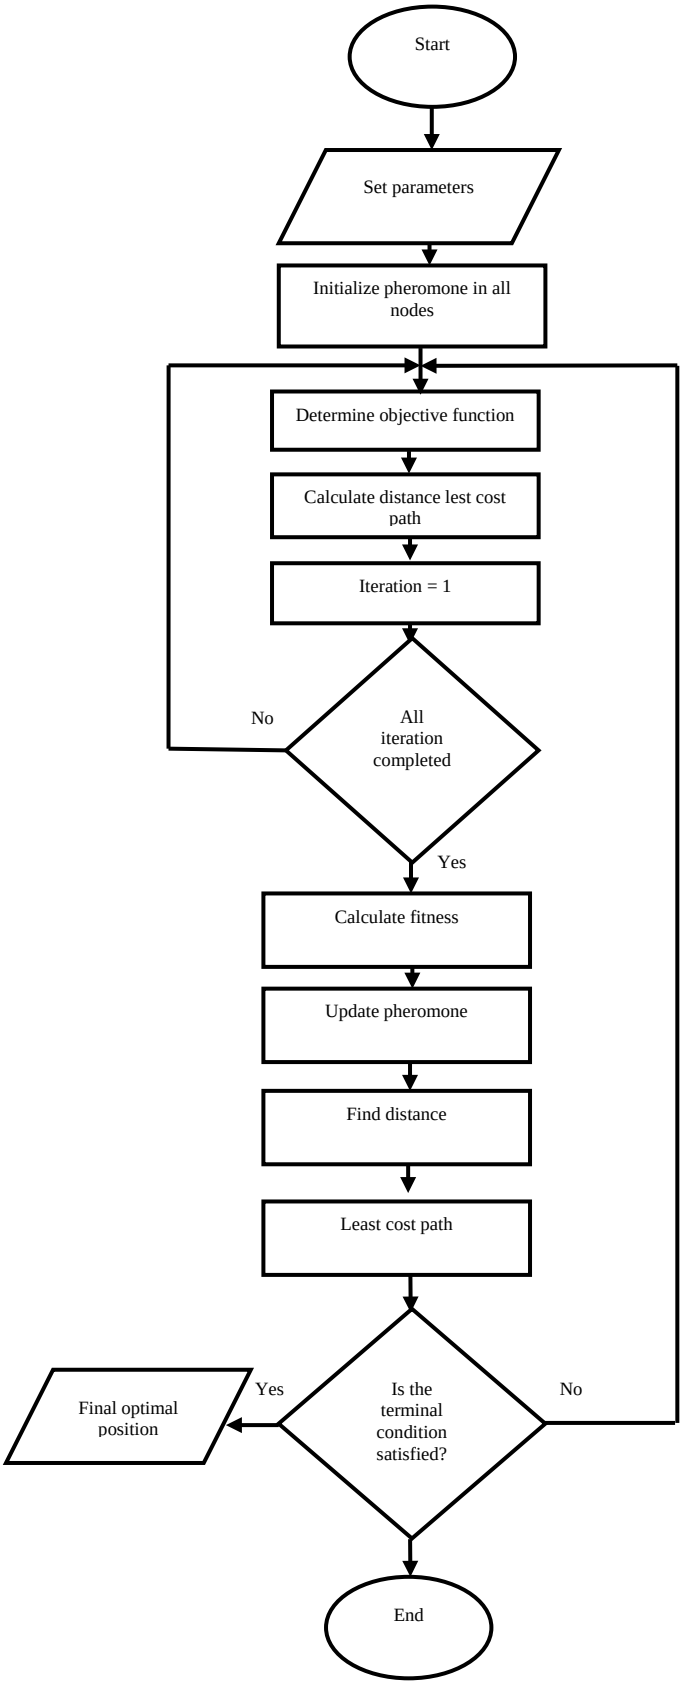

Fig. 3. Proposed Flowchart MOIAC.

V. Results and Discussion

This section discusses the experimental results of the model of determining the least cost path to reach the optimal and the most appropriate path using the proposed algorithms MOIPS and MOIAC in addition to Zipf random distributions. These algorithms are applied on a JAVA program. A comparison between these proposed algorithms and other algorithms has been held on the grounds of the time of their application, the cost, the time consumed, the high availability, determining the optimal and the most appropriate path, and the efficiency of the proposed system. The experiments have been carried out using a JAVA program that provides several classes to simulate and model the proposed system; we improve variant classes for the proposed system.

Fig. 4. Demonstrate the Cost for each Order.

In Fig. 4 compares between three algorithms on the grounds of the transportation rate and cost among suppliers and end customers. The algorithm determines the optimal and the shortest path according to MO with ACO and PSO. The experimental results show that MOIAC algorithm achieves the least cost when compared to MOIPS and MPACA algorithms. It is also the quickest in moving among nodes through the optimal paths. The results also show that the proposed algorithms have proven their excellence over the other algorithms according to the rate of goods transportation to the end customer.

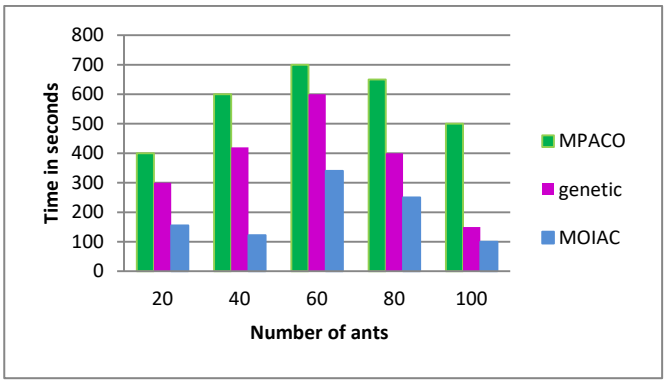

Fig. 5. Task Number of Ants.

Fig 5 shows that the proposed algorithm executes its missions in a lesser time when compared to the other algorithms. It also exceeds the other algorithms' performance when variant numbers of ants and scenarios are addressed. The results show that the proposed algorithm executes the scenario of 100 ants in a lesser time when compared to MPACS and Genetics algorithms.

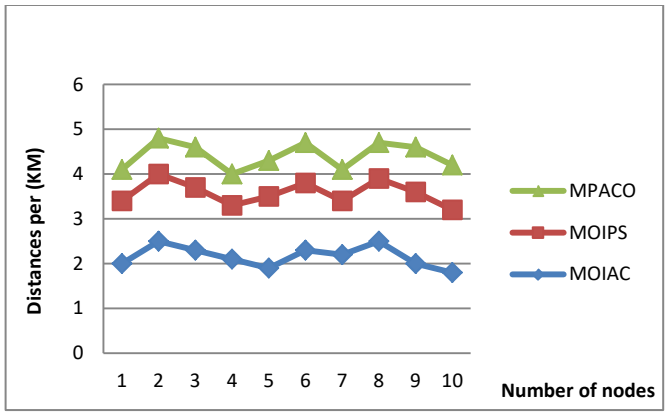

Fig. 6. Distances between the Number of Nodes.

Fig. 6 shows that the relation among the different algorithms reduces the time consumed and the cost of the transportation process done between the suppliers and the end customers using MOPSO and MOACO. The algorithm also considers determining the path with the least cost to reach the end customer. The experimental results show that the proposed algorithm surpasses the other algorithms.

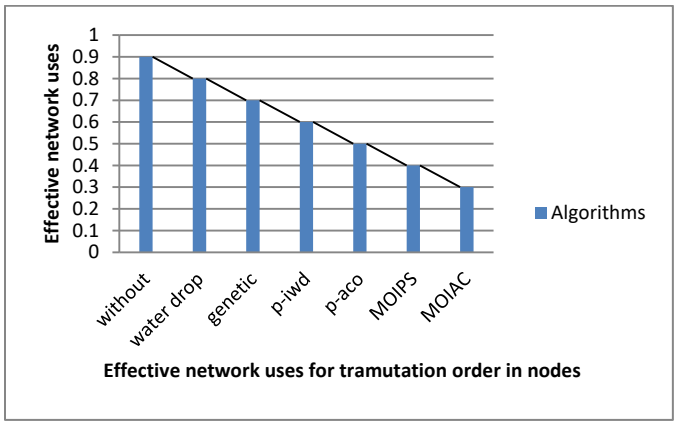

Fig. 7. Effective Network uses for Transmutation Order in Nodes.

Fig. 7 shows an effective version of the network and the percentages of goods crossing the nodes in the range of 0.1 to 1; the system detects the arrival time, the repetition frequency, and the response time among the nodes of the system. The improved bandwidth proves to be more effective with the proposed algorithm; it reaches 0.3 while it reaches 0.9 in the other algorithms. MOIAC algorithm surpasses the other algorithms on the grounds of efficiency, cost, and time.

Fig. 8 shows the determination of the optimal, shortest, and the least cost path among nodes, which positively affects the transportation process among the suppliers and the end consumers. When goods are ordered, the algorithm chooses the optimal, the shortest, and the least cost path among nodes on the proposed system. The proposed algorithm surpasses the other algorithms in the process of determining the optimal, the shortest, and the least-cost path. It is noteworthy that we have

tested the two proposed algorithms MOIAC and MOIPS, and the first surpasses the latter.

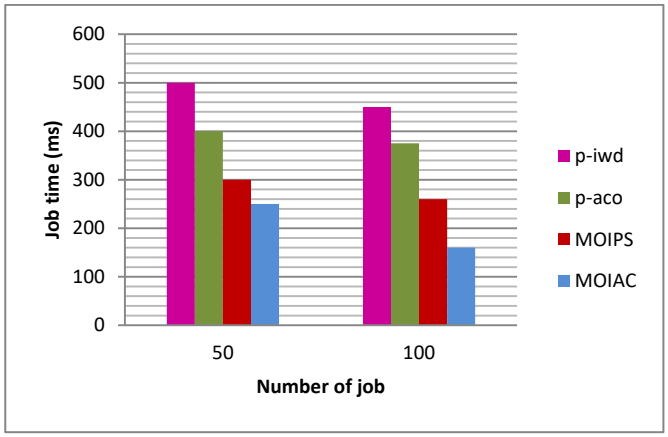

Fig. 8. Distances between the Number of Nodes.

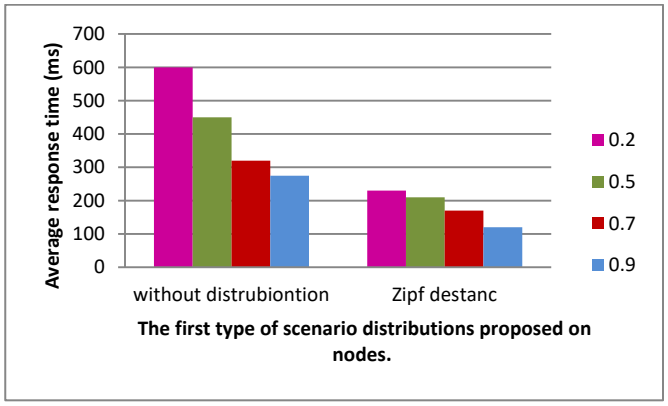

Fig. 9. Average Response Time of Zipf.

Fig. 9 shows the use of MOIAC algorithm with ZIPF distributions to determine the optimal and the most appropriate path to transport goods from the suppliers to the end customers. In determining the optimal path, variant distribution has ranged from 0.1 to 0.9. The experimental results prove the proposed algorithm's excellence in achieving optimal results in creating variant ZIPF distributions.

VI. Conclusion and Future Work

In this paper, we propose two algorithms to solve the problem of determining the optimal path between nodes, improving time-consumption and reducing cost simultaneously. The two proposed algorithms are used with Multi-Objective Optimization to improve the quality of transportation between the supplier and the end customers. MOIAC algorithm is designed to determine the optimal paths (the shortest and the least cost paths) among nodes. ZIPF distributions is integrated to create random distributions to reach the optimal nodes in each process. MOIPS algorithm is also designed to determine the optimal paths while reducing the time consumed in transporting goods from the suppliers to the end customers, and improving the transportation process following the least cost path. The proposed system has been tested on JAVA Program and has been also compared with other algorithms such as Water drop , genetic and bee.

Being integrated with Multi-Objective Optimization in the field of transportation and tested by AI techniques, the simulation results show the efficiency of the proposed algorithms. Many other objectives can be addressed in further works, such as improving means of transportation and reducing resource consumption using the least-cost paths. We also propose addressing other objectives, such as improving the cost, reducing the time consumed between the supplier and the end customer, speeding up the transportation process, and reducing risks. The two proposed algorithms are applicable with other objectives in the field of goods transportation.

***Abstract*—The machine vision-based defect detection for cylinder liner is a challenging task due to irregular shape, various and small defects on the cylinder liner surface. To improve the accuracy of defect detection by machine vision a deep learning-based defect detection method for cylinder liner was explored in this paper. First, a machine vision system was designed based on the analysis of the causes and types of defects to obtain the field images for establishing an original dataset. Then the dataset was augmented by a modified augmentation method which combines the region of interest automatic extraction method with the traditional augmentation methods. Except for introduction of the anchor configuration optimization method, an XML file-based method of highlighting defect area was proposed to address the problem of tiny defect detection. The optimal model was experimentally determined by considering the network model, the training strategy and the sample size. Finally, the detection system was developed and the network model was deployed. Experiments are carried out and the results of the proposed method compared with those of the traditional methods. The results show that the detection accuracies of sand, scratch and wear defects are 77.5%, 70% and 66.3% which are improved by at least 26.3% compared with the traditional methods. The proposal can be used for field defect detection of cylinder liner.**

***Keywords*—Cylinder liner; defect detection; deep learning; machine vision**

I. INTRODUCTION

Cylinder liner is one of the most important parts of engine. Its surface quality will directly affect the working performance and service life of an engine. The surface quality will inevitably deteriorate due to the comprehensive effects of friction, high temperature and corrosion. If there are cracks, sand holes, air holes and other manufacturing defects in the cylinder liner itself, the degradation process will be greatly accelerated. Therefore, defect detection is of great significance in the production process of cylinder liner.

Machine vision inspection technology has the advantages of non-contact, easy to realize automation, and easy to analyze and process the detection results by computer which has been widely used in metal surface defect detection. At present, machine vision based defect detection methods mainly include traditional methods and deep learning methods [1-6]. The traditional machine vision defect detection method constructs the feature descriptors for different defects through image segmentation, feature extraction and other image processing algorithms. Through the descriptors, the surface defects are located, identified, graded, counted, stored and inquired. However, due to the influence of image quality, the complexity of industrial scene, the difference of defect shape and size, the traditional methods still often fails.

In recent years, deep learning based methods have been applied to defect detection of metal surfaces. However, there is no relevant research on how to apply deep learning to detect the surface defects of cylinder liners, and systematically describe the design and implementation of the detection system so far. Therefore, this paper will explore the deep learning based method for the cylinder liner surface defect detection and give the design process and its implementation of the defect detection system.

The main structure of this paper is as follows: the related works in this field are introduced in the second section; the defects types are analyzed and the design method of machine vision system is discussed in the third section; the optimal deep learning model are experimentally determined for cylinder liner defect detection in the fourth section; the design of detection system and the field experiments are given in the fifth section; the last section will summarize this paper.

II. Related Work

A cylinder liner defect detection system based on X-ray and linear array camera was built by Han Yueping of North China University and its key technologies were studied, such as sequence image filtering, threshold segmentation and morphological processing and calculation of defect parameter chain code tracking method [7, 8]. Considering that the probability of defects is low and the defect area is relatively small compared with the whole image, so the cylinder liner X-ray image is highly sparse. The group also proposed the use of compressed sensing algorithm for defect detection [9].

In other metal surface defect detection, the traditional machine vision method is more widely used. A multi-scale defect recognition method was proposed by Yu Jiahui et al. which has good accuracy and detection speed [10]. Tian Hongzhi et al. designed a micro defect detection system for grinding surface by combining plane illumination mode with multi angle illumination mode [11]. Mentouri zoheir et al. employed an improved dual cross algorithm to online monitoring of steel surface quality [12]. Aiming at the problems of complex defect pattern and low contrast between defect and background in steel strip surface defect detection, Liu Kun proposed a total variation image decomposition algorithm based on self-reference template and improved index gradient similarity [13]. Cao Binfang et al. proposed a defect detection method based on spatial-frequency multi-scale block local binary pattern to solve the problem of complex geometry and texture distribution of the nickel foam surface defect images [14]. Sun qianlai uses singular value decomposition to identify and locate surface defects of strip steel without image segmentation [15]. Based on the research on pseudo defect elimination, patch texture description and adaptive threshold segmentation, Liu Kun et al. proposed a new unsupervised steel surface defect detection model based on Haar-Weibull-variance [16]. Jeon Yong Ju et al. proposed the dual-light switching lighting technology to solve the problems of uneven brightness and various defects on the steel surface [17].

The core of traditional methods is to design and use feature descriptors, which include local binary pattern (LBP), histogram of oriented gradient (HOG), gray-level co-occurrence matrix (GLCM) and other statistical features. Feature descriptors are sensitive to lighting, background and other environmental factors. So it is very important to collect high-quality images. Through the optimal design of the imaging system, the difficulty of algorithm development can be reduced and the robustness of algorithm can be improved, but the cost of detection system must increase. Moreover, due to the complexity of industrial sites and the difference of defect shape and size, the failure of traditional algorithms still often occurs.

In recent years, with the successful application of deep learning in many fields of machine vision, more and more researchers are committed to using deep learning for defect detection in industrial field, aiming at improving the accuracy, efficiency, stability and reliability of the detection system. RetinaNet with difference channel attention and adaptively spatial feature fusion was proposed for steel surface defect detection by Cheng and Yu [18]. Zhang Jiaqiao et al. employed a CP-YOLOv3-dense neural network in the steel strip surface defect detection [19]. Xiao Ling et al. [20] proposed a surface defect detection method based on image pyramid convolution neural network model. Wei Rubo et al. [21] proposed a method for steel defect detection based on the fast regional convolution neural network. A steel surface defect detection model based on deformable convolution enhanced backbone network and pyramid feature fusion was proposed by Hao Ruiyang et al. [22].

These above deep learning based methods mainly focus on deep neural network (DNN) model. However, the dataset with support samples is more important than the DNN model. It is often difficult to obtain enough support samples for surface defect detection in industrial field. Therefore, how to improve the accuracy of deep learning-based defect detection method has become a research hotspot under the condition of a small number of samples.

A segmentation-based deep-learning architecture for the detection and segmentation of surface anomalies was proposed and demonstrated by Tabernik Domen et al. which can be trained with a small number of samples. In their experiments, only approximately 2530 defective training samples instead of hundreds or thousands were employed [23]. To address the problem that the existing defect datasets are generally unavailable for on-site deployment due to the limitation of data scale and defect types, Lv Xiaoming et al established a dataset named GC10-DET using a linear array image acquisition system to collect images [24]. To meet the challenge of detection the micro defect from high resolution images, a novel machine vision method was proposed for automatically identifying micro defects by Lian Jian et al. [25] and the main contributions of the proposal can be summarized as follows: 1) a defect exaggeration approach based on regularization, 2) a defect sample production method based on a generative adversarial network (GAN) and a convolutional neural network (CNN), and 3) a data augmentation method based on GAN. A novel approach for data augmentation was proposed by Jain Saksham et al. using GANs to create synthetic images to address the problem of time-consuming and high cost of on-site image acquisition. According to the comparative experiment, the performance of CNN architecture is significantly improved with GANs-based augmentation data and the sensitivity and specificity of the synthetically augmented CNN are 5.59% and 1.12% higher than those of the classical enhanced CNN, respectively [26].

The deep learning method has been employed in metal surface defect detection, but it has not been applied in cylinder liner surface defect detection. Therefore, this paper will take the lead in exploring the deep learning-based defect detection method for cylinder liner, designing a cylinder liner surface defect detection system, proposing a defect detection process, and giving a design case of cylinder liner surface defect detection system.

III. Defect Type Analysis and Machine Vision System

A. Defects Types of Cylinder Liner Surface

As shown in Fig. 1, the common surface defects of the cylinder liners are the sand defect, the crack defect, the wear defect, the oil defect, the scratch defect and the collision defect.

When casting cylinder liner, gas and non-metallic impurities can not be discharged before solidification of liquid metal, resulting in the formation of sand defects on the surface of cylinder liner after machining. The size of the sand defect is small, its contour is usually elliptical and its edge is smooth. Sand defect is one of the main defects of cylinder liner which may appear in any part of the cylinder liner. The existence of sand defects may greatly reduce the impact and fatigue resistances of cylinder liner which is easy to cause cylinder collapse, water leakage and other faults.

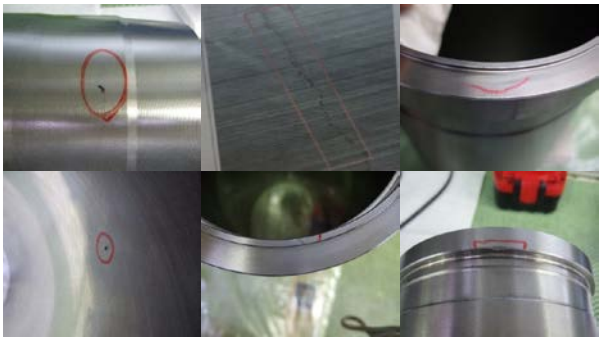

Fig. 1. Common Surface Defects of Cylinder Liner. From the Upper Left to the Lower Right, they are the Sand Defect, the Crack Defect, the Wear Defect, the oil Defect, the Scratch Defect and the Collision Defect.

In the process of machining, the cylinder liners were deformed under the combined action of various stresses. When the deformation exceeds the plastic limit, the slender flocculent or snowflake like cracks may appear on the surface of the cylinder liner. Most of the cracks occur on the inner and outer surface of the cylinder liner which may affect the reliability and replacement cycle of the cylinder liner.

Wear defect usually refers to drag, block or furrow deformation on the surface of cylinder liner during production and transportation. Compared with the normal area, the wear area is generally silvery white. Wear defects usually occur on the end face or outer surface of the cylinder liner which may reduce the sealing, corrosion resistance or wear resistance of the cylinder liner, resulting in the decrease of engine power.

Oil defect is a kind of pseudo defect which is formed by the air evaporation of the cleaning oil or antirust oil left on the outer or inner wall of the cylinder liner. Oil defects are charred black and long drop-shaped in appearance which are prone to false inspection.

Scratch defect is a kind of non-uniform and strip-shaped ravine defect which is caused by the friction between impurities and cylinder liner in the process of processing or transmission. Scratch defects often appear on the inner or outer wall of the cylinder liner which may lead to unreasonable fit clearance improper assembly and other problems, thus reducing the wear resistance and mechanical properties of the cylinder liner.

Collision defect are the falling off or blocky defects caused by the collision between the cylinder liner and the cylinder liner or the fence in the process of transportation. Most of them appear on the upper end face and skirt. Collision defects may reduce the cylinder liner sealing and engine efficiency, shorten the replacement cycle of cylinder liner, and lead to engine damage accidents.

In the field of cylinder liner surface quality inspection, there is no clear standard to identify the types and severity of the above six kinds of defects. However, the sand defect, scratch defect and wear defect are common in most enterprises. Therefore, the deep learning defect detection method with a small number of samples was studied to detect the above three types of defects.

B. Design of Machine Vision System

As shown in Fig. 2, the machine vision system for the cylinder liner defect detection consists of three area array cameras and a linear array camera. Camera 1, camera 2 and camera 3 are area array cameras. Camera 1 was employed to capture the image of top face and its object distance is about 270 mm. Camera 2 was employed to capture the image of the inner wall and its object distance is about 255 mm. The angle between its optical axis and the axis of camera 1 is about 62.5° ± 5°. Camera 3 was employed to capture the image of the skirt and its object distance is about 247 mm. The angle between its optical axis and the cylinder liner axis ranges from 26.5° to 36.5°. Camera 4 which is a linear array camera was used to capture the image of the outer wall and it object distance is between 338 mm to 358 mm.

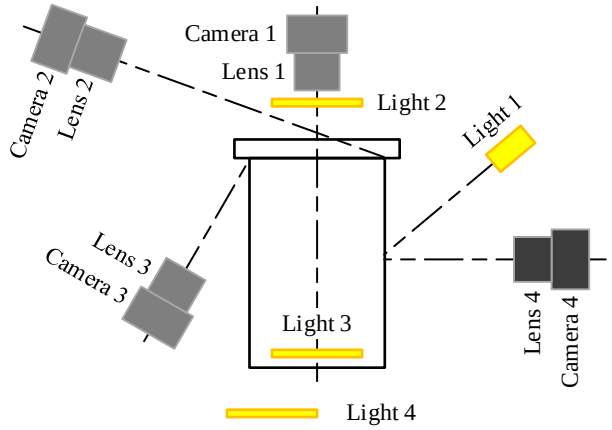

Fig. 2. Schematic Diagram of Machine Vision System for the Cylinder Liner Defect Detection.

The angle between the light 1 and the optical axis of the camera 4 is about 45°. The light 2 is a ring light source, the light 3 is a circular backlight and the light 4 is a ring light source of which the inner diameter is slightly larger than the outer diameter of the cylinder liner. Furthermore, the four light sources were installed at the determined positions.

With the above machine vision system, the images of the top face, skirt, inner wall and outer wall of the cylinder liner were collected, as shown in Fig. 3.

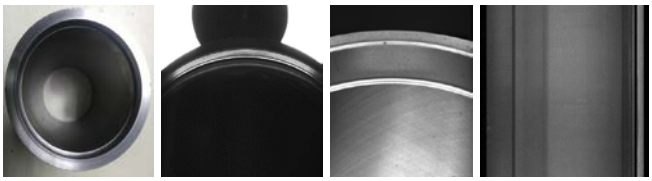

Fig. 3. Images of the Top Face, Skirt, Inner Wall and Outer Wall, Respectively.

IV. Optimal Depth Learning Model for Cylinder Liner Defect Detection

A. Establishment of Image Set

- Image Acquisition

There is no image set for cylinder liner surface defect detection. Therefore, 7500 images of cylinder liner were collected by using the above machine vision system with the guidance of field engineers and the image sizes are 2048 pixels × 2448 pixels. Among these images, 586 were defective. The sand defect images of the top face, the skirt, the inner wall and the outer wall of the cylinder liner are shown in Fig. 4, respectively.

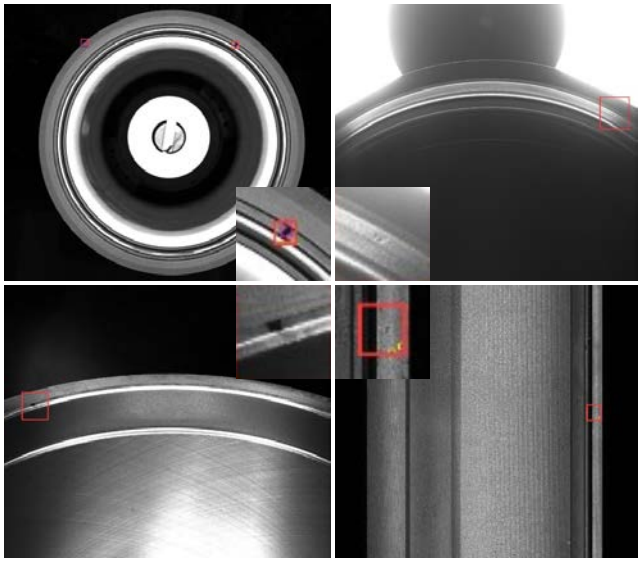

Fig. 4. Sand Defect Images of the Top Face, the Skirt, the Inner Wall and the Outer Wall of the Cylinder liner from Top Left to Bottom Right.

- Imageset Augmentation

The imbalanced datasets will make the results of convolutional neural network over biased to the classification of abnormal targets. In order to alleviate the over fitting problem and enhance the robustness of the network, considering that the cylinder liner image is gray image and the surface defects are small, we use upsampling method to expand the defect sample data to meet the requirements of neural network training data.

The common data augmentation methods mainly include rotation, offset, clipping and scaling. The rotation enhancements are accomplished by rotating the image to the right or left by 30°, 45°, 60° and 90°. The offset enhancements are to move the image around to change the original defect position. When the original image is converted in one direction, the remaining space can be filled with 0. The clipping enhancements are to cut the original image at 30°, 45°, 60° and 90° and fill the remaining space of the image with 0. The scaling enhancement makes the whole image scale in different ratios. In the convolution neural network training, more image invariant features can be learned to improve the detection accuracy.

The augmented dataset contains 5000 images which is basically balanced with the normal sample. The set was divided into the training set, the verification set and the test set by 8:1:1.

- Labelling Defects

Some regions of interest were extracted to reduce the search time of target region and the training time of neural network by the bi-dimensional maximum conditional entropy based threshold segmentation method of which a detailed derivation was carried out in our previous work. The mathematical model of grey entropy is as follows.

$$H(E \mid O) = -\sum_{i=0}^{s-1}\sum_{j=t}^{m-1} p_{ij} \log_2 p_{ij} \tag{1}$$

$$H(E \mid B) = -\sum_{i=0}^{n-1}\sum_{j=t}^{m-1} \tilde{p}_{ij} \log_2 \tilde{p}_{ij} \tag{2}$$

$$H(s,t) = \frac{1}{2}\big(H(E \mid O) + H(E \mid B)\big) \tag{3}$$

where m represents gradient levels of gradient image of gray image, n represents gray levels of gray image, p_{ij} represents the probability that a pixel with higher gradient but lower gray belongs to an edge and $\tilde{p}_{ij}$ represents the probability that a pixel with higher gradient and gray belongs to an edge.

(s*, t*) which makes the objective function H (s, t) take the maximum value is the optimal threshold for segmentation of a grayscale image and its gradient image.

t* was used to segment the cylinder liner image and extract the regions of interest such as the skirt and the top face. Labelimg which is a digital image labeling tool was employed to label the cylinder liner image. The label information is stored in an XML file which contains the image name, the image resolution, the defect size, the defect location and the defect names including the wear defect, the scratch defect and the sand defect and which is shown in Fig. 5.

B. Improvement of Anchor

A differential evolution search algorithm was employed to optimize the aspect ratios and scales of anchors to address the problem that the default anchor configuration turns out to be ineffective for detecting lesions of small size and large ratios [27].

Based on the default anchor configuration, this algorithm finds the optimal anchor setting of three scales and five ratios

through the iteration of the objective function. Suppose that the three scales are s_1, s_2, s_3 and $\varepsilon_1 > s_1, s_2, s_3 > \varepsilon_2 > 0$; the five ratios are β_2:1, β_1:1, 1:1, 1:β_1, 1:β_2 and $\varepsilon > \beta_2 > \beta_1 > 1$; where, ε_1, ε_2 and ε are constants. The optimal scales for detection of small size and large ratio objects are 0.680, 0.540 and 0.425 and the optimal scales are 3.27:1, 1.78:1, 1:1, 1:1.78 and 1:3.27. The anchor sizes remain unchanged which are still 32 pixels, 64 pixels, 128 pixels, 256 pixels and 512 pixels.

C. Determination of Optimal Deep Learning Model

Usually, the deep learning models were evaluated by the indicators of recall, precision and accuracy.

$$Recall = \frac{TP}{TP + FN} \tag{4}$$

$$Precision = \frac{TP}{TP + FP} \tag{5}$$

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{6}$$

Fig. 5. XML File with Defect Information.

AP value was employed to represent the recognition rate of the deep learning model on a certain type of defect, which is equal to the area of the trapezoid enclosed by the *P-R* curve formed by recall and precision and the coordinate axes. mAP represents the average recognition rate of the model on all types of defects and its value ranges from 0 to 1. The larger the value of AP or mAP, the higher the defect recognition rate. The mAP will be adopted to evaluate and determine the optimal target detection model.

Three groups of experiments were carried out to analyse the influence of factors of the detection models, the number of datasets and the training strategy on convolutional neural network. The random gradient descent method was used to optimize the parameters, the loss function was calculated by the softmax layer, the initial learning rate is 0.00001 and the decay rate of the learning rate is 0.1. These configurations remained unchanged in the experiments to ensure comparability.

As shown in Fig. 6, the mAPs of SSD, Faster-RCNN and Retinanet with transfer learning strategy are higher than those of detection networks without transfer learning strategy. Therefore, the transfer learning strategy can shorten the training time and contribute to achieving higher detection accuracy which is suitable for a small number of samples.

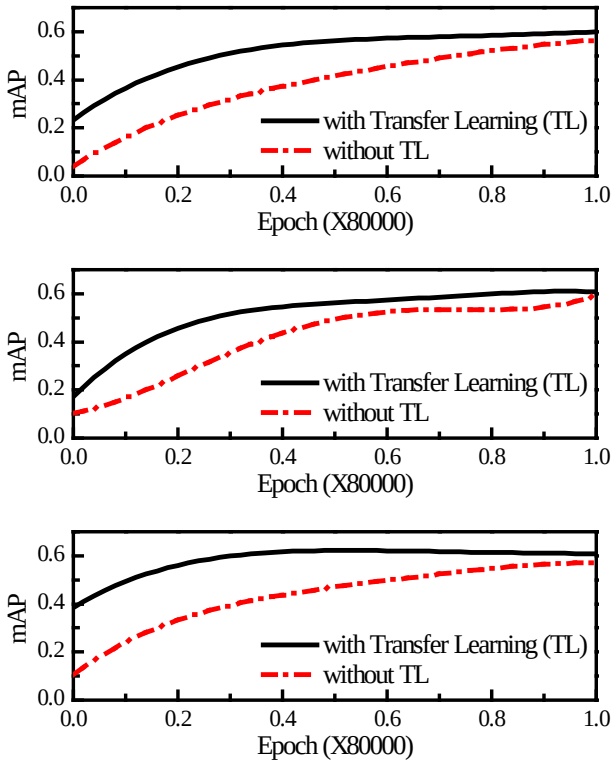

Fig. 6. Influence of Learning Strategy. (a), (b) and (c) is SSD, Faster-RCNN and Retinanet, Respectively.

The performance of the three networks with transfer learning strategy were compared and the comparison results are tabulated in Table I. According to the table, the mAPs of SSD, Faster-RCNN and RetinaNet are 0.597, 0.604 and 0.620, respectively. RetinaNet has the highest detection accuracy. In terms of time, the SSD is the fastest which takes 0.976 s and the RetinaNet is 0.212 s slower than the SSD. The RetinaNet will be employed as the main network for cylinder liner surface defect detection to achieve a good compromise in accuracy and speed.

TABLE I. PERFORMANCE COMPARISON OF THREE NETWORKS WITH TRANSFER LEARNING STRATEGY.

Detection Networks	Time (/s)	mAP
SSD	0.976	0.597
Faster-RCNN	1.360	0.604
RetinaNet	1.168	0.620

Furthermore, the effect of sample size on the performance of Retinanet was compared experimentally. Using 25%, 50%, 75% and 100% samples to train Retinanet, the mAP is 0.11, 0.40, 0.53 and 0.62, respectively. It can be seen that the more samples, the higher the accuracy of the network. Therefore, the data-driven deep learning model needs a lot of data to train its deep network, so as to obtain accurate feature extraction.

According to the above experiments, the Retinanet with the transfer learning strategy will be used for the cylinder liner defect detection.

D. Highlight Defect Areas of Support Samples

RetinaNet with transfer learning strategy achieves the highest mAP, but only 62%. By analyzing the dataset, it was found that the defect area only accounts for 0.25% of an image. However, the Retinanet uses the feature pyramid network (FPN) to produce feature maps with rich semantic. Most of the candidate image windows are background (negative classes) and only a few areas contain defects (positive classes). A large number of background cover up the defects which makes it impossible to fully extract the feature information of small defects in the process of the deep neural network training and finally leads to the low accuracy.

To highlight the defect to improve the detection accuracy, according to the location and area of the defect from the XML file, 100 pixels were extended to the top, bottom, left and right of the defect to form an image window to surround the defect. Then the defect area was updated by the formed window. Compared with the original image, the proportion of defect area was increased significantly and the detection accuracy is expected to be improved, as shown in Fig. 7.

The proportion of the redefined defect area in an image is significantly increased. Therefore, the accuracy of defect detection is effectively improved. Through the above method, the accuracy of Retinanet was improved from 0.62 to 0.71, which was increased by 14.52%. For the sand defect, scratch defect and wear defect, the AP value is 0.78, 0.69 and 0.66 respectively.

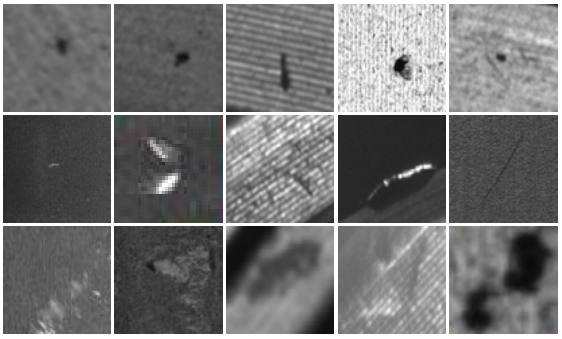

Fig. 7. Extended Defect Area. The First Line, the Second Line and the Third Line Respectively Correspond to Three Kinds of Defects: Sand, Scratch and Wear.

V. DESIGN OF DETECTION SYSTEM AND FIELD EXPERIMENT

A. Configuration of Detection System

The general layout of the cylinder liner surface defect detection system is shown in Fig. 8, the field oriented cylinder liner defect detection system is shown in Fig. 9, and the feeding system and image acquisition system are shown in Fig. 10.

According to Fig. 8 and Fig. 9, the workflow of the field oriented cylinder liner defect detection system is as follows: the cleaning subsystem cleans the cylinder liner; as shown in Fig. 10 (a), the feeding subsystem transports the cylinder liner to the end of the belt to trigger the position sensor; the lifting subsystem grabs and lifts the cylinder liner to the rotary platform accordingly; as shown in Fig. 10 (b), the rotary platform and the cylinder liner are sent to the detection room to complete the whole process of surface defect detection; they are sent out of the detection room and the sorting subsystem pushes the genuine and defective products to the corresponding conveyor belt according to the detection results.

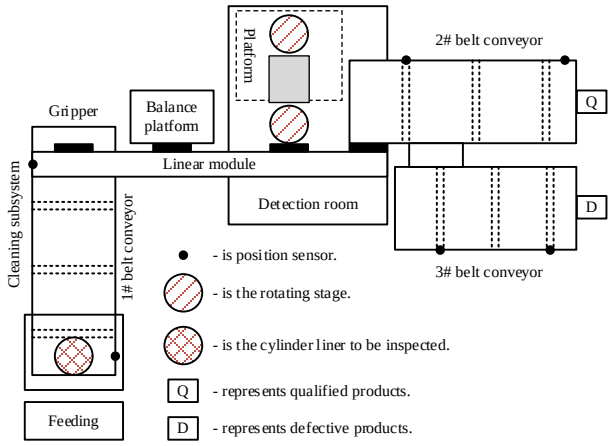

Fig. 8. Framework of the Detection System.

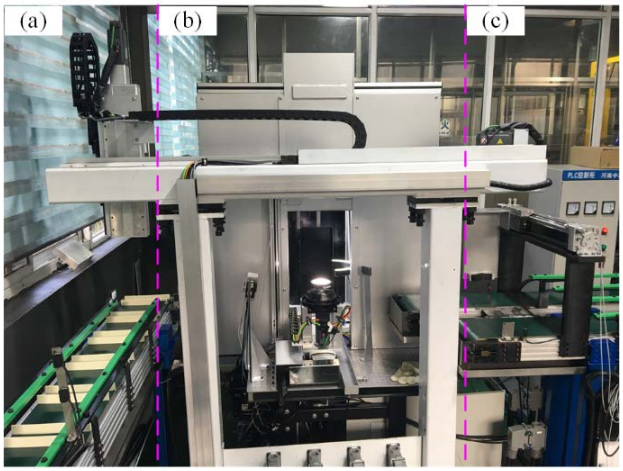

Fig. 9. On Site Cylinder Liner Defect Detection System. (a) is the Feeding Subsystem, (b) is the Detection Room and its Core Part is the Imaging Subsystem and (c) is the sorting Subsystem.

A workstation was used for network model training of which the memory is 256 GB, the model of the graphics card is NVIDIA Tesla P100, the video memory is 16 GB, and the operating system is Ubuntu 16.04. The framework of deep learning is tensorflow. The network model was offline trained by using the above dataset and it was deployed into an industrial-grade server successively.

B. Modular Design of Inspection System

After oil washed, the cylinder liner is easy to adhere to impurities such as lint and dust on the inner and outer walls which may easily lead to misjudgment during automatic optical inspection (AOI). Therefore, a cleaning subsystem was designed which mainly includes the air cylinder, air knife, oil buffer and other parts, as shown in Fig. 11 (a). The air knife forms an angle of 30 degrees with the axis of the cylinder liner to spray high-pressure gas to the surface of the cylinder liner to clean the surface of the cylinder liner and the air knife is pushed by the air cylinder to move up and down with the guidance of the guide rod to achieve the entire surface. The above cleaning process usually needs to be repeated twice. In addition, a shock absorber was employed at the joint between the cleaning device and the cylinder liner to reduce the impact of the start and stop impact of the air pump on the system.

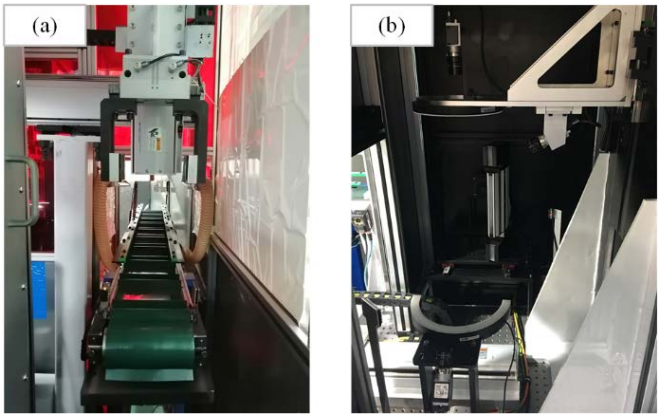

Fig. 10. Two subsystems. (a) is the Feeding Subsystem and (b) is the Imaging Subsystem.

The grasping device is the end executive device of the screw module of which the main design requirements include: (1) the clamping force should be large enough to ensure reliable clamping and avoid displacement or vibration during handling. However, it should not be too large to prevent the cylinder liner surface from being damaged. (2) The central line of the gripper coincides with the central line of the cylinder liner to ensure that the cylinder liner will not collapse during clamping to avoid secondary damage to the cylinder liner. (3) The gripper should be suitable for both D123 and D130 cylinder liners. Therefore, a gripper driven by air cylinder was designed. Oil resistant rubber was pasted on the inside of the claw to increase friction to prevent the cylinder from sliding, as shown in Fig. 11 (b).

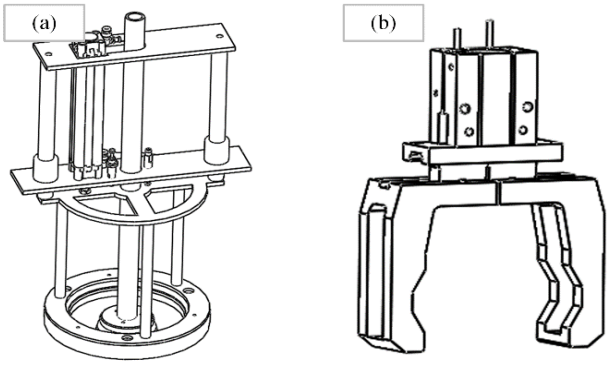

Fig. 11. Two submodular. (a) is the Cleaning Subsystem and (b) is the Grasping Device.

The design of detection room includes the design of rotating platform, as shown in Fig. 12 (a), and internal structure of the detection room. The cylinder liner is clamped on the rotating platform through the central positioning mode and the platform and the cylinder liner is driven to rotate to collect images of the inner and outer cylindrical surface to achieve the defect detection of the inner and outer walls. The higher the center positioning accuracy is, the greater the clamping force will be. If the clamping force is too large, it is easy to scratch texture on the inner surface, causing damage to the inner wall. If the positioning accuracy is too low, the cylinder liner cannot rotate reliably with the platform which affects the image acquisition. Therefore, the diameter of the rotating platform is 4mm smaller than the inner diameter of the cylinder liner and the motor drives the platform to rotate by the PLC. The internal structure design mainly includes the support and mechanical interface design for cameras, lights and rotating platform, as shown in Fig. 12 (b).

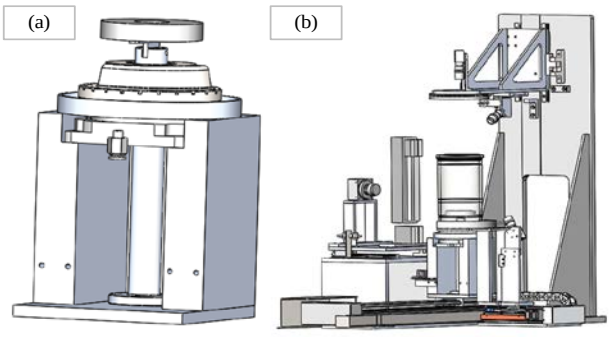

Fig. 12. Two Designs of Detection Room. (a) Rotating Platform and (b) Supports and Mechanical Interfaces.

VI. Experiments and Results

The field experiments were carried out using the network model trained in the third section and the dataset containing three types of defects: the sand, the scratch and the wear defect with 80 images for each type of defect. The experimental results were tabulated in Table II. The detection accuracy of sand defects is 77.5%, that of scratch defects is 70%, that of wear defects is 66.3% and the average accuracy is 71.26%.

TABLE II. Detection Results of Three Types of Defects

Defects	Images	Right	False detection	Undetected	Accuracy (%)
sand	80	62	13	5	77.5
scratch	80	56	15	9	70.0
wear	80	53	17	10	66.3

The comparison results of some traditional non-dedicated defect detection methods and the proposal were tabulated in Table III. The average accuracy of feature point registration-based method is 36.0% and that of morphology-based method is only 27.3%, but that of the method based on deep learning proposed in this paper is 71.3%. Compared with the feature point registration-based method, the proposed method improves the detection accuracies of sand, scratch and wear defect by 51.5%, 28% and 26.3%, respectively. Compared with the morphology-based method, the proposed method improves the detection accuracies of sand, scratch and wear defect by 51.5%, 44% and 36.3%, respectively. The deep learning-based method is more effective for cylinder liner defect detection compared with some traditional non-dedicated methods.

TABLE III. Comparison of the Proposal and Some Traditional Non-Dedicated Methods.

defects	Feature point based method	Morphology based method	Proposal
sand	26.0%	26.0%	77.5%
scratch	42.0%	26.0%	70.0%
wear	40.0%	30.0%	66.3%
mean	36.0%	27.3%	71.3%

The effect of proposed deep learning-based method was shown in Fig. 13. Our proposal can detect tiny defects such as the sand, the scratch and the wear defects, identify the types of defects and locate the defects in the very large cylinder liner images. The detection method can basically meet the actual cylinder liner surface detection requirements of the enterprise to continuously improve the product quality.

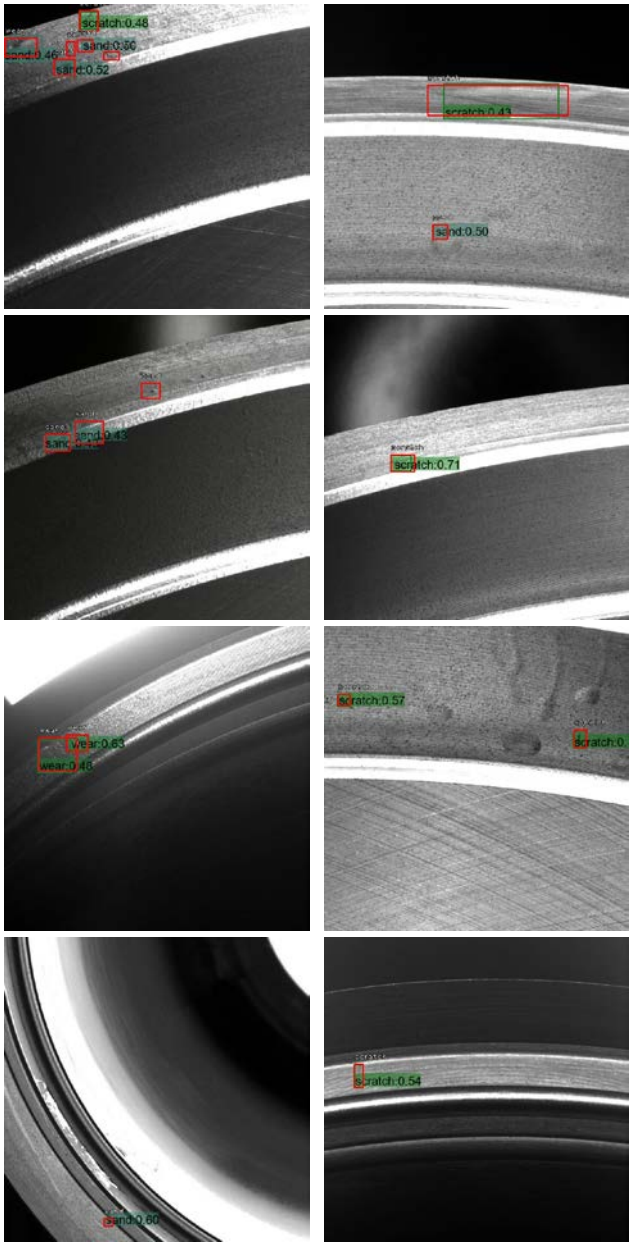

Fig. 13. Some Results of Proposed Deep Learning-Based Method.

However, the detection accuracy still needs to be improved. We can continue our research work from several aspects, such as the updated data sets [28], the motion platform control algorithms [29], the automatic labeling method [30], and the deep network model [31], which is expected to reduce the false detection rate and missing detection rate and further improve the accuracy of our method.

1) The network model can be further trained to improve its fitting accuracy by continuously adding the field data to the dataset to increase the amount of sample data.

2) The accuracy and reliability of the motion platform and its controller need to be further improved to ensure the acquisition of highly reliable images.

3) For the online defect detection, an automatic labeling method needs to be developed to avoid the missing labeling problem of manual labeling and improve the efficiency of defect labeling.

4) The network model can be improved and optimized to further improve its learning ability with a few samples and its detection ability for small defects.

VII. Conclusion

To address the actual needs of the cooperative enterprise, this paper developed a method and its system for cylinder liner surface defect detection based on deep learning. First, a machine vision defect detection system based on the causes and types of cylinder liner defects was built. Then, a dataset augmentation method based on the automatic extraction of region of interest was proposed which effectively increases the number of samples. Next, an automatic extension method of defect region was developed with the XML file which improves the detection ability of our proposal for small defects. After this, the network model and training strategy were experimentally determined and the influence of sample size on detection accuracy was discussed. Lastly, the scheme of implementing cylinder liner defect detection system in industrial field was given and the experiments were carried out. The results show that the detection accuracies of sand, scratch and wear defects are 77.5%, 70% and 66.3% which are improved by at least 26.3% compared with the traditional methods and that our method has achieved preliminary results and effects.

Acknowledgment

All authors express their gratitude to the Editor and the anonymous Reviewers for their valuable and constructive comments. And this research was supported in part by the National Natural Science Foundation of China (Grant No. 51705238) and the Promotion project for Modern agricultural machinery equipment and technology demonstration of Jiangsu Province (Grant No. NJ2021-58).

***Abstract*—The Near Field Communication embedded (NFC-embedded) smartphone consists of two ecosystems, namely Near Field Communication Subscriber Identity Module Secure Element (NFC-SIM-SE) and Near Field Communication Host Card Emulation (NFC-HCE). NFC-SIM-SE places secure elements in smartphones, while NFC-HCE places secure elements in the cloud. In terms of security, the location of secure elements in the cloud is one of the weaknesses of NFC-HCE. The APL-SE transaction model is developed as a solution to improve transaction security with NFC-enabled mobile. This model moves the secure elements of the NFC-HCE ecosystem from the cloud to the smartphone so that when the transaction is made, the smartphone does not communicate with the outside network to access the secure element. The APL-SE transaction model is tested using dummy data to calculate the processing time measurements for each step. The model is also tested for the encryption process. The encrypted data is compared with the original data, then the randomness is calculated. This transaction model is also tested by looking at the data randomness, which shows that the encrypted data is declared random. Random data increases data security. The transaction model test shows that the transaction runs well because the encrypted data is proven random, and the execution time is 1,074 ms. The time of 1,074 ms is far below an attacker's time to decipher the encrypted data. Random and fast encryption results indicate that transactions are secure. This achievement makes the opportunity for attackers to manipulate data small, so security is increased.**

***Keywords*—Transaction; near field communication; mobile; secure element; encryption**

I. Introduction

Smartphones have become tools and facilities that are used daily by people in general. The use of smartphones is not only for communication itself. It is also used for other purposes such as accessing news, doing office work with applications that can be installed on smartphones, and even for business transactions. According to [1], the development of non-cash transactions is increasing from time to time. Nowadays, mobile transaction uses digital wallets. It is already widely used by banks and non-banks [2].

Payment transactions using Near Field Communication (NFC) are an alternative digital payment method. Payments with NFC have advantages in transaction speed, secure storage of card data networks can be deleted remotely [3]. The implementation of devices for transactions with NFC has been carried out, including the existence of a payment authorization system using Near Field Communication - Radio Frequency Identification (NFC-RFID) devices [4]. Payment systems using a cam-wallet also use NFC to communicate with merchants [5]. Smartphones with NFC hardware were around 64 percent in 2018, and NFC-enabled Point of Sales (POS) reached 53 percent globally in 2007 [6].

NFC-enabled mobile communication has two ecosystems [7]. These ecosystems are NFC Subscriber Identity Module Secure Element (SIM-SE) and Host Card Emulation (HCE). NFC SIM-SE performs transactions without an internet connection because Secure Element (SE) is on the smartphone. NFC-HCE requires an internet connection because SE is in the cloud. This condition makes security a significant problem in using NFC-HCE, so appropriate actions are needed to protect payment security. SE being moved to the cloud causes the need to send credential keys from the cloud to the device. However, the NFC-HCE ecosystem that does not need to use a SIM in its implementation can be an advantage and will be more widely applied in the future. NFC-HCE is also a solution in several countries' NFC mobile payment systems, which enforces SIMs produced without SE.

Therefore, this study develops an application-based NFC-HCE Model to optimize the performance of NFC-HCE in a mobile payment system to allow the use of a SIM with or without an SE to securely make NFC mobile payment transactions. The model implements SE in the NFC-SIM-SE ecosystem into the NFC-HCE ecosystem and stays in the smartphone. This model allows communication between devices (smartphones and NFC readers) by implementing a transaction system with the support of a security system. Overall, the model consists of two main parts: initialization and transactions. The initialization stage involves preparing an NFC-enabled smartphone for transactions, namely by registering to the server, both users (smartphones) and cards (one user can have many cards). The initialization model ensures that the credential data is stored in the smartphone safely and verified [8]. The transaction stage contains transactions between NFC from the card owner's smartphone to the point of sales (POS). In this study, the discussion focuses on developing the transaction section, which sends secure data between the cardholder's smartphone and POS, namely APL-SE.

The result of this research is a model that can be developed into a payment system protocol. The model can be used on a small or large scale of payment. Sellers and buyers must have a smartphone that has NFC-HCE facilities. Payment systems at small and large shops that use online payment systems can use APL-SE as a means.

The structure of this paper is as follows. After this introduction, it will present the research on mobile payment systems that have been carried out before. Then it is connected with the study that will be made and its novelty analyzed. The following section discusses the proposed mobile payment system model. This proposed model performs transactions in the NFC-HCE ecosystem that does not connect to the internet because the secure elements are already stored in the smartphone. Thus, the model reduces the risk of data being misused due to the smartphone connected to the server via a public internet network. This model can prevent attacks that occur because of data retrieval at the time of use and stored for use at another time. The model can also prevent attacks that may occur because the retrieved data is used at other transaction times. Then, the model is tested and analyzed to get a conclusion whether the model can prevent the attack.

II. Related Work

Badra [9] uses a user identity accompanied by a random value for authentication. The Badra model uses the NFC-SE ecosystem, which emulates the card. The solution to prevent NFC-related attacks is using certificate-based authentication between PoS and TTP and shared-secret-based authentication between TTP and NFC-enabled devices. The assumption is that the secret key shared between the TTP and the mobile is securely stored in the SE. Its cryptographic calculations are also performed inside the SE. The Badra model uses five stages, is simpler, and can overcome some of the possible attacks.

Poughomi and Grønli et al. [7] proposed the NFC protocol to be implemented on the Web of Things (WoT). This protocol is divided into two parts; the authentication and transaction sections. Transactions from a merchant terminal (POS) to a communication smartphone use NFC and from a smartphone to an MNO using a GSM line with SMS. Currently, the model of communication with SMS done several times is not so popular anymore.

Nashwan [10] proposed a secure authentication protocol for NFC (SAP-NFC). It is a protocol to overcome replay attacks, impersonate attacks, to track attacks, and desynchronize attacks using the registration and authentication phases. This security model uses a hash function and multiple authentications. The SAP-NFC protocol is more likely to overcome attacks because authentication is carried out for each data exchange.

Cossman and Liu [11] proposed two authentication steps. This research shifts the protection of user data to a user-centered approach. The first authentication uses the system keystore, and the second uses a passcode. Meanwhile, the two-factor authentication proposed by Munch-Elinsen et al. [12] is by providing the user with a PIN code twice. This authentication is divided into five phases. The PIN is entered in the first phase, where the user enters the PIN into the application, and in the fifth phase, the user also enters the PIN again to be verified by the POS. The two proposals for two-factor authentication are attempts to secure transactions. Cossman's proposal is simpler because it does not require other parties, while Munch-Elinsen's proposal requires other parties to send and receive SMS.

Cryptography is used to design security tags by consuming less energy. The cryptographic methods used are Asymmetric Cryptography and Symmetric Cryptography; encryption and decryption using Advanced Encryption Standard (AES-128), and digital signature generation using elliptic curve digital signature algorithm. Özcanhan et al. [13] proposed The EKATE protocol. The protocol uses asymmetric encryption for secure data communication. The AES algorithm is used to encrypt the data to be sent to and from the tag.

The relay attack scenario is made on a system that involves smartcards; smartphones on both Relay attacks attack smartphones by changing peer-to-peer mode into Card Emulation mode, then reading the smartcard. The message is captured and forwarded to the proxy device, and the device sends the message as if it were the real owner of the smartphone. These relay attacks occur at the application layer, so they must take real-time countermeasures. Dang Zhou et al. [14] studied relay attacks on NFC by analyzing the weaknesses of ISO / IEC 14443-4 when facing relay attacks. This drawback appears to be quite common to all types of AFC systems that follow this standard globally. Then an experimental relay method was designed and carried out a relay attack. The results show that the protocol is vulnerable to attack. Two counterattacks are also proposed and discussed the feasibility and practicality of these countermeasures. The results show that the attacks carried out successfully generated delays during transactions. Sujithra et al. [15] proposed a data encryption protocol to be stored on a smartphone with three tiers tested in local smartphone and cloud environments. The test results show that in terms of the speedup ratio, the combined algorithm AES+MD5+ECC is better, and the AES algorithm is better in terms of average processing time.

Al-Fayoumi and Nashwan [16] use the registration stage to ensure that NFC devices are registered in the AuC database. This registration stage uses four steps: sending a registration request message containing identity and a random number, AuC generates a secret key based on the parameters in the request message, and a confirmation message is sent back to the NFC device by the AuC. The NFC device executes a derivative function to obtain the secret keys. The authentication phase is the second stage of the secure authentication protocol for NFC mobile payment systems (SAP-NFC). POS and mobile NFC carry out initial authentication. POS generates random numbers and sends them to NFC mobile. NFC Mobile uses this random number to initiate the authentication challenge message. After the message is processed using these parameters, it is sent to the NFC POS. AuC verifies NFC devices with a set of identity and authentication parameters. The design of the SAP-NFC protocol fulfills the following requirements. First, all parties involved in authentication can generate random numbers. Second, the AuC and the NFC device can update the secret key for each authentication session. Third, both the old secret key from the previous

authentication session and the new secret key from the current authentication session of the NFC device will be stored in the AuC database. Fourth, mutual authentication must be carried out between all parties involved in authentication. Fifth, the KDF function (Derivation function) derives the new session key. Sixth, the identity of the party performing the authentication is hidden by a series of hash functions. As a result, the SAP-NFC protocol claims to achieve the highest level of security with mutual authentication, forward/backward secrecy, anonymity, and untraceability. The SAP-NFC protocol can also defeat attacks such as replay attacks, impersonation attacks, tracking attacks, and desynchronization attacks.

Alatar and Achemlal [17] stated that pure HCE has not been trusted for payments but has attracted the attention of Visa and Master cards. It still needs efforts to earn that trust. Asaduzzman et al. [18] stated that NFC is suitable for IoT devices. This paper discusses the protocol for sending data in NDEF format. This protocol uses certificates. Transaction data security is carried out in several ways. The first way is a modified certificate. This method is initiated by requesting a certificate via a handshake and will terminate the transaction if the certificates are not the same. The second way is with modified data. If the signatures do not match, it means that there is a modification to the data, then the data is discarded. There is a hash code matching mechanism between the message and the signed hash. Jamming attacks can be detected in the presence of interference. So, if there is interference, data is prohibited from being stored.

Alzahrani [19] identified an attack with a reapplication tag with TRD by tracking how many times the tag was read. The tag should only be read once when the goods are distributed and reach their destination. The original tag is already considered a second reading if the verified tag is fake. Pourghomi, Piere, et al. [7] developed an NFC protocol that begins with user authentication. You do this by checking the validation by checking the PIN. Then the data is stored in the tamper-resistance chip. All of that is done in the NFC-HCE ecosystem. Wenxing [20] created an NFC communication mechanism to prevent eavesdropping using electronic circuits. As a result, it can reduce the threat of eavesdropping. Fan et al. [21] created a protocol beginning with initialization. At the initialization stage, a pseudorandom generator and key are generated. Then put both in the valid and legitimate reader tags. At the tag identification stage, the reader generates a random timestamp and random number and sends an authentication to the tag. The time received must be greater than the time to transfer, otherwise, authentication is not successful. From the security side, the attack is detected with a timestamp for an anti-DoS attack scheme.

Nour et al. [22] overcome Replay attacks and Man in the Middle Attacks that often occur in NFC-enabled mobile transactions by creating a security protocol. This security protocol is used for mobile transactions. Prevention of replay attacks is done by using random numbers and timestamps. Meanwhile, the prevention of the Man in the Middle Attack is prevented by mutual authentication between the client's payment device and the small merchant's NFC smartphone. This payment architecture can also facilitate mobility because it uses mobile devices and is secure because the proposed protocol can solve EMV vulnerabilities without changing EMV principles.

The use of cards for travel has been used, one of which is AFC payments using LessPay. Fan Dang et al. [23] research shows that tampering with entrance data and relay attacks on AFC cards must be watched. This study simulates the attack and provides a solution for its prevention.

The NFC transaction security protocol was proposed by Ali Al-Haj et al. [24]. This protocol is successful in preventing malicious network attacks such as the impersonation and replay attack, the session key security attack, the brute force attack, and the Man-in-the-middle attack. These attacks are prevented by mutual authentication, non-repudiation of transaction messages, data integrity, confidentiality, data privacy, and validity of Banking Data. This protocol involves actors. The first actor is NFC-enabled mobile. This device is the main device in this mobile payment. This NFC-enabled mobile will communicate with the Management Authentication Server (MAS) to obtain a session key. The second actor is POS. This POS communicates with NFC-enabled mobile for transactions and with the issuing bank (BI) via a secure channel (TLS). The third actor is BI. BI communicates with POS to verify Mobile payments in online EMV transaction mode. The fourth actor is MAS. MAS provides management and authentication for secure mobile payment transactions.

Prevention of attack by brute force was carried out by Madhoun, M et al. [25]. On payment processing, each transaction takes about 500ms; therefore, to achieve this attack, one needs to have access to the client's payment device for 38 minutes. Although NFC is claimed to be able to communicate at short distances (only up to 10 cm), it has been proven that relay attacks can carry out attacks when communication occurs with NFC. The attack is carried out by adding an amplifier to extend the reading distance. This attack can retrieve credential data and use it for online transactions at another time. Authentication to the client is carried out with a PIN that is verified with the PIN data stored on the server in two ways, namely online verification with symmetric encryption and offline with an asymmetric key to the issuing bank or by comparing the PIN stored in the memory of the client's payment device. Verification can also be done with a signature by the client or without the Cardholder Verification Method (CVM). Verification without CVMini is used for fast payments and in small nominal amounts.

The transaction begins by entering the username and password. If the authentication server identifies as a valid user, the server will send a one-time password (OTP). The transaction will time out after a particular time. The user will be notified if the attacker cannot complete the payment process within the specified timeframe (30 seconds for Apple Pay). It not only places a time limit on the attacker but also raises consent issues [26].

Security and user trust issues are issues that are widely discussed in research on NFC-based mobile payment systems. Protocols or models have been built trying to overcome these problems. However, existing models still have gaps in vulnerability to attacks. One of them is an attack carried out during the transaction because of the communication from the

smartphone to the financial institution server. This study reduces this vulnerability by creating a model that does not require communication between smartphones and financial institution servers during smartphone transactions with POS using NFC-enabled mobile. It also has advantages in the amount of data exchange and the absence of communication from smartphones to financial institutions during transactions. This situation occurs in the HFC-HCE ecosystem.

III. Proposed Method

The proposed NFC mobile payment system consists of two stages: initialization and transaction, and this paper focuses on developing the transaction stage. The payment card is declared safe to be stored on the smartphone during the initialization process. The payment card is ready to be used for transaction processing. The transaction model ensures that transactions between the cardholder's smartphone and the POS are safe and correct. The architecture of the proposed model is shown in Fig. 1.

This transaction model puts the security system in the HCE ecosystem into smartphones. A security system is created in the form of an application that will ensure data security and communication between smartphones and POS. The security system refers to the SE hardware inside the SIM card in the NFC-SIM-SE ecosystem. Element identification is made by synthesizing NFC-SIM-SE elements and NFC-HCE elements in the cloud into application elements. Elements in both ecosystems are analyzed and then adapted to security system applications.

This transaction model is a model for data usage. In this model, data security is carried out only when communication is carried out using NFC-HCE. Two things will be prevented. The first is to make data safe from attackers, and secondly, when there is a data request, the data will be sent to the right place. Secure element created we will refer to as APL-SE. APL-SE on smartphones was used for transactions, and at that time, three entities were involved, namely smartphones, POS, and Financial Institutions. This study focuses on the security of transactions between smartphones and POS.

The smartphone and the POS transaction model are carried out with NFC-HCE communication in card emulation mode. In this mode, when a transaction is made, the smartphone and the POS communicate by acting as the initiator and target. When sending data, the smartphone or POS acts as the initiator and the others as the target. This model is shown in Fig. 2.

The first step, POS as a target, sends data on the number of purchases to the smartphone. Currently, POS is the target, and the smartphone is the initiator. The smartphone activates the HCE service and starts the transaction by sending a connection request to the POS. The smartphone taps it for this delivery. The data sent is String data which contains information on the payment amount. This process is shown in Fig. 3.

The transaction model created to enable these two devices enables the HCE service. In the beginning, POS recorded transaction data, then saved the data to a shared preference variable. The smartphone sends a request as an APDU command to the POS, and the POS responds by providing a response that is processing the APDU command. This response brings the amount of transaction data prepared previously by the POS.

In the second step, the smartphone receives the data, then activates the SE software. Notification of approval to POS is done by sending card data to POS. The smartphone verifies the request from the POS, then activates the smartphone application. The smartphone application requests a pin from the user, and this pin is stored in the data stored on the smartphone during the initialization process. When a pin is entered, it is matched utilizing a pin stored in an encrypted state, decrypted first, and then matched with the input data. If the pin matches the data, the process is continued. Otherwise, it is closed. Currently, smartphones are the target, and POS is the initiator. If the pin is correct, an RSA encryption key (KeyRSA) will be generated. The selected card is retrieved data, then stored in a JSON Object (JSON (Dcard Key data and files, which are already stored during the initialization process, are encrypted (Enkr(Dtrans)). This encrypted transaction data is sent to the POS (ED).

In the third step, after the POS receives the card data, the POS verifies the card data to the financial institution server and gets an approval notification if the data matches. POS as the initiator and financial institutions as the target, the data sent from the smartphone is received by the POS and then decrypted. Previous data plus payment data.

$$Dtrans = Duser + Dpay \quad (1)$$

The data is encrypted by the POS and sent to the Financial Institution.

$$Etrans = E(RV, Dtrans) \quad (2)$$

In Financial Institutions, data is decrypted and matched with customer data. The authorization code is encrypted (OT) if the Financial Institution is verified. If it is not verified, an unverified message is sent. Financial Institutions send data or notifications to POS.

In the fourth step, the POS executes the payment and sends a notification to the smartphone if the transaction has been successful. POS is the initiator, while the smartphone is the target. Authentication data and smartphone data are decrypted, as are user data decrypted. Next, the payment process is carried out. The process is completed by sending a notification to the smartphone. Currently, POS is the initiator, and the smartphone is the target.

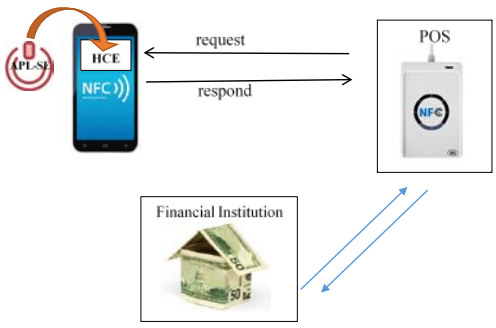

Fig. 1. APL-SE Architectural Design.

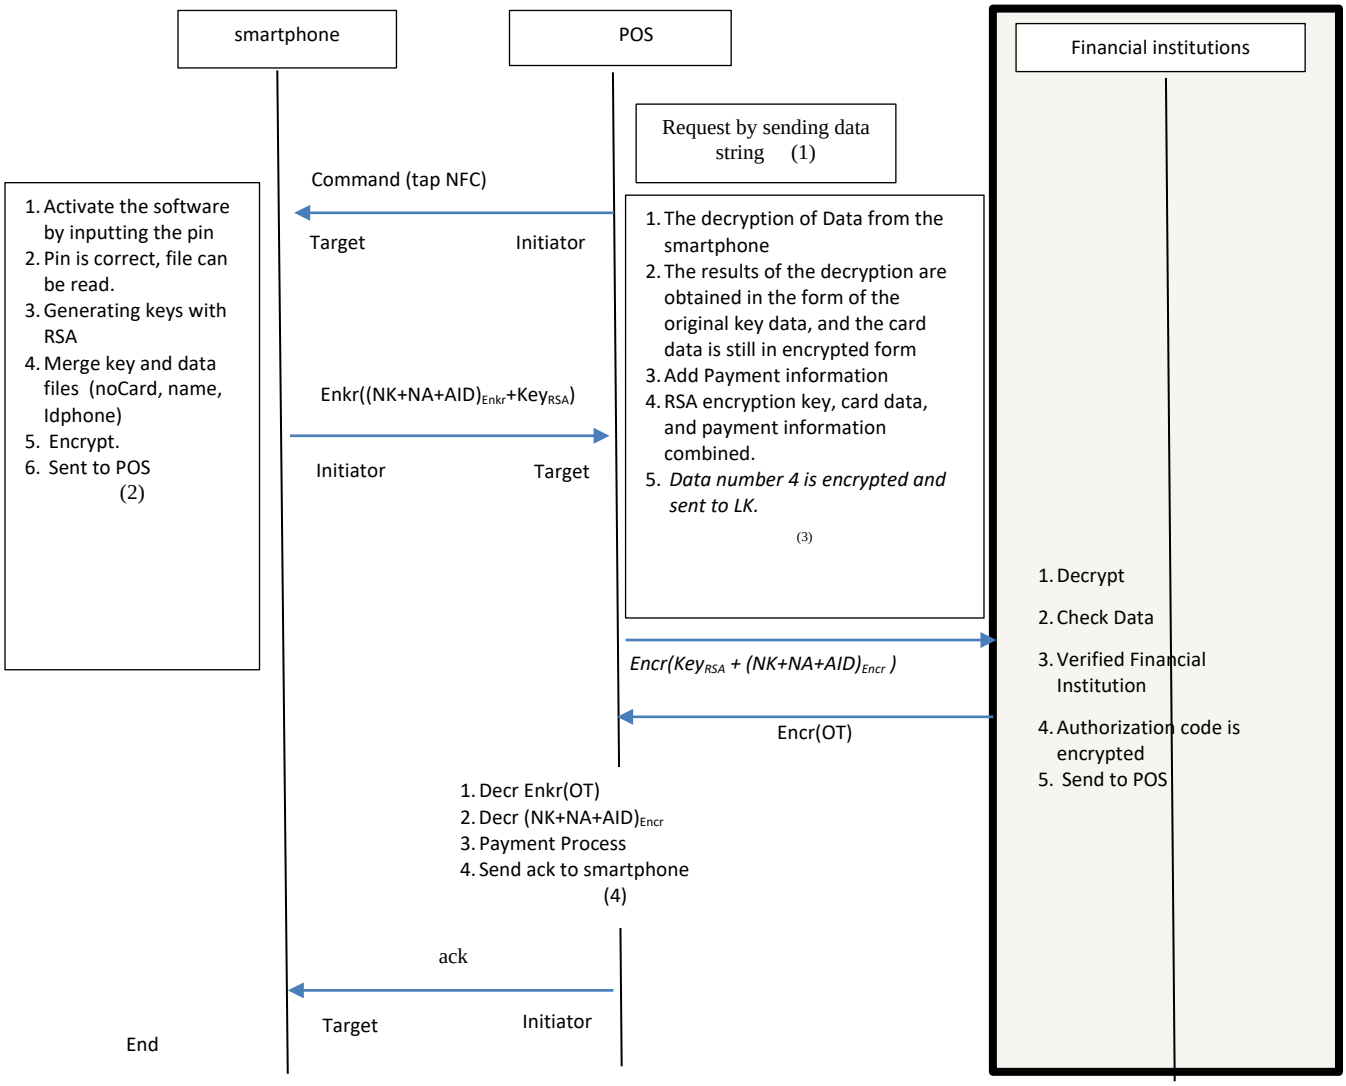

Fig. 2. NFC-HCE Transaction Model without Internet Connection between Smartphone and POS.

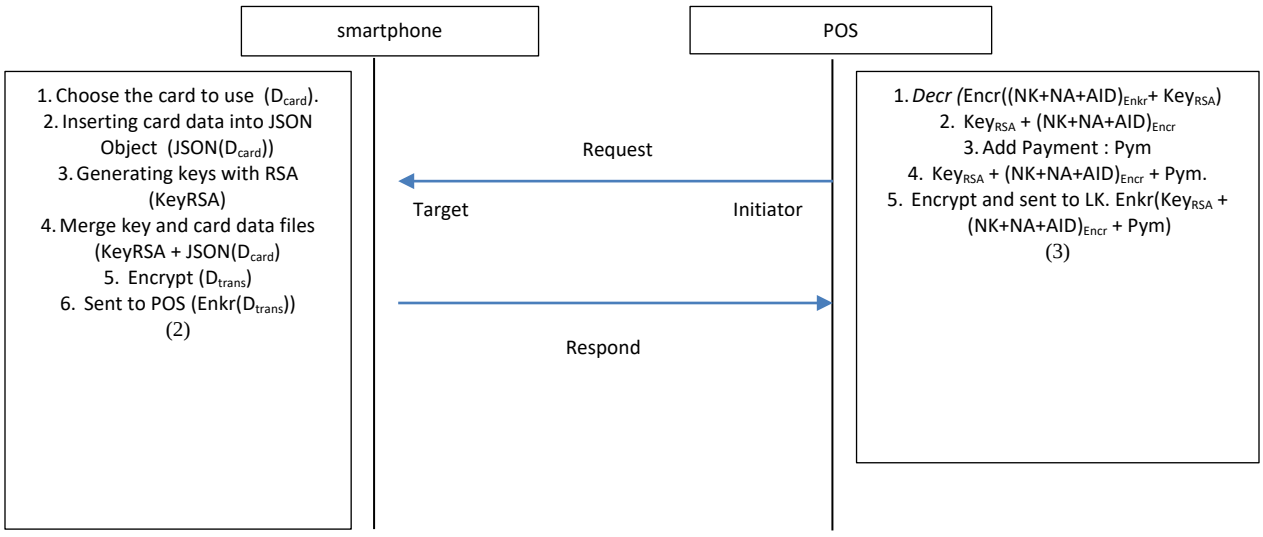

Fig. 3. Transaction Model Steps 2 and 3.

The data sent from the smartphone to the POS will be encrypted and encapsulated first. After the data reaches the POS, the data is parsed to get the original data. Encryption is done using the AES cryptographic algorithm. The algorithm chosen is simple, lightweight, and has modifiable parameters. It is because computing is done on smartphones that have limited memory capacity. At the same time, the parameter options can be modified to be used to add security by changing the parameter value every time there is a new transaction. Until this stage, the transaction model is complete. The model created is a model for normal transactions. Prevention of relay attacks is done by encrypting data when it is stored and transmitted between devices.

IV. Implementation and Evaluation

The proposed transaction model was tested on a smartphone with NFC facilities and the android operating system. The parameters tested were execution time and data randomness analysis using the monobit test.

The model was tested on a smartphone with differences in the android version and memory size. This test ensures that the model runs well and can improve security. Trials were also carried out on different smartphone conditions to determine the model's performance in different situations.

The data used for the trial is dummy data which describes the card user data that is widely used today. This data is inputted into APL-SE at the initialization stage, then used for transactions in this trial.

This encryption time is calculated from the beginning of the encryption process until the data is successfully encrypted. Based on the graphs in Fig. 4 and Fig. 5, we find that the time it takes is far below one second; the average time based on the test results is 1.074 milliseconds. This time is very short compared to the time it takes for the attacker to retrieve and translate the encrypted data, which takes more than one millisecond [25].

The entropy value shown in Fig. 6 and the P value shown in Fig. 7 also indicates that the data encryption results are declared random, based on Shannon Theory.

The communication made by the smartphone and the POS at the time of the transaction is the exchange of credential data needed to declare the transaction successful and correct. In this trial, the smartphone used by the user is a smartphone with the Android operating system, and the one used as a POS is an android smartphone.

Data exchange is carried out using the NFC-HCE ecosystem facilities on mobile devices. Fig. 8 shows the process of exchanging payment amount data from POS to the smartphone.

Data can be sent by POS if there is a request from a smartphone. For this reason, at this time, the smartphone is conditioned as the initiator and the POS as the target. In the beginning, the data sent from the POS to the smartphone is entered into the NFC POS card in the form of a shared preference. When the smartphone taps into the POS, the smartphone sends a request, namely the APDU command. POS receives this APDU command, then processes the APDU command. Payment data and select AID commands are combined and sent to the smartphone. The smartphone will receive the data, then retrieve the payment data. The first request-response process between smartphone (initiator) and POS (target) is finished here.

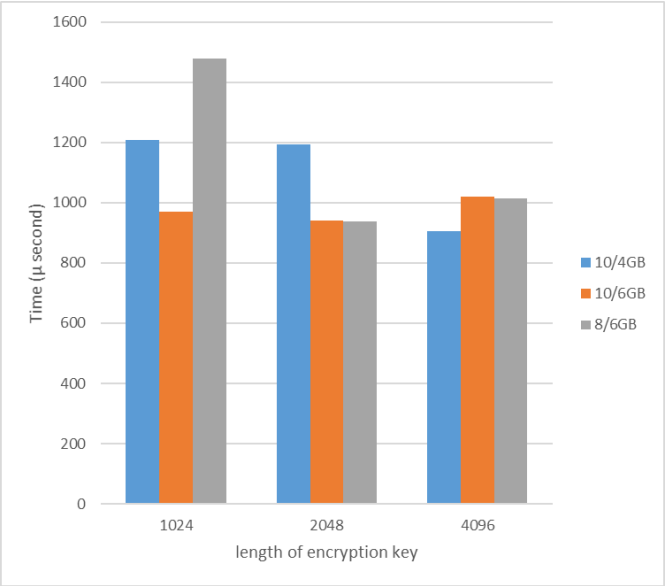

Fig. 4. Data Encryption Time on a Smartphone.

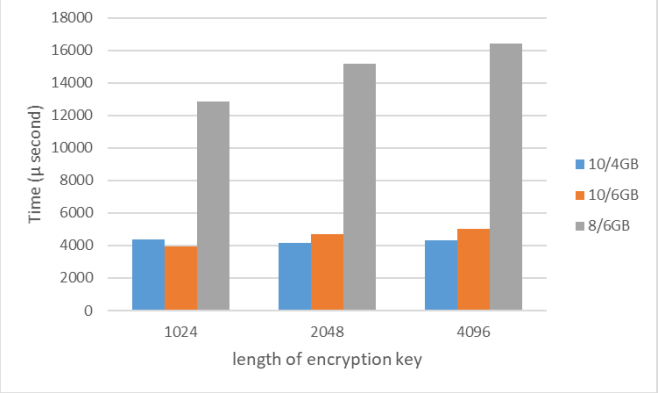

Fig. 5. Time to Send Customer Data to POS via NFC-HCE.

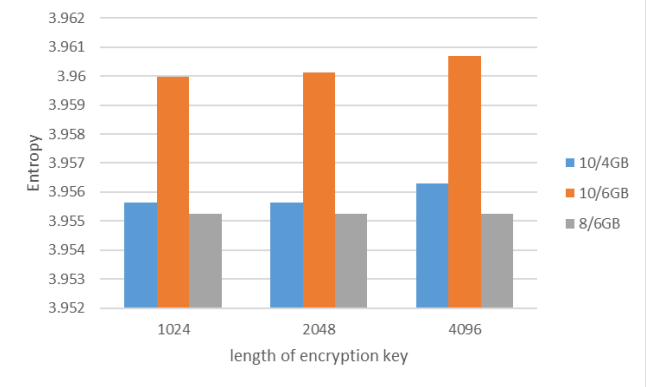

Fig. 6. Entropy Value of Data Encryption Results.

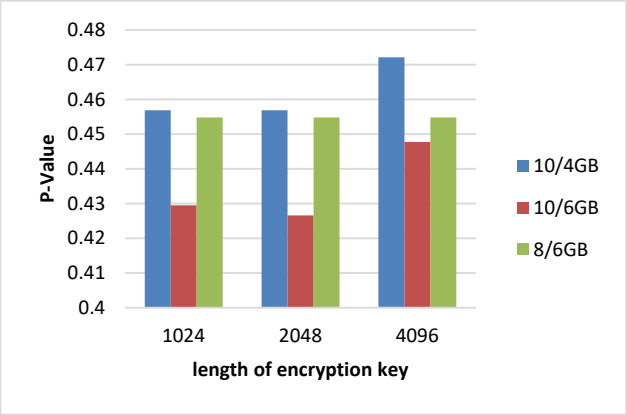

Fig. 7. P Value of Data Encryption Results.

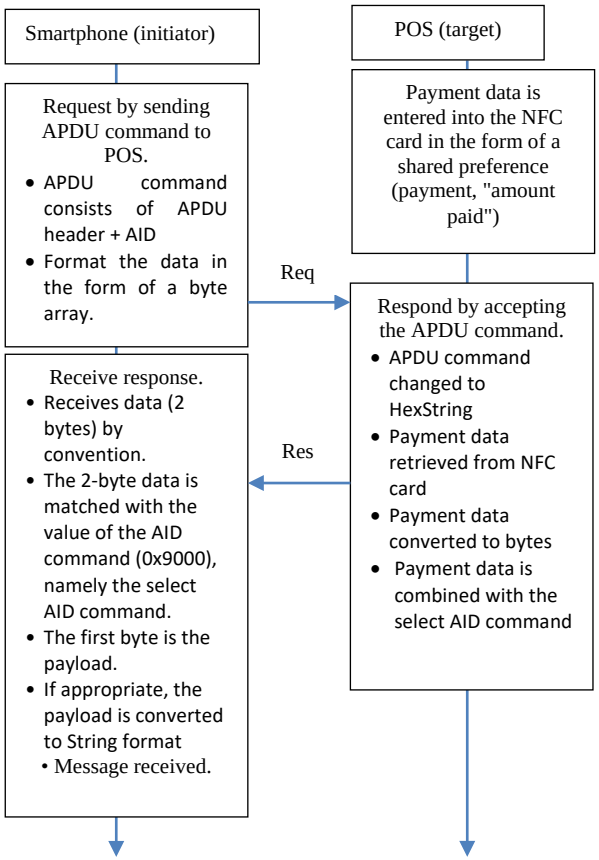

Fig. 8. Request-Respond when Sending Payment Data from POS to Smartphone.

The position of the initiator and target changes, POS as the initiator will make the request, and the smartphone as the target will respond. Fig. 9 shows this process. This process is similar to the process in Fig. 5. The data sent from the smartphone is the card data that will be used for payments. Card data is RSA encrypted in a JSON Object and sent in a shared preference format. When the card data reaches the POS, it is combined with the payment data, and the POS sends it to the server for verification.

Trials were also carried out by simulating smartphones with various positions during transactions. The model is tested using several smartphones to simulate a situation where there is another NFC within reach of the NFC reading area (POS or user) during a transaction. The test shows that the NFC that is read is the NFC that is closer to the NFC reader (reader/initiator). Because the physical situation that must be done is a situation where communication occurs with an NFC tap, then the two NFCs that will communicate are at a very close distance and do not allow other smartphones to occupy a closer position. This physical situation prevents NFC reading errors with unexpected devices.

NFC on smartphones, both POS and users, can be read at a distance of 0-5 cm. The NFC is not readable if their distance is above that distance. So, in that situation, the attack could be prevented because:

1) The data sent is in encrypted form.

2) The distance between smartphones must be close, and the NFC smartphone must be facing, meaning that the back of the smartphone must also be facing the back of the other.

3) The distance between smartphones is not more than 5 cm.

The second situation tested is when the user and the POS communicate, there is another NFC on the side of the user's NFC opposite the POS. When this happens, and the user's NFC is in reading mode (target), the user's NFC will be read by the POS because the NFC position is on the back side of the smartphone, which is facing the POS when communicating. Likewise, if the user's NFC is in reading mode (initiator), the user's NFC will read the NFC POS because the NFC position is on the back side of the smartphone facing the POS. This situation was tested by varying the distance between smartphones. 0-5 cm distance and NFC facing each other (meaning the back of the smartphone is facing each other) can communicate.

The third situation that is tested is if the POS and the user are going to make a transaction, and it turns out that another smartphone is in a position between the two devices. The first possibility is that the POS will read the NFC of another smartphone. Thus, communication between the POS and the user does not occur. If there were such a situation, the possible situation would be as follows:

1) If another smartphone has APL-SE, the transaction can occur, but the transaction is between the POS and another smartphone. In the transaction, authentication is carried out on the device's pin and id. If authentication is performed and another smartphone is identified, then the payment is made by the other smartphone and the accompanying identity.

2) If the other smartphone does not have APL-SE, there will be no transaction because the transaction will only occur if the two devices are connected as POS and user.

The second possibility is that the POS will read the user's smartphone because the NFC is the NFC of the POS and the user. So even though there are closer smartphones, because the NFC smartphones are not facing each other (there is NFC which is more in a straight line position), there is no NFC communication.

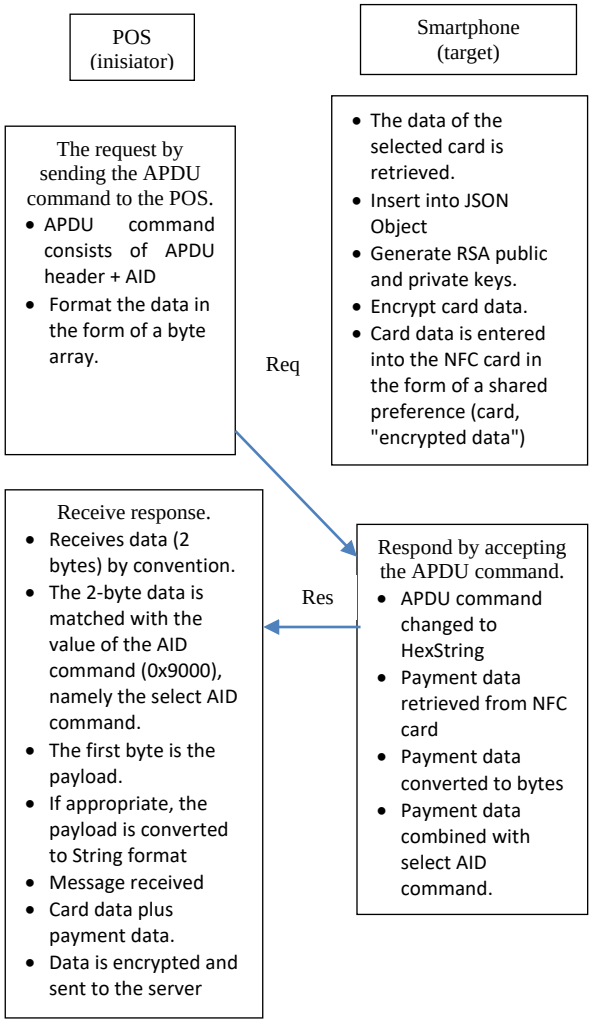

Fig. 9. Request-Response Sending Card Data from Smartphone to POS.

Mutual authentication between buyer and seller is as follows. The initialization model in this study ensures the client by registering client data, card data, and device data. The transaction model ensures that data is safe when sent and received back by the client device because the data is encrypted by each item and encrypted again as a single record before being sent. Smartphone users ensure POS for receiving payment data; POS ensure users receive payment card data. POS ensures financial institutions because the data is verified, and financial institutions ensure POS because the card data sent is correct and in accordance with smartphone owners.

Analysis for security against attackers is carried out as follows. The first attack is an attack that can take data at the time of a transaction, then use it at another time to ensure that the transaction is carried out by the right person (the real account owner). Several processes, namely prevent this attack:

1) Credential data stored on the smartphone is encrypted.

2) When the POS requests the customer's smartphone, the smartphone responds by sending encrypted personal data. The process of sending customer data to the POS can only be done when the customer enters a pin into the system.

3) Sending data from the POS to the Financial Institution for verification is done after the encrypted data from the smartphone is combined with the payment data from the POS, then encrypted.

4) Data originating from smartphones includes customer data and smartphone data. The two data are data pairs registered during the initialization process.

The second attack is an attack that can retrieve and analyze data and how the data can remain safe even though the attacker successfully retrieves the data. Several processes namely prevented the attack:

1) Customer data stored on the smartphone is in an encrypted state. And the results of the analysis of the encrypted data state that the data is random.

2) The encryption process and data transmission process takes place very quickly, far below the time required by the attacker to retrieve and analyze data.

3) Every time a transaction is made, a transaction key is generated, which will be different for other transactions.

The overall process created for this transaction model ensures that transactions are carried out safely and can prevent attacks, especially attacks by retrieving data that is being transmitted and attacks on transactions that use data that is already owned by the attacker.

Authentication in this research is kept simple and doesn't take many steps, but it can ensure that the registered account is correct. So, the account stored on the smartphone is an authenticated account, including the authentication of the smartphone device. Meanwhile, on the level of security, this study uses several levels of security. The first level with an encryption key, the second level encrypts every field of data, the third level encrypts all account data, and the fourth level converts the format to Base64 format.

The condition that requires NFC communication at a short distance and having to face each other on the back of the smartphone is one of the advantages so that the position of an attacker using a smartphone will be difficult. Meanwhile, if there is an attacker who uses another device but can access the data sent in APDU format, then there is a possibility that a third party can retrieve the data. But the format of the data sent does not allow the data to be interpreted in a fast time.

The model made in this study is quite reliable because the use of NFC will continue to grow in the future. The convenience of NFC with just a tap is an advantage, and the tendency of people to do and get more practical things from time to time is increasing.

The implementation of the initialization and transaction model is simple. The model is simply applied to the payment system at the POS, and financial institutions verify their customer account data, and smartphone owners download payment applications. The condition for this model to be implemented is that there is an agreement between POS and financial institutions, and there are customers who use applications that implement this model.

V. Conclusion

The APL-SE transaction model was created to improve the security of payment transactions using NFC-enabled mobile in the NFC-HCE ecosystem. The NFC-HCE ecosystem will be increasingly used because of its practicality in not needing to use a SIM as a place to store secure elements. Thus, financial institutions do not need to rent space from mobile operators. The test results show that the processing time is short and the encrypted data is random, thus increasing security.

This study has not discussed and tested data stored on smartphones when not in use. Data stored on smartphones has many security variables, such as user negligence, and lost or damaged data.

Computer Science Faculty, University of AMIKOM Yogyakarta
Yogyakarta, Indonesia

***Abstract*—Tracer Study is a mandatory aspect of accreditation assessment in Indonesia. The Indonesian Ministry of Education requires all Indonesia Universities to anually report graduate tracer study reports to the government. Tracer study is also needed by the University in evaluating the success of learning that has been applied to the curriculum. One of the things that need to be evaluated is the level of absorption of graduates into the working industry, so a machine learning model is needed to assist the University Officials in evaluating and understanding the character of its graduates, so that it can help determine curriculum policies. In this research, the researcher focuses on making a reliable machine learning model with a tracer study dataset format that has been determined by the Government of Indonesia. The dataset was obtained from the tracer study of Amikom University. In this study, SVM will be tested with several variants of the algorithm to handle imbalanced data. The study compared SMOTE, SMOTE-ENN, and SMOTE-Tomek combined with SVM to detect the employability of graduates. The test was carried out with K-Fold Cross Validation, with the highest accuracy and precision results produced by SMOTE-ENN SVM model by value of 0.96 and 0.89.**

Keywords*—Tracer study; support vector machine; synthetic minority oversampling technique; SMOTE; employability

I. Introduction

A decent University can be seen from the level of absorption of its graduates in working world, thus many universities are trying to improve the quality of their graduates [1], [2]. That is the reason why the Indonesian Ministry of Education requires all Universities to always report the results of tracer study anually for measuring University graduates employability. Tracer study is also a requirement for higher education accreditation set by the National Accreditation Board for Higher Education (BAN-PT) [3], [4].

Currently we live surrounded by data, data circulating around us can be collected and processed to produce new knowledge [5], including tracer study data. These data can be collected and processed to improve the quality of human resources and curriculum that can increase the absorption of university graduates in industries.[1], [6].

One of the machine learning models that have been widely used to meet these needs is classification [7], [8]. Using classification algorithm we can predict whether an alumni has the possibility of being absorbed in a job quickly or not [9].

There are many classification algorithms that are popularly used, one of which is the Support Vector Machine, from previous research the SVM algorithm is very well used to predict the employability of graduates [10], but basically the final result of an algorithm does not only depend on the quality of the algorithm used but also on the quality of the dataset applied to the algorithm, one of the criteria to get a reliable machine learning model is that the dataset must be balanced, to balance the dataset there are 2 methods, namely oversampling and undersampling, one of the oversampling algorithms that can be used is SMOTE, SMOTE itself has several variants, namely SMOTE, SMOTE ENN, and SMOTE Tomek[11], [12].

This study aims to find out the best method for predicting the employability of higher education alumni using the Amikom University tracer study dataset with attributes and formats determined by the Indonesian Ministry of Education which can be accessed on the web http://tracerstudy.kemdikbud.go.id/ frontend/.

II. Literature Review

A. Classification

Classification is a type of machine learning algorithm where the computer will automatically predict the class of a data from the input data given [7]. Several classification algorithms commonly used for tracer studies include Naive Bayes, Neural Network, SVM, Logistic Regression, etc [9], [13], [14]. In previous works, Tracer Study Data in Indonesia was analyzed using those classification algorithms, without using SMOTE or another imbalanced data handler model.

B. Balance Data

Balanced dataset is data in which the comparison of each data in a class is balanced, the data in which each class has a significantly different amount, the dataset is called imbalance. Unbalanced classes are a common problem in machine learning classification where there is a disproportionate ratio in each class. Class imbalances can be found in various fields , moreover in tracer study case. Classes that have more data are often called majority classes and classes that have less data are called minority classes[15]–[17].

C. Support Vector Machine

The Support Vector Machine algorithm is one of the algorithms included in the Supervised Learning category, which means that the data used for machine learning is data that has a previous label[18], [19]. So that in the decision-making process, the machine will categorize the testing data into labels that are in accordance with its characteristics.

Support Vector Machine is one of the machine learning algorithms that can be used for classification, where this algorithm will generate the best hyperplane where this hyperplane will separate the classes in the dataset [20], [21].

$$w.\ x - b = 0 \quad (1)$$

where:

w = Weight Vector

x = Input Vector

b = Bias

D. SMOTE

SMOTE is one of the algorithms that can be used to balance a dataset, using an oversampling approach, in which this algorithm will generate synthesis data from the minority class so that the minority class has the same amount of data as the majority class [15], [22].This synthetic data is obtained based on the value of k-neighbours from minority data.

$$\Delta(A,B) = W_A W_B \sum_{i=1}^{N} \delta(v1.v2)^r \quad (2)$$

$\Delta(A,B)$: observed distance between A & B
$W_A W_B$: observed weight
N: amounts of predictor variables
r: value of 1 (Manhattan distance) or 2 (Euclidean dist)
$\delta(v1.v2)^r$: the distance between observations A and B for each explanatory variable, with the formula;

$$\delta(v1.v2) = \sum_{i=1}^{n} \left| \frac{c_{1i}}{c_1} - \frac{c_{2i}}{c_2} \right| \quad (3)$$

$\delta(v1.v2)$: the distance between observations A and B which is included in the i variable

c_{1i}: the number of the 1st category which is included in the i-th explanatory variable category

c_{2i}: the number of the 2nd category which is included in the i-th explanatory variable category

c_1: number of category 1

c_2: number of category 2

n: the number of categories in the i-th explanatory variable

k: Constant

In this study, researchers will compare three variants of the SMOTE algorithm, namely, SMOTE, SMOTE ENN and SMOTE Tomek. SMOTE Tomek uses a combination of the SMOTE algorithm which is a balancing algorithm with an oversampling approach combined with ENN and Tomek which is an undersampling algorithm, where ENN and Tomek function to delete synthetic data that has similarities to the majority data so that data balance is obtained where each data class has a clear difference [11], [23].

III. RESEARCH METHOD

The dataset used in this study is data obtained from questionnaires filled out by alumni of Amikom University in 2018. The questionnaires that have been distributed are then filled out by (many) respondents and stored in csv form. The process can be seen in the Fig 1.

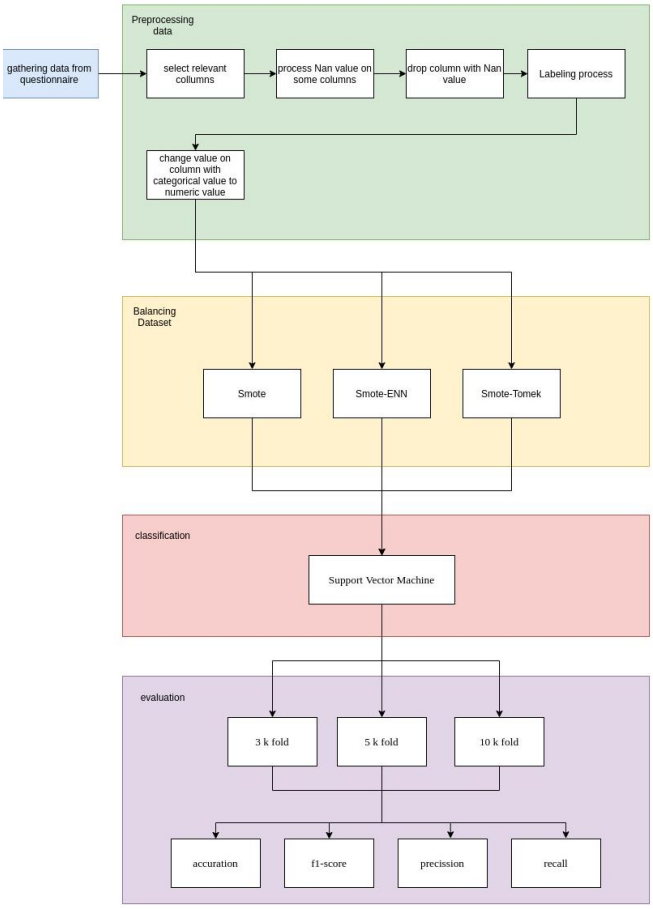

Fig. 1. Research Overview

A. Selection of Attributes and Collection of Survey Results

The first stage of this research is to collect the results of the questionnaire; which later the results from this questionnaire will be presented in csv form so that thereafter it can be processed using a predetermined model. There are 145 collumns consists of their hardskill level after graduate, sex, how long they study in college, when they start to search jobs, and many more, including the label (alumni employability). All of the atributes can be accessed at http://tracerstudy.kemdikbud.go.id/ frontend/.

B. Labeling Data

Data labeling is done by taking each respondent's answer to the question "How long did it take you to get your job after graduation?" In this research, based on that question, labels are divided into three classes. If a student gets a job before graduating from University, then the data will be labeled as "1". If the student gets a job three months or less after they graduate from University then it will be labeled "2". If the student takes more than 3 months to get a job get a job after graduation it will be labeled "3".

C. Data Preprocessing

In this process, preprocessing of data is carried out by converting data labeled string into integer form and also filling empty values in all existing columns with zero values, and deleting values with remaining null data. This have to be done to avoid anomalies in the mathematical modeling.

D. Data Balancing

In practice, classification requires balanced data, balanced data is data where each label has the same amount, if each label has a significantly different amount then the dataset is called imbalanced. Class that has more data is the majority class and the class that has less data is called the minority class [24].

In this study, to overcome the imbalanced data, SMOTE algorithm is used, SMOTE is an algorithm that is useful for balancing the amount of data with an oversampling approach, the SMOTE algorithm will create synthesis data obtained based on the value of k-neighbours from minority data [25].

E. Classification

After the data balancing process, the classification process is carried out with the Support Vector Machine algorithm.

F. Testing

The model testing process uses the K-Fold Cross Validation algorithm with Folds determined to be 3, 5, and 10 Folds. This is done so that the test is more valid and vary [26].

IV. Results

In this study, we will classify the normalized tracer study dataset. After collecting and normalizing the dataset , the dataset will be divided into three classes based on when the alumni got a job, the first class will contain data on alumni who got a job before graduating, less than or three months after graduation, and more than three months after graduating. Fig. 2 showed us the amount of data that has imbalance class. Fig. 3 showed that the amount of dataset significantly altered in every observation using different types of SMOTE.

There are three models of balancing algorithm that will be compared, those are SMOTE, SMOTE ENN and SMOTE Tomek algorithms when applied to the support vector machine classification algorithm. The best model will be calculated based on the average value of f1, accuracy, precision, and recall.

The SMOTE algorithm is a data balancing algorithm with an oversampling approach where the number of minority classes will be increased to balance the majority class. Fig. 4-6 show the dataset after being applied to SMOTE, SMOTE ENN and SMOTE Tomek algorithms

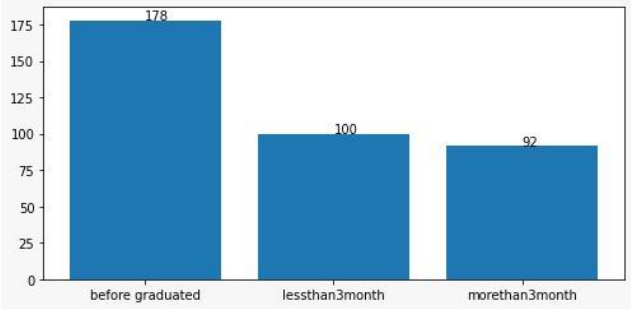

Fig. 2. Dataset before Balancing

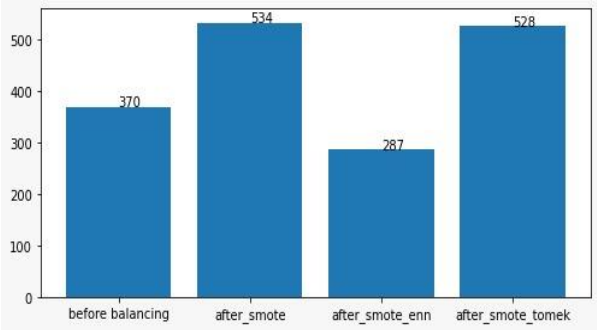

Fig. 3. All Dataset Amounts before and after Balancing

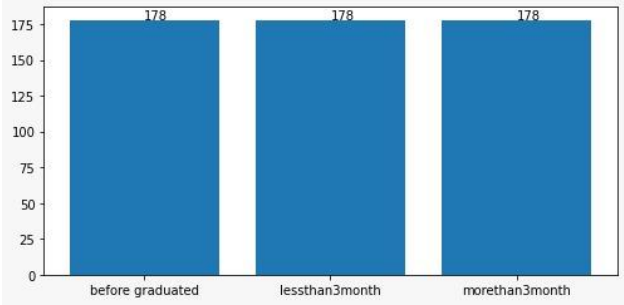

Fig. 4. Dataset after SMOTE

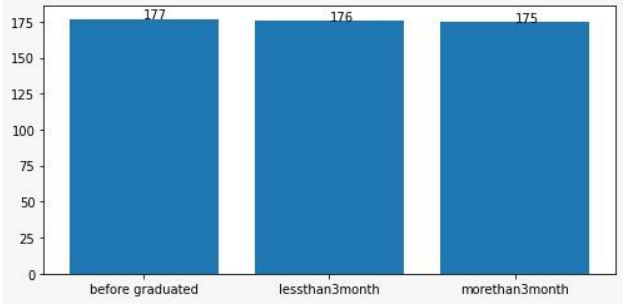

Fig. 5. Dataset after SMOTE-Tomek

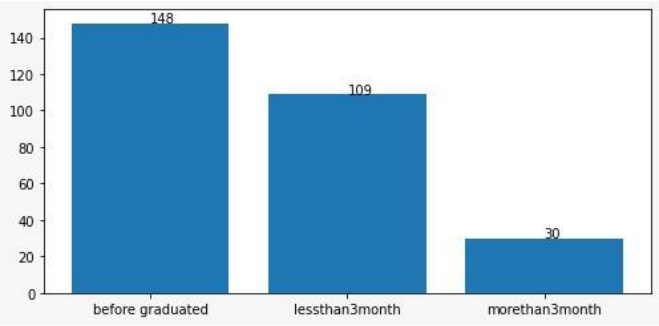

Fig. 6. Dataset after SMOTE-ENN

After the dataset are being processed by SMOTE and SMOTE-TOMEK algorithms, it produces classes that have balanced amount of data. But it did not happen in the SMOTE ENN algorithm, SMOTE ENN created a more normal dataset, this is because when data has an absolute balance, sometimes it may result in overfitting.[12]

Furthermore, after getting the data that we have balanced, the data will be applied to the Support vector machine classification algorithm and for model level measurements, cross fold validation measurements will be used with 3, 5 and 10 fold values for accuracy, f1 score, recall and precision for each model.

TABLE I. RESULT OF ACCURACY & F1 SCORE 3-FOLD

balancing	accuracy			avg	F1 score			avg
-	0.86	0.77	0.76	0.79	0.84	0.73	0.73	0.76
smote	0.78	0.86	0.96	0.86	0.77	0.86	0.96	0.86
smote-enn	0.98	0.94	0.94	0.95	0.97	0.86	0.86	0.89
smote-Tomek	0.86	0.91	0.95	0.90	0.86	0.91	0.95	0.90

TABLE II. RESULT OF RECALL & PRECISION 3-FOLD

balancing	precision			avg	recall			avg
-	0.86	0.82	0.82	0.83	0.83	0.72	0.70	0.75
smote	0.78	0.88	0.96	0.87	0.78	0.86	0.96	0.86
smote-enn	0.98	0.95	0.95	0.96	0.96	0.82	0.82	0.86
smote-Tomek	0.87	0.92	0.96	0.91	0.86	0.91	0.95	0.90

Shown in Table I and II, the experiment is done by using three fold cross validation to test the f1 score, accuracy, precision, and recall from SVM with SMOTE, SMOTE-TOMEK, and SMOTE_ENN and the results obtained that this research scenario has an average f1 accuracy result. score, precision and recall using SVM alone are 0.79.0.76, 0.83, 0.75 and after data balancing, the f1 score, precision and recall are respectively as follows

Smote : 0.86, 0.86, 0.87, 0.86

smote -enn : 0.95, 0.89 ,0.96, 0.86

Smote-tomek : 0.90, 0.90, 0.91, 0.90

These results indicate that the Three-Fold SMOTE, SMOTE-Tomek, and SMOTE-ENN validations are proven to be able to increase the accuracy value of SVM itself, with the highest average value generated by SVM Smote-ENN.

TABLE III. RESULT OF ACCURACY 5-FOLD

	balancing	accuration					avg
1	-	0.93	0.80	0.78	0.86	0.85	0.84
2	smote	0.86	0.75	0.89	0.94	0.99	0.88
3	smote-enn	0.93	0.98	0.98	0.96	0.91	0.95
4	smote-Tomek	0.97	0.82	0.91	0.94	0.99	0.92

TABLE IV. RESULT OF F1 SCORE 5-FOLD

	balancing	f1-score					avg
1	-	0.93	0.76	0.74	0.85	0.84	0.88
2	smote	0.86	0.75	0.89	0.94	0.99	0.82
3	smote-enn	0.89	0.96	0.99	0.92	0.79	0.91
4	smote-Tomek	0.97	0.82	0.90	0.94	0.99	0.92

TABLE V. RESULT OF RECALL 5-FOLD

	balancing	recall					avg
1	-	0.91	0.75	0.73	0.84	0.81	0.80
2	smote	0.86	0.75	0.89	0.94	0.99	0.88
3	smote-enn	0.86	0.94	0.98	0.89	0.76	0.88
4	smote-Tomek	0.97	0.82	0.91	0.94	0.99	0.92

TABLE VI. RESULT OF PRECISION 5 FOLD

	balancing	precision					avg
1	-	0.96	0.79	0.84	0.87	0.92	0.87
2	smote	0.86	0.78	0.91	0.95	0.99	0.89
3	smote-enn	0.95	0.99	0.99	0.97	0.93	0.96
4	smote-Tomek	0.97	0.84	0.92	0.95	0.99	0.93

In the test scenario using five cross fold validation that are shwon at Table III, IV, V and VI, the average results of the f1 score accuracy, precision and recall are 0.84, 0.88, 0.87, 0.80 after data balancing the f1 score accuracy, precision and recall values are equal to

Smote: 0.88, 0.82, 0.89, 0.88

Smote -enn: 0.95, 0.91 ,0.96, 0.88

Smote-tomek: 0.92, 0.92, 0.93, 0.92

then it can be seen from the data that the values of accuracy, precision, recall and f1 are close to perfect which indicates an overfitting, this is triggered by the distribution of test data that is less than the previous experiment.

2	0.93	0.95	0.86	0.89	1.00	1.00	1.00	1.00
3	1.00	1.00	1.00	1.00	0.81	0.85	0.81	0.80
4	0.97	0.97	0.89	0.92	0.87	0.88	0.87	0.87
5	0.97	0.98	0.97	0.97	0.92	0.93	0.92	0.92
6	1.00	1.00	1.00	1.00	0.94	0.95	0.94	0.94
7	0.97	0.97	0.89	0.92	1.00	1.00	1.00	1.00
8	0.96	0.97	0.89	0.92	0.91	0.91	0.91	0.91
9	0.93	0.95	0.78	0.81	1.00	1.00	1.00	1.00
10	0.89	0.92	0.74	0.77	0.98	0.98	0.98	0.98
avg	**0.95**	**0.96**	**0.89**	**0.91**	**0.94**	**0.94**	**0.94**	**0.94**

Just like the previous two experiments in the 10 cross fold validation experiment that can be read in Table VII and Table VIII, before the application of balancing the data model, the accuracy value was equal to 0.84, f1 was equal to 0.81, precision was equal to 0.87 and recall is 0.8, then after SMOTE being implemented, there was an increase in the accuracy of the f1 score, precision and recall. The four values increase after data balancing is done. The value of f1 score accuracy, precision and recall is equal to getting the average result

Smotes : 0.90, 0.90, 0.90, 0.91

smooth-enn : 96, 91 ,96, 89

Smote-tomek : 0.94, 0.94, 0.94, 0.94

However, in this experiment, it can be seen that there is an overfitting of the SVM model that uses a data balancing algorithm in several folds which is marked by perfect accuracy in all 3 algorithms. This happens because the test data is only 10% of the entire dataset, it can also be seen in the ENN and Tomek algorithms, cases of overfitting occur more than in the smote algorithm, this is due to the significant difference between the classes in the dataset after the application of the enn and tomek algorithms which is getting worse. enlarge the difference in the data in each class.

V. CONCLUSION

In this study, data balancing algorithms smote, and smote tomek can be used to produce balanced data in terms of the balance ratio formula. Both of these algorithms also produce accuracy, f1 score, precision and recall which are quite significant considering the results presented. However, compared to the SMote-ENN algorithm which produces a poor balance ratio value, the smote tomek and smote algorithms have a lower accuracy value of f1 score, precision and recall. Several fold-cross validation were performed to analyze the data, and found that SMOTE-ENN has the best accuracy in general. In 10-Fold Validation Without SMOTE produced 0.84 in accuracy, using SMOTE it produced 0.9 in accuracy, using SMOTE-Tomek it has 0.94 in accuracy point, and the last one SMOTE-ENN has 0.95 in accuracy.

The SMOTE-ENN-SVM algorithm produces a model with better quality, this can be seen from the accuracy score in each experiment which is higher than other algorithms. In the future, because Tracer Study Data that has many collumns and vary type of data, it would be better to perform feature selection algorithms to select the best feature to be analyzed.

***Abstract*—There are many email filters that have been developed for classifying spam and phishing email. However, there is still a lack of phishing email filters developed because of the complexity of feature extraction and selection of the data. There are several categories of features for classifying phishing emails, either on the email part or on the human part. The absence of which features are best for helping to classify phishing emails is one of the challenges; in the previous experiment, there was no benchmark for the features to be used for phishing email classification. This research will provide new insight into the feature selection process in the phishing email classification area. Therefore, this work extracts the features based on the category and determines which features have the most impact on classifying email as phishing or not phishing using a machine learning approach. Feature selection is one of the essential parts of getting a good classification result. Therefore, obtaining the best features from email and human behavior will significantly impact phishing classification. This research collects the public phishing email dataset, extracts the features based on category using Python, and determines the feature importance using machine learning approaches with the PyCaret library. The dataset experimented on three different experiments in which each feature category was separated, and one experiment was the combined feature selection. Binary classification is also done with the extracted features. The experiment verified that the proposed method gave a good result in feature importance and the binary classification using selected features in terms of accuracy compared to previous research. The highest result obtained is the classification with combined features with 98% accuracy. The results obtained are better compared to previous studies. Hence, this research proves that the selected features will increase the performance of the classification.**

***Keywords*—Phishing; phishing email classification; features selection; binary classification; email features; human features**

I. Introduction

In spite of the fact that numerous email filters have been created for spam emails, exceptionally few phishing email filters have been created [1]. Due to the complexity of current phishing attacks, detecting and classifying phishing attacks is a major challenge. Obtaining high-quality training data is one of the biggest problems with machine learning, as labelling data can be tedious and costly [2]. Valuating the dataset is hard because it involves figuring out the limits of the phishing email dataset and whether or not it is the same appropriate dataset as in the previous study. This is done by looking at the dataset that the previous researcher used.

For techniques used in the classification process, machine learning algorithms such as Naïve Bayes, Support Vector Machine, Decision Tree, Random Forest, and others are implemented according to the features used. From previous studies in the classification area, SVM and NB are the most commonly used methods in the phishing email classification area. The accuracy of the result from both algorithms is very satisfying. However, in this case, extraction and selection of features based on the email structures play an essential role in improving the result of email classification on specific content [3]. To improve the classification performance, a feature selection algorithm is presented, and feature selection methods are commonly used to reduce the dimensionality of datasets to improve the classification performance, reduce the processing time, or both [4]. In recent studies, there are several researches that implement word embedding for feature representation, which is one way to solve the text classification problem [5].

Phishing email classification requires clear features so that the classification produces accuracy and good performance evaluation results. The features that have been selected and extracted will represent the identity of an email itself; examples of some of the features used for email classification, especially phishing emails, are the body and URL features. Features will be extracted based on the feature type itself [6].

The relationship between features can also be determined by other fields, such as linguistic features. On the behavior side, the features extracted are classified as text feature extraction, which extracts text information that is used with the aim of representing a text message [7]. Stylometrics is one of the fields of linguistics related to the procedure for writing text, where this feature is used to identify the contents of phishing emails. Stylometric features have several categories, namely lexical, structural, content-specific, syntactic, and idiosyncratic [8]. Each category of features has its own characteristics. Email also has several main parts: a header, body, and URL.

Each corpus will be processed by following the research framework, including feature extraction. The first corpus used in this research is the IWSPA-AP 2018 dataset, which was requested by the committee of the Security and Privacy Analytics workshop [9]. The second is the custom-made corpus that combines 2 email datasets, the Enron CALO dataset and PhishCorpus [10] [11]. The detailed information about each corpus will be explained more in data collection.

Feature selection is an important stage that can affect the results of a classification process. The features to be used must have a significant impact that can make performance more accurate, especially in the machine learning area. Feature selection can be roughly classified into supervised, semi-supervised, and unsupervised methods [12]. There are standard feature selection methods for categorical data, namely Chi-Squared and information gain, but this method has drawbacks for data that has many categories. In phishing emails, some features are classified into categorical data with more than two categories. Therefore, this problem requires a new method to determine the effectiveness of the features in a dataset used. Also, there is no benchmark for the best features in the phishing email classification area [13]. PyCaret is a Python library that is useful for automating machine learning workflows. One of the features of PyCaret is feature importance, which is the process of evaluating the features that contribute the most to predicting target variables using a combination of supervised techniques, including Random Forest, Adaboost, and others [14].

The current issue regarding feature selection and extraction in the email classification area is that there is no benchmark for the feature set and which feature is the best for identifying phishing properly. Thus, it is promising that by using a combination of features on different fields with email features and using PyCaret's feature-critical algorithm can identify which features have the most significant impact on the area of classification of phishing emails. In addition, the list of best features can be produced and used as a benchmark for feature sets to help improve the performance of phishing email classification.

The rest of the paper is organized as follows: Section II discusses the works that are related to determining features. The framework for feature extraction in this experiment is in Section III, and an explanation of the data preparation and feature selection process is in Section IV. Section V will show the results of all the experiments carried out and closed with a conclusion in Section VI.

II. Related Work

This experiment is to determine the best feature for phishing email classification using feature importance, and several researchers used either stylometric features, email features, or both features for their experiments.

In [15] experiment, they proposed a classification method using the persuasion principle based on content-specific categories in the stylometric area. Several persuasion principles were used, namely: Authority, Reciprocation, and Scarcity were used as one of the feature selections in this experiment. They also used email features such as URL and body features which are included as part of feature selection. The dataset used is from Nazario PhishCorpus.

In [16], used word analysis features to detect spear-phishing emails. In contrast to the above study, this study uses a spear-phishing dataset collected from Enron Corpus because spear phishing has a specific target to attack. In the study, the analysis features used are those on the behavioral aspect, such as gender features, stylometric features, and personality features. The gender features will detect the gender of the email sender based on the choices of words in the email. The stylometric features are from the grammar side, and the personality features are emotion detection due to word selection. These features are classified as stylistic features, which is the study of the interpretation of each individual's text or spoken language in terms of accent, grammar, or word choices (lexicon). For author identification, stylistic features are often used in several journals and articles with different fields and areas, for example, author identification of a book or gender identification of a character in a novel. In this case, stylistic features are used for author identification to detect spear phishing.

Another comparison of the phishing classification using stylometric features is with [17]. The experiment extracted 26 human features more focused on syntactic feature categories. For machine learning, the classifiers used are DT, SVM, Naïve Bayes, Logistic Regression, and Neural Network. IWSPA is used as a dataset for phishing classification.

Features selection has become a crucial part of conducting email classification research. A better result will be given by selecting the best and most convenient features in the experiment. However, there are no such optimized features that can be equally applicable in all domains [18]. In the past years, the researchers tried different feature selection and extraction. The list of features to be tested is obtained based on the literature, which states that there is a lack of human features (stylometric) approaches in different research fields. In this case, stylometric features are combined with email features to detect phishing emails [19].

There are several categories from stylometrics that indicate the email is categorized as phishing or legit email. Table II shows the categories of stylometric features used in this study, namely lexical, syntactic, content-specific, structural, and idiosyncratic. The most commonly used features for phishing email classification are header, body, and URL for the email features. Features extracted are part of the main category of an email, where each category (header, body, and URL) has value in the form of text or numbers that will be analyzed at a later stage. The list of email features extracted is shown in Table I. Based on the literature survey, this research will combine features from two main features, namely human behavior focusing on stylometric features and email behavior features focusing on the structure, content, and metadata of the email itself and evaluating the effectiveness of the features extracted.

The use of PyCaret for feature engineering or classification tasks was also carried out in several experiments. The study [20] used PyCaret to focus on the feature engineering steps in the classification process using the Titanic dataset. Feature importance is used to select the best features to increase the efficiency of the classification model. PyCaret is also used for other areas, such as regression analysis. The author in [21] uses PyCaret to predict the price of a diamond. The dataset used is from the PyCaret repository. The best machine learning approaches for the experiment are Gradient Boosting Machine and Light Gradient Boosting Machine, respectively. Due to this library is newly developed in the area of machine learning

tools, there is still little research that uses PyCaret in other research fields as a supporting library.

In [22], the experiment used PyCaret to compare the selection of Polycystic Ovarian Syndrome (PCOS) attributes. The feature selection method used is GA which is the input for PyCaret. The results obtained from this experiment are accuracy of 87% with the extra tree algorithm that has been provided in PyCaret. However, the feature selection used is using another method (GA) in which Pycaret itself already has a feature for calculating feature importance which can be used to evaluate the feature that has been selected.

In [23], they proposed a classification model to detect cardiovascular disease using Pycaret. The features used have been selected in advance based on previous research in which there is no feature engineering process in this experiment. The research [24] compares 14 machine learning models from PyCaret to predict whether students will drop out or not. The results obtained by experimenting with all the features, with the Decision Tree as the most appropriate model, are pretty good. Feature importance is used to see which features affect the classification results, where feature importance is obtained according to the experimental feature analysis. Finally, experiments using PyCaret as a tool to compare models can be done well and get satisfactory results.

Clustering and classification are performed to analyze employee satisfaction using machine learning. A comparison of the best models was also carried out on 5 models included in PyCaret. The dataset used is the Kaggle-IBM analytics dataset, which consists of 1470 samples. This research uses Principal Component Analysis (PCA) for feature engineering to simplify the model features. PCA has several weaknesses, one of which is that it can eliminate information from these features because the correlation between data can be lost [25]. However, it can be seen that the flexibility of PyCaret can be applied to research in other areas as well.

It can be seen that several previous studies using PyCaret have not used the feature importance provided in PyCaret to evaluate the top features. In this study, PyCaret feature importance is used to determine the best features that can be selected to evaluate each extracted category feature.

III. Methodology

This section will determine which features significantly influence the phishing email classification process by experimenting with the dataset obtained and performing feature extraction. The results of this experiment will be a combined list of features that have a high impact on the classification of phishing emails from the email behavior part, namely the structure of email and human behavior, stylometric area. The framework for the feature extraction is shown in Fig. 1 below:

A. Data Collection

Phishing email datasets are very limited in number; there are only a few publicly available sources. In previous studies, the majority of researchers used the same dataset source, and modifications were made according to the needs of the research. In this experiment, two corpora were used to answer the question of which features had the most significant influence on the classification of phishing emails.

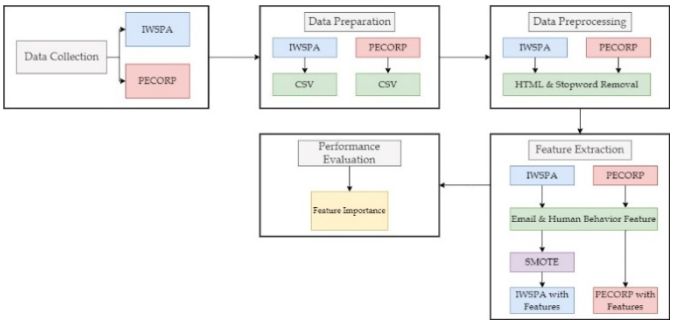

Fig. 1. The Framework for Feature Extraction

1) IWSPA-AP 2018 Corpus (IWSPA)

The first is the IWSPA-AP 2018 corpus, obtained by submitting an application to gain access to the dataset. IWSPA-AP 2018 has two different types of datasets: the IWSPA dataset with full header and no header. The full header IWSPA dataset consists of 4082 legitimate emails and 503 phishing emails, and no header IWSPA dataset consists of 5091 legitimate emails and 628 phishing emails. This corpus is classified as an unbalanced dataset because of the massive difference in the ratio of legitimate and phishing emails.

This corpus is provided in the form of text files in which every email is on a separate text file. In order to work efficiently with this data, combining all the text files into one CSV file is required to do further processing. The data extracted and transformed into CSV files is organized as follows: From, To, Date, Subject, and Body. There are additional columns, namely Label and Label Number, to determine the type of email, where 1 is for Phishing, 0 for Ham or non-phishing email.

2) Phishing Enron Corpus (PECORP)

The second corpus comes from a combination of two publicly available datasets, namely the Phishing and the Enron corpus. These two corpora are combined to create a full phishing email dataset in which the phishing emails from the Phishing corpus and legitimate emails from the Enron corpus.

A total of 2712 phishing emails come from the Online Phishing Corpus by Nazario, and 2801 legitimate emails come from the CALO Enron Email Dataset by Carnegie Mello University (CMU). This dataset was collected and prepared by the CALO Project (A Cognitive Assistant that Learns and Organizes). The CALO project dataset is the most widely used and is publicly available for download, as well as the Online Phishing Corpus by Nazario. Both corpora are combined into one CSV file. In this research, this combined corpus is called PECORP (Phishing Enron Corpus).

B. Data Preparation

Both corpora have a different format, IWSPA corpus is the text file type, and PECORP corpus is the "mbox" file type. To make the two corpora can be used as experimental material, a process is carried out to convert the two corpora into CSV format so that further processes can be carried out smoothly. Each corpus has different content of email and fields, either

from header or body that needs to be processed so that it can produce a good corpus. The corpora are converted from their original type to CSV format with the extraction of some column/fields, namely "FROM," "TO," "DATE," "SUBJECT," "BODY," and "LABEL." Both corpora's conversion and field extraction are done with Python using the PANDAS library.

The IWSPA corpus has an unbalanced amount of data ratio for the amount of data. In contrast, PECORP has been sorted for the same amount of data on phishing and legitimate emails, which was already explained in the previous section. To overcome unbalanced datasets, data processing stages are carried out so that the data in training can show good performance evaluation results. After the data preparation is complete, it will proceed to the next stage, namely data preprocessing.

C. Data Preprocessing

The preprocessing step is basically a data cleansing before the data is ready to move into the next classification process. It is crucial to preprocess the data with machine learning approaches [26]. Some preprocessing data is carried out so that the results obtained can be evaluated and meet the requirements of a good experiment. Several fields need to be preprocessed before performing feature extraction: punctuation removal for “FROM” fields, HTML checker and removal for “BODY,” and tokenization for each part of the email. The preprocessing results will be continued with the extraction of features that are in accordance with the research objective, namely human features and email features. For each corpus used, both IWSPA and PECORP will go through the preprocessing stages individually, which are carried out using the Python programming language. After this process, the data are technically feasible to pass the next stage, namely feature selection.

D. Feature Selection and Extraction

Feature selection is one stage for determining which features on the email and human side significantly affect phishing email classification. In this research, the list of features to be tested is obtained based on the literature, which states a lack of human features (stylometric) approaches in different research fields [19]. Both corpora will go through a feature extraction process after the preprocessing process has been carried out on them. The features will be extracted based on their respective categories, namely email and human behavior features. The extraction process is carried out using the Python programming language using various supporting libraries. “Pandas” library for the data frame, “re” library for regular expressions, BeautifulSoup4 for HTML file text usage, Spellchecker library for misspelt words and NLTK library for stopwords and tokenize usage. All features extracted will be placed in a new column with the appropriate data rows with the help of the Pandas library. The extracted features are as follows:

1) Email Features

Based on the observations in the literature review, the most commonly used email features for phishing email classification are header, body, and URL. Features extracted are part of the main category of an email, where each category (header, body, and URL) has value in the form of text or numbers that will be analyzed at a later stage. The process is done using Python, where each part of the email feature extraction is done in a separate function. Hence, the feature is obtained according to its category (header, body, URL).

Email feature extraction uses several Python libraries, with Jupyter Notebook as the tool. For the data frame, the Pandas library is used as the initial frame for the data analysis and manipulation. NLTK and BeautifulSoup4 libraries are used to tokenize the email field and detect HTML elements (URL and JavaScript), respectively. A regular expression is used to obtain the time from the email.

The dataset obtained and analyzed is in the form of full text, which means that the features that can be extracted are features that are in accordance with the type of data itself, for example, the number of several parts of the email, such as character length, token length, URL length, body shape, and others. Some of the URL features were extracted based on previous experiments [29]. There are several additional URL features that were extracted. The list of email features extracted is shown in Table I below:

TABLE I. LIST OF EMAIL FEATURES

Feature	Observed Field	Value	Description
Header	FROM	Char Length	Total number of characters in the “FROM” field
	SUBJECT	Token Length	Total number of tokens in the “SUBJECT” field
	TIME	Time	Time stamp when the email is received in “hour:minute” format
Body	BODY TEXT	Body Format	Boolean value that represents email body is an HTML format or non-HTML format
		JavaScript Presence	Boolean value that represents there are <script> tag in the HTML format
URL	BODY TEXT	URL Flag	Boolean value that represents the presence of URL in an email by detecting <a> tag
		URL Length	A total number of URLs character length
		URL Count	A total number of URLs found in the body text
		Presence of IP address	Boolean value that checks if the URL is on the IP address form.

2) Human Features

In terms of human features, there are 29 features from five categories that were observed and extracted. These features were extracted in each corpus, namely IWSPA and PECORP. The extracted features are based on the stylometric area, which has five categories: lexical, syntactic, structural, content-

specific, and idiosyncratic. Each category has its own characteristics which can be extracted into a feature in the body of the email. Thus, each stylometrics category produces features described descriptively in the following Table II.

TABLE II. LIST OF HUMAN FEATURES

Feature	Observed Field	Value	Description
Lexical	Full email	Character Count	A total number of characters in the email text
		Token Count	A total number of tokens in the email text
		Average Word Length	Difference between character count and token count
		Lexical Diversity	The ratio of different unique word stems (types) to the total number of words (tokens)
Syntactic	Body Text	Presence of function word	Function words include determiners, conjunctions, prepositions, pronouns, auxiliary verbs, modals, qualifiers, and question words.
Content-Specific based on [15]	Body Text	Presence of punctuation	A number of punctuations in the email text
		Authority	A total occurrence of each word of: Paypal, Verify, Fraud, Management, Identity, Debit
		Reciprocation	A total occurrence of each word of: Benefits, Bank, Customers, Accounts, Updates
		Scarcity	A total occurrence of each word of: Limited, Services, Suspension, Suspended, Terminated
Structural	Body Text	Line Count	A total number of lines in the body text
		Sentence Count	A total number of sentences in the body text
		Word Count	A total number of words in the body text
		Character Count	A total number of characters in the body text
		Average Sentence length in terms of Character	Average calculation of a total number of characters with a total number of characters
		Average Sentence length in terms of Word	Average calculation of a total number of words with a total number of words
		Average Line length in terms of Sentence	Average calculation of the total number of lines with a total number of sentences
Idiosyncratic	Body Text	Misspelt word count	Total number of possible amounts of misspelt word in the body text

The main library is the same for extracting the email features for this category, namely PANDAS and NLTK. However, several additional packages and libraries are used to extract the specific features. The feature extraction for obtaining function words is based on the syntactic feature category using the POS (Part-of-Speech) Tag method with NLTK POS Tag packages library. The packages are set to collect specific words according to function word definition (e.g., conjunction, determiners, prepositions, etc.). There is one additional package for sentence tokenization from the NLTK library. Lastly, the spellchecker python library is used for obtaining the total of a misspelt word, and the library provides the total number of possible misspelt words and the list of misspelt words.

E. SMOTE Implementation for IWSPA-2018 Corpus

The machine learning algorithm's performance is evaluated by the accuracy result and evaluation of the dataset or corpora in the experiment. The imbalanced dataset is not appropriate to get optimum results since the labelled data is not equal, and it will lead to a biased classification result [27]. There are several methods for overcoming this problem, such as random over-sampling and under-sampling, which are common approaches to solving the issue. However, these approaches have several drawbacks; under-sampling is likely to dispose of valuable data, whereas over-sampling can heighten the probability of overfitting [28]. In this research, the method used to overcome the problem regarding the imbalanced dataset is the SMOTE (Synthetic Minority Oversampling Technique) method.

SMOTE selects feature samples from the available dataset, draws a line between the samples in the feature space, and creates a new sample at a point along the drawn line. By choosing the minority class (label) for generating a new feature sample, a synthetic sample is created at a random point between the two nearest samples in the feature space [27]. IWSPA-AP 2018 has an unbalanced amount of data ratio for the amount of data, while PECORP has been sorted for the same amount of data on phishing emails and legitimate emails, which is already explained in the previous section. The balancing dataset technique is needed for the IWSPA corpus to overcome unbalanced datasets. The IWSPA-AP 2018 corpus has unbalanced data, which consists of roughly 4082 legitimate emails and 503 phishing emails. To avoid bias in the experiment result, SMOTE needs to be implemented on the IWSPA corpus, which is needed for identifying which features have the most relevant impact on phishing email classification using email and human features. For SMOTE implementation, several Python libraries and packages are required to solve the unbalanced dataset. The Imbalanced-Learn python library and SMOTE package are used to process the IWSPA corpus. By setting up the data frame that meets the requirements for the required library, the SMOTE method can be applied to the IWSPA corpus.

The balancing dataset technique is needed for the IWSPA corpus to overcome unbalanced datasets. The SMOTE technique is applied to the IWSPA corpus. The number of rows has increased from 4082 rows to 8164 rows, which means SMOTE has created feature values between each feature in the feature space. In this research, the IWSPA SMOTE will be called the IWSPA-SM corpus. Thus, the new dataset (IWSPA-SM) has been acquired and will be helpful to help determine the best feature from the selected feature set

based on email features and human features. Starting from this section down, the new dataset will be called IWSPA-SM for IWSPA SMOTE, and the old dataset will be called IWSPA-NS for IWSPA NON-SMOTE.

F. Method Implementation

The implementation of feature extraction is done using the Python programming language and is supported by Jupyter Notebook for the interface tool. The feature selection phase will determine which human and email features significantly influence the phishing email. Each corpus will undergo three experiments with different feature category selections: 1) email features, 2) human features, and 3) combining email and human features. By dividing the corpus with its extracted category features, the analysis will be able to identify which category contributed the most to the classification result. The list of experiments for feature selection is as follows:

a) IWSPA-NS (NON-SMOTE) with email features
b) IWSPA-NS (NON-SMOTE) with human features
c) IWSPA-NS (NON-SMOTE) with combined features
d) IWSPA-SM (SMOTE) with email features
e) IWSPA-SM (SMOTE) with human features
f) IWSPA-SM (SMOTE) with combined features
g) PECORP with email features
h) PECORP with human features
i) PECORP with combined features

The dataset generated from the extraction feature will be carried out to determine the importance of features for each category. Feature importance methods use various ways to obtain and calculate the feature set to determine which feature has the most impact on the current dataset. There are several types of feature importance scores, and commonly the methods are feature importance from coefficients and feature importance from a tree-based model. One way to implement feature importance is by using PyCaret, a python library that provides machine learning models for data classification, including the feature importance method. It uses a combination of several supervised techniques, including Random Forest, Adaboost, and Linear Correlation with the permutation importance technique, to select the subset of features that are most important for the model. Working with selected features instead of all the features will reduce the risk of over-fitting, improve accuracy, and decrease training time [14]. The experiment details and results are shown in the section below.

IV. Experiment and Result

This experiment has two main outputs, namely the best features in each experiment with each corpus and the performance results from binary classifications using each corpus. The feature importance result and the classification evaluation of this experiment were measured using the performance evaluation method provided by the PyCaret library; the results of the evaluation are as follows:

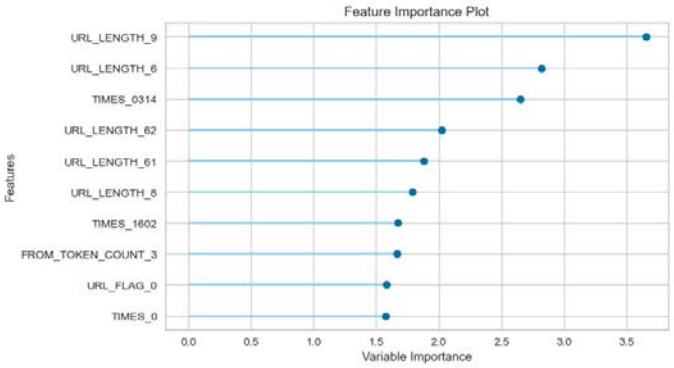

Fig. 2. IWSPA-NS Email Feature Importance Result

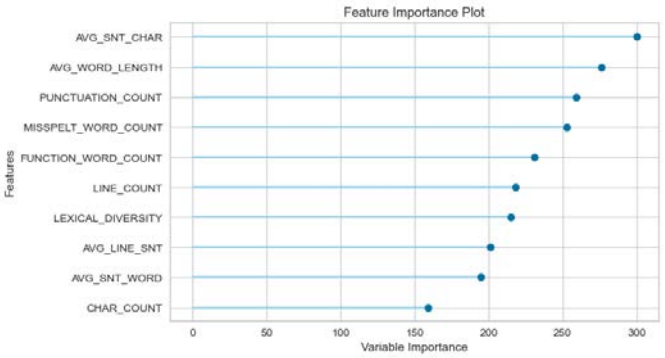

Fig. 3. IWSPA-NS Human Feature Importance Result

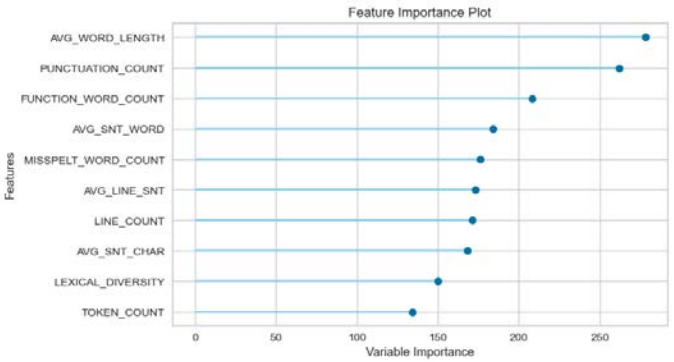

Fig. 4. IWSPA-NS Combined Feature Importance Result

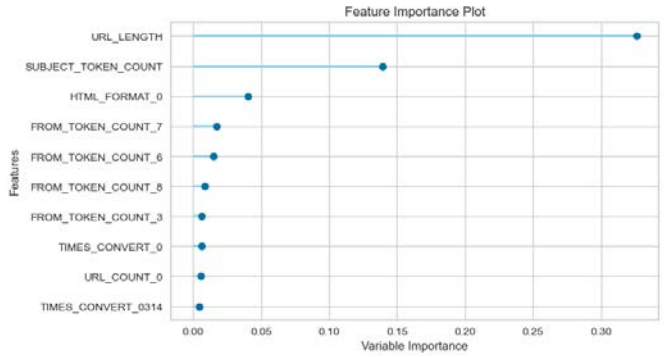

Fig. 5. IWSPA-SM Email Feature Importance Result

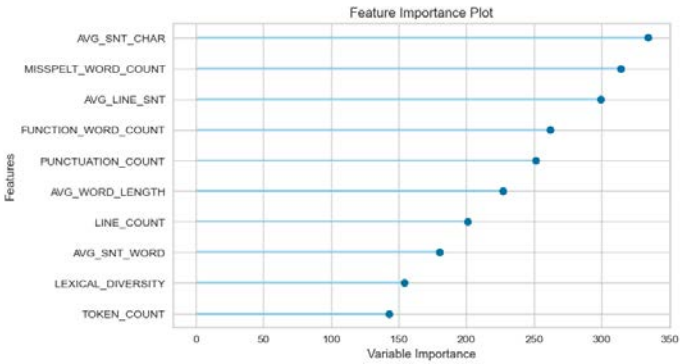

Fig. 6. IWSPA-SM Human Feature Importance Result

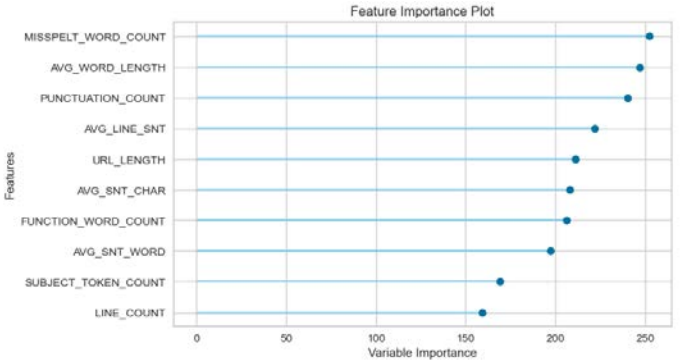

Fig. 7. IWSPA-SM Combined Feature Importance Result

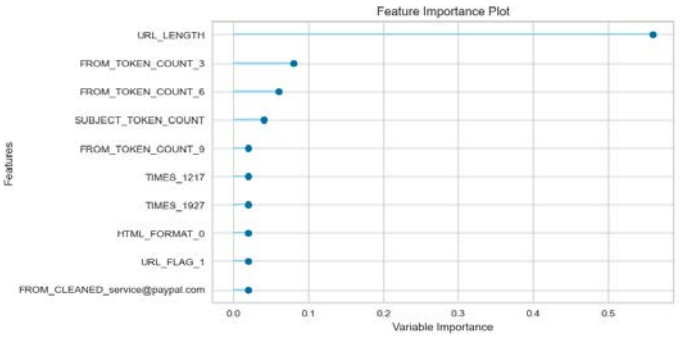

Fig. 8. PECORP Email Feature Importance Result

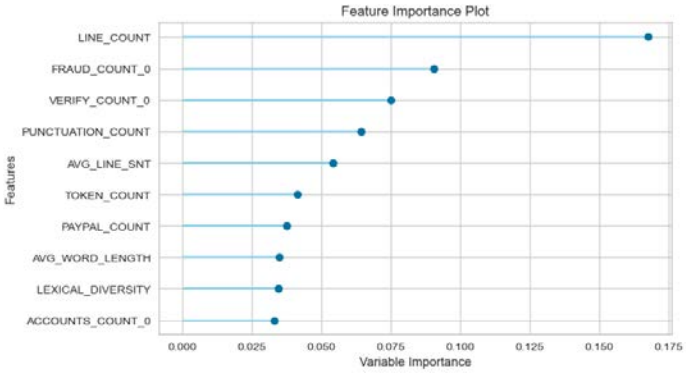

Fig. 9. PECORP Human Feature Importance Result

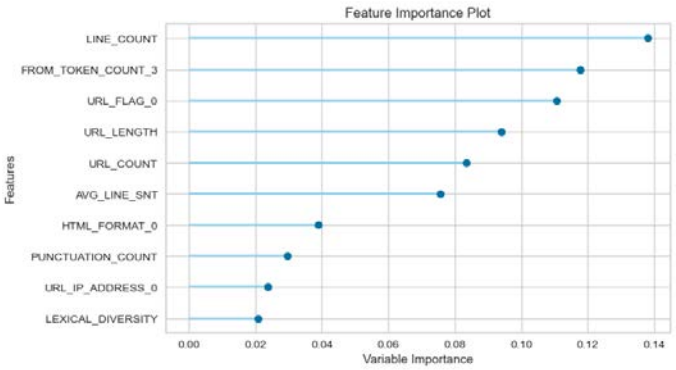

Fig. 10. PECORP Combined Feature Importance Result

The figures above are the result of the important feature of using the PyCaret library on all corpora. There are nine results obtained in each experiment where the experiment produces the output, namely the best feature that has the most significant impact in determining phishing emails in each corpus. The following are the explanations of each figure resulting from the experiment for determining the best features using feature importance with PyCaret.

Fig. 2 is the resulting diagram of IWSPA-NS with only email features extracted where the best feature is URL length. Fig. 3 is IWSPA-NS with only human features extraction, where the best feature is Average Sentence Length in terms of Characters. In Fig. 4, the best feature is the Average Word Length. In the IWSPA-SM corpus, the best features obtained are URL length for email features, Average Sentence Length in terms of characters for human features, and Misspelt Word Count for combined features, which can be seen in Fig. 5, Fig. 6, and Fig. 7 consecutively. Fig. 8 shows the result of the best feature in the PECORP corpus, namely URL length. Fig. 9 and Fig. 10 show that the best feature for experimenting with human features and combined features in the PECORP corpus is Line Count. The determination of the best feature based on the variable importance value of each feature from PyCaret uses a combination of permutation importance techniques, including Random Forest, Adaboost, and Linear correlation with the target feature. Therefore, the results obtained above are based on the algorithm of feature importance provided by PyCaret.

From the experimental results above, it can be seen that the variable importance value generated by this experiment is very diverse for several experiments on the corpus used. It can happen because the features used and extracted in each experiment are classified as "categorical features," where the coverage of the category features is extensive. For example, in the email category feature, the "Time" feature is a feature that contains numbers in time format extracted from the email header. In the human category, the "Lexical Diversity" feature contains decimal numbers with a wide range of values for each email. With a very diverse feature value of each feature extracted, the results of the variable importance value have a reasonably large range. Therefore, this experiment aims to find out what features have a significant impact on helping classify phishing emails. The scope of features that have been extracted can be in the form of numerical, boolean, or categorical values.

The results of this important feature are novelty results that can be used as a reference for the selection of features or feature engineering in the classification process using phishing email. It can be seen that some features are the same in the different corpora, for example, URL length and Line Count. This shows that the effect of these features is beneficial to improving the performance of the phishing email classification process. Moreover, further experiments can make it easier for the feature selection process to classify phishing emails with different approaches.

Tables III, Table IV, and Table V show the result of each experiment using different feature categories and corpus using the PyCaret library. The result shown above is the mean value of a 10-fold cross-validation classification with the performance metrics value for evaluation. Thirteen models are used in each classification, and the highest results from these models are shown as follows:

TABLE III. IWSPA-NS PERFORMANCE EVALUATION

Evaluation Performance	**IWSPA-NS with Email Feature**	**IWSPA-NS with Human Feature**	**IWSPA-NS with Combined Feature**
Model	Random Forest	Light Gradient Boosting Machine	Light Gradient Boosting Machine
Accuracy	0.9346	0.9698	**0.9713**
AUC	0.9001	0.9745	**0.9879**
Recall	0.4730	**0.7838**	0.7703
Precision	0.9171	0.9465	**0.9773**
F1	0.6218	0.8555	**0.8603**
Kappa	0.5904	0.8388	**0.8446**
MCC	0.6304	0.8447	**0.8528**

TABLE IV. IWSPA-SM PERFORMANCE EVALUATION

Evaluation Performance	**IWSPA-SM with Email Feature**	**IWSPA-SM with Human Feature**	**IWSPA-SM with Combined Feature**
Model	Random Forest	Light Gradient Boosting Machine	Light Gradient Boosting Machine
Accuracy	0.9107	0.9790	**0.9844**
AUC	0.9679	0.9969	**0.9982**
Recall	0.9180	0.9792	**0.9820**
Precision	0.9042	0.9786	**0.9866**
F1	0.9109	0.9789	**0.9843**
Kappa	0.8215	0.9580	**0.9688**
MCC	0.8219	0.9581	**0.9689**

TABLE V. PECORP PERFORMANCE EVALUATION

Evaluation Performance	**PECORP with Email Feature**	**PECORP with Human Feature**	**PECORP with Combined Feature**
Model	Ada Boost Classifier	Extra Trees Classifier	Decision Tree Classifier
Accuracy	0.9992	0.9964	**0.9997**
AUC	**1.0000**	0.9999	0.9997
Recall	0.9990	0.9990	**1.0000**
Precision	0.9995	0.9938	**0.9995**
F1	0.9992	0.9964	**0.9997**
Kappa	0.9984	0.9927	**0.9995**
MCC	0.9984	0.9928	**0.9995**

Table III shows the evaluation result of the experiment using the IWSPA-NS corpus with the PyCaret library. It can be seen in the comparison of the results of each category feature used in the phishing email classification process. The highest average result is in the experiment using combined features except for the recall value. Table IV shows the results of evaluating the IWSPA-SM corpus, where the highest average result was achieved in the experiment using combined features. Table V shows the experimental results of the PECORP corpus, which shows that the highest average result was obtained in the experiment using combined features. Based on the results obtained from the experiment, which are very promising, this shows that the combination of features used can improve the performance of phishing email classification. The result can be seen in Table VI.

TABLE VI. EXPERIMENT RESULT COMPARISON

Research	**Feature**	**Dataset**	**Accuracy**
IWSPA-NS Email Features	Email	IWSPA	0.9346
IWSPA-NS Human Features	Human	IWSPA	0.9698
IWSPA-NS Combined Features	Email + Human	IWSPA	**0.9713**
IWSPA-SM Email Features	Email	IWSPA	0.9107
IWSPA-SM Human Features	Human	IWSPA	0.9790
IWSPA-SM Combined Features	Email + Human	IWSPA	**0.9844**
PECORP Email Features	Email	PhishCorp + Enron	0.9992
PECORP Human Features	Human	PhishCorp + Enron	0.9964
PECORP Combined Features	Email + Human	PhishCorp + Enron	**0.9997**
Li (2020) [15]	Email + Human	PhishCorp	0.9960
Xiujuan (2019) [16]	Human	Enron	0.9505
Egozi (2018) [17]	Human	IWSPA	0.9700

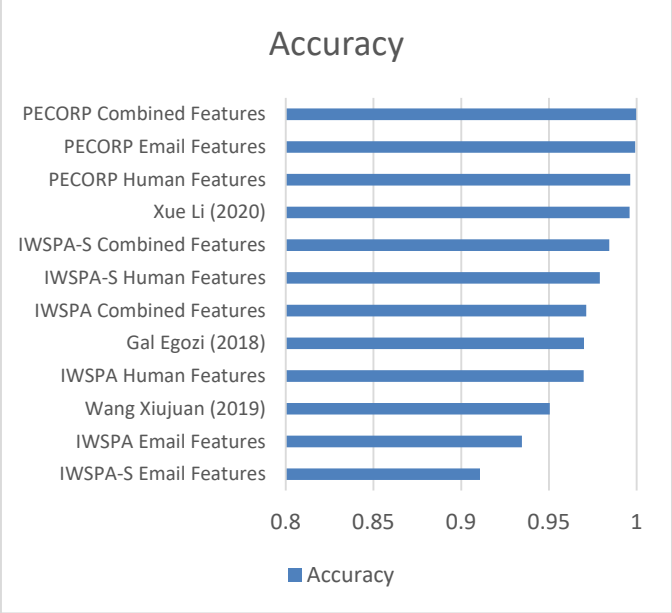

Fig. 11. Experiment Result Comparison.

A comparison of experimental results was carried out with previous related studies. In [15], this study conducted a classification of phishing emails using a combination of email and human features. The results obtained are fairly promising, but the proposed method using PyCaret is still superior, with a difference in accuracy value of 0.37%. The next comparison is with [16] and [17], where these two studies only maximize the use of human features for the classification process. With a difference in accuracy of more than 2%, the results of these studies are still just slightly below the proposed method that uses PyCaret.

Based on the comparison in Fig. 11, the experiment shows that the features selected are working best with high results even though the dataset is partly different. The Enron corpus is classified as a complex dataset because it has over 600.000+ emails on different topics and subjects. The Online Phishing corpus is more likely to ease up on preprocessing step for data analysis. Therefore, the overall comparison is categorized as a good result for this features selection experiment, especially with the combined features extraction with slightly higher accuracy than the previous research on phishing email classification with various corpora, namely [15], [16], and [17].

V. Conclusion and Future Work

By knowing which features have the most significant impact by using human and email feature extraction and selection experiments with the PyCaret library, looking at the value of the important feature for each category and corpus, and the overall high classification accuracy. Then the results of this feature selection experiment can be continued by developing embedding features that can be input for phishing email classification using a deep learning approach.

With the results of this experimental feature selection, further research can be continued using a deep learning approach for phishing email classification. The feature selection result with a high impact value on determining the phishing email classification is selected and processed for the deep learning approach by embedding the features. The feature embedding is created based on the highest feature selection, which becomes the document representation for the deep learning input. By analyzing these results, we can make a list of the features that will be used for the next step. Table VII shows the best features from the feature selection and importance experiment.

TABLE VII. Best Features

Dataset	Feature #1	Feature #2	Feature #3
IWSPA-NS Email	URL Length	Times	From Token Count
IWSPA-NS Human	Avg. Sentence by Char	Avg. Word Length	Punctuation Count
IWSPA-NS Combined	Avg. Word Length	Punctuation Count	Function Word Count
IWSPA-SM Email	URL Length	Subject Token Count	HTML Format
IWSPA-SM Human	Avg. Sentence by Char	Misspelt Word Count	Avg. Line by Sent
IWSPA-SM Combined	Misspelt Word Count	Avg. Word Length	Punctuation Count
PECORP Email	URL Length	From Token Count	Subject Token Count
PECORP Human	Line Count	“Fraud” Word Count	“Verify” Word Count
PECORP Combined	Line Count	FROM Token Count	URL Length

In Table VII above, the same features obtained from different experiments and corpora have a high impact on determining the phishing email: URL Length, Average Word Length, Average Sentence by Character, Misspelt Word, and Line Count. As a result, these features are the best features of human and email behavior for classifying phishing emails using machine learning. This feature set can become the set for experiments with phishing email classification using other approaches or as a benchmark to determine other features from human or email categories on phishing email classification using either a different dataset or the same as in this experiment.

For the next step in this research, those top selected features can be formed into a feature embedding for improving the phishing email classification results using deep learning approaches. Developing a feature representation based on the top features of each corpus and training with deep learning structures is expected to produce a better result in identifying phishing emails.

***Abstract*—Among the educational data mining problems, the early prediction of the students' academic performance is the most important task, so that timely and requisite support may be provided to the needy students. Machine learning techniques may be used as an important tool for predicting low-performers in educational institutions. In the present paper, five single-supervised machine learning techniques have been used, including Decision Tree, Naïve Bayes, k-Nearest-Neighbor, Support Vector Machine, and Logistic Regression. To analyze the effect of an imbalanced dataset, the performance of these algorithms has been checked with and without various resampling methods such as Synthetic Minority Oversampling Technique (SMOTE), Borderline SMOTE, SVM-SMOTE, and Adaptive Synthetic (ADASYN). The Random hold-out method and GridSearchCV were used as model validation techniques and hyper-parameter tuning respectively. The results of the present study indicated that Logistic Regression is the best performing classifier with every balanced dataset generated using all of the four resampling techniques and also achieved the highest accuracy of 94.54% with SMOTE. Furthermore, to improve the prediction results and to make the model scalable, the most suitable classifier was integrated with the help of bagging, and a well-accepted accuracy of 95.45% was achieved.**

***Keywords*—Educational data mining; resampling methods; feature selection technique; machine learning; imbalanced data**

I. Introduction

Due to the digitization and use of technology in the educational field, there is a large amount of educational data. Educational Data Mining helps to analyze and extract useful information, such as selecting the factors that affect the students' performance, predicting students' performance, etc., from a large amount of educational data. As students or youths are the future of any nation, predicting the success rate of students in their academic area is a very important and beneficial task. This may be achieved with the help of educational data mining, which utilizes various machine learning techniques.

Although the field of Educational Data Mining (EDM) is old and its definition was given by Fayyad et al. [1] in 1996, EDM emerged as a convincing research area after the establishment of the annual International Conference on Educational Data Mining and the Journal of Educational Data Mining in 2008 [2]. After that, Baker [3] identified the application of data mining in education to discover models for predicting students' performance by using the methods of prediction, clustering, relationship mining, and discovery with models. Among the applications of EDM, detecting student failure at an early stage has been an appealing research topic for researchers due to its social impact. The prediction of the students at risk of being dropouts from an institute or school becomes difficult due to the large number of factors that may influence the academic performance of the students. Thus, it is quite important to predict low-performing students at an early stage with higher accuracy, along with the important factors that may affect their performance.

To achieve this goal, the present study has three important research objectives: (i) to identify the influential features by using a filter-based feature selection technique. (ii) to identify the best performing classifier by comparing various single-supervised machine learning techniques, viz., decision trees, Naïve Bayes, k-Nearest Neighbor, Logistic Regression, and Support Vector Machine with various resampling techniques such as random oversampling, SMOTE, Borderline SMOTE, SVM-SMOTE, and ADASYN. (iii) to enhance the prediction rate of the students at-risk by using an ensemble model that integrates the most suitable data mining technique.

In rest of the paper, the work related to the present study is given in section II. The methodology used in the present work is explained in Section III. In Section IV, the obtained results are analyzed and discussed. Finally, the conclusion and future work are given in Section V.

II. Related Work

In the past, various review studies have been performed on educational data mining [4, 5], and many researchers have worked on identifying the factors that deteriorate the academic performance of students. Ahmed et al. [6] selected nine attributes such as department, attendance, high school degree, mid-term marks, student participation, lab test grades, assignment scores, seminar performance, and homework to predict the final grade and generate the rules set by the Decision Tree. Tomasevic et al. [7] have compared the performance of several data mining algorithms using past student performance, student engagement, and student demographic data. They concluded that students' engagement and past performance data have a significant influence, while

demographic attributes have a slight impact, on students' performance. Further, Verma and Yadav [8] used the cross-tabulation method and the chi-square test to analyze the effects of different attributes such as background, academic, social, and psychological characteristics on students' academic performance. In their finding, it was concluded that students' academic and background attributes were the most influential factors that may affect students' grades.

With knowledge of the factors that influence the students' performance, predictions can be made with the help of data mining algorithms to identify students at risk. To analyze students' performance, Asif et al. [9] implemented decision tree and clustering technique on a dataset of 210 students that contained pre-admission marks and all subjects' marks and found that the pre-university marks and subjects' marks in the first and second years had an impact on students' final year marks. Hamoud et al. [10] applied Bayesian classifiers, namely Naïve Bayes and Bayes Net, to the dataset of 161 students and found that Naïve Bayes outperformed for predicting the students' performance. Costa et al. [11] performed a comparison of the effectiveness of different educational data mining techniques to predict students' performance in introductory programming courses and concluded that the support vector machine outperformed. Moreover, Ha et al. [12] implemented rule-based learners, neural-based learners, and statistical-based learners (Naïve Bayes, and Support Vector Machine) on students' datasets, which consist of personal and past academic information, to predict students' performance. In their experiment, neural-based learners and Naïve Bayes achieved the highest accuracy of 86.19%.

A suitable approach towards feature selection and handling imbalanced class problems may enhance the prediction accuracy of machine learning models. Thammasiri et al. [13] compared random oversampling and SMOTE balancing methods along with four popular data mining models: logistic regression, decision trees, neural network, and support vector machine to assess the students' performance. In their results, Support Vector Machine (SVM) achieved the highest accuracy of 90.24% with SMOTE. Mueen et al. [14] applied Naïve Bayes, Neural Network, and Decision Tree to students' data having their general, academic, and forum-related variables along with feature selection and SMOTE oversampling method to solve the imbalanced data problem and found Naïve Bayes to be outperformed with 86% accuracy. Ghorbani and Ghousi [15] used and compared different resampling methods, viz., Borderline SMOTE, Random Over Sampler, SMOTE, SMOTE-ENN, SVM-SMOTE, and SMOTE-Tomek, by evaluating the performance of the various classifiers, and Random Forest obtained the highest accuracy of 81.27% with SVM-SMOTE. Further, Ghavidel et al. [16] solved the problem of imbalanced data by using a combination of the SVM-SMOTE (an over-sampling technique) and Edited-Nearest-Neighbor (an under-sampling technique) while predicting disease mortality. Recently, Desiani et al [17] applied k-Nearest Neighbor (k-NN), Artificial Neural Network (ANN), and C4.5 to students' educational background records along with SMOTE to make the dataset balanced, and that balanced dataset increased the accuracy of prediction, and for k-NN the maximum achieved accuracy was 83.71%.

Another aspect that enhances the prediction accuracy is the appropriate use of ensemble models. Teoh et al. [18] used feature selection and SMOTE oversampling techniques and then applied various ensemble machine learning methods, namely stacking, boosting, and bagging. In their findings, AdaBoost has achieved a maximum accuracy of more than 90%.

Although there are several studies to predict the students' academic performance, the study which considers all categories of variables, i.e., background, academic, social, and psychological, and predicts students at-risk at an early stage with adequate accuracy is lacking. Also, a single classifier-based prediction is not suitable from one perspective to another. Moreover, a classifier giving the highest prediction accuracy for a particular dataset may not be valid for a different dataset. Thus, the aim of the present study is to identify low performers at an early stage with a higher prediction rate by using a scalable approach.

III. METHODOLOGY

The main objective of the present paper is to predict the academic performance of students with higher accuracy. To achieve this goal, the different single supervised machine learning algorithms were applied with and without data balancing, and finally, by comparing the results, a model was constructed to enhance the prediction accuracy. The methodology applied in the present work may be given as follows:

- Dataset preparation.
- Data preprocessing including data transformation, feature selection, and data balancing.
- Identification of the best classification technique by comparing the results of classification models when applied to the preprocessed data.
- Make a scalable ensemble model with the help of the best classification technique.
- Result evaluation of the proposed ensemble model.

The workflow of the proposed methodology is given in Fig. 1.

A. Dataset

To make the data versatile, it is collected from the two different engineering colleges situated in different regions (the north and south of India). In the present paper, the sample size comprises 550 engineering students from two different engineering colleges in India, i.e., Bipin Tripathi Kumaon Institute of Technology, Dwarahat, Uttarakhand, and Cochin University of Science & Technology, Trivandrum, Kerala. The dataset includes information regarding background, past academic, social, and psychological factors with 30 different attributes, of which three attributes (roll-number, name, and branch) are used for identification purposes only and do not play any role in the prediction of low-performers. So, only 27 attributes were used for the present work, with first semester GPA as the output variable. For these attributes, data was collected online with the help of a multiple-

choice questionnaire created via outsourced technology, i.e., Google Form. As the aim of the paper is to identify the students having the highest risk of dropping out of college, the information about the output attribute for the dataset is divided only into two categories, i.e., low performers and high performers, based on the first-semester grade point of the students.

B. Data Preprocessing

Before applying any machine learning model to the dataset, data should be preprocessed so that any machine learning model can be performed efficiently. In the present study, the dataset is complete and free from noise, so there is no need to handle missing data and outliers. To preprocess the data, data transformation, feature selection, and data balancing have been performed.

1) Data transformation: In the present study, all the features were categorical except students' GPA as it was initially in numerical form. So, GPA was generalized into categorical values, i.e., "class A (high performer)" and "class B (low performer)". Finally, these categorical variables were encoded into the suitable format of machine learning models.

2) Feature selection: Feature selection is an important part of the students' performance prediction model for two main reasons:

- The main purpose of the prediction of students' academic performance is to provide timely support to the low-performing students in the area where they are lacking. Only after identifying the attributes that have a significant impact on the output variable, i.e., students' academic performance, suitable corrective measures may be taken to provide support to the low-performing students.
- With the help of feature selection, irrelevant attributes may be removed from the data without losing reliability in classification. Thus, the dimensionality reduction raises the processing speed, and hence the classifier can learn faster.

There are three main feature selection techniques: manual selection based on pedagogical theories or expert experience; filter-based selection; and wrapper feature selection [19]. In the present study, as all the attributes were categorical, a filter-based feature selection technique, namely "chi-square", was used by which p-values were calculated for each attribute [8]. The attributes having a p-value of less than 0.01 show a highly significant correlation with the student's grades.

3) Data balancing: Data balancing is an important part of preprocessing step by which class distribution have to make equal so that classifier do not assign every new sample to the majority class only. In the present study the distribution of "class A" and "class B" is shown in Fig. 2. From the figure, it may be revealed that the dataset contained more samples from "class A" (66%) than the "class B" (34%). Previous study [20] shows that if the percentage of minority class is less than 35% of dataset then it is called imbalanced and hence the dataset of present study is imbalanced to some extent. There are mainly three types of re-sampling techniques i.e., over-sampling, under-sampling, and hybrid-sampling [15] that may be used to balance the dataset. Due to the limited size of dataset, in the present study, only over-sampling techniques i.e., Synthetic Minority Oversampling Technique (SMOTE) [21], Borderline SMOTE [22], SVM-SMOTE [23], and ADASYN [24] were used and compared.

C. Machnie Learning Techniques

There are different types of classification machine learning models that may be used to predict the students' academic performance. In the present study, five single supervised machine learning models have been applied, including Decision Tree [25], Naïve Bayes [9, 26], k-Nearest-Neighbor [27], Support Vector Machine [28], and Logistic Regression [29]. To achieve the best performance of these machine learning models, the passing parameters for these models were set with the help of an algorithm called "GridSearchCV" which gives the best combination of passing parameters [30]. These combinations of passing parameters are listed in Table I.

TABLE I. CLASSIFICATION MODELS AND THEIR PASSING PARAMETERS

Machine learning model	**Passing parameters**
Decision Tree	Criterion="gini", max_depth=4, max_leaf_node=8
Naïve Bayes	No parameter
k-Nearest Neighbor	n_neighbor=21
Support Vector Machine	c=2, kernel="rbf"
Logistic Regression	No parameter

D. Model Validation and Result Evaluation

Model validation is used to check the effectiveness of the model across independent datasets. In the present study, the random hold-out method was used for model validation, in which 80% of the data was for training purposes and 20% of the data was reserved for testing purposes.

Furthermore, the performance of all the machine learning techniques was evaluated in terms of accuracy, precision, recall, and f1-score. These performance metrics are given as follows:

$$Accuracy = \frac{(True\ Positive + True\ Negative)}{Total\ number\ of\ samples} \quad (1)$$

$$Precision = \frac{True\ Positive}{Total\ classes\ predicted\ as\ positive} \quad (2)$$

$$Recall = \frac{True\ Positive}{Total\ number\ of\ actual\ positive\ classes} \quad (3)$$

$$F1 - score = 2 \times \frac{(Precision \times Recall)}{(Precision + Recall)} \quad (4)$$

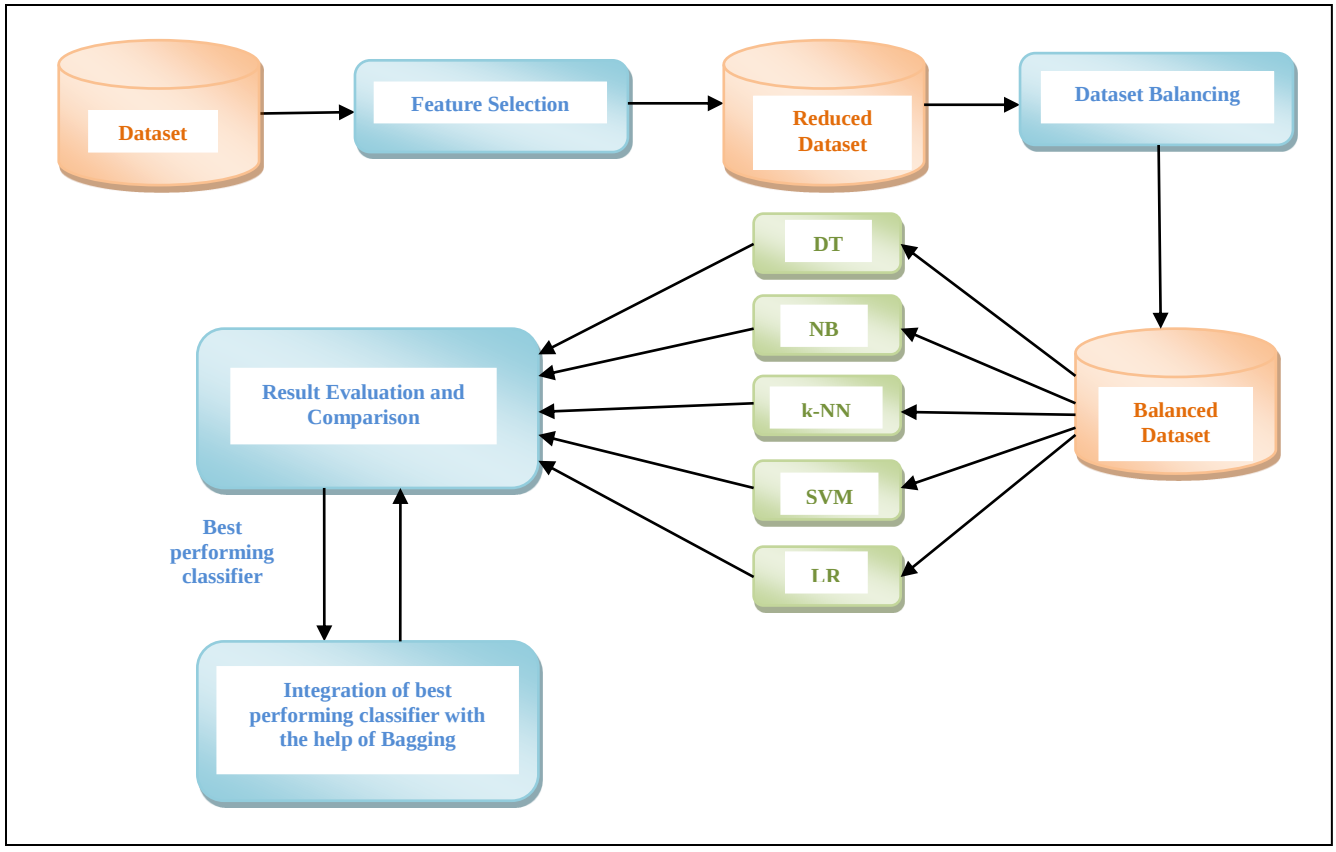

Fig. 1. Framework of Proposed Methodology.

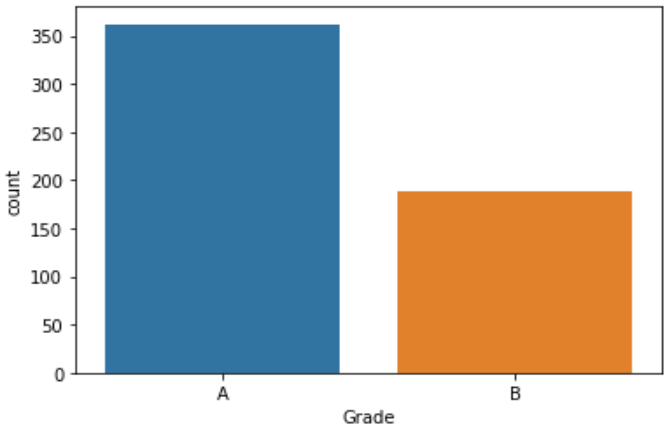

Fig. 2. Distributions of the Grades.

E. Construction of Ensemble based Classifier

In most of the previous studies [18, 31–38], it was shown that the ensemble model gives a higher prediction accuracy, so, to enhance the prediction accuracy, an ensemble model was constructed in the present study. For this, the best performing classifier was selected along with its suitable resampling method, after comparing the results of different single machine learning algorithms with balanced dataset. Finally, in order to make an ensemble classifier, the three best-performing classifiers were integrated with the help of bootstrap aggregation.

IV. Result and Discussion

In the present work, the whole experiment was done with the help of different libraries such as Pandas, Seaborn, and Scikit-learn of the Python programming language, which is a very powerful and user-friendly language for data scientists. The first aspect of the present work is to find out the influential attributes and to reduce the dimensionality with the help of a filter-based feature selection technique. For this purpose, the p-values were calculated for different attributes using the chi2 method of the sklearn.feature_selection library of Python programming and are shown in Table II. From this table, it is depicted that after applying the feature selection technique, the following 11 features are selected as influential features that affect students' academic performance: percentage in 10^{th} standard, percentage in 12^{th} standard, confidence, mathematics % in 12^{th} standard, punctuality, curiosity, medium/language of previous study, category, father's highest qualification, mother's highest qualification, and mental stress.

After selecting the most influential attributes, Decision Tree, Naïve Bayes, k-Nearest-Neighbor, Support Vector Machine, and Logistic Regression algorithms have been applied to the dataset, which contains only the 11 selected most influential attributes. The results obtained for accuracy, precision, recall, and f1-score of these algorithms are represented in Table III.

TABLE II. STUDENTS' RELATED INPUT FEATURES AND THEIR CORRESPONDING P-VALUES

Attribute Category	Attribute	p-value
Background Attributes	Gender	.0304
	Category	8.1425e-05
	Number of Siblings	.5330
	Status of Parent	.4112
	Father's Highest Qualification	.0001
	Mother's Highest Qualification	.0027
	Father's Occupation	.8812
	Mother's Occupation	.8034
	Annual Family Income	.2393
	Living Location	.1042
	Medium/Language of Previous Study	4.4161e-06

TABLE III. RESULTS OF THE CLASSIFIERS ON IMBALANCED DATASET

Classifier	Accuracy (in %)	Recall		Precision		F1-score	
		A	*B*	*A*	*B*	*A*	*B*
Decision Tree	91.81	0.99	0.79	0.90	0.97	0.94	0.87
Naïve Bayes	88.18	0.89	0.87	0.93	0.80	0.91	0.84
k-Nearest Neighbor	89.09	0.94	0.79	0.89	0.88	0.92	0.83
Support Vector Machine	90.90	0.99	0.76	0.89	0.97	0.93	0.85
Logistics Regression	92.72	0.99	0.82	0.91	0.97	0.95	0.89

From Table III, it may be observed that the highest accuracy, i.e., 92.72%, was achieved with Logistic Regression. In terms of recall and precision for classes A and B, no single algorithm can be declared best. This is because precision and recall for classes A and B are not the highest for the same algorithm. For example, in Naïve Bayes recall and precision for class B and class A is highest, respectively, but recall for class A and precision for class B is lowest. In such situations, the f1-score may be taken as an evaluation criterion, as the f1-score is the harmonic mean of precision and recall. Logistic Regression has achieved the highest accuracy and highest f1-score for both classes 'A' and 'B', and hence it may be considered the best performing algorithm with the imbalanced dataset. The dataset of the present study was imbalanced, and hence four resampling techniques (SMOTE, Borderline SMOTE, SVM-SMOTE, and ADASYN) have been used, and the performance of all the classifiers was evaluated with the balanced dataset.

The performances of different models with the different resampling methods are shown in Table IV. From Table IV, it may be noted that the accuracy of the models, except for Logistic Regression, was not significantly improved when applied to the balanced dataset. This may be because of the fact that, in the case of balanced data, all the algorithms considered both the classes "A" and "B" with equal weightage. So, it may be concluded that although in the case of balanced datasets, the accuracy of every classifier is not increasing; the prediction accuracy may now be trustable and sufficient to measure the model's performance. The performances of various classifiers using the resampling methods SMOTE, Borderline SMOTE, SVM-SMOT, and ADASYN are shown in Fig. 3-6 respectively. From these figures, it may be observed that Logistic Regression outperformed all the classifiers in every balanced dataset generated with all the four resampling techniques, and the highest accuracy of 94.54% and the highest F1-score were achieved when SMOTE was considered as a resampling method.

TABLE IV. RESULTS OF THE CLASSIFIERS ON BALANCED DATASET

Classifier	Evaluation Metric		SMOTE	Borderline SMOTE	SVM- SMOTE	ADASYN
Decision Tree	Accuracy (in %)		89.09	88.18	88.18	91.81
	Recall	A	0.89	0.86	0.89	0.92
		B	0.89	0.92	0.87	0.92
	Precision	A	0.94	0.95	0.93	0.96
		B	0.81	0.78	0.80	0.85
	F1-score	A	0.91	0.91	0.91	0.94
		B	0.85	0.84	0.84	0.89
Naïve Bayes	Accuracy (in %)		80.90	83.63	86.36	83.63
	Recall	A	0.86	0.83	0.85	0.83
		B	0.71	0.84	0.89	0.84
	Precision	A	0.85	0.91	0.94	0.91
		B	0.73	0.73	0.76	0.73
	F1-score	A	0.86	0.87	0.89	0.87
		B	0.72	0.78	0.82	0.78
k-Nearest Neighbor	Accuracy (in %)		85.45	82.72	83.63	81.81
	Recall	A	0.86	0.79	0.79	0.78
		B	0.84	0.89	0.92	0.89
	Precision	A	0.91	0.93	0.95	0.93
		B	0.76	0.69	0.70	0.68
	F1-score	A	0.89	0.86	0.86	0.85
		B	0.80	0.78	0.80	0.77
Support Vector Machine	Accuracy (in %)		90.90	90.00	89.09	90.90
	Recall	A	0.96	0.92	0.92	0.94
		B	0.82	0.87	0.84	0.84
	Precision	A	0.91	0.93	0.92	0.92
		B	0.91	0.85	0.84	0.89
	F1-score	A	0.93	0.92	0.92	0.93
		B	0.86	0.86	0.84	0.86
Logistics Regression	Accuracy (in %)		94.54	90.90	91.81	93.63
	Recall	A	0.99	0.93	0.94	0.97
		B	0.87	0.87	0.87	0.87
	Precision	A	0.93	0.93	0.93	0.93
		B	0.97	0.87	0.89	0.94
	F1-score	A	0.96	0.93	0.94	0.95
		B	0.92	0.87	0.88	0.90

TABLE V. RESULTS OF THE PROPOSED MODEL

Classifier	Evaluation Metric		Imbalanced dataset	SMOTE	Borderline SMOTE	SVM- SMOTE	ADASYN
Proposed Model	Accuracy (in %)		93.63	95.45	93.63	93.63	94.54
	Recall	A	0.99	0.99	0.96	0.96	0.97
		B	0.84	0.89	0.89	0.89	0.89
	Precision	A	0.92	0.95	0.95	0.95	0.95
		B	0.97	0.97	0.92	0.92	0.94
	F1-score	A	0.95	0.97	0.95	0.95	0.96
		B	0.90	0.93	0.91	0.91	0.92

Finally, after evaluating the performance of all classifiers, the best performing classifier, namely Logistic Regression, was chosen to create the ensemble model in order to improve prediction accuracy. In order to make the ensemble model, three Logistic Regression classifiers were integrated with the help of bagging. The result of the proposed integrated model is shown in Table V. The proposed model has achieved the highest accuracy of 95.45%, the highest prediction rate for low performers, and the highest f1-score for both classes while using SMOTE. It is pertinent to mention here that the accuracy of the proposed model increased by 1.82% after using the resampling technique SMOTE, while in the study of Desiani et al., the average accuracy was increased by 20.13%. The possible reason may be that the dataset used in the present study has a small sample size and was not highly imbalanced. In the case of a large sample size, the number of students at risk will be significantly lower, and hence, in such situations of highly imbalanced data, the present model may be quite useful.

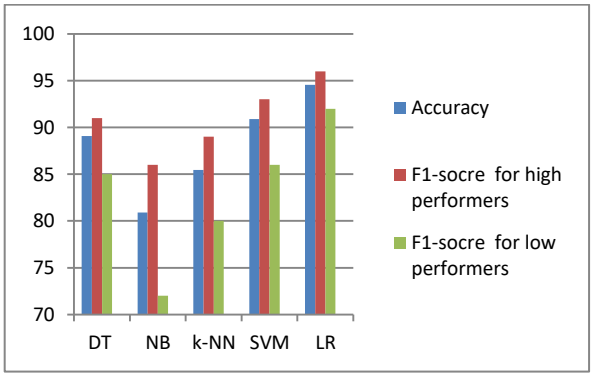

Fig. 3. Performance of Different Classifiers with SMOTE.

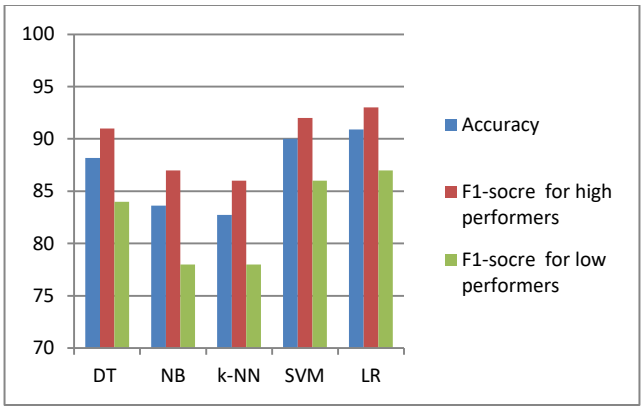

Fig. 4. Performance of Different Classifiers with Borderline SMOTE.

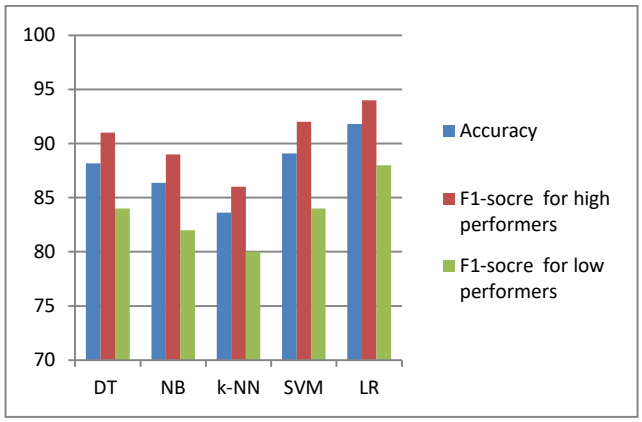

Fig. 5. Performance of Different Classifiers with SVM-SMOTE.

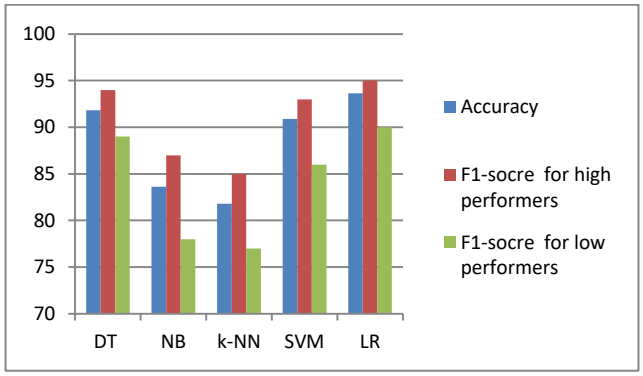

Fig. 6. Performance of Different Classifiers with ADASYN.

The highest prediction accuracy achieved in the present study is 95.45%, which is greater than most of the previous studies [12-18]. Along with the enhanced prediction accuracy, the main advantage of the present work is that the methodology proposed in the present study is scalable from one context to the other.

V. Conclusion and Future Work

From the present work, it may be concluded that students' past academic performance (10th standard %, 12th standard %, and Math's % in the 12th standard), their background (category, parents' qualification, and medium of the previous study), and their psychological features (mental stress, confidence, curiosity, and punctuality) were the relevant attributes. Thus, to increase the academic performance of the students, these factors may be considered as the focus points.

In the present study, all the used classifiers were able to predict students' outcomes with reasonable accuracy of more than 80%. Among all the used classifiers, Logistic Regression was the best performing algorithm with a balanced as well as an imbalanced dataset. Further, the accuracy and prediction rate for identifying low performers as well as for high performers were improved when the Logistic Regression was applied to the balanced dataset. The prediction accuracy was further enhanced with the use of an ensemble classifier in which three Logistic Regression classifiers (because of its highest performance) were integrated with the help of bootstrap aggregation. The proposed integrated model has achieved the highest accuracy of 95.45% and the highest precision and recall for low performers with the balanced dataset formulated with the help of the resampling technique SMOTE.

It should be noted that with different datasets, the different classifiers may give the highest prediction accuracy, and hence there is a need for the methodology to be scalable for every situation. Thus, the main advantage of the present approach is its scalability for different datasets. Further, this study may also be applied to the different domains of data mining and machine learning applications for enhancing prediction accuracy. The limitation of the present study is that the examined dataset has a small sample size and slightly imbalanced data, so in the future, the proposed methodology should be used with large sample sizes and highly imbalanced data for the prediction of students' academic performance.

***Abstract*—Academic advising has become a critical factor of students' success as universities offer a variety of programs and courses in their curriculum. It is a student-centered initiative that fosters a student's involvement with the institution by supporting students in their academic progression and career goals. Managing the knowledge involved in the advising process is crucial to ensure that the knowledge is available to those who need it and that it is used effectively to make good advising decisions that impact student persistence and success. The use of AI-based tools strengthens the advising process by reducing the workload of advisors and providing better decision support tools to improve the advising practice. This study explores the challenges associated with the current advising system from a knowledge management perspective and proposes an integrated AI-based framework to tackle the main advising tasks.**

***Keywords*—Knowledge management; artificial intelligence; academic advising; rule-based expert system; machine learning; chatbot; conversational agent**

I. INTRODUCTION

Student retention and persistence are the most critical objectives of Higher Education Institutions (HEIs) as they are striving to meet the demands of the global economy. Graduating students on time is not just a measure of student and institutional success but also has a positive impact on the economy and society at large. In the United States, one out of three students does not progress from freshman to sophomore year, while in Australia nearly 30% of students do not graduate with a degree [1]. In UAE the rates are similar, with nearly 25-30% of students dropping out from a degree program [2]–[4]. With the astounding rate of university dropouts worldwide, academic institutions are striving hard to develop initiatives that mitigate the early leavers and provide the necessary support to students for on-time graduation [2].

Academic advising has been widely accepted as a vital strategy to tackle the problem of persistence and retention [5]–[7]. Advising is an essential process in academic institutions for engaging, supporting, and guiding students throughout their academic tenure. Tinto's prominent study [8] on the theoretical framework of retention states that students' engagement within the institution has a direct impact on reduced attrition rates. A broad definition of academic advising is provided by [9], who state that advising is the process ensuring student success through various interactions and between a student and members of the academic institution. Although there are several facets of academic advising, the main objective of advising is to effectively manage a student's journey to ensure academic success.

The process of advising encompasses several tasks such as ensuring students are informed about the institutional policies, courses, and program requirements and that they enroll for courses according to their degree plan. Furthermore, advising ascertains that students follow a customized learning track based on their academic progression [10]. Academic advising also offers extra support and guidance to students who need it the most [6], such as the students on probation or at risk of dropping out or failing a course.

Knowledge management (KM) is an integral part of academic advising. The process of advising involves the use of tacit and explicit knowledge to guide and support students throughout their academic life. Academic advisors assist students in various tasks such as selecting ideal courses, supporting at-risk students, providing necessary information that is vital to the student's successful integration with college life. Moreover, academic advisors also utilize their knowledge in solving issues that students face in achieving their academic goals. At the institutional level, the knowledge of the advisors must be captured, stored, and shared to ease the process of advising for new advisors as well as to retain knowledge within the institution. To this effect, technology provides an efficient means of disseminating knowledge among institutional members.

In the current age of digital transformation, Artificial Intelligence (AI) offers a promising avenue to effectively support the advisory process by providing benefits that are otherwise not attainable using a traditional advisory system. AI-based systems can automate the task of identifying students at risk, recommending courses, and answering student queries. These systems have the potential to not only reduce the workload of advisors but also enhance the services provided to students and support their academic progression [10]. Although there is a vast amount of research on supporting students using AI, there is no study that has investigated a comprehensive AI solution that tackles all the challenges of the traditional advising process.

The purpose of this study is to investigate the limitations of academic advising under the lens of KM and propose an AI-based solution for an academic institution based in the UAE. The study explores the problems of the advising system currently in place and offers a holistic solution based on AI

technologies that integrate with the current information system. The key requirements of the proposed solution are discussed with an implementation strategy.

The rest of the paper is organized as follows. Section II presents the background information of the higher education institution of this study and the advising process thereof. Section III highlights the problems of advising at the institution of study. Section IV reviews AI-based advising solutions in the existing literature. Section V discusses the proposed AI-based solution for the HEI of this study, and finally, the paper ends with a conclusion that provides a summary of the paper, limitations of the study, and further research avenues.

II. Background Information

The process of advising and the roles of the institutional members involved thereof may differ from one academic institution to another. This section describes the advising process followed at the institution of study and explains the roles of the academic advisor.

The academic institution of this study is one the largest higher education institution in the middle-east region. The institution offers six undergraduate programs of study and has an intake of nearly 500 students each term. After enrollment, students are provided credentials to access online resources such as the portal, emails, and the learning management system. Orientation sessions are held for the new students and an academic advisor is assigned.

Academic advising, at the institution of study, is a role assigned to every faculty member. Each faculty is assigned 25-30 advisees, who are students enrolled in the same program. The advising tasks and the advising process are consistent across all the programs. Therefore, this paper does not focus on any particular program of study, but rather the advising process as a whole.

An advisor's role encompasses three main tasks – creating a customized study plan for academic progression, providing guidance and support to answer queries and recommend opportunities for personal and career growth, and finally, monitoring academic progression and supporting students at risk.

First, an advisor liaises with each advisee to create a study plan by recommending courses every semester. A good study plan ensures a smooth academic progression in the program of study. The advisor must select appropriate courses that best meet the academic requirements such as pre-requisites, minimum credits, specialization, and more. The advisor also prepares a graduation plan during the final year of an advisees study to ensure on-time graduation.

The second advisory task is to offer guidance for general academic queries. The advisor is the central contact point for advisees who need direction and support for any personal or academic. An advisor directs the student to support systems provided by the institution such as student services, academic tutorials, or answers their general queries about grades, volunteering hours, GPA requirements, work placement, and more. This type of advising strengthens the student's bond with the institution as they feel connected to their environment. The advisor also corresponds with the advisees to encourage them to participate in extracurricular opportunities, competitions, and programs related to their career and personal growth. Moreover, advisees often reach out to their advisors for general guidelines and information on policies and procedures. The close interaction of advisees with their advisor leads to enhanced satisfaction level with the institution and reduces attrition rate [8].

The third advising task is the most crucial one as it is directly related to student success in the academic journey. It involves a pre-emptive check to follow up on students' academic progression, especially the students who are struggling with their studies. The advisor identifies and provides support to students who are at risk. The support may involve arranging a meeting with the counselor or facilitating tutorial sessions through the academic success center, or more. This type of advising has a significant impact on student retention and persistence [11].

A. Knowledge Management and Academic Advising

Knowledge management (KM) activities are at the core of the academic advising process. Therefore it is essential to understand KM and its application within the various advisory tasks. As new faculty members, and thereby advisors, join the institution, and current advisors leave, it is crucial to ensure that knowledge is captured and stored adequately to prevent knowledge loss. This section describes the KM processes and mechanisms involved in the advising process at the institution of study.

KM processes are the methods used to create, share and utilize knowledge within an organization. Study [12] identified four main KM processes - knowledge discovery, knowledge capture, knowledge sharing, and knowledge application. These processes are encompassed in all the advisory tasks as described below.

Knowledge discovery is the process of acquiring knowledge from various sources to make decisions, solve problems or generate new knowledge. Advisors use various sources of information such as the program structure, course requirements, and student's academic portfolio to build a customized plan for each student. They often brainstorm with other advisors and attend training to acquire knowledge related to this task.

Knowledge capture is the process of storing the acquired knowledge in a format that is readily available for those who need to access it. Advisors store the advising plans they have created in a student information system and share them with their advisees. However, a lot of the communication during this process is also captured in an unstructured format such as email, and in-person and phone conversations making it challenging to access and utilize this knowledge effectively in the future. Knowledge is also captured in the form of documentation of the policies and procedures of advising and is stored in the employee portal and communicated via email.

Knowledge sharing is the process of sharing tacit or explicit knowledge with other members of the institution. Advisors share their knowledge with advisees in the form of counseling, advice, and recommendations when performing advising tasks.

Moreover, advisors also share their best practices through informal and formal professional development sessions organized at the institution.

Knowledge application is the process of utilizing the knowledge to solve problems and perform tasks. Advisors use directions and routines to apply their knowledge based on the problem at hand and advisees' maturity level. For example, when dealing with new advisees, advisors direct the students on what courses to take in the first semester. As the advisee's maturity level increases, advisors guide the students by explaining how to choose courses and plan their studies.

Knowledge may be further subdivided into two main types –tacit and explicit knowledge. Tacit knowledge resides in the individual's mind in the form of experience, insights, and wisdom and is difficult to transfer, while explicit knowledge is documented and stored in a format that can be shared, understood, and applied. Reference [13] developed the spiral SECI model to explain how tacit and explicit knowledge interact with each other to create new knowledge. The model consists of four phases – Socialization, Externalization, Combination, and Internalization. Fig. 1 shows the tasks of advising in each phase of the SECI model.

The socialization phase occurs when advisors mentor the advisees using face or online meetings, share best practices with their colleagues, and attend professional development sessions to understand new technologies or requirements for advising. Socialization facilitates knowledge discovery and knowledge sharing processes. In this phase, tacit knowledge is used, which is largely based on experience, and advisor intuition.

The externalization phase occurs when tacit knowledge is converted into documented form. In the advising process, the registration department publishes policies, manuals, guidelines. The admissions department provides documentation on the program structure and student academic performance. The advisors utilize this information for effective advising. Although the general knowledge of advising is captured in the documentation, the specific knowledge that the advisors possess when dealing with various cases is lost, as the advisors are not required to externalize their knowledge on advising cases they have dealt with.

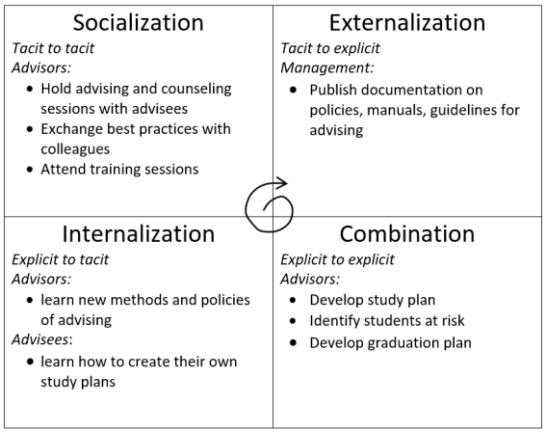

Fig. 1. SECI Model of Advising Tasks.

In the combination phase, the advisors integrate the explicit knowledge from various documentations to develop a customized study plan for every student and a graduation plan for final year students. The advisors also use the information to identify students at risk. Finally, in the internalization phase, the advisors learn new policies, methods, and systems essential for effective advising and students internalize the knowledge shared with them to create their own study plans.

This section provided an introduction to the paper, along with background information on the organization of the study and the role of KM in the advising process.

III. Problem Identification and Analysis

A. A KM Perspective of the Advising Challenges

People, processes, and technology are the three main interdependent elements of KM activities in an organization. The systematic integration of these three elements is essential to effectively implement KM practices in the organization [14], [15]. The current advising process at the institution of study has several limitations with regards to all these elements that hinder the integration of successful KM practices for the advising process. This section discusses the main challenges of the advising process.

1) People: People are the most essential element of KM practices in an institution as they are the possessors of knowledge. The people involved in the advising process are the advisors, students, and management staff. One of the main challenges is that the advisor does not have time to provide personalized advising to each advisee. The advisor's workload, of 20 teaching hours per week and involvement in research activities and other several administrative tasks, does not leave sufficient time for personalized interaction with 25 to 30 advisees. This has an impact on several tasks such as supporting students who are at risk, and maintaining a good level of communication and interaction with the advisees. The academic performance of a student is highly impacted by the quality of advising [9].

Another challenge is that new advisors do not have sufficient knowledge about the advising process to effectively advise students. Advisors must be aware of institutional policies, program structures, and academic requirements. Moreover, new faculty do not have the experience that advisors accumulated over the years. An inexperienced advisor does not have sufficient expertise to handle difficult cases such as students who have changed their programs and require course equivalency, or students on probation who need special attention in terms of planning courses. Erroneous advice in such cases may lead to a student repeating courses or taking courses that will not improve the GPA of a student on probation.

Communication between individuals in the advising process is vital to effective advising. Students are often shy to approach their advisors for queries as they do not know them personally. On the other hand, it is also observed that student queries are often repetitive relating to institutional policies and procedures such as registration times, applying for missed

assessment, following up registration, etc. Their general queries and concerns often go unaddressed, which in turn influences the student satisfaction level and integration at the institution. Moreover, advisors do not have the time to get to know each advisee personally. The lack of timely communication and interaction between advisee and advisor is a common challenge faced at the institution as it influences knowledge sharing negatively.

2) Process: The advising process includes tasks that are required for effective and efficient advising to capture and store the knowledge involved therein to make it available to those who need it. The SECI model for academic advising described in Section II, shows that the process of knowledge externalization is inadequate. Currently, the only form of documented explicit knowledge is provided by management in the form of manuals, policies, program requirements, and more. The knowledge accumulated by advisors over the years is not captured and shared in any formal way. This knowledge would be beneficial to both new advisors and current inexperienced ones. Furthermore, there is a risk of the knowledge being lost when a faculty members changes or leaves the job.

3) Technology: Technology acts as a supporting mechanism to facilitate the effective distribution and storage of knowledge to retain captured knowledge within the organization and make it available to individuals who need it [13]. At the HEI of study, several technologies are used to manage the information that is required for making informed decisions. For example, the advisee's academic performance data is stored in the banner system and available as reports for the advisor, the policies and procedures are stored in the SharePoint portal, and a degree audit system is used for managing and creating an advising plan. Moreover, email is also used for communicating new information, and requirements for advising. A lot of time and effort is spent in discovering knowledge from various sources for each student as these technologies are dispersed in different applications and not integrated.

Crucial information that is required by the advisor to track student progress and identify students at risk is currently not available during the semester. For example, the student's current semester's academic performance and attendance records are accessible by their teachers only. Due to this reason, advisors are unable to take pre-emptive measures at an early stage for an advisee who may be at risk of failure. Remedial actions are taken too late after the student has already failed the course.

The current system also does generate notifications to the advisor that are essential for their decision-making process. For instance, when an advisee drops the course or fails due to attendance, the advisor is not informed. This information is essential to modify the proposed study plan as it becomes a priority for the student to repeat the failed course to raise the GPA. At the end of the semester, when plans are updated based on student performance, the advisor has to manually check each student's academic record to update the student's plan.

TABLE I. ADVISING CHALLENGES AND ITS IMPACT

KM Element	Challenge	Impact
People	Lack of time	Advisors are unable to provide personalized advising and support to each advisee
	Lack of knowledge	Erroneous or inadequate advice by advisors, which may influence students' academic progression.
	Poor communication	Students find it challenging to integrate within the environment
Process	Lack of externalization	Organizational memory loss, advisors knowledge is not retained and shared in a formal way
Technology	Lack of structure	Knowledge is not captured in a structured format. Often involves email communication
	Lack of integration	Information is dispersed, requires time and effort to get access various information sources for decision making
	Lack of information availability	Advisors cannot take pre-emptive decisions and support advisees at risk at an early stage
	Lack of notifications	Cannot provide support at an early stage. Time-consuming to check each advisees' academic progression at the end of the semester.

Table I summarizes the advising problems faced at the institution of students and its impact on the institution and its members. The challenges highlighted below are the cause of inefficiencies in the advising process.

A software system is crucial to addressing the challenges of academic advising described in the previous section. Technology has the potential to automate tasks, reduce advising errors, improve communication, and provide insights on students' progress. To this effect, Artificial Intelligence (AI) based technology solutions offer a promising avenue to address the challenges of the current advising process. The AI-based tools can automate the low-impact tasks to reduce the workload of advisors and provide insights for key tasks to support better decision-making [16]. Moreover, AI also has the potential to enhance students' experience through machine intelligence supported by human advisors [9].

Fig. 2 presents a visualization of the analysis of terms in research studies related to AI in higher education over the last two decades. The visualization, constructed using VOSViewer depicts the relationships between frequently occurring terms in the research papers in the form of a network diagram [17]. Three main clusters are evident in the diagram. The red cluster shows that data mining is the predominant study in HEIs, which has been investigated by a vast majority of authors. The blue cluster shows that the main techniques researched are machine learning algorithms. The studies on academic advising are very limited. In addition to this, the studies that have investigated academic advising have only examined one aspect of advising rather than providing a comprehensive AI solution that tackles all the advising problems.

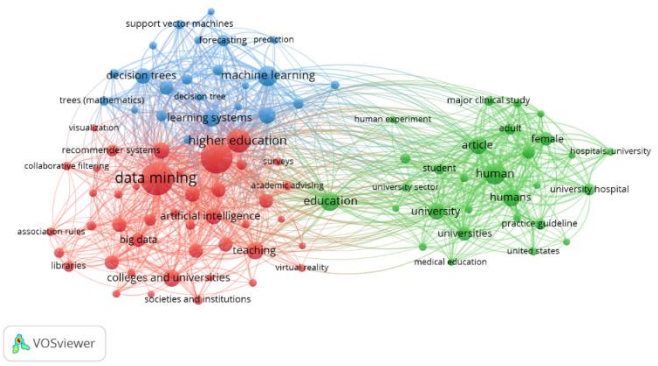

Fig. 2. VOSViewer Analysis of Terms.

This study proposes AI-based technologies that offer a comprehensive solution to make the advising process more effective and efficient. At the institution of study, the following three main tasks of advising have been identified that can be automated using AI-based advising tools to alleviate the underlying problems described in this section:

- Developing personalized study plans
- Early identification of students at risk
- Provide personalized assistance to students.

IV. Literature Review

This section provides a critical review of the use of AI-based solutions for advising in the existing literature. The review focuses on the three main advising tasks outlined in the paper. Several studies have investigated AI-based advising solution that merely examines one area of advising, while only a few have applied AI solutions to multiple advising tasks. Thus, this section reviews studies by categorizing them based on the type of AI solution proposed by reviewing studies that have focused on a single aspect of advising and those that have used AI-based solutions for more than one advising task.

A. AI-Based Solution for Study Plans

Numerous papers have researched the use of AI for creating study plans or recommending the ideal courses for students to maximize success. While some studies focus on rule-based systems, others are based on machine learning algorithms for recommending ideal courses to students that maximize their success.

A data-driven model is used by [18] to create a predictive analytics tool that supports academic advisors in advising decisions based on insights from historical data. They use a web application with a rich dashboard interface to display the chances of student success in the selected courses along with the details of the prediction. A multilevel clustering algorithm is used to predict the success rate in each selected course based on previous students' academic performance data such as course grades and the number of courses registered in a semester. The authors used a comparative study to verify their system in two universities. The participants of the study, experienced and inexperienced academic advisors, used traditional methods and the predictive analytical tool to perform advising for several cases. The results of the study showed that advisors explored more course options when using the AI-based tool to develop a suitable study plan with lower failure risk for each student. The main limitation of the study is that it relies on the academic advisor to select the courses for the student and the system merely provides a success rate of the selected courses. The system relies on the adivsors knowledge of institutional, course, and program requirements for selecting ideal courses.

Reference [19] proposed an intelligent advising system that assists students in course registration. The system is intended to be used by students without the need of a faculty advisor. Students are recommended courses based on their current performance, known preferences, historical data, and academic policies. The proposed advising system integrates with the current information system for the academic data required for predictive analytics. The system uses association rule mining to explore patterns in the academic dataset to identify the group of courses that should ideally be taken together. A rule-based expert system is used to assign a priority score to the courses based on academic policies and factors such as student GPA and nature of the course (prerequisite course, core or elective course etc.), course grade, and more. Finally, a recommendation algorithm is used to suggest courses to the students. A limitation of the study was that it considered student preference as a major factor in the recommendation model, but failed to describe the features used to determine students' interests. Moreover, the proposed model was not evaluated for the quality and accuracy of the recommendations.

Another model proposed by [20] recommends courses to university students based on personal traits and academic data. Student personal characteristics include features like gender, age, knowledge level, learning style, the term of study, and performance. The academic data consists of features such as courses, credit hours, semester of study. The proposed model uses a knowledge-based model to assign weights to selected courses based on the students' performance. The study does not apply institutional policies, course, and program requirements when recommending courses.

Study [21] designed an interactive system to recommend suitable courses to university students based on their interest and popularity of the course. The recommendation is based on historical enrollment data, course descriptions, topic, instructor, and time of study. A student searches for the offered course using keywords and may filter the popular course recommendations by providing preferences such as time of class, topic of interest, and more. The system has several limitations. First of all, it does not integrate with the current information system. Recommendations are not based on students' academic history or performance. Second, the system is only suitable for universities with a flexible curriculum where a student is free to explore and take various courses across different departments.

Both [22] and [23] developed a rule-based expert system that recommends courses for university students. The expert system rules are based on course pre-requisite requirements, year of study, and course eligibility. The system provides a rationale for each recommendation. The study [23] does not integrate the system with the data stored in the student

information system. The student is required to provide the courses they have completed, their current GPA, and their major as input to the system. Moreover, failed courses are not taken into account when making the recommendation. The research [22] integrated the expert system with data extracted from the institutional database. However, the system does not prioritize the recommended courses according to the importance of registration in the following semester.

B. AI-Based Solution to Identify Students at Risk

The use of machine learning algorithms to develop automated intervention systems that integrate with a learning management system (LMS) has been investigated by several researchers. Students' engagement in the online environment and their current academic performance can be used to predict course outcomes at an early stage [24]. Furthermore, studies have also shown that timely interventions and support for low-performing students are effective to help them manage their study patterns [25].

Study [26] used machine learning and deep learning algorithms for the early identification of students at risk using data collected from an online learning platform. The study predicts student failure at various stages of course completion based on the student demographic data, performance, and engagement data using click patterns. The study shows that the random forest algorithm performed the best with up to 92% precision, recall and accuracy. The study further recommends intervention strategies at the various course completion stages based on prediction outcomes by sending messages of encouragement, recommendation, or fear to students at risk. The study does not consider the involvement of the advisor or instructor in supporting underperforming students. Students who are at risk may not possess the mental or emotional capability to comprehend the motivational intervention messages. The involvement of the advisor is essential to determine the support a student may require to improve his performance.

Reference [27] used deep learning to identify students at risk of drop-out at an early stage in an online course. The study uses click patterns, discussion, and quiz scores to create prediction models using SVM, KNN, decision tree, and deep learning algorithm to predict student dropout at a weekly rate. The deep learning algorithm performed best with an average AUC (area under the curve) rate of 96%. The study further went on to suggest intervention strategies based on the probability of course dropout, such as varying levels of support by the instructor.

Both the studies [26], [27] were based on Massive Online Open Course (MOOC) dataset, that have a large number of enrollments and thus a huge dataset that is required for deep learning. On the contrary, enrollment in degree programs will not have the same dataset size collected from the virtual learning environment. Moreover, the models were not tested on different sized datasets for the generalization of results.

Study [28] used clickstream data collected from an ebook interaction log, along with student performance at various stages in the course to predict student performance. Comparisons of prediction accuracies during various weeks of the course showed that the earliest reasonable accuracy, of 79%, is achievable as early as week 3. The study is based on the assumption that the ebook is the main resource used by all students in the online learning environment. Furthermore, the study did not utilize data from the existing information system to generate the predictive model.

Eight machine learning algorithms were used by [29] to determine the optimal time during a semester-length course to predict student grades. The study uses student demographic data, academic data, weekly assessment scores, and LMS interaction data to create a prediction model. Weekly predictions revealed that the earliest reasonable prediction rate is achievable by week six to support early intervention for poorly performing students. The study relies on continuous weekly assessments for predictions, which is not applicable in most courses. Moreover, the study integrated LMS data with student admission and academic background data but did not consider attendance as a feature for prediction.

C. AI-Based Solution for Digital Assistance

With today's technological advancement students are constantly in need of information for their daily tasks and academic progression. Providing adequate channels for student communication is vital to help students integrate with their environment and feel connected and enhance student satisfaction. Students often have queries about the institutional and academic policies and procedures, academic progression, activities, and more. In reality, the student services team and the academic advisors are usually overwhelmed with such a large number of queries that they are not able to provide instant responses. As a result students' disconnection and dissatisfaction with the institution increases.

Chatbot systems have the potential of providing students with the information they need by answering their queries in a conversational style. They provide 24/7 service, unlike human advisors. Despite the numerous benefits of chatbots in improving levels of service, the use of chatbots in HEI for advising is very limited [30]. This section reviews the AI-based solutions that have used a chatbot system for improving communication and answering student queries.

Study [31] designed a rule-based expert system that answers students' queries on institutional policies and guidelines to familiarize students with the environment. The digital assistant, built with CLIPS and JAVA, uses both forward and backward chaining and is based on inference rules. The knowledge base for the expert system was gathered from the website, student feedback, and experts in the institution. User queries were classified into four categories – yes/no, what, where, and when questions. The automated virtual assistant was tested completeness and correctness using 70 participants and resulted in an accuracy of 99%. The main limitation of the study is that the chatbot system does not support conversational AI. The question type has to be selected from a predefined list. Interaction with natural language processing would be more intuitive and adaptive for end users.

An intelligent academic advisor using a DeepQA system built was built by [32] using IBM Watson. The system was used to answer queries from potential, new, and, current

students as well as faculty members pertaining to academic advising in a business school. The intelligent system was initially populated with a database of nearly 300 questions and answers, and other information extracted from FAQs, syllabus, and more. Moreover, the intelligent system has an engine to learn and increase its knowledge base. The chatbot does not provide personalized feedback to students.

Reference [33] used a conversational agent to support administrative tasks of recruiting students into degree programs. The AI system matched student skills to the program requirements by asking questions and using keywords from their answer to select suitable programs. The admin staff also utilize the system to query information about shortlisted candidates. The system was not designed mainly for administrative purposes and not for advising.

Study [34] used a chatbot to ease the process of selecting elective courses for a degree program in computing. The chatbot uses natural language to answer queries related to the courses, provide peer reviews about the courses, analysis of choices, and provide a personalized recommendation based on the student record. The chatbot had a very specific use and did not provide advising in other matters of academic life.

Reference [35] used a chatbot application, developed using the IBM Watson API, to provide support to students struggling in programming. The chatbot not only provides support for programming related queries, but also for personal issues such as depression, suicidal thoughts, etc. It directed students to the appropriate department call center for their issues or calls the ambulance based on the severity of the case. The chatbot was designed to detect student frustration while studying programming. It did not provide general assistance in other college related matters.

D. AI for Multiple Advising Tasks

Some studies investigated an AI-based solution for more than one aspect of advising. Latorre-Navarro (2014) developed an AI-based solution that answers student queries and recommends courses. A conversational agent was used to answer questions on a wide range of topics related to academic policies, procedures, and services. The authors also used an expert system that guides students to create their study plan and sends it to the advisor for approval. The main limitation of the system is that it is not integrated with the information system. Students are required to provide their academic progress such as current courses, failed courses, and completed courses. An error in providing this information could result in an incorrect plan.

An intelligent web-based advising system that supports effective advising was developed by [36]. The system is designed to be used by both advisors and students. A rule-based expert system is integrated with the current information system to extract a student's academic record and create a study plan for the following semester and view the graduation status. The system also answers basic queries related to institutional policies. Advisors can also use the system to view their advisees' profiles, and get access to all the advising documentation integrated in a single location. Notifications are sent to the advisor when there is an update to a policy, ensuring that all advising decisions are accurate. A limitation of the study is that it does answer any personalized queries or send reminders notifications to students.

Though both studies [16], [36] tackled more than one advising problem by leveraging AI-based technologies, yet they do provide a comprehensive solution. The studies did not investigate one of the main tasks of advising, which is to identify and support low-performing students with early intervention strategies.

An overview of the literature shows that, to the best of the author's knowledge, no study exists that provides a holistic advising solution using AI technologies to addresses all the challenges of advising faced at an academic institution. Hence the purpose of this study is to fill the gap in this area and recommend a comprehensive AI solution for the institution of study.

V. Identification and Evaluation of Alternate Solutions

This section discusses three AI-based solutions proposed for the institution of study – (1) AI-based solution for creating study plans (2) AI-based solution for identifying students at risk of failing a course at an early stage, and (3) AI-based solution for personalized digital assistance. All solutions are integrated with the institutional database to provide personalized information to the students to support their academic progression. The study proposes the use of a rule-based expert system to create ideal study plans, a machine learning model to identify students at risk, and a chatbot system to provide personalized digital assistance. Fig. 3 shows an overview of the proposed solution.

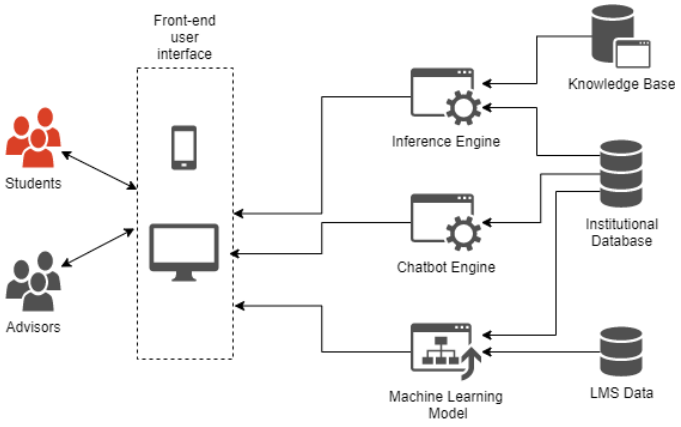

Fig. 3. Overview of Proposed Solution.

A. AI-Based Solution for Creating Study Plans

Studies have investigated the use of machine learning for recommending courses to students [21] as well as including features personal traits [20], and student preferences [19]. While this type of model is suitable for online courses with a large number of enrollments and course choices, this model does not work for the institution of study. The courses offered at the current institution are based on a program requirement that has a predefined number of courses with a few electives. The courses that must be taken according to the ideal semester plan, obeying the rules such as course sequence in the program

structure, minimum and maximum required credits (with the program area), catalog term, academic progression of the student, and more.

To this effect, this study proposes a rule-based expert system that captures the knowledge of domain experts to create a knowledge base. The expert system utilizes student data from the institutional database and applies registration rules and policies to recommend a list of ideal courses that maximize the chance of students graduating on time. Fig. 4 shows the architecture of the expert system.

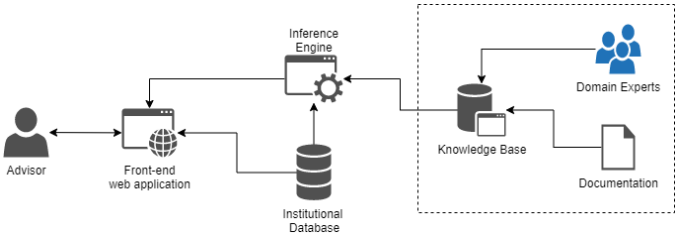

Fig. 4. Rule-Based Expert System.

The knowledge engineer will acquire the knowledge from domain experts such as the registration staff, and expert advisors to build a knowledge base. All the policies and registration requirements are also encoded as rules with the system. The system uses student academic data, program data, and course data from the institutional database as initial facts to map the student course requirements against the program requirements and applies the rules to identify a list of ideal courses.

- Student Academic Data consists of the catalog term, the program of study, placement scores, list of all completed courses, failed courses, and credit hours completed.
- Program Data consists of the requirements of the program such as the total credits required in each area (core courses, elective courses, concentration courses, and general studies courses).
- Course Data consists of the credit hours of the course and the pre-requisite(s), co-requisite(s), and equivalent courses.

The inference engine applies the knowledge base rules to the student, program, and course data that are the initial facts in the working memory. The eligible courses are assigned a priority based on the importance of completing that course in the following semester. For example, a higher priority is assigned to a course in which the student previously failed, or a course that is a pre-requisite of other courses in the following semester. Finally, a web-based interface is used to present the study plan to the advisor, in order of priority. The advisor analyzes the plan that is created by the system and makes any necessary modifications and advises the student accordingly.

B. AI-Based Solution for Identifying Students at Risk

Machine learning algorithms have been investigated in numerous studies to identify students at risk at an early stage during course progression. Some studies relied on LMS click patterns to predict low-performing students [26]–[28]. LMS interaction requires interacting with the course content online, which in turn generates a click pattern that can be analyzed for student engagement within the course. This model is not appropriate for the institution of the study, as most of the courses are face-to-face. Students mainly use the online environment to download course resources, attend online sessions, or submit assessments. Click patterns would not be an ideal indicator of student engagement especially when the student is using the course resources offline.

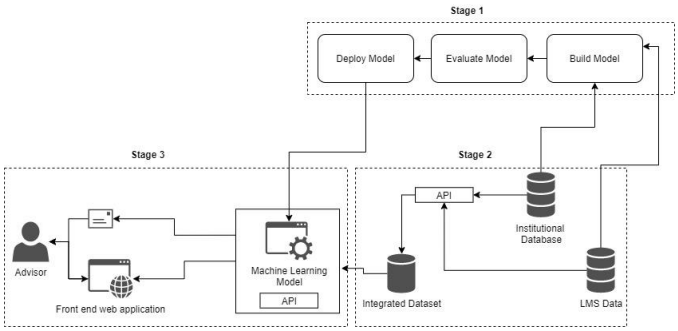

Fig. 5. Mahcine Learning Model for Identifying Students at Risk.

To this effect, this study proposes the use of course performance data and student academic history to predict the risk of failing a course. The proposed system will be used to low performing students as early as week six so early intervention strategies can be engaged. Howard et al. (2018) showed that reasonable machine learning performance can be achieved at week 5-6 to predict course attrition. Fig. 5 shows the architecture of the proposed advising system.

The system integrates LMS data and institutional data to build a machine learning model. The main elements of the system are explained in three stages:

1) Build and deploy the machine learning model: In this stage data historical is extracted from the institutional database and the LMS at the beginning of the academic year. The institutional database contains the following data:

- Students enrollment records that include the high school score, IELTS score, placement test scores, gender and status (working or not), and other profiling information
- Academic data such as program of study, credit hours completed, credit hours registered, courses completed, overall GPA, and attendance record.

LMS Data contains the coursework assessment data. Coursework assessments are usually conducted at regular intervals – week 6, week 12, week 15. The final assessment is scheduled on week 16.

In stage 1, the machine learning model is developed using historical data of the last 4-5 years. The data will be pre-processed and used for training and testing multiple machine learning algorithms. Several machine learning algorithms will be used and evaluated to determine the best performing algorithm suited for the data provided. At the end of this stage, the machine learning model will be deployed for use with the current records. This stage will be repeated once every academic year for monitoring and tuning the model to generate a new model based on new data acquired in the previous year.

2) Integrate LMS and institutional data: In this stage, the current semesters academic record is extracted from both the institutional and LMS and integrated into a dataset. It is recommended that the extraction takes place at week 6, week 12, and week 15. Based on the findings of previous researchers [28], [29], it is expected that good prediction rates of at-risk students are achievable by week 6.

3) Apply the machine learning model to generate a prediction: In this stage, the deployed machine learning model is applied to the extracted data of the current semester to determine students at risk of failure. A web application is used as a front-end interface for advisors to view the risk profile of their advisees. The system also sends notifications about advisees that require immediate attention.

C. AI-Based Digital Assistant

A conversational AI-based solution provides timely response to students' academic queries and improving the students' experience. Several studies have investigated the use of chatbots in an educational setting, however, the main purpose of the system was either administrative, such as recruiting students [33], or recommending courses [34]. Moreover, the studies that used chatbots for answering student queries [31], [32] did not integrate it with student's academic record to provide personalized information. None of the chatbots proposed in the reviewed studies send push notifications to students.

This study recommends the use of a conversational AI chatbot that integrates with the institutional database containing student's academic history, registration schedules, program requirements, course requirements, and a knowledge base of frequently asked questions. Unlike a human advisor, the chatbot will be available 24/7 to respond to various student queries. It will respond to general queries and personalized queries using the student's academic data. Furthermore, the chatbot will also initiate reminders to the student about general information such as upcoming deadlines, and initiate personalized reminders such as high absences rates to ensure that the student does not miss more classes. The notifications may also be personalized to the student's interest such as sports, clubs, and more.

Examples of general student queries are:

- When is the deadline for dropping a course?
- What is the pre-requisite for CIS 2203?
- How can I change my program?

Examples of personalized student queries are:

- What is my CGPA?
- How many volunteering hours have I completed so far?
- How many absences do I have?
- Who is my advisor?

Example of general notification:

- Add and drop period ends on Sunday, 10th October

Example of personalized notification:

- You have reached 7% absence in the advanced programming course.

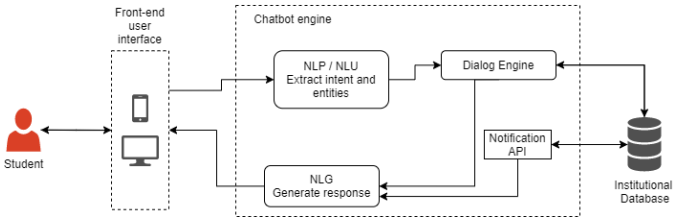

Fig. 6. Advising Chatbot Architecture.

Fig. 6 shows the proposed chatbot architecture. A brief explanation of the architecture is given below:

- The student writes a query in natural language using the chatbot client interface.
- The chatbot backend processes the query using a NLP (Natural Language Processing) engine, which converts the written text to structured data.
- The NLU (Natural Language Understanding) engine then extracts the intent and entities from the given structured query.
- Based on the processed query, the dialog engine of the chatbot retrieves the data from the institutional database and presents the response to the NLG (Natural Language Generator).
- The NLG processes the structured response into natural language and presents it to the student via the front-end interface
- The chatbot engine also contains an API, linked to a scheduler, which retrieves data from the database to send timely reminders and notifications to the students.

The proposed advising system reduces the workload of advisors by automating repetitive and mundane tasks. Advisors can spend their time getting to know their advisees and supporting them in their personal and career growth. The benefits of the proposed AI-based solution are summarized in Table II.

TABLE II. ADVISING CHALLENGES AND ITS IMPACT

AI-Based Solution	Benefits
Rule-based expert system for creating study plans	• Integrates with the existing information system to use accurate data of current student records, academic history, registration, and academic policies. • Minimizes/eliminates erroneous decisions of new or inexperienced advisors • Reduces workload of advisors
Machine learning model for identifying students at risk	• Provides early identification of students at risk before it is too late. • Support students with early intervention strategies that can possibly alleviate the risk of failure
Conversational AI chatbots for digital assistance	• Constant availability of support to students enhances student experience and increases loyalty towards the institution. • Provides equal opportunity for all students to ask questions, at any time 24/7 • Access to personalized assistant • Students are encouraged to stay on track with nudges from the system such as reminders

VI. CONCLUSION

Academic advising is a vital function in HEIs for providing guidance and support to students throughout their academic tenure [5]. Effective advising not only has a significant impact on students' academic performance but also has a positive influence on the overall academic experience [37] contributing to academic retention and persistence. The imperative nature of academic advising makes it crucial for institutions to invest in tools that support advisors in managing advising tasks effectively. This study explored the practice of academic advising at an academic institution based in the UAE. The study investigated the advisory process and the limitations under the umbrella of Knowledge Management. Finally, AI-based technologies are proposed to provide a comprehensive solution that automates advising tasks. AI-based systems can guide students through their journey with little intervention from the advisors, thus reducing the workload of advisors from menial tasks to focus their effort on key advising tasks such as development advice and career planning. Moreover, AI-based advisory systems may be personalized for individual student need and provides an equal opportunity for all students to access the information and service that they need.

The problems of academic advising are highlighted in this study from the perspective of the three KM elements - people, processes, and technology. Students and advisors are the people involved in the advisory process. The ratio of advisor to advisees makes it challenging for advisors to provide personalized guidance to each advisee. Moreover, an advisor's inexperience or lack of knowledge may lead to erroneous advice. Student queries often go unanswered leading to dissatisfaction and frustration. The advisory process involves creating study plans for students, dealing with issues, guiding and counseling students. An experienced advisor's knowledge is currently not captured in any formal way and may lead to organizational memory loss when the advisor leaves the institution. The current technologies at the institution are inadequate in supporting all the KM processes involved in advising effectively. The information is dispersed in different systems making it inefficient to look up for each student. Advisor's time and effort are consumed in analyzing student data, to create study plans. Furthermore, advisors need to set meetings with advisees, send reminders, and follow up on failed courses. Moreover, the current system does not provide insights to identify low-performing students so pre-emptive measures may be taken to manage the course of their studies.

The study proposes three AI-based systems as a comprehensive solution to alleviate all the problems associated with the current advising process – (1) Rule-based expert system for recommending courses and developing study plans for the following semester (2) Machine learning algorithm for identifying students at risk of failing a course at an early stage, and (3) conversational AI chatbots to provide personalized digital assistance to the student. All three systems integrate with the data in the current information system to provide personalized support and guidance to students and advisors. The systems are promising in terms of reducing the advisor's workload and improving student satisfaction with the institution, leading to student retention and persistence as an overall goal.

A. Limitations and Future Research

This study provides a framework for leveraging AI technologies in academic advising and focuses only on the three main tasks performed by an academic advisor. An avenue of future research is to investigate the implementation of the three systems as a prototype and a proof of concept. The systems must be verified for accuracy and quality of results.

One of the aspects of advising that is not considered in this study is the guidance provided to students during the enrollment stage to choose a program of study. This type of advising is done by the admission department and is crucial as most students are undecided about their career pathways when they enroll. Furthermore, studies have shown that students often receive inadequate guidance to make the right program choice, which in turn leads to changing programs during their studies [38], thus delaying graduation. In some cases, it may also lead to dropping out due to lack of interest or inability to cope with the program requirements. Machine learning algorithms may be investigated for recommending ideal programs to students that maximize their chances of success.

An Adaptation Layer for Hardware Restrictions of Quadruple-Level Cell Flash Memories

Se Jin Kwon
Department of AI Software
Kangwon National University
Samcheok, South Korea

***Abstract*—In recent years, major flash memory vendors have produced SSDs and fusion memories as substitution for hard disks. However, there has been a lack of studies on access restriction of QLC flash memory, since most researches have targeted small capacity flash memory. As a solution, we propose to implement an adaptation layer between the file system and FTL (Flash Translation Layer). Instead of immediately writing data given from file system to flash memory, the adaptation layer gathers and adjusts data in the unit of a page, and separates random data from sequential data. By implementing the adaptation layer, previous FTL algorithms can be fully applied on the QLC flash memory. According to our experiment, the adaptation layer forms smaller number of pages than the current data gathering algorithm.**

Keywords*—Cache storage; flash memory; SSD; nonvolatile memory

I. Introduction

The capacity of flash memory has been rapidly growing as it has been introduced as a new solution for substituting the hard disks. Current QLC flash memories such as SSDs and fusion memories contain pages that are four to eight times larger than file system's data sector [1]. Due to the large page size of QLC flash memories, it is required to re-access a page to write multiple file system's data sectors within a page. However, the number of partial programming (NOP) within a page is limited to only one to avoid program-disturb errors [2]. Therefore, QLC flash memory uses an internal buffer to gather data in a unit of a page before writing onto the flash memory.

Unfortunately current well-optimized FTLs do not contain data gathering algorithm for NOP restriction, since they are designed for small capacity flash memories [3]. In this paper, we are not concerned with developing efficient mapping algorithm, since the small capacity based FTL algorithms already give various solutions. Instead, we propose to implement an adaptation layer between file system and FTL. It enables the small capacity based FTL algorithms to be fully applied on the QLC flash memory. Instead of immediately writing data given from the file system to the flash memory, the adaptation layer gathers the data sectors and rearranges them suitably for the QLC flash memory.

II. Related Work

Fig. 1 shows the overall architecture of large capacity flash file system. The file system issues write commands along with logical sector numbers and data. In case of small capacity flash memories, the given logical sector number (LSN) is directly converted into a physical sector number of flash memory by the mapping algorithm provided by FTL [4]. However, in case of QLC flash memory, the following problem should be considered.

A. Problem Definition 1

In QLC flash memory, a page size is four to eight times larger than file system's data sector, although the NOP allowed within a page is only one [6]. With restricted NOP, the flash memory does not allow any additional access to a page [7]. Therefore, the QLC flash memory requires a data gathering algorithm which gathers data in the unit of a page before writing onto the flash memory.

The current basic data gathering algorithm [5] is used to gather data with same logical page number (LPN). When the file system issues a write command as "w LSN data: write data in the logical sector (LSN)", the basic data gathering algorithm calculates LPN by dividing LSN with the number of sectors per page. Each write command's data are collected in the buffer until a write command with different LPN appears.

Fig. 2 shows an example of the basic data gathering algorithm. In this figure, we assume there are four sectors within a page and one NOP per page. w 0 A, w 1 B, and w 2 C are gathered into one page, since all of them belong to LPN 0 (=0/4, =1/4, =2/4). However, when w 9 D (LPN 2 =9/4) occurs, the data in the buffer is sealed as a page and is written onto the flash memory. Finally the buffer is flushed and data D is written onto the emptied buffer. Likewise, other write commands are performed.

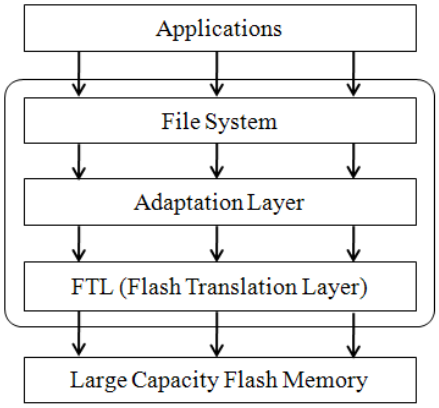

Fig. 1. Architecture of Flash File System.

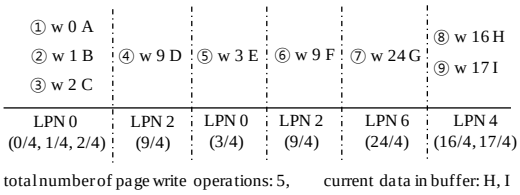

Fig. 2. Basic Data Gathering Algorithm.

The basic data gathering algorithm generates a total of five page write operations in Fig. 2, although there are only nine write commands. If each page were fully filled with data, nine write commands should generate only two to three pages since each page can store four write commands. As a solution, we propose to implement an adaptation layer between file system and FTL. The adaptation layer considers the following problem to fully gather data.

B. Problem Definition 2

The adaptation layer is required to separate random data from the gathering page. A file consists of sequential data and random data. The random data refers to file's meta data in which its LSNs are irregularly allocated and its data is frequently updated [3]. The irregular LSN allocation refers to the fact that the random data's LSNs are unlikely to be relevant to nearby LSNs. For example, in Fig. 2, the data corresponding to LSN 9 and LSN 24 are random data. Due to the update of LSN 9 and irregular allocation of LSN 24, the gathering page is sealed as a page whenever write commands with LSN 9 or LSN 24 appear. In order to solve Problem Definition 2, the adaptation layer contains an undefined buffer and two RAM pages: sequential and random.

Definition 1: The undefined buffer is an instant buffer which stores the write command that cannot be immediately decided as random or sequential. The adaptation layer requires maximum of two previous LSNs for decision; therefore, the capacity of undefined buffer is two sectors.

Definition 2: The sequential RAM page (SRP) and random RAM page (RRP) store the write commands that are defined as sequential and random respectively. The size of each RP is one page.

Each write command's LSN and its corresponding data is dynamically inserted into the undefined buffer or one of two RPs depending on the following algorithm.

1) Is the write command sequential to SRP?
2) Is the write command an update?
3) Analyze the write command with other LSNs of the undefined buffer.

First, the adaptation layer checks whether the write command belongs to SRP (<1>). If the write command does not belong to SRP, the adaptation layer checks whether the write command is an update of previous write commands. If the write command is an update, it is inserted into RRP since the update is one of characteristics of random data. However, when the write command does not belong to <1> or <2>, it is analyzed with other LSNs of the undefined buffer. The main role of <3> is to define LSNs with irregular LSN allocation as random data. The data gathering algorithm of adaptation layer is explained in detail in Section III.

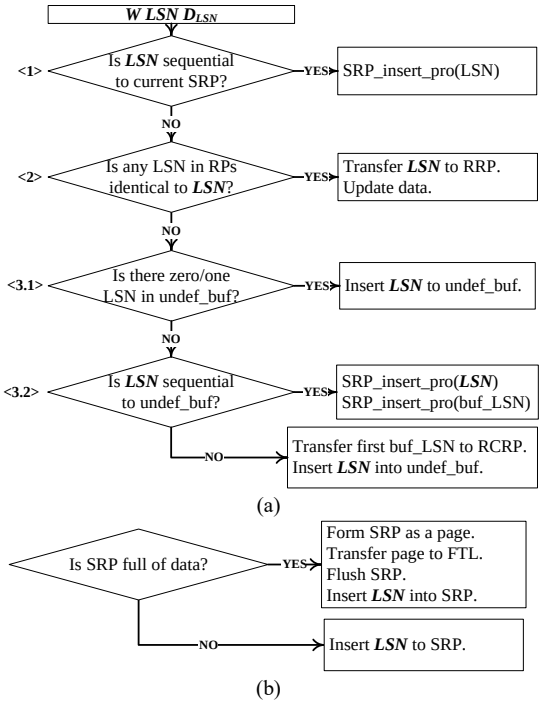

Fig. 3. (a) Data Gathering Algorithm, (b) SRP Insertion Procedure.

III. Data Gathering Algorithm of Adaptation Layer

When the system is initiated, there is no data stored in SRP or RRP. The adaptation layer requires previous LSNs to analyze the pattern of LSNs. Therefore, the adaptation layer simply accumulates the write commands with same LPN until a write command with different LPN appears. Finally the adaptation layer stores the write command with different LPN in the undefined buffer and finishes the initialization.

Example (Fig. 4(a)): For convenient understanding, we assume there are only four sectors per page. We have arbitrarily written LSN and its corresponding data within each sector as (LSN, data). Initially there is no data in SRP or RRP. (0, A), (1, B), and (2, C) are stored in SRP, since all of them belong to LPN 0 (=0/4, = 1/4, =2/4). (9, D) is stored in the undefined buffer since it belongs to LPN 2 (=9/4).

The write commands subsequent to the initialization follow the data gathering algorithm as shown in Fig. 3. Fig. 3 is a detailed view of the data gathering algorithm aforementioned in Section II. Each procedure of Section II corresponds to the procedure of Section III respectively except <3>, which is described in two parts (<3.1> and <3.2>) in Fig. 3. When the file system issues a write command, the adaptation layer checks whether the LSN is sequential to the SRP as shown in <1> of Fig. 3(a). The write command's LSN is decided as the sequential data when the differential between the write commands' LSN and the last LSN of SRP equals to the differential between two immediate last LSNs of SRP.

Example (Fig. 4(b)): w 3 E is sequential to SRP, because both result of LSN 3-LSN 2 and LSN 2-LSN 1 equals to one.

When a LSN is sequential to the SRP, the adaptation layer searches an empty sector within the SRP as explained in Fig. 3(b). If the SRP contains an empty sector, the LSN and its corresponding data can be directly inserted into the SRP. On the other hand, if the SRP is full of data, the data in SRP is sealed as a page, and it is sent to the FTL to be written onto the flash memory. Finally the SRP is flushed, and the LSN and its corresponding data are written to the SRP.

When a LSN does not belong to <1>, the adaptation layer checks whether the write command's LSN has previously appeared in the undefined buffer or RPs as explained in <2> of Fig. 3(a). If an identical LSN exists, the LSN's corresponding data is defined as the random data because one of random data's characteristics is the frequent update as mentioned in Section II. Therefore, the LSN is transferred to the RRP, and its corresponding data is updated.

Example (Fig. 4(c)): When w 9 F is issued from the file system, the adaptation layer searches for LSN 9. Due to (9, D), LSN 9 and its data F are written to the RRP and old data D is deleted.

If the write command's LSN does not belong to <1> or <2>, the adaptation analyzes the pattern of trace by comparing the write command's LSN with other undefined LSNs. Our algorithm requires two previous undefined LSNs for analysis; therefore, the LSN is temporarily stored in the undefined buffer (undef_buf) when there are less than two undefined LSNs as explained in <3.1> of Fig. 3(a).

Example (Fig. 4(d)): w 24 G does not belong to <1>, because LSN 24-LSN 3 does not equal to LSN 3-LSN 2. It does not belong to <2>, because there is no identical LSN in the undefined buffer or RPs. Thus, w 24 G must be compared to other undefined write commands. Unfortunately there is less than two LSNs in the undefined buffer so (24, G) is just stored in the undefined buffer. With same reason, next write command, w 16 H, is also stored into the undefined buffer.

When the undefined buffer contains two undefined LSNs, the adaptation layer checks whether the write command's LSN is sequential to them or not as shown in <3.2> of Fig. 3(a). The write command's LSN is considered as sequential, if the differential between the write commands' LSN and the last LSN of undefined buffer equals to the differential between two immediate last LSNs of undefined buffer. If the LSN is sequential to the undefined buffer, the undefined LSNs and write command's LSN are inserted into the SRP.

On the other hand, if the write command's LSN is not sequential to the undefined buffer, the first LSN and data of the undefined buffer is transferred to RRP, and the write command's LSN is newly inserted into the undefined buffer.

Example (Fig. 4(e)): When w 17 I is issued from the file system, the undefined buffer contains two LSNs: (24, G) and (16, H). The adaptation layer checks whether w 17 I is sequential to the undefined buffer or not. w 17 I is not sequential to the undefined buffer, because LSN 17-LSN 16 does not equal to LSN 16-LSN 24. In this case, (24, G) is transferred into RRP, and LSN 17 and its corresponding data I is newly inserted into the undefined buffer.

In Fig. 4(e), we have defined (24, G) as random data, even though LSN 24 has not appeared before. The adaptation layer defines the first LSN of the undefined buffer as random data due to the characteristic of irregular LSN allocation. The first undefined LSN is not sequential to the SRP and it does not have any chance of being a portion of sequential data in future. For example, (24, G) is not sequential to the SRP, and it is not sequential to next two commands: (16, H) and (17, I). On the other hand, second undefined LSN, LSN 16, remains in the undefined buffer, since it still has chance of being a portion of sequential data depending on the next write command (w 18 J).

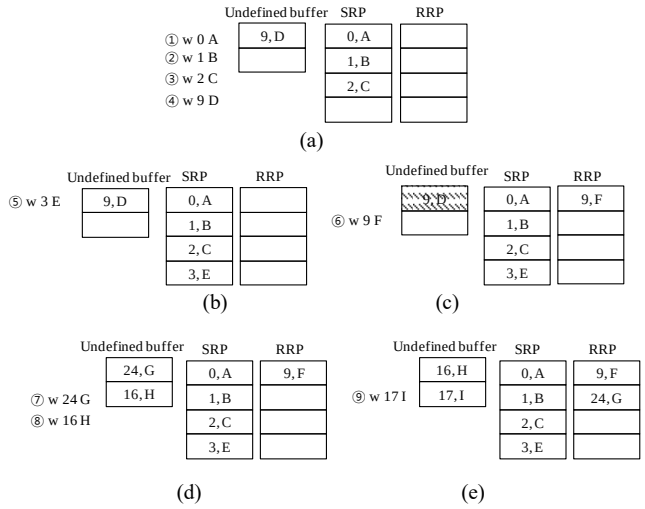

Fig. 4. (a) An Example of Initialization, (b) An Example of <1> of Fig. 3(a), (c) An Example of <2>, (d) An Example of <3.1>, (e) An Example of <3.2>.

TABLE I. NUMBER OF PAGES GENERATED BY PBM AND APRA

trace	total input	Basic data gathering algorithm (χ)	Adaptation layer (y)	difference (χ-y)
A	12,363,602	1,558,096	1,535,448	22,648
B	15,084,489	1,938,608	1,903,344	35,264

F	5,110	1,737	428	1,309
G	69,575	6,928	4,993	1,935
H	18,899	3,334	1,673	1,661

IV. Performance Evaluation

In this section, we have implemented our adaptation layer and compared it to current basic data gathering algorithm. We have analyzed the number of pages formed by each algorithm with the traces retrieved from various devices. Both algorithms are simulated on 256 Gbyte SSD, which consists of eight sectors per page and one NOP per page.

According to Table I, the adaptation layer forms smaller number of pages than current data gathering in overall environments. The adaptation layer has reduced over twenty thousand page write operations, and has reduced approximately one thousand page write operations in embedded devices. As we expected, separating the random data from the gathering page has fully filled pages with data, thus significantly reducing total number of page write operations. On the other hand, the basic data gathering algorithm formed many pages with empty sectors, because the page is likely to be sealed as a page whenever the random data interferes.

V. Conclusion

In this paper, we have dealt with the NOP restriction property of QLC flash memory. We have proposed to implement an adaptation layer between file system and FTL. It gathers and adjusts data in a unit of page so that small capacity based FTLs can be implemented on FTL without considering the NOP restriction. Furthermore, it separates random data from the gathering page, in order to reduce the number of page write operations. According to our experiment, the adaptation layer forms smaller number of pages than the current basic data gathering algorithm.

***Abstract*—Internet of things has an essential role in various application domains. The number of Internet of Things applications makes researchers try to formulate how to design the architecture of the Internet of Things platform so that it can be used generically in various domains. Commonly used architectural designs consist of data collecting, data preprocessing, data analysis, and data visualization. However, sensor data that enters the platform often experiences anomalies such as constant values or being stuck-at zero, which are processed manually at the data preprocessing stage. In this research, we try to design an anomaly detection system on the Internet of Things platform that can automatically improve the platform's performance in detecting anomalies. In this study, we compared the False Positive Rate of several anomaly detection algorithms tested to real datasets in the environmental sensor data application domain. The results showed that the anomaly detector system on the Internet of Things platform had an optimal False Positive Rate of 0.9%.**

I. INTRODUCTION

Recently some urban environments have extensively used internet of things (IoT) technology to perform environmental monitoring and control. The acquisition and control settings and the network protocols vary according to the urban environment's intended applications. These elements are critical to the ability of IoT networks to communicate successfully and transfer valuable data. Valuable data such as air temperature and relative humidity from inside and outdoor locations are essential for understanding the urban microclimate affecting the environmental condition. The monitoring process needs help from technology tools to automate the collection and understanding of data, for example, the internet of things platform.

The platform collects microclimate parameters from all sensor data. The platform also serves as a data management platform. The data platform architecture has a subsystem called the data analytics module. The data analytics module is responsible for analyzing the collected data. The data analytics module can be implemented through video, text, or other analytics techniques such as statistical analysis or machine learning [1]. Anomaly detection is one of the analyses performed on the data collected in an agricultural environment [2].

The common goal of anomaly detection is to find patterns in data that do not conform to "expected" or normal behavior [3]. Anomaly detection is used to monitor the environmental situation of the greenhouse [19]. When anomalous behavior is detected, an alarm can be send to the administrator to do something. Several techniques are used to detect anomalies, which can be classified into two categories: conventional and data-driven. A conventional technique like the statistical method has a long history of detecting an outlier in the data [20]. Parametric or non-parametric techniques are included in this category. The underlying distribution of the data is known for the parametric category, and the parameters are estimated using the data. Parametric methods include those based on the Gaussian distribution, the regression model, or a combination of Parametric Distributions [4]. Data-driven techniques are frequently used to refer to learning-based methods in which the lack of a robust underlying mathematical model is compensated for by the availability of large amounts of data from which useful information can be "learned." Machine learning is a large area of research with numerous application areas. Generally, it is divided into three distinct categories: supervised, unsupervised, and reinforcement learning. Additionally, due to technological advancements, deep learning is gaining popularity. Numerous machine learning techniques are frequently given a deep learning orientation or are combined with deep learning [18].

Several algorithms for detecting sensor abnormalities are used in agricultural environments. Several neural network algorithms were used, including artificial neural networks, autoencoders, recurrent neural networks, and long short-term memory. However, in complex environments where a clear variation pattern for some greenhouse parameters is complicated, environmental anomalies are rarely captured or recognized by univariate sensor data analysis or single machine learning models [5]. A multivariate anomaly detection approach is needed to be explored in Internet of Things area [16]. The anomaly detector system proposed in this study uses a GRU-based Variational Autoencoder. Guo proposed this method to handle IoT sensor data in Smart City [7]. The advantage of the GRU-based anomaly detection system is its reliability in discovering the data correlation and dependencies [14]. There are still weaknesses in actual labelling, which will be improved in this study by involving human knowledge as part of a multivariate anomaly detection system. The main contribution in this paper are summarized as follows:

- Anomaly detector framework for the Internet of Things platform handling type of sensors error combining data-driven and knowledge-driven.
- Algorithm comparison results that fit the Internet of things platform performing real-world datasets in the greenhouse system in the tropical country.

The rest of this article is organized as follows. The Gated Recurrent Unit (GRU) and Variational Autoencoder (VAE)-based anomaly detector are described in Section II, along with the proposed architecture combining GRU-VAE and Human-in-the-loop method. By incorporating knowledge into data-driven techniques, we can increase the detection rate of interesting anomalies [11]. Section III contains the results and discussion for three datasets. Finally, Section IV contains some concluding remarks.

II. System Model

In this section, the Gated Recurrent Unit and Variational Autoencoder-based anomaly detection are given along with the proposed model.

A. Gated Recurrent Unit

The GRU, or gated recurrent unit, is an improvement over the RNN, or recurrent neural network. It was first introduced by Cho et al. in 2014[6]. GRUs are strikingly similar to Long-Short-Term Memory (LSTM). Similar to LSTM, GRU utilizes gates to control the information flow. In comparison to LSTM, they are a more recent development. Consequently, they outperform LSTM and have a more straightforward architecture, as referenced in Fig. 1.

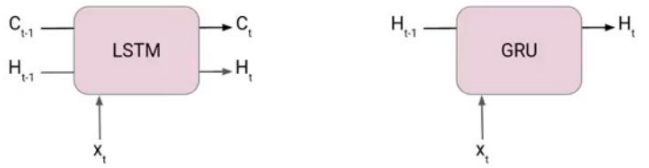

Fig. 1. Illustration Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU) Cell.

At each timestamp t, it accepts the input X_t and the hidden state H_{t-1} from the previous timestamp t-1. The new hidden state H_t is then output and passed to the subsequent timestamp. As shown in Figures 1 and 2, a GRU cell consists primarily of two gates instead of three in an LSTM cell. The reset gate comes first, followed by the update gate. The reset gate is responsible for the network's short-term memory, known as its hidden state (H_t). The equation for the reset gate is as follows.

$$r_t = \sigma\ (x_t * U_r + H_{t-1} * W_r) \quad (1)$$

The update gate for long-term memory is illustrated below, along with the gate's equation.

$$u_t = \sigma\ (x_t * U_u + H_{t-1} * W_u) \quad (2)$$

The only distinction is between the weight metrics U_u and W_u. To locate the hidden state H_t in GRU, a two-step procedure is used. The first step is to create a candidate's hidden state. The hidden gate formula is described.

$$H_t = tanh\ (x_t * U_g + (r_t \circ H_{t-1}) * W_u) \quad (3)$$

It multiplies the input and hidden state from the previous timestamp t-1 by the output of the reset gate r_t. This information is then passed to the tanh function, which returns the hidden state of the candidate. Important in this equation is how we use the reset gate's value to limit the previous hidden state's influence on the candidate state. If r_t equals 1, the previous hidden state H_{t-1} is evaluated in its entirety. Similarly, if r_t is 0, the information from the previous hidden state is completely disregarded. After determining the candidate state, it is used to generate the current hidden state Ht. The Update gate enters the fray at this point. This equation is highly intriguing because, unlike LSTM, we control the historical information in H_{t-1} and the new information in the candidate state with a single update gate.

$$H_t = u_t \circ H_{t-1} + (1 - u_t) * H_t) \quad (4)$$

Now, if U_t is close to 0, the first term in the equation will vanish, implying that the new hidden state will contain little information about the previous hidden state. On the other hand, the second part becomes nearly identical to the first, which implies that the hidden state at the current timestamp will contain only information from the candidate state. Guo uses GRU cells in both the encoder and the decoder to discover the data correlation and dependency [7].

B. Variational Autoencoder based Anomaly Detection

Anomaly detection is one of those domains where machine learning has had such a profound impact that it is almost axiomatic that anomaly detection systems must be based on some type of automatic pattern learning algorithm as opposed to a set of rules or descriptive statistics (though many reliable anomaly detection systems operate using such methods very successfully and efficiently). Combining Bayesian inference with an AE framework, VAE is a probabilistic model. As opposed to a reconstruction error, a VAE-based anomaly detection model generates a probabilistic measure for the anomaly score [14]. Reconstruction probabilities are more objective and principled than reconstruction errors because they do not require modeling specific thresholds for judging anomalies. In particular, VAE assumes that a large number of complex data distributions can be described by a smaller set of latent variables with more straightforward probability density distributions. Thus, the objective of VAE is to find a low-dimensional representation of the latent variables in the input data.

The VAE is distinct from conventional autoencoders because it is probabilistic and generative. The VAE generates partially random outputs (even after training) and can also generate new data similar to the data on which it was trained. The VAE is structurally similar to a conventional autoencoder at a high level. However, the encoder acquires additional coding; specifically, the VAE acquires mean and standard deviation coding. The VAE then generates the latent variables, z, by randomly sampling from a Gaussian distribution with the same mean and standard deviation as the encoder. To reconstruct the input, these latent variables are "decoded." The architecture is visualized by Fig. 2.

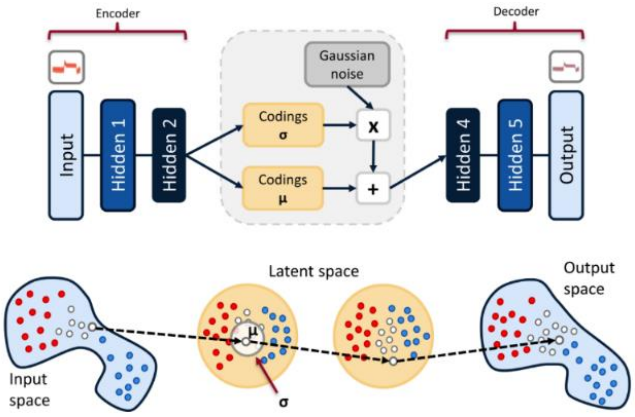

Fig. 2. A Variational Autoencoder Architecture (Top), and an Example of a Data Sample Going through the VAE (Bottom).

C. Human Knowledge-Driven

Human-driven machine intelligence is also known as "human in the loop." Human-in-the-loop (HITL) is a subfield of artificial intelligence that combines human and machine intelligence to create machine learning models [12]. In a conventional human-in-the-loop approach mentioned in Fig. 3, people are involved in a virtuous circle in which they train, tune, and test a specific algorithm. Humans initially assign labels to data, which provides a model with high-quality (and massive) training data. A machine learning algorithm learns to make decisions based on this data. Afterward, humans fine-tune the model. Humans typically score data to account for overfitting, to teach a classifier about edge cases, or to add new categories to the model's scope. Individuals can evaluate and validate a model's outputs, especially when an algorithm is uncertain about a judgment or overconfident about an incorrect decision [10].

D. Proposed Architecture

The proposed architecture for anomaly detection combines data-driven methods, specifically a GRU-based Variational Autoencoder, with expert-provided knowledge, as referenced in Fig. 4. The GRU-based variational autoencoder performs the anomaly detection process on the provided dataset and then compares it to the expert's knowledge [13]. On the greenhouse dataset, this knowledge-driven approach is used. The following diagram illustrates a multivariate anomaly detector's general architecture. The GRU-based VAE algorithm detects anomalies from multivariate sensors. Similarly, experts interpret anomalies in multivariate data.

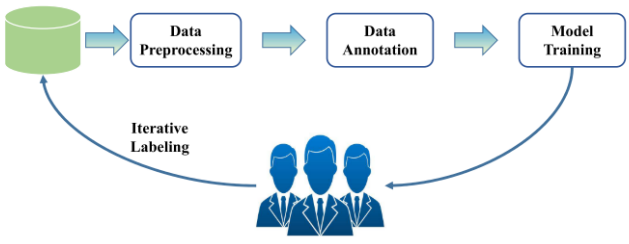

Fig. 3. The Development Cycle of Model [10].

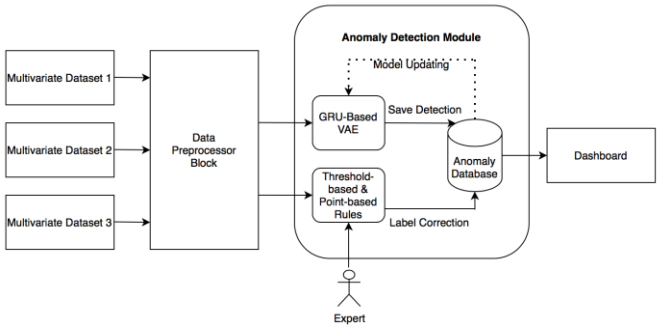

Fig. 4. Fusion Architecture Combining Data-driven and Knowledge- Driven.

This multivariate dataset is derived from three datasets: Intel Berkeley Dataset, indoor greenhouse sensors, and outdoor greenhouse sensors. Greenhouse sensors are being installed in Bandung, Indonesia, in the tropics. The data is cleaned of empty values in the preprocessing subsystem, and each dataset is resampled every 20 minutes. Following that, the feature scaling process is carried out, which is rescaling features to make them more suitable for training [15].

Data Preprocessing blocks are used to carry out several data management processes such as joining data, removing missing values, separating data according to sensor categories, resampling time and then entering into two different system blocks, namely data-driven block and human knowledge-driven block[17].

A data-driven anomaly detection architecture will be proposed in this study, which will make use of a GRU-based variational autoencoder with multivariate time-series data as input. First, greenhouse data is loaded from the database and split into two dataset categories, indoor module, and outdoor module. Each sensor contains four sensor variables, a battery sensor, a humidity sensor, and two temperature sensors.

The GRU input accepts four sensor inputs, each of which is connected to 150 cells in the first layer. Then, the output of the second layer is connected to the second layer's 100 inputs.

The human-in-the-loop method is used for knowledge-driven anomaly detection. Experts make label recommendations based on data using threshold-based and point-based methods. This threshold-based approach will be used to improve the anomaly detection threshold generated by the GRU-based VAE in the future. At the same time, the point-based is used by iteratively providing data to the expert and then labeling the points. The point-based anomaly detection process is measured by the amount of time it takes the expert to label it versus the amount of anomaly it takes to help the expert label it.

III. Experiment Result and Discussion

In this section, the proposed GRU-based VAE model is evaluated using the Intel Berkeley, greenhouse indoor sensor, and greenhouse outdoor sensor datasets. Shamshiri proposed microclimate parameters to be evaluated [8]. Four criteria, namely accuracy, the area under curve (AUC), true positive rate, and false positive rate, are used to evaluate the performance. All experiments were run on the Google Colab

with Intel Xeon @ 2.2GHz, 12 GB Ram, and 12GB NVIDIA Tesla K80 GPU. The algorithm was implemented using Python in Keras and Scikit-learn. The expert knowledge-driven method is evaluated using greenhouse indoor sensor and greenhouse outdoor sensor dataset. The expert will be given a set of preprocessed data and labeled them. The time execution and the number of anomaly data will be compared as the evaluation metric. The expert knowledge-driven method performs better when the time required to determine the number of known anomalies is reduced.

A. Intel Berkeley Dataset

This dataset was compiled using data from 54 sensors installed in the Intel Berkeley Research lab between February 28th and April 5th, 2004 [9]. Every 31 seconds, it contains time stamped topology information, humidity, temperature, light, and voltage values. For various sensors, there are some missing values at certain timestamps. To begin, we use the linear interpretation method to fill in the gaps. Then, every 20 minutes, we sample it and use the average as input. To balance the type of sensor that fits the greenhouse sensor, we only take temperature, humidity, light, and voltage sensors. In the meantime, we normalize the data.

With GRU-based VAE, the average testing MAE is 0.04 and MSE is 0.01 with training time 194s. Table I shows GRU-Based VAE performance. The testing accuracy, Area Under Curve (AUC), Optimal True Positive Rate (Opt. TPR) and False Positive Rate (Opt. FPR) of 81%, 69%, 4%, and 1.8% for light sensor, 39%, 89%, 14.9% and 0% for voltage sensor, 34%, 84%, 5% and 1.6% for humidity sensor and 25%, 82%, 8.4% and 1.4% for temperature sensor, respectively.

TABLE I. GRU-BASED VAE PERFORMANCE

GRU-Based VAE				
Sensor Type	**Accuracy**	**AUC**	**Opt. TPR**	**Opt. FPR**
Light Sensor	81%	69%	4%	1.8%
Voltage Sensor	39%	89%	14.9%	0%
Humidity Sensor	34%	84%	5%	1.6%
Temperature Sensor	25%	82%	8.4%	1.4%

With Gaussian Mixture Model, the testing accuracy, Area Under Curve, Optimal True Positive Rate (Opt. TPR) and False Positive Rate (Opt. FPR) of 61%, 65%, 3.7%, and 1.2% for light sensor, 27%, 94%, 12.8% and 0% for voltage sensor, 32%, 84%, 4.9%, and 1.7% for humidity sensor and 23%, 49%, 0% and 23.7% for temperature sensor, respectively. Table II summarizes the evaluation result.

TABLE II. GAUSSIAN MIXTURE MODEL PERFORMANCE

Gaussian Mixture Model				
Sensor Type	**Accuracy**	**AUC**	**Opt. TPR**	**Opt. FPR**
Light Sensor	70%	65%	3%	1.8%
Voltage Sensor	73%	7%	0%	1%
Humidity Sensor	68%	16%	2%	4.9%
Temperature Sensor	25%	51%	2.4%	0%

With K-Means, the testing accuracy, Area Under Curve, Optimal True Positive Rate (Opt. TPR) and False Positive Rate (Opt. FPR) of 70%, 65%, 3.3%, and 1.8% for light sensor, 73%, 7%, 0% and 1.29% for voltage sensor, 68%, 16%, 1.7%, and 4.9% for humidity sensor and 78%, 51%, 2.4% and 0% for temperature sensor, respectively. Table III summarizes the evaluation result.

TABLE III. K-MEANS PERFORMANCE

K-Means				
Sensor Type	**Accuracy**	**AUC**	**Opt. TPR**	**Opt. FPR**
Light Sensor	70%	65%	3%	1.8%
Voltage Sensor	73%	7%	0%	1.3%
Humidity Sensor	68%	16%	1.7%	4.9%
Temperature Sensor	78%	51%	2.4%	0%

Based on the multivariate correlation between all sensors, there are no concurrent anomalies on the four sensors. There are 0.625% concurrent anomalies on the three sensors. There are 8.125% concurrent anomalies on the two sensors.

B. Greenhouse Indoor Dataset

This dataset was compiled using data from four sensors installed outside the Greenhouse Smart City Living Lab between October 16th, 2020, and July 19th, 2021. It contains timestamped information about the topology every 60 seconds, as well as humidity, two temperatures with distinct locations, and voltage values. There are some values missing at certain timestamps for various sensors. To begin, we will fill in the gaps using the linear interpretation technique. After that, it is sampled every 20 minutes, and the average is used as an input. We take two temperatures with a different locations, humidity, and voltage sensors to balance the sensor type that fits the greenhouse sensor. Meanwhile, we standardize the data.

With GRU-based VAE, the average testing MAE is 0.015 and MSE is 0.16 with training time 196s. Table IV shows GRU-Based VAE performance. The testing accuracy, Area Under Curve (AUC), Optimal True Positive Rate (Opt. TPR) and False Positive Rate (Opt. FPR) of 82%, 58%, 7%, and 3.2% for battery sensor, 93%, 74%, 8% and 1.4% for humidity sensor, 70%, 68%, 2.1% and 0.9% for temperature sensor DS-type and 71%, 70%, 6.4% and 2.8% for temperature sensor SHT-type, respectively.

TABLE IV. GRU-BASED VAE PERFORMANCE

GRU-Based VAE				
Sensor Type	**Accuracy**	**AUC**	**Opt.TPR**	**Opt. FPR**
Battery Sensor	82%	58%	7%	3.2%
Humidity Sensor	93%	74%	8%	1%
Temperature Sensor DS	70%	68%	2.1%	0.9%
Temperature Sensor SHT	71%	70%	6.4%	2.8%

With Gaussian Mixture Model, the testing accuracy, Area Under Curve, Optimal True Positive Rate (Opt. TPR) and False Positive Rate (Opt. FPR) of 64%, 55%, 5.5%, and 2.9% for battery sensor, 98%, NaN, 0% and 1.8% for humidity sensor,

66%, 69%, 0.2%, and 3.4% for temperature sensor DS-type and 69%, 72%, 1.4% and 8.8% for temperature sensor SHT-type, respectively. Table V summarizes the evaluation result.

TABLE V. GAUSSIAN MIXTURE MODEL PERFORMANCE

Gaussian Mixture Model				
Sensor Type	**Accuracy**	**AUC**	**Opt. TPR**	**Opt. FPR**
Battery Sensor	64%	55%	5.5%	2.9%
Humidity Sensor	98%	NaN	0%	2%
Temperature Sensor DS	66%	69%	0.2%	3.4%
Temperature Sensor SHT	69%	72%	1.4%	8.8%

With K-Means, the testing accuracy, Area Under Curve, Optimal True Positive Rate (Opt. TPR) and False Positive Rate (Opt. FPR) of 51%, 54%, 4.9%, and 2.7% for battery sensor, 98%, 100%, 100% and 1.8% for humidity sensor, 68%, 69%, 3.3%, and 2% for temperature sensor DS-type and 70%, 71%, 8.7% and 1.6% for temperature sensor SHT-type, respectively. Table VI summarizes the evaluation result.

TABLE VI. K-MEANS PERFORMANCE

K-Means				
Sensor Type	**Accuracy**	**AUC**	**Opt. TPR**	**Opt. FPR**
Battery Sensor	51%	54%	4.9%	2.7%
Humidity Sensor	98%	100%	100%	1.8%
Temperature Sensor DS	68%	69%	3.3%	2%
Temperature Sensor SHT	70%	71%	8.7%	1.6%

Based on the multivariate correlation between all sensors, there are 0.024% concurrent anomalies on the four sensors. There are 0.16% concurrent anomalies on the three sensors. There are 1.85% concurrent anomalies on the two sensors.

C. Greenhouse Outdoor Dataset

This dataset was compiled using data from 4 sensors installed in the Greenhouse Smart City Living Lab between October 16th, 2020, and July 19th, 2021. It also contains timestamped information about the topology every 60 seconds, as well as humidity, two temperatures with distinct locations, and voltage values. There are some values missing at certain timestamps for various sensors. To begin, we will fill in the gaps using the linear interpretation technique. After that, it is sampled every 20 minutes, and the average is used as an input. We take two temperatures with a different locations, humidity, and voltage sensors to balance the sensor type that fits the greenhouse sensor. Meanwhile, we standardize the data.

With GRU-based VAE, the average testing MAE is 0.05 and MSE is 0.007 with training time 72s. Table I shows GRU-Based VAE performance. The testing accuracy, Area Under Curve (AUC), Optimal True Positive Rate (Opt. TPR) and False Positive Rate (Opt. FPR) of 86%, 59%, 5.3%, and 1.1% for battery sensor, 78%, 60%, 1.5% and 1.5% for humidity sensor, 68%, 69%, 4.7% and 1% for temperature sensor DS-type and 69%, 63%, 1.2% and 0.6% for temperature sensor SHT-type, respectively.

TABLE VII. GRU-BASED VAE PERFORMANCE

GRU-Based VAE				
Sensor Type	**Accuracy**	**AUC**	**Opt. TPR**	**Opt. FPR**
Battery Sensor	86%	59%	5.3%	1.1%
Humidity Sensor	78%	60%	1.5%	1.5%
Temperature Sensor DS	68%	69%	4.7%	1%
Temperature Sensor SHT	69%	63%	1.2%	0.6%

With Gaussian Mixture Model, the testing accuracy, Area Under Curve, Optimal True Positive Rate (Opt. TPR) and False Positive Rate (Opt. FPR) of 61%, 57%, 3.3%, and 0.7% for battery sensor, 29%, 65%, 1.7% and 0.9% for humidity sensor, 68%, 67%, 5.4%, and 0.6% for temperature sensor DS-type and 73%, 62%, 1% and 0.7% for temperature sensor SHT-type, respectively. Table VIII summarizes the evaluation result.

TABLE VIII. GAUSSIAN MIXTURE MODEL PERFORMANCE

Gaussian Mixture Model				
Sensor Type	**Accuracy**	**AUC**	**Opt. TPR**	**Opt. FPR**
Battery Sensor	61%	57%	3.3%	0.7%
Humidity Sensor	29%	65%	1.7%	0.9%
Temperature Sensor DS	68%	67%	5.4%	0.6%
Temperature Sensor SHT	73%	62%	1%	0.7%

With K-Means, the testing accuracy, Area Under Curve, Optimal True Positive Rate (Opt. TPR) and False Positive Rate (Opt. FPR) of 48%, 57%, 0.7%, and 2.6% for battery sensor, 73%, 62%, 1.9% and 1.3% for humidity sensor, 68%, 67%, 5.5%, and 0.6% for temperature sensor DS-type and 72%, 63%, 0.7% and 0.9% for temperature sensor SHT-type, respectively. Table IX summarizes the evaluation result.

TABLE IX. K-MEANS PERFORMANCE

K-Means				
Sensor Type	**Accuracy**	**AUC**	**Opt. TPR**	**Opt. FPR**
Battery Sensor	48%	57%	0.7%	2.6%
Humidity Sensor	73%	62%	1.9%	1.3%
Temperature Sensor DS	68%	67%	5.5%	0.6%
Temperature Sensor SHT	72%	63%	0.7%	0.9%

Based on the multivariate correlation between all sensors, there are 0.13% concurrent anomalies on the four sensors. There are 0.19% concurrent anomalies on the three sensors. There are 0.58% concurrent anomalies on the two sensors.

D. Threshold-based & Point-based Human Knowledge Driven

This paper introduces point-based anomaly detection as part of a proposed method for determining how human-in-the-loop evaluation can be performed. This proposed method describes how an expert can provide anomaly recommendations through the threshold and point annotations. An agricultural expert was involved in determining the point anomaly in the Greenhouse Smart City Living Lab context in this greenhouse case study.

Experts are given raw data in stages, and the amount of raw data given is used to determine how much raw data is required to make it easier for experts to annotate anomalies. The time the data is displayed before the expert can provide annotations is then calculated. Based on the results of tests with data ranging from n = 1 to n = 100, it was discovered that the optimal expert produced the fastest results with n = 5 and an annotation time of 7.12 seconds. That is, the expert requires a minimum of five data samples in order to draw an annotation conclusion. Human knowledge is used as an adaptive threshold in the threshold-based approach, which can replace sigma, which is currently used as a threshold limit. With human knowledge stored in the database, the anomaly detection process will become more adaptive by adjusting the context or rules provided by humans based on point annotations or specific conditions such as a crop disease [20].

E. Discussion

GRU-based VAE has performed well in detecting anomalies, particularly the relationship between the detected variables. However, GRU-based VAE does not produce the best results in some datasets because it necessitates layer adjustments based on the data conditions. However, the deficiency in the anomaly detection process is compensated for by the assistance of human knowledge. Unlike the other algorithms, it has not been able to demonstrate the correlation between anomalies from multiple sensors simultaneously. However, a more detailed assessment of this correlation is required. Correlation is only indicated in this study by the classifications of no correlation or correlates.

This study also proposes a new metric for measuring human-in-the-loop by comparing the amount of data required for annotation and the time it takes the expert to annotate. The comparison curve of the anomaly n and the required time t is generally close to a quadratic function, making it difficult for the expert to annotate due to a lack of data. However, having too much data will also make it difficult for the expert.

IV. CONCLUSION

The greenhouse, outfitted with sensors, generates a large amount of data that must be processed. Of course, the data cannot be separated from anomalies, which may be an anomaly that must be removed because it corrupts the data, or the anomaly may represent hidden information that can be used to make future decisions. The Gated Recurrent Unit-based Variational Autoencoder is proposed in this study as an anomaly detection algorithm capable of detecting anomalies in the multivariate term. This algorithm is also a component of the anomaly detection architecture, which is enhanced by threshold-based and point-based anomaly detection based on human knowledge, which can improve anomaly detection performance.

This anomaly detection model and architecture were evaluated using the Intel Berkeley Lab Dataset, Greenhouse Smart City Living Lab Dataset, and indoor and outdoor sensors. The evaluation results demonstrate that the proposed model is superior at detecting multivariate anomalies and identifying variable correlation. Our proposed architecture using GRU-based VAE and expert feedback can examine correlations between multivariable time series data. The human knowledge module enhances the performance of the GRU-based VAE by correcting false alarms and detecting errors.

Future works are necessary to validate the kinds of conclusions that can be drawn from this research. For example, it is necessary to measure point-based and threshold data for future case studies that may generate different curves. In addition, it is anticipated that this human knowledge will be utilized automatically to enhance the GRU-based VAE anomaly detection model in the future research.

***Abstract*—Industry 4.0 has changed various aspects of human life towards an era heavily influenced by information technology. The impact of industry 4.0 on the education sector has led to the emergence of the term education 4.0. The Internet of Things (IoT) is one of the pillars of industry 4.0. With its capabilities, IoT can provide opportunities to develop innovations in the field of education. Several studies show that teaching aids can improve the quality of learning and learning outcomes. In Indonesia, mathematics is a compulsory subject taught from elementary school to higher education. Previous studies that used mathematical (math) balance aids to help students learn mathematical operations showed positive correlations between the learning process and student learning outcomes in the materials related to arithmetic operations. This study aims to develop an IoT-based mathematical balance tool to support three education 4.0 trends: remote access, personalization, and practice and feedback. This study used modifications of Fahmideh and Zogwhi's IoT development method. There are five phases of IoT development: initialization phase, analysis phase, design phase, implementation phase, and evaluation phase. From each phase of IoT development, IoT-based mathematical balance assistance systems have been successfully built and it complies with the functionality described in the analysis phase. The system performance also shows optimal results with 100% accuracy for reading the student's learning activities. Moreover, it uses less than 10 seconds for processing 1000 data requests.**

Keywords*—Arithmetic operation; education 4.0; internet of things development; math balance aids

I. Introduction

In 2009, Jerald summarized that automation, globalization, workplace change, and policies increasing personal responsibility had changed the trend of school student skills known as 21st-century skills [1]. In 2011, the High-Tech Strategy project organized by the German government brought up the term "Industry 4.0" or IR4.0 to promote a new manufacturing revolution based on computerization and the potential of new technologies [2]. The impact of IR4.0 on the education sector has resulted in the emergence of the term "Education 4.0" as a response to the need for educational outcomes that are aligned and meet the needs of IR4.0 [3], [4]. Fisk defines education 4.0 in nine trends, namely (1) anywhere anytime (diverse time and place), (2) personalized learning, (3) free choice (flexible delivery), (4) project-based (modular and projects), (5) field experiences (practical application), (6) data interpretation (why/where not what/how), (7) completely change of exams (evaluated not examined), (8) student ownership, (9) mentoring and peers [3]. Miranda formulates the core components of education 4.0, which are composed of (1) competencies, (2) learning methods, (3) information and communication technologies (ICT), and infrastructure [4].

ICT has a crucial role in the educational system in providing access, distribution, calculation, and collection of information [5]–[7]. ICT revolutionizes the traditional paradigm to a student-centered model, changes the way of teaching, collaborates between educational stakeholders, and creates various innovations in teaching and learning activities. Miranda classifies ICT into two groups based on the basic components and the combination of the basic components of ICT that results in various innovations and new services. One of the technologies from ICT in Miranda's core education 4.0 core component is the Internet of Things (IoT). The ability of IoT to connect various "things" through the Internet network and the ability of IoT to be programmed with computational intelligence provide opportunities to develop innovations in the education sector[8]–[10].

In the field of education, Kassab et al. have summarized in their publication a systematic literature review on the benefits and challenges of IoT in education. [11]. IoT, with its capabilities, can provide various innovation opportunities to improve the quality of teaching and learning activities at various levels of education. One of the criteria used by Kassab in conducting a systematic literature review is Ambrose's seven effective learning principles, namely previous knowledge, knowledge organization, course climate, motivation, mastery, practice and feedback, and self-directed learning [12]. In another study, Saeed et al. summarized the advantages of implementing IoT in higher education to build a smart campus (smart parking, smart inventory, smart student tracking, etc.), as the main component in smart classrooms (interactive whiteboards, attendance tracking system, wireless door locks, etc.), and develop intelligent labs (integrating IoT with LMS) [13]. Although in many publications, the focus of education 4.0 is explicitly for the secondary school or higher education level, in its implementation, the concept and technology of education 4.0 can be applied at various levels of education, starting from the elementary school level.

In Indonesia, mathematics is one of the compulsory subjects taught to students from the elementary school level. Mathematics is crucial for building children's ability to think logically, problem-solving, creativity, and cultural development [14]. However, many studies have shown that mathematics in primary schools in Indonesia is a difficult and frightening subject. This condition occurs due to various factors such as general factors (physiological, pedagogic,

*Corresponding Author.

intellectual, infrastructure, school environment) or particular factors (difficulty understanding concepts, deficiency of arithmetic operation skills, or difficulty understanding context) [15]. Teaching aids in mathematics subjects help motivate students to learn, provide a concrete picture of the concepts of mathematics lessons that tend to be abstract, and help provide an overview of the relationship between mathematics and the surrounding natural conditions [16]. Examples of mathematics teaching aids are mathematical balance aids to help students understand the material for basic operations in mathematics [17]–[22].

Integrating math balance teaching aids with IoT technology will provide added value, especially to support the education 4.0 trend and support one of Ambrose's effective learning principles, namely practice, and feedback. The integration process between teaching aids and IoT has challenges in meeting the characteristics of education 4.0. These challenges include how to identify system functionality (such as remote access, personalized learning, practice, feedback, etc.), how to determine variables and how to measure performance, how to select system components, how to system architecture, how to implement the system, and how to evaluate the system based on system objectives. This study aims to design and implement mathematics teaching aids using IoT technology that can support the education 4.0 trend: remote access, personalized learning, practice, and feedback. This research provides guidelines for developing an IoT-based teaching aid system in various types of subjects or courses to support the implementation of education 4.0.

The structure of this article consists of five sections. The first section discusses the world of today's education and the development of IoT technology, problems in the world of education, especially for learning mathematics in elementary schools in Indonesia, as well as a statement about the purpose of this research. The second section describes the research method applied in this research, starting from the initiation phase to the evaluation phase. The results of system implementation are discussed in the implementation section. The evaluation and discussion section explains the evaluation of the implementation results and discusses the achievements and opportunities for system development in the future. The last section is a conclusion that summarizes the entire section of this paper.

II. Literature Review

This section summarizes the latest opportunities and conditions for the development of IoT in the field of education. There have been several publications that discuss the implementation of IoT with teaching aids at various levels of education. The integration of IoT technology with game tools that support children's gross motoric training for children aged 4-6 years was published by Shonia et al. which integrates bag toss games with IoT [23]. Shonia et al. implement the system and test the system from the aspect of functionality and system performance. System functionality is tested by checking whether the devices can work according to their functions. Testing system functionality includes testing the microcontroller (whether the microcontroller can run a program to calculate game scores), infrared sensor testing (whether the infrared sensor can detect beanbags), testing the Wi-Fi module (whether the Wi-Fi module can send results to the IoT platform via the internet), and LED testing (whether the LED can provide color according to the bag toss hole). Meanwhile, the system performance was tested based on data communication criteria and the accuracy of reading student activity data. System testing involved four children in measuring the condition of their motor development.

Another research study on IoT to support education was published by Rahmanto et al. and by Jati et al., who use the IoT-integrated variant of the hopscotch game [24], [25]. Rahmanto et al. integrate IoT with hopscotch built using puzzle carpet. The IoT component consists of a microcontroller (using Arduino Mega 2560), a vibration detection sensor (piezoelectric ceramic vibrate sensor), a child activity indicator (buzzer), and a communication module (ESP8255-01). Meanwhile, Jati et al. built hopscotch using aluminum foil and capacitive sensors to detect children's activities. The system architecture of the two studies is the same. However, in the research of Jati et al., the game leveling system has been implemented. Game leveling can be managed using a website application. The two systems built were tested based on system functionality and system performance. Both publications test the functionality of the system by testing each hardware component of the system. While the performance test, Rahmanto et al. tested the aspects of reading speed and accuracy of the assessment. Meanwhile, Jati et al., apart from testing system delay and system accuracy, also tested system gameplay. These two studies did not measure children's motor development achievement.

Wajdi et al implemented IoT in drop-box games to help children's gross motor development [26]. The drop box game utilizes a 32cm x 40cm board with 3-5 holes. The ball is placed on the board. The child's task is to move the board to put the ball in the hole on the board. IoT functions to detect incoming balls and evaluate children's activities. The results of the activity will be stored on the IoT platform. The hardware components of this system are a microcontroller, IR obstacle avoidance sensor, buzzer, and drop box board. In this study, Wajdi et al. tested the system hardware's functionality and tested its performance based on two criteria: the accuracy of scoring children's activities and reading speed. In this study, Wajdi et al. proposed an IoT architecture based on four layers: constrained devices layer, console devices layer, communication network layer, and management services layer.

The previously mentioned studies published the integration of IoT with games to support motor development of preschoolers. Setiawan et al. build an IoT system integrated with Kobela aids at the elementary school level [27]. Kobela is an abbreviation of “Kotak Belajar Ajaib” (Magic Learning Box) which is used to support students in learning multiplication and division of numbers in mathematics. In this study, the authors tested the system based on hardware functionality and system performance: accuracy of children's activities and reading speed from sensors to the IoT platform. The integration of teaching aids in physics subjects was developed by Sakinah et al. and Fauzan et al. Sakinah et al. developed integrated props for Lorentz force practice with IoT

[28]. The system built by Sakinah et al. uses magnets and KY-024 module to detect magnetic fields. The data read by the KY-024 module is sent to the microcontroller to be sent to the system. The interaction of teachers and students to the system uses a website-based application. While in Fauzan et al.'s research, the author integrates IoT with free fall props to help students learn the concept of free fall [29]. These studies tested the system based on hardware functionality and system performance.

From the literature discussed, the development of IoT-based learning aids only focused on system development. In these studies, the researchers did not identify comprehensively: aspects of compliance with education 4.0, analysis of system functionality requirements, system performance analysis, system component analysis, system architecture design, system communication design, and system implementation and system evaluation. This study proposes a flexible and comprehensive model for developing an IoT-based teaching aid system that supports the implementation of education 4.0.

III. Proposed Method

The research method used in this study is the IoT development model proposed by Fahmideh and Zowghi. Fahmideh and Zowghi's method was modified in its sub-phases to suit the functionality and operation requirements of educational teaching aids. [30]. This model describes the process of developing an IoT application sequentially. Fig.1. shows the research method for the development of the IoT model. There are five phases in the development of IoT-based mathematical balance aids.

The first phase is the initialization phase. The purpose of this phase: to identify arithmetic operations learning problems that have solutions using IoT-based technology, conduct a literature study to identify development opportunities and current solutions, and examine the feasibility of environmental infrastructure to implement the system. The next phase is the analysis phase. This phase aims to identify functionality to support part of the education trend 4.0, namely free access, personalized learning, practice, and feedback. Designing the system architecture, then connecting between the hardware, designing the data flow diagrams, and designing the database are the goals of the design phase. Detailed explanations and components of the first, second, and third phases are explained in this second section.

After completing the design phase, the next phase is the implementation phase. In this phase, the implementation includes hardware implementation, software implementation, and system integration. The last phase in the research method is the evaluation phase. In the evaluation phase, there are two evaluations carried out. First, activities evaluate the achievement of system functionality that has been implemented. Second is the activity of assessing system performance based on aspects of system accuracy and delay. The two stages are explained in detail in Section III for the implementation stage and Section IV for the evaluation stage.

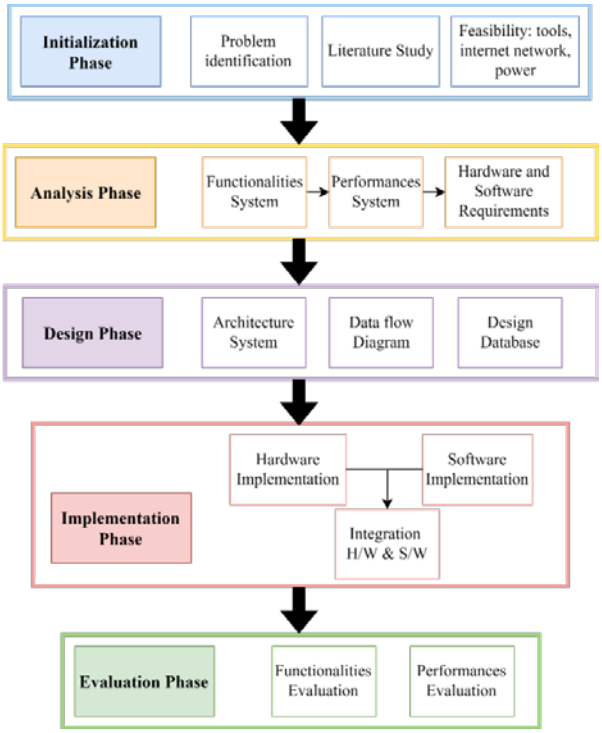

Fig. 1. Method for Integration Mathematical Balance aid with IoT based on Fahmideh and Zowghi [23].

A. Initialization Phase

The initialization phase is the first phase of this research. There are three activities in this phase. The first is to identify the problems of learning mathematics for elementary schools in Indonesia from the perspective of education 4.0. The next activity is to review the study literature to find out the position of this research in the scope of the application of IoT in the education sector. Section II carried out the literature review stage of this study. Checking the feasibility of supporting infrastructure to implement IoT-based solutions is the last activity in this phase. The authors identified problems from publications regarding the effect of using mathematical balance tools on learning outcomes and identification regarding the potential of IoT in providing opportunities for improving the quality of education and changing the character of education in the Industrial 4.0 era is conducted.

The last part of this phase is to check the feasibility of the availability of mathematical balance aids, hardware for IoT such as microcontrollers, and gyroscope sensors, the availability of internet networks in the classrooms, and the availability of electrical networks for the systems in the classrooms. After checking, the result is that all components and infrastructure are available to build an IoT-based mathematical balance teaching aid system.

B. Analysis Phase

The second phase in this research is the analysis phase which consists of three activities. The first activity is to define system functionalities based on research objectives, the second is to determine system performance, and the last activity is to determine hardware and software requirements following the specified functionality.

1) Functionalities system: System functionalities are determined based on research objectives. The objectives of this research are:

- to design and implement mathematical balance aids that students can use anywhere and anytime,
- to design and implement systems that can read and store activity results, and
- to design and implement systems that can provide real-time (i.e., the processing time in the system is less than 1 minute) and accurate feedback, and
- to be available from anywhere and anytime via the internet.

The functionality of this system is as follows:

- The system can be accessed using the internet network.
- The system has an application interface for users to interact with the system
- Mathematical balance aids integrated with IoT
- The system can send data on the results of student learning activities to the IoT platform
- The system has a database that stores student activities
- The system can identify users
- The system can evaluate activities accurately
- The system can display the evaluation results in real-time

2) Performances system: In this research, the evaluation of the system performance using accuracy parameters and delay parameters. The accuracy parameter ensures that student learning activities using mathematical balance aids are assessed correctly. This parameter is essential to determine the results of the feedback given to students. The delay parameter plays a role in ensuring it can meet Ambrose's feedback principle. Students need appropriate feedback immediately so that students can evaluate their activities.

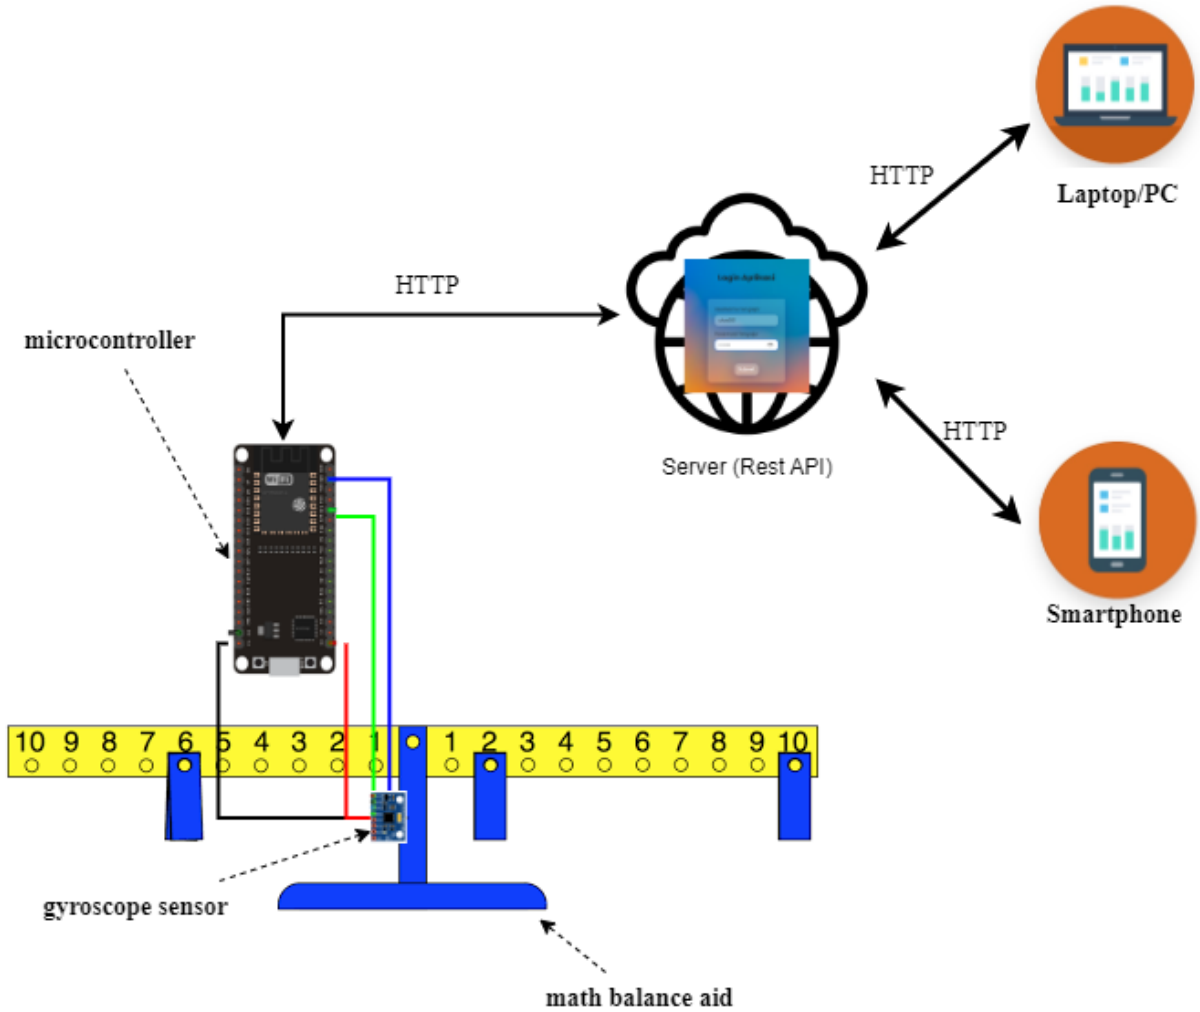

Fig. 2. Architecture System.

3) Hardware and software requirements: Based on the functionality and performance of the system that has been determined in the previous stage, at this stage, the requirements for hardware and software are defined. The hardware and software requirements to build an IoT-based mathematical balance teaching aid system are shown in TABLE I.

TABLE I. HARDWARE AND SOFTWARE REQUIREMENTS

Type	Component Name	Description
Hardware	Math balance Aids	Learning aids to support students learning about arithmetic operations
	Sensor gyroscope	Device for maintaining and measuring X-axis and Y-axis of math balance aids
	Microcontroller (with wire)	Board for receiving data and connecting math balance aids and gyroscope sensors to the application
	Battery or DC power supply	As a source of power to the system
	PC/Laptop/Smartphone	Device to access the application
Software	Web Application	An application that displays the login menu, calibrates the sensor, starts the class, and views the student's score.
	Database	An application for storing student data, grade data, class data, and teacher data
	Platform Communication	An application to connect the system to the internet network

C. Design Phase

The design phase consists of three component designs. The first component design is the system architecture. The system architecture shows how the components system and the communication between system components. The next component design is a data-flow diagram describing the developed application's data flow. Database design is the third component that shows the tables and the relationships between these tables.

1) Architecture system: Fig. 2 shows the system architecture for the IoT-based mathematical balance aids. In the system architecture, there are three components. The end node component consists of a mathematical balance teaching aid, gyroscope sensor, microcontroller, and wire. This component is used for student learning activities. The communication component consists of protocol communication (in this research use HTTP and TCP communication protocols). The website-based application is the last component, which functions to access and display student data, class data, grade data, and teacher/user data.

2) Data flow diagram: The data flow diagram shows the activity or operation of the system based on the data flow. The data flow diagram becomes a reference for designing the database. Fig. 3 shows the data flow diagram in this study, which consists of four functions: login, calibrate the sensor, start the class, and view student scores. In the login function to secure user/teacher data, the system provides additional functionality for credential data.

3) Database design: Database design refers to the data-flow diagram. This research designed the database to store data on student identity, student grades, classes, and users (teachers), and designing relationships between tables. The database label using the Indonesian language. In Indonesian, "murids" means student, "nilai" implies score, and "kelas" means class. There are two collections in the database design. The "murids" collection consists of two tables, namely the "murids" table and the "nilai" table.

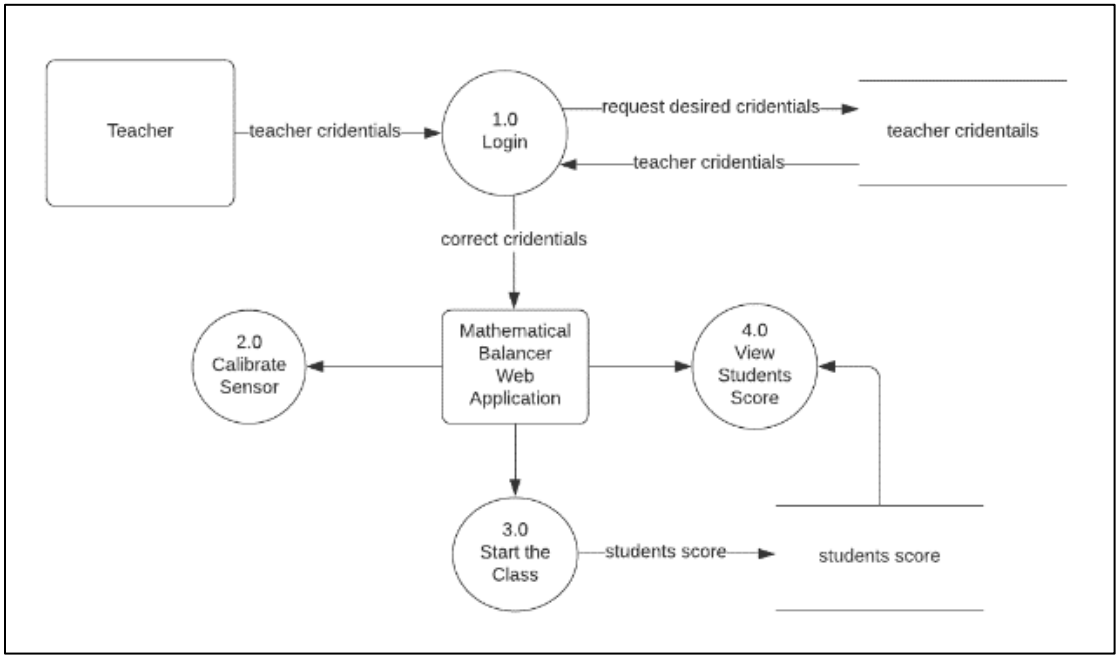

Fig. 3. Data-Flow Diagram.

The "murids" table stores student data such as name, age, and grades. The grades table has a date column, the number of grades (which contains the accumulated student activity grades) column, and the _id of the student column. In the "kelas" collection, there are two tables: the class table and the users' table. "Kelas" table store all registered student ids. The "kelas" table is related to users (or teachers). A user can relate to several different classes. Especially for table users, for data security, this research use salt and hash columns. The database design is shown in Fig. 4.

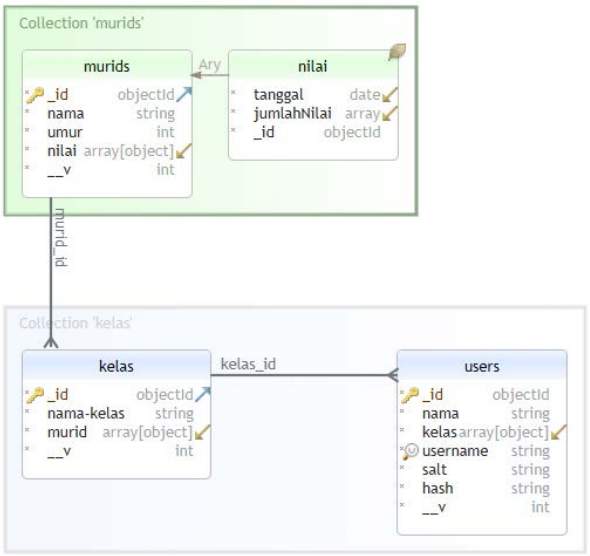

Fig. 4. Database Design.

D. Implementation Phase

The authors implement the system based on the design phase results in the implementation phase. There are three stages of implementation: hardware implementation, software implementation, and system integration. Hardware implementation describes how the author installs the hardware components of the IoT hardware and math balance aids.

The software implementation phase describes the stages of building software components. The stages of software implementation start from creating application interfaces, creating databases, and connecting application interfaces and databases. After the hardware and software components have been successfully implemented, the next step is integrating the two components. The discussion of system implementation is discussed in detail in Section III.

E. Evaluation Phase

The system's functionality and performance is tested in the evaluation phase. System functionality is tested by checking the suitability of system functionality with functionality in the analysis phase. Performances evaluation measures accuracy and delay. Accuracy is evaluated by comparing the student's answers with the expected answers, while for the delay, it will calculate the activity processing time. The author use test cases to evaluate system performance using 10, 100, and 1000 requests per second. A discussion of the evaluation phase is presented in Section IV.

IV. System Implementation

A. Hardware Implementation

Hardware implementation refers to the system architecture in Fig. 2. In implementing hardware components, the first step is to provide mathematical balance visual aids, gyroscope sensors, microcontrollers, wiring, power source support, and other required supporting components. The next step is to combine and configure the math balance aids with the gyroscope sensor. In a static position, all the gyroscope sensor's x, y, and z axes must have a value of 0. After the static position is obtained, the next step is to identify the pinout on the gyroscope sensor (in this study, the type of gyroscope sensor used is MPU6050), such as pins for power, pin for ground, pin for I2C communication, pin for I2C address, and an interrupt pin.

The next step is to prepare the Arduino IDE to program the microcontroller (in this study, the system uses ESP32). Prepare the libraries needed to integrate the ESP32 with the MPU6050 sensor module. After all the libraries have been prepared, the ESP32 and MPU6050 are integrated with the designed schematic diagram. The program is written on the ESP32 to read the axes and accelerometer from the gyroscope sensor. In this step, must ensure that under static conditions, the value of all axes is zero, and the acceleration value on the z-axis approaches the gravitational force value of 9.8 m/s2. For the x and y axes, the value is 0. If there is still a discrepancy in the value, it is necessary to calibrate the sensor.

The mathematical balance aid is integrated with the gyroscope sensor. The system sends data to the internet network to be stored in the system database. Communication between the website and the microcontroller is two-way communication. The system allows setting the gyroscope sensor calibration via the website. The math balance aid is integrated with the gyroscope sensor to read the x, y, and z axes. The system assesses students' answers based on changes in the angle of the gyroscope sensor. The results of the system implementation are shown in Fig. 5.

Fig. 5. Implementation Hardware for Math Balance Aids Integrated with IoT.

B. Software Implementation

The data flow diagram in Fig. 3 is the basis for implementing the software or application in this study. From the data flow diagram, the authors create an application interface design. Website-based applications allow users to access applications via the internet with various types of devices, such as personal computers, laptops, smartphones, or tablets. In this study, the application was built using node.js. The system implementation results are shown in Fig. 6 (a-d).

Fig. 6. (a) Login Page, (b) Calibration Page, (c) Start Class, (d) View Student Score.

Fig. 7. Database Implementation on MongoDB.

Fig. 6 (a) shows the display of the login page. Teachers use the login page to manage class activities for learning mathematical operations using IoT-based mathematical balance aids. Fig. 6 (b) shows a page for performing an application-based scale calibration. Before starting an activity, the teacher must calibrate the device to ensure the device is in a static state. After the class is started by the teacher, the display that appears in the application is Fig. 6 (c). At this stage, students carry out learning activities using IoT-based teaching aids. After completing the learning activity, Fig. 6 (d) shows the results obtained by the students. The database system is built based on the database design described at the design stage. The database system was built using the MongoDB application. Fig. 7 shows the implementation of the database according to the database design. After the interface and database have been successfully implemented, the next step is to integrate the two components.

C. Integration System

The microcontroller has a significant role in the integration process. The microcontroller stores the angle change data on the gyroscope sensor and sends it to a system that has been hosted online. So that student activity data can be accessed by users using various devices via the internet. The implementation phase is complete when all data can be read, stored, processed, and accessed according to the system design.

V. Evaluation and Discussion

This section discusses the evaluation of the system applied in the previous section. This section discusses the potential for improving the systems that have been built and the opportunities for developing IoT-based learning systems in education in the future.

A. Evaluation Phase

1) Functionaliy evaluation: This stage evaluates the functionality that has been defined in Section 2.2.1. The evaluation was conducted by measuring the achievement of functionality in the system. The summary of achieving the functionality defined by the system functionality is shown in Table II.

Testing of website functionality and website menus is carried out using the test case method. The test results for each website's functionality and website menu are shown in Table III.

TABLE II. SYSTEM FUNCTIONALITIES

No	Functionalities	Implementation
F1	The system can be accessed using the internet network.	The authors build a website-based software system so that it can be accessed via the internet and can be accessed with various devices such as personal computers, laptops, or smartphones. The interface of the system is shown in Fig. 6.
F2	The system has an application interface for users to interact with the system	The system has an interface that allows users to perform interactions such as logging in, calibrating teaching aids, starting class activities, and viewing student grades. As shown in TABLE III.
F3	Mathematical balance aids integrated with IoT	Mathematical balance aids are successfully integrated with IoT. System integration with IoT can be seen from the system architecture in Fig. 2. and the system implementation in Fig. 5.
F4	The system can send data on the results of student learning activities to the IoT platform	The results of arithmetic operations learning activities using IoT-based balance aids can be sent to the IoT platform as shown in Fig. 6(d).
F5	The system has a database that stores student activities	The authors implement the database based on the database design in Fig. 4., and the results of the database implementation are shown in Fig. 7.
F6	The system is able to identify users	The system checks the login process to ensure that only authorized users can log in to the system and send error message notification. An example of a login process that does not meet system authentication is shown in the figure
F7	The system can evaluate activities accurately	The system can process the input into the output of the assessment system, as shown in TABLE IV.
F8	The system is able to display the evaluation results in real-time	The system can process the assessment results in real-time with the specified number of requests, as shown in TABLE V.

TABLE III. TEST CASE FOR WEBSITE PAGE FUNCTIONALITIES AND THE TEST RESULTS

No	Functionality	Test Case	State
1	Login	Verify credentials	succeed
2		Sending error message if the credentials are incorrect	succeed
3	Calibrate Sensor	Checking connection from the microcontroller	succeed
4		Sending error message if microcontroller is not connected properly	succeed
5		Generate the angle of inclination value from the microcontroller	succeed
6		Calibrate the sensor and make sure the angle of inclination is 0 radian	succeed
7	Start the Class	The teacher can choose a class to teach	succeed
8		The class name provided by the system is the same as the teacher signed at	succeed
9		The teacher able to start the class after providing class name and the current date	succeed
10		The system only able to process number from zero to ten	succeed
11		The angle of inclination from each student microcontroller are displayed correctly	succeed
12		The system sends the angle of inclination value to database	succeed
13		The system would show error message if the data failed to be sent to database	succeed
14	View Students Score	The teacher can choose a class where he teach	succeed
15		The class name provided by the system is the same as the teacher signed at	succeed
16		The system can process and evaluate the final students score correctly	succeed
17		The system can export the scores to a .xls file	succeed

2) Performance evaluation: There are two aspects to evaluating system performance. The first is to test and evaluate the accuracy between the results obtained from the angle of inclination of the mathematical balance aids with the expected result. The tolerance limit for the angle of inclination in this study was 0.14 degrees. For answers with angles below or equal to 0.14 degrees, the value is 1. In contrast, at angles that exceed the limit, the value is 0. The results of the device testing for five types of questions given to eight children got the results as shown in TABLE IV. For question number one, there is a question of adding the number one to number 2. On one side of the balance tool arm will be given a load on the number 1 and number 2. The student's task is to put the burden on a certain number that is the answer to the question. When a student puts a load on a specific number, and the inclination angle exceeds 0.14 degrees, the student's response is worth 0. The result of this answer is then compared with the expected result. If both the result and expected result are the same, then the tool assesses the answer accurately. For example, a student named Vino Hakim gave an answer that caused an angle of inclination of 0.04 degrees so that the result is worth 1, when compared to the expected result, which is worth 1, so the authors give a valid status.

TABLE IV. ACCURACY OF IOT-BASED MATH BALANCE AIDS

Question	Student	Angle of Inclination (degrees)	Result	Expected Result	Status
1 + 2	Vino Hakim	0.04	1	1	Valid
	Nurul Hasanah	0.09	1	1	Valid
	Violet Mayasari	0.2	0	0	Valid
	Ulya Hartati	0.13	1	1	Valid
4 - 3	Endah Riyanti	0.02	1	1	Valid
	Adinata Mansur	0	1	1	Valid
	Kuncara Januar	0.07	1	1	Valid
	Ilsa Hartati	0.14	1	1	Valid
3 x 2	Vino Hakim	0.17	0	0	Valid
	Nurul Hasanah	0.15	0	0	Valid
	Violet Mayasari	0.31	0	0	Valid
	Ulya Hartati	0.07	1	1	Valid
4 ÷ 2	Endah Riyanti	0.02	1	1	Valid
	Adinata Mansur	0.32	0	0	Valid
	Kuncara Januar	0.12	1	1	Valid
	Ilsa Hartati	0.02	1	1	Valid

The following evaluation is to measure system delay. In this study, the system delay is calculated from the time of reading data from the gyroscope sensor to the microcontroller to accessing the user's device using the internet network. This study uses a simple architecture from one mathematical balance aid to multiple user devices to measure the delay time. In the microcontroller, the authors set the data reading from the gyroscope sensor to 10 milliseconds, and the connection delay from the microcontroller to the WIFI is one second. The speed of WIFI is approximately 10 Mbps. This configuration sends one hundred data from the sensor to the website in less than two seconds. The next is the measurement of a delay from the website to the user's device. By using a web performance test, the test results for 10, 100, and 1000 requests to the system resulted in 100% completed requests and with a total time of fewer than 4 seconds, as shown in TABLE V. Total time required to read a hundred data from the sensors to the application with 1000 requests in less than 10 seconds.

TABLE V. PERFORMANCE TEST RESULTS

Requests	Total Errors	Completed Request	Request/s (per second)	Total Time
10	0	10	97	0.10s
100	0	100	216	0.46s
1000	0	1000	276	3.6s

B. Discussion

The modification of the IoT development method proposed by Fahmideh and Zowghi in this study provides a comprehensive guide for developing IoT-based teaching aids. This study used the development method to build math balance aids to help students learn arithmetic operations. The development of an IoT system based on mathematical balance aids with the proposed method shows the successful integration of mathematical balance aids and IoT functionality to achieve the three characteristics of education 4.0: remote access, personalized learning, and practice and feedback.

Fahmideh and Zowghi's IoT development method does not discuss the specifics of IoT implementation in certain fields. The modification of Fahmideh and Zowghi's method in this study is specifically intended for the field of education. The method proposed in this study provides guidance in identifying the need for IoT integration with education 4.0. In the future, the method in this research can be used to implement IoT with teaching aids at various education levels and various subjects or courses.

Although this study succeeded in building a prototype of an IoT-based math balance aid in accordance with each phase of the proposed method, several limitations have not been resolved in this study. From the aspect of durability and hardware packaging, the system still has to be developed to be more robust. The gyroscope sensor must be corrected in several tests to obtain valid results. In future, research that examines the durability and packaging of the system will be necessary. From the software aspect, applications must be developed by considering aspects of the user interface (UI) and user experience (UX). There is potential for UI/UX development to develop applications for IoT systems by considering user personas and human factor considerations so that the resulting application is an application that is easy, interactive, and convenient for users (teachers, students, and education staff) [31].

Furthermore, from the educational aspect, application development is integrated with existing educational applications to provide comprehensive feedback data. Integrating the system with data science or artificial intelligence to improve the quality of feedback based on student learning activity data is a future research opportunity [32]. Gamification can be combined with the system to increase student motivation or engagement. There are still many opportunities to conduct research on gamification in IoT, especially for education and industry 4.0 [33]. This research is still being tested on a laboratory scale. It needs to be tested in the classroom to determine technology acceptance by teachers, students, or academic staff. This research also provides an opportunity to examine the impact of the system on student learning outcomes. Another aspect that is not discussed in this study is the aspect of data security and privacy. Based on various studies, the security and privacy issue in IoT is one of the biggest challenges in IoT implementation [11], [34], [35]. Activity result data is published on the internet network, which has an impact on the emergence of opportunities for theft or use of data by unauthorized parties.

VI. CONCLUSION

In this study, an IoT-based mathematical balance tool has been successfully developed to support arithmetic operational learning for elementary school students in Indonesia. The purpose of implementing IoT in teaching aids in this study is to design education that supports education 4.0. This study proposes an IoT development method modified from the method proposed by Fahmideh and Zowghi. The IoT development method consists of five stages. The proposed IoT development method defines each stage comprehensively. The first stage is the initialization stage, which identifies research problems, conducts related literature studies, and identifies the feasibility of supporting infrastructure. The second stage is the analysis stage with the following objectives: defining system functionality according to research objectives and defining system performance based on system accuracy and delay. The third stage is the design stage, to determine the requirements for hardware and software. The system architecture, data flow diagrams, and database design are also designed at this stage. The results of the third stage become a reference for the next stage, namely the implementation stage. The evaluation of the system implementation showed that all functionality was successfully implemented with 100% accuracy for reading, recording, and evaluating student activities. While the results of the evaluation of the system performance show system delay for 1000 requests is less than 10 seconds.

ACKNOWLEDGMENT

This work is supported by internal funding from Telkom University.

An Efficient Patient Activity Recognition using LSTM Network and High-Fidelity Body Pose Tracking

Thanh-Nghi Doan
Faculty of Information Technology, An Giang University
Vietnam National University Ho Chi Minh City
An Giang, Vietnam

***Abstract*—The need for healthcare services is growing, particularly in light of the COVID-19 epidemic's convoluted trajectory. This causes overcrowding in medical facilities, making it difficult to manage, treat, and monitor patients' health. Therefore, a method to remotely observe the patient's behavior is required, to aid in early warning and treatment, and to reduce the need for hospitalization for patients with minor diseases. This paper proposes a new real-time smart camera system to monitor, recognize and warn the patient's abnormal actions remotely with reasonable cost and easy to deploy in practice. The key benefit of the proposed methods is that patient actions may be detected without the usage of ambient sensors by employing pictures from a regular video camera. It carries out the detection using high-fidelity human body pose tracking with MediaPipe Pose. Then, the Raspberry Pi 4 device and the LSTM network are used for remote monitoring and real-time classification of patient actions. The test dataset is built from reality and reuses the existing datasets. Our system has been evaluated and tested in practice with over 96.84% accuracy, runs at over 30 frames per second, suitable for real-time execution on mobile devices with limited hardware configuration.**

***Keywords*—Human body pose tracking; LSTM; raspberry Pi 4; patient monitoring system**

I. Introduction

The development of efficient and reliable remote patient action recognition systems has been receiving much attention from the scientific research community. The benefits of patient monitoring from a distance include the ability to detect illnesses early and in real time, monitor patients continuously, stop illnesses from getting worse and prevent untimely deaths, lower hospitalization costs, fewer hospitalizations, and more accurate readings while still allowing patients to go about their daily lives normally. By using communication technology, emergency medical services, care for patients with mobility issues, emergency care for injuries sustained in traffic accidents and other types of accidents, and non-invasive medical interventions, healthcare services are made more efficient. In recent years, action recognition methods have focused heavily on the use of image and video analysis technologies. There are different definitions of action recognition presented in the study by Herath et al. [1]. The rapid development of smart devices and deep learning techniques have spurred the development of action recognition systems. These techniques have been widely applied in life such as entertainment, monitoring and human health care [2]. However, according to the survey by Szegedy et al. [3], the identification of complex and specific actions is still a big challenge to study. The articles [4], [5] presented a comprehensive review of fall detection systems and remote patient action recognition. Researchers have built a large variety of systems that can operate with the many technologies used to monitor patient behavior. These systems are broadly characterized as wearable, ambient, and computer-vision-based [6]. Researchers have created a vast array of systems that can work with the various technologies that are used to track patient activity. In general, these systems can be divided into wearable, ambient, and computer-vision-based ones [6].

The first block, wearable systems, includes sensors carried by the monitored individual. This set of systems employs a wide range of technologies, including accelerometers, pressure sensors, inclinometers, gyroscopes, and microphones, among others. The authors of [7] carefully evaluate and study these systems. The study attempts to assess the state of the art in such monitoring, both in terms of the most commonly used sensor technologies and their placement on the human body. These techniques, however, have the problem of requiring the devices to be put on the individuals' bodies. Because this sort of sensor must be worn continually, it might be unpleasant and not always viable [8]. The second block contains devices with pressure, acoustic, infrared, and radio-frequency sensors that are positioned around the monitored individual [9], [10]. However, the expense of installing these systems is very costly, and they are only appropriate for specialist patient care rooms, making them difficult to employ in everyday living at home. The last block, which is the focus of this research, groups systems capable of identifying human recognition using image-based computer vision. In recent years, convolutional neural networks (CNN) [11] have been widely used in image classification problems in many fields. Due to CNN's superior performance [12], many studies have started to use CNN for video classification. Long Short-Term Memory (LSTM) neural networks and conventional CNNs, or a combination of the two, have both been shown to perform well in human action recognition (HAR). In which CNN has been used to analyze sensor data for HAR with exceptional results [13]. Previous studies have proposed to supplement the feature vector extracted by CNN with some statistical features [14]. Aviléz-Cruz et al. [15] have developed a three-input CNN model to

recognize six human actions. The usefulness of LSTM networks for HAR has been demonstrated by additional studies as well [16]. Finally, several studies have suggested enhancing CNN with LSTM layers [17]. Recently, the article [18] proposed a network model that combines LSTM, MobileNetV2 and Raspberry Pi 4 in remote patient action monitoring and identification. However, these methods in the last block have the drawback of making it difficult to distinguish between closely related actions, such as waving and clapping, walking and running. Furthermore, training network models takes a long time due to direct learning of data from video frames, where CNN models are used to extract features from video frames. Because of this, these methods require extensive hardware configurations and have slow response times.

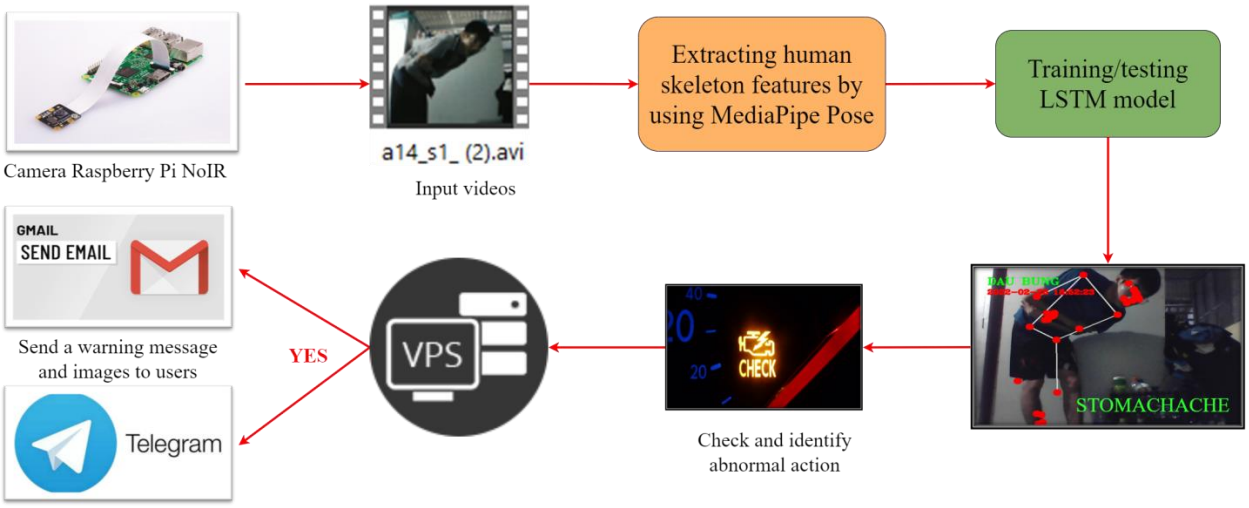

Fig. 1. Overview of our Proposed System for Monitoring Patient Healthy.

On the other hand, studies on the skeleton features extraction method for patient action identification [19], [20], and [21] have demonstrated a number of benefits that can get around the issues raised above. As a result, this paper proposes a new system for real-time identification of patient actions that is low in cost, efficient, has a fast response time, and is simple to install and implement in practice using hardware devices with limited configuration. The main contributions of the paper include:

- A novel method for patient action recognition using MediaPipe Pose framework [22], LSTM network model and Raspberry Pi 4 device [23].
- A new dataset was created using 541 videos of 16 different types of patient actions that were preprocessed and labeled in accordance with benchmark dataset standards.
- An action recognition system that is fully developed, user-friendly, and capable of continuous monitoring and alerting of abnormal human activity of the patient at home.

The rest of the article is arranged as follows. Section II describes the materials and methods used to describe overview of our system, data collection, patient action recognition model, Raspberry Pi and Camera Raspberry Pi NoIR . The experimental results and discussion are reported in Section III. Section IV presents the conclusions, limitations, and recommendations for future research.

II. Materials and Methods

A. Overview of our System

The overview of the proposed system for the remote patient monitoring camera system is shown in Fig. 1. In which the Raspberry Pi 4 Camera Module NoIR [23] is used to continuously monitor the patient's activities at home in real time. The generated video sequence is recognized and labeled in real time using the MediaPipe Pose framework [24] and the LSTM network model [25] trained and saved on a Raspberry Pi 4 device. If the patient's actions are considered to be abnormal, there is a health problem, and the system will immediately send a warning message, along with a photo of the odd activity, to the patient's relatives via email and the *Telegram* messaging application. The labeled videos are then saved on a virtual server on a regular schedule. Videos labeled as abnormal actions will be kept on the server for a long time, whereas normal actions will be kept for a short time and deleted after a certain period of time to save storage space. The algorithm to recognize real-time patient actions in videos and send warning messages with images of abnormal actions to users is summarized and shown in Fig. 2.

B. Data Collection

There are many published datasets on human action recognition such as ActivityNet [26], Kinetics [27], UCF101 [28], HMDB51 [29], STAIR-Actions [30], KARD [31], and NTU RGB+D [32]. However, these datasets do not include recordings of patient activities, and there is presently no published official benchmark dataset for these types of activities. Therefore, this study self-constructed a new dataset on patient actions to test our proposed approach. This dataset combines existing data with data generated by us from the actual world. A summary of this dataset is presented in Table I.

```
BEGIN
    Input: LSTM model, patient body skeleton points
    Label = "Nomarl action"
    The model predict the result based on the skeleton points
    IF Result = 1:
        Label = 'Hand swing'
    ELIF Result =2:
        Label = 'Hand clap'
     .
     .
     .
    ELIF Result =14:
    {
        Label = 'Stomachache'; Save the stomachache images
        Send emails, messages, images via Gmail and Telegram
    }
     .
     .
     .
    ELSE
        Label = 'Normal action'
    RETURN: Label
END
```

Fig. 2. The Algorithm Processes Skeleton Point Data, Returns Results and Sends Notification Messages to GMAIL, TELEGRAM.

TABLE I. A SUMMARY OF OUR DATASET ITH 16 TYPES OF PATIENT ACTIONS

ID	Description	Avg frame	Frame		Frame/s	Number of videos
			Width	Height		
a01	Hand swing	2500	640	480	25	81
a02	Hand clap	2500	640	480	25	23
a03	Body swing	2500	640	480	25	24
a04	Drink	2500	640	480	25	51
a05	Sit down	2500	640	480	25	34
a06	Stand up	2500	640	480	25	33
a07	Walking	2500	640	480	25	55
a08	Side kick	2500	640	480	25	66
a09	Phone call	2500	640	480	25	34
a10	Hand pain	2500	640	480	25	15
a11	Leg pain	2500	640	480	25	22
a12	Headache	2500	640	480	25	25
a13	Neck pain	2500	640	480	25	25
a14	Stomachache	2500	640	480	25	22
a15	Backache	2500	640	480	25	19
a16	Fall down	2500	640	480	25	12
Total number of videos						**541**

Due to time and staffing restrictions, we could only create a test dataset with 16 examples of the patient's actions. These actions are collected and separated into two groups: (i) the patient's normal actions (shown in the blue bounding box of Fig. 3) and (ii) the patient's abnormal actions (shown in the red bounding box of Fig. 3. This dataset includes four actions taken from the KARD dataset [31] and 12 actions we independently created by recording patient action video clips in the real experimental setting. KARD is a dataset that includes 18 different types of indoor daily activities with a resolution of 640x480 and reasonably clear action gestures. Consequently, they can be utilized to develop and evaluate a patient health monitoring system at home. However, only four action classes that are appropriate for this problem are used in this study: sit down, stand up, side kick, and phone call. We recruited volunteers to carry out 12 distinct types of actions for fact-generated data. Each type of action was performed three times and video recorded for three seconds each, using a Webcam HD 720p with the detailed specifications shown in Table II.

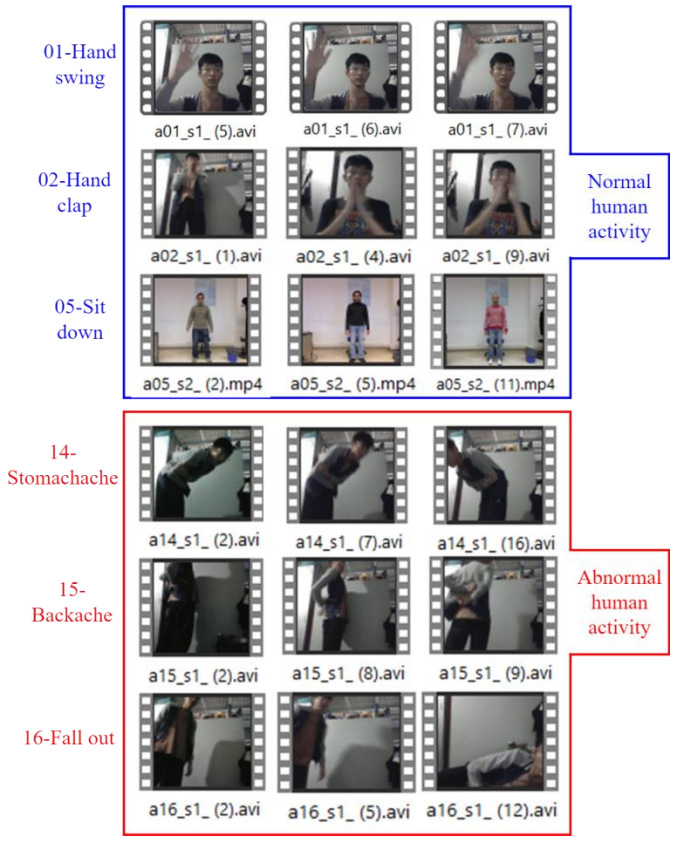

Fig. 3. Video Samples of our Patient Activities Datasets.

TABLE II. THE DETAILED SPECIFICATIONS OF WEBCAM HD 720P.

Specifications	Value
Camera	HD webcam 720p
Resolution	800x600
FPS	25 frames/second
Camera color	Color
Flash mode	No
Focus type	Fixed focus
Video format	AVI

The total number of videos we have collected is over 700 videos. These videos are then preprocessed, and the videos that do not meet the quality requirements are removed, yielding a video dataset of 541 files. The total size of the video dataset is 241 MB in which, the number of videos of each action type ranges from 12 to 81 videos, as shown in Table I. Each video is

shot at a frame rate of 25 FPS. This dataset is annotated in order of videos in each folder according to each action type, i.e. a01_s1_(1).mp4, a01_s01_(2).mp4,…, a02_s1_(1).mp4, a02_s01_(2).mp4,… equivalent to actions labeled as a01 (Hand swing), a02 (Hand clap), a03 (Body swing), a04 (Drink), a05 (Sit down), a06 (Stand up), a07 (Walking)), a08 (Side kick), a09 (Phone call), a10 (Hand pain), a11 (Leg pain), a12 (Headache), a13 (Neck pain), a14 (Stomachache), a15 (Backache) and a16 (Fall down). Some sample videos of the dataset consisting of 09 normal actions and 07 abnormal actions of the patient, are presented as shown in Fig. 3.

C. Patient Action Recognition Model

1) Extract Human Body Features with MediaPipe Pose:

MediaPipe Pose is a machine learning solution for high-fidelity body pose monitoring that uses the BlazePose research [22] to infer 33 3D landmarks and a background segmentation mask on the entire body from RGB video frames. The network can generate 33 body keypoints for a single human during inference and performs at over 30 frames per second on a Pixel 2 phone. Therefore, it is well suited to real-time applications such as fitness tracking and sign language recognition. The benefit of this skeletal feature extraction method is its real-time speed, fast response time, and good results even with low-quality and low-resolution video clips, independent of ambient variables such as light, shadow, and the ability to identify many objects at the same time.

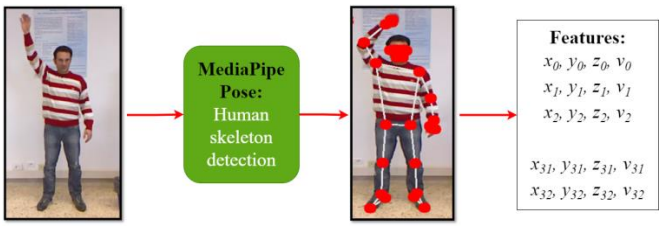

Fig. 4. Extracting Human Skeleton Features using MediaPipe Pose [24].

In this study, skeleton features are extracted from each frame of video using the algorithm described in the paper [22]. As shown in Fig. 4, the result of extracting each video frame is 33 skeleton points corresponding to 33 coordinates (*x*, *y*, *z*) and a visibility value *v* numbered from 0 to 32. Each skeleton point is assigned a different ID number when stored in the file used for model training. Since the video is recorded at a frame rate of 25 FPS, the number of captured frames is calculated as 25 x video recording time in second. As a result, the total number of frames collected from the dataset of 16 action classes is 19,345 frames, as shown in Table III.

2) LSTMs for Patient Activity Recognition:

Long Short-Term Memory [25] is a Recurrent Neural Network (RNN) that has been increasingly used in the field of deep learning and human action recognition. LSTM, as opposed to standard feedforward neural networks, includes feedback connections. A recurrent neural network of this type can analyze not just individual data points (such as photographs), but also whole data sequences (such as speech or video). For instance, LSTM may be used for handwriting recognition, speech recognition, and anomaly detection in network traffic or intrusion detection systems. A typical LSTM unit comprises of a cell, an input port, an output port, and a forget port (shown in Fig. 5). The cell stores values for an indefinite amount of time, and the three gates control the flow of information into and out of the cell.

LSTM networks are well suited for classification, processing, and prediction based on time series data because they can handle indeterminate delays between significant events in time series. LSTM was developed to solve the vanishing gradient problem that can be encountered when training traditional RNNs. The benefit of LSTM over standard RNNs, Hidden Markov models, and other sequential learning approaches is its low sensitivity across a particular length range. RNNs can, in theory, follow any long-term relationships in input sequences. The problem with RNNs, however, is computational nature: when training an RNN using backpropagation, the backpropagation gradients can be degraded (i.e. tend to move towards zero) or "explode" towards infinity. Because LSTM units allow gradients to remain constant, RNNs utilizing LSTM units can partially alleviate the gradient degradation problem. However, these LSTMs can still suffer from gradient "explosion" problems.

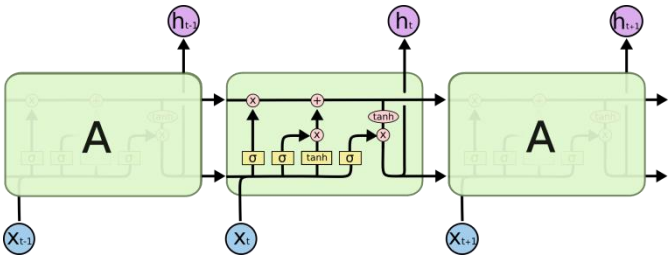

Fig. 5. Illustration of an LSTM Cell and Architecture. The Repeater Module in an LSTM Contains Four Interaction Layers.

In this work, a multi-layer LSTM with four layers have been implemented for patient activity recognition. Each layer has 50 units and is followed by a dropout layer designed to decrease the model's overfitting to the training data. Finally, a dense fully connected layer with 27 units is utilized to interpret the features retrieved by the LSTM hidden layer before making predictions with a final output layer with softmax function. The efficient Adam version of stochastic gradient descent will be utilized to optimize the network, and the categorical cross entropy loss function will be used because we are learning a multi-class classification problem.

D. Raspberry Pi and Camera Raspberry Pi NoIR

The Raspberry Pi [23] is a tiny computer developed by the Raspberry Pi Foundation in collaboration with Broadcom in the United Kingdom. The original Raspberry Pi project's goal was to promote basic computer literacy education in schools and developing countries. This device, however, became unexpectedly popular and was marketed for the purpose of building robots. Because of its inexpensive cost and open design, it is frequently utilized in various sectors, including weather monitoring. After the second version was released, the Raspberry Pi Foundation produced a brand-new gadget called the Raspberry Pi Trading. Raspberry Pi 4 Model B was released in June 2019 [33] with a 1.5 GHz quad-core ARM Cortex-A72 processor, 802.11ac Wi-Fi, Bluetooth 5, gigabit Ethernet (unlimited throughput), two USB 2.0 ports, two USB 3.0 ports, 2-8 GB RAM, and dual monitor support via a pair of

micro HDMI ports for up to 4K resolution. When used in conjunction with an appropriate power supply, the Raspberry Pi 4 is also powered via a USB-C port, allowing additional power to be provided to downstream peripherals (Fig. 6).

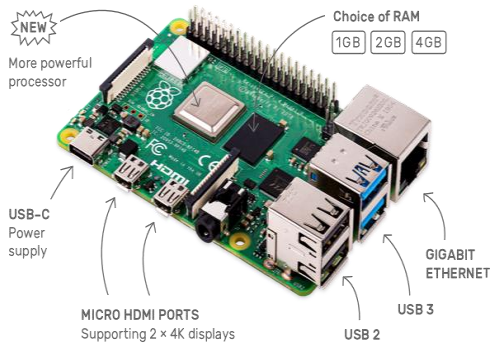

Fig. 6. Raspberry Pi 4 Model B.

The Raspberry Pi NoIR V2 IMX219 Camera (Fig. 7) is the latest version of the Camera Module for Raspberry Pi that uses the 8-megapixel IMX219 image sensor from Sony instead of the old OV5647 sensor. With the 8-megapixel IMX219 sensor from Sony, the Camera Module for Raspberry Pi has achieved a remarkable upgrade in both image and video quality as well as durability. Raspberry Pi NoIR V2 IMX219 8 MP camera can be used with Raspberry Pi to take photos and videos in low light conditions with HD 1080p30, 720p60, or VGA90 quality. It's also very simple, as we only need to connect the Raspberry Pi's Camera port and config to run the program. The Raspberry Pi NoIR V2 IMX219 8 MP camera is controllable via MMAL and V4L APIs, there are many libraries developed by the Raspberry Pi community on Python that make learning and using it much easier.

Fig. 7. Camera Raspberry Pi NoIR V2.

III. Experimental Results and Discussion

A. Experimental Settings and Evaluation Metric

All experiments were conducted on the laptop Asus TUF Gaming FX506LH i5 10300H, 8 GB RAM, NVIDIA GeForce GTX 1650 4GB, with the Ubuntu operating system. The real-time recognition system's algorithm is written in Python and implemented on the Linux operating system using the open-source libraries Keras and OpenCV (Raspberry Pi OS). Accuracy is a metric used to evaluate how well classification models perform and is calculated using the formula (1).

$$Accuracy = \frac{\text{Number of samples correctly classified}}{\text{Total number of samples}} \quad (1)$$

B. Model Training and Evaluation

The dataset of 16 action classes was split into two subsets that were used to train and evaluate the model at an 80:20 ratio, as was done by Luhach et al. [34]. Thus, the dataset has 15,476 frames for training and the remaining 3,869 frames for model evaluation. The system uses the data converted from video frames to coordinates (x, y, z) and the visibility value of the skeleton point features to train the model when using MediaPipe Pose. All this data is stored in CSV format file. Dataset for training and evaluating models are described in Table III.

TABLE III. Dataset Information for Model Training and Evaluation

Number of samples	Training	Testing	Timesteps	Dimension
19,345 frames	19,345 × 0.8 = 15,476 frames	19,345 × 0.2 = 3,869 frames	20	132 (33 points x 4 values) × Time-steps × number of frames

Since elaborate hyperparameter optimization methods like grid search were judged too time-consuming for the scope of this study, the various parameter-settings for the training process were developed via trial and error. As a result, many parameter choices have been attempted and tested by repeatedly running the model, and values for the hyperparameters that are thought to be near to an equilibrium between time-efficiency and performance have been chosen. In the selection process, several settings that reduced the difference between high and low values were tested, which is not unlike to how many root finding techniques in mathematics operate.

Different batch sizes (number of samples per gradient update) were examined, and 32 was found to be an appropriate value in terms of both effectiveness and performance. It was decided to iterate through the full dataset 50 times because epoch sizes greater than 50 produced negligible to no improvements. The mean squared error is employed for loss function. Adam produced the best results of the several optimizers available and was hence chosen over stochastic gradient descent. Finally, in the LSTM network model, the time-steps K are the most critical parameters affecting model performance. The time-steps are how many lagged variables the model receives as input to forecast the following step. Therefore, various number of time-steps are examined to determine how they impact the model's performance. The time-steps chosen to be tested are 5, 10, 15, and 20. The model is trained and evaluated five times for each of these time-steps in order to gather sufficient data to compare their relative performance. The performance of the model using different time-steps is illustrated in Table IV.

TABLE IV. The Overall Performance of the Model with Different Time-Steps.

K	5	10	15	20
Accuracy	92.26%	95.63%	96.44%	96.84%
Loss	0.1838	0.1047	0.0914	0.0854

Table IV shows that as the number of time-steps *K* is increased, the model's performance improves (accuracy increases and loss lowers), but training time increases. For instance, a model with 10 time-steps segments performs better than one with 5 time-steps (95.63 percent vs 92.26 percent). This result demonstrates that the model will learn more information from earlier frames if many time-steps *K* are used. As a result, the resulting features of the videos will be more robust and high-abstract, improving the model's classification precision. However, when *K* is increased to 20, the model performance exhibits evidence of saturation at 96.44% as opposed to 96.44% with *K* = 15. Therefore, we set *K* equal to 20 for the model to achieve the best classification performance while keeping training and evaluation time to a minimum. Fig. 8 depicts the curve reflecting the model's accuracy and loss after 50 iterations.

After training, the resulting model size is only 1.2 MB, making it appropriate for installation on Raspberry Pi devices with limited memory configuration. According to the article [22], the FPS of BlazePose Full is 102, while that of BlazePose Lite is 312, making it ideal for developing real-time applications. The model training process is quite fast, averaging about 5–10 seconds for an iteration with 16 action classes, because the video data has been converted to a text file in CSV format, so it doesn't take a lot of hardware resources. The model is trained in 50 iterations taking from 5 to 10 minutes. The resulting model has achieved an accuracy of 96.84% on our dataset. After the real-time action recognition model's training and evaluation on the Rapberry Pi 4 system produced good and consistent results, the system was installed and tested to send alert messages and emails if the camera detects unusual patient health-related behaviors (shown as shown in Fig. 9 and Fig. 10). Fig. 11 depicts our system's successful detection of six real-time patient actions: hand clap, sit down, stomachache, backache, and fall down. Our next step is to collect more data from a variety of patient actions and then to investigate mobile devices with better hardware configurations, such as the Jetson Nano Developer Kit [35] and CNN models that are efficient, accurate, and suitable for the latest mobile devices.

IV. Conclusion and Future Research Work

This study has proposed a novel system with basic functions of a smart surveillance camera, supporting remote patient monitoring. A model for remote skeletal patient activity detection was developed using MediaPipe Pose, an LSTM network, and a Raspberry Pi 4. The numerical results show that our proposed model performed well in classification, with an accuracy of 96.84% on a dataset of 16 activities gathered and constructed by ourselves. In addition, because the MediaPipe Pose library and the LSTM network are used for recognition, the recognition model size is small, and the network training parameters are few, making it appropriate for deployment on mobile devices with limited hardware, such as the Raspberry Pi 4. Therefore, our method offers numerous benefits in terms of real-time patient action recognition, low cost, simple installation, and practical implementation. A dataset of 541 video files of patients' actions in indoor was built to evaluate our method. Although the amount of data is little and there isn't much actual patient data, this provides the foundation for future larger, better-quality data sets that will help the research community better understand patient activities.

A Covid-19 Positive Case Prediction and People Movement Restriction Classification

I Made Artha Agastya
Informatics
Universitas Amikom Yogyakarta
Yogyakarta, Indonesia

***Abstract*—The world experienced a pandemic that changed people's daily life due to Coronavirus Disease 2019 (covid-19). In Jakarta, the covid-19 cases were discovered on March 18, 2020, and the case increased uncontrollably until the government conducted a movement restriction called pembatasan sosial berskala besar (PSBB). The effectivity of movement restriction was not evaluated in detail. Therefore, we investigated the covid-19 cases in the PSBB period to understand the contribution of movement restriction. Moreover, a prediction model is proposed to computerize the decision of movement restriction. The models are divided into regression and classification models. The regression model is developed to forecast the number of infected cases. At the same time, the classification model is used to identify the best movement restriction type. We utilize data transformation named Principal Component Analysis (PCA) to reduce the number of features. In our case, the best regression method is Multiple Linear Regression (MLP). Then, the best classification method is the Support Vector Machine (SVM). The MLP results are 148.38, 37036.37, and 0.250336 for Mean Absolute Error (MAE), Mean Square Error (MSE), and R^2, respectively. In contrast, the SVM achieved an accuracy of 84.81%. Moreover, the prediction system on the website were successfully deployed.**

Keywords*—Covid-19; movement restriction; machine learning; positive case; infected prediction

I. Introduction

The Coronavirus Disease 2019 (COVID-19) was first detected in China at the end of 2019. The virus causes breathing symptoms such as fever, coughing, pneumonia, and diarrhea in patients [1]. The World Health Organization (WHO) received a report from the Chinese government on December 31, 2019, regarding this disease with reports on the case of pneumonia or wet lungs in Wuhan, in Hubei Province, China. A week later, the Chinese government confirmed that Covid-19 had been identified as the cause of pneumonia [2]. Then the media reported that many new cases were recorded in other countries because international travel and trade were operating as usual.

As the center of government and trade in Indonesia, Jakarta has the highest population density compared to other places [3]. Consequently, an increased number of positive confirmed Covid-19 in Jakarta. Based on data on March 18, 2020, there were 171 cases. In Jakarta, the number of positive cases of Covid 19 drastically expanded since there were ten times increasing positive cases on April 9, 2020, compared to March 18, 2020. Jakarta suffered 1776 cases at that time. While the average increase per day for the period March 18 until April 9, 2020, is 70 cases. However, at that time, the government had not taken any corrective actions. In contrast, Malaysia held a national scale MCO (Movement Control Order), which began on March 18, 2020 [4]. After three weeks without corrective action, then on April 10, 2020, the DKI Jakarta Regional Government imposed a pembatasan sosial berskala besar (PSBB) consisting of two categories, namely a strict PSBB and a transition PSBB. The Strict PSBB was valid from April 10 - June 4, 2020, and September 14 - October 11, 2020. And the Transition PSBB took place from June 5 - September 10, 2020, and October 12 - October 25, 2020.

Based on [5], [6], the positive confirmation trend per day when Strict PSBB is carried out tends to be stable when compared to No-PSBB. This shows the effect of restrictions on community movements. To reduce the economic burden, the government relaxed community activities by imposing Transition PSBB. However, there is a significant increase in the number of positive cases per day. Comparing the Transition PSBB and No-PSBB, the condition of the Transition PSBB is more worrying as the rate, and cumulative cases are much higher. A comprehensive data collection can be an excellent choice to gain more insight. Moreover, an artificial intelligence system can help the government to decide the type of movement restriction. Therefore, the research question can be determined as follow:

1) What factors or features affect the number of daily positive cases?

2) How to predict the number of daily positive cases?

3) How to determine the type of movement restriction in certain conditions?

This paper is organized into five sections which are the introduction, related works, methods, result and discussion, and conclusion and future work. The introduction section consists of a brief explanation of the problem and the purpose of investigation. The related work section contains the summary of other researcher works that solved a covid-related prediction problem. The methods section shows the data acquisition, preparation, exploration, transformation, and frameworks. After that, the result and discussion section report the experimental findings. The conclusion and future work section contain a final comment on the current work and the potential research in the future.

II. Related Work

The infectious disease outbreaks such as food contamination, severe acute respirations syndrome (SARS), dengue, malaria, and influenza [7]–[9] have been analyzed using the artificial intelligence (AI) approach. The most common research is to forecast the number of infected individuals using the machine learning method. As the data is mostly time series, the model can be following a linear or nonlinear model [10]–[12]. The AI system can be used to prevent the outbreak become uncontrollable as the estimated number of diseased people is calculated. The government can prepare the medical facilities and their staff to match the number of patients. The anticipation of the worst-case scenario makes us more ready to confront the outbreak.

The machine learning-based model [13] has been deployed to predict the positive case of covid-19. The result is satisfying as the R^2 of 0.9998, 0.9996, and 0.9999 for Gompertz, Logistic, and Artificial Neural Networks models, respectively. Based on the results, trends can be forecasted and extended until the termination of the pandemic in Mexico. However, their models were only able to predict new COVID-19-positive cases. Velásquez and Lara [14] utilized a reduced-space Gaussian process regression model to forecast 82 days of positive, dead, and recover cases in the USA. Compared to the actual values, it is discovered that the model can generate the expected case value with a significant correlation coefficient. Buckingham-Jeffer [15] performs prediction using stochastic SIR (susceptible infectious removed) and SEIR (susceptible-exposed infectious removed) models. Both models can immediately forecast the number of positive cases using maximum likelihood inference in a time frame period.

A typical time-series experiment uses the Autoregressive Integrated Moving Average (ARIMA) model to produce a prediction model to estimate the amount of COVID-19 confirmed cases, fatalities, and recoveries [16]. If the current trend in Pakistan continues, the number of actual instances might triple by May. The investigation result concludes that the statistics are accurate and that the trends will continue to rise in the next month. Fortunately, the ARIMA model cannot comprehend the provided historical data pattern, so their findings are questionable.

A comparison of ARIMA with machine learning methods has been conducted by Kamarudin et al. [17] for positive, dead, and recovery cases in Malaysia. They compare support vector regression (SVR), Gaussian process (GP), linear regression (LR), neural network (NN), and ARIMA. They found that the NN outperforms most of the methods in positive and recovery case prediction. The ARIMA can predict the number of dead cases accurately. The most unreliable model is LR because it overestimated the case number so much. Meanwhile, the GP and SVR have shown a promising result as the Root Mean Square Error (RMSE) value is around the ARIMA value.

The previous literature shows the machine learning method can forecast the outbreak damage level by predicting the number of infected people. In this study, the number of positive cases is not only expected but the type of movement restriction can be predicted using the machine learning method. The move restriction has been proved by many countries can reduce the number of positive and dead cases [4], [18]–[23]. The comparison of Multiple Linear Regression (MLR), Support Vector Regression (SVR), Random Forest Regressor, and Decision Tree Regressor are conducted to know the best regression method [24]–[26]. In contrast, the classification methods are implemented to determine the movement restriction status. The Logistic Regression, Support Vector Machine (SVM), Decision Tree, Naïve Bayes, KNN, Adaboost, and XGboost methods are compared to know the most successful approach to predict the correct movement restriction. Moreover, the Particle Component Analysis (PCA) and grid search algorithm are implemented to understand the features reduction and hyperparameter optimization effect in accuracy, Mean Absolute Error (MAE), and Mean Square Error (MSE) [27]–[29].

The number of positive cases can be predicted by using a regression model, and the number of expected cases is combined with factual information (e.g., number of public transport passengers, wind speed, and congestion level) at that time to predict the type of the restriction. The number of positive cases needs to be predicted because the data of positive cases is unknown at that specific time. Therefore, a prototype of the website application is developed and deployed to show the proposed system in a real environment.

III. Method

We collect all data such as COVID-19 patient data, weather, and climate data as well as air transportation user data. Then the data is cleaned using imputation method to recover the missing data and scaling method if the data is not on the same scale. Then the clean data is processed with statistical and visual analysis. Only then after getting a deeper understanding, the data can be added or reduced depending on the findings with visualized data. After the data is ready, the data can be trained with a regression algorithm to obtain predictions of the number of patients with Covid 19 in daily basis. The results of the prediction are entered into the classification system and the type of restrictions can be determined. The mean absolute error (MAE), the mean square error (MSE), and accuracy are used as measuring instrument.

A. Data Accuisation

Based on the problems formulation, we collect data that might affect the number of positive cases. To get complete COVID-19 data in Jakarta we access the following website: https://corona.jakarta.go.id. The display form of the website above is shown in Fig. 1. We can see various information related to Covid-19 in Jakarta such as the number of specimens being tested, the number of people who are vaccinated, the amount that recovered, etc.

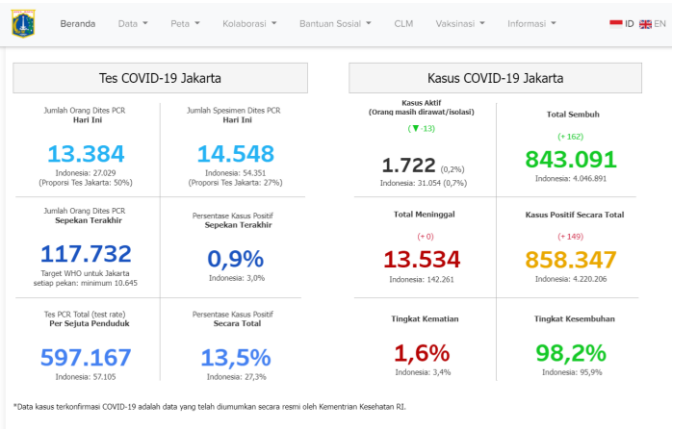

Fig. 1. The Main Menu of https://corona.jakarta.go.id.

Because we cannot access the data from the website, we traced the data source and found that the dashboard was made using the tableau application. Then we found the tableau address as follows:

https://public.tableau.com/app/profile/jsc.data/viz/dashboardcovid-19jakarta_15837354399300/dashboard22

From the website, we can download data in the form of a PDF File, as shown in Fig. 2. Then, from the PDF data, we change it to Excel File with the help of the PDF Editor application (Nitro Pro).

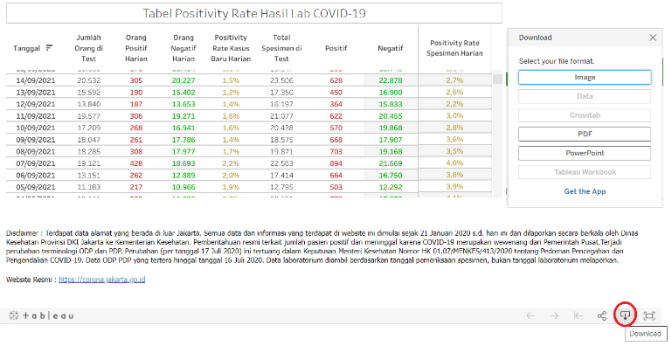

Fig. 2. Covid-19 Data in Jakarta at Tableau Site.

Then we searched the movement data of Jakarta people by looking at the number of users of public transportation modes. For train user data, we take from the following site: https://www.bps.go.id/indicator/17/72/2/sum-penumpang-kereta-api.html. From that website, we can download the data in an excel file, as shown in Fig. 3.

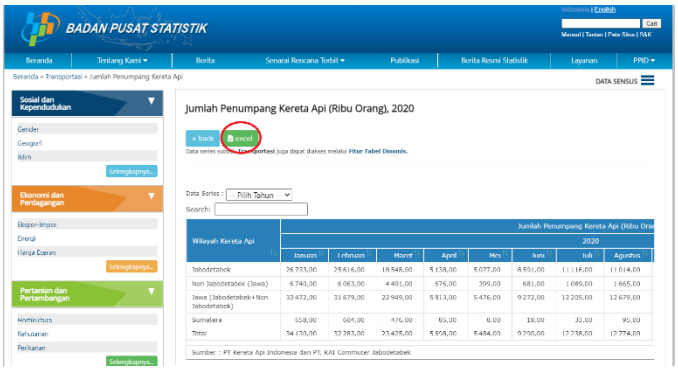

Fig. 3. The Data of Train Users in Jakarta.

Then we took the data of users of Transjakarta, Mass Rapid Transport (MRT), and LRT (Integrated Rail Cross) via https://data.jakarta.go.id/dataset. In addition to the three-transportation data, we can also obtain other data, such as data on the number of residents moving to Jakarta, the number of family planning participants, and others, as shown in Fig. 4.

Fig. 4. Jakarta Open Data Site.

We can perform a search, as shown in Fig. 4, and then select the data we want to access. For MRT data, we can download the data by clicking Download Data, as shown in Fig. 5. Then, we get a comma-separated value (CSV) from it. For the LRT and Transjakarta data, we used the same method as previously described to obtain the data. The addresses of the datasets are as follows:

https://data.jakarta.go.id/dataset/data-penumpang-transjakarta-2020/

https://data.jakarta.go.id/dataset/data-penumpang-mrt-di-provinsi-dki-jakarta

https://data.jakarta.go.id/dataset/data-penumpang-lrt-di-provinsi-dki-jakarta

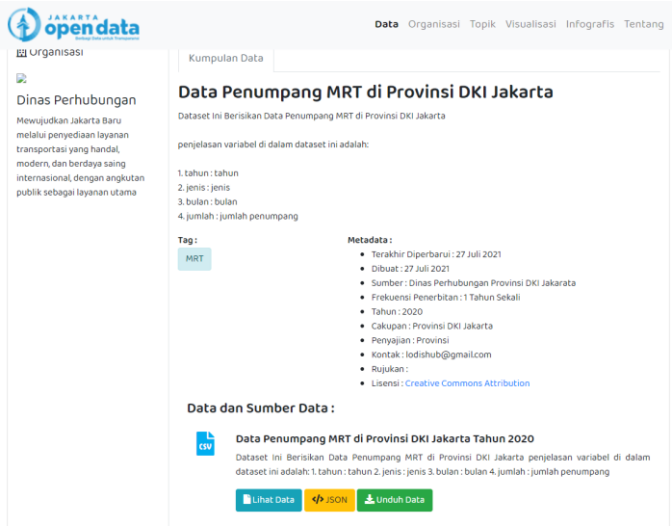

Fig. 5. Download Section in MRT, Jakarta Open Data.

For data on weather conditions and air quality in Jakarta, we take from two sources, namely:

1) https://dataonline.bmkg.go.id/data_iklim
2) https://aqicn.org/data-platform/covid19/

For Badan Meteorologi, Klimatologi, dan Geofisika (BMKG) online data, we need to create an account first, and we can only download it for a period of 30 days, as shown in Fig. 6. While on the Air Quality Open Data Platform we can download air condition data around the world from 2015 to 2021 as shown in Fig. 7. From BMKG we can obtain data on rainfall, duration of exposure, wind speed, humidity, etc. Meanwhile, on the Air Quality Open Data Platform, we collected PM10 and PM2.5 data, which are international standard air condition indexes.

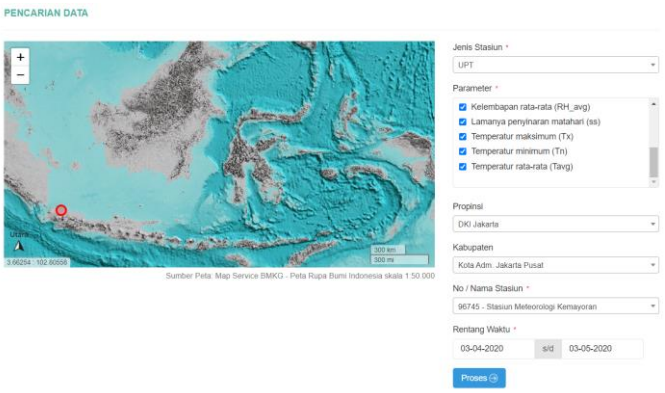

Fig. 6. Badan Meteorologi, Klimatologi, Dan Geofisika (BMKG) Data.

For congestion data, we take from https://www.tomtom.com/en_gb/traffic-index/jakarta-traffic/. We can only take data every month as an indicator of congestion, as shown in Fig. 8. The index is between 0 – 1, where 0 is the value without congestion and 1 is a great traffic jam.

For data on the status of people's movement restrictions, we take the following news:

https://news.detik.com/berita/d-5167032/timeline-psbb-jakarta-to-tarik-rem-darurat

From this news, we can determine the period of strict PSBB, transitional PSBB, and no PSBB. So that the data we need is complete but still not well organized and validated.

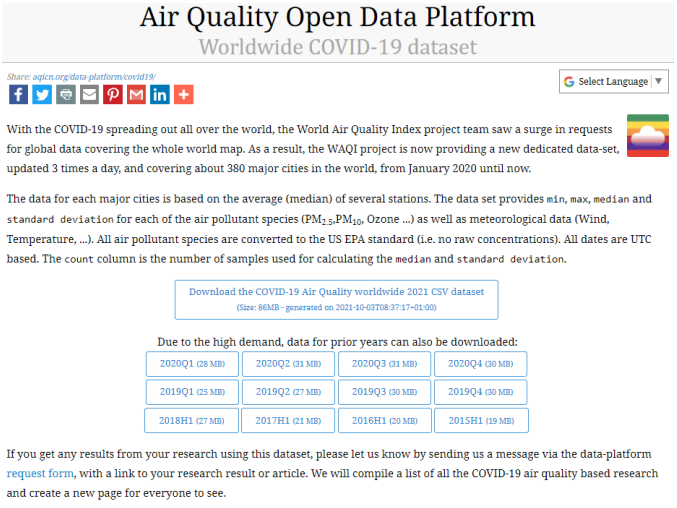

Fig. 7. Air Quality Open Data Platform

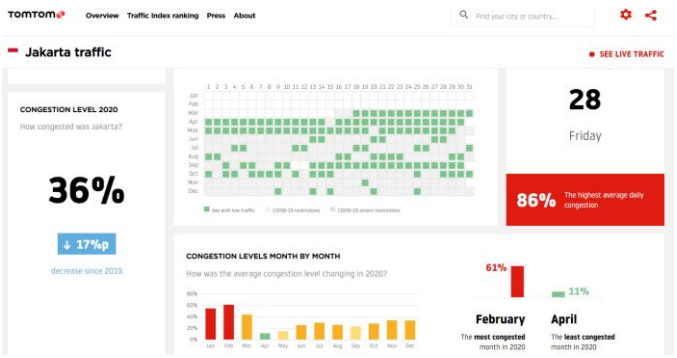

Fig. 8. Jakarta Congestion Data

B. Data Preparation

Once we get all the required data, we look at the data. The first criterion used is the availability of data during the PSBB period, which is March 10, 2020 – November 25, 2020. After investigating the dataset, the downloaded data meets these criteria. Then we discard the unnecessary information, such as the highest wind direction, maximum wind speed, maximum/minimum temperature, etc. We delete the data because we only used average values such as average wind speed and average temperature. In addition, we also discard data on the number of suspects, the number of negative covid-19, and the daily percentage of cases because this has been explained in the daily positive number and daily test number. After the needless data is removed, we then combine the data into a comprehensive table.

The overview of this research problems are the daily positive case prediction and the movement restriction type classification problems. We expect that the predicted positive case will be used as pseudo data to indicate the type of people's movement restrictions. Table I contains information

as follows, KRL Passenger, MRT Passenger, LRT Passenger, Bus Passenger, Congestion level, Rain drop rate, Day time, Humidity, Pm10, Pm2.5, Temperature, Wind, Restriction Status, Tested sample, and Positive Case.

TABLE I. COMBINATION OF ALL DATA

Date	KRL	..	Status	Tested Sample	Positive Case
10/03/2020	618266	..	NO_PSBB	52	2
11/03/2020	618266	..	NO_PSBB	48	26
12/03/2020	618266	..	NO_PSBB	56	10
13/03/2020	618266	..	NO_PSBB	30	7
14/03/2020	618266	..	NO_PSBB	44	16
15/03/2020	618266	..	NO_PSBB	41	2
..	..	..	..	..	..
25/11/2020	387400	..	NO_PSBB	15,381	1,124

C. Data Exploration

Descriptive statistical analysis can be seen in Table II below. From Table II, we can find out the average, maximum value, and minimum value of each attribute or feature. From Table II, there is nothing strange about these statistical values, so we can say that the combined data is valid.

TABLE II. STATISTICS OF ALL DATA

	KRL	MRT	LRT	Bus	..	Positive Case
count	261	261	261	261	..	261
mean	326717.6	14614.85	727.3257	251539.8	..	6080.831
std	117980.5	11273.04	461.2927	131444.5	..	4425.058
min	169233	1451	198	80396	..	30
25%	286366	11351	613	149401	..	2211
50%	337600	12991	632	285011	..	5295
75%	370533	17393	872	307195	..	10021
max	618266	46787	2024	559231	..	17871

Fig. 9 shows that the daily positive number changes along with the number of people being tested (blue) for COVID-19 per day. This indicates that the daily positive number (red) is strongly influenced by the number of people who test for Covid.

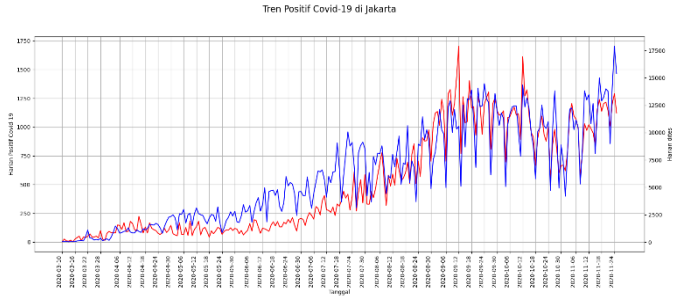

Fig. 9. The Positive Case vs the Sample Tested.

Fig. 10 shows a strong correlation between the number of daily tests and daily positives. There is a weak correlation between the number of Bus passengers and the daily test. There is also a weak correlation between congestion levels and daily tests.

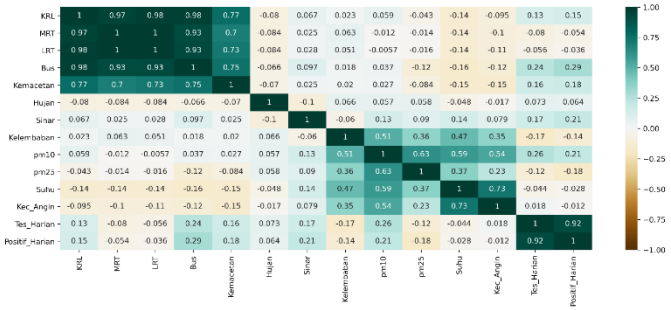

Fig. 10. The Correlation Matrix.

Based on Fig. 11 the distribution shows a positive correlation between the number of daily tests and the number of daily positives.

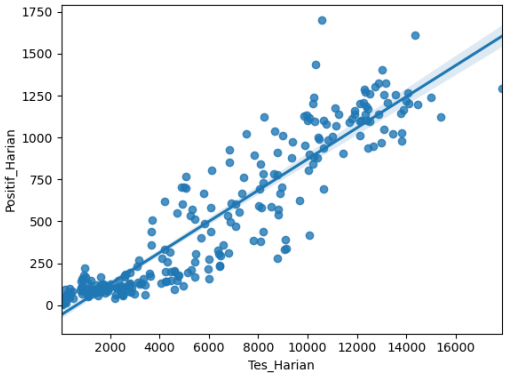

Fig. 11. Tested Sample vs. Positive Case.

Since we don't have daily data on congestion levels, we use monthly data, creating a scatter plot graph as shown in Fig. 12. There is a weak correlation between congestion with a positive total.

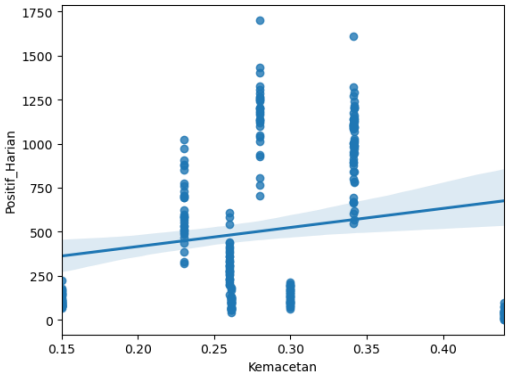

Fig. 12. Congestion vs. Positive Case.

Because data on the number of bus passengers per day is not available, we use the average per day of the number of passengers per month as shown in Fig. 13. We get a weak positive correlation between Bus vs. Total positive.

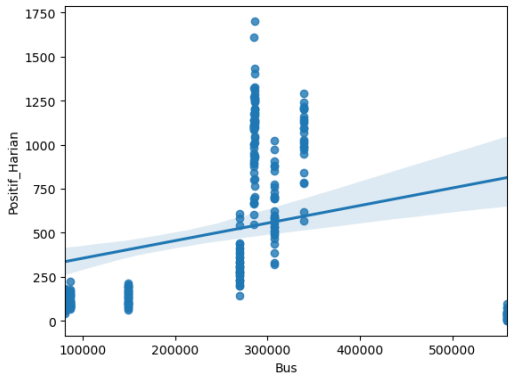

Fig. 13. Bus Passenger vs. Positive Case.

There is a very weak correlation between solar irradiance and daily positive, as shown in Fig. 14.

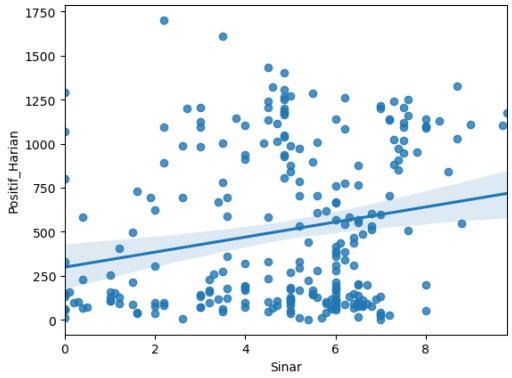

Fig. 14. Day Time vs. Positive Case.

There is a very weak negative correlation between wind speed and positive total, as shown in Fig. 15.

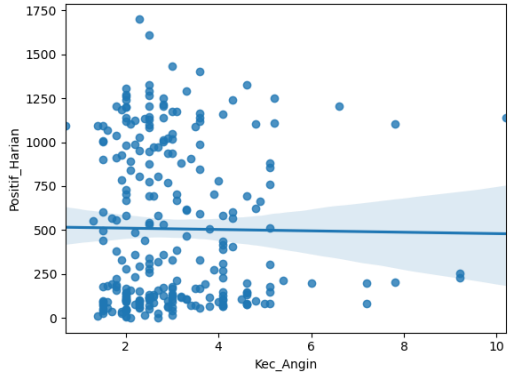

Fig. 15. Wind Speed vs. Positive Case.

Based on Fig. 16, there is a difference in the median value between no PSBB and strict PSBB. However, there was no significant difference between the three PSBB statuses in the number of daily positive cases.

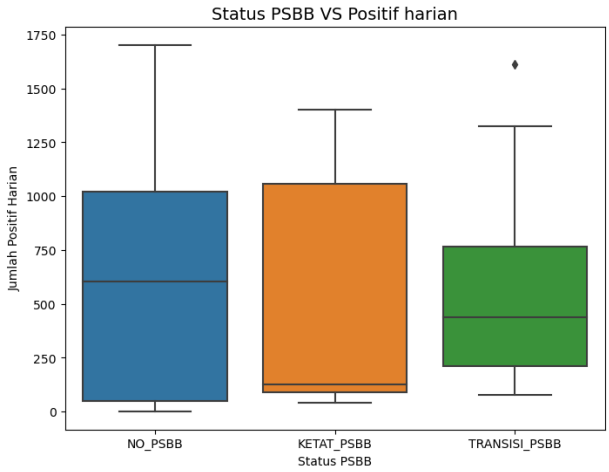

Fig. 16. Block Plot of People Restriction Status.

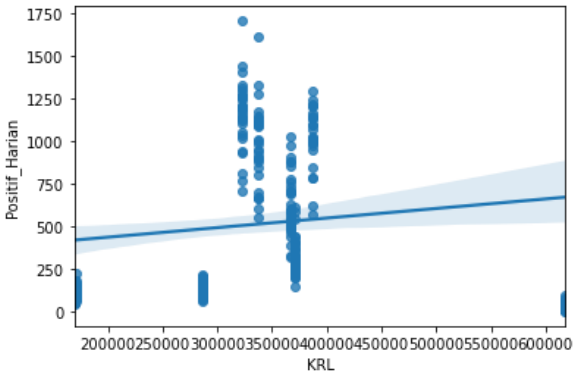
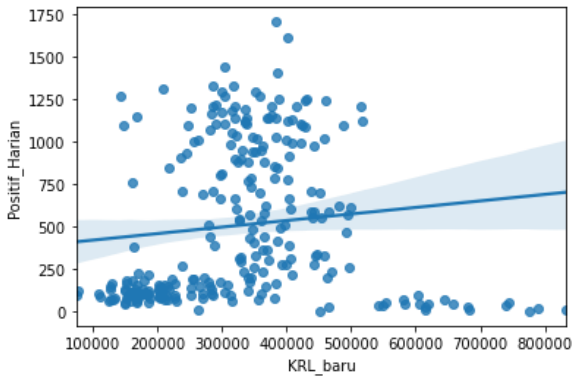
D. Data Transformation

Since we do not have daily data on the number of KRL passengers, we use the mean of total monthly passengers. However, giving the same value for one month is very unrealistic, so we need to transform the data to be more realistic by generating random data that meets the criteria for the mean of total passengers and standard deviation = 0.2 * mean, as shown in Fig.17.



(a)



(b)

Fig. 17. KRL Passenger Data Transformation.

To be able use total monthly passengers, number of LRT, number of Bus passengers, and daily data of congestion in realistic way, data transformations must be done. The random data are generated using mean and standard deviation (it is calculated by 0.2 * mean) of the respective datasets. The transformations of the dataset have shown in Fig. 18, Fig. 19, Fig. 20, and Fig. 21 respectively.

(b)

Fig. 21. Congestion Data Transformation. (a) Before Transformation, (b) After Transformation.

To be able to see the correlation between PSBB status and other attributes, it is necessary to transform the data from PSBB status with one hot encoding. Then by using the Pearson correlation method, a correlation table is obtained as shown in Fig. 22.

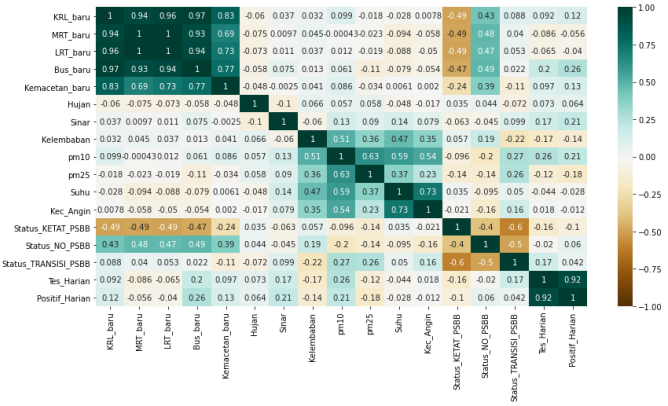

Fig. 22. Correlation Analysis after Data Transformation.

Based on Fig. 22, the daily test has the most significant correlation, which is 0.92. Then Bus_baru, which is the number of bus passengers per day, has a weak correlation of 0.26. Then the light, which is the length of irradiation in hours, has a correlation of 0.21. Then pm10, the air pollution index, has a weak correlation of 0.21. And humidity has a weak correlation of -0.14.

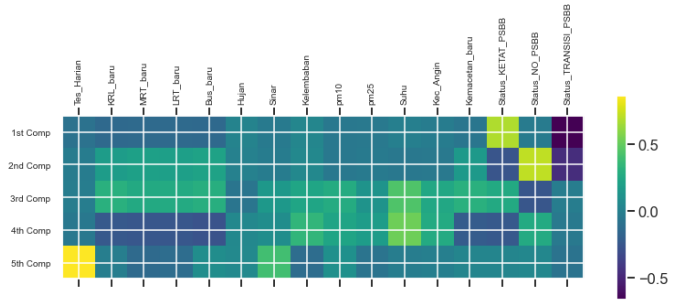

Fig. 23. The Contribution of Each Feature to PCA Value.

Based on Fig. 23, the strict PSBB status gave a positive contribution to the 1st component. In addition, the No PSBB status made a positive contribution to the 2nd component. The transitional PSBB status made a negative contribution to 1st component. Then the daily test made a very large contribution to the 5th component. The top five of Principle Component Analysis (PCA) value for each component can be found in Table III.

TABLE III. PCA VALUE

1st Comp	2nd Comp	3rd Comp	4th Comp	5th Comp
-0.30117	1.454034	0.571142	-0.52336	-0.3233
-0.18254	1.251233	0.288714	-0.26551	-0.23284
-0.22774	1.363212	0.258748	-0.54626	-0.30674
-0.33262	1.537455	0.586097	-0.69514	-0.45323
-0.33639	1.458526	0.629993	-0.52833	-0.28187

E. Framework

Based on the aim of this project is to create a system that can predict the number of people infected with Covid-19 and determine what restrictions should be made. Therefore, the PSBB status and the number of daily positive confirmations are labeled to be predicted. We created two models, namely the regression model and the classification model. The Regression Model is used to indicate the daily confirmed number of Covid-19 under certain conditions, and the classification model is used to determine what restrictions should be placed on the state of the daily positive count, as shown in Fig. 24.

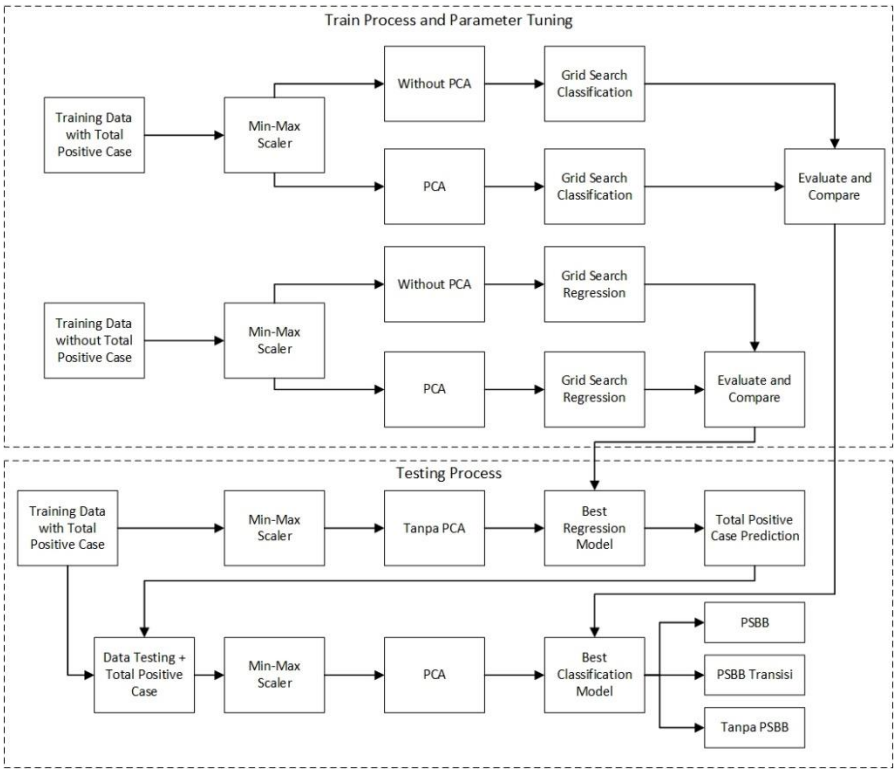

Fig. 24. Covid-19 Case Prediction and Movement Restriction Classification System Framework.

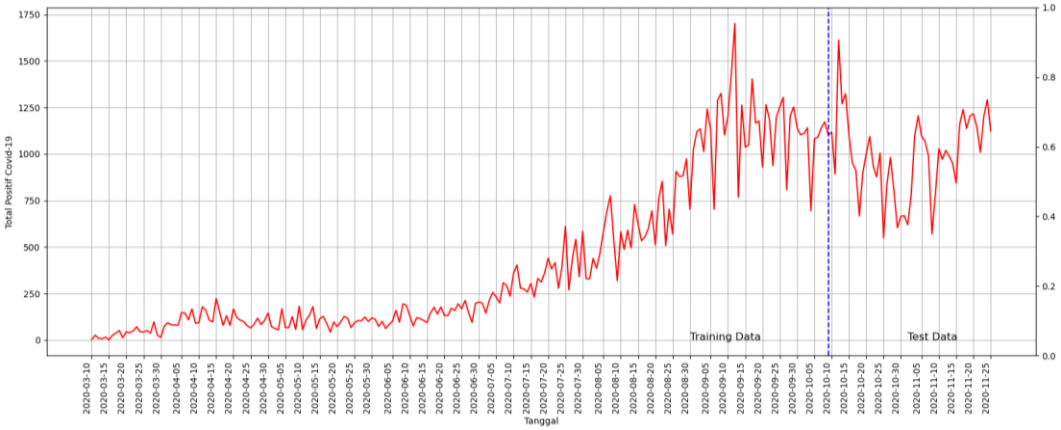

Fig. 25. Data Training and Testing Separation.

IV. Result and Discussion

We first made a regression model by comparing the evaluation results using PCA and without PCA. The Grid Search Method is used to determine the best method and the best parameters. To produce a model that can predict future values, it is necessary first to divide the training and testing data as shown in Fig. 25. The best methods, parameters, and evaluation results are shown in Table IV. Based on Table IV the best method is Multiple Linear Regression (MLR) with MAE = 148.3892 and MSE = 37036.37. If you look at the R2 value, only MLR without PCA gets a positive value. So, the MLR method without PCA was chosen as the regression method used.

Next, we need to determine a suitable method for classification, using PCA and without PCA, and determine the best parameters with grid search. The results of the grid search are shown in Table V. Based on Table V, the classification method used is a support vector machine (SVM) with PCA with a training accuracy of 0.72 and a testing accuracy of 0.8481. Because the testing accuracy exceeds 0.7, the SVM method is good enough to predict what kind of tightening will be done to the people of Jakarta. In Fig. 26, after all, forms are filled in, the system can predict the confirmed number of Covid-19 on that day totaling 871 people. In addition, we are recommended to implement the Transition PSBB by the system.

V. Conclusion and Future Work

In this study, the data collection and data preprocessing were explained in detail to show the reader how to collect and prepare the data before it is fed to the classification or regression methods. By detailed explanation of both the tasks, the reader can follow and develop their own data acquisition and preprocessing tasks. From the correlation analysis, it was found that the number who carry out the Covid-19 test affects the number of confirmed Covid-19 significantly. Adding data transformations such as PCA can enhance the accuracy of SVM. However, the MLR did not gain improvement. In addition, based on the test results, we were able to obtain an accuracy of 84%, which is a pretty good result. With this level of accuracy, we can be confident in using the model in actual cases. From the deployment results, we can see that the machine learning model can make predictions as we desire. The model can predict the number of Covid-19 sufferers and provide recommendations for restricting the movement of people.

Even though the accuracy of classification is relatively high, the system is still limited to the Jakarta region. The research expansion to the whole nation (Indonesia) can be more conclusive and comprehensive. The challenge will be the data collection that most of the regions do not have interactive web base covid data. So, collaboration with the government must be established. The provided data transformation is still limited to PCA. The extensive study in data transformation can be exciting as a lot of feature extraction and selection methods are available. Moreover, the technique is still limited to conventional machine learning approaches. The exploration of deep learning algorithms such as long short-term memory (LSTM) and convolutional neural networks (CNN) can be interesting discussions.

***Abstract*—Osteoporosis is a bone disease that raises the risk of fracture due to the density of the bone mineral being low and the decline of the structure of bone tissue. Among other techniques, such as Dual-Energy X-ray Absorptiometry (DXA), 2D x-ray pictures of the bone can be used to detect osteoporosis. This study aims to evaluate deep convolutional neural networks (CNNs), applied with transfer learning techniques, to categorize specific osteoporosis features in knee radiographs. For objective labeling, we obtained a selection of patient knee x-ray images. The study makes use of the Visual Geometry Group Deep (VGG-16), and VGG-16 with fine-tuning. In this work, the deployed CNNs were assessed using state-of-the-art metrics such as accuracy, sensitivity, and specificity. The evaluation shows that fine-tuning enhanced the VGG-16 CNN's effectiveness for detecting osteoporosis in radiographs of the knee. The accuracy of the VGG-16 with parameter fine-tuning was 88% overall, while the accuracy of the VGG-16 without parameter fine-tuning was 80%.**

Keywords*—Osteoporosis; transfer learning models; convolutional neural network; fine-tuning

I. Introduction

Osteoporosis is a severe illness common in about 9% of citizens, above 50 years, in the United States [1] and about 200 million women worldwide. One in three people in developed nations may experience an osteoporotic compression fracture (OCF) [1]. The likelihood of recurrent fractures greatly increases after the initial fracture [2] [3] [4]. Even one OCF is linked to a greater death rate and a lower quality of life [5].

Osteoporosis, which is defined as porous bone, is a condition in which the mass of the bone is low and the bone tissues have undergone microarchitectural deterioration. Osteoporosis increases fracture risk of the wrist, hip, and spine, among other bones, and lowers bone mineral density (BMD). Additionally, osteoporosis alters the quantity and type of proteins in bones. Osteoporotic fractures are described as those that happen at a site where there is low BMD and are more likely to happen beyond the age of roughly 50 [6] [7].

Every individual irrespective of gender and race could be affected by the disease and as the population ages, its prevalence would also increase. Among specialists, it is known as a silent bone disease because its symptoms are not spotted before a fracture and thus, pose threats to a patient by inducing other secondary bone problems like arthritis and the likes [8]. In the skeletal system, there is a continuous activity of bone tissues been lost by resorption, and also bone tissues have been rebuilt back by formation. The system is said to be at a bone loss when bone tissue formation is less than bone tissue resorption [9].

It has long been believed that deep learning is effective at learning feature categorization from medical images [10]. Deep Learning (DL) classifiers utilize high-dimensional features to improve the performance of DL networks in object detection and image classification. Machine Learning (ML) techniques, in contrast to DL techniques, rely on explicitly categorized features [11].

Deep CNNs have been proved to be efficient tools for categorizing images, but they are difficult to employ with medical radiographic image data since they require a large amount of training data. Transfer learning is recognized as an efficient method in training deep CNNs when the dataset is small to prevent overfitting [12].

We use a dataset of knee radiographs (or knee X-rays) to apply and assess deep transfer learning algorithms for classifying osteoporosis. This work objectively assessed the impact of parameter fine-tuning on a transfer learning deep CNN model's performance for identifying knee radiograph pictures based on the BMD value (T-score).

II. Related Work

Authors in [13] performed a comparison of classification systems for osteoporosis prediction using feature selection based on wrappers. As classification methods, multilayer feed-forward neural network (MFNN), Naive Bayes, and logistic regression were employed. Single Nucleotide Polymorphisms (SNPs), age, menopause, and BMI of Taiwanese women were all included in the dataset utilized for the study.

The three classifiers, utilizing SNP, were tested using a 10-fold cross-validation method both with feature selection and without feature selection. Without using wrapper-based feature selection, the Area under Curve (AUC) for the MFNN was 0.489. The AUC for naive Bayes was 0.462, and the AUC for logistic regression prediction was 0.485 [13].

The performance metric for classifiers utilizing a wrapper-based strategy yielded an AUC of 0.631 for MFNN, AUC of 0.569 naïve Bayes, and AUC of 0.620 for logistic regression models [13]. The experimental results demonstrated that the MFNN model with the wrapper-based technique was the most accurate predictive model for predicting disease susceptibility in Taiwanese women based on the complicated interplay between osteoporosis and SNPs. The findings reveal that the proposed technology can help patients and clinicians make better decisions based on clinical data such as SNP genotyping data [13].

The study proposed by [14] investigates whether adding clinical information improves diagnosis when compared to images alone when using deep learning. 1131 images from patients who had skeletal bone mineral density testing and hip radiography at the same general hospital between 2014 and 2019 were gotten. From hip radiographs, five convolutional neural networks (CNN) models were employed to assess osteoporosis [14]. Adding clinical values increased accuracy, sensitivity, and specificity.

Using only hip radiograph images, without clinical covariates, GoogleNet and EfficientNet b3 models displayed the highest levels of model performance. EfficientNet b3 demonstrated the best accuracy, sensitivity, and other metric core among the five ensemble models when patient factors were taken into account [14]. Increasing clinical covariates increased the accuracy of the deep learning models [14].

The authors in [15] revealed that dental panoramic radiographs can be used to accurately diagnose osteoporosis using CNNs. Additionally, integrating patient factors in common clinical contexts enhanced all predictions' performance measures in comparison to using the image-only mode. The study hypothesized that advanced inference, which is possible by deep learning, which, in turn, simultaneously takes important information about clinical factors into account that cannot be determined from dental panoramic X-ray images alone, led to an increase in diagnosis precision [15].

Various implementations of EfficientNet and ResNet were employed in the study by the authors. The most accurate ResNet and EfficientNet techniques, respectively, were ResNet-152 and EfficientNet-B7. However, EfficientNet-b7 obtained better results than other CNN models [15]. Gradient-weighted Class Activation Mapping (Grad-CAM) was used to visualize learning. ResNet concentrated on the cortical bone at the base of the jaw. Contrarily, EfficientNet concentrated on the area above the cortical bone as well as the cortical bone at the bottom border of the jaw.

The authors in [16] developed a cutting-edge, reliable bone disease prediction model based on recognized risk factors. Then it was feasible to discover the early risk factors for determining the beginnings of bone disorders using Pre-training and fine-tuning. The most significant risk factors are coupled with model parameters during the pre-training phase to calculate contrastive divergence, which minimizes record size.

Using the ground truth values "g1" and "g2," where "g1" stood for osteoporosis and "g2" for a rate of bone loss, the outcomes of the preceding phase were compared [16]. The model was produced using a Deep Belief Network (DBN), and it was then contrasted with models made both before and after essential feature identification. The study's conclusions indicated that adding pertinent variables might improve the predictive model's performance.

The authors in [17] built a model to predict the risk of osteoporosis using supervised machine learning. The study made public the variables that experts considered while determining the risk of osteoporosis. Developing a predictive model for the identification of people in Nigeria who are at risk for osteoporosis was the study's main objective. The supervised machine learning techniques Nave Bayes (NB) classifier and Multi-layer Perceptron were utilized to develop the predictive model for osteoporosis risk (MLP). The identification and data collection from patients in Nigerian hospitals found that there were 20 risk markers, including CD4 count levels classified as low, moderate, and high risk [17]. According to their finding, NB got 71.4% accuracy while the MLP had the best got 100%.

There has been a scarcity in the use of DL to interpret and predict osteoporosis from a knee radiograph. This research aims at filling this gap in the existing knowledge that points to the need for further understanding and investigation of osteoporosis prediction using DL from knee radiographic images.

III. METHODS

A. Research Design

This research tries to classify osteoporosis in knee radiographs. To replicate the osteoporosis diagnostic range in the DXA approach, we employed a segmented dataset. In addition, the Keras Deep Learning (DL) packages were employed for data normalization and augmentation. The diagnosis of osteoporosis from knee radiographs was performed using the VGG-16 transfer learning deep neural network. We examined the accuracy of the osteoporosis prognostic diagnostic using the transfer learning model with and without parameter fine-tuning using cutting-edge performance metrics.

B. Dataset

The dataset, published in August 2021, was gotten from Mendeley data uploaded by [18]. The dataset images were statistically augmented (i.e. increased) using data augmentation in python. Fig. 1 shows two images from the dataset indicating osteoporosis cases and normal cases.

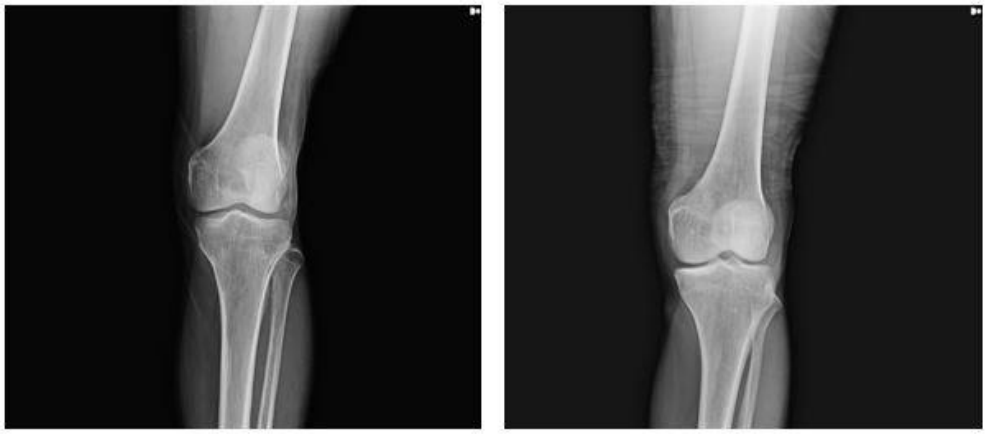

Fig. 1. Osteoporosis Case and Normal Case [18].

The dataset, after statical augmentation using python augmentation functions, comprises 323 normal knee radiograph images and 323 osteoporotic knee radiograph images of patients. Table I shows the splitting of image data into train, test, and validation data.

TABLE I. IMAGE DISTRIBUTION

Class	Total	Training	Testing
Normal (0)	323	259	65
Osteoporosis (1)	323	259	65

C. Grayscale Conversion

The dataset consists of images in Red Green Blue (RGB) format. A three-dimensional byte array (i.e., RGB image) stores a color value for each pixel. RGB format increases the complexity of training the model. Grayscale (i.e., black and white images) are preferred as they simplify computational complexity.

The modality of our research is based on knee x-ray data and thus, in an x-ray, color is irrelevant to diagnosis. Due to this reason, and the fact that grayscale images are easier to train a deep learning network, the images were converted from RGB to grayscale using the OpenCV python library.

D. Data Normalization

It is the process of converting image data pixels to a predetermined range : (0, 1) or (-1, 1). The pixel values in most images range from 0 to 255. Training a deep neural network with large integer values can interfere with or slow down the learning process. Therefore, picture normalization is a recommended practice: pixel values range between 0 and 1.

The images in the dataset were normalized (rescaled) using the python ImageDataGenerator method and passing rescale=1. /255 as its argument.

E. Data Augmentation

When working with deep learning models, it is paramount to ensure that the model gets a sufficient amount of training data. Data augmentation is the application of various changes to original images, resulting in several altered copies of the same image. Each replica, however, differs from the others in some ways due to the augmentation procedures used.

For this study, augmentation was done using Keras ImageDataGenerator in python. Itemized below are some of the techniques applied:

1) Standardization
2) Rotation
3) Shifts
4) Brightness changes, among others

The Keras ImageDataGenerator class is intended to give real-time data augmentation, which is said to be its key advantage. Every epoch, the model is given fresh versions of the images due to the ImageDataGenerator python class.

F. Transfer Learning Model Used (VGG-16)

In this work, two CNN study groups were used: VGG16 and the parameter fine-tuning model from VGG16. The difference between the two implementations is that the latter used parameter fine-tuning while the former did not. This was performed by unfreezing a couple of the original model's top levels and training the newly added classifier layers alongside the base model's final layers. The schematic diagram for the two transfer learning models used in this work is depicted in the block diagrams in Fig. 2 and Fig. 3.

The VGG16 architecture was chosen since it had been widely adopted and considered cutting-edge in image classification applications trained on a large dataset [10] [19].

G. Training the Model

Five folds were randomly selected from the training dataset of the chosen images. This prevented bias or overfitting while performing a five-fold cross-validation on the model training. The dataset was split into independent training and validation sets within each fold using an 80 to 20 split. A validation set that was completely different from the other training folds was chosen to assess the training state throughout training. Once one model training phase was complete, the other independent fold was utilized as a validation set, and the previous validation set was recycled as part of the training set to evaluate the model training. Fig. 4 shows a five-fold cross-validation done in this study.

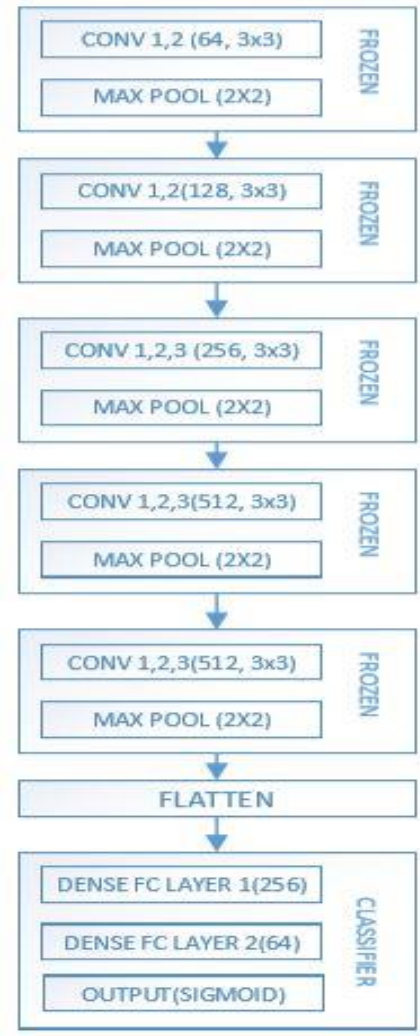

Fig. 2. VGG-16 without Parameter Fine-Tuning.

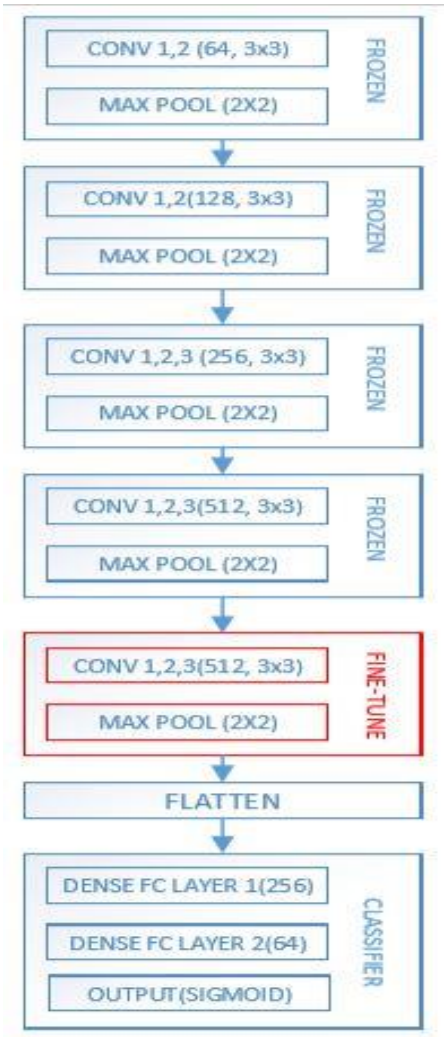

Fig. 3. VGG-16 with Parameter Fine-Tuning.

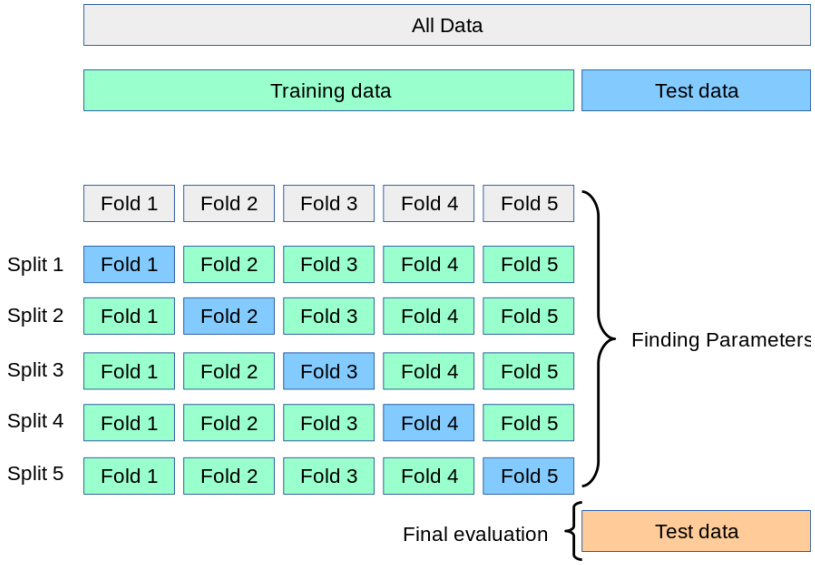

Fig. 4. Overview of 5-Fold Cross Validation.

This process of cross-validation was repeated for the VGG-16 without parameter fine-tuning and for the VGG-16 with parameter fine-tuning. The Google colabs Graphics Processing Unit (GPU) was used to train and test all models. The Keras library and TensorFlow were used throughout the process of applying the transfer learning deep learning models.

IV. RESULTS

A. Performance Metrics

The following metrics were established for each model to fully assess its performance: (1) sensitivity, (2) specificity, (3) accuracy, (4) precision, and (5) F1-score. The formula for the specified metrics is expressed below.

$$\text{Sensitivity} = \frac{true\ positive}{true\ positive + false\ negative} \quad (1)$$

$$\text{Specificity} = \frac{true\ negative}{true\ negative + false\ negative} \quad (2)$$

$$\text{Accuracy} = \frac{true\ negative + true\ positive}{all\ cases} \quad (3)$$

$$\text{Precision} = \frac{true\ positive}{true\ positive + false\ positive} \quad (4)$$

$$\text{F1} = 2 \times \frac{precision \times recall}{precision + recall} \quad (5)$$

B. Confusion Matrix

A method for summarizing a classification algorithm's performance is the confusion matrix (CM). In addition to giving insight into the mistakes the classifier is making, it also reveals the specific mistakes that are occurring. The confusion matrix helps to overcome the limitation of using classification accuracy alone. Fig. 5 and Fig. 6 show the confusion matrix for the VGG-16 model without parameter fine-tuning and the VGG-16 model with parameter fine-tuning respectively.

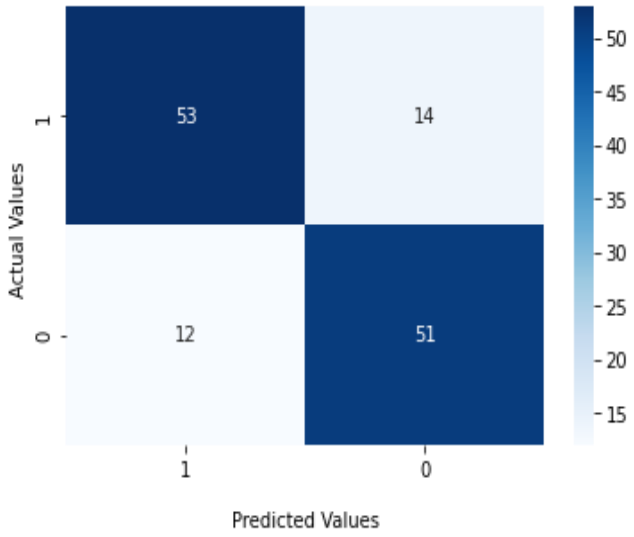

Fig. 5. Confusion Matrix for VGG-16 without Parameter Fine-Tuning.

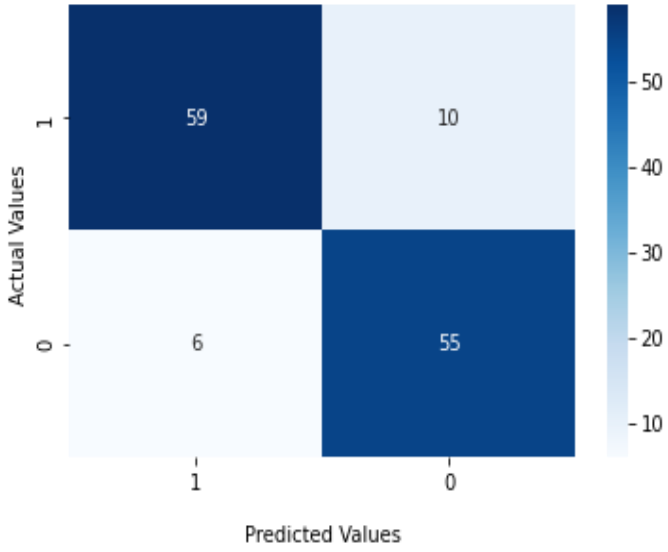

Fig. 6. Confusion Matrix for VGG-16 with Parameter Fine-Tuning.

C. Prediction Performance

The osteoporosis patient knee x-rays dataset has been tested using the CNN models utilized in this work. The dataset was divided into training and testing portions in an 80:20 ratio for all transfer learning models. The overall accuracy obtained for the two classifiers on the dataset is summarized in Table II. Each model underwent 50 epochs of training. For all models, as the loss metric, binary_crossentropy was used as the dataset target has two classes (i.e., binary classification problem). RMSprop is the chosen optimizer, and its learning rate is 0. 001.

The Keras evaluate function was invoked on the compiled model with the test data as an argument to evaluate the accuracy of the models. Table III provides a comparison of our work with similar works. Fig. 7 shows a chart visually depicting the performance difference between the two implementations of the VGG-16 transfer learning model.

D. Algorithm Justification

The justification for choosing VGG-16 architecture was that it had been widely adopted and recognized as state-of-the-art in both general and medical image classification tasks but has not readily been applied to osteoporosis classification from patient knee radiographs. Additionally, VGG-16 has been trained on large-scale datasets, so that a transfer learning approach could be adopted for large-scale image recognition.

The reason for using parameter fine-tuning is that research shows it boosts the performance of a deep learning model over random initialization [20].

E. Dataset Justification

The reason for choosing the knee radiograph dataset is because deep learning research on osteoporosis classification using knee x-ray is still relatively scarce.

F. Limitations of the Study

A deep learning model requires massive amounts of data to be efficient. The number of training observations in the dataset was not large enough and hence poses a limitation to the study. However, data augmentation was applied to mitigate such limitations.

G. Recommendation and Future Work

The perception based on the findings stipulates that overfitting in transfer learning due to few data samples can be avoided using certain techniques: cross-validation, data augmentation, and parameter fine-tuning. Findings also show that parameter fine-tuning in transfer learning can be used to significantly increase the accuracy, sensitivity, specificity, precision, and F1 of a deep learning model.

Osteoporosis is caused not just by low bone mineral density, but also by other factors such as age, gender, weight, height, and so on. These are clinically important risk factors for osteoporosis. For future work, we would like to extend our methods by adding patient variables such as age, and gender, amongst others, as clinical covariates to create an ensemble model with the transfer learning models

TABLE II. RESULTS OBTAINED

	Ac	Se/Re	Sp	Pr	F1

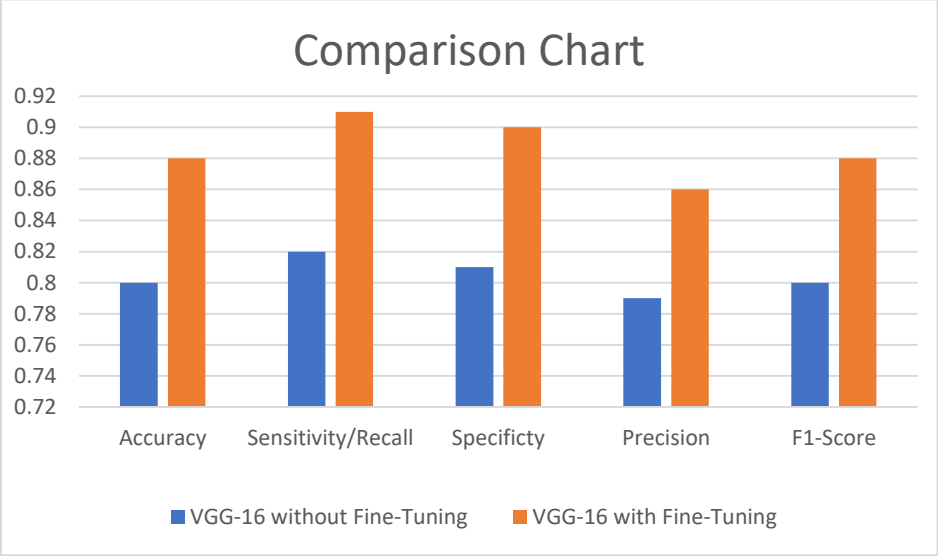

Fig. 7. Comparison Chart.

V. CONCLUSION

In circumstances when there is a small training dataset, this study demonstrates the efficacy of deep CNN tuning and transfer learning for detecting osteoporosis in knee x-ray images. On networks that have already been trained for the categorization of osteoporosis, we have used the VGG-16 transfer learning technique. According to the experimental findings, the fine-tuning technique enabled transfer learning to obtain an overall accuracy of 88%, which was higher than that of 80% achieved by transfer learning without fine-tuning.

The results show that parameter fine-tuning in transfer learning can be used to significantly increase the accuracy, sensitivity, specificity, precision, and F1 of a deep learning model. For future work, we would like to extend our methods by creating an ensemble approach of adding patient clinical covariates to classify osteoporosis with VGG-16 from knee radiograph.

This research was broken into several parts: Introduction, related works, methods, results, and conclusion. The method section provided details as to how the dataset was acquired, the augmentation techniques used, the grayscale conversion of images from RGB to grayscale, the cross-validation split used, and the transfer learning model applied. The results section depicted some state-of-the-art deep learning evaluation metrics used to evaluate the transfer learning variations of the VGG-16 model used.

***Abstract*—The characteristics of port dangerous goods are complicated and diverse in danger, which is very likely to cause chain effects once a fire and explosion accident occurs. Based on the distribution characteristics of dangerous goods container yards and the special national storage requirements for dangerous goods containers, the paper establishes a multi-objective optimization model with a double priority of safety and economy, starting from reducing the number of reversals. The improved non-dominated sorting genetic algorithm based on the elite strategy was used to solve the model and the algorithm was tested and improved. Based on the Pareto optimal solution set, the entropy weight-TOPSIS method was used to optimize the sorting of multiple solution sets, which improved the performance of the algorithm. The analysis further clarifies the important relationship between attributes, and the running time is shortened by 85.7% compared with the traditional NSGA algorithm. The optimization model and algorithm can provide decision support for the actual operation and management of container storage, and provide a good reference for accident risk prevention and control.**

***Keywords*—Dangerous goods containers; container allocation; improved NSGA-II algorithm; entropy weight-TOPSIS**

I. Introduction

The wide range of chemicals in port, hazardous chemical yards, their high hazardousness, and mobility poses a double challenge for business process optimization and risk control in the yards. In 2015, the "8.12" fire and explosion accident in Tianjin Port caused serious casualties and property damage, which was mainly caused by the irregular management of dangerous goods container yard storage, and the serious phenomenon of overloading, over-height, and irregular mixed storage. To further strengthen the safety management of dangerous goods in ports and to prevent and reduce dangerous goods accidents, the Ministry of Transport of the People's Republic of China revised the Provisions on the Safety Management of Dangerous Goods in Ports in 2017, putting forward higher requirements on the risk management of dangerous goods in ports.

The allocation of container yard space is a key factor that restricts the efficiency of terminals and increases the operational costs of the terminal. Reducing the number of unloads to increase terminal efficiency and reduce operating costs has become the focus of research in this field. Zhang and Ambrosino et al. [1], [2] consider the weight of the container and develop a dynamic model to reduce the number of reversals. Galle et al. [3] established the optimization model of container pre-marshaling by considering the loading order. A new unified integer programming model was designed to solve the problem of reducing the number of containers unloaded. In addition to the weight and shipping order, the uncertainty of delivery time [4], exit box entry time [5], [6], and pick-up time [7], [8] are also critical factors that affect unloading operations. Besides the number of box dumps, the task allocation of the bridge [9] and moving path [10] also affect the box allocation strategy. All the strategies mentioned are used for ordinary containers, with no consideration of dangerous goods container stowage rules, Zhou et al. [11] established a distribution optimization model for dangerous goods containers by considering the storage height limit, and this model was solved using the Monte Carlo tree algorithm, it improves the efficiency of putting boxes away, but it does not take into account the impact of the number of reversals on safety.

Many algorithms to solve bin allocation exist, such as the heuristic algorithm [6], [12] particle swarm algorithm [13], tabu search algorithm [14], mixed harmony simulated annealing algorithm [10], [15], and genetic algorithm [9], [16], [17]. Among these, the genetic algorithm is used more widely used. Tang et al. [18] designed a genetic algorithm-based heuristic to solve the storage problem of a large iron ore terminal; Jun and Chen [19] established a mixed-integer programming model based on yard crane resource optimization and used a genetic algorithm to solve it. Based on the above studies, it can be found that genetic algorithms are used more than the other types and can better solve the problem of bin allocation. However, most of the previous studies used traditional genetic algorithms and traditional NSGA-II algorithms, which lack a diversity of solutions. Therefore, this research focuses on the control of the elite range in the algorithm design and proposes an improved NSGA-II algorithm to improve the diversity of solutions and realize the convergence of the search algorithm to the global optimal solution.

In summary, it can be seen that the current research on the allocation of container yard space is mostly directed at ordinary containers, with the core objective of improving operational efficiency and lacking attention to the safety of dangerous goods yards. Taking into account the special characteristics of dangerous goods containers and the efficiency requirements of

storage operations, the storage process should be regarded as a multi-objective optimization problem with the double priority of safety and economy.

This research mainly takes dangerous goods containers as the research object and establishes a storage yard optimization model based on safety and economic benefits. At the same time, in order to further improve the diversity of solutions and realize the convergence of the search algorithm to the global optimal solution, it focuses on the control of the elite range and proposes an Improved NSGA-II algorithm. Then entropy weight-TOPSIS sorting method was used to conduct the multi-attribute decision-making analysis and the Pareto optimal solution is obtained, to obtain the optimal solution to further reduce the storage risk of dangerous cargo containers and improve the operation efficiency.

II. Mathematical Model

A. Problem Description

A dangerous goods storage yard is where Dangerous goods containers are stored. Therefore, once an emergency occurs, the hazard is extremely high. The safety of hazardous chemical container yards is embodied in the following three aspects: classified storage, number of container dumps, and storage height. The required storage height depends on the type of dangerous goods. According to the "Safety Regulations for Port Operation of Hazardous Chemicals Containers" flammable and explosive Dangerous goods containers should only be stacked up to two tiers, and other Dangerous goods containers shall not exceed three tiers. Moreover, effective isolation should be prepared according to the nature of the dangerous goods. Generally, since the storage height is low, the movement of Dangerous goods containers employs manual truck operations, which do not involve the problem of the yard and bridge schedules. Most hazardous chemical container yards in ports have been zoned according to the isolation requirements of hazardous chemicals. Therefore, this study focused only on Dangerous goods containers with fixed zones.

From a safety perspective, reducing unnecessary container handling operations and minimizing the storage height can reduce the crane workload, prevent stacks from being overly high, and dumping over to reduce the safety hazards caused by Dangerous goods containers during operation. From an economic perspective, reducing the operation of unloading can increase the efficiency of yard operation and reduce costs. The exit time is known for containers entering the hazardous chemical container yard. When a container enters the yard, it is necessary to optimize the bin allocation sequence to reduce the unloading operation. The exit time was early on the top floor. Generally, heavy containers are placed on the lower layer to ensure safety when shipping containers, and lighter boxes are placed on the upper layer. Therefore, when allocating bin positions in the yard, it is common to place heavy boxes on the upper layer and lighter boxes on the lower layer.

The problem of optimizing the allocation of Dangerous goods containers can be summarized as minimizing the operation of unloading containers in a range of storage yards when the number of bays, rated height, and initial storage status is known. Moreover, the order of appearance, the weight of the box, and the height of the stack also affect the unloading operation. Therefore, it should be considered when establishing the optimization model.

B. Model Assumption

Based on the nature of the hazardous chemical container and storage yard scenario, the following assumptions were made to achieve the goal of optimizing storage:

The loading and unloading equipment are fault-free, and all the operation links are normal.

All the boxes on-site meet the isolation requirements for Dangerous goods containers.

Only for Dangerous goods containers.

The type of dangerous goods and the quality, size, and time of entry and exit of the dangerous chemical container are known.

C. Notations and Variables

I: The set of all containers, $I = \{1,2,3, \dots, N_i\}$, $i, j \in I$;

N_i: Total container arrivals;

K : The set of all fields, $K = \{1,2,3, \dots, N_k\}$, 1 represents $K1$, 2 Represents $K2$, 3 represents $K3$, 4 represents $K4$, 5 represents $K5$, 6 re $c$presents $K3$, 7 represents $K8$, 8 represents KD, 9 represents KE, 10 represents KF, 11 represents $N1$, 12 represents $N2$, 13 represents $N3$, 14 represents $N4$, 15 represents $N5$, 16 represents $N6$;

B: The set of all shells, $B = \{01,02,03, \dots, N_b\}$;

R: The set of all rows, $R = \{1,2,3, \dots, N_r\}$;

T: The set of all layers, $T = \{1,2,3, \dots, N_t\}$

Q : The set of all container locations, $Q = \{10111,10111, \dots, 100111,100112, \dots, N_k \times 1000 + N_b \times 100 + N_r \times 10 + N_t\}$;

s_i : 1 if put into the designated field according to the category, 0 otherwise;

$E_{i,j}$: 1 if the container in the first field is on the lower level, 0 otherwise;

$x_{i,b,r,t}$: 1 if container i is placed in the container spaces (b, r, t), 0 otherwise;

z^e: 1 if container i enters the yard earlier than container j and is stacked on the lower floor; 0 otherwise;

z^o: 1 if container i leaves the yard before container j and is stacked on the upper level; 0 otherwise;

z^w: 1 if the heavier container in container i and container j is stacked on the upper layer; 0 otherwise.

D. Objective Functions

The number of containers that exited first at the lower level was the smallest.

$$MinF^o = \sum_{i,j,r,t1<t2}((y - z^o) \times (t2 - t1)) \quad (1)$$

The number of containers with a high weight in the upper level was the smallest.

$$MinF^{w} = \sum_{i,j,r,t1<t2}((y - z^{w}) \times (t2 - t1)) \quad (2)$$

Minimum stacking height.

$$MinF^{h} = \sum_{i,j,r,t1<t2}(X_{i,b,r,t} \times t^{2}) \quad (3)$$

E. Constraints

$$z^{e} \geq y + E_{i,j} - 1; \forall i, j, b, r, t1 < t2 \quad (4)$$

$$z^{e} \leq y \times E_{i,j};\ \forall i, j, b, r, t1 < t2 \quad (5)$$

$$y \geq X_{i,b,r,t1} + X_{i,b,r,t2} - 1; \forall i, j, b, r, t1, t2 \quad (6)$$

$$y \leq X_{i,b,r,t1} \times X_{i,b,r,t2}; \forall i, j, b, r, t1, t \quad (7)$$

$$\sum_{i}(X_{i,b,r,t}) \geq \sum_{i}(X_{i,b,r,t+1}) \quad (8)$$

$$s_{i} = 1; \forall i \quad (9)$$

$$\sum_{i,b,r,t}(X_{i,b,r,t}) \leq b \times (r \times t - 3); \forall b, r, t \quad (10)$$

Constraints (4) and (5) indicate that z^{e} is 1 when i is placed below j and i enters the field before j, and 0 otherwise; constraints (6) and (7) indicate that the value of the decision variable y is 1 only when containers i and j are assigned to container spaces (b, r, t_1) and (b, r, t_2), respectively, and 0 otherwise; constraint (8) indicates that boxes cannot be placed in suspension; constraint (9) indicates that all hazardous materials are stored in the field area where they should be stacked; constraint (10) indicates that a buffer container space should exist within each field area.

III. Dangerous Chemicals Container Yard Bin Allocation Algorithm And Plan Optimization

A. NSGA-II Algorithm

The multi-objective functions of hazardous chemical container storage optimization are not completely co-directional functions. In most cases, optimizing one function leads to a decrease in the performance of other objective functions. Therefore, it is difficult to simultaneously optimize all objectives. Therefore, when solving the multi-objective optimization problem, the solution set obtained is optimal for one optimization objective, and may not be optimal for other optimization objectives, which causes the multi-objective function to have multiple optimal solutions. This study adopted the NSGA-II algorithm to avoid the lack of diversity of the NSGA algorithm in later stages and improved the crowding distance and crowding degree comparison operators in the algorithm. The main purpose is to maintain the diversity of the population to the best extent possible while avoiding local precocity.

Table I Comparison of traditional NSGA algorithm and improved NSGA- II shows that the improved NSGA-Ⅱ has more advantages than traditional genetic algorithms in solving multi-objective optimization problems. The steps to improve the NSGA-II algorithm are as follows.

TABLE I. Comparison of Traditional NSGA Algorithm and Improved NSGA- II

Traditional NSGA algorithm	Improved NSGA-Ⅱ algorithm
Higher computational difficulty	A fast non-dominated sorting method is proposed to reduce the computational complexity
Need to specify a shared radius	Improved crowding and crowding comparison operator to maintain the diversity of the population
No elite strategy	Introducing elite strategy, controlling elite range, and expanding sampling space

1) Initialization parameters: Generate the initial population X, the population size x_size, and the maximum number of iterations generation_size

2) Chromosome coding: This algorithm adopts the form of real number coding, as shown in Fig. 1. More specifically, there are m possible storage positions for the container after the arrival of the container, where the first n represents the distribution position and order of the container. For example, [10111 10112 10113 1012130122 10123 10131 10132 10133 10141 10142 10143], means that there are 12 locations for 1 shell in a certain area, and the storage location and order of 10 containers are [10111 10112 10113 1012130122 10123 10131 10132 10133 10141], among them, "10111" indicates that the position allocated to the stack is 1 zone, 01 shells, 1 column, and 1 floor. One chromosome corresponds to the distribution plan of the container. Under the assumption that there are n containers of the same chemical nature and m positions that can be stacked, an m-bit array needs to be generated that indicates the order in which the n containers enter the yard.

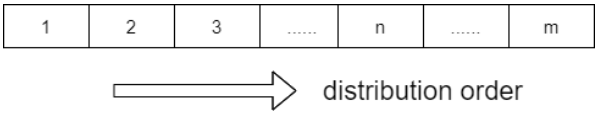

Fig. 1. Coding Scheme.

3) Fitness function: The non-dominated sorting multi-objective genetic algorithm can directly use $MinF^{o}$ $MinF^{w}$ $MinF^{h}$ as fitness functions.

4) Fast non-dominated sorting process: The solution of a multi-objective genetic algorithm is to obtain a Pareto solution set by the evolutionary approximation of the constructed genetic algorithm class. Once the fitness function is evaluated, the objective functions $MinF^{o}, MinF^{w}$, and $MinF^{h}$ are sorted by fast non-dominated solutions. The specific sorting process is illustrated in Fig. 2.

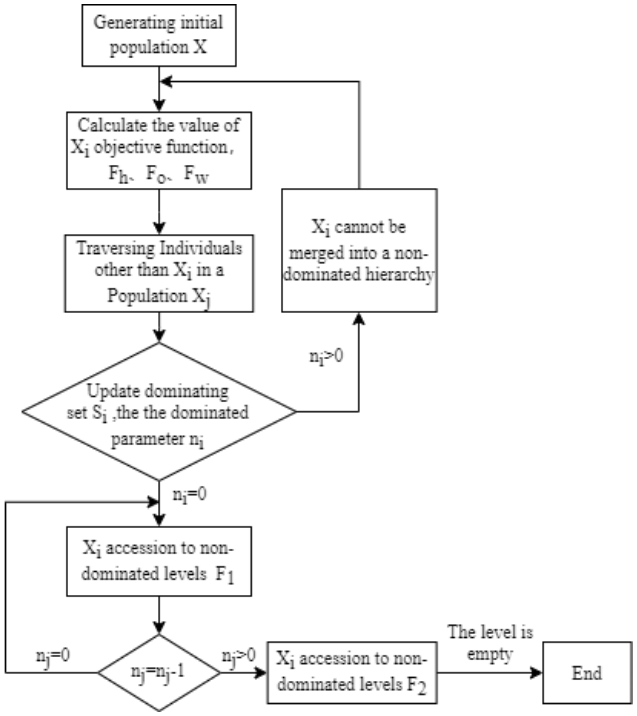

Fig. 2. Fast Non-Dominated Sorting Process.

When traversing other individuals in the population x_i, if it satisfies $F^o(x_i) > F^o(x_j)$, $F^w(x_i) > F^w(x_j)$, $F^h(x_i) > F^h(x_j)$, then it is said that individual x_i dominates individual x_j, and individual x_j is stored in the dominating set s_i. If it satisfies $F^o(x_i) < F^o(x_j)$, $F^w(x_i) < F^w(x_j)$, $F^h(x_i) < F^h(x_j)$, then it is said that individual x_j dominates individual x_i and the dominant parameter $n_i + 1$.

5) Improve the calculation method for congestion" The selection of NSGA-II will allow excellent individuals to continue to breed in iterations until the maximum population size is reached, which will easily lead to a loss of individual diversity. Ultimately, it will lead to premature convergence of the algorithm. This study has improved the algorithm to avoid obtaining the local optimal solution: first traverse the individual x_i in the non-dominated level, calculate the function value of a certain objective function, arrange it in descending order according to the function value, and set the individual congestion degree on both sides of the sequence to the maximum value that can be guaranteed to be always selected. Before calculating the crowdedness of individual x_j, first, judge whether x_j is the same as the previous individual. If they are the same, the crowning degree of individual x_j is no longer calculated, and the non-dominated level value of individual x_j is directly added to the population size. If it is not, the calculation is performed according to Equation (11). The non-dominated sorting after mixing the parent population with the offspring population produced can effectively avoid redundant individuals.

$$i_d = i_d + \frac{f_i(x_{i+1}) - f_i(x_{i-1})}{f_i^{max} - f_i^{min}} \tag{11}$$

6) Improved elite retention strategy: The elite retention strategy causes the parent and offspring to merge, and redundant individuals are prone to exist. Based on the NSGA-II algorithm, this study made some improvements to its elite retention strategy. The improved strategy is marked to judge redundant individuals and merge them into a temporary level. Finally, when the newly generated population is insufficient, the corresponding redundant individuals are removed and merged into the new population, thereby increasing the diversity of the population, as shown in Fig. 3.

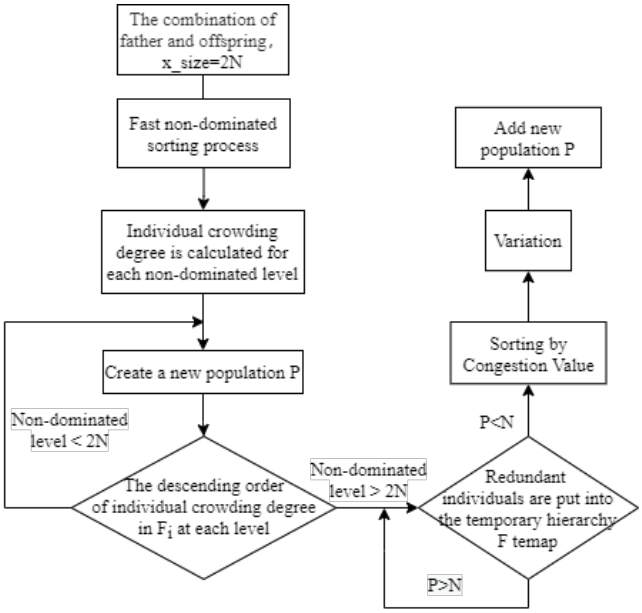

Fig. 3. Improved Elite Retention Strategy Process.

7) Genetic operation: The selection operation has adopted the roulette selection operator.

The crossover operation adopted a crossover operation to simulate a binary single-point crossover operator. The criteria were as follows:

$$\tilde{x}_{1j} = 0.5 \times \left[(1 + r_i) \cdot x_{1j}(t) + (1 - r_i)x_{2j}(t)\right]$$
$$\tilde{x}_{2j} = 0.5 \times \left[(1 + r_j) \cdot x_{1j}(t) + (1 - r_j)x_{2j}(t)\right] \tag{12}$$

$x_{i,j}$, $\tilde{x}_{i,j}$ $(i = 1,2)$ represent the j genes of the father and offspring, respectively; $r_i = \begin{cases} (2u_j)\frac{i}{\eta_c+1}, & u_j \le 0.5 \\ \left(\frac{1}{2(1-u_j)}\right)\frac{i}{\eta_c+1}, & \text{others} \end{cases}$, $u_j \in U(0,1), \eta_c > 0$ is the distribution index.

The work done in this study improved the mutation operation to determine whether the mutation is performed according to the size of the random number generated by rand (0, 1). If a mutation is needed, the gene value at one position on the individual chromosome is replaced with the gene value at another position on the chromosome.

The process set of the improved NSGA-II algorithm is shown in Fig. 4.

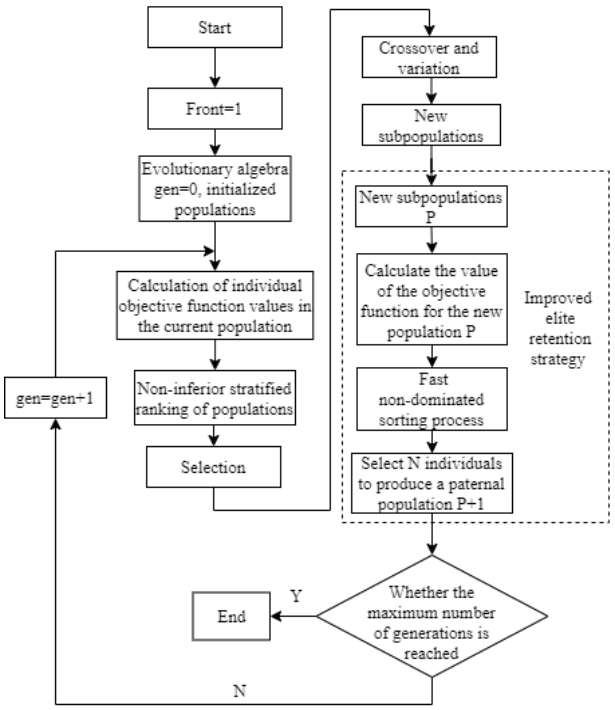

Fig. 4. Improved NSGA-II Algorithm Process.

B. Multiple Scheme Optimization

Entropy weighting is an objective method of assigning weights, which determines the weight of each indicator by the uncertainty of the information provided by the different attribute indicators. The TOPSIS method is a multi-objective decision-making analysis method that is suitable for the comparative study of multiple schemes. As a better way to avoid the subjectivity of the method, the study first used the entropy method of objective weighting to solve the weights before using the TOPSIS method to obtain Pareto optimal solution sorting. The preferred steps of the scheme are as follows:

According to the model, it can be seen that the attribute indicators affecting the decision on the stacking scheme in this paper are the order of exit, weight, and height. The entropy weight method is used to calculate the weight coefficients of these three indicators and obtain the weight matrix ω.

Use the vector normalization method to obtain the normalized weighted decision matrix.

Suppose the decision matrix $A = \{a_{ij}\}$ of the multi-attribute decision-making problem, and the standardized decision matrix $B = \{b_{ij}\}$, then

$$b_{ij} = \omega_j \cdot \frac{a_{ij}}{\sqrt{\sum_{i=1}^{m} {a_{ij}}^2}} \qquad i = 1,2,3\ldots m; j = 1,2,\ldots,n \tag{13}$$

Apply the weighted distance to construct the Euclidean distance between the target solution and the ideal solution and the negative ideal solution.

$$d_j = \sqrt{\sum_j^n (x_{ij} - x_j)^2} \qquad i = 1,2,3\ldots m \tag{14}$$

Calculate the comprehensive evaluation index of each plan and rank the superiority and inferiority of the plan according to the value C_i in descending order. Get the optimal stacking solution.

$$C_i = \frac{d_i^-}{d_i^+ + d_i^-} \qquad i = 1,2,3\ldots m \tag{15}$$

Based on the above analysis, the process settings of the improved NSGA-Ⅱ algorithm are shown in Fig. 5.

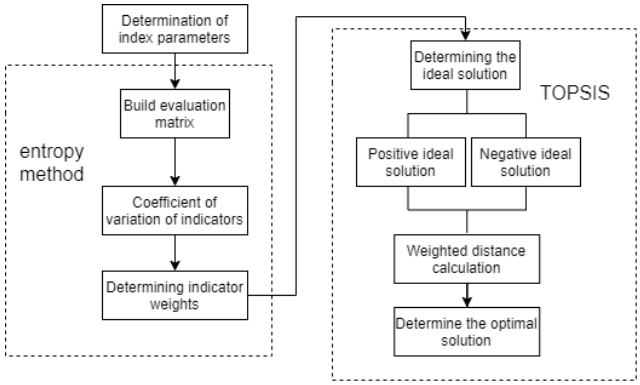

Fig. 5. Entropy TOPSIS Method Calculation Process.

IV. Case Analysis

A. Known Conditions

Consider a container area of a hazardous chemical container yard in a port as an example. The considered container area has 14 shell positions, each of which has three rows, and the maximum stacking height is three layers. The study randomly selected 50 containers of hazardous chemicals to be processed from 0:00 to 1:00 on June 2, 2020. The types of substances in the containers include category 6.1 (toxic substances), category 8 (corrosive substances), and category 9 (miscellaneous hazards). After the selected containers are classified according to the existing isolation rules of the storage yard, the 43 selected containers are all stacked in the same content area, and stacking is allowed for up to three layers. The initial number of layers of each shell in the container area is shown in Fig. 6.

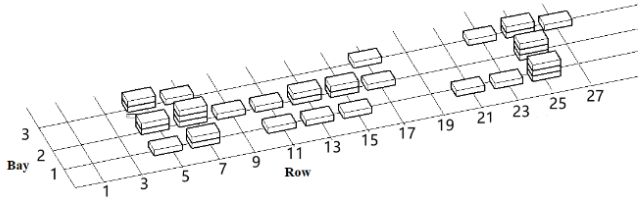

Fig. 6. The Initial Number of Stacking Levels in Each bay of the Box Area

The information of 43 containers to be processed is shown in Table II.

B. Optimization Results and Analysis

1) Improve the calculation method for congestion: The algorithm of the stack optimization model established in Section III is used, and the algorithm settings are as follows:

Population size $x\_size = 100$, maximum iteration $generation\_size = 500$, crossover probability $p = 0.8$; the mutation probability $q = 0.02$.

MATLAB was used to compile the code and run the program, and the iteration was terminated 500 times. The fitness of the iterative process changes, as shown in Fig. 7.

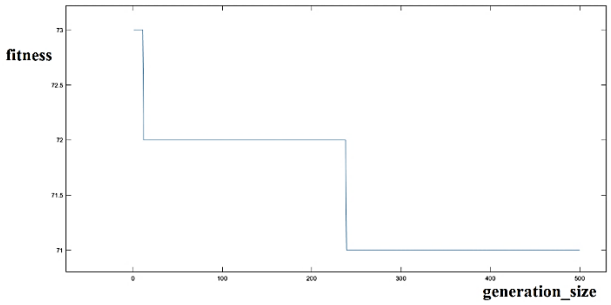

Fig. 7. Improved NSGA-II Algorithm Convergence Process.

As the number of iterations increases, the fitness value of the chromosome eventually converges, and a good convergence effect is achieved. After the program runs, 92 sets of Pareto solutions that simultaneously satisfy the requirements were obtained (Table III).

Based on the 92 Pareto solutions obtained, a 92 × 3 decision matrix A was constructed, and the attribute weights of the order of appearance, weight, and height were obtained using the entropy method in the following way: w_1=0.4685, w_2 =0.2954, w_3 =0.2360. It is evident that the order of appearance has the greatest impact on the container storage plan.

Based on the 92 Pareto solutions obtained, this study constructs a 92 × 3 decision matrix A (results in the C_i column in Table II). According to the TOPSIS method evaluation criteria, the solution with the highest score is selected as the final satisfactory solution; that is, the 34th solution set in Table III is the heap, and the optimal solution is stored. The stacking plan for the solution set is shown in Fig. 8.

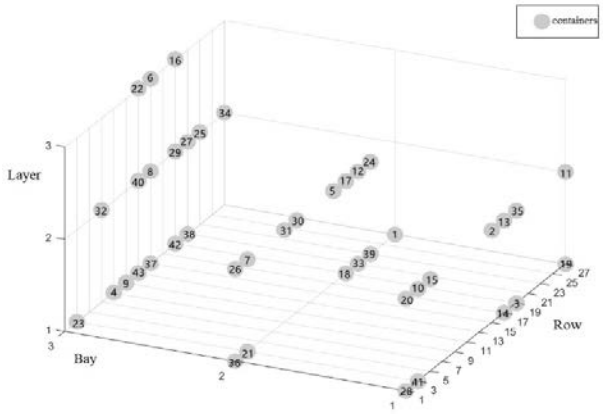

Fig. 8. Box Allocation Result.

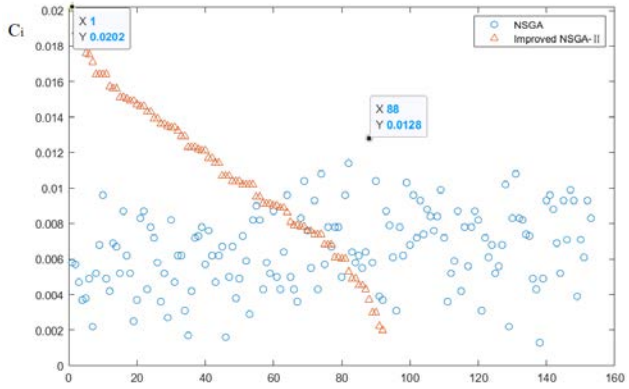

Fig. 9. Comparison between Traditional NSGA Algorithm and Improved NSGA-Ⅱ.

In practical engineering applications, decision-makers can choose other non-inferior solutions given by the algorithm according to the actual situation. For instance, when weight is a prominent consideration, the scheme with the smallest F^w can be selected, and when height balance is a prominent consideration, the scheme with the smallest F^h can be selected.

2) Algorithm performance analysis: In this study, we used the same container data and crossover and mutation probabilities to verify the effectiveness of the improved algorithm and solve it with the traditional NSGA algorithm. In total, 153 Pareto solution sets were obtained. (Table IV).

The results show:

a) Under identical conditions, for 500 iterations, the comprehensive scores of the traditional NSGA algorithm and the improved NSGA-II algorithm are shown in Fig. 9. It is evident that the highest weighted comprehensive score of the objective function obtained by the traditional NSGA algorithm is lower than that of the improved NSGA-II algorithm, which indicates that the solution obtained by the improved NSGA-II algorithm is closer to the optimal solution.

b) After 500 iterations, the operational time of the traditional NSGA algorithm was 68.8 s, and the time of the improved NSGA -II algorithm was 9.86 s, which is a reduction by 85.7%, indicating that the time consumed by the improved NSGA -II algorithm is considerably shorter.

V. Conclusion

The improvement of operational efficiency and the optimization of stacking safety have always been critical issues in the management of yards containing dangerous goods containers at ports. Combined with the needs of the application level, a multi-objective optimization model was constructed and the algorithm was optimized. The following conclusions can be drawn:

1) Combined with the operation process of the dangerous goods container yard and the technical requirements of the storage, a multi-objective optimization model is established, which realizes the dual consideration of safety and efficiency, and provides the theoretical basis and technical support for the safe and efficient operation of the dangerous goods container yard.

2) The NSGA-II algorithm was introduced to solve the optimization model and the algorithm was tested and improved. Compared with the traditional NSGA algorithm, the running time of the improved algorithm was shortened by 85.7%, which not only improved the efficiency of the algorithm but also enriched the diversity of understanding. The sorting algorithm improves the pertinence of the solution.

3) The container location allocation in this study focuses on storage optimization within the same container area. The coordinated storage problem of multiple container areas for

multi-category containers will be further explored in the future study.

***Abstract*—Sindhi is one of the most ancient languages in the world and it has its own written and spoken scripts. After the rigorous study it was found that a lot of research work has been done in different languages, but word by word labelling of Sindhi language had not been done yet. In this research study, word labelling was done on 100 sentences of Romanized Sindhi texts using Python online tool. The dataset was collected from different sources which include Sindhi newspaper, blogs and social media webpages. From this dataset, a rule-based model has been applied for the Parts-of-Speech (POS) tagging of the Romanized Sindhi sentences. A total of 624 words of Romanized Sindhi texts were tested and successfully tagged by the SindhiNLP tool in which 482 words were tagged as nouns and pronouns, 92 words tagged as verbs and 50 words tagged as determinants.**

Keywords—Romanized sindhi; word labelling; rule-based model; POS tagging; SindhiNLP tool

I. Introduction

Sindhi is one of the most ancient languages in the world which has its own script in written and spoken forms [1-3]. Communication technologies are increasing day-by-day for different purposes, while different applications and software are used for daily communications such as WhatsApp, Facebook, Twitter, Telegram and Instagram [4-5]. In the community that uses Sindhi as their main language, Romanized Sindhi texts are used in daily communication especially in writing text messages on mobile phones, WhatsApp and other social media platforms [6].

Natural Language Processing has a vital role in the field of machine learning. This field provides language processing tasks such as of Parts–of–Speech tagging, tokenization of text (i.e., words, sentences, and paragraph) to the users [7-8]. In this research study, 100 sentences of Romanized Sindhi texts were labelled. The word labelling process which consists of two natural language processing tasks which is tokenization and POS tagging was performed using an online SindhiNLP tool [9]. Before performing the two tasks, a rule-based model has been applied for the POS tagging of the sentences to improve the accuracy of the POS tags [10-12].

After the review of the literature it was observed that a lot of vacuum is still available for the Sindhi language. This research study presents the word by word labelling of Sindhi language after Romanization.

II. Methodology for Labelling of Romanized Sindhi

The procedure for labelling of the Sindhi Romanized text has been divided into various stages as shown in Fig. 1. The first phase involves the data collection process from different sources of Sindhi scripts, the second stage is the conversion of Sindhi scripts into Romanian scripts (i.e., Romanization), the third stage identifies the issues in word labelling after applying the rule-based model and the final task is to do a thorough analysis on the results produced [13].

A. Dataset of Sindhi Text

Sindhi language is one of the oldest, historical and most commonly used languages in the world. Sindhi language is more difficult than other languages due to the difficulty in reading, writing and understanding the scripts [13-14]. Sindhi language is spoken by the people in the province of Sindh which is the second largest populated province of Pakistan. Sindhi is the official language of the Sindh province in which almost 15% of the population use Sindhi as their mother tongue [14-15]. As Sindhi language is mostly used in Sindh-Pakistan, the data for this research study was collected within the province of Sindh. Data was collected from different sources (Sindhi newspaper, blogs, and social media webpages) which provided the rules and guidelines of Romanized Sindhi for text communication.

B. Sindhi Alphabet

Sindhi language has its own script and written style like other languages (Arabic, Urdu, and English) [16]. In Sindhi script there are 52 alphabetical letters for writing and speaking purposes and presented in Fig. 2. Sindhi language has one of the largest numbers of alphabetical letters as compared to other languages. Similar to Arabic and Urdu scripts, the Sindhi script is written from right to left with a total of 52 alphabets [17].

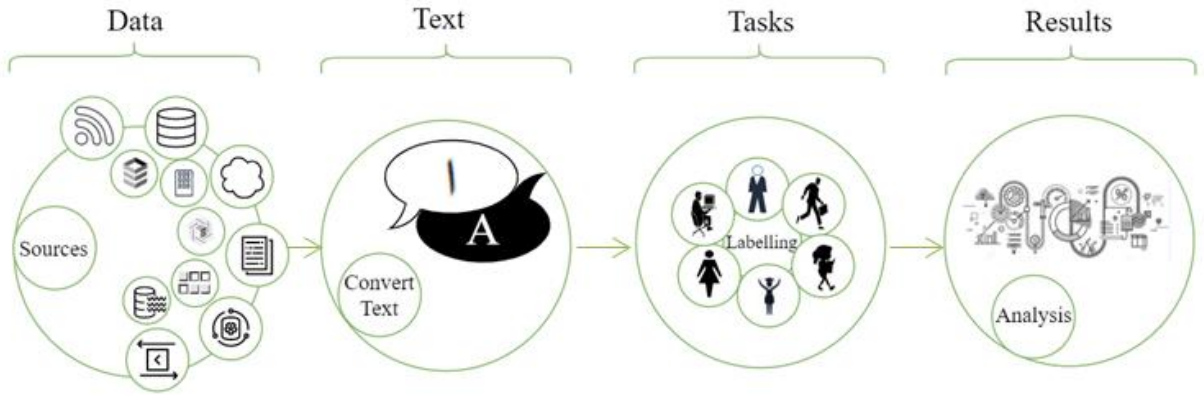

Fig. 1. Methodology of Labelling of Sindhi Text.

Sindhi Alphabet									
ٿ	ٽ	ٺ	ٹ	ت	ٻ	ب	ب	ا	Sindhi alphabet
s	th	t	th	t	bh	b	b	a, u	Roman
ڇ	ڃ	ڇ	ڇ	ج	ڄ	ج	ج	پ	Sindhi alphabet
kh	h	ch	ch	j	jh	j	j	p	Roman
ز	ڑ	ر	ذ	ڊ	ڊ	ڈ	ڈ	د	Sindhi alphabet
z	r	r	z	dh	d	d	dh	d	Roman
ف	غ	ع	ظ	ط	ض	ص	ش	س	Sindhi alphabet
f	ga	a	z	t	z	s	sh	c, s	Roman

l	g	gh	ga	g	kh	k	q	ph	Roman
		ي	ء	ھ	و	ڻ	ن	م	Sindhi alphabet
		y, e	a	h	o, w, v	n	n	m	Roman

Fig. 2. Sindhi-Roman Alphabet [17].

C. Romanization of Sindhi Text

In this research study, 100 sentences were used for the word labelling of Sindhi texts. After the collection of Sindhi sentences for the data set for this research study, the collected dataset was converted from Sindhi scripts into Romanized Sindhi text by using rules for Romanization of Sindhi text. Romanization of Sindhi text was successfully done following the rules for Romanized Sindhi text.

III. Pre-processing of Romanized Sindhi

Pre-processing is the basic components of NLP to filter the raw the data to useful and remove unnecessary data from the text. The pre-processing step consists two steps first is performing tokenization and second one assigning tag on each token [10].

A. Tokenization of Romanized Sindhi Text

The tokenization of Romanized Sindhi text has been done using the online SindhiNLP Python tool [9]. The Romanized texts were prepared following the rules of Sindhi on 100 sentences. The statistical information after the tokenization process of the Sindhi text is shown in Table I. This table consists of five different columns which are: total number of sentences, total number of words, total number of characters (with space), total number of character (without space) and total number of word tokens. In this table, two types of sentences were used: sentences from Sindhi text and sentences from Romanized Sindhi text. A total of 652 words, 2,816 characters with space and 2,262 characters without space were extracted as shown in below Table I.

TABLE I. Statistical Study Data of Token

Description	*Total number of sentences*	*Total number of words*	*Total number of characters (with space)*	*Total number of characters (without space)*	*Total number of word tokens*
Sentences in Sindhi scripts	100	652	2816	2262	---
Sentences in Romanized Sindhi	100	624	3275	2740	624

B. Parts-of-Speech Tagging

The POS tagging task for Sindhi was designed such that the whole process was divided into a few steps. The first step involved the pre-processing of the Romanized Sindhi sentences. Subsequently, the ruled-based model of Sindhi was applied for the Romanization process as described in Table II. This Romanized Sindhi text was then used as input to the SindhiNLP tool, after the input Romanized Sindhi text, the text was pre-processed using the online SindhiNLP Python tool [9] in which the sentences were split into words (i.e, tokenization). Next, the Match step was performed which was also sub-divided into two categories: Assigned Tag and Incorrect Tag. If the tag was incorrectly assigned, we apply the rule-based model and repeat the process again.

C. Algorithm for POS Tagging of Romanized Sindhi Text

The algorithm for the Parts of speech tagging of Romanized Sindhi text was designed before the start of the research work. The algorithm used was based on the ten steps described below. The same step applies following the algorithm for every new input data of Romanized Sindhi text.

Step 0 Start

Step 1 Take input sentence

Step 2 Split text → words

Step 3 Repeat steps 2→7 when ⩾ get appropriate output

Step 4 If word is matched, continue to assign tag separately, word by word

Step 5 If same tag is assigned to multiple words, apply rules for words and assign one tag for each word

Step 6 If one tag is assigned to one word, display the word with tag

Step 7 Else, select one or more morphological rules and apply to words to extract word with appropriate tag.

Step 8 Display as output the tagged words

Step 9 Apply rules for new words when entered

Step 10 End

D. Rule-Based Model for Labelling of Romanized Sindhi Text

The rule-based model used in the word labelling of Sindhi text is a supervised machine learning model or hybrid model. This model combines the use of online and manual approach. This type of model is commonly used to create rules for language analysis and is a popular NLP technique to perform different tasks on different languages as it is easier to understand while the results are based on ground truth values [19-20]. Fig. 3 illustrates that the S1, S2, S3 until Sn are input sentences while R1, R2, R3 until R10 are the rules. These rules are applied on the Sindhi sentences to get the appropriate output, Y. The rules for Romanized Sindhi texts are described in Table II.

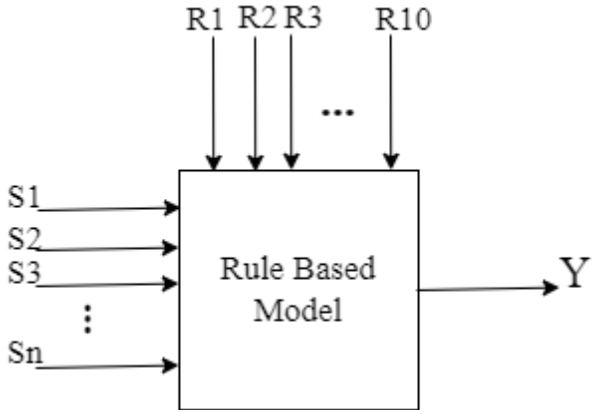

Fig. 3. Rule-Based Inputs and Output for Sindhi POS Tagging

There are ten rules that have been created for the word labelling of Romanized Sindhi texts [21-22]. Rule 1 describes the structure of a sentence and the restructuring of an input sentence by applying the SVO structure (Subject + Verb + Object) [18]. Rule 2 is used to define the prefixes of Sindhi sentences (i.e., ma, mounkhe, huwa, manhon, na, wanu sijh, cha, eho, kethe, Ali, Sara) as starting words and refers to nouns. Rule 3 describes the prefix that appears in sentences (i.e., he) as an initial word which is considered as pronouns. Rule 4 is used for the words that appear at the beginning of input sentences (i.e., Ma, Mounkhe, Huwa, Manhon, Na, Wanu sijh, cha, eho, kethe, Ali, Sara, he, etc.), considered as nouns as well as pronouns. Rule 5 describes the words that appear in the middle of an input sentence (i.e., Sadyo, Parhyo, maryo, likhyo, budho, khedan) known as the verb class. Rule 6 is used when the infix letters (i.e., a, d, e and o) appear in between words in a sentence which refers to a verb class. Rule 7 is used for postfix letters (i.e., e, o, n, i, u), if they appear in the middle of a word in a sentence which refers to a verb class. Rule 8 is used for the postfix letters (i.e., d, e, h, o, and y) if they appear at the end of the final word in a sentence, which belongs to a noun class. Rule 9 applies when the part-of-speech tagger fails to identify when the input sentences are interrogative. Rule 10 is used when the parts-of-speech tagging is performed on sentences with negation (without subject in the sentence), otherwise it was not identified. The rules used for Romanized Sindhi Text help in performing POS tagging on the SindhiNLP tool [9] to produce a more accurate part-of-speech.

TABLE II. RULES FOR ROMANIZED SINDHI TEXT FOR POS USING THE TEMPLATE

R #	Rule Description	Related Examples
1	Sentence structure should be built by applying the SVO (Subject +Verb +Object) structure.	You are teacher ⇩ ⇩ ⇩ Subject Verb Object ⇩ ⇩ ⇩ Tou ahen teacher
2	Prefixes (Ma, Mounkhe, Huwa, Manhon, Na, Wanu sijh, cha, eho, kethe, Ali, Sara etc.) in sentences as starting words, refers to noun class.	I am a Student ⇨ Ma/NNP ahyan/VBD shagrid/JJ ⇨ مان آهيان شاگرد ⇨
3	Prefix (he) in sentences as starting words, refers to pronoun class.	He is intelligent He/PRP ahy/VBD hoshar/NN ⇨ هي آهي هوشيار
4	Prefixes (Ma, Mounkhe, Huwa, Manhon, Na, Wanu sijh, cha, eho, kethe, Ali, Sara, he etc.) in sentences as starting words, refers to noun as well as pronoun class.	I play game ⇨ Ma/NNP khedan/VBD rand/NN ⇨ مان کيڈان راند
5	Infixes (Sadyo, Parhyo, maryo, likhyo, budho, khedan etc.)	I wrote article ⇨ Ma/ NNP likhyo/VBD article/NN ⇨ مان لکيو آرٹيڪل

	that appear in the middle of sentences, known as verb class.	
6	Infixes (a, d, e, o) that appear in the middle of the words in sentences refers to verb class.	I am happy Ma/NNP ahyan/VBDkush/JJ ⇨ مان آهيان خوش
7	Postfixes (e, o, n, i, u) that appear in the middle of the words in a sentence refers to verb class.	I learn Sindhi ⇨ Ma/NNP sikhan/VBD thi/NN Sindhi/NNP ⇨ مان سکان ٿي سنڌي
8	Postfixes (d, e, h, o, and y) that appears at the end of the last words in a sentence refers to noun class.	You are teacher ⇨ Tou/NNP ahen/VBD ustad/NN ⇨ تون آهين استاد
9	Parts of speech not identified when sentence is interrogative.	Do I like banana? Kayan/NN thi/NN ma/NN pasand kela/NN? ⇨ کيان ٿي مان پسند کيلا
10	Parts of speech perform on sentences with negation (without the subject in the sentence), otherwise not identified.	Do not forget ⇨ Na/NNPwesaryo/ VBD ⇨ نه وساريو Negative Verb

IV. Word by Word Labelling of Romanized Sindhi

Word labelling of Romanized Sindhi Text was performed using the free online SindhiNLP Python tool [9]. Word Labelling of Romanized Sindhi text has been performed after completing the two pre-processing tasks for Sindhi Romanized text: the tokenization and part-of-speech tagging tasks as shown in Table III.

TABLE III. Word by Word Labelling of Romanized Sindhi Text (Examples)

#	Sindhi Sentence	English Sentence	Romanized Sindhi	Word Tokens	Word Labelling
01	اهي پلي هاڻي ڪم ڪن	They better work now	Ehe kamu kan bhale hanne	Ehe, kamu, kan, bhale, hanne	Tagged Text: Ehe/NNP kamu/VBD kan/NN bhale/NN hanne/NN
02	اسين هاڻي پلي آرام ڪريون	We should rest now	Aseen kryon bhale hanne aram	Aseen, kryon, bhale, hanne, aram	Tagged Text: Aseen/NNP kryon/VBD bhale/NN hanne/NN aram/NN
03	هوءَ هڪ ڊاڪٽر هُئي	She was a doctor	Huoa hue hek doctor	Huoa, hue, hek, doctor	Tagged Text: Huoa/NNP hue/VBP hek/NN doctor/NN
04	مان ڪراچيءَ ۾ هيس	I was in karachi	Maa'n huoas Karachi maen	Maa'n, huoas, Karachi, maen	Tagged Text: Maan/NNP huoas/VBD Karachi/NNP maen/NN
05	توهان هڪ خوبصورت ڇوڪرا هُو	You are a handsome boy	Tawhan Huoao hek khubhsorat chokra	Tawhan, Huoao, hek, khubhsorat, chokra	Tagged Text: Tawhan/NNP Huoao/NNP hek/NN khubhsorat/NN chokra/NN
06	هوءَ هڪ موهيندڙ ڇوڪري هُئي	She was an attractive girl	Huoa hui hek mohendar chokri	Huoa, hui, hek, mohendar, chokri	Tagged Text: Huoa/NNP hui/NN hek/NN mohendar/NN chokri/NN
07	اهو ڏکوئيندڙ هو	It was painful	Eho dukhoindar ho	Eho, dukhoindar, ho	Tagged Text: Eho/NNP dukhoindar/NN ho/WP
08	اسين هتي آفيس ۾ هئاسين	We were here in the office	Aseen huoaseen hite office maen	Aseen, huoaseen, hite, office, maen	Tagged Text: Aseen/NNP huoaseen/VBD hite/JJ office/NN maen/NN
09	هي پهرين سال واري ڪلاس ۾ هو	He was in the first year class	He ho pehreyen saal ware class maen	He, ho, pehreyen, saal, ware, class, maen	Tagged Text: He/PRP ho/VBD pehreyen/VBN saal/JJ ware/NN class/NN maen/NN
10	اهي ڪله راند جي ميدان ۾ هئا	They were in the playground yesterday	Uhe huoa rand maidan mean kalh	Uhe, huoa, rand, maidan, mean, kalh	Tagged Text: Uhe/NNP huoa/NN rand/NN maidan/NN mean/NN kalh/NN

A. Analysis of the Parts-of-Speech Tagging

The output from the word labelling task of Romanized Sindhi text performed using the online SindhiNLP Python tool [9] and Sindhi rule-based model was analyzed in which 13 different POS categories were identified. The detailed statistics of the word labelling task are shown in Table IV.

TABLE IV. DETAIL STATISTICS FOR WORD LABELLING OF ROMANIZED SINDHI TEXT

Description	***Total Number of Words***	***Total number of POS Tagged Words***	***Word Labelling of Romanized Sindhi Text***	
Romanized Sindhi Text (100 sentences were used)	624	624	POS	No. of Words
			NNP	110
			NN	372
			PRP	11
			JJ	13
			RB	11
			WP	4
			VBD	54
			VBZ	0
			VBN	4
			VBP	30
			VB	4
			WDT	0
			DT	11
			Total	624

From the results produced by the SindhiNLP POS tagger, 624 Sindhi words was successfully tagged in which 482 are noun and pronouns, 92 verbs and 50 determinants were found as illustrated in Fig. 4.

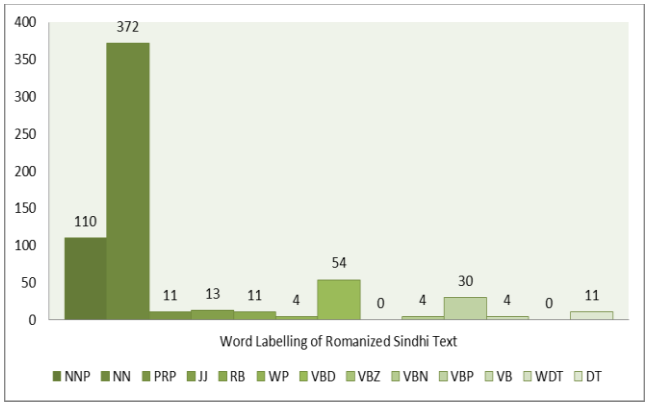

Fig. 4. Word Labelling of Romanized Sindhi Text.

V. CONCLUSION

In research study of Word by Word Labelling of Romanized Sindhi Text the conclusion is based on the following outcomes.

- A hybrid approach was used that combines online and manual approaches and a rule-based algorithm was designed and applied to the word labelling tasks.
- From the results 13 different POS categories were identified and 654 words of Romanized Sindhi Text were tested by using the SindhiNLP Python tool and all words were tagged successfully.
- From the results 482 noun/pronouns were found while the remaining 172 words were found to be adjectives, adverbs, verbs and determiners.
- For future work, Romanized Sindhi text from different domains will be used in the word labelling tasks and results will be compared using different machine learning techniques and tools.

***Abstract*—Forests are vital ecosystems composed of various plant and animal species that have evolved over years to coexist. Such ecosystems are often threatened by wildfires that can start either naturally, as a result of lightning strikes, or unintentionally caused by humans. In general, human-caused fires are more severe and expensive to fight because they are frequently located in inaccessible areas. Wildfires can spread quickly and become extremely dangerous, causing damage to homes and facilities, as well as killing people and animals. Early discovery of wildfires is vital to protect lives, property, and resources. Reinforced imaging technologies can play a key role to detect wildfires earlier. By applying deep learning (DL) over a dataset of images (collected using drones, planes, and satellites), we target to automate the forest fire detection. In this paper, we focus on building a DL model specifically to detect wildfires using transfer learning techniques from the best pretrained DL computer vision architectures available nowadays, such as VGG16, VGG19, Inceptionv3, ResNet50, ResNet50V2, InceptionResNetV2, Xception, Dense-Net, MobileNet, MobileNetV2, and NASNetMobile. Our proposed approach attained a detection rate of more than 99.9% over multiple metrics, proving that it could be used in real-world forest fire detection applications.**

I. Introduction

Forests are one of the most important natural resources on our planet. They support a diverse range of plants and animals' lives, play an important role in climate regulation, and provide numerous economic and social benefits. However, forests are vulnerable to damage and destruction, and wildfires are one of their most serious threats [1]. A wildfire can start accidentally (with a spark from a campfire), or it can be deliberately set by someone who intends to cause harm. Wildfires can quickly spread, destroying everything in their path. They can also cause significant environmental damage, such as the death of trees and other plants, the removal of soil, and the release of harmful emissions into the atmosphere [2].

In recent years, wildfires have become increasingly severe. Wildfires raged through Algeria, Tunisia, and Morocco in mid-July 2021, as well as Italy and Greece in the Mediterranean. The fires, which are believed to have been started by arsonists, burned through thousands of acres of land, killing dozens of people and injuring many more [3], [4]. The fires were especially devastating to the local economies, causing widespread agricultural damage as well as the destruction of businesses and homes. Furthermore, the tourism industry suffered as many people canceled their trips to the affected areas. Despite the efforts of firefighters and volunteers, the fires kept burning for weeks, leaving a trail of destruction in their wake.

We can do a lot to reduce the risk of wildfires, such as properly managing forests and using fire-resistant materials when building houses and other structures. In addition, we need to address the root cause of these fires.

The detection of wildfires at a preliminary phase is critical for protecting people, property, and resources. Imaging technology has the potential to aid in the early detection of wildfires. High-altitude drones, aircraft, and satellites can detect wildfire heat signatures by top shooting the fire area [5].

In this paper, we aim to build the most accurate DL model for forest fires using transfer learning out of the most achieving and well-known computer vision architectures pre-trained models available today, such as VGG, Inceptionv3, ResNet50, InceptionResNetV2, Xception, Dense-Net, MobileNet, and NASNetMobile.

The rest of the paper is organized as follows. The second section provides a focus on the used techniques, while the third section deals with the related works. Then the fourth section

presents our proposed method. Before concluding, the fifth section examines and discusses our study's findings.

II. Background

A. Computer Vision (CV)

CV is the process of extracting useful information from digital images. This data could be used for tasks such as object recognition, scene description, and motion tracking [6]. There are two kinds of computer vision algorithms: low-level and high-level. Low-level algorithms work on individual pixels; whereas, high-level ones work on more abstract features such as edges and corners. Low-level algorithms are typically faster and more accurate, but they are also more complex and require more processing power. High-level algorithms are less accurate, but they are also faster and easier to implement. On the other hand, deep learning has shown great promise in this area and has been used to achieve impressive results in tasks such as object recognition and scene understanding [7]. Deep learning-based computer vision can recognize objects in images, recognize faces, and read text. It can also be used for automatic image tagging and classification [8].

B. Convolutional Neural Networks (CNN)

CNNs are a type of deep learning (DL) network, which means they are made up of multiple layers of neurons organized in a hierarchical structure. A deep learning network's goal is to learn representations of input data by gradually extracting more and more information from it. Because of their ability to learn features of the input data, CNNs are particularly well-suited for computer vision tasks [9]. This is accomplished through a process known as feature extraction, which involves identifying the important features in the data and representing them in a way that the network can learn from. In contrast, traditional machine learning algorithms require the programmer to explicitly specify which features the algorithm should use [10].

CNNs have the ability to learn features that are specific to the task at hand, which is one of their advantages [11], [12]. It is made up of several layers, each with its own function. The first layer is the input layer, which receives input data in the form of a numerical value matrix and feeds it into a series of convolutional and pooling layers. This combination of convolutional and pooling layers is known as a kernel. The output layer is the final layer in a CNN; it produces the network's results (see Fig. 1).

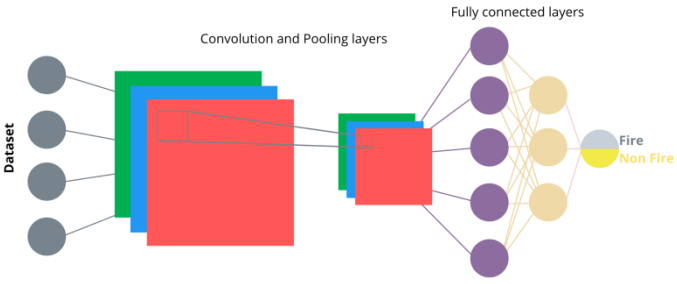

Fig. 1. CNN Layers Architecture.

We list below the most successful deep learning CNN architectures for image recognition:

- VGG is a deep learning architecture (created by the Visual Geometry Group) that was also created for the ILSVRC contest (ImageNet Large Scale Visual Recognition Challenge). The VGG16 is made up of 16 layers, including five convolutional layers, four dense layers, and a final fully connected layer, while the VGG19 model has 19 layers [13].
- Inception is a deep learning model that performed well in the ImageNet competition. It is made up of a deep convolutional network with a large number of layers (more than 20) [14].
- ResNet (Residual neural network) is a deep neural network that performed well in the ILSVRC. It is made up of a deep convolutional network with a large number of layers (more than 100), one of ResNet's major purposes is a so-called “identity shortcut connection” that skips one or more layers [15].
- InceptionResNetV2 is a variant of the original Inception-v2 model, designed to improve its performance on the ImageNet dataset. The model is composed of an Inception module followed by a ResNet module [16].
- Xception (Xtreme Inception) is a deep learning model, based on a CNN with a large number of layers (more than 150) [17].
- DenseNet is a CNN model with a large number of layers (more than 500), designed to increase the number of connections between neurons. This helps to improve the overall accuracy of the network.[18].
- MobileNet is a deep learning framework that enables developers to create sophisticated neural networks for mobile devices. It is designed to be efficient and lightweight, making it suitable for running on a wide range of mobile devices. MobileNet50 version has a depth of 50 layers and can be used for both classification and detection tasks [19].
- NASNet (Neural Architecture Search Network) is a CNN model trained on the ImageNet dataset [20]. It automates network architecture engineering by searching for the best algorithm to achieve the best performance on a certain task, while automatically configuring the number of layers, the number and type of neurons in each layer, and the architecture of the network. The NASNetMobile version is suitable for mobile devices [21].

III. Related Work

Dutta S. et al [22] proposed a hybrid architecture of separable convolution neural networks and digital image processing employing thresholding and segmentation for reliably detecting small-scale forest burning, which generally heralds the beginning of more terrible catastrophes. Performance examination of the test data on the suggested design provided outstanding results in terms of high sensitivity (98.10 %) and specificity (87.09 %).

Aslan S. et al [23] proposed a smoke detection approach based on Deep Convolutional Generative Adversarial Neural Networks (DC-GANs). In order to ensure a robust representation of sequences with and without smoke, the training framework includes regular training of a DCGAN with real pictures and noise vectors, as well as training the discriminator separately using smoke images without the generator. With a TNR of 99.45% and a TPR of 86.23%, the suggested approach is able to identify smoke pictures in real time with minimal false positives.

Wang Y. et al [24] proposed a forest fire image identification system based on traditional image processing methods and convolutional neural networks, and an adaptive pooling methodology was established to identify fire automatically. Using this technique, the features of the fire flame may be segmented and learned in advance. It has been shown in experiments that the adaptive pooling convolutional neural network approach has greater performance and a higher recognition rate, with an accuracy as high as 90.7%.

Chen Y. et al [25] proposed a UAV-based forest fire detection approach based on a convolutional neural network method in order to identify a probable fire in its early stages. Experimentation with generated flames in an indoor testbed proves that the suggested fire detection system works.

We will make a comparative study between a wide range of deep learning models, practically all of those that have demonstrated their effectiveness in computer vision, in order to propose the most accurate model possible for forest fire detection

IV. Proposed Method

Our proposed solution is to detect wildfires before they spread out of control using drones and deep learning algorithms. Drones are used to fly over forests and identify hot spots that could spark a wildfire. Once a hot spot has been identified, the deep learning algorithm can be used to determine whether it is a wildfire, and notify the authorities via a cloud server (Fig. 2).

This scheme has several advantages over traditional methods. First, drones can fly over large areas much faster than ground crews. Second, the deep learning algorithm can identify wildfires much more accurately than human observers can. Third, the use of drones and deep learning algorithms can help to protect firefighters and their assistants and keep them safe from danger by alerting them earlier.

Our main contribution in this paper is to build the most accurate DL model specifically for detecting wildfires in forests from the best resulting DL computer vision architectures available at the time, by leveraging previously known knowledge from pre-trained models. These models are already trained to know certain categories, and we narrow their knowledge to focus only on two categories (Fire or Non-Fire).

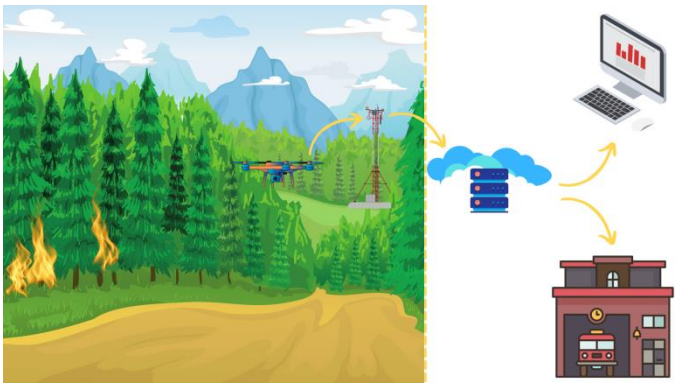

Fig. 2. Components and Functions of a UAV-Based Forest Fire Detection Platform.

A. Dataset

A common challenge in deep learning is obtaining datasets that are sufficiently large and diverse in nature for the task at hand [26], [27]. The dataset used for training our models is comprised of a large number of images captured of wildfires in different locations around the world, as well as images of forest landscapes with no fire. It was constructed by mixing and merging multiple smaller datasets from search engines and Kaggle [28], resulting in 4661 images in our new dataset; 2525 images with the label "no fire" and 2136 images with the label "fire", after cleaning some corrupted images.

In addition, we performed data augmentation on the dataset, allowing us to significantly increase the size of our training dataset and, as a result, the quality of the trained models [29]. With data augmentation, we added new data to the dataset that is similar to the original data, but with some slight modifications, which can improve the performance of neural networks learning from data and improve their accuracy [30]. We used different data augmentation techniques [31], such as:

1) Random rotation: this can help to reduce overfitting by creating new images that are rotated versions of existing images. This also gives the model a chance to learn how to recognize objects from different angles.

2) Horizontal and vertical mirroring: they can also help to reduce overfitting by providing the model with new images that are mirror images of existing images. This can also help the model learn to recognize objects that may be upside down or rotated in different orientations.

3) Gaussian blur: it can help to improve the robustness of the model by making the images less detailed and more forgiving of small changes. This can help the model to generalize better to new data.

4) Pixel level augmentation: it can help to improve the model's ability to learn from small changes in the input data. This can be useful for learning from data that may be noisy or have low resolution.

B. Building the Models

A model can be trained in a variety of ways. In this section, we will stare at transferring pre-trained models to a new task. Transfer learning models are typically constructed by first training them on a large dataset, such as the ImageNet dataset. This model is then used as the "base model" for another model trained on a smaller dataset (see Fig. 3). In our case, the smaller dataset is often a more specialized dataset (images of fires and forests). The smaller model is then tuned to better fit the dataset on which it is being used. This process is frequently repeated, with the final model trained on a dataset even smaller than the original. This process of model training is commonly referred to as fine-tuning [32]. We used this same strategy for each of the state-of-the-art models, importing the pre-trained DL model class [33], while ensuring that we can add our own custom input and output layers according to our data. While leveraging the previously learned weights during the initial training on the old data, a massive amount of time and space is saved while minimizing the model's complexity. (see Fig. 3).

Afterward, we inserted a fully connected and output layer (new classifier) after the pre-trained model was imported so that new real learning could take place; the fully connected layer is a flatten layer and a dense layer with 512 neurons [34]. The sigmoid activation function is used in the output layer with only one output neuron matching the binary label in our data (Fire or Not). Finally, we train our models on 80% of the augmented new dataset (Training set) and validate the obtained results with the remaining 20% (Validation set).

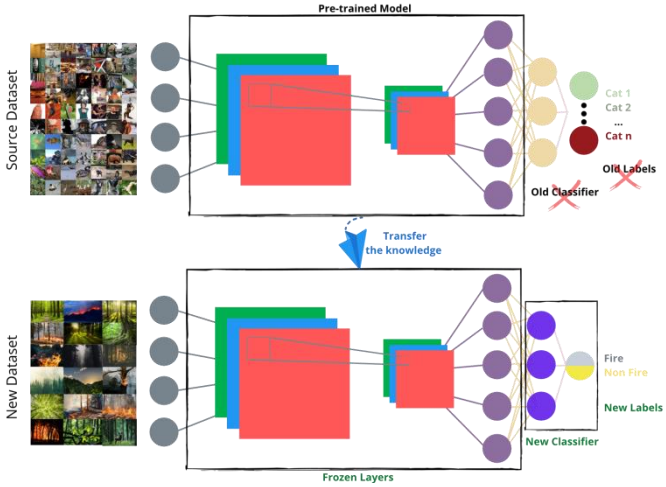

Fig. 3. Transfer Learning Technique.

V. Results and Discussions

A. Hardware and Software Characteristics

In order to get our results, we used TensorFlow on an HPC system with the following hardware specifications:

- 2x Intel Gold 6148 (2.4 GHz/20 cores) CPUs
- 2x NVIDIA Tesla V100 graphics cards, each having 32GB of RAM

TensorFlow v2.7.0 was used in our experiments, it is an open-source data analysis and machine learning software library. It was first developed by engineers and researchers at the Google Brain team in 2015. TensorFlow provides a wide range of capabilities for data analysis and machine learning, including numerical computing, linear algebra, graph processing, and deep learning [35].

B. Evaluation Metrics

It is necessary to have a proper evaluation metric in place in order to find the best model during the training phase [36]. When evaluating deep learning models, certain metrics must be used, such as Accuracy, Precision, Recall, and Loss. In order to calculate these metrics, four different parameters are used [37]:

- True Positive (TP): is the total of successfully categorized positive class records.
- True Negative (TN): is the total of successfully categorized negative class records.
- False Positive (FP): is the total of incorrectly categorized positive class records.
- False Negative (FN): is the total of incorrectly categorized negative class records.

1) Accuracy: Accuracy is the percentage of correctly classified items. It is the most basic and common evaluation metric for classification tasks. The accuracy is simply the ratio of correctly predicted labels out of all predicted labels [34]:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

2) Loss: It is a measure of how far off the algorithm is from the desired output. The lower the loss, the better the algorithm is performing [38]. The cross-entropy loss is a commonly used loss metric for classification problems. It is calculated by this formula:

$$Loss = -\sum_i y_i * \log(p_i) \quad (2)$$

Where y_i is the output of the true label and p_i is its predicted probability. The cross-entropy loss is used to assess the performance of a classifier by penalizing incorrect predictions.

The higher the cross-entropy loss, the more incorrect predictions the classifier is making.

3) Precision: Precision is a metric estimating how well a model predicts true positives. True positives are those instances that are correctly identified as positive by the model [39].

A model with high precision will correctly identify the most positive examples, while a model with low precision will misclassify many positive examples as negative. The Precision metric is given by:

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

4) Recall: The recall is the ratio of correctly predicted positive instances to all positive instances (see formula (4)). It is also known as the true positive rate or sensitivity. A model with high recall is capable of detecting the most positive

instances [39]. A model with low recall is not informative as it classifies most positive instances as negative.

$$Recall = \frac{TP}{TP + FN} \quad (4)$$

In general, Recall should be used alongside other metrics such as Precision and Accuracy to get a complete picture of a model's performance.

5) The number of parameters: The number of parameters in deep learning refers to the number of variables that are used to define the structure of the neural network. These variables can be the weights and biases of the network, the size of the network, or the type of activation function used. It reflects the learning capacity of the model; A deep learning model with a large number of parameters has the capacity to learn more complex patterns than a model with fewer parameters [40]. The number of parameters also determines the amount of memory required to store the model; A model with a large number of parameters requires more memory than a model with fewer parameters [41]. The number of parameters in the models will vary from the original pre-trained models owing to the change in the fully connected layers (the convolution base was unmodified as it was frozen).

C. Evaluating the Results

In Table I and Figures 4-7, we present the obtained results on multiple metrics; the accuracy, loss, precision, and recall, along with the number of parameters for each model (this number differs from the original pre-trained models, due to our new classifier). To maximize effectiveness, we trained all of the models over one hundred epochs. These obtained results show that the ResNet50, VGG16, and VGG19 algorithms have higher accuracies, lower losses, and higher recalls and precisions, achieving a near-perfect score. Meanwhile, MobileNet and DenseNet came in second place with more than 97% in three metrics (accuracy, precision, and recall), but with a loss of around 5 to 6%; On the other hand, MobileNetV2 achieves close results, more than 96% in the three metrics and a loss of more than 9%. Then, Xception, which received more than 94% in the three metrics, and a high Loss averaging 14 to 15%. ResNet50V2 obtained mediocre results; even though its first version (ResNet50) got good results, around 84-85% in the three metrics, but with high losses up to 34% (higher errors are related to high loss, which means that the model does not do a good job). NASNetMobile and InceptionV3 performed similarly to ResNet50V2 in all metrics. On the other side, the mixed-model InceptionResNetV2 performed the worst in the accuracy, precision, and loss metrics, but reached the best score in the recall metric (100%). This shows that the model has a low false-negative rate (down to zero), but with a high false-positive rate due to the low precision results. At the end of this discussion, the best models retained are ResNet50, VGG16, and VGG19. Then, we compared their number of parameters. They have the respective numbers: ResNet50 (24.6~ million), VGG16 (~14.9 million), and VGG19 (~20.2 million). if we are looking for a model with the best learning capacity, ResNet50 is the accurate candidate; On the other hand, if we are targeting a lightweight model to deploy on a limited resource and battery-connected devices such as a drone or an IoT thing [42], VGG16 is the suitable one among the three. It has60% fewer parameters in comparison with the ResNet50. With fewer performances, DenseNet is the best lightweight model (after VGG16) with only 7.5 million parameters. Also, if we prioritize model size, MobileNet will be the best choice with only 3,7m parameters and an accuracy close to 98%, MobileNetV2 is the lightest model in this case study with only 2,9m with a modest accuracy of more than 96% just a little behind it first version MobileNet.

For the other models, ResNet50V2 has about the same number of parameters as ResNet50, while Xception and InceptionV3 have respectively ~24.6m and ~21.9m, but produced modest results. Despite its high number of parameters (55.1m), InceptionResNetV2 is the poorest model in our case study, indicating that deeper networks or more neurons do not always produce the best results.

TABLE I. ACHIEVED RESULTS FOR THE IMPLEMENTED MODELS

Deep Learning Algorithm	Number of parameters	Accuracy	Loss	Precision	Recall
VGG16	14.977.857	99.81%	0.49%	99.77%	99.89%
VGG19	20.287.553	99.78%	0.48%	99.83%	99.78%
InceptionV3	22.852.385	83.23%	37.48%	83.47%	87.21%
ResNet50	24.637.313	99.94%	0.19%	99.94%	99.94%
ResNet50V2	24.614.401	84.89%	34.89%	85.20%	87.68%
Inception ResNetV2	55.124.193	55.19%	68.78%	55.19%	100%
Xception	21.911.081	94.09%	15.54%	94.58%	94.84%
DenseNet	7.562.817	97.50%	6.88%	97.84%	97.62%
MobileNet	3.754.177	97.87%	5.24%	98.02%	98.13%
MobileNetV2	2.914.369	96.28%	9.53%	96.74%	96.47%
NASNetMobile	4.811.413	85.09%	33.14%	84.13%	89.98%

NASNet Mobile is the lightweight model in our case study (~4.8m) it is an edge devices model however its performance is insufficient for our purposes.

Fig. 8 shows predicted image samples that demonstrate that our system can almost perfectly distinguish between fire and normal forest state regardless of all the features and variety of objects (people. snow. different types of trees. etc.). Fig. 9 shows the incorrectly predicted images using the VGG16 and ResNet50 models (these images are collected from the Web and not seen by the model neither in training nor in validation) which can easily explain why the model wrongfully predicted the bad labels. The most likely explanation for the negative results is that they can really deceive the human eye; in the first image the sun and its radiation in the clouds and the lake can be easily misinterpreted as fire because we see the same

features and patterns of flames. In the second and third images our system incorrectly misidentifies fog as fire.

No system is perfect, but these findings show that deep learning can be extremely accurate in detecting wildfires, with a success rate of more than 99.9%. Thanks to its ability to identify the unique signatures emitted by wildfires, this can provide an early warning of a wildfire, allowing fire crews to be dispatched to the scene before it spreads too far. This solution could be a valuable tool for fire departments and other emergency responders in identifying and responding to wildfires.

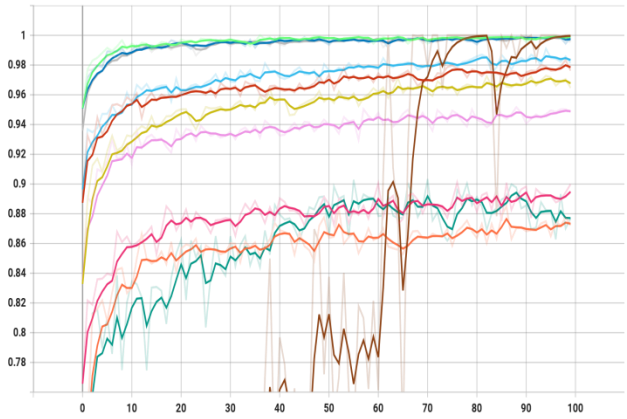

Fig. 7. Achieved Recall (over 100 Epochs) for the Implemented Models.

Fig. 8. Examples of Predicted Wildfires.

Fig. 9. Examples of Wrongly Predicted Wildfires.

In the future, we will deal with the incorrect negative cases, in which the system can be confused between flames and the sun, fog and clouds, and smoke. Furthermore, we will try to

implement these models as the feature extractor backbone in other DL algorithms such as the R-CNN (Region-Based Convolutional Neural Networks) family [43], SSD (Single Shot Detector) [44], or applying YOLO (You Only Look Once) [45], [46] in order to detect not only fires but also its precise coordinates.

VI. Conclusion

Deep learning has revolutionized computer vision by enabling computers to learn from data to recognize patterns and classify objects with high accuracy. This has led to the development of powerful computer vision algorithms and applications that can detect and identify objects in photos and videos with a high degree of accuracy. Our proposed approach in this paper involves building a deep learning model specifically for detecting wildfires in forests using the transfer learning technique. Our discussion based on the obtained results has given us VGG16 and ResNet50 as relevant models for our issue; they are able to achieve higher scores in accuracy, recall and precision of more than 99.9% and a loss down to 0.19% for ResNet50 and down to 0.48% for VGG16. Fire departments and other emergency responders may benefit from these techniques to better identify and control wildfires before they spread too far. Through future works we will try to improve and develop these models by using object detection approaches such as the R-CNN family, SSD and YOLO to identify fires based on their precise location coordinates.

Acknowledgment

This work is supported by the Mohammed First University under the PARA1 Program (Low-cost and real-time Forest Fire Detection System based on Wireless Sensor Networks - SDF-RCSF). The used computational resources of HPC-MARWAN are provided by the National Center for Scientific and Technical Research (CNRST). Rabat. Morocco.

An Enhancement Technique to Diagnose Colon and Lung Cancer by using Double CLAHE and Deep Learning

Nora yahia Ibrahim, Amira Samy Talaat
Computers and Systems Department
Electronics Research Institute, Cairo, Egypt

***Abstract*—The most common and deadly cancers are lung and colon cancers. More than a quarter of all cancer cases are caused by them. Early detection of the disease, on the other hand, greatly raises the probability of survival. Image enhancement by Double CLAHE stages and modified neural networks are made to improve classification accuracy and use Deep Learning (DL) algorithms to automate cancer detection. A new Artificial Intelligent classification system is presented in this research to recognize five kinds of colon and lung tissues, three malignant and two benign, with three classes for lung cancer and two classes for colon cancer, based on histological images. The results of the study imply that the suggested system can accurately identify tissues of cancer up to 99.5%. The use of this model will aid medical professionals in the development of an automatic and reliable system for detecting different kinds of colon and lung tumors.**

***Keywords*—Artificial intelligent system; machine learning; cancer detection; image classification; deep learning**

I. Introduction

Cancer is one of the top causes of death worldwide, according to the Organization of World Health. Autonomous growth, genetic instability, and substantial metastatic potential are acquired by cancer cells. Colon and lung are the most affected organs, with the largest number of deaths. Colon cancer is the major cause of 9.2% of cancer mortality worldwide, while lung cancer is the major cause of 18.4% of all cancer mortality [1, 2]. The combined frequency of colon and lung cancer is estimated to be around 17%. Although this is improbable, cancer cell spread across these two organs is highly common in the absence of early diagnosis [3].

Only effective treatment and early detection can now minimise cancer deaths [4]. The faster a patient is diagnosed, the more effective the treatment and the better the patient's chances of survival and healing.

To search for cancer cells and rule out other probable diseases, many tests are performed, including sputum cytology, imaging sets (CT scan, x-ray), and biopsy (tissue sampling). The examination of microscopic histopathology slides by trained pathologists while performing the biopsy is important in determining the diagnosis [5, 6] and identifying tumour forms and subsets [7]. This study uses just histopathology images to diagnose colon and lung cancers automatically.

Health specialists frequently employ histopathological images for analysis, and they are crucial in determining the survival chances of patients. Usually, health specialists had to go through a lengthy process to diagnose cancer by reviewing histopathological images. However, with the technological tools accessible now, this process may be completed with less time and effort [3]. Artificial intelligence systems have recently gained popularity for their capability to analyze data quickly and give conclusions.

II. Literature Review

In biomedical applications, machine learning techniques are used to predict and classify various types of signals and images. Machines can now deal with large-scale data such as anatomical multidimensional videos and images because of deep learning (DL) methods. Deep learning is a machine learning field that builds algorithms to produce an artificial neural network built on the human brain's structure and function [8]. The majority of previous research used DL to categorise lung and colon cancer images simultaneously. Some writers concentrated on colon cancer detection, while others concentrated on lung cancer detection.

A deep learning-based algorithm is used by Masud [9] to classify colon and lung histological images. They used two types of domain modifications to obtain four image categorization feature sets. They joined the properties of the two categories to arrive at the final categorization result. They were 96.33% accurate. By employing a shallow neural network design, Mangal [10] was able to classify colon and lung cancers based on histological images. In classifying lung and colon malignancies, they reached an accuracy of 97% and 96%, respectively.

Hatuwal [11] proposed a deep learning method based on CNN. In the method, they present samples of only lung tissues from the dataset. This approach could only identify two malignant and one benign tissue in the lung, and no information on colon cancer categorization was given. Their suggested lung tissue categorization model attained an accuracy of 97.20%, a recall of 97.33%, and a precision of 97.33%. Sarwinda [12] suggested a classifier of KNN with characteristics retrieved for colon tissues by a DenseNet-121 pretrained network. Their approach mines the information for colon tissues and distinguishes between benign and malignant tissues of the colon. For colon categorization, their

model achieved 98.53% accuracy and 98.63% recall. Their model, however, was unable to collect lung tissues and provided no information about lung classification. According to Kumar [13], DenseNet-121 extracts more significant characteristics than other CNN pre-trained networks. This is because of the use of small links to improve the accuracy and efficiency of the network. Wang [14] built a Python library based on deep learning to detect cancer image categories. In their proposed strategy, they combined the CNN model and the SVM algorithm. The SVM model's overall accuracy was 94%.

Chehade [15] identifies colon and lung cancer subtypes, and the model of XGBoost offers the best classification rate in terms of recall, accuracy, and precision. XGBoost had a 99% accuracy and a 98.8% F1 score.

Hlavcheva [16] employed convolutional neural networks to analyze medical images using deep learning techniques. The dataset was used to compare the accuracy of several CNN designs in classification. The accuracy of 94.6% was achieved using neural network theory and statistical mathematical methodologies.

The study's primary goal is to develop a medical analytical intelligent support system for colon and lung imaging and, using machine learning, develop an automated method for properly classifying the subtypes of lung and colon cancer from histopathological images so we can achieve high levels of accuracy.

The following is a summary of the contributions of this paper:

- We proposed a novel colon and lung Image classification technique by applying the Image enhancement technique combination of DWT (discrete wavelet transform) and Double-CLAHE (Double Contrast Limited Adaptive Histogram Equalization) in the Preprocessing phase of the image.
- CLAHE is applied twice, first for the low frequency decomposed part of the Image DWT component and after the inverse DWT of the reconstructed image, which makes image details more enhanced.
- We proposed a new hybrid combination of an enhanced image from DWT with Double-CLAHE, EfficientNetB7 Deep learning technique, and adding Modified Neural Network method to fully discover the multi-class deep-broad characteristics of the colon and lung Image dataset.
- The proposed method demonstrates outstanding improvement in the performance for the training and testing datasets and gives a very high classification accuracy of 99.5%.

The following is how the article is organized. Section III discusses the datasets on the colon and lungs. Section IV Methodology with implementation details and results evaluation. Section V of Experimental results, comparisons, and conclusion

III. Dataset on Colon and Lung

The proposed technique is tested using the LC25000 dataset [17], a new colon and lung cancer histopathology image dataset that was published in 2020. This collection, which was put up by Andrew A. Borkowski and his colleagues, has 25000 colour images of five lung and colon tissues of different types [18], namely Benign Colonic Tissue, Benign Lung Tissue, Colon Adenocarcinoma, Lung Squamous Cell Carcinoma, and Lung Adenocarcinoma. Table I shows the details of the dataset as well as the allocated class names.

TABLE I. The Details of the LC25000 Database

Cancer Type	***Name of Category***	***Number of Images***
Colonic _Benign _Tissue	Col_Be	5000
Lung _Benign _Tissue	Lun_Be	5000
Colon _Adenocarcinoma	Col_Ad	5000
Lung _ Carcinoma _Squamous _Cell	Lun_Sc	5000
Lung _Adenocarcinoma	Lun_Ad	5000
Total	5	25000

Adenocarcinoma is the most frequent type of colon cancer, accounting for more than 95% of all cases. When a form of polyp (tissue growth) called an adenoma grows in the large intestine, it becomes an adenocarcinoma and progresses to cancer. Lung adenocarcinoma makes up around 40% of all lung tumors, and it affects more females than males. This form of cancer generally starts in glandular cells and spreads to the lungs' alveoli. All tumours that grow in the colon and lungs are not malignant and do not travel to other regions of the body.

These tumours are classified as benign, and they aren't usually fatal. They must, however, be removed surgically and biopsied to determine if malignancy is present. Lastly, lung carcinoma squamous cell is a type of small cell tumour that arises in the airways or bronchi of the lungs. It is the second most frequent kind of lung cancer, accounting for roughly 30% of all cases. Only 500 images of the colon and 750 images of the lung are included in the original LC25000 dataset. They enlarged the dataset to 25,000 images by using augmentation strategies to flip and rotate the original images under various situations (each class has 5000 images).

The original images were 1024 x 768 pixels in size. However, to make them square, they were resized to 768 x 768 pixels before using the augmentation methods. Sample histopathology images from the LC25000 dataset from these five classes are shown in Fig. 1.

IV. Methodology

This section describes the suggested deep learning-based classification method for colon and lung cancer diagnosis. The Convolutional Neural Network is a method for distinguishing cancers from other cells or tissues that has been shown to be effective [19].

The EfficientNet-B7 network was fine-tuned in this paper to classify colon and lung tumours. Histopathology images are

shown in Fig. 2. The proposed method structure consists of three main stages: image pre-processing with enhancement, EfficientNetB7, and the Modified Neural Network (MNN) stages, as shown in Fig. 2.

EfficientNetB7 takes the resized images from the first stage Fig. 3 to train these images for solving the classification problem. EfficientNetB7 is also used to extract the feature maps of colon and lung cancer histopathology images. However, the MNN takes the extracted feature from the second stage as input and a class label as output.

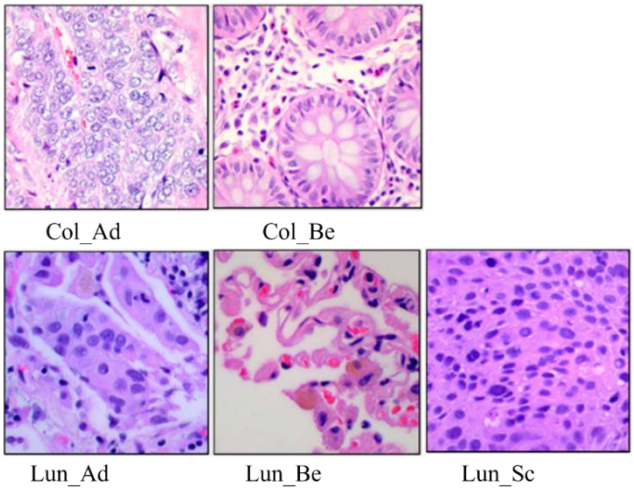

Fig. 1. LC25000 Dataset Sample Images.

The details of the proposed method with MBConv (Mobile Inverted Bottleneck Convolution), the resolution, number of channels, number of levels of each feature map, and the details of the MNN stage are also shown in Fig. 2. In the following subsection, each stage will be described in detail.

A. *Stage of Image Pre-Processing using DWT and Double-CLAHE*

The pre-processing image stage is required before the feature extraction procedure to prepare and clarify the images with labels for training the model.

Blurriness, poor border recognition, artifacts, and overlapping problems in histopathology images were caused by uneven staining of the slide because of human error.

As shown in Fig. 3, The Double-CLAHE approach (Double Contrast Limited Adaptive Histogram Equalization) is intended to eliminate these types of imperfections or uneven staining. The CLAHE method improves image contrast by increasing poor boundary edges in each pixel of an image through restricted amplification [20], as well as improving local contrast in an image. As a result, it's ideal for enhancing the features of histopathological images. This paper proposes a new image enhancing method that combines CLAHE and DWT (Discrete Wavelet Transform). Preprocessing of images in Fig. 2 was done using the DWT and CLAHE approaches in Fig. 3.

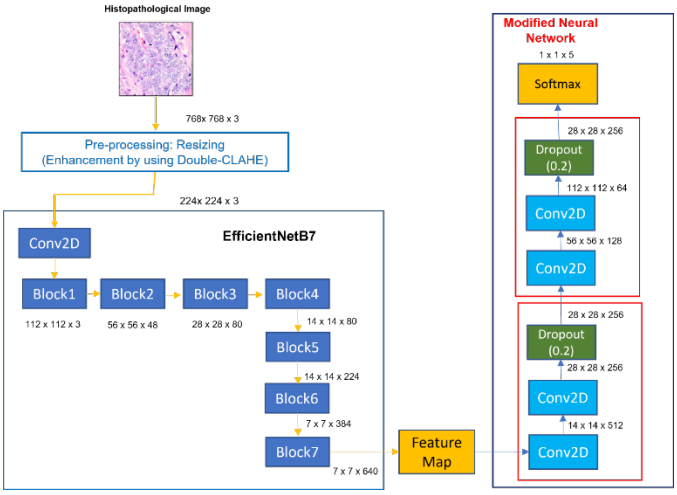

Fig. 2. The Proposed Framework for Image Classification.

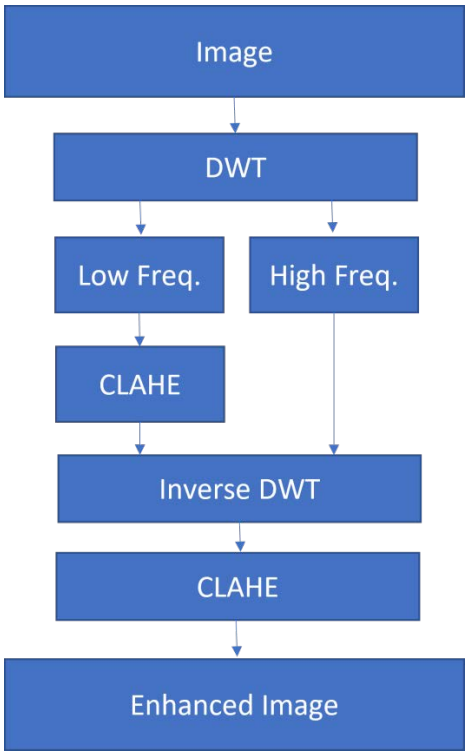

Fig. 3. The Steps of Enhancement by DWT and Double-CLAHE.

The new technique consists of four major steps: The original image is first decomposed into high-frequency and low-frequency components by DWT. The low-frequency values are then boosted by CLAHE while the high-frequency values are left untouched to limit noise amplification. This is because the high-frequency component refers to detailed information and comprises the majority of the original image's noise. Third, reconstruct the image using the inverse DWT of the new coefficients. Finally, after obtaining the reconstructed image, CLAHE is required to enhance the image in order to make the details more abundant.

The colon and lung cancer histopathology images are resized from 768x768 to 224x224 in RGB format to train the suggested model with the dataset.

B. Stage of EfficientNetB7

One of the most powerful CNN structures is EfficientNet. It employs a compound scaling strategy to increase network depth, width, and resolution, resulting in good capacity in a variety of benchmark datasets while using fewer computational resources than other models [21].

EfficientNets come in eight different models, from EfficientNet-B0 to EfficientNet-B7. The simplest model, EfficientNet-B0, is designed automatically by the Neural Architecture Search. Using the compound scaling method, the EfficientNet family is created by scaling up EfficientNetB0. Scaling the network increases model performance by balancing all architecture image resolution, depth, width, and compound coefficients.

Excitation optimization and squeeze in mobile inverted bottleneck convolution (MBConv) [22] is the core of the EfficientNet architecture. Fig. 4 depicts the MBConv concept.

The number of MBConv blocks in the EfficientNet network family varies. The depth, width, resolution, and model size keep increasing as EfficientNetB0 through EfficientNetB7 improve, as well as the accuracy [21]. Efficient-NetB7 exceeds previous CNNs on ImageNet in terms of accuracy, and it is furthermore 6.1x faster and 8.4x smaller than the best available CNN [21]. MBConv is the fundamental building block of the network. The filter size identifies each MBConvX block. It corresponds to X=1 and X=6 which represent the standard ReLU and ReLU6 activation functions, respectively. Fig. 5 depicts the characteristics of the seven blocks' architecture.

Flattening the extracted feature-maps yields a single vector of features once the features are extracted from the dataset images. A Modified Neural Network stage takes this vector as its input.

C. The Modified Neural Network Stage

It is the last stage of the proposed method of the classification process. As clarified in Fig. 2, the Modified Neural Network stage contains four convolution layers, two dropout layers, and a softmax layer. The softmax layer (output layer) of the proposed method is customized with the number of our classes.

The aim of this phase is to add variety to the extracted knowledge and assist it to have a better understanding of the samples, allowing them to be categorized more accurately.

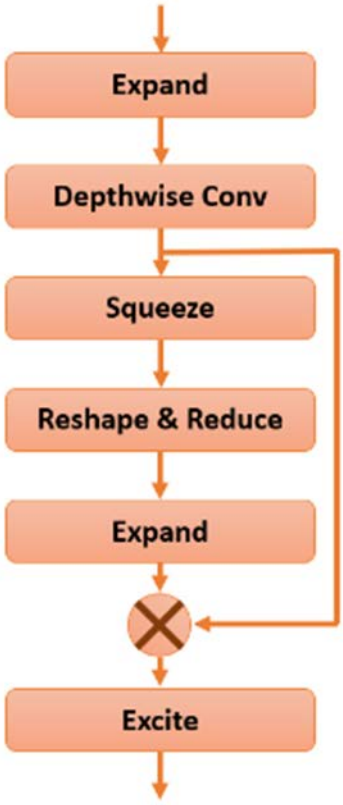

Fig. 4. EfficientNet Basic Building Block (MBConv).

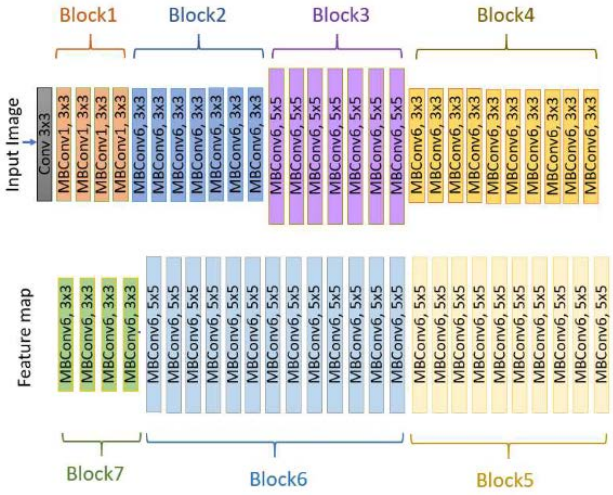

Fig. 5. The Architecture of Block1 to Block 7 of EfficientNetB7.

V. Experimental Results Using

A. The Implemented Details

The obtained outcomes of the implemented experiment are mentioned in this section. The input dataset is split into 85:15, with 85% of the images (randomly chosen) for training and

15% for validating. Because our dataset is balanced (every class contains the same number of images), the system will be less subject to bias while making decisions.

TABLE II. THE IMPLEMENTED DETAILS OF THE PROPOSED CNN MODEL FOR CLASSIFICATION TASK

Variable	***Value***
Image dimensions	224 x 224
Initial channels	3
Dropout	20%
Batch Size	64
Epochs	22
Convolutional layer activation	Relu
Learning rate	0.001
activation of Dense layer	Softmax
Compiler-optimizer	Adam
Compiler-loss	Categorical-cross-entropy

The proposed model was developed using Tensorflow 2.0. As shown in Table II, the system is trained on an image with a size of 768x768 pixels by scaling it to 224x224 pixels, using a batch size of 64 and 22 epochs. For initializing the training, the weights that have been pre-trained by EfficientNetB7 on ImageNet are used, and they are fine-tuned. For training, the ADAM optimizer with a learning rate of 0.001 and a categorical-cross-entropy loss function is utilised. The proposed framework's performance in a classification problem is measured using accuracy, average precision (AP), average recall (AR), and the F1 measure, which will be discussed in the next section.

B. Evaluation of Performance

Machine learning models are evaluated using a variety of criteria. The confusion matrix, as well as associated metric factors like precision, F1-score, accuracy, and recall, are utilized to measure in this paper.

The classifier's accuracy is a measure of its capability to correctly classify instances. It refers to the percentage of valid results or correctly identified samples among all samples.

$$\text{Accuracy}=\frac{TP+TN}{TP+FP+TN+FN} \quad (1)$$

The True Negative, True Positive, False Negative, and False Positive values are represented by TP, TN, FP, and FN, respectively. TP denotes true disease, i.e., the true value is positive, and it is classified positively, indicating that the patient has the disease and that the test is positive.

A false Negative (FN) shows that the patient has the disease while the test is negative, suggesting that the real value is positive but the classification is negative. A False positive (FP) denotes the presence of a disease when none exists, implying that the real value is negative when classed positively. A True Negative (TN) denotes that the patient is healthy and the test is negative, signifying that the true value is negative, and the test is negative.

Precision is denoted as the proportion of correctly identified samples (true positives) to positive samples identified.

$$\text{Precision}=\frac{TP}{TP+FP} \quad (2)$$

Recall is the percent of positive samples of a specific class that are accurately identified. The proportion of real positive samples to total positive samples is used to compute it.

$$\text{Rec}all=\frac{TP}{TP+FN} \quad (3)$$

The F1-score is known as the harmonic average of accuracy and recall.

$$\text{F1-score}=\frac{2\times Precision\times Recall}{Precision+Recall}$$

C. Results

The outcome of the proposed framework for the classification of colon and lung cancer histological images is shown in this section. To determine their performance, the models were evaluated using test data.

Fig. 6 shows the proposed model's each epoch classification accuracy. The experiment has 22 epochs in all. The classification accuracy on the testing subset was 99.36% at the last epoch; however, the greatest results were at epochs 12, 13, and 14, all of which had a 99.47% accuracy. The training accuracy curve increased gradually and almost steadily towards the top, as shown in the figure.

At epoch number 18, the greatest training accuracy was 99.5%, which is quite similar to the accuracy of the previous epoch 99.36%. The curve of testing accuracy is similar to the training accuracy curve, with the outcome improving as the training progresses. At 20 epochs, the curve drops to 96.7%, indicating that the model is able to give a satisfactory classification result even if it is constructed with fewer epochs.

Fig. 7, on the other hand, shows the training and validation loss, which represents the percentage of data loss for each classification attempt.

As seen in Fig. 7, both the training and validation subsets' loss values decreased as the number of epochs grew.

The normalized (ROC) Receiver Operating Characteristic and confusion matrix curves of the testing subset classification at the 18th epoch are shown in Fig. 8. For the test data given labelled categories, the confusion matrix compares the images' true labels against their predicted labels. Only 3% (112 samples) of the testing images (3750 samples) were misclassified, as shown by the normalized confusion matrix.

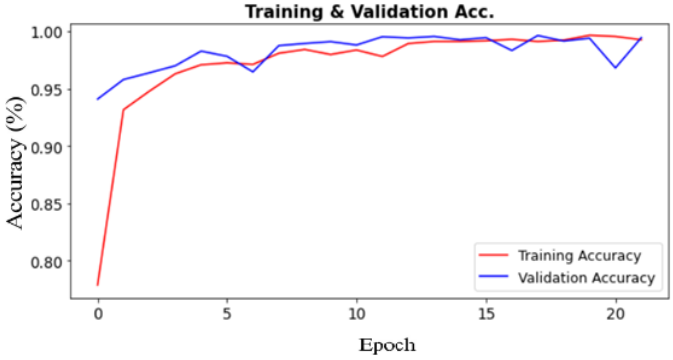

Fig. 6. The Visual Display of the Accuracy Rate of the Proposed Classification Model at Each Epoch.

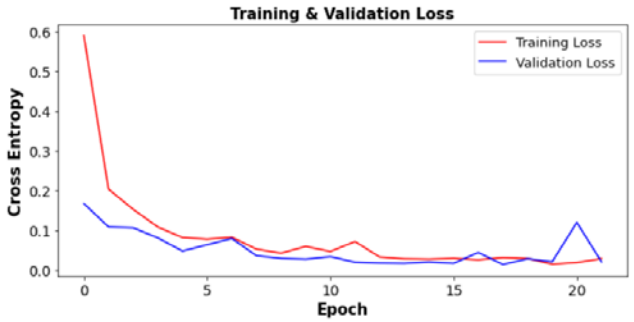

Fig. 7. The Proposed Classification System's Optimal Training and Validation Loss.

The best classification results are in the Col_Be and Lun_Be categories, while the other categories, Lun_Ad, Col_Ad, and Lun_Sc, have the same misclassification rate. These results can also be seen in the ROC curves.

Because the classifier was quite successful at separating the samples, the Lun_Be and Col_Be curves have reached the top-left corner. Overall, the suggested deep learning approach is highly precise in classifying these classes.

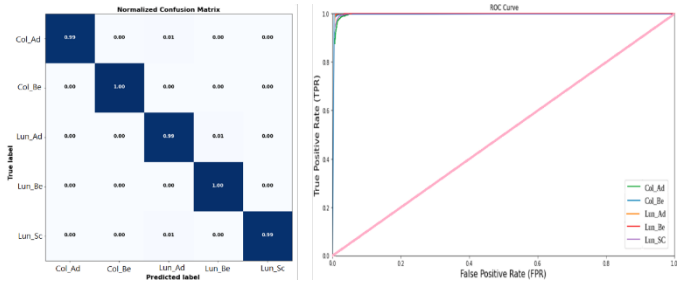

Fig. 8. Representations of Classification Results: (a) Normalized Confusion Matrix (b) Epoch 18th ROC Curve.

Table III displays the recall, F1-score, and precision of the proposed classification model on the test data for five classes of histological images. Table III shows that the average recall, precision, and F1-score for each of the five categories is more than 0.994. In addition, except for Lun_Sc, our classification approach attained the highest precision in all classes.

TABLE III. THE RECALL, PRECISION, AND F1-SCORE FOR HISTOLOGICAL IMAGES OF COLON AND LUNG CANCER

Categories	*Precision*	*Recall*	*F1-score*
Col_Ad	**1.00**	0.995	**1.00**
Col_Be	**1.00**	**1.00**	**1.00**
Lun_Ad	**1.00**	0.98	0.99
Lun_Be	**1.00**	**1.00**	**1.00**
Lun_Sc	0.98	**1.00**	0.99
Average	0.996	0.994	0.996

D. Comparison

We compare our model to current models in the literature, which are given in the introduction, to evaluate the proposed method. Table IV compares the results of the lung and colon cancer subtype classification with other approaches using the same dataset. As shown in Table IV, our system outperforms existing cancer detection technologies in terms of maximal classification accuracy.

TABLE IV. COMPARISON OF THE RESULTS FOR THE SAME DATASET WITH OTHER METHODS

E. Conclusion and Future Work

A deep learning technique is presented in this paper to classify images and will help us detect colon and lung cancer more precisely in the future. For this study, we utilised a histopathology image dataset that is freely accessible on Kaggle [17]. The model training accuracy achieved is 99.5% for the colon and lung dataset.

This paper proposed a method for colon and lung cancer classification problems. The method has two main sections: the enhancement of images by DWT and Double-CLAHE stages; and the modified neural network to enhance classification accuracy.

The result shows that: accuracy 99.5%, precision 99.6%, recall 99.4%, and F1-score 99.6%, which proves that the presented method is effective for solving colon and lung cancer classification problems. It also outperforms the previous approaches in terms of performance.

The optimized method that provided improved accuracy must be used in upcoming models. In the future, combining YOLO, 3D-CNN, and a variety of other approaches that are applied to various image datasets will allow us to construct more powerful and effective models in the future.

***Abstract*—A health crisis caused by the SARS-CoV-2 virus is still ongoing. That is why an important factor for the resumption of on-site classes is the creation of sanitary measures to help control Covid-19. The present research is a literature review, The PRISMA methodology is used and 265 articles are collected from various databases such as EBSCO Host, IEEE Xplore, SAGE, ScienceDirect, and Scopus. According to the inclusion and exclusion criteria, the most relevant articles aligned to the topic were identified, systematizing 119 articles. Showcasing digital technologies used in mobile applications that allow better control, tracking, and monitoring of the health status of students, teachers, and staff of educational centers, in addition to the parameters and quality attributes that must be taken into account for the effective sanitary control of the disease, finally, a development model is proposed.**

***Keywords*—Mobile application; sanitary control; systematic review; digital technologies**

I. Introduction

Covid-19 is caused by the severe acute respiratory syndrome called SARS-CoV-2. One of its most common symptoms is a lung infection or pneumonia [1]. Covid-19 is an epidemic that has spread rapidly throughout the world. That is why we must be alert to information on how to take care to prevent contagion [2]. The World Health Organization declared the coronavirus (Covid-19) a pandemic on March 11, 2020. Making all countries take preventive measures against the emerging Covid-19 virus [3].

Due to the distancing measures by Covid-19, education went from being face-to-face to virtual, therefore, schools, universities, and institutes closed their doors, and teachers and students had to adapt to the use of technological tools, making way for e-learning [4], [5].

Another very important area in which Covid-19 has had an impact has been in the area of life and mental health [6]. The impact was greater on students, as there were school closures, fear generation due to Covid-19, the interruption and change of modality in education, and the excessive use of digital devices. These factors have caused students to suffer from mental health problems such as stress, anxiety, depression, and sleep disorders during the quarantine period. With the vaccines, it was possible to reduce the mortality rate of the disease, and eventually return to face-to-face teaching in schools, so it is important to know the best digital technologies used for the control and monitoring of the virus.

The objective of this literature review is to analyze articles in order to have a better understanding of the problem, that is, to know which technologies, parameters, and quality attributes were used to have better sanitary control against Covid-19 in educational centers, as well as to identify the countries with more experiences in this field. Section II shows the methodology used in the search and selection of articles, Section III shows the results obtained through graphs and tables, Section IV the discussion in which the research questions posed are answered, and Section V shows the proposed model to be followed in future research, to finally write in Section VI the conclusions of the research.

II. Methodology

The methodology used consisted of three steps. First, the PRISMA methodology was used [7] (Preferred Reporting Items for Systematic Reviews and Meta-Analyses of Preferred reporting elements for systematic reviews and meta-analyses) which helped to find and identify the most appropriate articles for the present literature review. Second, bibliometric analysis was used to find the common terms that influence the disclosure of the implementation of health surveillance against Covid-19 in schools using digital technology. Finally, the most important factors and statistical methods used for the implementation of a sanitary control against Covid-19 in educational centers are extracted and related to the results of the bibliometric analysis.

Following the PRISMA methodology [7], this section is structured as follows: (1) Type of study, (2) Research questions, (3) Search strategy, and (4) Inclusion and exclusion criteria.

A. Type of Study

A systematic review of the literature will be used to prepare the article.

B. Research Questions

The proposed research questions are as follows:

RQ1. Which digital technologies allow better control, follow-up, and monitoring against Covid-19 of the health status of students, teachers, and staff in educational centers?

RQ2. What parameters should be taken into account to make effective sanitary control against Covid-19 in educational centers through the use of a mobile application?

RQ3. What quality attributes must it contain for the viability of the mobile application for the implementation of a health control against Covid-19 in educational centers?

RQ4. Which countries have the most research, in the last three years, related to health monitoring against Covid-19 in schools?

C. Search Strategies

To answer the research questions, a search for published articles was conducted in the main databases EBSCO Host, IEEE Xplore, SAGE, ScienceDirect, and Scopus. A total of 265 scientific articles were collected.

At the time of applying the search for our research, the following keywords were considered: "Covid-19" AND ("health control in schools" OR "in the schools" OR "using mobile application" OR "health control in schools app" OR "in the schools using mobile application" OR "prevention and control in schools"), "mobile application for" AND ("prevent Covid-19" OR "control in schools during Covid-19" OR "Covid-19 health control in schools" OR "prevent Covid-19" OR "the school to prevent Covid-19"), "app mobile for" AND ("health" OR "Covid-19" OR "Covid-19 in the schools"), "app mobile for Covid-19 in schools", "app control of Covid-19 in schools" y "control of Covid-19 in schools". The item collection process is shown in Fig. 1.

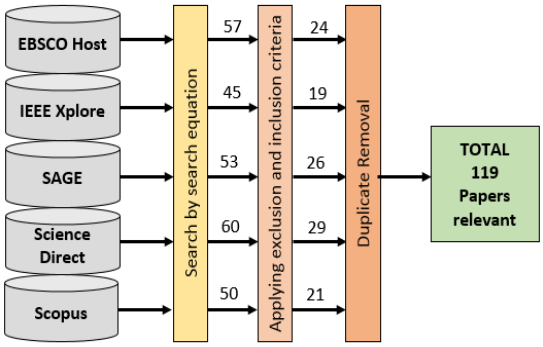

Fig. 1. Item Inclusion Chart.

D. Inclusion and Exclusion Criteria

For the systematic review study, the following inclusion and exclusion criteria were applied, as shown in Table I.

TABLE I. INCLUSION AND EXCLUSION CRITERIA

CRITERIA		
Inclusion	I01	Articles related to digital technologies for Covid-19 preventive control.
	I02	Articles published since the start of Covid-19 2019 – 2022.
	I03	Articles that consider at least one prevention parameter against Covid-19.
Exclusion	E01	Articles not related to digital technologies for preventive control against Covid-19.
	E02	Articles published before 2019.
	E03	Articles related to Covid-19 but do not make use of digital technologies.

III. RESULTS

A total of 265 articles found in the databases related to the research topic were analyzed, of which two duplicate articles were discarded or did not contribute similar topics. After reviewing the articles, 119 were selected, excluding 144 according to the exclusion criteria and which did not contribute to answering the research question. Obtaining 119 articles for the systematic review. Fig. 2 shows the selection process following the Prisma methodology.

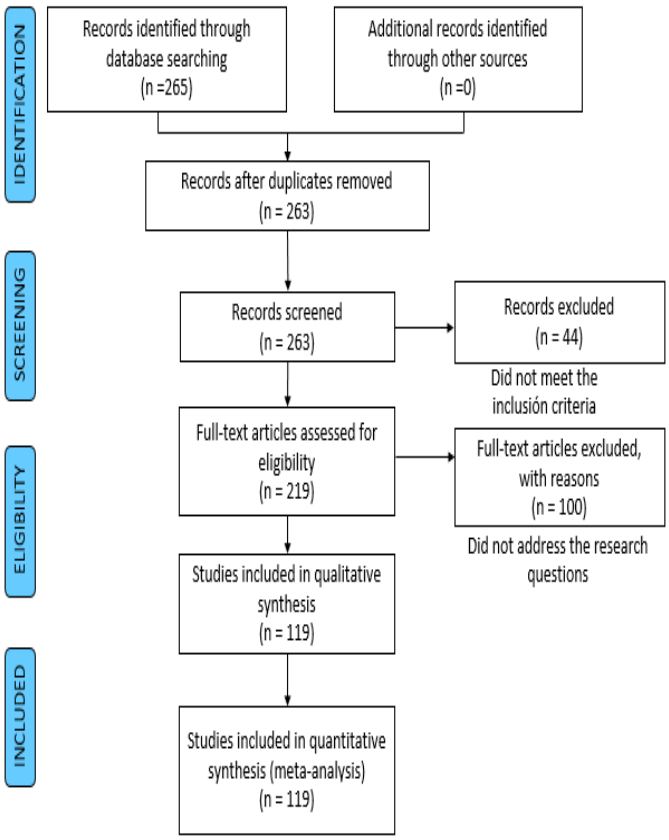

Fig. 2. PRISMA Diagram Methodology.

Fig. 3 shows the number of articles found by the database.

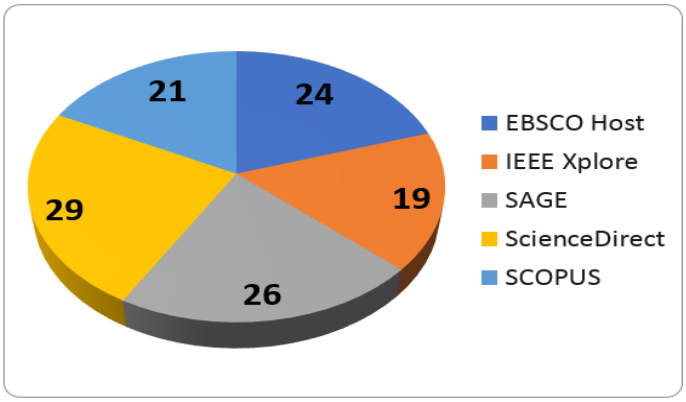

Fig. 3. Articles by Database.

Fig. 4 shows the number of articles published by year and database, selected in times of pandemic.

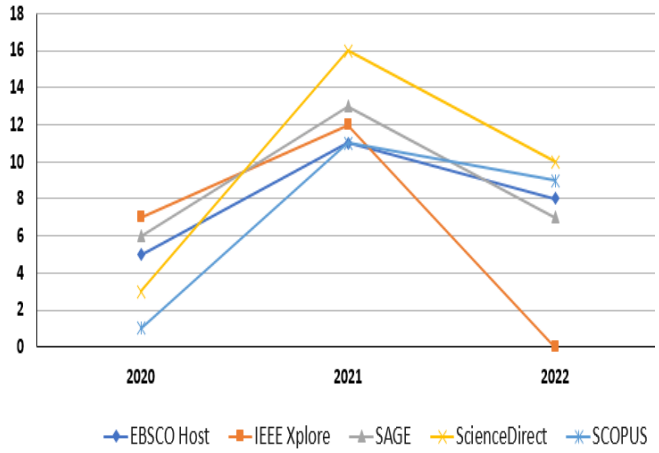

Fig. 4. Articles by Year and Database.

Fig. 5 shows the number of articles published by continent.

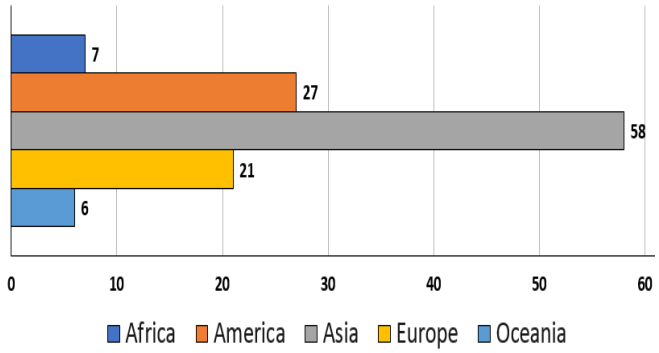

Fig. 5. Articles by Continent.

The number of articles published by country is shown in Fig. 6 on a scale from 1 to 17.

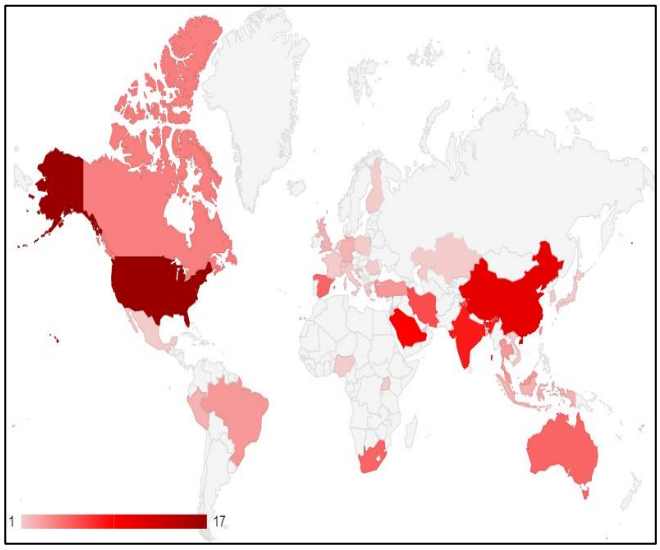

Fig. 6. Articles by Country.

Fig. 7 shows the network visualization based on a bibliometric analysis filtered by keywords, using the VOSviewer software.

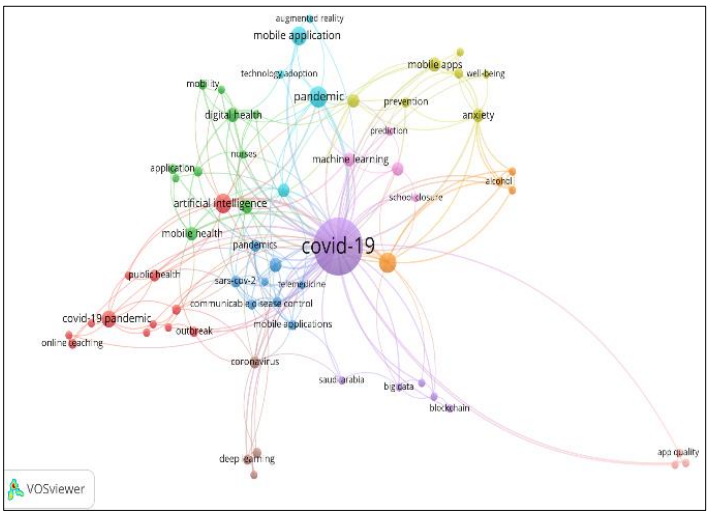

Fig. 7. Network Visualization of Bibliometric Analysis.

Fig. 8 shows the analysis of bibliometric data considering the year of publication of each article.

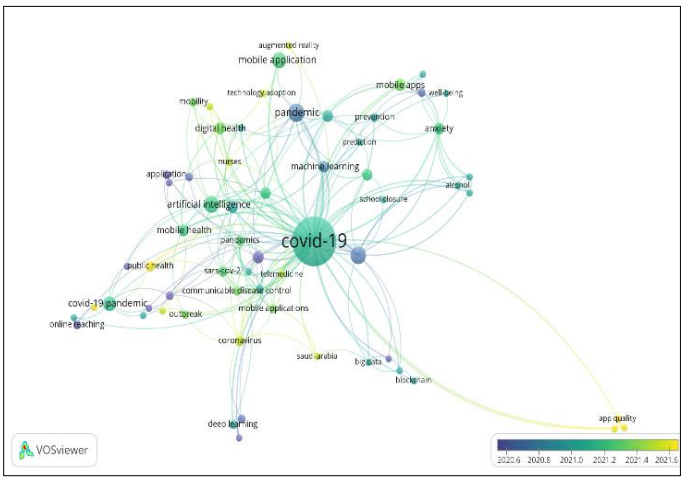

Fig. 8. Overlay Visualization of Bibliometric Analysis

It was in 1926 when Alfred Lotka introduced the term "bibliometrics" by analyzing the production patterns of different authors, concluding with the presentation of the first criteria for bibliometrics [8]. Bibliometrics is part of scientific research, as time goes by scientists become interested in this field and even academic institutions use it in their research work. It is a very effective technique to retrieve, evaluate and analyze, in a statistical way, quantifiable data in the academic literature, merits of a particular thematic area, or a particular publication containing indicators to obtain a better evolution of the research direction. Bibliometric analysis is expected to contribute to filling gaps in the research field, provide new perspectives for future research and promote collaboration [9].

VOSviewer is a software tool that allows us to construct and visualize bibliometric networks (including individual publications, authors, and scientific journals); it is constructed from co-authorship relationships, co-citation, bibliographic coupling, citation networks, and co-occurrence of important terms extracted from a body of scientific literature [10].

VOSViewer was used to obtain networks based on co-occurrences of important terms, from which visualization maps were created as shown in Fig. 7, Fig. 8, and Fig. 9.

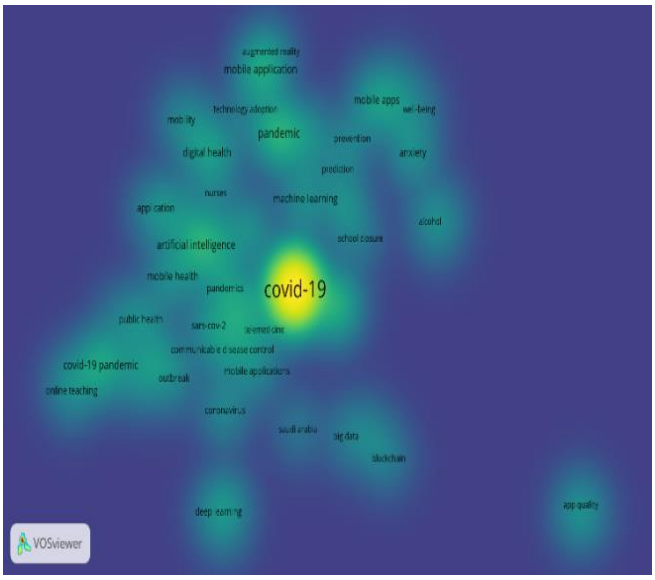

Fig. 9. Visualization of Density of Bibliometric Analysis.

In Fig. 9 it can be observed that Covid-19 is the most important term co-occurrence of all cited articles, such term co-occurrence is aligned to the present literature review. It is also observed that artificial intelligence and mobile application are the digital technologies with the highest term co-occurrence in relation to all cited articles.

After performing the bibliometric analysis, sixty-three (63) items were generated, grouped into ten (10) clusters shown in Table II. Finally, the clusters and their respective items were identified using the network visualization of the bibliometric analysis (Fig. 7), segmenting the clusters by their specific colors:

- Cluster 1 is colored magenta, "artificial intelligence".
- Cluster 2 is green, "application".
- Cluster 3 is colored blue, "pandemics".
- Cluster 4 is mustard-colored, "mental health".
- Cluster 5 is colored purple, "covid-19".
- Cluster 6 is light blue, "mhealth".
- Cluster 7 is colored orange, "mobile app".
- Cluster 8 is salmon-colored, "coronavirus".
- Cluster 9 is colored fuchsia, "machine learning".
- Cluster 10 is colored pink, "app quality".

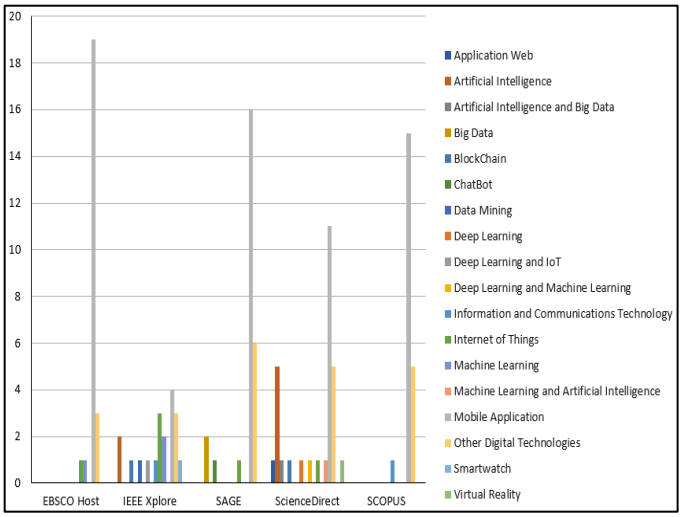

Fig. 10. Articles by Database and Digital Technologies.

Table III shows the digital technologies of the articles according to the results found.

TABLE III. CLASSIFICATION OF ARTICLES ACCORDING TO THE RESULTS OBTAINED

DIGITAL TECHNOLOGIES	ARTÍCLE
Application Web	[11]
Artificial Intelligence	[12]–[18]
Artificial Intelligence and Big Data	[19]
Big Data	[20], [21]
BlockChain	[22], [23]
ChatBot	[24]
Data Mining	[25]
Deep Learning	[26]
Deep Learning and IoT	[27]
Deep Learning and Machine Learning	[28]
Other Digital Technologies	[29]–[50]
Information and Communications Technology	[51], [52]
Internet of Things	[53]–[59]
Machine Learning	[60]–[62]
Machine Learning and Artificial Intelligence	[63]
Mobile Application	[64]–[126]
Smartwatch	[127]
Virtual Reality	[128]

Table IV shows the classification of articles according to the results found.

TABLE IV. CLASSIFICATION OF ITEMS ACCORDING TO CATEGORIES AND TOPICS OF FUNCTIONALITY

THEMES AND FUNCTIONALITY	REFERENCES
This article argues that the web pages allow informing about Covid-19, making it possible for the reader to become duly aware in order to have better sanitary control against Covid-19.	[11]
These articles argue that artificial intelligence allows a better study of the situation in order to achieve better health control against Covid-19.	[12]–[18]
This article argues that the use of artificial intelligence and Big Data make it possible to analyze a large amount of data in order to predict future Covid-19 scenarios and patterns, thus obtaining better health control against Covid-19.	[19]
These articles argue that the use of Big Data makes it possible to analyze a large amount of data in order to make a decision about Covid-19 and obtain better sanitary control against Covid-19.	[20], [21]
These articles argue that the use of the Block Chain makes it possible to share immutable data from medical research against Covid-19 and also to avoid misinformation, achieving better health surveillance against Covid-19 based on accurate information.	[22], [23]
This article argues that the use of ChatBots makes it possible to diagnose Covid-19 based on already defined questions, also, they can fulfill the role of informing to obtain better health control against Covid-19, based on truthful information.	[24]
This article argues that the use of data mining provides accurate information about a query, helps to have real statistics about Covid-19 allowing better health control Covid-19.	[25]
This article argues that the continuous use of Deep Learning makes it possible to refine it to anticipate responses and/or actions in certain scenarios in which Covid-19 is simulated, thus achieving better health control.	[26]
This article argues that the combination of Deep Learning with IoT opens up the possibility of creating intelligent objects that are refined according to their use, the IoT would be responsible for storing data while Deep Learning interprets it, obtaining tools that help health control against Covid-19.	[27]
This article argues that the combination of Deep Learning with Machine Learning opens the way to more accurate results as the algorithm to be used will adapt and learn to give us results that will help us to have better health control against Covid-19.	[28]
These articles argue that effective health control against Covid-19 requires the use of digital technologies.	[29]–[50]

THEMES AND FUNCTIONALITY	REFERENCES
These articles argue that ICTs play a very important role in helping us to have quick and easy access to global information and in times of pandemics they were of great help in promoting better health control against Covid-19.	[51], [52]
These articles argue that the use of the internet of things allows the development of new technologies, and, also, to rely on them, opening the way to telemedicine in times of pandemic, and obtaining better health control against Covid-19.	[53]–[58]
These articles argue that the application of Machine Learning, in the context of the topic, makes it possible to find patterns of Covid-19 infections and thus predict them in order to have better health control against Covid-19.	[60]–[62]
This article argues that the combination of Machine Learning and artificial intelligence opens the way to machines capable of learning on their own, in the present context, making possible the creation of robots that serve to monitor patients with Covid-19, thus avoiding contact with other human and the risk of contagion, achieving a better health control against Covid-19.	[63]
These articles argue that mobile applications are very useful because having an application related to Covid-19 allows us to be informed, consult and even monitor to achieve better sanitary control against Covid-19.	[64]–[126]
This article argues that the Smartwatch enables the detection of Covid-19 in the wearer as it can monitor heart rate and body temperature for diagnosis, thus achieving better health control of Covid-19.	[127]
This article argues that the use of virtual reality opens the way to being able to simulate Covid-19 patients and even scenarios to evaluate future decision-making in order to obtain a better health management of Covid-19.	[128]

Fig. 11 shows the number of selected items grouped by database and parameter.

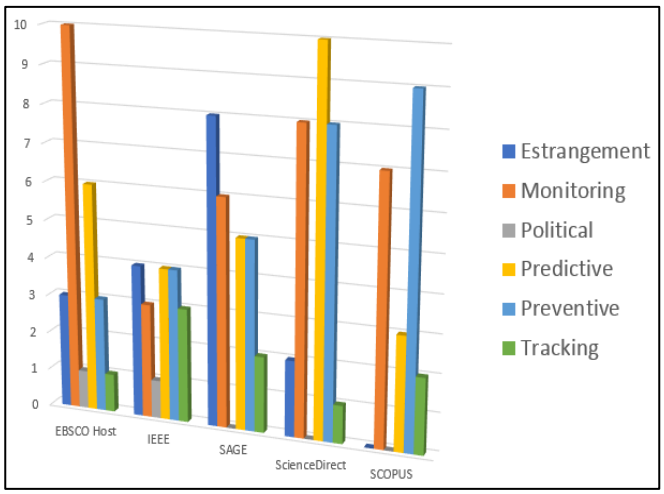

Fig. 11. Articles by Database and Parameter.

Table V shows the parameters of the articles according to the parameters found.

TABLE V. CLASSIFICATION OF ITEMS ACCORDING TO THE PARAMETERS OBTAINED

PARAMETERS	ARTÍCLES
Estrangement	[29]–[32], [51], [53], [54], [64]–[72], [127]
Monitoring	[12], [24], [27], [33]–[35], [52], [73]–[88], [90], [92]–[97], [129]–[132]
Political	[13], [98]
Predictive	[14]–[17], [19], [25], [26], [37]–[41], [60], [61], [63], [99]–[102], [104]–[109], [128], [133]
Preventive	[11], [20]–[22], [28], [42]–[47], [56]–[58], [110]–[122], [134]
Tracking	[18], [23], [49], [50], [123]–[126], [135]

Table VI shows the classification of articles according to the results found.

TABLE VI. CLASSIFICATION OF ITEMS ACCORDING TO PARAMETERS AND FUNCTIONALITY ISSUES

THEMES AND FUNCTIONALITY	REFERENCES
These articles take into account the parameter of distancing as they focus on creating strategies, and making use of technology, for the prevention of Covid-19, in scenarios where there is no rapprochement of individuals.	[29]–[32], [51], [53], [54], [64]–[72], [127]
These articles take into account the monitoring parameter as they focus on creating mobile applications and strategies based on Machine Learning, Deep Learning, and Artificial Intelligence since they can be monitoring an area where there was Covid-19 and even monitor the relationship between individuals and Covid-19.	[12], [24], [27], [33]–[35], [52], [73]–[88], [90], [92]–[97], [129]–[132]
These articles take into account the policy parameter as they encourage the use of technological tools in daily life and work so that, in times of pandemic, we adapt to study and work virtually, they also argue to consider very seriously the measures demanded by governments, to prevent Covid-19.	[13], [98]
These articles take into account the prediction parameter as they analyze data and facts, with the help of technological tools and Artificial Intelligence, making it possible for them to predict where Covid-19 could reemerge or if a community is about to suffer from it.	[14]–[17], [19], [25], [26], [37]–[41], [60], [61], [63], [99]–[102], [104]–[109], [128], [133]
These articles take into account the prevention parameter since they postulate measures, with the help of technological tools and Artificial Intelligence focusing on events that have already occurred, against Covid-19 to reduce contagion or a new outbreak.	[11], [20]–[22], [28], [42]–[47], [56]–[58], [110]–[122], [134]
These articles take into account the traceability parameter since they are based on following people or societies that have already suffered from Covid-1toto collect data and avoid possible Covid-19 infections.	[18], [23], [49], [50], [123]–[126], [135]

Fig. 12 shows the number of selected items grouped by database and quality attributes.

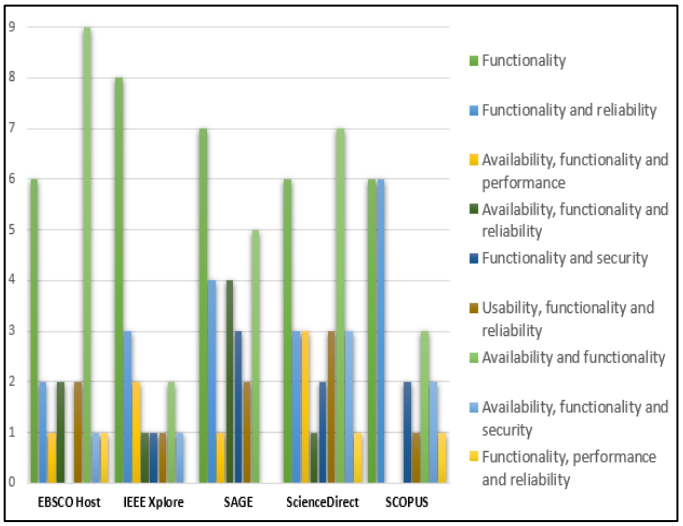

Fig. 12. Items by Database and Quality Attributes.

Table VII shows the quality attributes of the items according to the quality attributes found.

TABLE VII. CLASSIFICATION OF ARTICLES ACCORDING TO THE QUALITY ATTRIBUTES OBTAINED

QUALITY ATTRIBUTES	ARTÍCLES
Availability and functionality	[12], [25], [30], [31], [34], [35], [38], [48], [56], [63], [69], [74], [77], [79], [82], [88], [92], [105], [112], [115], [117], [120], [128], [133], [136]
Availability, functionality, and reliability	[24], [40], [66], [73], [80], [87], [100], [114]
Availability, functionality, and performance	[11], [16], [29], [46], [62], [86], [110]
Availability, functionality, and security	[37], [44], [58], [64], [95], [122], [137]
Functionality	[14], [15], [23], [27], [28], [32], [36], [39], [43], [45], [47], [49], [51], [55], [57], [60], [61], [65], [71], [72], [75], [81], [83], [90], [97], [101], [102], [108], [116], [119], [124], [138], [139]
Functionality and reliability	[17], [19], [20], [26], [41], [52], [53], [67], [68], [76], [94], [96], [99], [104], [109], [121], [123], [127]
Functionality and security	[18], [21], [22], [50], [54], [70], [125], [126]
Functionality, performance, and reliability	[107], [113]
Usability, functionality, and reliability	[33], [78], [84], [85], [89], [93], [106], [111], [118]

Table VIII shows the classification of articles according to the results found.

TABLE VIII. CLASSIFICATION OF ITEMS ACCORDING TO QUALITY ATTRIBUTES AND FUNCTIONALITY ISSUES

THEMES AND FUNCTIONALITY	REFERENCES
These articles take into account the quality attributes of availability and functionality, mentioning that these quality attributes are the priorities for the development of effective and viable software for sanitary control against Covid-19.	[12], [25], [30], [31], [34], [35], [38], [48], [56], [63], [69], [74], [77], [79], [82], [88], [92], [105], [112], [115], [117], [120], [128], [133], [136]
These articles take into account the quality attributes of availability, functionality and reliability, taking into account this, it will be possible to develop software for sanitary control against Covid-19 with high-quality standards.	[24], [40], [66], [73], [80], [87], [100], [114]
These articles take into account the quality attributes of availability, functionality and performance, which would serve to develop software with the necessary functions to solve the problems presented by Covid-19.	[11], [16], [29], [46], [62], [86], [110]
These articles take into account the quality attributes of availability, functionality, and security, since the development of software that is ready for use at any time, works as designed, and contains a level of resistance to be breached, would be completely viable to combat Covid-19.	[37], [44], [58], [64], [95], [122], [137]
These articles take into account the quality attribute of functionality since they consider that it is the main quality attribute for the software to be able to perform the functions for which it was programmed or developed, being highly effective in time of pandemic by Covid-19.	[14], [15], [23], [27], [28], [32], [36], [39], [43], [45], [47], [49], [51], [55], [57], [60], [61], [65], [71], [72], [75], [81], [83], [90], [97], [101], [102], [108], [116], [119], [124], [138], [139]
These articles take into account the quality attributes of functionality and reliability since a software must fulfill the functions for which it was created, but also that software must remain operational over time, these requirements are perfectly aligned to address the problems that Covid-19 is presenting.	[17], [19], [20], [26], [41], [52], [53], [67], [68], [76], [94], [96], [99], [104], [109], [121], [123], [127]
These articles take into account the quality attributes of functionality and security since they emphasize that all software must do the job for which it was developed and, nowadays, all software must have a decent degree of security since the Covid-19 pandemic has increased the rate of cybercrime.	[18], [21], [22], [50], [54], [70], [125], [126]
These articles take into account the quality attributes of functionality, performance, and reliability, they mention these quality attributes because they consider that software must perform its functions correctly with speed and accuracy, being able to operate with a large amount of data, such as the data generated by the Covid-19 pandemic, without having a long waiting time.	[107], [113]
These articles take into account the quality attributes of usability, functionality, and reliability, since a viable and effective software that is focused on the study of Covid-19, must be simple and understandable for all audiences, with correctly programmed and operational functions.	[33], [78], [84], [85], [89], [93], [106], [111], [118]

IV. DISCUSSION

This systematic literature review is intended to answer the following questions.

RQ1. What digital technologies allow for better control, follow-up, and monitoring of the health status of students, teachers, and staff in educational centers against Covid-19?

According to Fig. 10, it can be seen that the articles related to the present topic in question use the digital technologies of; Mobile Application, Artificial Intelligence, Other Digital Technologies, etc. This result indicates that these technological categories allow sanitary control against Covid-19.

According to Table III, and commenting on it in Table IV, it can be seen that the digital technologies related to the present topic use the digital technology of "Mobile Application". This result indicates that this digital technology is one of the most used in allowing to have sanitary control against Covid-19 and is aligned to today's technological era, where we all use a mobile device.

RQ2. What parameters should be taken into account to make effective sanitary control against Covid-19 in educational centers through the use of a mobile application?

According to Fig. 11, it can be seen that the articles related to this topic use the technology of distancing, monitoring, policy, prediction, prevention, and tracking. This result indicates that these parameters allow sanitary control against Covid-19. According to Table V, and commenting on it in Table VI, it can be seen that the parameters related to the present topic use the "Monitoring" parameter. This result indicates that this parameter is one of the most used in allowing sanitary control against Covid-19 since constant monitoring makes possible the collection of data and its subsequent analysis.

RQ3. What quality attributes must it contain for the viability of the mobile application for the implementation of a sanitary control against Covid-19 in educational centers?

According to Fig. 12, it can be seen that the articles related to the present topic use the quality attributes; functionality, availability and functionality, functionality and reliability, etc. This result indicates that these quality attributes allow the creation of an effective software directed to have sanitary control against Covid-19.

According to Table VII, and commenting on it in Table VIII, it can be seen that the parameters related to the present topic use the "functionality" parameter. This result indicates that this quality attribute is one of the most used in allowing sanitary control against Covid-19 since this attribute focuses on the ability of the system to perform the task for which it was developed.

RQ4. Which countries have the most research, in the last three years, related to health monitoring against Covid-19 in schools?

According to Fig. 5, it can be seen that the articles related to this topic come from the continents of Asia, America, and Europe (from highest to lowest). This result indicates that there is a greater knowledge of the technologies related to sanitary control of Covid-19.

According to Fig. 6, it can be seen that the articles related to this topic come mostly from the United States and China. This result indicates that there is more experience in sanitary control against Covid-19 in these countries.

V. Proposed Model

The following is a proposed model based on mobile applications for the implementation of sanitary control against Covid-19 in educational centers, aligned with the data collected from the articles related to the present topic (Fig. 13). The proposed model is related to the article [140]. In Fig. 12 we can see the proposed model, which includes the phases of the data set: It is the literature systematization of all articles found related to the topic and complying with the standards of the article inclusion chart (Fig. 1) and the inclusion and exclusion criteria (Table I). In the ideal characteristics of the mobile applications for the implementation of sanitary control against covid-19 in educational centers, three main characteristics have been taken into account, which are:

Additional digital technologies: After systematizing the literature, we were able to identify, according to Fig. 10 and commenting on it in Tables III and IV, the additional digital technologies that are most used at the time of the development of a mobile application for the implementation of a sanitary control against Covid-19. Beginning to order them by their level of use (except for mobile applications and digital technology), in the first instance we have artificial intelligence because the additional technology mentioned would allow a better study based on complex algorithms which would be interpreted by the machines making more effective the functions of the mobile application. In the second instance, we have the internet of things since the implementation of communication between the mobile application and the intelligent sensors of the mobile device would make the mobile application more complete and could use data provided by the user himself, such as his location via GPS his daily steps or speed of movement through the accelerometer.

Parameter: Another ideal characteristic for the development of an effective and viable mobile application is the parameter on which it will be based. In the present systematic review of the literature, the parameters on which the cited articles were based to obtain a better sanitary control against Covid-19 were identified according to Fig. 11 and commented in Table V and VI. It was evident that the most used parameter was monitoring, since it allows collecting, studying, and analyzing the information obtained for a constant follow-up, i.e. it will be possible to analyze the information of patients or communities where there was Covid-19 to identify symptoms of the virus, precedents and even to identify where it could outbreak, Following this parameter, it would be possible to have a better sanitary control against Covid-19 since it would be evaluating, in every certain period, the health avoiding contagions, identifying possible resurgence and possible people prone to contract Covid-19, currently, the mobile device would be aligned to support itself in the monitoring to give more accurate results of an individual diagnosis and that would be thanks to the sensors contained in each mobile device. The second most used parameter is preventive since its main objective is to reduce future Covid-19 infections, that is to say,

to study real, truthful, and reliable data so that later they can carry out a better control against Covid-19, besides, with the help of technology and the creation of software and apps, more accurate data could be obtained to identify the infected areas, obtaining, as a result, an alert in that area, achieving to reduce infections or a new outbreak.

Quality attributes: Finally, we have identified a third and last ideal characteristic. When the systematization of the literature was done, quality attributes were identified to reach the development of a mobile application for the implementation of sanitary control against Covid-19. According to Fig. 12 and comments in Tables VII and VIII, the most frequent quality attribute is the functionality, since it allows the system to perform the work for which it was created, that is, to give us accurate results of the operations we perform, so that when we want to consult the Covid-19 infection rate or perform a diagnosis of Covid-19 using the software, Another example is when we use a mobile application that by me using bits, our daily route and monitoring it by means of using us with certain information for which it was developed and thus fulfills its functionality. The second quality attributes were availability and functionality, previously we have already explained the functionality so we would complement the explanation now with reference to concerning, then when you mention availability, we refer to the ability of all software to be executed when the user needs it, i.e. it must be accessible and usable.

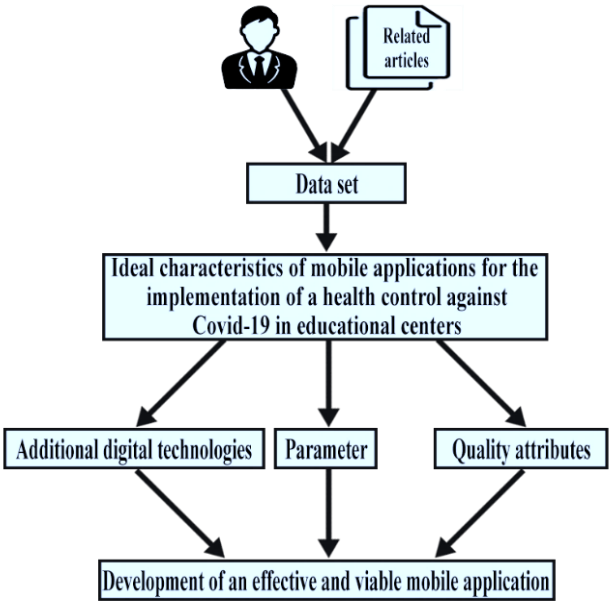

Fig. 13. Proposal Template.

Development of an effective and viable mobile application: With the three ideal characteristics, identified at the time when the systematization of the literature was performed, this point could be fulfilled, because while a mobile application contains additional digital technologies then the final product will be more complete, will contain many functions, will obtain more precision in its results or final functions. Do not forget that the parameter on which the mobile application will be based can get improved and be clearer about the functions that we would like to fulfill for the mobile application to develop. Finally, the quality attributes are very essential in all software because they are indicators that reflect how well the system meets the needs of stakeholders.

VI. Related Articles

Other systematic literature review studies conducted such as [141] based on the identification of the factor affecting the intention of continuous use of the mHealth application, compared to the present systematic review, they identified 354 articles which by removing the irrelevant and duplicated ones, 25 selected articles were left for the systematization of the literature. From this, they identified the factors for the continued use of mHealth applications (identifying a total of 39) some factors are satisfaction, quality of service, monetary cost, age, and education, among others. It concludes by identifying the five most frequent factors, which are satisfaction, the usefulness of the mHealth, quality service, training of the service, and ease of use of the service. It shows that users prefer mHealth to meet this expectation, since a mobile application should not only be easy to use but also have quality service and trust in it.

On the other hand, the following systematic review of the literature [142], searched for articles in the PubMed and Scopus databases to identify mHealth applications used for the prevention, treatment, or management of COVID-19. They identified a total of 728 articles of which, using the PRISMA methodology, they were left with 12 articles for the systematization of the literature. The author concluded that the studies in the articles he reviewed were not of high quality since Covid-19 had to generate responses and very premature development of digital tools for health by the scientific community. He emphasizes that a more longitudinal study with a rigorous design is required for a better evaluation of mobile applications against Covid-19.

Finally, in the following systematic review of the literature, [143] based on the study of data privacy during pandemics: a systematic literature review of smartphone applications Covid-19, identified 808 articles, using Liao's methodology, they were left with 35 articles for systematization of the literature. It relates that data privacy or information privacy often revolves around whether or not the data stored in the mobile application is shared with third parties. He also emphasizes that there are security policies for users and this is very important because in pandemic times there was a high increase in the use of mobile applications, especially against Covid-19, so this point of data protection is vital for the current technological era.

VII. Conclusion

After having carried out systematic literature research of 119 articles related to the topic in question, it is concluded that:

The digital tools or technologies that allow better control, follow-up, and monitoring against Covid-19 of the health status of students, teachers, and staff in educational centers are the digital technologies associated with "Mobile application", "Digital technology" and "Artificial intelligence". Likewise, most of the authors, from the articles reviewed, choose to base their article on a parameter focused on monitoring Covid-19.

Therefore, it was evident that most authors rely on the parameter "Monitoring" because they can observe and study patients who have contracted Covid-,19 and even take a study of the locality where there was Covid-19 which would help them to obtain updated reports and conduct accurate research.

Regarding the quality attributes that must be contained for the viability of the mobile application for the implementation of a sanitary control against Covid-19 in educational centers, they are availability, and functionality since this allows the system to perform the work for which it was created and to be available for use, meeting the needs of users. It was also concluded that the countries with the most research, in the last three years, related to sanitary control against Covid-19 in educational centers are the United States and China, showing that these countries have greater experience in sanitary control against Covid-19.

Finally, a proposed model was postulated to achieve the development of an effective and viable mobile application based on the three ideal characteristics previously explained. This systematic review can also be useful for use in future research on digital technologies, parameters, and quality attributes for the implementation of a health control against Covid-19 in educational centers, as well as identifying the countries that have more experience in this subject. In contrast, we can also rescue from the article [140] a graphic suggestion aligned to our conclusion (Fig. 14):

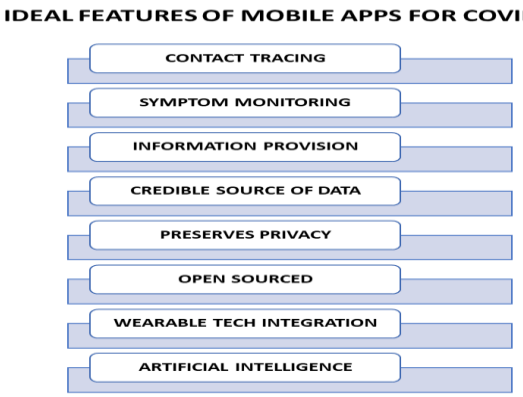

Fig. 14. Ideal Features of Mobile Apps for COVID-19.

Fig. 13 suggests some features that should be available in mobile applications for Covid-19. Other important functionalities that can be integrated into these contact-tracking apps include features for automatic symptom monitoring and information provision. The addition of these features will provide a more holistic public health approach in response to the situation. As technology advances, the symptom tracking algorithm can be enhanced and adapted to the pandemic to improve its diagnostic accuracy. Wearable devices, such as smartwatches and smart bracelets, will become more common and integrated into everyday life; therefore, these can potentially assist in vital monitoring of the health status of vulnerable populations. Through machine learning and artificial intelligence methods, automatic and rapid identification of suspicious infections will be more accurate in the future.

***Abstract*—The advancement of communication technologies has led to the interconnection of different sensors using the Internet of Things (IoT) and Wireless Sensor Network (WSN). WSN for healthcare applications has expanded exponentially due to evolving advantages such as low power requirement of sensors, transmission accuracy, and cost-efficiency. For heart attack patients, the future lies in ECG monitoring in which wearable sensors can be used to acquire patient information. In this paper, an attempt has been made to develop a novel IoT-enabled WSN to record patient information for detection of heart attack and to update queue of patients to ensure prioritized medical attention to critical patients. In the WSN, the Rayleigh Fading channel has been used to transmit data that can be accessed using the cloud repository by the medical staff remotely. The distance from the patient to the medical staff is calculated using Euclidean distance. Further, SNR in comparison to throughput and BER has been computed. The higher SNR indicates the maximum information transfer from patient to hospital staff. The proposed system uses the Grasshopper Optimization and CBNN based disease classification system and bubble sort algorithm has been used for updating patient queue. The proposed GHOA and CBNN has shown improved accuracy of 2.14% over existing techniques like CNN which has accuracy around 82% for R-R feature selection of ECG signals as compared to 82.72% shown by GHOA-CBNN.**

***Keywords*—WSN; cloud; ECG monitoring; wearable sensors; IoT; queue updation**

I. Introduction

Wireless Sensor Network (WSN) consists of various sensors used to sense the information and process the same for different applications. Internet of Things (IoT) can allow a seamless communication between patient and medical staff, by transferring data from a WSN to cloud computing platforms to always ensure uninterrupted health monitoring. In healthcare applications [1], availability of wearable sensors allows the continuous monitoring of patient parameters, with distinctive threshold levels for serious conditions such as heart failure, pulse rate, diabetes, and many others. Wearable devices enable long-term, continual assessment of the patient's critical indicators while allowing them total freedom of movement. The WSN-based healthcare systems use biosensors to collect physiological information from patients. The collected information can be shared using the Wireless networks directly with the server or doctors for clinical review. A promising technology in the healthcare field, Wireless Body Area Network (WBAN) offers higher-quality applications and services. Consequently, a more trustworthy analysis may be carried out by the doctors [2] using this vast amount of data rather than relying on the one recorded during a brief stay in the hospital. WBAN is a sophisticated monitoring system made from computing-capable wearable and implantable nodes that are positioned in, on, and nearby a person's body. This fastens the decision-making process and is useful for quick monitoring of the patient. Moreover, the integration of IoT with WBAN-enabled applications significantly reduce the cost of travel, and time, especially for long-term applications of monitoring in which doctors wait for a long time to record the ECG patterns. Researchers in [3] have been actively engaged in using the IoT and wearable sensor technology for the detection of cardiovascular diseases.

IoT-WSN based ECG monitoring systems in [4] are one of the powerful technological advancements to monitor the health of the patient remotely in real-time. An IoT-based ECG monitoring system enables the collection and analysis of ECG data for remotely monitoring patients. The data collected wirelessly can be directly stored or processed using the cloud computing devices. To create a decision support system that could aid in early diagnosis and treatment, the medical staff in [5] uses this data for additional analysis which can result in saving precious lives.

Heart disease is the leading cause of mortality worldwide. Hence, there is a need for the development of intelligent tools to detect heart-related diseases timely and accurately using a low-cost device. An IoT-WSN enabled ECG monitoring system has been developed in [6] which is a widely accepted method for the diagnosis of heart-related diseases. Conventional 12- electrode ECG monitoring systems are bulky and non-portable making it mandatory for the patient to be in the hospital for the process. A survey conducted in [7] presented trends and techniques related to IoT in healthcare applications. Researchers in [8] integrate the ECG monitoring and classification using IoT and deep neural networks that make the process easier and faster.

In contrast to the conventional approach presented in [9], 3 or 5-electrode ECG devices are now often utilized because they can provide precise ECG signals. These IoT-based heart rate monitoring sensors are portable that collect patient ECG signals and send the information to a mobile application via a wireless communication module. Numerous monitoring and analytic tools for heart rate monitoring such as RR wave peaks analysis were described in literature and related devices are being introduced in [10] and [11] for implementation. Additionally, several methods had been developed for peak

detection, such as the Hidden Markov model and Pan Tompkin's. The major issues with such methods are absence of standardized features, lack of robustness, real-time monitoring of ECG samples, and portability, and lack of sustainable solutions and there is a need for medical acceptance for the analysis of the signal.

Therefore, understanding these limitations, there is a need of WSN enabled ECG monitoring device that is faster and medically accepted. The proposed framework in this paper deals with acquisition of ECG data of a patient using wearable sensors which is transmitted to the medical team using the Rayleigh Fading channel, data can be stored and processed using cloud devices where a R-R peak analysis is performed. The R-R peak interval in healthy individuals ranges from 0.6 to 1.2 seconds. Any variation in the R-R interval helps to identify heart disease conditions. The proposed model uses the MIT-BIH Arrhythmia Dataset using five different classes such as N, S, V, F and Q. The main contribution of this paper is as follows:-

- Modelling of IoT-WSN enabled ECG monitoring system that works for remote locations.
- The ECG signal acquired through wearable sensors is transmitted from the patient to the allotted medical advisor using the Rayleigh Fading Channel and evaluation of parameters like throughput, Signal to Noise Ratio (SNR) and Bit Error Rate (BER) has been done.
- An Application is developed for remote as well as local supervision for patients in which proposed system displays the initial queue and updated queue of patients based on their seriousness levels.

The main motivation of this article is to present an ECG monitoring system using the integrated IoT-WSN technology for a healthcare monitoring system that can address the challenges of the existing systems. The advancement in wearable sensor technology allows the practitioners to use the WSN and IoT for the development of cost effective and reliable patient monitoring system. The present study is a continuation of research conducted in [12] to collect the vital signs using the wearable sensors. Furthermore, the real motivation behind this research is to save time, patients have to wait for long hours in hospitals for medical care and in critical cases that can prove fatal also. So, with the development of this WSN-IoT enabled ECG monitoring application, queue is updated based on the patient seriousness, and thus ensuring immediate and precise medical care to the patient.

The organization of the article is as follows: Section II details the related work to discuss the existing techniques for ECG monitoring. The next section discusses the research methodology in which different techniques adopted for communication has been detailed. Results and discussion are illustrated in section IV and the conclusion is given in section V.

II. Related Work

The authors in [13] proposed an IoT-based ECG monitoring for health care applications. The authors used the ECG sensor and development boards to send the information to remote locations. The Bluemix device had been used in conjunction with MQTT (Message Queuing Telemetry Transport) for the integration of different types of devices. The use of this protocol supports Machine to Machine communication without human intervention. The main advantage of the proposed system is its low cost but it also has limited ability to provide the results in a controlled manner.

The research conducted by Satija et al. [14] in which a novel ECG telemetry system had been developed for continuous cardiac health monitoring applications that is IoT enabled and lays emphasis on signal quality. The implementation of this work had been done using the ECG sensors, Arduino, Android phone, Bluetooth, and a cloud server. The interconnection of these devices enables the authors to create and build a lightweight ECG monitoring device for automatically categorizing the acquired ECG signal into acceptable or unacceptable classes and to implement Sensor enabled ECG monitoring program in real-time.

The study conducted by Gogate and Bakal [15] used the WSN for the development of the three-tier architecture for a healthcare monitoring system. The patient parameters such as heart rate, oxygen saturation, and temperature had been measured. The biosensors had been directly connected to the Arduino board to send the information to the server using wireless channel. The emergency patients were notified using alert systems from mobile phones and the accuracy of the developed system was about 95% with a minimum response time of around 10 seconds.

The authors of [16] created a wearable medical device that uses a three-lead ECG sensor to collect ECG data to detect arrhythmias in real-time. To detect arrhythmia and do real-time heart monitoring, this study offers a workable and simple method. It carries out ECG signal interpretation and wirelessly notifies the patient's doctor of arrhythmia at once. For instance, the Pan-Tompkins and adaptive filtering framework were used to find premature ventricular contractions (PVCs), a prevalent kind of arrhythmia. MIT-BIH arrhythmia database benchmark records were used to successfully test the robustness of the research work. The device is low-cost and uses the Raspberry Pi module for communication.

Practitioners in [17] proposed a novel system for the monitoring of remote healthcare using Machine Learning and IoT enabled devices. The authors allow the monitoring in real-time and associate the data with cloud computing. The paper also throws light to evaluate the prediction system for the measurement of heart diseases. The experimental results have been compared using machine learning classifiers such as Decision Tree, Random Forest, Support Vector Machine, and K-nearest neighbor. The highest accuracy of about 57.37% was obtained using Linear-Support Vector Machine. The limitation of the paper is that it is unable to provide the required security level for patient data.

Researchers in [18] integrated the concept of Big Data, IoT, and Nano-electronics to resolve the issue of inconspicuous monitoring. The use of Nano-electronic devices allows the users to send the data to numerous users such as physicians, medical advisors, and caretakers to analyse the data. The

transmission of signal had been done using the sensor considering the communication protocols such as Zigbee and LAN etc. The physicians at the remote location access the data and can view the reports using the sensor devices. The integration of these three technologies allows doctors to fasten the data analysis and decision-making process. The main limitation of this paper is increase in system complexity due to the use of different computational devices and system is less reliable due to the use of Nano tubes.

Huda et al. [19] developed a low-cost and low-power ECG monitoring system in conjunction with a deep learning model to facilitate the automatic detection of arrhythmia cardiovascular disease. The authors used the AD8232 chip to process the ECG signal and Convolutional Neural Network had been used for the classification of MIT-BIH arrhythmia disease. The accuracy of the developed system was 94.03% and provided effective results.

A low-cost ECG monitoring system to measure the seriousness of the patient was developed in [20]. The use of low-energy devices efficiently measures the arrhythmia detection, saturation level of oxygen, and temperature of the body that can be directly sent to the medical advisor via sensor devices. Further, the GSM module had been used to send an alert to the doctors in case of emergency conditions, and a web application equipped with deep learning facilitates the communication process between doctor and patient. The proposed device serves remote areas and is also helpful for telehealth care.

The authors in [21] offered a cloud-based method for remotely monitoring heart disease. To enable data visualization, fast reaction, and long-term connectivity between equipment and users, Hyper Text Transfer Protocol (HTTP) and Message Queuing Telemetry Transport (MQTT) servers had been employed. A communication technology called Bluetooth which relies on low energy (BLE 4.0) had been used to transmit information between a device and a wireless gateway. Filtration methods were used in the developed framework to suppress interruptions, background noise, and motion artifacts. It provides ECG signal analysis to identify several parameters, including beats, QRS complex intervals, PQRST wave, and breathing rate. The designed model was examined and found to be trustworthy for remote ECG monitoring. The main drawback is an inefficient system which is not portable. The research conducted by Ghafil et al. [22] had used medical sensors to collect physiological information from the patients. Wearable sensors had been used for the continuous monitoring of the patient. Holter machine had been used to access the ECG signals and WSN had been used for the transmission of the signal. Moreover, a cloud server had been used to store the recorded signals and the decision-making process finally had been done using medical sensors.

The authors in [25] used the cooperative Nano network for communication using the vivo technology. The authors used the WSN for communication and results show improvement from existing techniques.

The development of ECG monitoring systems has been an extensive field of research for the last many years. The need of timely medical care to cardiovascular patients motivated the authors to present a mechanism in the present paper that can overcome the delay in getting medical care. The study of literature and analysis of numerous projects related to this subject helped authors conclude that the queue Updation system has not yet been developed. This paper thus presents a novel system using IoT-WSN enabled ECG monitoring with the use of cloud repository, to maintain a queue based on the seriousness of the patient.

III. Research Methodology

The system architecture is divided into two phases in which phase 1 includes the use of WSN architecture to sense and collect the information. The phase 2 includes the storage and processing of information on the cloud architecture.

In Phase 1, the interconnection of various devices such as sensors, cloud processors, etc. using IoT for the monitoring of ECG signal for the detection of arrhythmia diseases is shown in Fig. 1. WSN mainly consists of wearable sensors employed for the detection of ECG signal and the Wireless communication channel such as the Rayleigh fading channel that has been used to transfer the information from the remote location to the hospital. The real time implementation of this work will involve placing ECG sensors on the patient's body. The different types of wearable sensors used to acquire the information are already discussed in article [12].

The data set used for this research is the MIT BIH Arrythmia dataset, which is accessed from the Kaggle link mentioned below: (https://www.kaggle.com/datasets/shayanfazeli/heartbeat).

MIT-BIH arrhythmia database, The MIT BIH dataset consists of ECG recordings of 47 different subjects recorded at a sampling rate of 360 Hz. The MIT-BIH dataset includes five different types of classes N, S, V, F and Q which are labeled as 0, 1, 2, 3, 4 for current study. The main aim is to select the relevant attributes and then train the data using the appropriate training algorithm. Grasshopper Optimization algorithm and CBNN have been used to determine the relevant attributes from the Kaggle ECG dataset [24].

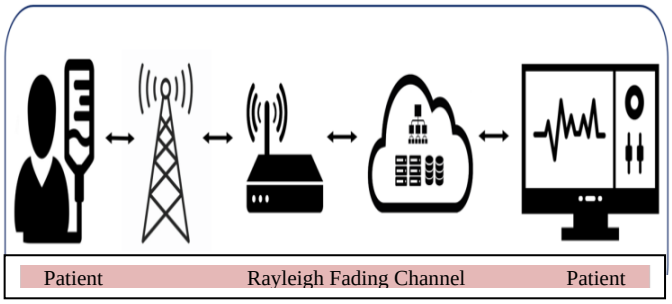

Fig. 1. IoT WSN Patient Monitoring System

A. WSN Framework

The proposed WSN framework includes the registration of patients, active patients, and initialization of network, determining the patient information, initiating the medical procedure, and associating medical staff with active patients considering distance between the two.

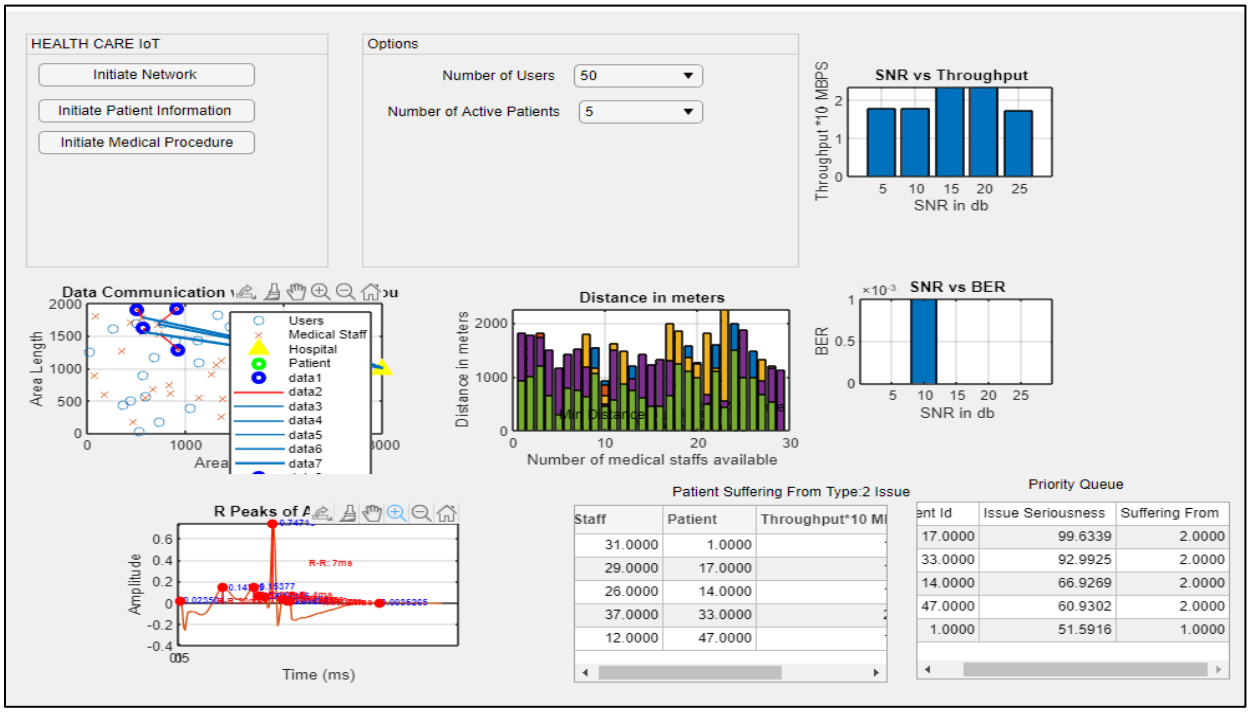

Fig. 2. The Proposed Framework IoT-WSN Enabled Healthcare System.

The proposed framework is shown in Fig. 2. In the developed framework, it is seen that number patients who have been registered is 50 and the queue is updated by experimenting with different or same number of active patients during different iterations of the program. When the initiate network button is pressed then information about the patients is recorded. The entire information is stored and processed using the cloud technology. When the initiate medical procedure button is pressed, then the RR peak analysis and sorting of patients based on seriousness starts and updated queue is displayed along with the initial queue in which staff allocation to patients and throughput and BER of the channel are displayed for each patient.

Another important information that is displayed is the classification of heart disease based on RR peak analysis, patients are classified as being suffering from disease type 0,1, 2, 3 and 4 that corresponds to the N, S, V, F and Q categories of MIT BIH Arrhythmia database respectively.

B. Rayleigh Fading Channel

Rayleigh fading is a model for describing the kind of fading that happens when multipath propagation is present. The Rayleigh fading channel has been used to transmit the ECG information of patient in the form of RR peaks from a remote location. However, the studies conducted in [23] used the Rayleigh Fading channel with Internet of Medical Technology for the transmission of signals. The integrated technology helps the practitioners to transmit the patient information for better communication. This channel is used for amplification and transmitting or relaying the signal, a simple technique that can be employed with a lesser number of associated overhead bits and therefore chosen for implementation and analysis of the proposed work. The parameters of Rayleigh channel are shown in Table 1.

TABLE I. PARAMETERS OF RAYLEIGH CHANNEL

Parameter Name	Value
Input symbol rate	9600
Number of samples per input symbol	10
Input sampling frequency (samples/s)	9600*10
Input sampling period (s)	1/Fs
Number of input symbols to simulate	1e6
Number of channel samples to simulate	1e6*10
Maximum Doppler frequency shift (Hz)	100
Number of samples of auto-covariance	5000
Number of transmit antennas	1
Number of receive antennas	1
Number of sinusoids	48
Frame length	10000
Number of frames	1e6*10/10000

C. Channel Parameters

Specifically, there are two nodes - Source node and the Destination node. The simple computation and detection process has been done using the source node and data is transmitted using the relay nodes. The relay node receives the signal, amplifies the signal, and then simply forwards the signal further to the destination node which is located at a certain distance. The destination node transmits the information through the Rayleigh Fading channel to a remote hospital for the monitoring of the signal. The received data from the channel is analyzed using the Bit Error Rate (BER) and Throughput of the signal which is also referred to as signal strength. The mathematical representation for throughput and BER is as follows.

$$Throughput = \frac{t_p}{pl+I} \quad (1)$$

Where t_p is the transmission power, pl is the path loss, and 'I' is the interference in the system as in (1). To calculate path loss, the following mathematical representation is used:

$$pl = 32.4 + 21 * \log(d_{2_h}) + 20 * \log10(fc) \quad (2)$$

Where d_{2_h} is the distance to the hospital from the user, fc is the central frequency viz. 3.5 GHz as in (2). BER is simply calculated by looking up a total false bit received to total sent bits.

Considering, that there are 'm' number of serious patients and 'n' number of relay nodes make the cooperative network for communication, the net SNR computed at the destination end has been determined as in equation 3[25].

$$SNR_{net} = \sum_{i=1}^{m} \frac{SNR_{source} SNR_{Destination}}{SNR_{source} + SNR_{Destination} + 1} \quad (3)$$

SNR has been computed using equation 3

$$SNR(dB) = 10 \times \log\left(\frac{Power_{transmission}(T_P) - Path\ Loss\ (P_L)}{Power_{noise}(P_N)}\right) \quad (4)$$

T_P is recommended to be less than 1mW in this case and Path Loss has been computed using equation 2.

$$f = \frac{c}{\sqrt{\epsilon} \times \lambda} \quad (5)$$

ϵ is the permittivity and it is about 0.2625 for human tissue near the surface of the skin [2] and further, the comparative study of SNR has been done with throughput. The lower value of path loss and higher value of SNR signifies an error-free transmission process at the destination end. The collected information is stored in the cloud technology that can be further accessed by the doctors and medical advocates.

D. ECG Data Analysis and Queue Updation

After the computation of SNR in relation to throughput, the classification process has been carried out. The medical practitioners have been allotted based on the seriousness of the patient. The data communication with a hospital as shown in Fig. 2 has been taken place and the distance between the patient and medical staff has been computed.

The distance from the patient to the medical staff is calculated using Euclidean distance which is defined as follows.

$$d = \sqrt{[(ux - mx)^2 + (uy - my)^2]} \quad (6)$$

where ux, uy, mx, and my are the geostationary coordinates of the ECG Data.

These are related to the patient and the medical staff. The nearest medical representative to the patient has been allotted accordingly. The patient is treated by extracting the RR features; the disease is classified using the Grasshopper Optimization algorithm (GHOA). The optimization algorithm plays a significant role in selecting the features having maximum information. The algorithm works on the behavior of grasshopper for both exploration and exploitation phase, and use the novel fitness function used to select the RR features. Further, training and testing has been done in which 70% data is trained using Conjugate based Neural Network (CBNN) and same technique is used for classification of 30% test data. The proposed technique was compared against CNN; GHOA-CBNN resulted in 82.72% accuracy and CNN was at 80.58%, resulting in an improvement for R-R feature selection accuracy by 2.14%.

When the patient data is received at the receiving end, it is first processed for the R-R peak analysis and then furthermore the type of issue is determined that a patient is suffering from. Here in this scenario in Fig. 3, the classification engine compares the supplied R-R peak values against the stored values. The matching score is calculated based on the correlation of the supplied data to the repository data. A high matching score represents more seriousness in the patient data whereas a low matching score represents less seriousness in the patient data. The patient with a high matching score is treated before any other patient if there is no other patient that has a higher matching score than that of the current patient. To update the queue, the proposed algorithm utilizes the factor of seriousness for the patient using the following equation (7).

$$Seriousness\ of\ Patient = (Categorized\ class\ score - Original\ Score) * 100 \quad (7)$$

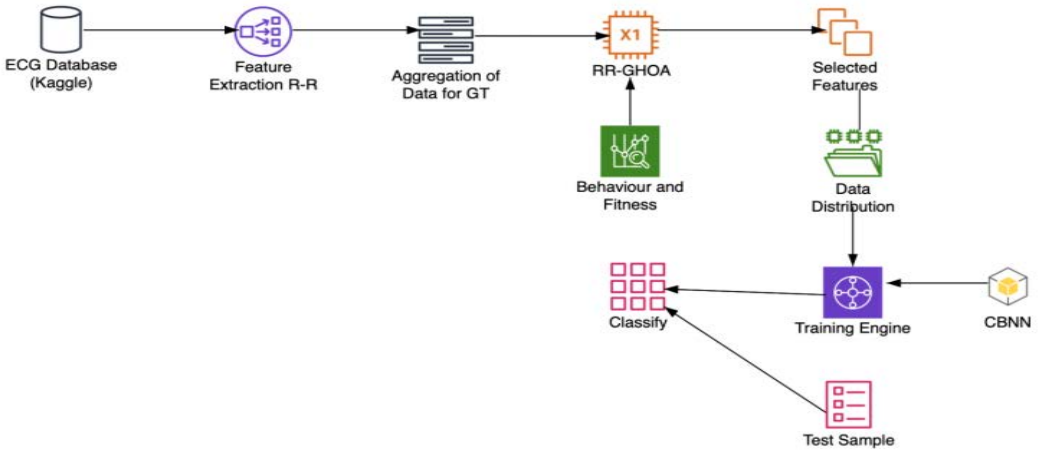

Fig. 3. Analysis and Disease Classification

When the classified result is attained, the disease is decided on the basis of the classification score that represents the matching value with the original class.

If the classified score is close to the original score, the patient is close to the exact disease and hence requires special attention at the very same time.

IV. Results and Discussion

The proposed work is analyzed using wearable sensors to monitor the ECG signal. The Rayleigh fading channel is used for wireless communication from the source node to the destination node. The information is transmitted with the preamble of 32 bits and a payload of 80 bytes of information transmitted using the ECG data acquisition system. The simulation has been performed for a different number of patients registered for monitoring of ECG. The simulation has been performed with SNR ranging from – 10 to 30 dB. Further, throughput and Bit Error Rate (BER) analysis have been determined considering the proposed framework. In this paper, the queue is updated based on the seriousness of the patients. The seriousness is organized in descending order and patients are treated in that manner only. Staff allocation to patients and throughput and BER is listed in Table II. The serious patients have been prioritized and arranged accordingly in the list and then the queue is updated as shown in Table III.

Table II shows the throughput for different patients and BER is listed which is 0.0002 for almost all patients. The throughput value varies from patient to patient. For instance, patient id 1 has throughput of 1.98 Mbps and for 47th patient id, it is 1.99 Mbps as shown in Fig. 4.

Table III shows the arrangement of patient queue based on the level of seriousness and different class of disease. It is seen that patient id 17 having maximum level of seriousness and thus arranged on the top in the queue. Patient id 14 suffered from type 2 disease had a seriousness of 66.92%, is listed as number 3 in the list. Patient id 1 suffered from type 1 disease and had a seriousness of 51.5916%, is queued at number 5.

TABLE II. Medical Staff Allocation to Patients

Staff ID	Patient ID	Throughput*Mbps	BER
31	1	1.9893	0.0002
29	17	1.9947	0.0002
26	14	1.9860	0.0002
37	33	2.0560	0.0002
12	47	1.9971	0.0002

TABLE III. Arranging the Patient's Queue based on Seriousness

Patient ID	Seriousness	Class of Disease
17	99.6339	2
33	92.9925	2
14	66.9269	2
47	60.9302	2
1	51.5916	1

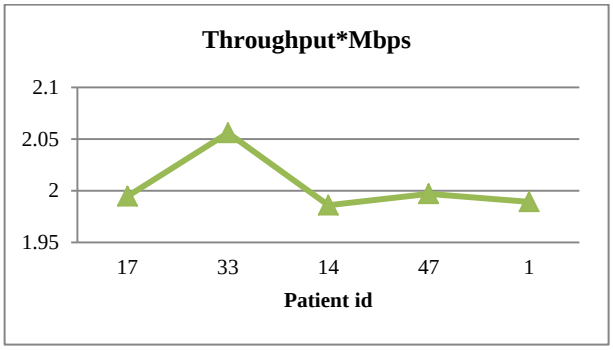

Fig. 4. Throughput of Different Patients.

V. Conclusion

In this paper, we proposed a model for healthcare applications which is based on IOT-WSN architecture. The ECG signal can be collected using the wireless wearable sensors but for this paper MIT BIH Arrhythmia dataset has been considered. The IoT-enabled framework performs better in terms of throughput and BER. The use of the optimization approach classifies the disease efficiently and updates patient queue based on the seriousness level of the patient. The presented study is simple and convenient and its real time implementation can help save precious lives. The proposed IoT-WSN system uses less power, and the complete framework has been simulated in MATLAB. This work can be extended further to display the queue in the hospitals that are visible not only to doctors but also to the patients and staff and such a system can be developed for disease specific applications or for random patients reporting in the emergency OPD.

***Abstract*—Deep learning has become one of the crucial trends in the modern era due to the huge amount of data that has become available. This paper aims to investigate and improve a generic framework for Arabic Text Classification (ATC) with different deep learning techniques. Besides, it deals directly with a word in its original style as a basic unit of modern Arabic sentence and on a different level of N-grams versus a combination of Intersected Consecutive Word proposed method (ICW). However, it aimed to discuss the results of the different experiments for the enhancements of the proposed method on different deep learning algorithms such as Scaled Conjugate Gradient (SCG) and Gradient descent with momentum and adaptive learning rate backpropagation (GDX) on ATC. The results showed that the proposed framework applied with the SCG algorithm and TF-IDF outperforms the GDX algorithm with an accuracy ratio of 90.65%.**

***Keywords*—Text classification; arabic text classification; scaled conjugate gradient; TF-IDF; GDX; ICW**

I. INTRODUCTION

The classification of texts is becoming more crucial every day due to the tremendous diversity in the use of different human knowledge sources. This usage of cognitive resources resulted in the momentum and abundance of information and data circulating between many devices with large volumes, rapid and remarkable development of artificial intelligence. Therefore, it was necessary to work effectively in containing this momentum in order to classify these texts effectively, not only to facilitate the retrieval of information but also for machine learning uses.

Text classification (TC – also known as text categorization, or topic spotting) is the task of automatically sorting a set of documents into categories (or classes, or topics) from a predefined set. This assignment falls at the intersection of Information Retrieval (IR) and Machine learning (ML). It can be defined as the process of classifying or structuring documents into a predefined set of categories according to a group structure that is known in advance [1]. Also, Khorsheed defined it as "The assignment of free-text documents to one or more predefined categories based on their content" [2].

Valuable information can be elicited out of organized/unorganized textual resources like documents and classified into a stable number of predefined categories that are established in advance, they express the fundamental idea of text categorization. Each document can be in multiple, solo, or no class at all [3],[4].

The problems of classifying texts are not only represented in the tremendous diversity in the use of cognitive sources or in the momentum but also the abundance of information and circulating data, which sometimes reach millions of terabytes. Moreover, there is a crucial factor which is the language in which these texts are written [28].

In the field of Natural Language Processing (NLP), different languages were interested in researches development more than the others. Whatever, some of these researches are concerned with the Arabic language as it has a gorgeous impact even it became one of the most commonly used languages all over the world; despite it considers the fifth spoken one. It uses profusely in many of the different Arab countries as it is the main language of the Holy Quran. Moreover, various applications are still limited for the Arabic language owing to its enormous variation in shape, structure, and component, although different studies were carried out for text classification using the English language [5], [26], [27].

There are many challenges concerning the documents written in the Arabic language. From these challenges the common characteristic of the language, e.g., richness of vocabulary, the complexity of grammar, combinations of orthography, the existence of short vowels, …, etc. These problems are particularized in detail in [6], [7]. Besides, the algorithms that were developed for English perform unwell for Arabic [8].

Different researchers interested in the field of NLP are concerned with applying and studying deep learning algorithms in order to explore many results for the reasons of development and improvement [31]. Deep learning is a

coherent and integrated set of algorithms that interpret and link data to each other in order to achieve the greatest degree of accuracy in order to identify and extract new information that was previously unknown [33]. However, the method of learning these algorithms is a representation of the way human brain cells work in transmitting and interacting signals.

Machine learning techniques can be classified for ATC under two categories. The first category is the classical machine learning techniques which contain approved algorithms such as SVM, KNN, NB, and others. Whereas, the second category, is modern machines learning techniques which contain algorithms such as stochastic gradient descent (SGD), convolutional neural network (CNN), and bi-directional long-short term memory (BLSTM).

The contribution of this paper is presenting a novel framework for handling the binary classification problem in Arabic text by employing a new proposed ICW method as a feature representation. Also, the proposed framework handles the effects of deep learning techniques in binary classification problem in Arabic text.

The rest of the paper is organized as follows: The second section mentions the Arabic text classification phases. The third section mentions a literature study of deep learning algorithms and the related works in ATC. The fourth section, introduces some crucial background to facilitate the understanding the following sections. Section five presents the proposed framework based on deep learning techniques. Section six presents the experimental study and discusses the experimental results obtained. Finally, the seventh section concludes the paper's contributions and future work.

II. Arabic Text Classification Phases

Building a generic framework depends on previous phases of text classification. Fig. 1 shows the generic framework extracted based upon [9], [10] was able to take a step forward towards applying deep learning techniques in ATC. Six phases are considered as the main phases for achieving the text classification and dimensionality curse problems.

A. Data Collection Phase

According to the huge usage of the Internet and social media, there are different types of data which are differed in shape and volume. For that, data can be collected through the Internet or detected system in a represented shape such as text, documents, web pages, videos, spreadsheets, or database files. Data can be retrieved through different resources which can be categorized under defined symmetric or asymmetric data. Also, it can be categorized into three categories i.e., structured, unstructured, and semi-structured in the same group.

B. Pre-Processing Phase

Different steps are made for cleaning and preparing the collected data as a result of the last preprocessing phase. Preparing the different data collected from different resources in a homogeneity manner is a prerequisite objective for the classifiers in the classification phase [30]. However, there are general steps used in the Arabic text classification phase such as excluding stop words which include pronouns, conjunctions, and prepositions. Also, exclude digits, punctuation marks, Latin alphabet, removal of isolated letters, and non-Arabic words.

The text prepared before is tokenized and divided by representing it in different manners under the conditions of usage purposes. There are two popular models for the reason of tokenizing text N-gram and bag of words (BOW) models.

C. Representing Phase

After preparing the data, it is represented through an indexed matrix vector space. Indexing is a crucial process in (IR) systems [25], [29]. It reduces the documents into the informative terms contained in them.

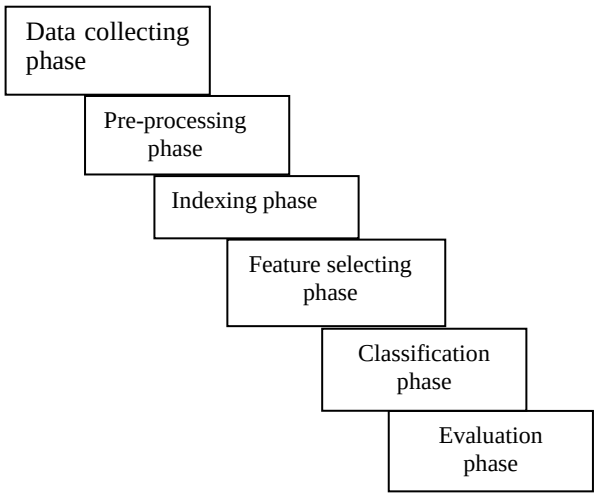

Fig. 1. Conceptual View of Text Classification Steps.

It provides a mapping from the terms to the respective documents containing them [11]. The produced indexed matrix-vector can be represented as equation number (1).

$$M = X * Y \quad (1)$$

Where $X = (D_0, D_1, D_2, \ldots\ldots, D_{n-1}, D_n)$ where D_n represent documents on data set

$Y = (w_0, w_1, w_2, \ldots\ldots, w_{n-1}, w_n)$ where w_n represent the words in the document and $Y \subset D_n$.

When training a machine or a deep learning classification model on a dataset, a matrix of vector space is prepared considerably. The rows of the matrix represent the actual documents that were contained in the training dataset, and the columns represent the features represented in each document.

D. Feature Selecting Phase

In this phase, a matrix of vector space is represented among all extracted features of documents represented in the data set. A massive number of features extracted through the data-set crash with the “Curse of dimensionality” problem. Features reduction algorithms are adaptable techniques for solving that problem that reduces the low priority of features in consideration of the high quality of the text classification process.

E. Classification Phase

It's the important phase through all the previous processes. In this phase, the classifier is trained as a model based on previous train data-set. The objective of this phase is to train the classifier to generalize the method of classifying data on another symmetric data-set.

F. Evaluation Phase

The last phase is evaluating the generated classification model from the previous phases. A symmetric test data-set is prepared for the purpose of measuring the accuracy of the classifier according to the confusion matrix.

III. Related Work

Different studies concerned with machine learning techniques were interested in defining Neural Networks as a biased term for complicated deep learning techniques. CNNs are very similar to ordinary Neural Networks, they are made up of neurons that have learnable weights and biases. Each neuron receives some inputs, executes a dot product, and may follow it with a non-linear function. The entire system still expresses a single differentiable score function: from the inputs to the classes in the outputs. Moreover, they still have a loss function on the last layer. CNN is typically a sequence of layers, and the outputs of every layer are the inputs of the next layer. Those layers are convolutional, pooling layers, and fully connected layers [12], [13].

Sagheer et al, discussed applying deep learning techniques for Arabic sentence classification. They presented a CNN model to achieve the purpose of classifying the text in the used dataset into three labels. The used dataset contained the Arabic sentence withdraw from Essex Arabic Summaries Corpus (EASC). They used different techniques for preparing text for the deep learning algorithm, they first tokenized the words of text and then transformed them to sequences represented by word indices. According to the variation of the sequence length of words, they used a padding technique to trim the sequence length into a unified length. They used the word embedding layer for comparing three models of CNN. For avoiding the overfitting issues through the training phase of the algorithm, they used dropout layers and weighting regularization functions. The results showed that CNN models in top of word embedding layer achieved high-performance accuracy in the NLP task, Arabic sentences classification [14].

In other work, Helmy et al., proposed a deep learning-based approach for keyphrase extraction of Arabic text. As mentioned before a shortage in Arabic text datasets was found for adapting deep learning models for Arabic keyphrase extraction. However, they established a new dataset that was prepared to consist of 6,000 abstracts of scientific Arabic documents. They apply a word embedding representation method for representing the tokens of the documents which are divided into sentences. The embedding layer works as a lookup table that transforms discrete features such as the words of Arabic text into continuous real-valued vector representations, which are then concatenated and provided to the neural network. Also, they proposed applying the BLSTM network for utilization instead of a feed-forward network. They used two hidden layers forward and backward hidden sequence to generate the output. Then, a cunctation layer is connected to a softmax output layer with three neurons for each word. A dropout technique was implemented between Bi-LSTM and the dense layer to prevent overfitting. The evaluation results showed that the proposed approach achieves state-of-the-art performance in the Arabic KPE domain [15].

Also, Samir Boukil et al., proposed a method for Arabic text classification. The proposed method that followed depends mainly on the known steps for preparing the Arabic text as preprocessing steps. Also, they used a stemmer for purpose of extracting and selecting the features. They used TF and TF-IDF techniques as feature weighting techniques for representing the text. For the classification phase, they compared three classifiers CNN, SVM, and Logistic Regression. In the CNN experiment, they employed stochastic gradient descent (SGD) to train the network and use a backpropagation algorithm to calculate the gradients. Besides, they used a learning rate of 0.001 and a dropout ratio with a value of 0.5 to enhance the classifier performance. They argued that the CNN algorithm achieved high results in large and big datasets versus the traditional algorithms [16].

Whatever, deep learning can be a coherent and integrated set of algorithms that interpret and link data to each other in order to achieve the greatest degree of accuracy in order to identify and extract new information that was previously unknown. The method of learning these algorithms is a representation of the way human brain cells work in transmitting and interacting signals. Because of the lack of research in the field of ATC, the previous methodologies used in the mentioned research are considered important points. Also, these researches are characterized as the basic steps in the direction of building generally proposed frameworks to improve deep learning algorithms to classify texts in the Arabic language. Moreover, as mentioned in the literature review several deep learning techniques differ between them in architectures and performance and not all of them have been applied to the ATC problem.

The previous issues have motivated us to propose a large and accessible benchmark dataset of binary-label Arabic texts classified under a legal text. Besides, it has motivated us for exploring in a comparative manner the effect between two deep learning algorithms, i.e., GDX and SCG for ATC.

IV. Background

A. Data Preprocessing based Techniques

In the following, we demonstrate the proposed combination of words for representing the Arabic text based on the structure of the Arabic sentence. Arabic sentence contains in its normal structure two types of sentences, i.e., noun sentence and verbal sentence. The noun sentence consists of two parts or tokens "mobtada" and "khaber" whereas the verbal sentence consists of three parts or tokens subject, verb, and object. For extracting all possible sentences from the text the next two definitions were formulated for that purpose.

Definition 1: Arabic text can be represented by T= (w_0, w_1, w_2, …, w_{n-1}, w_n) Noun Sentence (NS) can represented by NS =

(w_0+w_1,w_1+w_2,……., w_{i-1}+w_i) where w_{i-1}+w_i ⊂ T and w_{i-1}+w_i ≤ w_{n-1}+w_n and i=n .

According to the last definition, several noun sentences NS will be represented by several tokens each one consisting of (wi-1+wi) Ɛ T.

Definition 2: Arabic text can be represented by T= (w_0, w_1,w_2,w_3…,w_{n-2},w_{n-1},w_n) Verbal Sentence (VS) can represented by VS = (w_0+w_1+w_2,w_1+w_2+w_3,……., w_{i-2}+w_{i-1}+w_i) where w_{i-2}+w_{i-1}+w_i ⊂ T and w_{i-2}+w_{i-1}+w_i ≤ w_{n-2}+w_{n-1}+w_n and i=n .

ICW Proposed method

Input: file of text contains a number of lines

Output: separated files each one contains one of a line of words equals to the token value

1: For each (line in lines)

2: If the line is not empty then

3: Read the words in each line

4: For each line do

5: Read the token value

6: Divide the words equals to token value

7: Create a separated file for each line;

8: Write to file the words equals to token value;

9: Exit

B. Feature Selection Phase

The feature selection phase is crucial in our proposed framework as it's the last step in drawing the features vector space for each class. However, two methods are proposed for applying to establish the features vectors are TF and TF-IDF [32]. Term frequency is concerned with how frequently a word or a combination of words occurs in a detected one document. Where TF-IDF is concerned with how frequently a word or a combination of words occurs within the overall document [28].

For calculating TF-IDF assuming that a given a group of documents D, a word w, and an individual document d ϵ D, we calculate *wd* the weight of the word w by applying (1) and (2).

$$wd = TF * IDF \quad (2)$$

$$wd = fwd * log(|D|/fwd) \quad (3)$$

Where fwd is the number of times the word w appears in the document d, |D| is the size of the corpus, and fwD is the number of documents in which w appears in D [17].

C. Classification Phase

In this phase, the algorithm is trained on the data-set for purpose of achieving the classification task. Whatever the well-defined deep learning classification algorithms we choose SCG and GDX.

1) Scaled conjugate gradient back propagation algorithm: This algorithm was developed by (Moller,1990). It was built based upon a network training function that updates weight and bias values according to the scaled conjugate gradient method. It depends on conjugate directions, though it does not perform a line search at each iteration for avoiding the time-consuming linear search of conjugate and optimal direction that occurs with other algorithms.

The scaled conjugate gradient method relies on fast strategy search using information from the second-order approximation [18]. The mathematical equations used for that algorithm can be summarized as follows:

$$E(w+y) \approx E(w) + E'(w)Ty + 1/2yTE(w) \quad (4)$$

The quadratic approximation to E for the point w can be achieved through Eqw(y) in eq (5)

$$Eqw(y) = E(w) + E'(w)Ty + 1/2yTE^{"}(w)y \quad (5)$$

For determining minima to Eqw(y) the critical points must be detected in equation (6). The critical points are the primitive keys for linear systems [19].

$$Eqw(y) = E^{"}(w)y + E'(w) = 0 \quad (6)$$

Assume that conjugate systems with start point Y_1, and $P1…PN$. We can consider a linear combination of the points from Y_1 to Y^* till PN. Where Y^* is a critical point.

$$Y^* - Y1 = \sum_{i=1}^{n} \propto ipi \; where \;\; \propto_1 \in R \quad (7)$$

$$P_j^T\left(-E'(w) - E^{"}(W)y1\right) = \propto jP_j^T E^{"}(w)P_j \quad (8)$$

$$\propto = \left(P_j^T\left(-E'(w) - E^{"}(w)y1\right)\right)/\left(jP_j^T E^{"}(w)P_j\right) \quad (9)$$

Using Eqs (7), (8), and (9), we can iteratively determine the value of the critical point which is Y*. Eqw(Y), is given by the equation,

$$E_{qw}(Y) = E_{qw}(Y^*) + 1/2(Y - Y^*)TE^N(W)(Y - Y^*) \quad (10)$$

2) Gradient descent with momentum and adaptive learning rate back propagation: The algorithm can be defined as it updates weight and bias values according to gradient descent momentum and an adaptive learning rate. Momentum factors can be accomplished by adding a fraction of the previous weight change to the current weight change. This term encourages movement in the same direction on successive steps. The addition of such a term can help smooth out the descent path by preventing extreme changes in the gradient due to local anomalies. Therefore, it is likely to suppress any oscillations that result from changes in the slope of the error surface [20].

Back propagation is used to calculate derivatives of performance *perf* with respect to the weight and bias variables X. Each variable is adjusted according to gradient descent with momentum,

$$dX = mc * dXprev + lr * mc * dperf/dX \quad (11)$$

where, *dXprev* is the previous change to the weight or bias.

D. Evaluation Measures

Precision and recall are widely used for evaluation measures in information retrieval and machine learning [21]. Precision is the fraction of retrieved documents that are relevant to the query. In other words, it concerns how useful the search results are. Recall is the segment of the documents which is exactly related to the inquiry that is absolutely recalled. However, it concerns with how complete results are. F-measure is approximately the average of precision and recall.

TABLE I. DOCUMENTS POSSIBLE SETS BASED ON A QUERY IN IR

Iteration	Relevant	Irrelevant
Documents Retrieved	true positives (tp)	false positives (fp)
Documents not Retrieved	false negatives (fn)	true negatives (tn)

According to Table I, precision, recall, and (macro average) measures can be computed as the following equations:

$$Precision = \frac{tp}{(tp+fp)} \quad (12)$$

$$Recall = \frac{tp}{(tp+fn)} \quad (13)$$

$$F - measure = \frac{2*Precision*Recall}{Recall+Precision} \quad (14)$$

V. PROPOSED FRAMEWORK BASED ON DEEP LEARNING TECHNIQUES

For building a generic framework, it builds based upon the conceptual view of text classification. Fig. 2 shows the generic framework which extracted based upon [9], [10]. Moreover, it is able to take a step forward towards for applying deep learning techniques in ATC. In addition, a new legal dataset for requests of prosecutors was presented for the purpose of testing and training the proposed framework in different experiments.

In the data collection phase, data from two courts of the council state of Egypt are collected and reviewed by three technical reviewers. The reviewing process was performed according to the spatiality of each document of the previously detected two classes.

Different steps have been made for cleaning and preparing the collected data in preprocessing phase such as excluding stop words which include pronouns, conjunctions, and prepositions. Also, exclude digits, punctuation marks, Latin alphabet, removal of isolated letters, and non-Arabic words [24].

Besides, the adding point of the proposed method for representing the text is in the features representation phase. The proposed method was built based upon definition [1, 2] and the ICW algorithm. Two combination forms for representing the text were proposed for evaluating the proposed framework. Firstly, it evaluates the combination between the uni-word and noun sentence. Secondly, it evaluates the combination between noun sentences and verbal sentences.

A comparison between two representation methods in the features representation phase showed. On one hand, the N-gram model with three aspects of a word-level uni-gram, bi-gram, and tri-gram is established. On the other hand, the proposed method for representing the text with its two combinations of uni-word, noun sentence, and verbal sentence is presented.

In classification phase two deep learning algorithms are applied for the purpose of classifying data into its class SCG and GDX. They applied for the purpose of measuring their accuracy with the previous steps of preparing the data of two classes with TF representing features vector in one side. In the other side, they also applied for measuring their accuracy in classification with TF-IDF. Besides, deep learning architectures changed in a manner for evaluating and exploring the effects of changing the number of both hidden learning layers and neurons of each layer in the accuracy of the classifiers. Fig. 2 shows the different steps from collecting the data from documents to the evaluation step of the classifier.

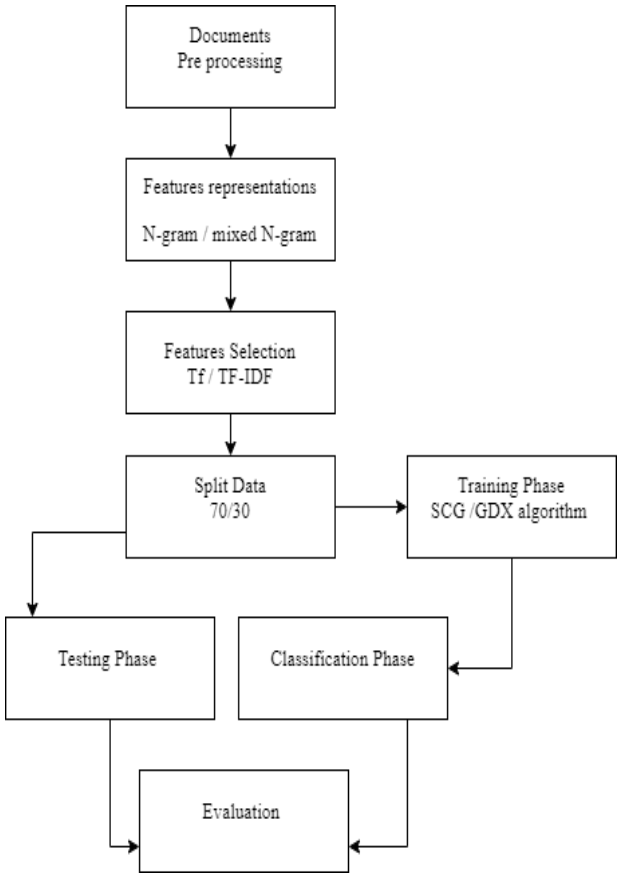

Fig. 2. Proposed Framework for ATC with Deep Learning Techniques.

VI. EXPERIMENTS AND RESULTS

A Matlab software with deep learning toolbox version 2018b was used for implementing different steps of the proposed framework of Fig. 2. Besides, the hardware machine used for implementing the different experiments was a server machine with a specification of Xeon processor 1.96 and memory 32 gigabytes.

A. Dataset

To evaluate any categorization system, text collection which consists of different categories must be available for training and testing purposes. There is no standard Arabic text collection as a benchmark dataset to the best of our knowledge for researchers who work on classifying Arabic text in the legal environment [22], [23]. Wherefore, one of the main purposes of this study is to contribute to the research community by representing a legal dataset written with Arabic text. Its value stems from the real addition to the trends of digital transformation and digitization of the work of the Egyptian judiciary. In addition to establishing the principle of complete justice, transparency, and facilitating the work of the judiciary, within the framework of Egypt's plan for sustainable development 2030.

We collected a subset of the Arabic text for requests of Prosecutors covering two topics from an Arabic dataset built locally at the council state of Egypt. The reasons for choosing these Prosecutors' requests are firstly, each Prosecutors request has a unique label. This makes it easier for us to access and fetch the files by their label. Secondly, each request has been reviewed by two different phases of technical reviewing.

Two categories were collected of this dataset containing 500 text documents for each class the total size is 1000 text documents. The total features extracted from these data exceed thousands of words beginning from a least 2000 words and in some cases exceed 16000 features. For more details of the dataset, description sees Table II.

The following statement is an example of ATC problem which labeled as class one:

اولا: قبول الدعوى شكلا. ثانيا: وفي الموضوع الحكم بالزام المدعى عليهم بصفتهم بان يؤدوا للطالبه اجرا مضاعفا عن عملها ايام الراحات الاسبوعية والعطلات والاجازات والبالغ قدرها 326 يوم ثلاثمائة وستة وعشرون يوما مع الزام الجهة الادارية بالمصروفات والاتعاب على ان ينفذ الحكم بمسودته دون اعلان.

Moreover, the following statement is labeled as class two.

اولا: قبول الدعوى شكلا. ثانيا: وفى الموضوع الحكم بالزام المدعى عليه بان يؤدى للطالب اجر مضاعف عن جميع ايام الراحات الاسبوعية والعطلات الرسمية واجازات الاعياد منذ التحاقه بالعمل حتى الان مع الزام المدعى عليه بالمصروفات والاتعاب مع حفظ كافة حقوق الطالب الاخرى.

Different preprocessing steps have been made for handling the last data such as removing the duplicated words and digits etc.…another example for tokenizing the text into the different methods such as N-gram or ICW method is described below.

Example one: tokenizing the text into a bi-gram method.

باحقية المدعى # المدعى المعاملة # المعاملة المالية # المالية طبقا # طبقا لقرار # لقرار رئيس # رئيس مجلس # مجلس الوزراء # الوزراء رقم # رقم لسنة # لسنة فترة # فترة ابتعاثة # ابتعاثة لدولة

Example two: tokenizing the text into a tri-gram method.

باحقية المدعى المعاملة # المدعى المعاملة المالية # المعاملة المالية طبقا # المالية طبقا لقرار # طبقا لقرار رئيس # لقرار رئيس مجلس # رئيس مجلس الوزراء # مجلس الوزراء رقم # الوزراء رقم لسنة # رقم لسنة فترة # لسنة فترة ابتعاثة # فترة ابتعاثة لدولة

TABLE II. DATASET DESCRIPTION ACCORDING TO N-GRAM AND PHRASE STRUCTURE

	Features of Class one	**Features of Class two**	**Before remove duplicate**	**After remove duplicate**
uni-gram	1331	1489	2820	2182
bi-gram	3826	3734	7560	6831
tri-gram	5220	4910	10430	9582
one word and noun phrase	5115	5198	10313	8952
noun phrase and verbal phrase	8997	8613	17610	16339
one word, noun phrase and verbal phrase	10286	10077	20363	18460

B. Experimental Configuration

The experimental configuration was built based on illustrating the effect of changing the learning layers architecture for the algorithm on the classifier's accuracy. Also, it was built based on illustrating the effect of using the proposed method for representing Arabic text based on noun and verbal sentences with various combinations versus N-gram. Different types of experiments with detailed sub-experiments were configured for achieving the last two objectives. First, experiments were set up for comparing the accuracy of the classifier between representing the uni-gram with TF and representing the uni-gram with TF-IDF with the increasing number of layers respecting two a constant of the number of neurons in each layer. Second, experiments were set up for comparing the accuracy of the previous deep learning algorithm represented in SCG algorithm with (TF) and (TF-IDF) features selection method with a proposed ICW method of a uni-bi gram and bi-tri gram.

Other experiments were set up for comparing the accuracy of the SCG algorithm versus the GDX algorithm with a two and three hidden layer with 100 neurons for each layer. However, according to the main objective of the comparisons (TF-IDF) and TF features selection method is still used for unifying the configuration of the experiments.

C. Evaluating the Accuracy of SCG Algorithm through Changing the Architecture Layers:

The experiment was executed based upon the framework in Fig. 2 with the detailed steps which have been discussed before. This experiment was established for the purpose of exploring the effects of changing the architecture layers in the accuracy level of the classifier. The first factor is increasing the number of learning hidden layers whereas the other factor is fixing the number of neurons. We measure the accuracy level of the classifier with equation number based on the confusion matrix and equation (14). Comparisons have been made between representing the uni-gram with TF and the uni-gram with TF-IDF with the increasing number of layers.

$$Layer\ size = nl * N \quad (15)$$

Where nl >= 2 and N is a constant equal 100.

The factor nl is the number of layers and N in the number of neurons.

The experiments are executed till the stopping condition is achieved. The stopping condition is the accuracy level is lower than the first experiment with the number of layers being 2.

TABLE III. ACCURACY OF SCG ALGORITHM WITH CHANGING THE ARCHITECTURE LAYERS

Number of layers	Uni-gram TF	Uni-gram TF-IDF
LayerSize = [2*100]	88.02	86.29
Layer Size = [3*100]	88.74	87.18
Layer Size = [4*100]	88.77	89.67
Layer Size = [5*100]	88.53	88.69
Layer Size = [6*100]	88.08	86.90
Layer Size = [7*100]	88.89	87.21
Layer Size = [10*100]	86.98	84.85
Layer Size = [20*100]	89.61	87.41
Layer Size = [30*100]	89.19	90.07
Layer Size = [50*100]	87.12	86.86
Layer Size = [80*100]	85.1	86.11

The results in Table III showed that increasing the number of hidden layers with a fixed number of neurons affects the accuracy of the classifier with TF and TF-IDF representation methods. Also, Fig. 3 showed a variance of accuracy ratios changed with increasing the number of hidden layers. However, it has been detected that the SCG algorithm achieved the best accuracy ratio with 90.07% with the number of hidden layers equaling 30 layers.

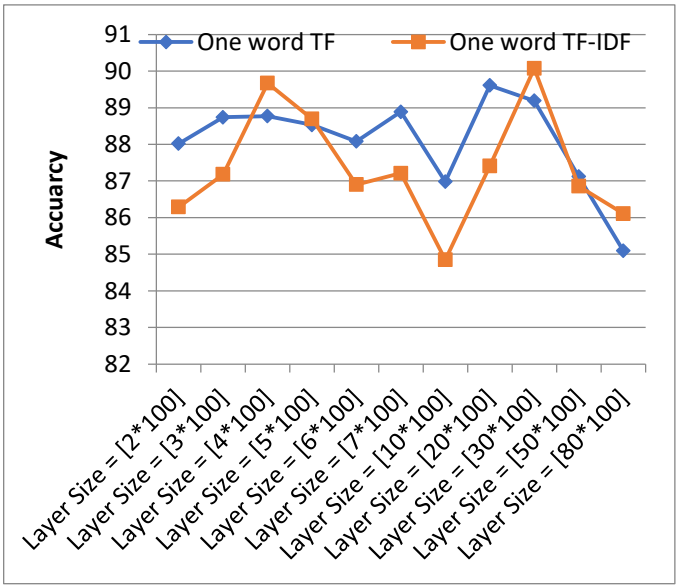

Fig. 3. The Effect of Accuracy According to the Change of Layers Number with Fixed Neurons.

D. Accuracy Ratios of SCG Algorithm According to TF and TF-IDF Features Selection with Fixed Layers and Neurons:

The experiment was executed based upon the framework in Fig. 2 with the detailed steps that have been discussed before. This experiment was established for the purpose of exploring the effects of two factors in the accuracy level of the classifier. The first factor is a fixed number of learning hidden layers whereas the other factor is a fixed number of neurons for each layer. Table II showed the number of words represented as features used in this experiment. We measure the accuracy level of the equation number based on the confusion matrix. Comparisons have been made between two different methods on one hand a combination between (uni-gram and bi-gram) and (bi-gram and tri-gram) on the other hand the typical N-gram model. The last two combinations are compared with TF and TF-IDF representing methods with a fixed number of layers. The fixed number of layers is represented with an assumed number of neurons which equals 100 neurons for each one of the layers.

Table IV shows the results for discussing the factors that affects the accuracy of the classifier with both representation methods TF and TF-IDF. The main purpose of the experiment stills the highest accuracy for text classification that achieved with two detected layers and 100 of neurons. It has been showed that representing the text with TF-IDF representation method outperform TF representation method in bi-gram, tri-gram, and (uni-bi) gram with ratios 90.34%,88.36%, and 90.65% respectively.

TABLE IV. ACCURACY OF SCG ALGORITHM ACCORDING TO TF AND TF-IDF FEATURES SELECTION WITH FIXED LAYERS AND NEURONS

	Tf	Tf-idf
Uni-gram	88.02	86.29
Bi-gram	89.78	90.34
Tri-gram	87.79	88.36
(Uni,Bi)-gram	89.55	90.65
(Bi,Tri)-gram	88.76	88.55

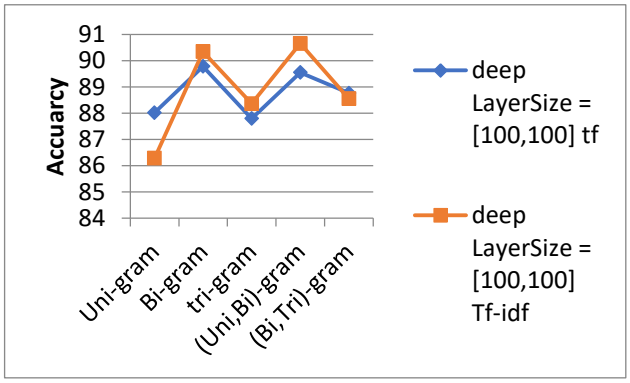

Fig. 4. The Change of Accuracy for Proposed Method versus N-Gram Model.

Moreover, the best result achieved absolutely in this experiment was in the proposed combination of (uni-bi) gram with ratio 90.65%. Fig. 4 shows the highest of accuracy ratios between the N-gram and the proposed combination of words with TF and TF-IDF representation methods.

E. Comparing of the SCG and the GDX According ICW Proposed Method Versus N-Gram Method

The experiment was executed based upon the framework in Fig. 2 with the detailed steps which have been discussed before. This experiment was established to explore the effects of both fixed number of hidden learning layers and fixed number of neurons for each layer in the accuracy level of the classifier. Besides, it compares different combination methods such as uni-bi gram, bi-tri gram versus the N-gram with different representation methods. We measure the accuracy level of the equation number based on the confusion matrix.

Tables V and VI shows the results for discussing the factors that affect the accuracy of the classifier with both representation methods TF and TF-IDF. The main purpose of the experiment stills the highest accuracy for text classification that achieved with a detected number of layers and 100 neurons between the proposed combination method (ICW) and the N-gram. It has been shown that the proposed combination uni-bi gram with the SCG algorithm outperforms the other technique with three layers and 100 neurons even with the TF representation method or with the TF-IDF representation method with ratios of 89.45% and 89.60%, respectively.

TABLE V. COMPARING OF THE SCG VERSUS THE GDX ACCORDING N-GRAM METHOD

Feature selections	Layer size	Algorithm	Uni-gram	Bi-gram	tri-gram
			ACC	ACC	ACC
Tf	Ls[2*100]	scg	88.02	89.78	87.79
		gdx	85.82	82.23	80.12
	Ls[3*100]	scg	88.74	88.35	87.86
		gdx	87.35	81.98	79.52
Tf-idf	Ls[2*100]	scg	86.29	90.34	88.36
		gdx	86.07	81.95	79.68
	Ls[3*100]	scg	87.18	87.86	87.55
		gdx	84.22	83.94	79.90

TABLE VI. COMPARING OF THE SCG VERSUS THE GDX ACCORDING ICW PROPOSED METHOD

Feature selections	Layer size	Algorithm	(Uni,Bi)-gram	(Bi,Tri)-gram
			ACC	ACC
Tf	Ls[2*100]	scg	89.55	88.76
		gdx	84.93	80.52
	Ls[3*100]	scg	89.45	86.62
		gdx	83.93	83.20
Tf-idf	Ls[2*100]	scg	90.65	88.55
		gdx	83.62	80.27
	Ls[3*100]	scg	89.60	87.66
		gdx	83.99	80.31

Moreover, the best result achieved absolutely in this experiment was in the proposed combination of (uni-bi) gram with a ratio of 90.65% with the TF-IDF representation method, two layers, and 100 neurons. In addition, the last comparison mentioned that the SCG algorithm outperforms the GDX algorithm in all experiments.

VII. CONCLUSION

This paper aims to investigate and to improve a generic framework for Arabic text classification. It deals directly with a word in its original style as a basic unit of modern Arabic sentence and on different levels of N-grams versus ICW proposed method. However, it aimed at discussing the results of the different experiments for studying the effect of changing the architecture concerning learning layers of different deep learning algorithms on ATC as a case study. In addition, a new legal dataset for requests of Prosecutors was presented for the purpose of testing and training the proposed framework in different experiments.

The main results that are drawn from this work showed that with increasing the number of hidden layers with a fixed number of neurons affects the accuracy of the SCG classifier with TF and TF-IDF representation methods respecting to uni-gram. However, it has been detected that the SCG algorithm achieved the best accuracy ratio with 90.07% with the TF-IDF representation method; also, in comparing the accuracy of the SCG algorithm between N-gram and the proposed method (ICW) with a fixed number of layers and neurons. It has been shown that representing the text with the TF-IDF representation method and the proposed method (ICW) (uni-bi) gram outperforms TF representation method with ratio 90.65%. Moreover, it has been shown that the proposed method (ICW) (uni-bi) gram with the SCG algorithm with TF-IDF representation method outperforms the GDX algorithm with a ratio of 90.65%.

For future work, the proposed model needs to be tested with different large datasets as a benchmark for generalizing and extracting a lot of results. Besides, the proposed model needs to integrate an optimization technique as feature reduction for enhancing the "curse of dimensionality" problem.

***Abstract*—Decision makers for decades have used SWOT analysis for strategic planning. However, the problems that arise in the SWOT analysis are subjective, so decision-making becomes inefficient. Therefore, SWOT analysis is often combined with other methods to make decision-making strategies more focused and measurable according to priority interests. The SWOT analysis basis in this study is Simultaneous Importance-Performance (SIPA) analysis by observing each indicator's weights. In addition, this study proposes a new method by focusing on competitor factors in strategies mapping to improve services for Electronic-Based Government Systems (SPBE). The object of this study was two local governments in Indonesia, namely the Meranti Islands Regency and the Limapuluh Kota Regency. The results showed that a SIPA-based SWOT analysis has succeeded in showing the Strengths, Weaknesses, Opportunities, and Challenges of the district government. Furthermore, based on the results of hypothesis testing, SIPA-based SWOT identification has reflected a valid organizational situation.**

Keywords*—Importance performance analysis; strength weakness opportunity threat analysis; service quality; electronic based government systems

I. Introduction

For approximately 60 years, Strengths, Weak, Opportunities, and Threat analysis (abbreviated as SWOT) have been a key and fundamental tool in strategic planning [1]. This analysis evaluates the organization's position to see its position in its internal and external environment. Strategic planning generally uses SWOT analysis, but the method is subjective and only focuses on solving weaknesses separately [2]–[4]. This problem is because the basis for SWOT analysis traditional approach is a qualitative analysis where SWOT factors tend to have a subjective view on the assessment of managers and planners, so they are considered inefficient and lead to wrong business decisions [2]. To prove its validity and accuracy, researchers often combine SWOT analysis with other techniques in various problems solving such as educational, industrial, agricultural, environmental, and economic [5]. The combination of SWOT analysis with other methods such as Analytical Hierarchy Process (AHP), Fuzzy AHP, Analytic Network Process (ANP), and Importance-Performance Analysis (IPA) shows that SWOT analysis is a flexible model [2], [6]. Based on several combinations of these methods, the combination of the SWOT-IPA method is considered accurate and valid to describe the organizational situation. Initially, managers used the IPA method as a marketing tool. However, its application extended to various fields, such as tourism, teaching, food service, health care, money-saving, human resources, and data innovation [7]–[13]. We find that each indicator has equal weight in some of these areas. Nevertheless, in some instances, each measure may have a different weight and need to be compared with other research objects to see the difference.

The combined IPA and SWOT methods [14] have not involved the problem for each indicator's initial weight. However, the indicator's weight determines a value's importance and performance. In addition, the IPA method only considers internal organizational aspects and dismisses the company's external factors. One of the improvements to the IPA method, namely Simultaneous Importance-Performance Analysis (SIPA), is a modification of the IPA method that map the relationship between the importance and performance of product/service quality attributes [9], [13], [15]–[17]. The modification made by SIPA is to pay attention to competitors' aspects in an organization's analysis [18]. In order to reduce these two deficiencies, this study applied SIPA to identify SWOT based on an SPBE survey conducted by the central government and local governments (self-assessment). In order to evaluate the SPBE services in Indonesia, the government has formulated each factor's weight [19].

The authors hope that by using SWOT-based SIPA analysis, organizations (in this case, local governments) can formulate strategic planning efficiently because the SWOT factors that must be maintained and improved can be identified based on the community's point of view. This study compares two local governments, namely the Meranti Islands Regency and the Limapuluh Kota Regency. These two regencies' location is on the island of Sumatra, Indonesia, with almost the same area and population. However, the Meranti Islands Regency was only established in 2008 and is a division of the Bengkalis Regency. Therefore, to accelerate the implementation of e-government, it is necessary to map various indicators of strengths, weaknesses, opportunities, and challenges. This paper consists of six sections: Introduction,

literature review, proposed method, result, discussion, and conclusions.

II. Literature Review

A. SPBE Service Indicators

SPBE services, according to the Regulation of the Ministry of State Apparatus Utilization and Bureaucratic Reform of the Republic of Indonesia Number 59 of 2020 concerning Monitoring and Evaluation of Electronic-Based Government Systems, consist of measuring the organization's service capability [19]. Therefore, the indicators used to measure the maturity level of SPBE services are electronic-based government administration services and electronic-based public services. Furthermore, there are five levels of measurement for service capability maturity: information, interaction, transactions, collaboration, and optimum. Therefore, the indicators listed in the SPBE service domain can be described as the aspects of electronic-based government administration services and aspects of electronic-based public services as follows:

The aspect of Electronic-Based Government Administration Services, with the weight of each indicator (ω_i), is 0.0604.

a) Indicator 1 Maturity Level of Planning Services.

b) Indicator 2 Maturity Level of Budgeting Service.

c) Indicator 3 Maturity Level of Financial Services.

d) Indicator 4 Maturity Level of Procurement Services.

e) Indicator 5 Maturity Level of Personnel Services.

f) Indicator 6 Maturity Level of Dynamic Archival Services.

g) Indicator 7 Maturity Level of State/Regional Property Management Services.

h) Indicator 8 Maturity Level of Government Internal Supervision Services.

i) Indicator 9 Maturity Level of Organizational Performance Accountability Services.

j) Indicators of 10 Maturity Level of Employee Performance Service.

The aspect of Electronic-Based Public Services, with the weight of each indicator (ω_i), is 0.0659.

a) Indicator 11 Maturity Level of Public Service Complaints Service.

b) Indicator 12 Maturity Levels of Open Data Services

c) Indicator 13 Maturity Level of Documentation Network and Legal Information

d) Indicator 14 Maturity Level of Public Service Sector 1

e) Indicator 15 Maturity Level of Public Service Sector 2

f) Indicator 16 Maturity Level of Public Service Sector 3.

B. Simultaneous Importance-Performance Analysis (SIPA)

SIPA is a modification of IPA which added competitor factors in evaluating the organization [20]. The description for some of the stages in conducting the SIPA analysis is as follows:

Step 1. Define the weight ω_i of each SPBE service indicator by expert or government regulation, which i is the number of attributes.

Step 2. Collect data through questionnaires performance (χ_{ij}), and importance (γ_{ij}) indicator of item i in the local government j as χ_{ij} and γ_{ij} multiplied with ω_i. Then, calculate the performance and importance as formula (1).

$$\chi_{ij} = \omega_i \cdot \chi_{ij}; \gamma_{ij} = \omega_i \cdot \gamma_{ij} \quad (1)$$

Step 3. The coordinates of SIPA are then divided by equation (2). Then, a judgment on the quadrant SPBE service indicator should be put on each local government (see Fig. 1).

$$\bar{\chi} = \sum_{i=1}^{k}\sum_{j=1}^{l}\chi_{ij} \Big/ K; \bar{\gamma} = \sum_{i=1}^{k}\sum_{j=1}^{l}\gamma_{ij} \Big/ K \quad (2)$$

Fig. 1 shows 4 quadrants, quadrant 1 (top priority), quadrant 2 (keep achievement), quadrant 3 (low priority), and quadrant 4 (excessive).

Step 4. Summarize and categorize the results as below:

If the indicator is in quadrants 1 and 4, it is labeled strength. If the indicator is in quadrants 2 and 3, it is labeled weakness.

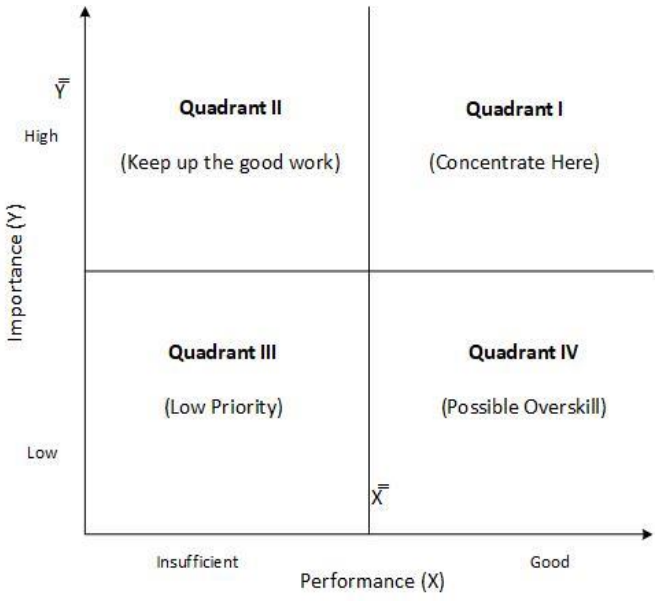

Fig. 1. IPA Matrix [21].

C. Strength, Weakness, Opportunity, and Threat (SWOT) Analysis

The analysis of strengths (S), weaknesses (W), opportunities (O), and threats (T) (SWOT) summarizes the central elements taken by studying the external and internal environment of each organization. Strengths include the organization's internal capabilities, resources, and positive situational factors in achieving its goals. On the other hand,

Weaknesses are internal limitations and negative situational factors that can hinder the organization [3]–[5]. The SWOT table generates the Importance-Performance analysis results, with the researchers' provisions in Table I.

TABLE I. SWOT IDENTIFICATION TABLE

Strength-Weakness		***SWOT Aspect***	***Implication***
Organization	Competitor		
S	S	S	Head-to-head competition
	W	O	Competitive advantage
W	S	T	Competitive disadvantage
	W	W	Neglected opportunities

III. PROPOSED METHOD

The method proposed in this study consists of several stages: filling out questionnaires by the central government (performance) and local governments (importance). Then the second step is to simultaneously conduct an importance and performance analysis on a local government and competitors. Finally, the results of the SIPA analysis become the basis for a SWOT analysis in a local government. Fig. 2 describes the proposed method.

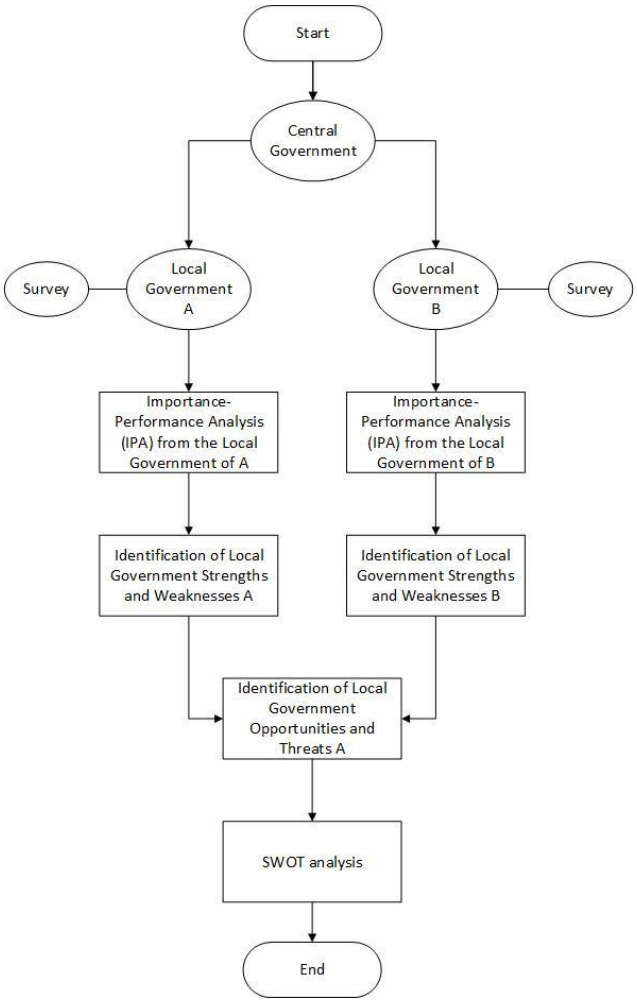

Fig. 2. Proposed Method.

IV. RESULT

A. Case Studies in the Meranti Islands Regency and Limapuluh Kota

This study reviewed two local governments of the Meranti Islands Regency and Limapuluh Kota Regency, Indonesia. These two local governments have almost the same area and population. However, the Meranti Islands local government is still quite young because of the expansion of the Bengkalis Regency. The Meranti Islands Regency has the vision to create good, clean, and responsible governance to provide excellent service, including implementing SPBE. Therefore, the Meranti Islands Regency needs a special strategy to map the appropriate needs and activities to achieve its goals.

B. SIPA Analysis

Based on the results of the SIPA analysis, the importance value was obtained from an independent assessment by Meranti Regency (district A) and Limapuluh Kota Regency (B). Meanwhile, the researchers used a questionnaire to obtain the performance value from a central government assessment through the Ministry of Administrative and Bureaucratic Reform of the Republic of Indonesia. The questionnaire to fill out is on the web https://monev.spbe.go.id/. Each indicator value is multiplied by its weight and entered in the corresponding quadrant. The quadrant determination is as follows:

1) If the performance value (χ_{ij}) is less than the overall average value $\sum \chi_{ij}$, it falls into the insufficient category. On the contrary, if the performance value exceeds the overall average value, it falls into the good category.

2) If the value is importance (γ_{ij})less than the average value of the overall importance $\sum \gamma_{ij}$, then it falls into the low category. On the contrary, the importance value is more than the overall average value, so it falls into the high category.

Table II shows that in District A, the indicators in quadrant 1 (Q1) are 9, 13, and 14. While in quadrant 2 (Q2) is indicator number 1-4, 12, 15-16. In quadrant 3 (Q3), there are indicator numbers 6-8 and 10-11. District B's indicators in quadrant 1 (Q1) are 2, 4, 11, and 15. In Q2, its indicator number is 16; in Q3, the indicator numbers are 6-9 and 13. Finally, in quadrant 4 (Q4), the indicator is 1, 3, 5, 12, 14.

Fig. 3 and Fig. 4 show more detail on the IPA matrix. The pictures show that the value in quadrant 1 is an indicator value with high importance (high) and good performance (good), so the indicators in this quadrant can be maintained. Whereas quadrant 2 shows high importance indicator values (high) but poor performance values (insufficient), it is an indicator that must be aware. Organizational concentration needs to focus on increasing the value of these indicators. Quadrant 3 contains the indicators of importance value that are less important (low) and have poor performance (insufficient), so they are indicators with low priority. Quadrant 4 contains low importance indicators (low) but good performance (good), so the indicators in this quadrant are excessive, allowing them to be the final priority.

TABLE II. IMPORTANCE-PERFORMANCE OF THE TWO DISTRICT

Indicator	District A			District B		
	I	*P*	*IPA Quadrant*	*I*	*P*	*IPA Quadrant*
Indicator 1	0.181	0.060	Q2	0.181	0.242	Q4
Indicator 2	0.181	0.060	Q2	0.242	0.242	Q1
Indicator 3	0.181	0.060	Q2	0.181	0.242	Q4
Indicator 4	0.181	0.060	Q2	0.242	0.242	Q1
Indicator 5	0.181	0.060	Q2	0.181	0.242	Q4
Indicator 6	0.060	0.060	Q3	0.181	0.181	Q3
Indicator 7	0.060	0.060	Q3	0.181	0.181	Q3
Indicator 8	0.060	0.060	Q3	0.181	0.181	Q3
Indicator 9	0.181	0.121	Q1	0.181	0.181	Q3
Indicator 10	0.060	0.060	Q3	0.181	0.181	Q3
Indicator 11	0.066	0.066	Q3	0.264	0.264	Q1
Indicator 12	0.198	0.066	Q2	0.198	0.264	Q4
Indicator 13	0.198	0.132	Q1	0.198	0.132	Q3
Indicator 14	0.198	0.132	Q1	0.198	0.330	Q4
Indicator 15	0.198	0.066	Q2	0.264	0.264	Q1
Indicator 16	0.198	0.066	Q2	0.264	0.198	Q2
Average	**0.149**	**0.074**	-	**0.207**	**0.222**	-

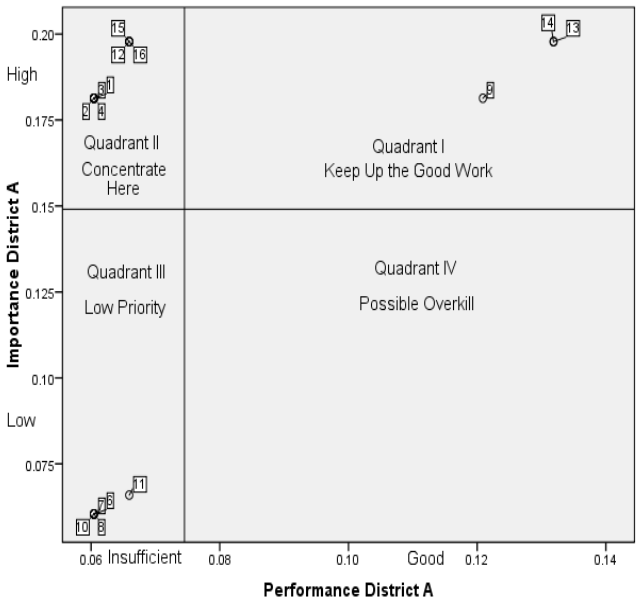

Fig. 3. IPA Quadrant for District A.

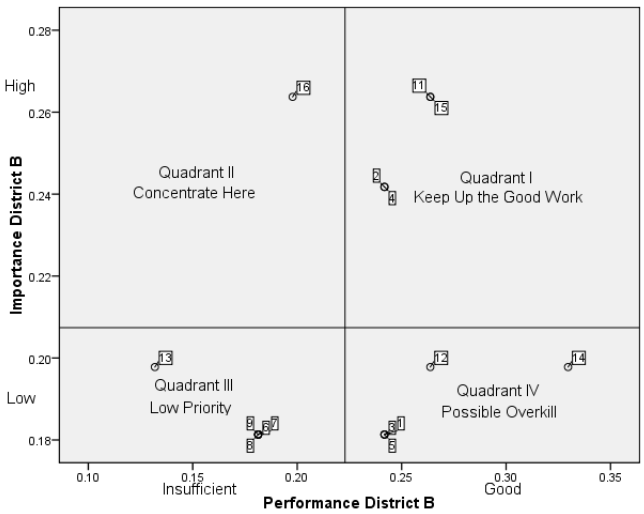

Fig. 4. IPA Quadrant for District B.

Based on the results in Fig. 3 and Fig. 4, the next step is to create the Strength-Weakness table. If the indicator is in quadrants 1 and 4, the label is strengths, and if it is in quadrants 2 and 3, the label is weakness. According to the SWOT identification in Table I, a SWOT analysis was formed for District A. The researchers calculate the aggregate weight value from the importance value multiplied by the final performance. The sign (-) indicates Threat or Weakness, while the sign (+) on the Aggregate Weight indicates Strength or Opportunity. Table III shows the SWOT analysis of District A in detail.

TABLE III. STRENGTH-WEAKNESS OF DISTRICT A

Indicator	*Strenght-Weakness*		*SWOT District A*	*Aggregate weight**
	District A	District B		
Indicator 1	Weakness	Strength	Threat	-0.0109
Indicator 2	Weakness	Strength	Threat	-0.0109
Indicator 3	Weakness	Strength	Threat	-0.0109
Indicator 4	Weakness	Strength	Threat	-0.0109
Indicator 5	Weakness	Strength	Threat	-0.0109
Indicator 6	Weakness	Weakness	Weakness	-0.0036
Indicator 7	Weakness	Weakness	Weakness	-0.0036
Indicator 8	Weakness	Weakness	Weakness	-0.0036
Indicator 9	Strength	Weakness	Opportunity	0.02191
Indicator 10	Weakness	Weakness	Weakness	-0.0036
Indicator 11	Weakness	Strength	Threat	-0.0043
Indicator 12	Weakness	Strength	Threat	-0.0130
Indicator 13	Strength	Weakness	Opportunity	0.02608
Indicator 14	Strength	Strength	Strength	0.02608
Indicator 15	Weakness	Strength	Threat	-0.0130
Indicator 16	Weakness	Weakness	Weakness	-0.0130

[a.] Compute by multiplying the importance by positive/negative performance (for strength, opportunity/weakness, threat)

Table III shows the indicators in the SWOT category in District A,

Strength:

Indicator 14 Maturity Level of Public Service Sector 1.

Opportunity:

1) Indicator 9, Maturity Level of Organizational Performance Accountability Services.
2) Indicator 13, Maturity Level of Documentation Network and Legal Information.

Threat:

1) Indicator 1, Maturity Level of Planning Service.
2) Indicator 2, Maturity Level of Budgeting Service.
3) Indicator 3, Maturity Level of Financial Services.
4) Indicator 4, Maturity Level of Procurement Services.
5) Indicator 5, Maturity Level of Staffing Services.
6) Indicator 11, Maturity Level of Public Service Complaints Service.
7) Indicator 12, Maturity Level of Open Data Services.
8) Maturity Level of Public Service Sector 2.

Weakness:

1) Indicator 6, Maturity Level of Dynamic Archival Service.
2) Indicator 7, Maturity Level of State/Regional Property Management Services.
3) Indicator 8, Maturity Level of Government Internal Oversight Services.
4) Indicator 16, Maturity Level of Public Service Sector 3.

Thus, 8 threat and 4 weakness indicators should be an important concern of stakeholders in determining the priorities of the SPBE implementation strategy in District A.

V. Discussion

We tested the results using a questionnaire to ascertain whether the proposed method has met stakeholders' satisfaction. We used another questionnaire of 6 District A staff respondents to clarify these findings. The survey is done for evaluation purposes since there is no direct method or tool to validate the effectiveness of an IPA-based SWOT analysis [2]. The evaluation questionnaire consisted of closed questions asking the respondents' approval level in District A for the results of the IPA-based SWOT analysis shown in Table IV. Each question uses a score of a four-point Likert scale (1 = Strongly disagree to 4 = Strongly agree) without a midpoint that acts as a neutral choice. The hypothesis formulated is as follows:

H_0: The mean response is equal to 2.5.

H_a: The mean response is not equal to 2.5.

The tested hypothesis is at a significance level of 5%, with one sample t-test analysis shown in Table IV.

TABLE IV. Strength-Weakness of District A

Variable	*Mean*	*SD*	*Mean difference*	*t*	*df*	*Sig. (2-tailed)*
W_{avg}	3.08	0.10	0.58	12.124	3	0.001
O_{avg}	3.58	0.12	1.08	13	1	0.049
T_{avg}	3.25	0.31	0.75	6.87	7	0.000

Table IV shows that the average respondent's weakness, opportunity, and threat assessments are at 3.08, 3.58, and 3.25. Whether to accept or reject the hypothesis shown from the calculated *t* values on weakness, opportunity, and threat, respectively, namely 12.124, 13, and 6.87, with degrees of freedom 3, 1, and 7. This data shows that the table t values for weakness, opportunity, and threat are 3.182, 12.71, and 2.365.

The decision-making is done by comparing the calculated t-values and t of the table. When observed, the calculated t values for weakness, opportunity and threat are greater than t of the table; this means the results reject H_0. Similarly, when viewed from the significance values of the three variables below 0.05, it also rejects H_0. This result means that the respondent (District A staff) agreed with the IPA-based SWOT results' Strengths, Weaknesses, Opportunities, and Threats. Based on the analysis, this model is recommended for decision-making by considering the weight of the criteria and competitor factors.

VI. Conclusion

This research results from implementing a SIPA-based SWOT analysis that measures the level of importance as a representation of expectations from the organization to performance assessed by other parties. This method also considers the weights on each of the indicators and also the competitors of an organization. Taking into account internal and external factors, shows that district A has 8 indicators of threat and 4 indicators of weakness out of 16 indicators of electronic-based government system services. In this analysis, respondents confirmed and approved the results regarding the Strengths, Weaknesses, Opportunities, and Threats of District A on the SPBE service indicator. Thus, this model can be used for decision-making by considering the weights of indicators and competitor factors in various cases. The future work in this research is to combine the SWOT method with other methods, such as the Simple Additive Weighting (SAW), Technique for Order by Similarity to Ideal Solution (TOPSIS), Profile Matching (PM), and other appropriate procedures. Further development can also be focused on the number of additional research objects.

Acknowledgment

Thank you to LPPM Institut Teknologi Telkom Purwokerto for funding this research with IT contract number Tel2411/LPPM-000/Ka. LPPM/IV/2022 on behalf of Tenia Wahyuningrum. Thank you to Mr. Amat Safii, head of the communication and information section of the Meranti Islands Regency, and Mr. Fery Chofa, head of the communication and information service of Limapuluh Kota Regency, Indonesia, who have been willing to become the object of research.

***Abstract*—The not so long ago, Artificial Intelligence (AI) has revolutionized our life by giving rise to the idea of self-learning in different environments. Amongst its different variants, Federated Learning (FL) is a novel approach that relies on decentralized communication data and its associated training. While reducing the amount of data acquired from users, federated learning derives the benefits of popular machine learning techniques, it brings learning to the edge or directly on-device. FL, frequently referred to as a new dawn in AI, is still in its early stages and is yet to garner widespread acceptance, owing to its (unknown) security and privacy implications. In this paper, we give an illustrative explanation of FL techniques, communication, and applications with privacy as well as security issues. According to our findings, there are fewer privacy-specific dangers linked with FL than security threats. We conclude the paper with the challenges of FL with special emphases on security.**

Keywords*—Federated learning; communication; security; deep learning; Artificial Intelligence

I. Introduction

In the modern era, ubiquitous mobile gadgets are coupled with computation and sensor capabilities that collect large volumes of data. Such massive quantities of data are used to train various learning algorithms. These learning techniques, when combined with Data Mining and AI in other words with Deep Learning (DL) breakthroughs, enable a wide range of beneficial applications, including image analysis, speaker identification, healthcare, vehicular networks, among others. Machine Learning (ML) techniques need to be checked in and generally have to be consolidated on internet-based cloud services. However, due to the enormous volumes of data and privacy-critical nature, login into such cloud services to train supervised learning is cumbersome. As a result, major challenges such as excessive latency and transmission inefficiencies arise. The notion of Federated Training or Learning (FL) has now been proposed in face of emerging privacy rules in various nations. Mobile phone users in Federated Learning (FL) can train a feature map by pooling their native models without disclosing their confidential material. In ML, a model is usually developed by training locally on the user's own server (PC) whereas, in FL, the model is built by training on different machines located at distributed locations and there is no dedicated connection between the servers. They have their dataset or database sample at their ends. In simple terms, a form of machine learning that is decentralized is termed federated learning [1]. While there has been some research on this subject, there is not enough progress in terms of comprehending FL's security and privacy implications. This paper aims to provide a full review of FL in terms of a formal definition, then we compare ML models with salient features and tabulate. We also discuss the pros and cons graphically along with the challenges. Finally, we provide some recommendations, making this unique among previous studies. The following is a summary of this paper's contributions to the field's recent literature:

- Providing a categorization and review of the FL methods and strategies.
- Identifying and examining pros and cons in FL environments.
- Delineating potential applications of FL environments.
- Highlighting challenges faced by FL systems with special emphasis on the security.
- Providing recommendations to enhance the security and privacy of the FL implementation.

II. Federated Model and Critical Analysis

ML techniques traditionally require that all the training data be centralized on a single server in a datacenter or the cloud. With enormous increase in the number of mobile devices and the training data available on various machines, the challenge of assimilating the relevant data arises. Federated learning uses the model training approach that enables a device to train from the collaboration of shared models. Proxy data on the server initially trains the shared model. Subsequently, the model is downloaded on each device and then improved by data locally stored on the device, which is also termed as federated data. ML algorithms assume that all learning data is available and maintained in a centralized dataset. In order to facilitate such training, centralized learning networks are created. These networks have serious privacy concerns, high communication costs, and scalability challenges. Federated Learning (FL) has been introduced to enable remote supervised learning without a centralized training classifier, considering the aforementioned difficulties. It can be observed from Fig. 1(b) that the federated learning network is composed of multiple Edge Devices (EDs)

and servers. According to a survey, in federated learning networks, a machine-learning model is trained with two iterative steps such as local model training and global model aggregation at EDs and server respectively [2]. In the first stage, EDs update the local model with the downloaded model from the server, algorithms of Stochastic Gradient Descent are executed to learn the local model with their dataset and upload the updated model to the server. In the next phase, model updates received by the server are aggregated with weighted average to previous global model and thus the new model is obtained. These two steps involve a training round. In a federated learning model or network, the parameters of the ML model are exchanged instead of data and this prevents and reduces privacy issues with the reduction of communication overhead. Federated learning is deployed with flexibility in multiple environments including the mobile environment that is a complicated one [3]. Comparison of machine learning models with salient features is given in Table I.

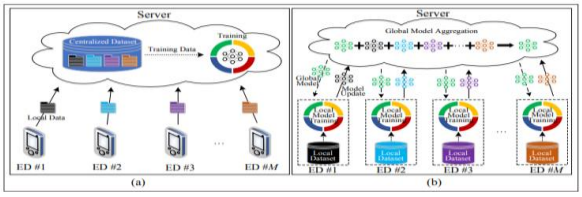

Fig. 1. System Model between Centralized ML Network vs Decentralized FL Network [4].

Federated Learning Network (FLN) has also been adopted to orchestrate various mobile devices across the world for training language models with BERT [7]. All such mobile devices are owned by different users and then connected to multiple types of links such as WiFi, mobile network, etc. Hence, in terms of ownership, capabilities, and computing, Edge Devices (EDs) in federated learning model are heterogeneous [1].

TABLE I. COMPARISON OF MACHINE LEARNING MODELS WITH SALIENT FEATURES [2]

Scheme	Salient features	Used in percentage according to survey
Distributed learning	Provision of holistic estimation of parameters	21%
Parallel learning	Distribution of data in laid fashion	27%
Federated learning	Model training using natural database, massive distribution of data over local learners	45%
Ensemble learning	Production of an optimal model	7%

Federated Learning (FL) is reliable for joint ED's efforts for the training of the ML model. Even with an abnormality of few EDs, Machine Learning model can be tampered. Besides all this, the FL model or network has multiple attack surfaces concerned with the security of federated learning such as malicious EDs, and insecure connections. These attack surfaces are vulnerable to many security issues in FL networks such as data positioning as well as model positioning [4]. Survey analysis of the given graph shows the results of two cases in comparison with using active federated learning framework (Fig. 2).

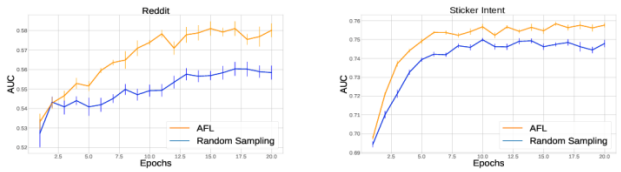

Fig. 2. Comparison of AUC on Reddit and Sticker Intent using Active FL Framework [8].

III. ADVANTAGES OF FEDERATED LEARNING

Diversity of data: Large-scale ML models may be unable to merge datasets from diverse sources. The reasons for impediments are partially due to the information security, reluctance and connection unavailability among the edge devices. On the other hand, Federated learning makes it easier to access diverse data, even when sources of data could only interact at a particular period (Fig. 3).

- Real-time learning continuity: There is no requirement for aggregate data in continuous learning because algorithms are constantly upgraded using client information.
- The efficiency of hardware: Since decentralized learning methods do not require a single, complex cloud database to interpret data, this strategy requires less complex hardware infrastructure [6].

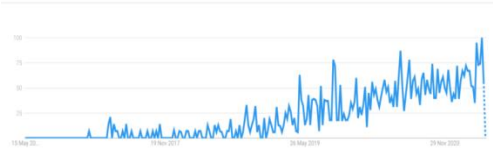

Fig. 3. Interest Overtime Related to use of Federated Learning [5].

IV. APPLICATIONS OF FEDERATED LEARNING

In terms of distributed machine learning, FL is a viable approach with the inherent characteristics of privacy. Without communicating data, many nodes can work together to develop a collaborative learning model. Data access rights, privacy, security, and access to a variety of data types can all be managed in this way. It is believed that FL has applications in a wide range of areas such as Industrial IoT, healthcare, smart transportation, self-driving cars; traffic forecasting; smart buildings, recommender system, Fintech, the insurance sector, and telecommunications [13-14].

FL is a revolutionary technique for machine learning. It has the potential to have a profound impact on the healthcare sector. It can also help healthcare workers in many ways. Sharing health care data raises a number of privacy issues. In addition, strict laws like HIPPA make it more challenging to exchange critical data, which has made it more difficult to conduct studies that could lead to new medical advancements. All parties, including hospitals, AI businesses, and regulatory

authorities, have a responsibility to protect extremely sensitive information. Researchers are currently investigating how FL may be utilized to protect patients' privacy while beneficially utilizing their data. FedHealth [14] is the first federated transfer learning framework for wearable healthcare, capable of providing precise and individualized healthcare without risking patient privacy. A community-based federated learning algorithm (CBFL) [15] proposes a system that clusters distributed data into clinically significant communities based on shared diagnoses and geographical locations and then develops a model for each community. Li et al. [16] develop a brain tumor segmentation FL system using differential privacy to protect patient data. Patients with uncommon tumors will benefit from Owkin's FL-based platform, which will be used in tests to determine drug toxicity, predict disease progression, and assess survival rates [17].

Zhang et al. [18] propose an Industrial Internet identification using blockchain and federated learning technologies, which provides privacy protection. Liu et al. [19] develop an on-device FL-based deep anomaly detection system for IIoT time series data sensing, which detects edge devices' failure in IIoT industrial product production. Edge device failures adversely affect IIoT industrial product production. Khanal et al. [20] examine the value of proactive content caching in self-driving cars to reduce content retrieval costs and improve QoE with edge cloud infrastructure. It extracts local content popularity patterns in self-driving automobiles utilizing LSTM-based prediction mechanisms in a federated scenario to predict regional content popularity.

Machine learning is constantly growing and reshaping the technological landscape. FL applications, like any other machine learning technique, face challenges. In spite of its flaws, it has the potential to transform numerous industries. There will be tremendous progress in FL and its diverse applications soon. When applied effectively, it can aid in the evolution of numerous sectors and benefit users.

Another area where FL finds its rigorous application is data communication. For instance, the feasibility of FL for its using in 6G communication systems has been investigated in [21]. The FL key challenges for 6G include security, cost-effective systems, and privacy concerns. FL can also be used for data augmentation in wireless communication. For instance, edge users can cooperate by sharing certain parameters, which in turn significantly reduces the communication overhead [22]. FL also finds its application in Wireless Power Transfer (WPT) where Wireless-Power enabled can be enabled. A complete wireless-power enabled FL has been investigated in [23].

V. Challenges of Federated Learning with Special Emphases on Security

There are multiple disadvantages related to security issues of the federated learning model. These include data positioning as well as model positioning. The main aim of the positioning attack is to degrade the accuracy of the machine-learning model. This happens by tampering the aggregation of global models with updates of the poisoned model of federated learning [9]. The attack surfaces for such insecurities are Malicious Edge Devices (MEDs) and insecure connections. MEDs are set by the attackers in smart devices through malware. As new smart devices are more sophisticated and have inescapable flaws. Hence, it is convenient for attackers to join the Federated Learning Networks (FLNs) through malicious EDs. Moreover, security of all connections through which the EDs of federated learning model are connected to the network needs be monitored. Wireless connection has vulnerability through various channels. Through such insecure connections, the uploaded model updates of Federated Learning might be manipulated or hijacked. In data poisoning attacks on the security of federated learning, these intentional attacks intend to achieve low accuracy of machine learning models on certain classes. Attackers to the federated learning securities flip labels of training data in those concerned classes [5].

In model poisoning attack on the security of federated learning, the attack is concerned with the ML model updates that are generated from Gaussian distribution (see Table II). In this, the attacker manipulates updates of the benign model into poisoned updates. To achieve this purpose, attackers use updates of pre-model designs to craft the updates of the poisoned model and replace the ML model with the pre-designed poisoned models. The vulnerability points for all these attackers are insecure connections and malicious Edge Devices (EDs). Furthermore, other disadvantages are performance limitations, indirect leakage of information, and a degree of centralization [10].

TABLE II. Attacks at Securities of Federated Learning [8]

Security attacks	**Description**	**Methodology for attacks**	**Target users**
Data poisoning	Training data is modified by attackers and EDs training is made incorrect as well as poisoned updates of the model are generated.	Labels of training data are flipped intentionally, and labels of training data are also flipped in certain classes.	Unintentionally
Model poisoning	Poisoned updates of the model are created by attackers Benign model updates are manipulated based on pre-designed rules.	• Model updates are generated using pre-designed poisoned model to impact the security of federated learning. • Flipping signs of model updates.	Intentionally

Lots of investment is required for federated learning models with frequent communication and large storage capacity with high bandwidth. Data is not collected on a single entity, which increases attack surfaces [1]. The below Fig. 4 depicts the secure aggregation of private federated learning. In this scenario, aggregator or server builds a global model jointly without revealing the security of training data. Hence, it is powerful in terms of keeping privacy while computing millions of data in parallel [3] (Fig. 5).

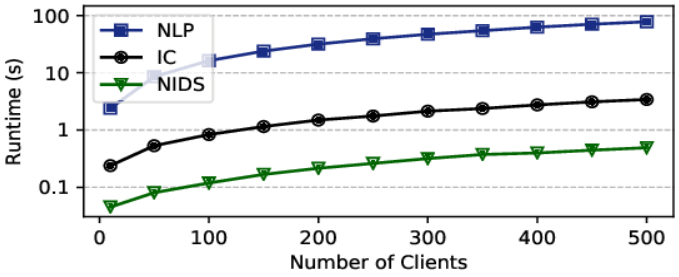

Fig. 4. Secure Aggregation of Private Federated Learning [1].

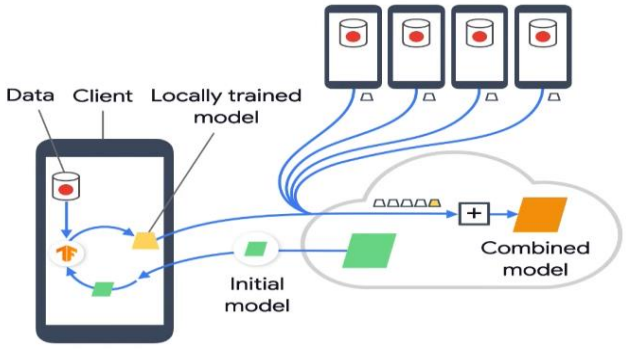

Fig. 5. A Typical Federated Learning Model.

A. Active Federated Learning

The gadgets obtain a training program (which is normally small size in terms of few bytes).

- The gadgets are programmed to learn from local data.
- The sensing notes the computer anonymized updates mostly on variables.
- The data from devices are aggregated by the administrator. The server combines the information it receives from each variety of technologies to conduct an approach with regards to the present system by each grouping.
- The newly added model is delivered to the gadgets with an assessment (again, the idea of decentralization is at work here) as well as a fresh round between training after several rounds of learning [8] (Fig. 6).

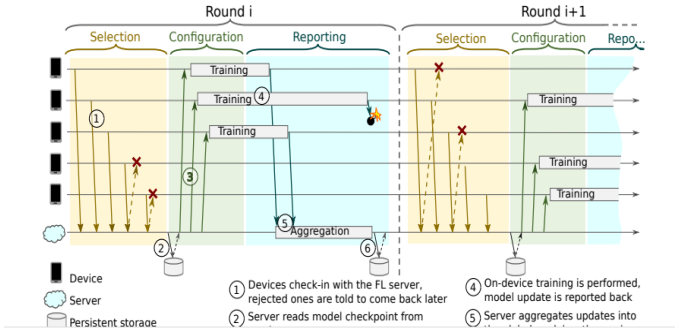

Fig. 6. Federated Learning Protocol [11].

VI. Recommendations and Suggestions

Privacy preservation, safe multiparty processing, and cryptography are examples of confidentiality technologies that can be utilized to improve the data protection possibilities of federated learning. A variety of measures is suggested in this section. First, sharing less information about the generic model updation at the server can maximize the privacy of the Federated-learning model [12]. Moreover, the use of deep neural network also makes complex the use of available gradients. There is also possibility for developers to choose or create an algorithm that has less chance of data breaching and attack on the security of federated learning system. Using more privacy regulations will also inevitably make data acquisition easier and less vulnerable to exploitation [1].

VII. Conclusion

The paper discussed the federated learning techniques and applications with respect to privacy as well as security issues. Federated learning has been successfully implemented in a variety of settings, such as the challenging mobile environment. Despite the advantages of federated learning, there are many privacy and security issues related to the model. When contrasted to exchanging personal data across data centres, federated learning offers certain privacy benefits. The capability to immensely develop machine-learning algorithms depending on user input, while minimizing bandwidth impacts for uploading confidential information over the network is also one of the advantages. Data poisoning and model poisoning are two major security attacks on federating learning networks. Among communication networks, wireless connections are vulnerable. Federated learning system updates can also be altered or hijacked over such unsafe connections. In information poisoning threats on supervised learning of federated model security, these deliberate attacks aim to achieve poor sensitivity of machine learning techniques on specific classes. These attacks are vulnerable through two attack surfaces of federated learning mode such as internet connections and Edge Devices (EDs) of the federated learning model.

Machine Learning in OCR Technology: Performance Analysis of Different OCR Methods for Slide-to-Text Conversion in Lecture Videos

Geeta S Hukkeri, R H Goudar, Prashant Janagond, Pooja S Patil
Department of CSE, VTU
Belagavi, India

***Abstract*—A significant percentage of a lecture video's content shown is text. Video text can therefore be a crucial source for automated video indexing. Researchers have recognised printed and handwritten text extracted from pictures using a variety of machine learning techniques and tools before digitising it. A machine learning technology called optical character recognition (OCR) enables us to recognise and retrieve text information from documents, converting it into searchable and editable data. This study primarily focuses on text extraction from lecture slides using Google Cloud Vision (GCV), Tesseract, Abbyy Finereader, and Transym OCR and compares the results to develop a lecture video indexing scheme for the non-linear steering in lecture videos to watch only the interesting points of topics. We have taken a total of 438 key-frames in 10 categories from seven different lecture videos that range in length. First, binary and greyscale versions of the input colour images are created. Before using the OCR APIs, the frames are additionally preprocessed to improve the image quality. The recognition accuracy demonstrated that the GCV OCR performs effectively, saving computing time by collecting image text with the highest accuracy of other tools, 96.7 percent.**

Keywords*—Video lectures; keyframes; Google cloud vision (GCV); Tesseract; Abbyy Finereader; Transym; text extraction

I. INTRODUCTION

A branch of machine learning known as optical character recognition (OCR) is focused on identifying characters in visuals such as scanned papers, printed books, or photographs. Despite being a promising technology, there are currently no OCR solutions that can reliably recognise every type of text. Machines can directly handle texts found in the current world thanks to optical character recognition [13]. Education, banking, government, and medical sectors are just a few of the industries where OCR is used. The pre-processed image is fed into the OCR Engine, which then extracts the text that has been written on it. Due to the different written and printed text formats, modern OCR methods use deep learning to increase accuracy. The issue of text recognition can be solved using a variety of conventional deep learning techniques. The most well-known ones include YOLO [1, 2], SSD [2], Mask RCNN [3], and Faster RCNN [2]. These designs may be trained to do character recognition and are essentially entity detectors. Region-based detectors use algorithms like Faster RCNN and Mask RCNN. This implies that the method first scans the image for objects (text) before classifying them (characters). It is slower but more accurate because of this two-step approach. Single Shot Detector (SSD) algorithms like YOLO and SSD simultaneously scan the items and classify them. They are quicker because of the single step procedure, but they do poorly with smaller items, like text in our example. These systems are trained on any of the aforementioned datasets, and the trained systems can be used to anticipate or identify the text in any given image. The goal of qualified neural network (NN) rule generation has spurred a variety of research efforts. The primary classification method for such algorithms is in the manner in which they generate rules. The decomposition method compares each hidden and production node separately, and a pattern is derived from it for precise word detection from images. In a feed-forward NN, each neuron's output is quantified as:

$$R_j = \left(\left(\sum_i W_{ij} \times A_i\right) + \vartheta_j\right) \quad (1)$$

where $A_i = \frac{1}{1+e^{-ax}}$

here, A is the level of activation of neuron i, W_{ij} represents the weight of the relationship between neuron i and j, and is the level of activation of neuron j that controls the gradient of the sigmoid. The breakdown method's most important feature is that almost all of neurons in the NN have either 0 or 1 activations. Binary inputs trigger this in the hidden layer's neurons.

Numerous artificial intelligence scholars have attempted to address the issue of OCR difficulty in order to develop effective OCR systems able to operate in an accurate and timely manner since the advent of computerised systems [28–30]. Even though there are a variety of OCR techniques and toolkits now accessible in the literature, we will be comparing four popular OCR toolkits: Google Cloud Vision (GCV) OCR [24], Tesseract [25], ABBYY FineReader [26], and Transym [27].

Due to the enormous amount of data that deep learning demands for model training, businesses like Google have an advantage in achieving promising outcomes with their OCR services. The specifics of Google Vision OCR are covered in this paper. Using a straightforward REST API interface, the GCV API [7] constructs highly complicated machine learning models focused on image recognition. It has a wide range of image recognition abilities. In this paper, we've concentrated on the OCR module, which scans an image for text before parsing it into data for our computers to use.

A. Objectives

The following are the objectives of this study:

- Data Acquisition by extracting key-frames from lecture videos
- Pre-process the raw input dataset to improve the image quality
- Appy OCR engines to extract text from the key-frames
- Compare the performance OCR engines to decide the best OCR

II. Literature Survey

Deep learning is used in computer vision to build NNs that direct image analysis and evaluation [23]. The OCR methods were mechanical machines, not computers, that could recognise characters at first, but the performance was extremely slow, and the results were less accurate. Although OCR is not a recent issue, its roots can be seen in methods used before the development of computers [12]. OCR has been applied in a wide range of fields. The Transym and Tesseract OCR technologies, for instance, were used by Patel and Patel to analyse car licence plates [17].

The paper [18] used the GCV API to analyse images in another scenario involving an autonomous vehicle to increase the accuracy of object identification and give tough-environment autonomous robots the capacity to recognise objects. Additionally, many industries employ this system to speed up data entry and decrease human error when removing information from document management systems [19], [20]. Additionally, such innovation has been used more and more in smart systems, cloud computing, IoT, and robots. Examples include IoT-based car verification systems [22] and road sign text interpretation [21].

On text in floor plan pictures, conventional and deep learning text detection techniques were contrasted [14]. Four approaches were compared in the study: EAST, Maximally Stable Extremal Regions (MSER), Connectionist Text Proposal Network (CTPN), Stroke Width Transform (SWT), Tesseract, and a normal image processing methodology are the first four options. The last option combines all four of the first three options. Extra sub images were employed for the CTPN approach at the border since CTPN had trouble reading text that was near to the picture borders [14]. The combined technique produces an output that depends on voting by comparing the outcomes from all three previous methods against one another. All approaches to combining particular text boxes into a single text item underwent post processing. Initially, the text was categorised according to the rules. Next, room characteristics were compared to a dictionary of acceptable terms, and the nearest keyword was substituted according to edit distance and term frequency. The proposed approaches were tested on datasets with different levels of quality. The noisy and low quality images were demonstrated to have substantially reduced efficiency with the CTPN approach. The combination technique had the best accuracy on the poor quality images, while the EAST approach seemed to have the greatest recall and F1-score. The efficiency of the detected text was not thoroughly examined, and none of the suggested algorithms could recognise slanted or curving text items. However, it was reported that Tesseract did not make correct estimates on the low resolution pictures.

For image analysis, the GCV API was utilised [8]. Their effort locates and recognises printed text hidden within images, as well as particular items and faces inside images. The adaptability of the GCV API to input noise is assessed in the paper. In particular, when noise is applied to a group of images, the API would be unable to identify the appropriate text or object since, when the noise is cleared, the output is equivalent to the original image. Noise filtering is available for the GCV API. A model that enables users to hear the image's main message in their own language has been proposed in [9]. Text is first taken from the picture and afterwards transformed into the person's native language speech. After being captured by the camera, the image is converted to text by the OCR engine. The gTTS is then used to translate text into speech [9]. A system that interprets words from a taken image has been suggested. Tesseract OCR is used to extract text from digital documents, and the text is then converted to voice. In order to reduce noise, the first acquired image is first transformed to grayscale. After using thresholding, the image is transformed to a binary format, cropped, imported into tesseract OCR for word recognition, and outputted as a text file that can be used as an input for E-speak to generate audio [10]. As of right now, any language's text can be manually entered and converted to any other language as necessary. A whole text book's images cannot be translated from one language to another. Some mobile applications that attempted to convert the above exhibited significant faults. The current system [11], which uses classic OCR, is unable to distinguish text from blurry or poor resolution, blurriness, high noise, and distorted images. The final product is distorted by the image noise. Consequently, consumers experience a challenge with comprehension.

This study primarily focuses on text extraction from lecture slides using Google Cloud Vision (GCV), Tesseract, Abbyy Finereader, and Transym OCR and compares the results to develop a lecture video indexing scheme for the non-linear steering in lecture videos to watch only the interesting points of topics. The dataset is total of 438 key-frames in 10 categories from seven different lecture videos that range in length. First, binary and greyscale versions of the input colour images are created. Before using the OCR APIs, the frames are additionally preprocessed to improve the image quality. The recognition accuracy demonstrated that the GCV OCR performs effectively, saving computing time by collecting image text with the highest accuracy of other tools.

III. Steps Involved in OCR

OCR is a programme that converts text into an appropriate machine-readable format [18, 19]. OCR technology is often used in businesses for automation and processing of written receipts [20]. Researchers now have access to a wide collection of electronic texts that can be analysed using just a few keywords thanks to the OCR technique. Fig. 1 depicts the general OCR approach for text extraction:

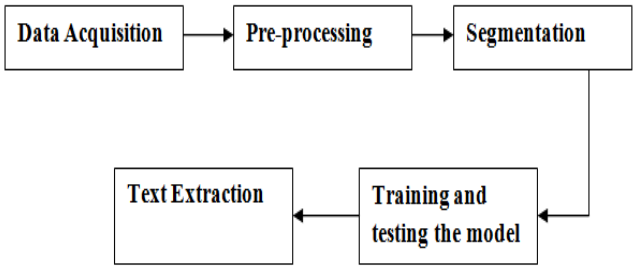

Fig. 1. General Text Extraction using OCR Model.

A. Data Acquisition

The data is a picture of text with straightforward or intricate layouts or backdrops in a scene or document from nature. We can get the text's visual representation via digital camera and handheld scanner [15]. There are several different types of text image databases that can be used for study. They are used to establish standards for processing speed, accuracy, and storage. A few of the datasets available for text extraction is given in [16].

B. Pre-Processing

Before using the OCR method, the raw input dataset must be cleaned up in this step to improve the image quality. The input image must be turned to grayscale and gaussian blur. The 1-dimensional and 2- dimensional Gaussian formula is given below in equations 2 and 3, respectively.

$$\text{GB (i)}=\frac{1}{\sqrt{2\pi\sigma^2}}e^{-\frac{i^2}{2\sigma^2}} \quad (2)$$

$$\text{GB (i, j)} = \frac{1}{\sqrt{2\pi\sigma^2}}e^{-\frac{i^2+j^2}{2\sigma^2}} \quad (3)$$

where i and j are the horizontal and vertical axis's distance from the origin respectively, and σ is the Gaussian distribution's standard deviation.

C. Segmentation

The pre-processed images are divided into several sections during segmentation. This comprises scanning an image for clusters of pixels that contain character-containing elements; each of these elements has a class applied to it. Any thresholding method must be used in order to allow for additional analysis. In general, using the right settings makes adaptive thresholding operate best. The segmentation procedure is carried out as follows:

$$S_\sigma(I[l_m, l_n]) = \sqrt{\sum_{I=l_i}^{m} prbden(i) + \left(T - l_i\left(I[l_i, l_j]\right)\right)^2 \times p_l^{I[l_i,l_j]}} + \theta \quad (4)$$

where $prbden$ (probability density) is,

$$prbden(i) = \frac{Histogram\,(i)}{mn} + threshold\ + intensity\,(i) \quad (5)$$

for i=0,1,…..n-1

A feature for an immediate layer's adaptive pixel set is calculated as follows:

$$o_i = \mu p_{i(i)} + \delta(i,j) \quad for\ i = 1,2,\ldots\ldots\ldots m \quad (6)$$

$$o_i = \mu q_{i(j)} - 2(x) + \delta(i,j) \quad for\ j = 3,4,\ldots\ldots n \quad (7)$$

here, μ is the layer importance taken into account when organising the layers in a sequential manner for precise and distinctive text recognition. The created single layer has a fixed total and estimates the result as the sum of all the pixels which make up a set. A fresh layer is produced as:

$$o_i = \frac{\sum \overline{w}(i)h(i)+\theta}{\sum \overline{w}(i)} + \delta(j,k)f_i \qquad for\ k = 1,2,\ldots\ldots m-n \quad (8)$$

D. Training and Testing the Model

The crucial OCR phase is model training. Numerous hyperparameters are engaged in this situation. These have either been generated from the training data or have default values set. Following their definition, a model that creates a generic picture -> text modelling for the data processes the data in the training event. The below Fig. 2 depicts the training and testing phase of the model.

On the provided image, feature extraction is carried out using FEL to produce a feature map. CRGL uses a 3×3 hole convolutional and the anchor procedure to create basic areas in an image by clearing dublicate features. CASL uses Soft-Nonmaximum Suppression (NMS) to get the preliminary areas in the image. A Region of Interest (RoI) can be obtained from the image by using the ROI pooling method in TDL. The training model is established as:

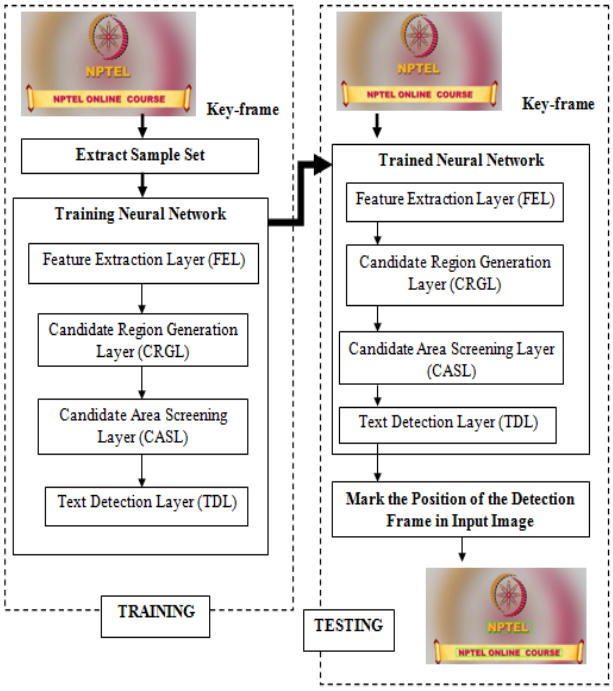

Fig. 2. Training and Testing Phase.

$$TR_1(B,A) = \sum_{i=0}^{m}\sum_{j=0}^{n}\left[\begin{array}{c}\sqrt{\frac{\mu_A^2(a_y)+\mu_B^2(b_y)}{2}} \\ +\sqrt{\frac{1}{m-1}\sum_{i=1}^{n}\left|p_{i-\mu}\right|^2} \\ +\sqrt{\frac{(1-\mu_A(a_y))^2+(1-\mu_B(b_y))^2}{2}}+\end{array}\right] \quad (9)$$

Since NN is used, the hidden layers are taken into account for precise text extraction. Each hidden layer's input is:

$$H(I(i,j)) = I_{i,j} + \sum F_i * W \quad (10)$$

where W and F are the weights between hidden layer and input, and the hidden layer's bias value respectively. As a result, the output of each hidden layer is determined using:

$$o(I(i,j)) = \frac{\sum_{j=1}^{n}(A_{ij}^{M}+B_{ij}^{N})x_j}{\sum_{i=1}^{m}(A_{ij}^{M}+B_{ij}^{N})} \quad (11)$$

E. Text Extraction

To increase the model's ability to extract text accurately, an analysis step is taken after processing through first four steps. The text that was retrieved from the image is given by the following pixels:

$$T(X,Y) = \sum_{(i,j)\in F_s, i\in W, j\in T} o(i) + W_i + \frac{(i*j)(i,j)}{(H_{i,j(P,Q)})} \quad (12)$$

An interface utilising Google OCR technology has been developed in order to provide users with a simple and practical method of text extraction from images. Additionally, this will automate a few processes through the use of the Google OCR engine. The goal of this work is to extract text from English-language lecture slides. The user can choose a language and start the text extraction process. For the purposes of OCR, the regions are separated into unoccupied and occupied regions. Following that, a machine learning model is used to scan the data before a number of processes, including area segmentation and extraction, creating the necessary line images for line segmentation inputs, ground truth output, and more.

IV. Proposed OCR in Slide-to-Text (STT) Conversion

With an emphasis on image recognition, the GCV API transforms extremely complicated machine learning models into a straightforward REST API interface. We concentrate on the OCR module in this work. A Python script was used to construct the Fig. 3 workflow in Tensorflow.

- We have considered seven different lecture videos (machine learning, network, DBMS, Algorithms, two cryptography, and data science for engineers) of variying duration.
- We have first extracted the key-frames (images) from each lecture videos [total 438 images of 10 categories, including: 1) Digital Images, 2) Machine-written characters, 3) Hand-written characters, 4) Machine-written digits, 5) Hand-written digits, 6) Multi-oriented text strings, 7) Black and white images, 8) Noisy images, 9) Skewed images, and 10) Blurred images].
- The obtained images are transformed from the colour to grayscale and binary images. The pre-processing procedures (sharpening, contrast adjustment, and brightness adjustment) are also used to improve the image quality before applying the OCR APIs.
- The processed images are then uploaded to Google Cloud Storage (GCS). Vision API and background processes are started by a GCS event to Create a transcription of the GCS-stored image.
- The converted images are yet again saved in GCS for use in the future. The Natural Language API is used to extract entities from the converted images. The tool initially segments the image's structure to determine where the text is located. The OCR module then does a text recognition on the proper area to generate the text after detecting the general location.
- In a post-processing step, errors are finally fixed by running the data through a language model. The convolutional neural network (CNN) used to do all of this merely connects each neuron to a portion of the neurons in each layer. CNN is designed to mimic the hierarchical organisation of our visual system in terms of object (characters) recognition.

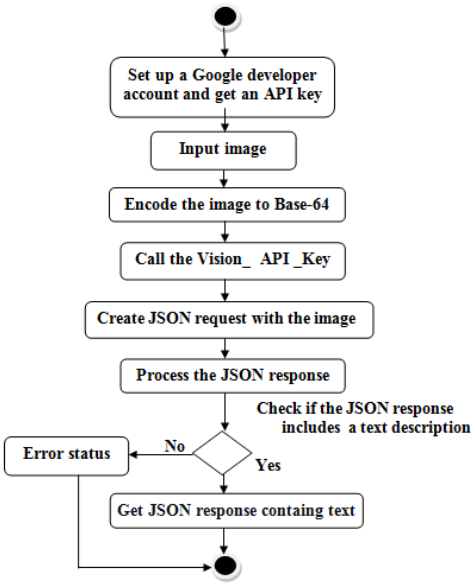

Fig. 3. Text Extraction using Google OCR.

V. Results and Discussion

This paper used a desktop computer with an i8 processor, 8 GB of RAM, 512 GB of storage, and an HDD (Hard Disk Drive). The text extraction results from each lecture video using the acquired key-frames demonstrated that GCV performed better than other OCR APIs in extracting text from the key-frames, with an average accuracy of 96.7 percent, as shown in Table I. Tesseract's is 92 percent, Abbyy Finereader's is 90.5 percent, and Transym's is 80.8 percent.

TABLE I. A COMPARISON OF OCR APIS

Dataset (key-frames of LV)	Method	Pr (%)	Re (%)	F1-Score (%)
38	Google OCR	97.2	94.7	**97.4**
	Tesseract	88.2	89.4	88.7
	Abbyy Finereader	87.8	86.8	87.2
	Transym	65.6	84.2	73.7
39	Google OCR	94.7	97.4	**96.0**
	Tesseract	86.1	92.3	89.0
	Abbyy Finereader	91.4	89.7	90.5
	Transym	72.7	84.6	78.1
38	Google OCR	97.2	97.3	**97.2**
	Tesseract	88.8	94.7	91.6
	Abbyy Finereader	88.2	89.4	88.7
	Transym	62.5	84.2	71.7
75	Google OCR	97.2	97.3	**97.2**
	Tesseract	91.5	94.6	93.0
	Abbyy Finereader	91.3	92.0	91.6
	Transym	83.3	88.0	85.5
72	Google OCR	98.5	98.6	**98.5**
	Tesseract	92.6	94.4	93.4
	Abbyy Finereader	95.5	93.0	94.2
	Transym	86.1	90.2	88.1
51	Google OCR	98.3	96.0	**97.1**
	Tesseract	93.4	90.1	91.7
	Abbyy Finereader	88.6	86.2	87.3
	Transym	75.6	80.3	77.8
125	Google OCR	89.4	98.4	**93.6**
	Tesseract	96.6	96.8	96.6
	Abbyy Finereader	94.1	95.2	94.6
	Transym	88.8	93.6	91.1

The GCV OCR's accuracy is much higher than that of other techniques while taking into account the file size and resolution. Additionally, the accuracy of the low-resolution or small-size images is the lowest. The three parameters listed below are used to evaluate performance.

$$Recall\ (Re) = \frac{Extracted\ text}{Total\ key-frames} \quad (13)$$

$$Precision(Pr) = \frac{Correctly\ extracted\ text}{Extracted\ text} \quad (14)$$

$$F1 - score = \frac{2 \times Re \times Pr}{Re + Pr} \quad (15)$$

The images were reduced to 720 x 480 pixels because the more pixels an image has, the longer OCR would take to process it into grayscale. To cut down on the amount of time needed for STT translation, all preprocessing stages were completed. Everything in the GCV OCR is contained within a RESTful API that provides a JSON structure with the text and bounding box (containing image text area with x and y co-ordinates). It takes about 15 seconds to translate a STT. The sample output of text extraction using GCV OCR is shown in Fig. 4. Precision, recall, and F-score of different OCR APIs is shown in Fig. 5.

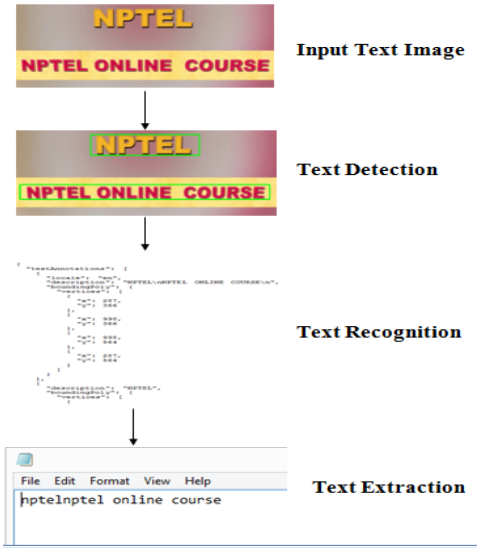

Fig. 4. Text Extraction from an Image.

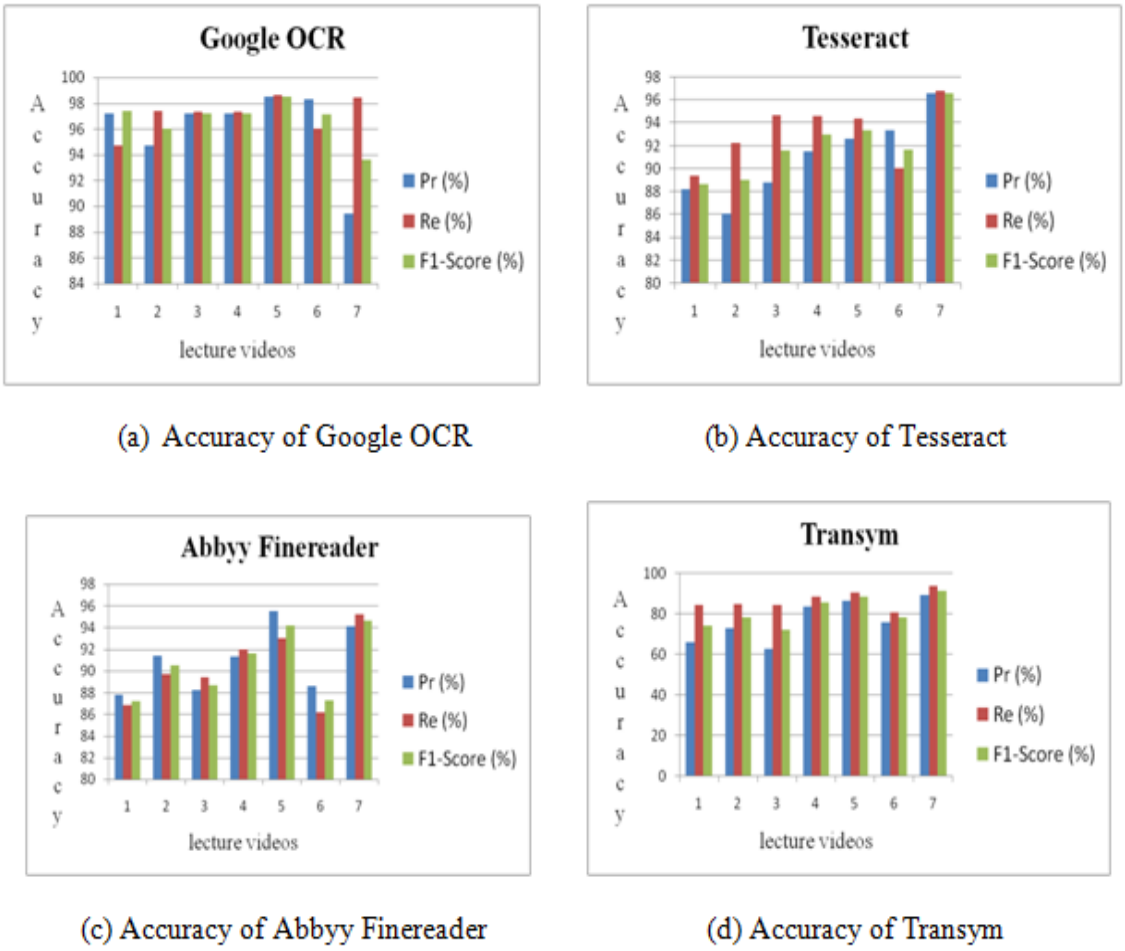

Fig. 5. Precision, Recall, and F-Score of Different OCR APIs.

From this result we can clearly say that the GCV OCR is much better than Tesseract, Abbyy Finereader, and Transym, with accuracies of 96.7%, 92.0%, 90.5%, and 80.8%, respectively, in STT conversion (shown in Fig. 6).

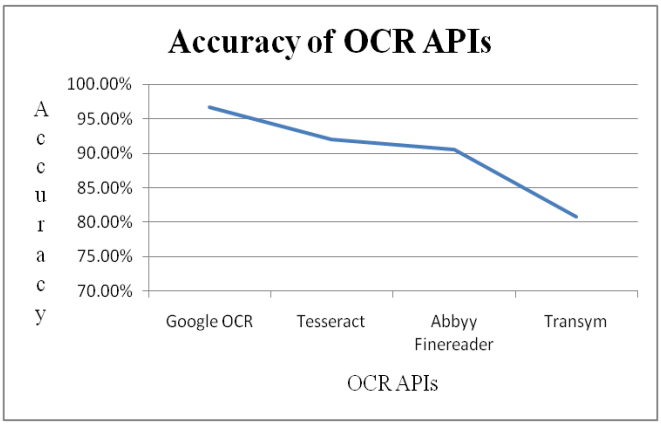

Fig. 6. Performance Comparison of Different OCR APIs.

A comparison of a number of quality criteria provided by the OCR systems is summarised in Table II.

A. Discussion

In order to make the tools more effective in identifying and processing information, this section addresses some noteworthy results, fascinating difficulties, and other usage domains or areas of study. In terms of size and image attributes, the GCV API is more accurate than competing APIs. In terms of additional factors, we discovered the following:

- All the tools were able to recognise English letters with comparable proficiency.
- Slightly elevated images could be detected by all the tools with a high degree of accuracy, while very small, distant, or blurry images could not be recognised by both the Abbyy Finereader and Transym tools.
- The supplied image's watermark background and grey-colored text significantly lower the text identification performance.

TABLE II. OCR SYSTEMS

OCR methods	Pros	Cons
Transym [27]	• Available as a SDK • Multilingual support • Support machine written characters	• Not available online • Not open source
ABBYY Finereader [6]	• Best for business users • Supports Automation • Batch processing • Support for 192 languages	• Not for general users • Not open access
Tesseract [4] [5][6]	• Quite powerful and accurate • Supports over 100 languages	• Not for business users
GCV API [4]	• Quick and easy OCR software for general users • Support for over 200 languages • Mobile app support • Available on almost all platforms • Quite powerful and accurate	• Not open access

The Tesseract and GCV APIs outperform the other two. Because Tesseract is open-source software that can be developed, customised, and managed according to particular needs, it is great software for developers. Tesseract, however, can be somewhat challenging to install and configure. Due to the availability of a variety of services, the GCV API performs better than Tesseract. It is also straightforward to connect to, configure, and use services on. The following are some potential strategies to enhance the functionality of OCR technologies to make them more effective at recognising and evaluating information:

- To cut down on extra reading material and prevent wrongly positioned images, the programmer should define the border, frame, or template matching.
- Before the recognition process, the programmer should make any necessary colour adjustments to the character, as well as remove the extra watermark backdrop.
- To aid with the understanding difficulties with the presentation slides, the programmer should create a programme that can connect models, enabling both printed and handwritten text recognition.
- The effectiveness of the post-processing outcomes can be increased by using natural language processing techniques.

VI. CONCLUSION

Extracting text from lecture slides is crucial for indexing the lecture video. This study evaluates the text extraction capabilities of the GCV OCR, Tesseract, Abbyy Finereader, and Transym in order to develop a lecture video indexing scheme for the non-linear steering in lecture videos so that viewers only watch the interesting points of topics. According to the test findings, Google Cloud Vision had accuracy rates of 96.7 percent, 92.0 percent, 90.5 percent, and 80.8 percent, which were higher than those of Tesseract, Abbyy Finereader, and Transym. The amount of time needed for processing an image grows as its resolution does. In order to reduce the time needed for STT translation, the images are first reduced to 740 x 480 pixels and then converted to grayscale. According to this study, resizing and preprocessing an image before performing OCR can greatly increase the OCR's accuracy. It takes about 15 seconds to translate an STT. This study gives an idea for the researchers who work on OCR.

Our future work will include an effort to assess additional OCR services utilising substantial datasets and more statistically significant analyses for their accuracy and durability. We will make use of cutting-edge image processing techniques and assess how they may be used to create OCR systems that are more precise and effective. In the future, we'll also work on turning the audio from the lecture into text and creating the index points using an effective ASR tool. The results of this study will help to generate index points.

ACKNOWLEDGMENT

We are very thankful to our parents, family, and friends for supporting to complete this work.

Disease Prediction Model based on Neural Network ARIMA Algorithm

Kedong Li*
Jining Center for Disease Control and Prevention
Jining, China

***Abstract*—Because the morbidity data of infectious diseases do not only have a single linear or nonlinear characteristic, but also have both linear and nonlinear characteristics, the combination model prediction method is often used to predict the morbidity of infectious diseases in recent years. Compared with the single model prediction analysis method, the combination model can combine the advantages of a single model to extract the effective information contained in the original time series more scientifically and fully. In the context of big data, for the medical field, massive medical data is complex, and the traditional manual data processing method has been unable to meet the current needs. With the help of the computer, data mining can discover new knowledge that is potentially useful and understandable by clearing, integrating, selecting, and transforming the original data. Using data mining, we can organize and reproduce the useful medical knowledge hidden in medical big data. In this paper, an ARIMA-GRNN model is established; the fitting value and the corresponding time are used as the input of the neural network. The actual morbidity is used as the output to train the network and construct the ARIMA-GRNN combined model. Due to the different information flow of BP neural network and neural network, this study also constructed ARIMA-GRNN combined model and ARIMA model, and compared the modeling effect and prediction performance of various models. The average absolute percentage error of the experimental results in this paper is less than 8.63%, and the average absolute percentage error is less than 5%. Compared with other models, it has a better prediction effect, higher accuracy, and more obvious advantages. In this paper, the prediction of disease is dynamic and continuous. It is of great significance for disease prevention and control to use monitoring data to study the epidemic trend and periodic change law, and to make a reasonable prediction.**

Keywords*—Disease prevention and control; trend prediction; neural network; combination model; ARIMA algorithm

I. INTRODUCTION

At present, feature learning technology is mainly divided into two categories: domain knowledge-driven and data-driven. Domain knowledge- driven methods extract features from image data or non-image data based on domain knowledge. For image data, it is mainly to extract low-level features such as artificially designed texture and wavelet, or qualitative indicators such as capsule and peritumoral blood vessels [1]. Non-image data mainly include some clinical characterization indicators of liver tumors, such as quantitative indicators, age, and gender, or qualitative and laboratory indicators, such as protein level and liver function, quantitative and qualitative characterization indicators in non-image data, and artificial design features in image data. The heterogeneity between the two brings difficulties to knowledge-based feature learning. From another point of view, the representation fusion between image data and non-image data brings hope to the performance improvement of the feature learning model [2]. Knowledge-driven feature learning method has good interpretability and robustness through artificial feature extraction and algorithm design, but its disadvantage is that it needs artificial participation, low efficiency, and difficult model processing. Data-driven methods are represented by deep learning techniques.

The data-driven neural network has a powerful self-learning ability, which can automatically learn features from a large number of data samples, and is the mainstream of data-driven methods [3]. With the increasing number of convolutional neural network layers and the increasing network width, the low-level pixel-level features can be gradually abstracted into high-level semantic features layer by layer to better extract the rich features hidden in large-scale image data [4]. As an effective learning method for extracting high-level semantic features, convolutional neural networks have achieved good results in many image classification and segmentation tasks. Data-driven feature learning methods are more efficient, but less interpretable and robust, and depend heavily on the number of labeled samples [5]. Especially when the convolutional neural network which has achieved better performance in the field of natural images is directly transferred to the field of medical images with small samples. The network is easy to overfit and has poor robustness [6]. Thus, in small-scale medical image feature learning, the mainstream CNN network is still difficult to meet the VMI. The structure of the network, the training mode, and the scale of the parameters need to be redesigned and adjusted to suit the specific VMI prediction task.

In 2015, Wei Wu et al. used the ARIMA model, ARIMA-GRNN combined model, ARIMA, and feedback dynamic nonlinear autoregressive neural network to establish a combined model based on monthly incidence data of hemorrhagic fever with renal syndrome. The study showed that the prediction performance of the combined model based on a dynamic neural network was higher than that of the static neural network. The prediction accuracy of the combination model is higher than that of the single model [7]. In 2016, Tian Dehong used the monthly incidence data of human brucellosis in China to establish the ARIMA model, BP neural network, ARIMA, and BPNN to establish the combination model. The study showed that the prediction accuracy of the combination

*Corresponding Author.

model was significantly higher than that of the single model [8]. In 2017, Wang Yongbin and others used the incidence data of hand, foot and mouth disease to establish ARIMA model, RBF neural network and ARIMA and RBF neural network to establish a combination model. The results showed that the prediction accuracy of the combination model was better than that of the RBF neural network model and ARIMA model [9]. The above literature analysis shows that compared with the single model prediction analysis method, the combination model can combine the advantages of a single model to extract the effective information contained in the original time series more scientifically and fully.

In this study, the ARIMA model was chosen to establish neural network and Elman neural network, considering that the predicted value of ARIMA model can fit the seasonality and periodicity, and has a similar trend to the measured value. Therefore, the fitting value and time of the disease Arima model are used as the input of the network. The actual morbidity is used as the output to train the network. Its core is to use the nonlinear mapping ability of the neural network to correct the random effect part to improve its prediction accuracy. The realization of the prediction model can realize the prediction of the disease epidemic situation and assist the medical staff to predict and manage the disease epidemic situation. Therefore, this study can effectively assist in the diagnosis and prognosis of the disease, and play an unlimited clinical and social value on the basis of the use of limited medical resources, especially in critically ill patients.

The main contents of this paper are as follows:

1) The background and significance of the research are introduced.

2) The basic theory of the prediction model is introduced.

3) The modeling steps of the BP neural network are analyzed.

4) The empirical part of the combination model is done.

5) Comparison of the fitting diagram of the combined model, comparison of the actual prediction effect and conclusion are done.

6) Conclusions and prospects for the whole paper are made.

II. Related Work

A. Artificial Neural Network

ANN (Artificial Neural Network) is an artificial model based on the function of the human brain and connected with various problems in real life with the relationship between mathematics and physics [10]. The research of artificial neural networks is based on the structure of the biological nervous system. The smallest element in the nervous system of the biological world is the neuron, which consists of nerve cells and multiple processes [11]. The artificial neural network is constructed with reference to biological neurons, and the composition of a single artificial neuron is shown in Fig. 1.

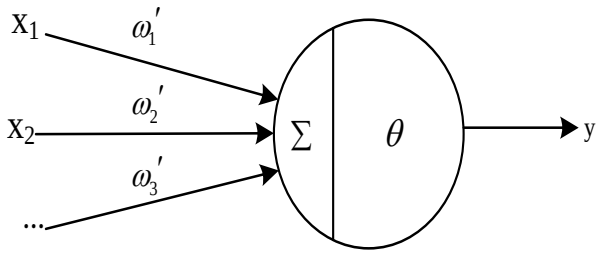

Fig. 1. Diagram of Single Neuron Model.

The composition of artificial neurons mainly includes three elements:

1) A series of input signals and the weight at each connection point represent the strength of each signal. When the connection weight is positive, the neuron is activated; and when the connection weight is negative, the neuron is inhibited.

2) A summation module for integrating all the input signals was used [12].

3) A nonlinear activation function, which acts as a nonlinear mapping by limiting the output interval of the neuron is adopted.

In addition, there is a deviation, namely the threshold θ.

All of the above processes are expressed mathematically as follows:

$$net = \sum_{i=1}^{n} X_i \omega_i ; o = f(net - \theta) \tag{1}$$

Where *net* represents the cumulative sum of the input neurons; *o* represents the sum of the neuron outputs; X_i represents the input quantity of the *ith* input neuron, and ω_i represents the connection weight of the *ith* input neuron of this neuron; $f(x)$ is the activation function, which describes the connection between the neuron input and output [13]. The selection of these parameters depends on the size of the training data, the characteristics of the studied sequence and some subjective experience. The quality of parameter selection will play a key role in the final prediction results.

B. Types of Neural Network Structures

The activation functions in the neural network structure are as follows:

1) Hard limit function: The expression for the hard limit function is as follows:

$$y = f(u) = \begin{cases} 1, u \geq 0 \\ 0, u < 0 \end{cases} \tag{2}$$

Or:

$$y = f(u) = \text{sgn}(u) = \begin{cases} 1, u \geq 0 \\ -1, u < 0 \end{cases} \tag{3}$$

Where $\mathrm{sgn}(\square)$ is the sign function. The hard limit function in Equation 2 is also called the single limit function, and the hard limit function in Equation 3 is also called the double limit function.

2) Linear function: The expression for the linear function is as follows:

$$y = f(u) = u \tag{4}$$

The output neurons of neural networks with linear functions realize the function approximation [14].

3) Saturation linear function: The saturation linear function is expressed as follows:

$$y = f(u) = \frac{1}{2}(|u+1| - |u-1|) \tag{5}$$

The curve of the saturation linear function is shown in Fig. 2. This activation function is also commonly used in classification problems.

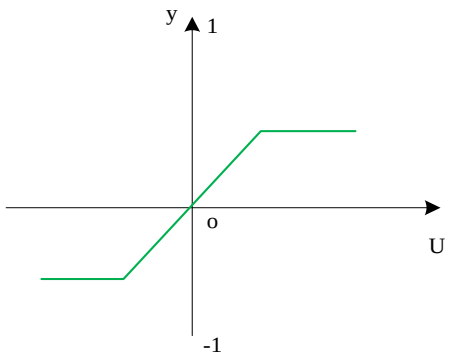

Fig. 2. Saturation Linear Function Diagram.

4) Sigmoid function: Sigmoid function is the most frequently used activation function in neural network algorithms. The Sigmoid function is a strictly monotonically increasing smooth function and has the asymptotic property [15]. The logarithmic tangent function is a form of the Sigmoid function, and its functional form is:

$$y = f(u) = \frac{1}{1+e^{-\lambda u}} \tag{6}$$

In the equation, the parameter λ is called the gain of Sigmoid function, which is the slope parameter of sigmoid function. By changing this parameter, sigmoid functions with different slopes can be obtained. The larger the value of λ, the steeper the curve [16]. The logarithmic tangent function, also known as the unipolar Sigmoid function, is differentiable and varies continuously from 0 to 1 [17]. The plot of the unipolar Sigmoid function is shown in Fig. 3.

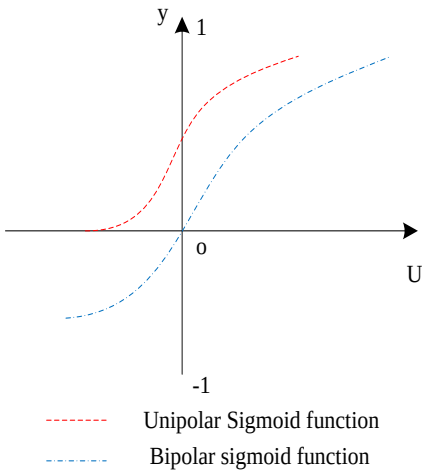

Fig. 3. Sigmoid Function Diagram.

The sigmoid activation function defined in the equation has a range of 0 to 1. Sometimes, the range of the activation function needs to vary from -1 to 1 and be odd symmetric about the origin. A double tangent sigmoid activation function can be used for this purpose [18]. Its functional form is:

$$y = f(u) = \tanh(\lambda u) = \frac{e^{\lambda u} - e^{-\lambda u}}{e^{\lambda u} + e^{-\lambda u}} \tag{7}$$

C. BP Neural Network

In the BP neural network, backward propagation is a learning method requiring supervised learning, which is mainly reflected in the training process of BP neural network. Feedforward network is a structure, which is reflected in the network architecture of BP neural network. A typical feedforward neural network is shown in Fig. 4.

The BP neural network has the characteristics of simple structure, easy to use and high efficiency, which is why more and more studies use the neural network [19]. The algorithm of error backward propagation gradually optimizes the connection weights between neurons by iterative processing so that the error between the final output result and the expected result tends to be stable and minimum.

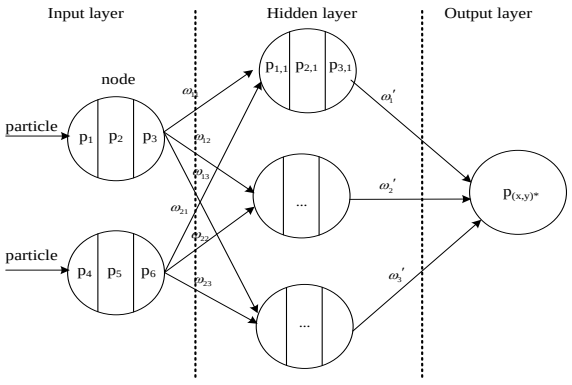

Fig. 4. Typical Feedforward Neural Network Diagram.

III. Modeling Steps of BP Neural Network

The steps of BP neural network modeling and prediction are as follows:

1) Select samples and construct a training set. The use of appropriate samples is an important prerequisite for model construction [20]. Select the appropriate structure according to the actual situation, and try to make the selected structure contain the maximum information.

2) Data preprocessing: the BP neural network has special requirements for the data of training samples. If the data interval changes too much, it cannot be used as output data.

3) Network structure design: this process includes the selection of the number of network layers, the number of hidden layer nodes, the number of input layer nodes and output layer nodes, learning rate, training function, the selection of hidden layer activation function and the output layer activation function.

4) Initialize that network, and randomly distribute the weight value and the threshold value of each connection.

5) Input the divided data.

6) Recalculate and adjust that weight value and the threshold value of each connection in accord to the error.

7) Obtain the latest parameters before proceeding from step.

8) At the beginning, when the given training times are reached or the output error is not higher than the given error standard, terminate the training.

9) Predict that time series by using the model and obtaining a prediction result.

The general process is shown in Fig. 5.

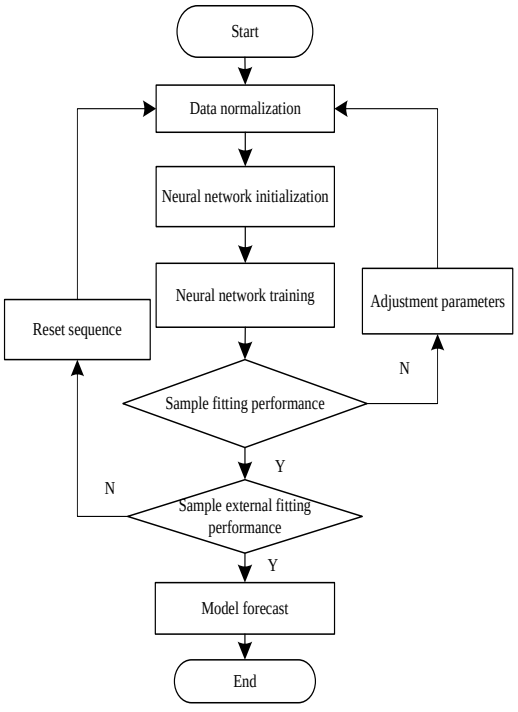

Fig. 5. FLOW Chart of BPNN Model.

IV. Empirical Analysis of BP Neural Network

The raw data is split into two data sets: a training set and a test set. The training set is used to train the model and select the optimal network model; the test set is used to evaluate the performance of the selected optimal network model [21]. The data before January 2021 is used as the training set, and the data for the whole year of 2021 is used as the test set. By dividing the data set in this way, most of the information contained in the original data can be retained so that the network model can be better learned and trained [22]. At the same time, the problems of over-learning and over-fitting can be avoided.

1) Activation Function: in this study, the Sigmoid function is selected as the activation function of the hidden layer, which can well increase the nonlinear mapping ability of the network [23]. Although this study belongs to the regression algorithm, the Sigmoid function is also selected as the activation function of the output layer because the monthly incidence rate of major diseases is between 0 and 1.

2) The number of neural nodes in each layer, the number of iterations and the learning rate: the number of neural nodes in the input layer and output layer is usually determined by referring to the characteristics of their own data. In this study, according to the splitting of the data set, the number of neural nodes in the input layer is 3, and the number of neural nodes in the output layer is 1 [24]. The empirical formula used in this study to estimate the number of neural nodes in the hidden layer is as follows:

$$m = \sqrt{M + N} + a \tag{8}$$

Where, m represents the number of neural nodes in the hidden layer; M represents the number of neural nodes in the input layer; N represents the number in the output layer; and *a* is an adjustment constant ranging from 1 to 10 [25].

Since the amount of data in this study is not too large, the number of iterations is fixed at 1000. The learning rate is 0.15, and the hidden layer is 3-12 for comparison. The data set is shown in Table I.

TABLE I. Training Set MSE and Test Set MSE with Different Number of Hidden Layers

Number	Training set MSE	Test set MSE
3	0.0026	0.0038
4	0.0026	0.0032
5	0.0026	0.0032
6	0.0027	0.0032
7	0.0026	0.0033
8	0.0026	0.0032
9	0.0026	0.0031
10	0.0026	0.0030
11	0.0026	0.0031
12	0.0027	0.0031

In Table I, the selection of the number of hidden layers from 3 to 12 has no obvious effect on the MSE of the training set of data. When the number of hidden layers is from 7 to 11, the MSE of the training set is relatively small. When the number of layers is 10, the test set MSE is the smallest, and the MSE at this time is 0.0030.

V. Experimental Analysis

A. Model Evaluation Comparison Index

Three error evaluation indexes are used to evaluate and compare the prediction effect of each prediction model.

1) Mean Square Error (MSE): The mean square error is the square of the difference between the true value and the predicted value and then averaged over the range [0, + ∞), which is equal to 0 when the predicted value exactly matches the true value, that is, the perfect model; the larger the error, the larger the value. In this study, it refers to the average value of the square sum of the error between the real value and the predicted value of the monthly incidence rate of major diseases. Its calculation formula is formally close to the variance. The formula expression is:

$$MSE = \frac{1}{m}\sum_{i=1}^{m}(y_i - \hat{y}_i)^2 \tag{9}$$

2) Mean absolute error: The mean absolute error is the average of the absolute errors. The absolute error represents the absolute value of the deviation between all observed values and the true value. Its range is [0, + ∞). When the predicted value is completely consistent with the true value, it is equal to 0, that is, the perfect model. The larger the error, the larger is the value. Relative to the average error, because the deviation of the average absolute error is absolute, there is no problem of positive and negative offset between the errors, which can better show the true level of the predicted value error than the average error. In this study, the mean absolute error refers to the mean value of the sum of the absolute value of the deviation between the true value and the predicted value of monthly incidence of major diseases, and its formula expression is:

$$MAE = \frac{1}{m}\sum_{i=1}^{m}\left|y_i - \hat{y}_i\right| \tag{10}$$

3) Mean absolute percentage error: The mean absolute percentage error is the absolute percentage deviation of all individual observations from the true value, and its value range is [0, + ∞). A MAPE of 0% indicates that the model is a perfect model, and a MAPE greater than 100% indicates that the model is an inferior model. The mean absolute percentage error has one more denominator than the mean absolute error. The specific expression is as follows:

$$MAPE = \frac{1}{m}\sum_{i=1}^{m}\left|\frac{\hat{y}_i - y_i}{y_i}\right| \times 100\% \tag{11}$$

Mean square error (MSE), mean absolute error (MAE) and mean absolute percentage error (MAPE) are all affected by the difference between the real value and the predicted value, but all the deviations are squared or absolute in the calculation process, so there will be no negative number, and there will be no positive and negative offset of errors. It can more accurately reflect the error between the predicted value and the real value.

B. Fitting Effect of each Prediction Model on Monthly Morbidity of Major Diseases

The fitting effect between the monthly incidence rate of major diseases obtained by each prediction model and the national monthly incidence rate of major diseases is shown in Fig. 6. Since the fitting data obtained by these prediction models are not much different from the real data, it is not convenient to display them in the same figure, so each model is compared with the real value separately.

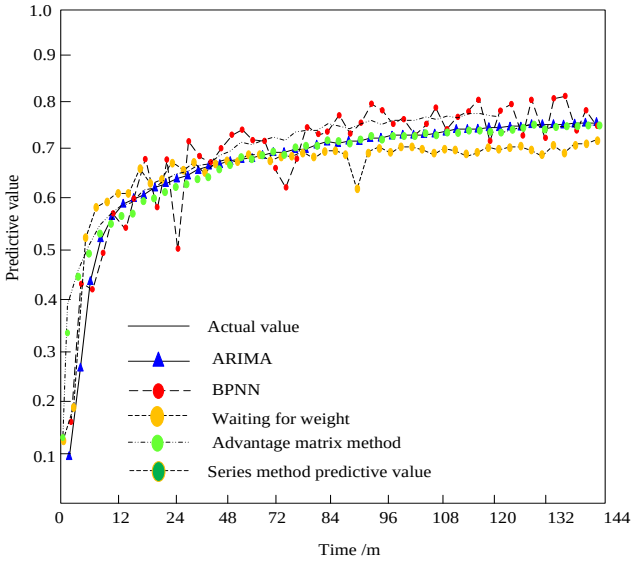

Fig. 6. Comparison between Predicted Value and Real Value by Series Method.

In Fig. 6, the fitting effect of each model is relatively good, which can reflect the change trend of the true value. The fitting effect of the series combination forecasting model is better, especially in the later period.

C. Comparison of Prediction Effect among Different Prediction Models

The annual morbidity data of major diseases in 2021 predicted by all the models used in this study are put into the same table with the real data, as shown in Table II.

TABLE II. PREDICTED VALUES OF EACH MODEL

Time	Real value	BPNN	ARIMA	Equal weight method	Dominance matrix method	Series connection method
2021.1	0.2380	0.2513	0.2367	0.2440	0.2415	0.2273
2021.2	0.1840	0.2483	0.2696	0.2589	0.2625	0.2596
2021.3	0.3835	0.3801	0.4037	0.3919	0.3958	0.4121
2021.4	0.3339	0.3528	0.3471	0.3500	0.3490	0.3446
2021.5	0.4023	0.3731	0.3944	0.3838	0.3873	0.4008
2021.6	0.4178	0.4216	0.4458	0.4337	0.4377	0.4632
2021.7	0.3804	0.3657	0.4078	0.3868	0.3938	0.4170
2021.8	0.4136	0.3778	0.4119	0.3949	0.4006	0.4221
2021.9	0.4427	0.3886	0.4138	0.4012	0.4054	0.4243
2021.10	0.4188	0.3454	0.3614	0.3534	0.3560	0.3613
2021.11	0.5483	0.4343	0.4613	0.4478	0.4523	0.4819
2021.12	0.5680	0.4798	0.4992	0.4895	0.4927	0.5272

By comparing the monthly prediction results of each model with the real data, it can be seen that the prediction effect of the single ARIMA and series combination model is better than that of other models. The advantage of the single ARIMA model in the first few months is more obvious, which is similar to the real value. In the last few months, the prediction effect of the series combination model is better than that of other models. But on the whole, the prediction effect of all models in the last three months from October is obviously not as good as that of the previous months.

The overall evaluation indicators of each model are shown in Table III.

TABLE III. EVALUATION INDEXES OF EACH MODEL

	MSE	MAE	MAPE(%)
ARIMA	0.0021	0.0356	10.0636
BPNN	0.0030	0.0427	11.1487
Equal weight method	0.0024	0.0375	10.1644
Dominance matrix method	0.0023	0.0368	10.0996
Series connection method	0.0016	0.0334	9.6914

The MSE, MAE and MAPE of the series combination model are the smallest. The MSE, MAE and MAPE of the single BP neural network are the largest. Therefore, on the whole, the series combination model shows its advantages.

The average absolute percentage error of the single ARIMA model was 10.06%. The average absolute percentage error of the single BP neural network was 11.15%, and the average absolute percentage errors of equal weight method, dominance matrix method and series method were 10.16%, 10.10% and 9.69% respectively. Only when the mean absolute percentage error of the prediction results obtained by the series method is less than 10%, it can be considered that the prediction accuracy of the series method is higher and superior to other models.

If we only want to predict the national epidemic morbidity in the short term, the single ARIMa model has good prediction effect and high accuracy. However, if we want to apply it to the long-term prediction, the advantages of the series combination model are more obvious, and its overall prediction effect is the best.

VI. CONCLUSION

The disease prediction model studied in this paper has both linear and nonlinear time series characteristics. However, BP neural network just has an excellent performance in nonlinear prediction, so the combination model can make up for the shortcomings of a single model in practical application. It can also make full use of the advantages of ARIMA and BP neural networks, and greatly improve the accuracy of prediction. The experimental results show that the average absolute percentage error of the prediction results obtained by the series method in this paper is less than 10%, and its prediction accuracy is higher and better than other models. It can provide scientific references for disease prevention and control measures.

In this paper, the sample size of the training set is not large enough, and the high dimensionality of the data brings a lot of redundant information, which easily leads to over-fitting of the model and the reduction of prediction performance. To minimize the problems caused by small sample size and high dimensionality data, future work will continue to accumulate and supplement the complete samples of clinical follow-up data, expand the sample size of the training set, and use the new samples to evaluate the two classifiers constructed in this paper.

***Abstract*—The 21st century might be considered the "boom" period for social networking due to the fast expansion of social media use. In terms of user privacy and security regulations, a plethora of new requirements, issues, and concerns have arisen due to the proliferation of social media. With the increase in social media use, images on social media are often modified or fabricated for certain purposes. Therefore, this work implements and evaluates the SPIRAL-LSB algorithm for common attacks for social media images. Image compression was also discussed as images published to social media platforms was often compressed. An analysis was performed to assess the algorithm's output on social media images. The experiments were carried out prior to and after uploading to the Instagram platform. The dataset was subjected to image splicing, copy-move, cut-and-paste, text insertion, and 3D-sticker insertion attacks. The outcome of SPIRAL-LSB was effective for text insertion attacks solely. Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index Measure (SSIM) were selected as the experiment's metrics. The average PSNR value is 63.25, and the SSIM value is 0.99964, both of which are regarded high. This indicates that the watermark has not degraded the quality of the images. This work was designed for usage on social media for intellectual property reasons and may be used to validate the validity of social media images and prevent issues with image integrity, such as image manipulation.**

Keywords*—Spiral pattern; fragile watermarking; social media; LSB substitution

I. Introduction

The application of social media is rapidly intensifying, and the twenty-first century may be defined as the "boom" time for social networking. According to Smart Insights data, there were approximately 3.484 billion social media users in February 2019. The Smart Insight survey reported the number of social media users is increasing by 9% every year, and this trend is expected to continue [1]. Currently, the social media users symbolize 45% of the worldwide population [2]. The most frequent users of social media are digital natives, a group of people who were born or grew up in the digital age and are familiar with numerous technologies and systems, and the Millennial Generation, individuals who became adults around the turn of the twenty- first century.

Moreover, according to [3], the usage and sharing of information through the internet is an inherent or intrinsic element of university students' lives. The study's results indicate that students often use Facebook to share information. Numerous individuals disclose their personal information without thinking of the consequences. Consequently, social media platforms have developed into a vast repository of sensitive data. Users are more receptive to friend invitations and trust goods sent to them by friends [4].

The move toward visual social media is being pushed in part by changes in social media user behaviors as a result of the enhanced mobile internet experience. Due to the widespread use of advanced software applications such as Picasa and Photoshop, image manipulations have become a fairly popular and effortless action for everyone. Edited images are often aesthetically appealing and difficult to differentiate from unaltered ones. There is a growing tendency toward the use of modified images in every aspect of our daily lives, such as news reporting, blogging, and advertising [5]. This often leads to user deception [6] which has the potential to influence and manipulate public opinion, ranging from teens' self-esteem and personal health choices to public opinion in significant political areas.

Although manipulated images are often uncovered, it may take weeks, and by that time, millions of people's opinions have already been influenced. This may raise severe concerns about the trustworthiness of digital multimedia, since it puts questions on the face value of the information we receive on a regular basis through the Internet [7]. This issue is getting more severe, presenting major difficulties to society. Revolution of Internet and technology enables pirates to unlawfully utilize the features to manipulate images [8]. Thus, the necessity for digital media authentication techniques becomes vital to ensuring that work is not tampered with, particularly in crucial circumstances such as social media politics, medical safety, internet banking, military data transmission, and forensic investigations.

In disciplines such as forensics, medical imaging, and military and industrial images, the integrity of a digital image is critical [9]. Digital watermarking is considered a technological category in dealing with integrity issues [10]. Hence, to preserve social media images and identify ownership, digital watermarking is essential. Without watermarks, images on social media are vulnerable to theft and illegal use [11]. In theory, digital watermarking can distinguish between various sorts of third- party manipulations and attacks.

A. Integrity and Authentication of Digital Images

In between the techniques for securing digital data, digital watermarking has grown in popularity among academicians and users due to its variety and ability to retain the integrity

and authenticity of digital images. The term "image authentication" refers to the process of determining the legitimacy of digital images. Among the methods for establishing image authenticity are location of tampering. As mentioned in the previous section, digital watermarking may potentially discriminate between different types of manipulations and assaults by a third party. Manipulations in this instance include those that are permitted and those that are not permitted [12].

There are three techniques to watermarking that includes fragile watermarking, robust watermarking, and semi-fragile watermarking, which combine fragile and robust aspects. Watermarking images is critical for preserving personal data privacy and avoiding image tampering [10]. In general, an image authentication technique is composed of two stages: embedding and validation. The embedding stage embeds the authentication data in an image and stores it as proof of the image's validity; the validation stage compares two images: one evaluated for the watermarked image, and another extracted from the watermarked image and determines whether the image has been modified or not [13].

Authentication through fragile watermarking is performed by embedding a watermark into the image, which is quickly altered or destroyed when the watermarked image is manipulated or attacked. When compared to the image's real content, the presence or absence of the watermark is identified [12]. Several prominent strategies allow for the localization and recovery of changed regions in a block-wise manner. While embedding, certain techniques may provide metadata about the image. In contrast, systems based on robust watermarking assume that a good watermark is impervious to image manipulations.

Digital watermarking, among current approaches and owing to its exceptional qualities, is an efficient option for protecting multimedia data in a variety of industries. The primary benefit of digital watermarking is that the authentication data is included directly in the image data. The authentication information is preserved, even if the watermarked image is converted to a different format and the retrieval procedure is described as simpler and less complex [14]. Table I shows the key contrasts between these three notions namely cryptography, steganography, and watermarking. These three methods are commonly used as data security techniques. Fig. 1 shows the data security techniques.

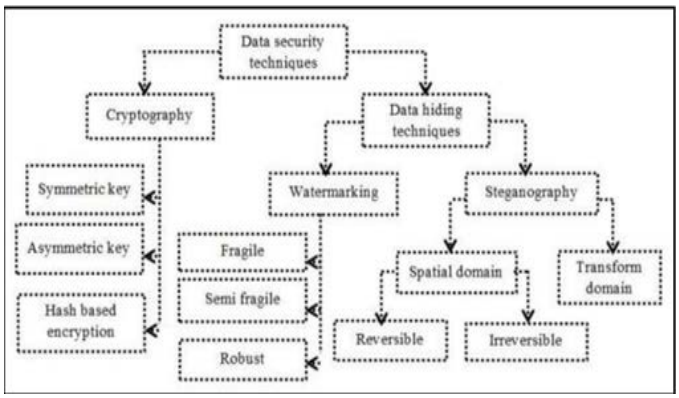

Fig. 1. Data Security Techniques [14].

TABLE I. COMPARISON OF CRYPTOGRAPHY, WATERMARKING AND STEGANOGRAPHY [14]

Criterion	Cryptography	Watermarking	Steganography
Objective	Encrypted communication	Content authentication and copyright preservation	Covert communication
Authentication	Yes	Yes	No
Cover selection	Not required	Usually image, audio, or video	Any digital object
Key	Mandatory	Optional	Optional
Attacks	Cryptanalysis attacks; Ciphertext only attacks; Known-plaintext attack; Chosen-plaintext attack; Brute-force attack; Man-in the-middle attack; Birthday attack; Timing attack; Dictionary attack.	Image processing attacks; Salt and pepper noise; Cropping attack; Rotation attack; Sharpening attack; JPEG attack; Median filtering attack; Quantization; Temporal modification.	Steganalysis attacks; Regular and singular analysis; Pixel difference histogram attack; Chi-square attack; Sample pair analysis.
Robustness	Not required	Should be high	Should be high
HC	Not required	Should be high	Should be high
Imperceptibility	Not required	Should be high	Should be high
Visibility	Always visible	Depending upon the type of watermarking, it can be visible or invisible	Always visible
Output	Encrypted text	Watermarked object	Camouflage object
Merits	It offers both authentication and integrity, along with confidentiality	It offers both authentication and integrity, along with confidentiality	None apart from the sender and receiver can suspect the existence of the communication
Demerits	The communication is visible to the outsider	HC is usually low	Steganography itself alone cannot provide authentication and integrity
Purpose is lost	If the communicating message is decrypted	If the watermark is abolished or heavily tampered	If the attacker knows communication
Origin	Very ancient	Modern era	Very ancient

The remainder of this paper is organized as follows: Section 2: Literature Review, Section 3: Methodology, Section 4: Results and Discussion, Section 5: Conclusion, Section 6: Acknowledgement and Section 7: References.

II. LITERATURE REVIEW

A. Related Works

An overview of fragile watermarking systems for image authentication is presented by [15]. The limited embedding capability and amount of tampering are two major challenges

that motivate study in this field. This review covers the overall framework of the fragile watermarking system, as well as the many types of assaults and parameters used to evaluate the methods. The researchers will be able to quickly analyze current achievements in this field by using comparative analysis and quantitative comparisons of fundamental schemes and their variants with enhancements.

The authors [16] propose a secure fragile image watermarking system that is used to identify image content alteration or manipulation. The proposed approach consists of two steps: computing a secure authentication code/watermark bit from some of each pixel's most significant bits, and then hiding the watermark bit in the least significant bit (LSB) of each pixel using a recommended watermark embedding procedure. On a series of grayscale images, the proposed watermarking method is evaluated, and the watermarked image's quality is shown.

The authors [17] present a dual watermarking technique capable of integrating authentication, copyright protection, and image recovery functionalities into a single cover image. The robust scheme protects against copyright infringement by utilizing a single watermark in the discrete cosine transform (DCT) domain, whereas the fragile scheme protects against copyright infringement by utilizing two self- embedding watermarks in a spatial domain for authenticating and restoring digital image content.

The authors [18] presented a new technique for copyright protection, data security and content authentication of multimedia images. The authentication of the content has been ensured by embedding a fragile watermark in the spatial domain while copyright protection has been taken care of utilizing a robust watermark. The fragile watermark embedding makes the system capable of tamper detection and localization with average value more than 45% for all signal processing and geometric attacks. The average Peak-Signal- to-Noise Ratio (PSNR) achieved for both schemes are greater than 41 dB.

The author [19] developed a unique spiral numbering pattern for fragile digital watermarking schemes. The developed scheme is designed to achieve a good numbering pattern, exact detection, and image recovery. The limitations of the proposed scheme are works on gray-scale images only and square images.

To address the identified gap in the watermarking literature, the majority of studies have been conducted on medical images; however, there are a few studies that have been conducted on the security of social media images via digital watermarking, and the aforementioned studies have their own limitations and weaknesses. Thus, this work implemented and evaluated a fragile watermarking method on social media images. Initially, this algorithm was shown to function for medical images but has not been demonstrated to work for social media images. Thus, our effort adds to the security and integrity of images shared on social media platforms such as Instagram.

B. Popular Social Media Platforms

- Facebook: Facebook is a large social networking website where users may share comments, photos, and links to news or other relevant items on the web, as well as live chat and watch reels. Shared information may be made publicly available or restricted to a small group of friends or family members, or to a single individual. Since its inception on February 4, 2004, Facebook has grown to over 1.59 billion monthly active users, making it one of the finest platforms for connecting people from all over the globe.

- Twitter: Twitter is ranked as one of the top social networks in the world by active users. Twitter has 192 million marketable daily active users and gains 5 million daily users in the fourth quarter of 2020 [20]. Twitter gains 5 million daily users in Q4, Projects 20 Twitter is a popular social media site because it is personal and rapid. Twitter combines instant messaging, blogging, and texting, but with brevity and mass appeal. Most people nowadays have Twitter accounts including celebrities who use Twitter to engage with followers.

- Instagram: Instagram is one of the most popular social media platforms in the modern day. Without Instagram, it is difficult to run an effective social media marketing strategy. As an image and video-centric social network, Instagram gained popularity due to its easy filter tool, which can instantly transform any shot into a high-quality one. Live video, Instagram TV-IGTV, geotagged posts, hashtags, stories, and advertisements all appear as attractive features for users. Hence, the site has around 400 million active users and was acquired by Meta in 2012. Most people utilized Instagram to share information on travel, fashion, nutrition, and craftsmanship.

- WhatsApp: WhatsApp is a cross-platform instant messaging application available on smartphones, tablets, and personal computers. This program requires an Internet connection in order to transmit photos, text, documents, audio, and video messages to other users who have installed the app on users' devices. WhatsApp Inc. was founded in January 2010 and was acquired by Meta on February 19, 2004, for about $19.3 billion. Today, over a billion people use the internet to communicate with their friends, families, and even customers.

- Snapchat: Despite the competition from other social media platforms, Snapchat continues to be one of the most popular social media platforms today, especially among younger users. Indeed, in 2021, Snapchat had approximately 428 million users worldwide. Snapchat initially used it for private image sharing, video, and messaging, as well as generating caricatures like Bitmoji characters and sharing a chronological story with users' followers.

- Reddit: Reddit is a community-driven news website where users may produce and share content. The reason users of Reddit are attracted to the site is the promise of high-quality material. Reddit members are very active and often publish something fresh and intriguing. Reddit was one of the most popular mobile social applications in the United States as of June 2021, with around 48 million monthly active users.

C. Image Compression on Social Media

Working with larger photos with a higher bit depth, the images become too enormous to send over a regular network connection. To show an image in a fair length of time and utilize a reasonable amount of space to retain the image, approaches to minimize the image's file size must be used. These approaches analyze and compress visual data using mathematical algorithms, resulting in reduced file sizes. This is known as compression.

There are two types of image compression methods: lossy and lossless. Both systems conserve storage space, but the strategies used are different. Lossless compression expresses data in mathematical formulae while retaining all the original image's information. The integrity of the original image is preserved, and the decompressed image output is bit-for-bit identical to the original image input [21].

Lossy compression shrinks files by removing extra image data from the original image. It eliminates features that are too fine for the human eye to distinguish, resulting in close approximations of the original image, but not a perfect reproduction [21]. One of the most apparent advantages of lossy compression is that it results in a much lower file size compared to lossless compression, but at the expense of quality. With lossy compression, it is necessary to establish a compromise between file size and image quality. As shown in Fig. 2, with 50 percent compression, we reduced the size of the image file by 90 percent. With a compression ratio of 80%, we were able to reduce the image file size by 95%.

Lossless compression, on the other hand, is the process of reducing the size of an image without compromising its quality. Typically, JPEG and PNG files are stripped of unnecessary information. Lossless image formats include RAW, BMP, GIF, and PNG. With small reductions in image file sizes, there is no loss of image quality. Fig. 3 depicted the original and lossless compressed image.

Huge volumes of fresh data are constantly posted to Instagram's servers as a result of the millions of new posts submitted daily. The problem might soon spiral out of control if terabytes of data are uploaded every day. Instagram compresses both image and video postings to decrease server strain and maintain a steady flow of content. The user experience is also a factor in the compression. Some large videos and images would take a long time to upload if compression were not available. Users may be dissuaded from uploading further data if there are lengthy wait periods. In turn, this would result in decreased Instagram traffic and user engagement. Instagram has effectively avoided this problem, whether on purpose or not, by imposing rigorous limits and limitations on image sizes.

Fig. 2. Degree of Lossy Compression [22].

Fig. 3. Original Image and Lossless Compressed Image [22].

The issue arises due to Instagram's excessive JPEG compression of uploaded and shared images. JPEG employs lossy compression, which discards data, increasing the likelihood that watermarked data may be discarded. When users upload JPEGs to Instagram, they are compressed again, but by Instagram. In essence, users are double the compression and sacrificing quality. PNG uses lossless compression and hence should be less impacted by Instagram's. Uploading images in PNG format is advised to maintain a small size and good quality of images.

D. Common Attacks on Social Media Images

Digital images may be manipulated or attacked to deceive by changing some of the image's critical information. These attacks can be performed on social media images and lead to negative consequences such as financial loss, business fraud, defamation and to serious extent, cybercrime proceedings. These alterations are extremely destructive to some critical images, such as military and medical images, and such images should be preserved. The authors [23] categorized image forgery techniques into two basic approaches: active and passive, as seen in Fig. 4.

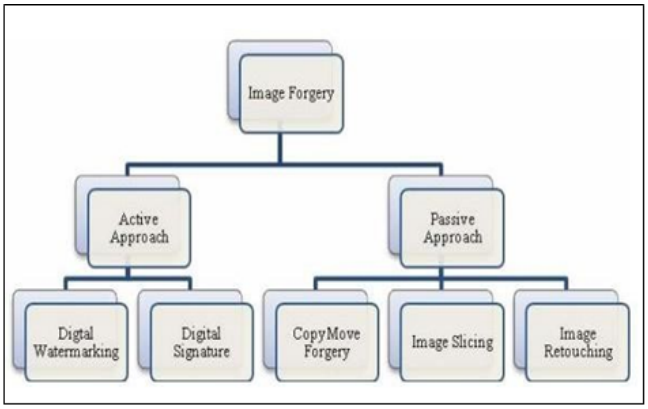

Fig. 4. Image Forgery Techniques.

1) Image splicing: Image splicing to generate counterfeit photos is more aggressive than image editing. Image splicing is a fundamentally basic procedure that may be done as crops and pastes regions from the same or other sources. This approach refers to a paste-up done by gluing together images utilizing digital tools available such as Photoshop.

In image splicing method there is composition of two or more photos, which are merged to generate a false image. Examples include some notorious news reporting situations involving the use of falsified images. Fig. 5 illustrates how to generate a forge image; by transferring a spliced piece from the source image into a target image, it creates a composite image of scenery which is a forge image.

The authors [24] describe image splicing as a collage created by adhering photographic images together. Image splicing is a method that combines two or more images to generate a new fictitious image. The image splicing technique is more aggressive than the resampling technique [24]. It is often followed by post processing such as blurring, compression, and scaling. It is often employed as the first stage in photomontage, a technique that is very popular in digital image content modification.

The authors [25] identified an image splicing approach that is based on image texture analysis, which defines image portions based on their texture richness. The texture content of an image is used to describe it in this manner. The modified image created by splicing might be utilized in news stories, photography contests, or as major evidence in academic papers, which could have a decisive impact.

2) Copy move attack: The copy move forgery is one of the commonly utilized forms of image manipulation method. In this approach, one has to cover a section of the image in order to add or delete information. In a copy-move attack, the objective is to disguise anything in the original image with some other section of the same image. The example of copy-move type is as shown in Fig. 6 when a troop of soldiers are cloned to cover George Bush.

The authors [24] claimed that copy move attack is when a portion of an image is copied and pasted into different locations within the same image to conceal information or change the meaning of the image. The digital image copy-move forgery technique involves the repetition ozone or more areas at various positions inside the same image. Frequently, duplicated portions are extended, shrunk, or rotated to increase the convincingness of forgeries, making it more difficult to identify forgeries.

3) Image retouching: Previously, retouched images were intended for magazine covers and mostly used on celebrities. The advancement of technology has increased the ease with which images may be retouched, resulting in a rise in over-perfect images. For example, Zendaya has taken to Instagram to criticize publications for retouching magazine figures as seen on Fig. 7.

Most alarming consequence of image retouching is the booming of selfie culture, which promotes a society preoccupied with money, beauty, power, and fame. Photoshop and Beauty Camera paving the way for unattainable beauty standards and are thereby contributing to the rising pandemic of body dysmorphia and mental health problems among today's youth. The image is not drastically altered during image retouching, but some characteristics of the image are enhanced or diminished, a technique that is quite common in the majority of photo editing software. In most image magazines, there is a need for image attractiveness, which results in the enhancement of some aspects of an image, oblivious to the fact that such approach is illegal.

4) Meme manipulation: The term "meme" derives from the Greek "mimesis," which refers to the way art imitates life [26]. Memes have been used as a weapon in cultural battles for more than a decade. Memes are more convincing than most people believe. On a social media timeline, a well-placed meme might lead down a rabbit hole of radicalization, misinformation, and extremism. In this scenario, Internet Memes stepped in as a compelling tool for users to express themselves in the ironic format, which often combines visual and text materials. Fig. 8 shows an example of a political meme between North Korea and America.

The authors [27] define Internet memes as artifacts of participatory digital culture, an excellent description of the functional purpose. Memes have the capacity to be made, utilized, spread, and remixed by anybody with Internet connection creating previously unimaginable opportunities for engagement in social and political concerns. To date, research on memes has been concerned with their contribution to the expression of political ideas and of subcultural identity [28].

III. Methodology

In the image authentication phase, collected sample images are input into the algorithms and output are obtained. Data collection starts the flow of the work. 15 original colored-images are acquired which acts as the host image. Host image was fed in the algorithm to be embedded with a watermark. The authentication watermark was a 2-bit authentication watermark, intended to compare the intensity (v) and the parity bit (p) for the detection of tamper in the colored-image. Following that, the host image undergoes block division to produce an image block (in pixels) using block numbering in a spiral pattern. After the embedding process, a watermarked image is produced.

For the purpose of testing, the watermarked image was manipulated with five different attacks, namely, image splicing, copy-move forgery, cut-and-paste, sticker insertion and text insertion. These five attacks are the most common attacks performed on social media images. The 15 sample images were manipulated with each type of attack, thus producing 75 attacked images as the input to the algorithm. To depict the image compression influence on social media images, the image authentication process was performed twice, first prior to the upload into social media and second after uploaded into social media.

The functional block diagram for watermark numbering, mapping, generation, and embedding was shown in Fig. 9. The technique in numbering is in a spiral manner. The following algorithms describe how the 2-tuple watermark of each sub-block was generated and embedded, which adapted from [19]:

1) Set the LSB of each pixel within the block of B to zero.

2) Calculate the average intensity of the block, AvgB and each of its sub-blocks, AvgBs, respectively.

3) Generate the authentication watermark, v, of each sub-block. V is 1 if the AvgBs is bigger than AvgB or 0 if otherwise,

4) Generate the parity check bit, p of each sub-block. P is 1 if the parity number is odd, and 0 if otherwise.

5) Obtain the original image, A, from the mapping sequence done at the first phase.

6) Compute the average intensity of each sub-block again within A, AvgAs.

7) Embed the 2-tuple watermark (v, p) each in one LSB of each pixel in Bs.

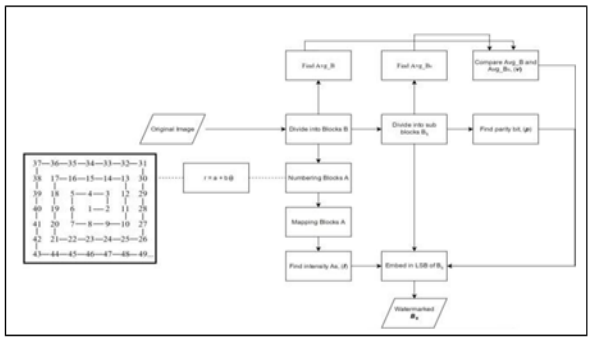

Fig. 9. Embedding Process [19].

In the SPIRAL-LSB scheme, two levels of detection phase were developed to guarantee no missing tamper when detecting. The first level would examine the parity bits and values of the average intensity in the sub-blocks, while the second level would examine the parity bits and values of the average intensity in the blocks containing the sub-blocks examined on the first level. This is done to ensure a high detection rate.

The experimental images were initially separated into non-overlapping 8 by 8-pixel blocks, similar to the watermarking embedding procedure. For each Br block, the LSBs of each Br pixel were set to zero and its average intensity, designated by Avg_Br, was computed. Then, a two- level detection was conducted. The procedure of hierarchical tamper detection scheme from [29, 30] is outlined below:

- Level 1 detection: For each 4 × 4-pixel sub-block Brs inside the block Br, do the following operations:

1) Extract v and p from Brs.

2) Set the LSBs of each pixel within each Brs to zero and compute the average intensity for each sub-block Brs, denoted as avg_Brs.

3) Set the algebraic relation v'=1 if avg_Brs >= avg_Br, otherwise, set it to 0.

4) Calculate the total number of 1s in avg_Brs and denote it as Ps.

5) Set the parity check bit p' of Brs to 1 if Ps is even, otherwise, set it to 0.

6) Compare p' with p and compare v' with v. If unequal, mark Brs as tampered and complete the detection for Brs; otherwise mark it as valid.

- Level 2 detection: For each valid 8x8 pixel block Br, do the following operations:

1) Search the block number of block C, where block C is the one in which the intensity feature of block Br is embedded.

2) Locate block C.

3) If block C is marked tampered, assume block Br is valid and complete the test.

4) If block C is valid, perform the following steps:

a) Get the 7-bit intensity of each Brs by extracting the LSBs from each pixel in the corresponding block within block C, padding one zero to the end to make an 8-bit value.

b) Compare with avg_Brs and mark Br tampered if they are different.

IV. Results and Discussion

After The samples to test the SPIRAL-LSB scheme were in PNG and JPG format with RGB colored type. The images were in square-sizes. From the algorithm applied, our result showed that embedding scheme with the block spiraling and starting the numbering in the middle would produce significant PSNR values, which as a whole, we can say all were above 55 dB, with average of 65.09 dB reported from the output data of 15 samples.

The highest value was 67.5 dB and lowest was 58.98 dB. Fig. 10 depicted the graph of the recorded PSNR values. Moreover, the SSIM value produced a correlation average value of 0.99964 which we regarded as very high. The produced SSIM value corresponds to one, indicating that the watermarked image closely resembles the original. The highest and lowest values were 0.9992 and 0.9998, respectively. Fig. 11 shows the graph of the recorded SSIM value.

A. Text Insertion Attack

In Fig. 12, a text "Vaccinated!" was inserted on the image (a) to produce tampered image (b). After acquiring the tampered image, it was tested prior to uploading it to Instagram. Figure (c) is the result before uploading while figure (d) shows the result after uploading. The tampered region is detected in red color. The tamper was detected and marked it in red, as shown in Fig. 12(d).

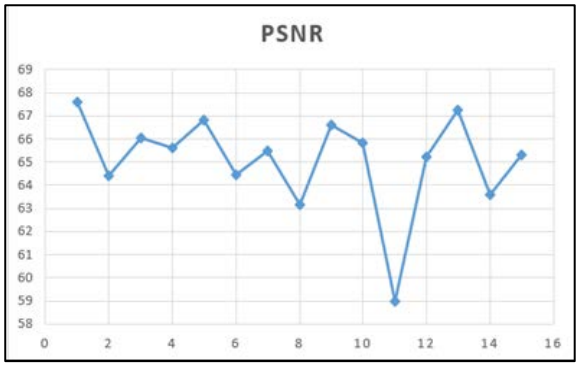

Fig. 10. PSNR Value.

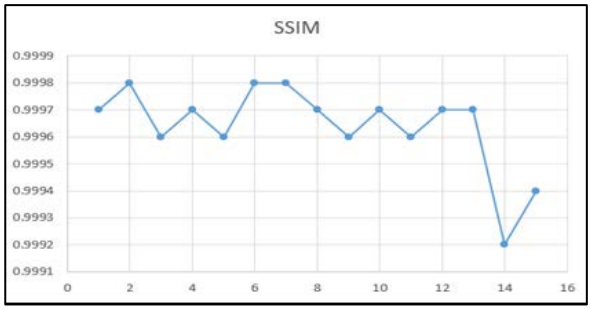

Fig. 11. SSIM Value.

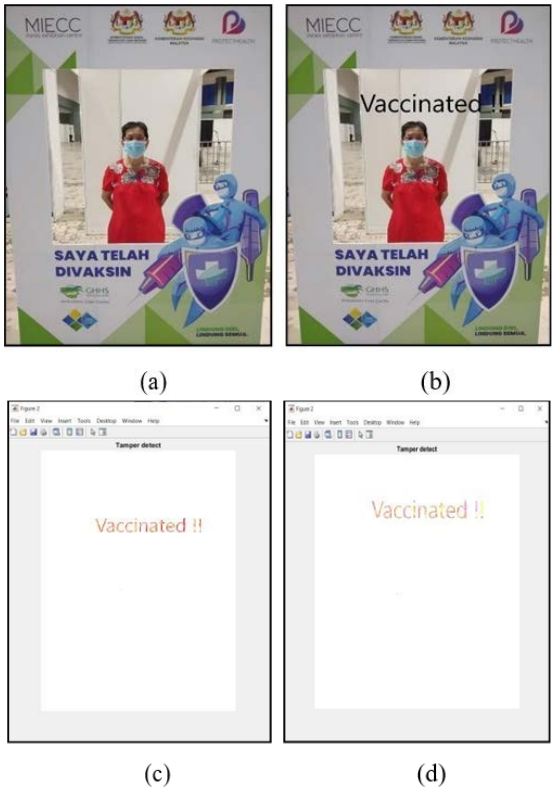

Fig. 12. (a) Original Image, (b) Tampered Image (c) Before Post, (d) After Posted.

In Fig. 13, a text "Sail boat" was inserted on the image (a) to produce a tampered image (b). After acquiring a tampered image, it was tested prior to upload in Instagram. Figure (c) is the result before uploading while figure (d) shows the result after uploading. Figure (a) was a general image taken from an image database, so the result shows no noise detected even after being uploaded to social media. The tamper was detected and marked it in red, as shown in Fig. 13(d).

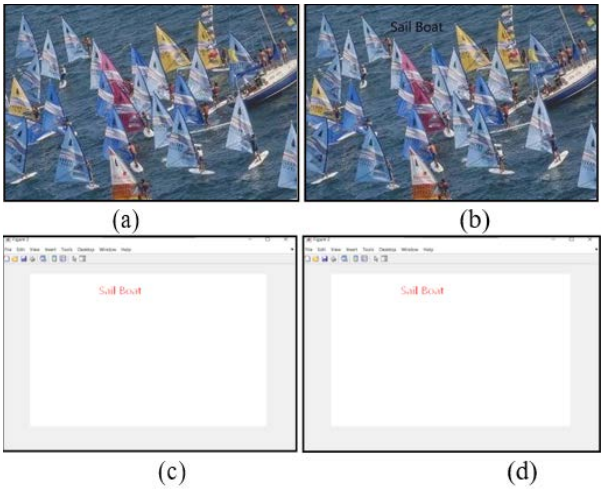

Fig. 13. (a) Original Image, (b) Tampered Image, (c) Before Post, (d) After Posted.

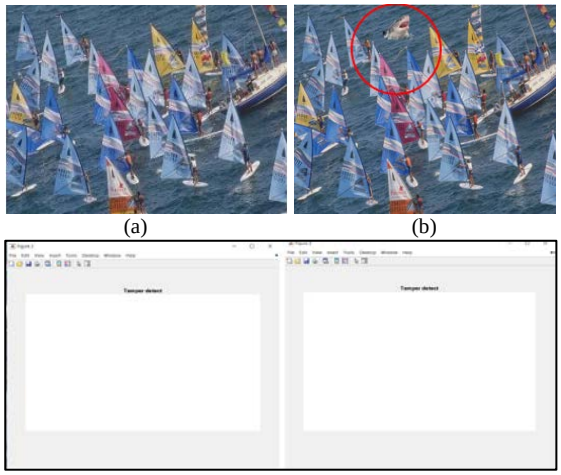
B. Image Splicing Attack

For image splicing attacks, Fig. 14(b) shows a spliced image. The objects were circled in red. Fig. 14(c) displays the results before uploaded into Instagram while Fig. 14(d) depicts the results after uploaded into Instagram. The results show that the tampered regions failed to be detected. JPEG compression applied by Instagram for uploaded images has not greatly affected the performance of the algorithm, since all the experiments provide identical result prior upload and after uploaded to Instagram platform.



(a) (b)

(c) (d)

Fig. 14. (a) Original Image, (b) Spliced Image, (c) Before Post, (d) After Posted.

Various attacks were done based on the studies revealing the common attacks to social media images. From the findings of the output, we can deduce that SPIRAL-LSB is able to detect text insertion attacks exclusively. Although some detection results display little fading after uploaded into social media. However, watermark is still intact with the host image as detection of tamper is successful. From the text insertion output, the deduction of the scheme was robust against JPEG compression because the tampered region is detected clearly after posted to Instagram.

From the 15 images that have image splicing attack, all of them were unable to be detected regardless of compression issue. Copy-move, cut-and-paste, and 3D-sticker insertion attacks produced identical outcomes. Hence, we can conclude that SPIRAL-LSB is inefficient to detect tamper for image splicing, copy-move, cut-and-paste and 3D-sticker insertion attacks. The watermarking scheme failed to detect the tampered region before the images posted to Instagram. Thus, SPIRAL-LSB is suitable for social media uploaded images that have been attacked by text insertion. For image splicing, copy-move, cut-and-paste and 3D-sticker insertion attacks, it is not suitable to be used.

The failure to detect for copy-move attack might be SPIRAL-LSB scheme was using comparison of intensity and parity bits to detect whether there was any tamper in the image or not. However, image splicing, copy-move, cut-and-paste and 3D-sticker insertion attacks may need the use of another approach to identify and key point-based forgery detection method have been proven helpful in detecting copy-move forgeries [31]. For image splicing, using two Markov features: coefficient-wise Markov features and block-wise Markov features in the discrete cosine transform (DCT) domain produce high detection accuracy [32]. Thus, SPIRAL-LSB was not effective to detect image splicing attack.

In this work, we used Least Significant Bit (LSB) which is a spatial domain technique. According to [33], the embedding of the watermark into the original image is done by selecting a subset of pixels and substituting the least significant bit of the selected pixels with the watermark bits. The LSB techniques, are easy to implement and requires a little computation cost for both embedding and extraction processes. On the hand, they are sensitive to signal processing operations and generally show reduced robustness to different attacks. Even though there are a large number of suggested LSB algorithms, there is still a lack of a robust solution, necessitating further study in this field.

Spatial domain techniques are simple and have a high payload, work directly on the pixel level, but these are not robust against various attacks [34]. In spatial domain the information is added simply by just varying the pixel values of the host signal. The values of some colors or pixels are also directly editable in the spatial domain techniques. In the least significant bit (LSB) substitution technique, the watermark is added in the least significant bit of each pixel. When the extraction of information is needed, the LSB of each pixel is read. However, the major disadvantage of this watermarking is that it is not robust again various attacks according to [35]. So, the weakness of least significant bit technique is shown in the experiments in this study. SPIRAL-LSB could not detect the tampered regions of image splicing, copy-move, cut-and-paste and 3D-sticker insertion attacks.

In our experiment, the performed attacks can be considered as pixel level tampering. Thus, SPIRAL-LSB algorithm is a block-wise technique, and it cannot detect pixel-level tampering. This drawback is called a localization problem and it was reported by [36] in 2002. Subsequently, fragile watermarking techniques have been developed to address localization problem [37, 38]. Recently, the authors [39] proposed two related fragile watermarking techniques. The first method is a statistical technique which is capable of detecting pixel-level tampering if the tampered area is small. The second one improves the tamper detection capability for a larger area by incorporating a hybrid of block-wise and pixelwise mechanism. However, the use of block information reduces its tamper resistance capability.

From the previous research done by other researchers, it is proven that LSB substitution techniques have weaknesses and limited robustness under various attacks such as lossy compression which implemented by Instagram sites. Instagram uses a lossy compression technique (JPEG compression) that reduces the image's quality and size to save storage space, reduce the amount of computing resources required for image processing, and speed up the loading or display of an image on a user's timeline. In comparison to the original image, the image posted on social media contains distortion and noise. Thus, the watermarking scheme also detected noise which is in yellow color in posted images.

As it worked in a spiral manner, which started at the center, the image processed should be in square size to ensure all the blocks were numbered. The scheme could only number the image blocks in the square which also led to generating the watermarking data in the square too, not in total if the image were in a rectangle shape. This limitation made the scheme not compatible with other social media sites images such as Facebook as Facebook support images vary in sizes.

V. Conclusion

Social media attacks represent the largest modern threat vector and are at all-high because roughly 3.5 billion people are on social media. Image splicing, copy-move, cut-and-paste, text, and 3D-sticker insertion were the most common types of attacks on social media. Social media platforms are often used for authentication to other website, applications, thus, this is a major attack vector. It can also be used to compromise various sectors for damage to reputation, operation, and financial gain. Hence, authentication on social media images is needed to protect the integrity of images.

This research has demonstrated that watermarking can provide authenticity for social media images. The fragile watermarking techniques for authentication with unique numbering, SPIRAL-LSB have been devised. This research has proven the existing techniques in fragile watermarking of color images by offering a way to embed in LSB in each plane of RGB without having the problem of less space or high data capacity. SPIRAL-LSB offers a novel way to number the blocks of the original image before being mapped while embedding. The spiral scan allows the data to be located farther and the operation time to be short. Although the watermarking scheme is only effective on text insertion attacks, it is proven to be robust against the effect of applying lossy compression, for instance JPEG, to such images. Despite the completion of this project, the necessity for more improvement in the future is required as the world is going through changes.

Computational Study of Quantum Coherence from Classical Nonlinear Compton Scattering with Strong Fields

Huber Nieto-Chaupis
Universidad Autónoma del Perú
Panamericana Sur Km. 16.3 Villa el Salvador
Lima Perú

***Abstract*—From the covariant formulation of radiation intensity of Hartemann-Kerman model entirely constructed in the classical electrodynamics scenario, a formulation of coherent states has been obtained in an explicit manner represented by the infinite sum of integer-order Bessel functions. Both linear and nonlinear Compton scattering are included, suggesting that Compton processes can be perceived as coherent states of light-matter interaction.**

***Keywords*—Quantum coherence; bessel; compton scattering**

I. Introduction

Compton scattering is seen as a "golden processes" inside Quantum Electrodynamics [1]. This has played in the understanding role in the understanding of quantum mechanics of light-matter interactions. In fact it is pure quantum effect in the which the electron absorbs one single photon and emits one photon with different kinematics than the first one. In a full quantum theory, the Lagrangian of interaction can be written as:

$$\mathcal{L}_{\rm INT} = -ie\int dx^4 \bar{\Psi}\gamma_\mu A^\mu \Psi, \tag{1}$$

with $\bar{\Psi}$ and Ψ the final and initial states, while γ the 4×4 matrices, and A^μ the 4-vector potential that satisfies the Lorentz's gauge $\partial_\mu A^\mu$ = 0. In a nutshell the incorporation of a propagator in Eq. (1) and the subsequent operations yields commonly the well-known Feynman's diagrams [2]. Compton scattering was also boarded at the scenario of strong electromagnetic fields. In this case the states $\bar{\Psi}$ and Ψ are solutions of Volkov and obey the equation of Dirac with a external field. In the scenario of high regime where the incoming electromagnetic field has a high density of photons it is usual to define the intensity parameter:

$$\xi^2 = \frac{e^2\mathbf{A}^2}{m}. \tag{2}$$

introduced by I.I. Goldman [3] who derived the energy of emitted photon given by:

$$\omega' = \frac{2nE\omega}{E(1+{\rm Cos}\theta) + [2n\omega + \frac{m^2(1+\xi^2)}{E}(1-{\rm Cos}\theta)]}, \tag{3}$$

where the product $n\omega$ is denoting the absorption of n photons. From this $n = 1$ the Klein-Nishina formula is restored. The integer n is linked to the nonlinear processes at the which the electron can absorb various photons simultaneously. These non-linearities can be compacted in the language of Quantum Electrodynamics (QED in short) as a Dirac-Delta function:

$$\delta(E_{\rm I} + n\omega - E_{\rm F} - m\omega'), \tag{4}$$

that indicates the conservation of energy with m an integer number. This non-linearity is theoretically obtained in the emission and absorption of various laser photons by Reiss [4] and Ritus [5] whom have derived quantization of laser in a semi-classical arena with the laser modeled through an circularly polarized infinite wave. This was also seen at [6] and the works of Eberly [7]. A noteworthy attention was paid at the 90s because the prospective construction of a photon-photon collider [8] and the potential apparition of non-linearities as corroborated at the experiments observed at SLAC [9] where nonlinear Compton was observed with strong lasers supporting the fact that these processes can be well modeled by an infinite classical monochromatic wave. In photon collisions one expects that the Compton backscattering can create new particles in according to the reactions:

$$\gamma + \gamma \Rightarrow \tilde{\ell}^+ + \tilde{\ell}^- + \sum_q^Q \Xi_q$$

with the production of Q particles, was predicted inside the framework of new physics of elementary particles [10]. In 1996 nonlinear Compton backscattering have been obtained in an entire arena of classical electrodynamics by Hartemann and Kerman [11] (HK model in short) from the intensity of radiation $\frac{dI(\omega)}{d\Omega} =$

$$\frac{\omega^2}{4\pi^2c^2}\left|\int dt\int d^3x\mathbf{n}\times[\mathbf{n}\times\mathbf{J}(\mathbf{x},t)]e^{i\omega[t-\frac{\mathbf{n}\cdot\mathbf{x}}{c}]}\right|^2. \tag{5}$$

Here, it was shown that Compton scattering governs the low intensity whereas in super-strong fields the nonlinear Compton scattering emerges as the apparition of high harmonics that are interpreted as emission of photons with different frequencies. Based at all this background where quantum effects can be retrieved from classical formalisms, this paper tries to derive the quantum coherence from the HK theory. Inspired at the theory of Glauber [12][13], coherent states

proportional to Bessel functions are derived. In second section Compton processes are derived from classical electrodynamics. In third section the quantum coherence is derived. Finally at last section the conclusion of paper is presented.

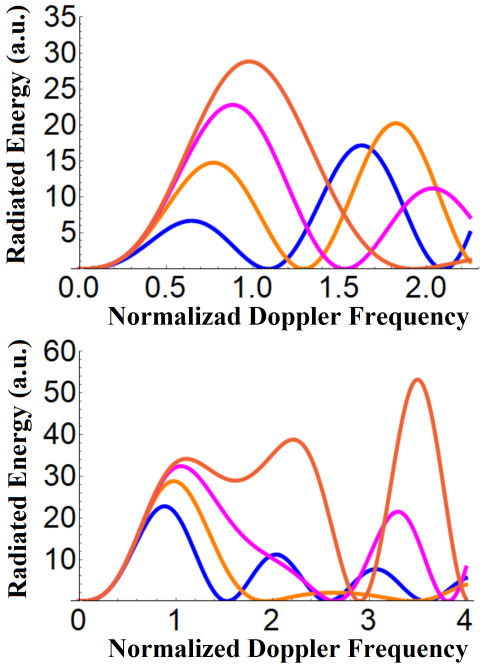

Fig. 1. Classical Distributions of Radiated Energy from Eq. 7 Once the Bessel Expansion as Done at Eq. 14 are Plotted. Up: q Runs from 2 to 5. Down: q from 4 to 7. It should be Noted the Peaks at χ=1.0, Denoting the Simple Classical Compton Scattering.

II. Classical Nonlinear and Linear Compton Scattering

The HK model was developed under a covariant framework in the sense that $\phi = k_\mu \cdot x^\mu$ yielding the well-known radiation intensity of a single electron in an external super intense polarized laser. The radiation intensity is depending on the Doppler-shifted frequency χ. As seen in HK model, Compton and nonlinear Compton scattering was obtained for different values of pulse width. Therefore, one can arrive to the fundamental equation of HK model that can be written down as the distribution of energy radiated per solid angle and frequency and with the definition:

$$\lambda = \frac{e^2}{4\pi^2} u_0^2 \chi^2, \tag{6}$$

then the fundamental equation of covariant HK model can be written as:

$$\frac{d^2I}{d\omega d\Omega} = \lambda \left| \int_{-\infty}^{+\infty} A_x(\phi) \exp\left\{ i\chi \left[\phi + \int_{-\infty}^{\phi} \mathbf{A}^2(\psi) d\psi \right] d\phi \right\} \right|^2. \tag{7}$$

Clearly one can appeal to different mathematical approaches to extract the quantum mechanics (if any) of Eq. 7 in different ways. At [14], from the HK model the argument of Dirac delta functions have been obtained as well as interpreted as the absorption and emission of photons even when the external field was an infinite wave as commonly expected from QED. Although of course the applicability of advanced mathematical methodologies cannot guarantee not any kind of quantization of external field, a suitable methodology turns out to be the usage of the Fourier expansion. In fact, consider the identity based in the series of Fourier-Bessel so that from the exponential of Eq.7 one gets:

$$\mathrm{Exp}\left\{ i\chi \left[\phi + \int_{-\infty}^{\phi} \mathbf{A}^2(\psi) d\psi \right] \right\} = \sum_{\infty}^{\infty} J_q(\chi) \mathrm{Exp}[iq\theta], \tag{8}$$

with the usage of the crude approximation:

$$\sin\theta = \left[\phi + \int_{-\infty}^{\phi} \mathbf{A}^2(\psi) d\psi \right] \tag{9}$$

$$\Rightarrow \theta = \sin^{-1} \left[\phi + \int_{-\infty}^{\phi} \mathbf{A}^2(\psi) d\psi \right], \tag{10}$$

that to some extent θ can be seen as a phase. In this manner by putting Eq. 8 and Eq. 9 into Eq. 7 one can see that the Bessel functions can be out of the integration. With this Eq. 7 can be written in a more transparent manner as:

$$\frac{d^2I}{d\omega d\Omega} = \lambda \left| \sum_{-\infty}^{+\infty} J_q(\chi) \right|^2 \left| \int_{-\infty}^{+\infty} d\phi A_x(\phi) \mathrm{Exp}\left(iq\mathbf{sin}^{-1}[\theta(\phi)] \right) \right|^2. \tag{11}$$

As expressed in the HK model, the external field is a super intense laser that is characterized by the width $\Delta\phi$ that is entirely an experimental input. Therefore one can define a function depending on ϕ in the sense that:

$$F(\Delta\phi) = \left| \int_{-\infty}^{+\infty} d\phi A_x(\phi) \mathrm{Exp}\left(iq\mathbf{sin}^{-1}[\theta(\phi)] \right) \right|^2. \tag{12}$$

It is because once the integration is done through the variable ϕ it yields only a pure dependence on the pulse's width $\Delta\phi$ then one can rewrite Eq.11 as:

$$\frac{d^2I}{d\omega d\Omega} = \lambda \left| \sum_{-\infty}^{+\infty} J_q(\chi) \right|^2 F(\Delta\phi). \tag{13}$$

Subsequently, one can arrive to a normalized backscattered spectrum that would depend on the Doppler-shifted frequency χ. On the other hand by knowing the input value for $\Delta\phi$ then $F(\Delta\phi)$ can opt a finite value, for instance ρ. When λ is written in an explicit manner from Eq. 6 and inserting it into Eq. 13 then the resulting radiation intensity can be written as:

$$\frac{4\pi^2}{e^2\mu_0^2\rho} \frac{d^2I}{d\omega d\Omega} = I(Q,\chi) = \chi^2 \left| \sum_{q}^{Q} J_q(\chi) \right|^2. \tag{14}$$

The way as it is written Eq. 14 allows to displayed it in a straightforward manner. In fact, in Fig. 1 the normalized backscattered spectrum is plotted for two scenarios. Here $\frac{4\pi^2}{e^2\mu_0^2\rho} \approx \xi$. For this exercise, the Up-panel displays various

curves of radiated classical energy. Here the sum ran from 2 to the 5th harmonic as given by:

$$I(Q,\chi) = 25\chi^2 \left| \sum_{q=2}^{Q} J_q(3.2\chi + 1) \right|^2 . \quad (15)$$

One can see there, the Grey color line is denoting the sum of all 4 orders, and it is peaked denoting the fact that still at the classical formulation, scattering Compton can be derived. At the Down-panel where the sum runs from 4 to 7, is exhibiting for instance the Grey liine, a deformed shape in contrast to Up-panel.

$$I(Q,\chi) = 25\chi^2 \left| \sum_{q=4}^{Q} J_q(3.2\chi + 1) \right|^2 . \quad (16)$$

In on the other side, the Grey line the sum of all four orders, is revealing that high orders might be distorting the peaked centered at χ=1. It is because the highest order are certainly connected to nonlinear Compton scattering. In fact, such deformation at the Grey line is due also to the contribution of more photons to the state of absorption by the electron at the strong electromagnetic field, so that the electron has much energy to emit. Of course, although it is argued in a fully classical scenario, the implementation of integer-order Bessel functions, allows to examine the radiated energy spectra from this perspective. Under the hypothesis that Eq. 14 is an element of an infinite sum then one can generalize it with the change $\xi = \frac{4\pi^2}{e^2\mu_0^2\rho}$ one can write below that:

$$1 + \xi \frac{d^2I}{d\omega d\Omega} \approx 1 + \frac{\chi^2}{2!} \left| \sum_{-\infty}^{+\infty} J_q(\chi) \right|^2 + ... + \frac{\chi^n}{n!} \left| \sum_{-\infty}^{+\infty} J_q(\chi) \right|^n \Rightarrow \xi \frac{d^2I}{d\omega d\Omega} = \mathrm{Exp}\left\{ \left| \chi \sum_{-\infty}^{+\infty} J_q(\chi) \right|^2 \right\}, \quad (17)$$

so that Eq. 9 with the hypothesis that $\chi^n = 0$ for $n \geq 3$ thus it can finally be written as:

$$\xi \frac{d^2I}{d\omega d\Omega} = \mathrm{Exp}\left\{ - \left| \chi \sum_{-\infty}^{+\infty} J_q(\chi) \right|^2 \right\}. \quad (18)$$

III. Derivation of Quantum Coherence

The mathematical structure of Eq. 10 allows to link it to the quantum mechanics territory in the sense that quantum coherence can be extracted. For this one should assume the following hypothesis:

$$\left| \chi \sum_{q=-\infty}^{Q=+\infty} J_q(\chi) \right|^2 = \frac{\alpha^2}{2}, \quad (19)$$

by which one arrives to:

$$\xi \frac{d^2I}{d\omega d\Omega} = \mathrm{Exp}\left(-\frac{|\alpha^2|}{2} \right), \quad (20)$$

that in the quantum scenario on gets:

$$|\langle 0|\alpha\rangle|^2 = \mathrm{Exp}\left(-\frac{|\alpha^2|}{2} \right), \quad (21)$$

with α the eigenvalue of the equation $\hat{\mathbf{a}}|\alpha\rangle = \alpha|\alpha\rangle$. From Eq. 20 and Eq. 21 one arrive to:

$$\xi \frac{d^2I}{d\omega d\Omega} = |\langle 0|\alpha\rangle|^2 = \mathrm{Exp}\left\{ - \left| \chi \sum_{-\infty}^{+\infty} J_q(\chi) \right|^2 \right\}, \quad (22)$$

so that one finds that the quantum mechanics amplitude can be written in terms of classical electrodynamics observables:

$$|\langle 0|\alpha\rangle| = \sqrt{\xi \frac{d^2I}{d\omega d\Omega}}, \quad (23)$$

and the eigen values of coherence can be expressed in terms of interger-order Bessel functions:

$$\alpha^2 = 2 \left| \chi \sum_{-\infty}^{+\infty} J_q(\chi) \right|^2 , \quad (24)$$

indicating that the values of coherence depend on the χ variable, the normalized Doppler-shifted frequency. It should be noted the relevance of orthogonal polynomial at the classical formulation of coherence [15][16][17][18] In other words, the coherence is directly linked to the frequencies of the emitted photons (or another observable as commonly done in quantum mechanics [19][20][21][22][23][24]). Indeed, the eigenvalues equation involving the annihilation operator and the states of coherence is written below as:

$$\hat{\mathbf{a}}|\alpha\rangle = \alpha|\alpha\rangle = \sqrt{2} \sum_{-\infty}^{+\infty} \chi J_q(\chi)|\alpha\rangle \quad (25)$$

In Fig. 2 (Up panel) square of coherence Eq. 19 as well as $|\langle 0|\alpha\rangle|^2$ have been plotted as function of normalized Doppler-shift frequency. Interestingly in left-side up two peaks for $2 < \chi < 10$ The one of interest (blue line Q=2) because one finds minor peaks $\chi = 3, 6$ and $\chi = 9$ as well as one can see a large peak at $\chi = 10$ for Q=10. In the right-side it is easy to note that all lines are centered at $\chi = 0$ indicating that the classical view the system has null energy to emit photons at the Compton range, however one can see minor peaks for $\chi > 4$. In (Down panel) the square of amplitude $|\langle 0|\alpha\rangle|^2$ is plotted.Here one can see that the orange line Q=10, appears to be deeply degraded. In the contrary case. the blue line denoting Q=2 exhibits high values above 50%. Thus one can see that while the lowest values of Q exhibit high values, thus one can see that the orders of Bessel function dictated by:

$$x^2 \frac{d^2y}{dx^2} + x\frac{dy}{dx} + (x^2 - q^2)y = 0 \quad (26)$$

might be relevant for $n = 0$ yielding (after of dividing over x^2) one arrives to:

$$\frac{d^2y}{dx^2} + \frac{1}{x}\frac{dy}{dx} + y = 0 \quad (27)$$

that might be strongly related to the high values of $|\langle 0|\alpha\rangle|^2$

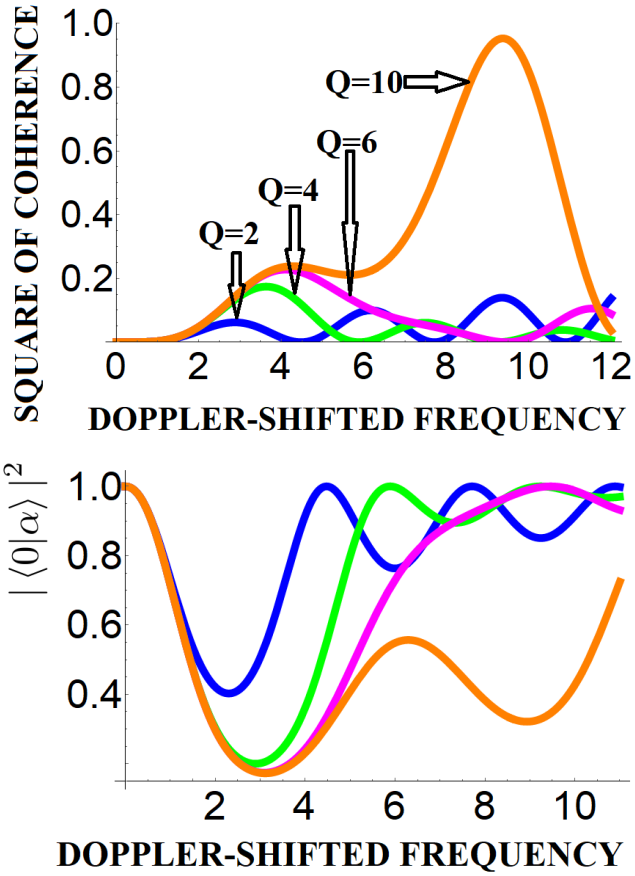

Fig. 2. (Up-Panel) Plotting of Eq. 19 Normalized to 1 for up to 4 Values of Integer Q. One can See that the Normalized Coherence Plotted as it Square Acquires a Similar form as the Radiation Intensities Plotted at Fig. 1. (Down-Panel) Plotting of Eq. 22 with Colors Same as Left-Panel Indicating that not any Peak at $\chi = 1$. Plots of Up and Down Panels were done with the Package [25].

A. Identifying the Doppler-Shifted Frequency Orthogonal Basis

The mathematical structure derived at Eq. 25 might be suggesting the existence of an orthogonal basis whose dependence would be given at the variable χ (see for example [26][27][28][29][30]). In fully accordance to the quantum mechanics formalism it is feasible to write down the completeness relationship for the normalized Doppler-shifted frequency χ as follows:

$$\int d\chi \, |\chi\rangle \langle\chi| = \mathbb{I}, \tag{28}$$

and in the other hand one has also that: $\int_{-\infty}^{\infty} d\alpha \, |\alpha\rangle \langle\alpha| = \mathbb{I}$ in conjunction to a discrete basis: $\sum_q |q\rangle \langle q| = \mathbb{I}$. In this way one can combine all these completeness relationships to arrive to:

$$\mathbb{I} \otimes \mathbb{I} = \sum_q \int d\chi \, \langle\chi|q\rangle \, |\chi\rangle \langle q| \, . \tag{29}$$

Now, one can include the coherent states also at the chain of multiplication of unitary operators in the form:

$$\begin{aligned} \mathbb{I} \otimes \mathbb{I} \otimes \mathbb{I} &= \int_{-\infty}^{\infty} d\alpha \, |\alpha\rangle \langle\alpha| \sum_q \int d\chi \, \langle\chi|q\rangle \, |\chi\rangle \langle q| \\ &= \sum_q \int d\chi \int_{-\infty}^{\infty} d\alpha \, |\alpha\rangle \langle\chi|q\rangle \langle\alpha|\chi\rangle \langle q| \end{aligned}$$

and the multiplication by the ket $|q\rangle$ in both sides one arrives to:

$$\begin{aligned} \mathbb{I} \otimes \mathbb{I} \otimes \mathbb{I} \, |q\rangle &= \sum_q \int d\chi \int_{-\infty}^{\infty} d\alpha \, |\alpha\rangle \langle\chi|q\rangle \langle\alpha|\chi\rangle \langle q|q\rangle \\ &= \sum_q \int d\alpha \, |\alpha\rangle \langle\alpha|\chi\rangle \int_{-\infty}^{\infty} d\chi \, \langle\chi|q\rangle \end{aligned}$$

where $\langle q|q\rangle = 1$. Indeed with the assumption:

$$\langle\alpha|\chi\rangle = \left(\frac{\alpha}{\chi}\right) \tag{30}$$

$$\langle\chi|q\rangle = \left(\chi \frac{d(\chi J_q(\chi))}{d\chi}\right) \tag{31}$$

then one gets from Eq. 27 in a straightforward manner the integration over χ:

$$\int_{-\infty}^{\infty} d\chi \frac{d(\chi J_q(\chi))}{d\chi} = \chi J_q(\chi) \tag{32}$$

so that the integral over α is trivial:

$$\int_0^{\sqrt{2\sqrt{2}}} d\alpha\alpha = \sqrt{2} \tag{33}$$

and by putting these integrations into Eq.27 then one can see that Eq. 25 is restored:

$$\mathbb{I} \otimes \mathbb{I} \otimes \mathbb{I} \, |q\rangle = |q\rangle = \sqrt{2} \sum_{q=-\infty}^{+\infty} \chi J_q(\chi) \, |\alpha\rangle \tag{34}$$

and multiplying Eq. 34 by the $\langle q|$ in both sides and with the definition of the polynomial $\langle q|\alpha\rangle \Rightarrow \langle\alpha|q\rangle = \left(\alpha \frac{d(\alpha J_q(\alpha))}{d\alpha}\right)$ derived from Eq. 31, then one can arrive to:

$$\sqrt{2} \sum_{q=-\infty}^{+\infty} \chi J_q(\chi) \left(\alpha \frac{d(\alpha J_q(\alpha))}{d\alpha}\right) = \mathbb{I} \tag{35}$$

Therefore, the derivative can be carry out:

$$\sum_{q=-\infty}^{+\infty} \left[\alpha\chi J_q^2(\alpha) + \chi\alpha^2 J_q(\chi) \frac{dJ_q(\alpha)}{d\alpha}\right] = \frac{1}{\sqrt{2}} \tag{36}$$

IV. Conclusion

In this paper, the quantum coherence has been extracted from the backscattered radiation intensity obtained in classical electrodynamics. While the HK model has been used, the results of this paper confirms that in the super intense regime the classical picture can restore quantum effects in particular the coherence of emitted radiation that to some extent is encompassing with requirements of advanced experiments that require backscattered radiation at the GeV energies to create unseen states of matter. Because these results can be understood as preliminary, in a next work the derivations from the HK model and its validation with current theories of quantum optics [31][32] shall be done.

***Abstract*—Most universities rely heavily on Information Technology (IT) to process their information and support their vision and mission. This rapid advancement in internet technology leads to increased cyberattacks in Higher Education Institutions (HEIs). To secure their infrastructure from cyberattacks, they must implement the best cybersecurity risk management approach, which involves technological and education-based solutions, to safeguard their environment. However, the main challenges in existing cybersecurity risk management approaches are limited knowledge of how organizations can determine or minimize the significance of risks. As a result, this research seeks to advance understanding to establish a risk assessment model for universities to measure and evaluate the risk in HEIs. The proposed model is based on theoretical aspects that we organized as follows: First, we review the existing cybersecurity frameworks to identify the suitability and limitation of each model. Next, we review current works on cybersecurity risk assessment in HEIs to evaluate the proposed risk assessment approaches, scope and steps. Based on the information gathered, we developed a risk assessment model. Finally, we conclude the study with directions for future research. The result presented from this study may give an insig1ht for HEIs staff to analyze what is to be assessed, how to measure the severity of the risk, and determine the level of risk acceptance, improving their decision-making on risk management.**

***Keywords*—Cyber security; risk assessment; university**

I. Introduction

Higher education institutions (HEIs) are prime targets for cybercriminals because their networks hold sensitive personal information about students, including their academic and financial data. Several education organizations and institutions have been victims of cyberattacks [1]. Cybercriminals in Asia exploit flaws in IT systems that support schools and universities in carrying out various attacks. Even before the pandemic, a massive data breach that had reportedly hit a prominent Malaysian university resulted in the personal data of over one million people being leaked online [2].

During the COVID-19 pandemic, every industry faces significant change and ongoing challenges. Like many other industries, the higher education sector has been overturned by the COVID-19 pandemic. In place of classroom instruction, many students are learning virtually and remotely. While the shift to remote education may have helped the governments better contain the spread of COVID-19, it is also added a layer of cybersecurity risks that higher education institutions (HEIs) are forced to confront.

When the pandemic forced HEIs to use online platforms to conduct classes and evaluates students, it created a new entry point for cybercriminals to target due to the vulnerabilities in online platforms. These platforms include video chat programs like Zoom and Microsoft Teams and curriculum, technology, and services providers. According to Malwarebytes, the education sector is the top target for Trojan malware [3]. Kaspersky discovered 356,000 malicious files while investigating infected online textbooks, including 233,000 malware-infected essays and 123,000 malware-infected books [4]. A recent Kaspersky study showed that the number of users exposed to various threats using common online learning sites as a lure reached 270,171 in January 2021, up 60% from the first half of 2020 [5]. The rapid development of internet technologies and online platforms among students has led to increased cyberattacks in HEIs.

Since new and more advanced threats arise at an unprecedented pace, it is evident that HEIs are at risk of potentially disastrous security incidents if adequate security measures and workforce preparation initiatives are not implemented. Representatives from every campus department, such as administration, facilities, communications, and IT, must work together to analyze potential risks and create policies to address them [6]. To secure their infrastructure from cyberattacks, HEIs must implement the best cybersecurity risk assessment approach, which involves technological and education-based solutions, to safeguard their HEI environment.

Risk assessment provides organizations with an accurate evaluation of the risks to their assets. It can help them prioritize and develop a comprehensive strategy to reduce risks [7]. As highlighted by Panchal [8], many institutions have limited or no visibility of their IT risk exposure. Furthermore, available resources are not utilized effectively to manage the risks. The primary concerns in current risk assessment methodologies are how HEIs can estimate the significance of risks and develop resolution capabilities to deal with or minimize the risks. [9].

Therefore, this study aims to establish a cybersecurity risk assessment model for HEIs. The proposed model is based on theoretical aspects that we organized as follows: First, we review the existing cybersecurity frameworks to identify the suitability and limitation of each model. Next, we review current works on cybersecurity risk assessment in HEIs to

evaluate the risk assessment approaches, risk metrics and steps proposed. We developed a risk assessment model combining ISO 27005 and NIST SP 800-30 framework based on the information gathered.

II. Review of Current Cybersecurity Risk Assessment Literature

A. Cybersecurity Risk Assessment Frameworks

Risk assessment is an important methodology for cybersecurity that employs techniques to assist organizations in dealing with uncertain events [10]. It is a tool for assessing factors that contributes to a failure or loss that hinders the success of a project or business. Various risk assessment models are available, some of which are qualitative while others are quantitative, with a common goal of estimating the overall risk value.

The Software Engineering Institute developed OCTAVE (Operationally Critical Threat, Asset and Vulnerability Evaluation) at Carnegie Mellon University to help the U.S. Department of Defense (DoD) address its security risks and challenges [11]. OCTAVE has two variants: OCTAVE-S and OCTAVE Allegro [12]. OCTAVE-S has fewer processes, adhering to the overall OCTAVE philosophy and thus simplifying application for small businesses. OCTAVE Allegro is a later variant focused on protecting information-based critical assets. The OCTAVE framework is workshop-oriented, requiring knowledge from three levels: senior management, operational area management, and staff. Many risk assessment practitioners agree that the detail level and complexity of the OCTAVE assessment approach have made it hard to adopt on a wide scale [13].

Facilitated Risk Analysis Process (FRAP) is a method where information security provision is considered as part of the risk management process. The main objective of the Facilitated Risk Analysis Process (FRAP) was to develop an efficient and disciplined process to ensure that information-related risks to business operations are considered and documented [14]. Table I shows how each risk analysis procedure is separated into three distinct sessions.

However, this model requires expert communications and internal managers' participation to collect data, making the process more time-consuming. Besides that, this framework is designed to analyze business and not comply with security requirements.

Another prominent framework is ISO 27005, the international standard that guides information security risk management processes that are needed for the implementation of an effective information security management system (ISMS) [13]. The stages of risk assessment consist of context establishment, risk identification, risk analysis, risk evaluation, and risk management [15]. ISO 27005 provides good examples of a threat catalogue, vulnerabilities, and various computation and plotting techniques for rating risk. However, the limitation of this framework is that it focuses on objectives, guidance, and concept but does not provide any criteria, scoring, or decision matrices.

National Institute of Standards and Technology (NIST) published the latest version of the Cybersecurity Framework. This framework categorizes cybersecurity practices in five domains: Identify, Protect, Detect, Respond and Recover. As for the NIST method, the risk assessment process is refined into nine steps. Each step has a clear goal and all the possible approaches to accomplish the goal, which alleviates the bias brought by merely depending on participants' or security evaluator's knowledge [16].

Table II summarizes the differences between all four frameworks. Each framework has been categorized based on five criteria: phases, data collection method, approach and complexity. The OCTAVE framework phases focus more on assets while ISO 27000 and NIST focus on data security. The FRAP framework focuses more on business analysis than security assessment. The data collection method for OCTAVE and FRAP is largely dependent on the participants' knowledge which can be time-consuming. Meanwhile, NIST's and ISO 27005 framework data collection method is not limited to participants' knowledge but includes conclusions and discoveries mentioned in other related documentation.

In terms of approach, the OCTAVE framework is based on methodology and has an implementation guide. The FRAP framework is based on guidelines and participants' decisions. Meanwhile, ISO 27005 focuses on objectives, guidelines, and concepts and does not really provide criteria, scoring, or decision matrices. The NIST framework enumerates all the possible approaches to process the data and has a specific target to facilitate the procedure.

The complexity of each framework is defined by the time consumed to process and gather the data, and it can be categorized as high, medium and low. High complexity requires more participation in data collection and more time to process the data. Medium complexity is when it requires an average number of participants in data collection and an average time to process the data. In contrast, low complexity is when fewer people are required for data collection and less time is required to process the data. As a result, NIST SP 800-30 and ISO 27005 frameworks provide the most complete and scientific approach among all the methods.

TABLE I. Risk Analysis Procedure in FRAP

FRAP Session	Description
PRE FRAP	It takes about an hour and involves the business manager, project lead and facilitator. The project outcome depends on five key components: scopes statement, visual mode, FRAP team, meeting mechanics and agreement on definitions.
FRAP SESSION	It takes between 7 and 15 hours to complete and includes 15 people in the organization. The second session is to access threats with the existing control place. It has three phases: risk analysis, safeguard implementation and security assessment.
POST FRAP	It takes about an hour with the same attendees. The deliverables for this meeting include a summary of threats and existing controls, as well as a final report.

TABLE II. COMPARISON OF FOUR CYBERSECURITY RISK ASSESSMENT FRAMEWORKS

Framework	Phases	Data Collection Method	Approach	Complexity
OCTAVE	1. Development of a profile of threats related to the asset 2. Identification of vulnerabilities 3. Development of security strategies and plans	Requires knowledge from all three levels: senior management, operational level and steps but does not imply third-party experts	Method based	High
ISO 27005	1. Context of risk establishment 2. Risk Identification 3. Risk Analysis 4. Risk Evaluation	Requires knowledge from internal managers	Guidelines	Low
FRAP	1. Pre frap meeting 2. FRAP session 3. Post FRAP process	Requires knowledge from internal managers and experts	Guidelines	Medium
NIST SP800-30	1. System characterization 2. Threat identification 3. Vulnerability identification 4. Control analysis 5. Likelihood determination 6. Impact analysis 7. Risk determination 8. Control recommendations 9. Results documentation	Non-government organizations	Guidelines	Medium

B. Related Works on Cybersecurity Risk Assessment in HEIs

Jufri et al. [17] conducted a risk assessment on the Academic Information System asset on OCTAVE Allegro and ISO framework. This research focuses on the Academic Information System in Langlangbuana University that functions to protect its critical assets. The process of risk assessment is conducted based on the OCTAVE framework. The implementation of security control is based on ISO 27002.

Similarly, Chanchala Joshi [18] has also proposed a quantitative information risk assessment model based on the OCTAVE framework for the university computing environment. The proposed model quantitatively measures security risks by identifying threats and information processes within university network configuration. The first phase focuses on knowing weak points. The next phase concentrates on understanding which areas have the highest risks. The last phase pivots with creating an actionable remediation plan over the university environment's unique factor and finally generate powerful reporting to track recursive risk measurement activities. The major drawbacks of OCTAVE are its complexity and that it does not allow organizations to quantitatively model risk. In order to improve the security organization system, some standard principles are required.

Meanwhile, Hom et al. [19] and Suroso et al. [20] proposed a risk assessment model to identify, analyze and manage the risk of academic information systems in higher education using the OCTAVE Allegro method. The risk assessment was conducted based on four stages, where first they establish drivers, profile assets, identify threats and mitigate risks. This approach differs from the OCTAVE approach because OCTAVE Allegro focuses on information assets within the context of how they are used, where they are stored, transported and processed, and how they are affected by the threat, vulnerability, and disruption as a result [8].

Sulistyowati et al. [21] proposed a model to reduce the risk of security breaches with the combination of the OCTAVE framework and ISO 27001. The risk assessment was conducted based on the OCTAVE framework, while the information security control and risk mitigation analysis is based on ISO 27001. The sustainability of the proposed improvement method is based on lost expectancy and return on investment. However, this model focuses solely on the security requirements of information assets and not on data security in HEIs.

Table III summarizes the evidence discussed in this section which highlights that most risk assessment work in HEIs based on OCTAVE, OCTAVE Allegro and risk management is based on the ISO framework. Besides that, the scope of those proposed risk assessment models focuses more on the security of assets in HEIs rather than data security. Therefore, our study aims to explore risk assessment based on the NIST SP 800-30 and ISO 27005 framework.

III. PROPOSED MODEL

The proposed model is based on ISO 27005 framework for context establishment and NSIT SP 800-30 framework for risk assessment process. Fig. 1 illustrates the proposed model for this study.

A. Context Establishment

In our study, the context establishment is based on ISO 27005 framework. This process establishes essential criteria for information security management. The context establishment explained the scope and restriction of risk that are adjusted based on the information security level to be achieved.

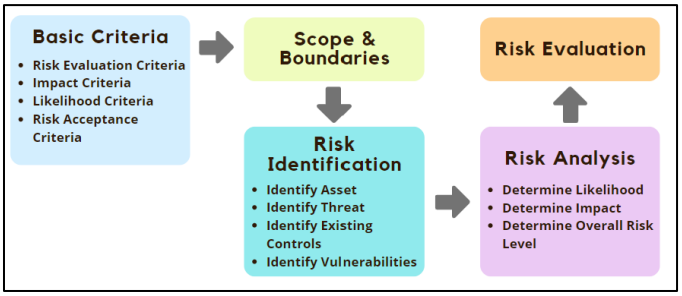

Fig. 1. Proposed Model.

TABLE III. RELATED WORKS ON CYBERSECURITY RISK ASSESSMENT IN HEIS

Authors	Objective	Scope	Framework	Phases
[17]	To assess the Academic Information System asset risk.	Academic Information System asset.	OCTAVE Allegro and ISO 27002	Risk assessment is conducted based on the OCTAVE framework. Implementation of security controls is based on ISO 27002.
[18]	To reduce the risks of a security breach.	Network configuration security	OCTAVE	Phase 1: Identification of weak points in university network configuration. Phase 2: Quantitative risk level measurement for the university's campus network. Phase 3: Enhancement of the university's security position.
[19]	To identify, analyze and manage the risk of academic information systems in HEI using the OCTAVE Allegro method.	Academic Information System	OCTAVE Allegro	Phase 1: Establish drivers Phase 2: Profile assets Phase 3: Identify threats Phase 4: Identify and mitigate risks
[20]	To identify the risk that affects the security of information assets and design some protection strategies for securing those risks.	Assets of Information System	OCTAVE Allegro	Phase 1: Establish drivers Phase 2: Profile assets Phase 3: Identify threats Phase 4: Identify and mitigate risks
[21]	The purpose of the proposed model is to reduce the risk of security breaches. The feasibility of the proposed improvement method is based on lost expectancy and return on investment.	Assets	OCTAVE and IS027001	Phase 1: • Understanding the information security needs. • Identify threats and vulnerabilities. Phase 2: • Identify likelihood. • Identify severity. • Risk assessment. Phase 3: • Analysis of Information security controls based on ISO 27000. • Calculation of loss expectancy. • Remediation plan.

1) Basis Criteria

a) Risk Evaluation Criteria: This study establishes the consideration in evaluating risk with these criteria:

- Confidentiality refers to the safeguarding of data against unauthorized access. NIST defined confidentiality as preserving authorized information access and disclosure restrictions, including safeguards for personal privacy and proprietary information [22]. In this study, when a hacker or other unauthorized individual gains access to a student information system, the students' data has lost its confidentiality.
- Integrity refers to the assurance that the data are unchanged from creation to reception. In this study, loss of integrity occurs when HEI data is accessed or modified by unauthorized parties, resulting in data accuracy and authenticity loss. For example, when a student's data is accessed or modified by a third party, the data's authenticity is not lost.
- Availability means the asset is always available to the authorized user [7]. In this study, loss of availability is defined as the state of an information system being unavailable, resulting in data loss and accuracy. The unavailability could be due to system disruption or malicious attacks by attackers.

b) Impact Criteria: The impact and likelihood of occurrence criteria are determined based on NIST SP 800-30 revision 1, where the rating scale is assessed from 5 being "Very High" to 1 being "Very low" and determined based on CIA triad of Confidentiality, Integrity and Availability. These criteria are presented in Table IV.

c) Likelihood Criteria: The likelihood of occurence criteria and likelihood of threat event resulting in adverse impact are adapted based on NIST SP 800-30 guidelines. Table V shows the likelihood of threat event resulting in adverse impact adapted based on NIST SP 800-30 guidelines. Table VI shows likelihood of threat event resulting in adverse impact.

d) Risk Acceptance Criteria: Risk acceptance is defined as the level of risk taking acceptable to achieve a specific business objective. Determining risk tolerance allows HEI to articulate how much risk the organization is willing to accept [23]. Table VII shows the risk tolerance appetite matrix based on NIST SP 800-30 guidelines.

TABLE IV. IMPACT RATING CRITERIA

Scale	Description	Value
Very High	Unauthorized disclosure of confidential data with a high number of records resulted in an adverse impact on HEIs. The unauthorized modification of the confidential data resulted in data damage or loss which cannot be recovered. The student system is not accessible for more than 24 hours.	5
High	Unauthorized disclosure of confidential data with a medium or low number of records seriously impacted HEIs. The unauthorized modification of the confidential data resulted in data being damaged/ missing, but data can be recovered. The student system is not accessible between 12 hours to 24 hours.	4
Moderate	Unauthorized disclosure of internal data resulted in a moderate impact on HEIs. The unauthorized modification of the internal data resulted in data being damaged/missing but can be recovered. The student system is not accessible between 2-12 hours	3
Low	Unauthorized disclosure of public data resulted in a low impact on HEIs. The unauthorized modification of the internal data resulted in data being damaged/missing but can be recovered. The student system is not accessible between 1-2 hours.	2
Very low	Unauthorized disclosure of unclassified data resulted in a low impact on HEIs. The unauthorized modification of the internal data resulted in data being damaged/missing but can be recovered. The student system is not accessible for less than 1 hour.	1

TABLE V. LIKELIHOOD CRITERIA

Scale	Frequency Number of a Possible Occurrence	Value
Very high	Between 20 to 30 times a year	5
High	Between 10-20 times a year	4
Moderate	Between 5 to 10 times a year	3
Low	Between 2 to 5 times a year	2
Very low	Less than 2 times a year	1

TABLE VI. RESULTING IMPACT SCALE

Scale	Impact Description	Value
Very High	Definitely give a negative impact	5
High	Almost certainly give a negative impact	4
Moderate	A medium probability gives a negative impact	3
Low	A small probability gives a negative impact	2
Very low	Very unlikely to have a negative impact	1

TABLE VII. RISK TOLERANCE MATRIX

Risk level	Impact Description	Scale
Low and Very Low	Risks are acceptable	1 - 4
Medium	Risks can be mitigated	5 - 15
High and Very High	Must be mitigated	15 - 25

2) Scope and boundaries: The scope of the risk assessment determines what will be considered in the assessment and what risk scenarios HEIs could anticipate. Risk assessment scope affects the range of information available to make risk-based decisions and is determined by the organizational official requesting the assessment and the risk management strategy. HEIs risk is not limited to information systems and security but includes financial, strategic, technological, and reputational risks [9]. In this study, our scope covers five types of risks as follows:

a) Strategic Risk: Strategic risk is related to corporate risk. It impacts the development and implementation of an organization's strategy. Strategic risk influence the organization's ability to achieve its long-term goals and objectives [13]. To effectively learn and adapt to new changes, top management needs to carefully define and implement a strategy. When a university implements a new strategy for its business process, the risk associated with that strategy should be considered. Since the COVID 19 pandemic, HEIs have shifted their teaching delivery from physical to online. If staff and students do not adapt to the new environment, the teaching procedures and academic achievement may deteriorate.

b) Operational Risk: The operational risk focuses on managing the risk that occurs in daily operations [9]. It is an occurrence that affects the organizations' ongoing management processes and procedures. Meanwhile, operational risk is defined by Panchal as the likelihood of human error or fraud in manual or automated environments. It also refers to potential threats to an institution's administrative process [11]. Inefficient or defective internal processes, people, control, system, or external events are the causes of business failures. For example, when a new learning management system is implemented in HEIs, teaching and learning activities are modified. If the changes are not effectively implemented, they may severely influence the ongoing student learning process, caused to system downtime and failure.

c) Compliance Risk: Compliance risk is concerned with the adherence to externally imposed laws and regulations, as well as internally bound policies and procedures concerning safety, conflicts of interest, and other issues. [20]. It is associated with conformance to federal, state, and regional rules and regulations [11]. It is concerned not only with externally imposed laws and regulations but also with internal policies and practices. This study investigates compliance risk in relation to research activities undertaken in an academic institution. The institution's research department must follow the laws and regulations of both the university and the government. Failure to comply with or violate applicable laws might result in severe penalties and accreditation revocation.

d) Financial Risk: Financial risk is associated with an initial assessment of HEIs revenues and expenditures and how to manage them [21]. Asset loss, conflict of interest, and

technological risks are financial management or transaction events that harm an organization's profitability and efficiencies. In this study, financial risk refers to the negative consequence of a cyberattack. Attackers can steal sensitive information, disable critical system access, and demand payment before restoring access. They have also threatened institutions with the publication or stolen critical information if they disagree with their requests. Some organizations must pay a ransom to regain access and recover lost data and systems. The sum paid may reduce the university's budget or create insolvency, resulting in insufficient cash for other operations such as research, teaching, maintenance, and development.

e) Reputational Risk: Reputational risks are related to an organization's brand or public image and emerge from the organization's inability to handle any other type of risk accurately [20]. It also includes the external perception of the organization's reputation. Reputational risk is frequently seen as a critical issue [13]. Political difficulties or unconstructive occurrences are examples of events that harm an institution's reputation and public view. The impact of external perception on an institution's image and brand is the focus of reputational risk [11]. This risk may occur due to an institution's failure to manage any or all of the other risks effectively. HEIs must protect their valuable data, assets, and images from sustaining the university's trust among students, parents, alumni, and the general public. Failure to successfully manage this risk will harm the university's reputation, the inability to meet the target of student enrollment, and the failure to meet the target of business and research initiatives.

B. Risk Assessment

In this study, the risk assessment process will be based on NIST SP800-30 because the guidelines contain detailed criteria to analyze the risk.

1) Risk Identification

a) Identify Asset: Typically, a risk assessment encompasses all the organization's critical assets that directly impact the confidentiality, integrity, and availability of the organization's information resources [13]. Table VIII shows the example of information assets in the student information system.

b) Identify Threats: NIST [24] defined a threat as any circumstance or event that has the potential to negatively affect the organization, individuals, other organizations, or the nation's operations and assets via an information system through unauthorized access, destruction, disclosure, or modification of information, and/or denial of service caused by threat sources. In this study, a threat is defined as a potential cause of an adverse event that may harm the HEI environment. Table IX shows an example of threat listings based on NIST SP-800 threat catalogues.

c) Identify Existing Control: The primary aim of this process is to consider both existing and proposed controls when determining the chance that a threat source would exploit the vulnerability. Hence, the more effective the control, the less likely a weakness would be exploited and vice versa.

d) Identify Vulnerabilities: This activity focused on identifying vulnerabilities that the identified threats could exploit. Examples of threat vulnerabilities scenarios are presented in Table X based on NIST SP 800-30 vulnerabilities catalogue.

TABLE VIII. EXAMPLE OF INFORMATION ASSETS IN THE STUDENT INFORMATION SYSTEM

Category	Information Asset
Student information system	Personal sensitive information. Student financial information. Student academic details. Student accommodation details. Study records of course completion and achievements.

TABLE IX. THREAT LISTING

Threat Agent	Threat Action
Students	Possible weak passwords due to lack of password complexity controls
Malicious insiders	System intrusion and unauthorized system access.
Hackers	Send phishing e-mails requesting students to enter their confidential details.

TABLE X. THREAT VULNERABILITIES SCENARIOS

Threat Agent	Threat Action	Vulnerabilities
Students	Open an e-mail requesting sensitive information or click on a malicious link that unknowingly downloads malware onto their device.	Lack of anti-virus and malware prevention.
Malicious insiders	System intrusion and unauthorized system access.	Weak password or due to lack of password complexity.
Hackers	Send phishing e-mails requesting students to enter their confidential details.	Insufficient security awareness and best practices.

2) Risk analysis: Risk analysis is about analyzing the elements that make up each risk scenario to determine [24]:

- The overall likelihood of a risk scenario occurring is calculated based on the combination of the likelihood that the event will occur and the likelihood that the event will have a negative impact.
- The impact (i.e., magnitude of harm) resulting from the occurrence of a risk scenario.

Table XI shows an assessment scale based on the NIST SP800-30 guideline to determine the overall likelihood.

The final risk rating is determined based on the intersection of the impact and overall likelihood for each identified threat and vulnerability pair. The formula to evaluate the risk is:

Risk = Overall Likelihood x Impact.

TABLE XI. OVERALL LIKELIHOOD

Likelihood of threat event initiation occur	Likelihood of threat event results in adverse impact				
	Very Low (1)	Low (2)	Moderate (3)	High (4)	Very High (5)
Very High (5)	Very Low	Moderate	High	Very High	Very High
High (4)	Very Low	Moderate	Moderate	High	Very High
Moderate (3)	Very Low	Low	Moderate	Moderate	High
Low (2)	Very Low	Low	Low	Moderate	Moderate
Very Low (1)	Very Low	Very Low	Very Low	Low	Low

Table XII depicts the risk appetite matrix used to determine risk. If the risk scores are in the black range, the risk is considered high. Meanwhile, if the risk falls into a grey shade, it is classified as moderate risk. If the risk is in the white shade, then the risk is categorized as low risk.

TABLE XII. RISK APPETITE MATRIX

Impact	Overall likelihood				
	1	2	3	4	5
1	1	2	3	4	5
2	2	4	6	8	10
3	3	6	9	12	15
4	4	8	12	16	20
5	5	10	15	20	25

3) Risk evaluation: Lastly, the derived risks will be evaluated according to the risk matrix score and compared to the risk tolerance level specified in the risk criteria. The output will take the next course of action to keep the risks within the organization's risk tolerance level.

IV. DISCUSSION

The core to effective university risk management is cybersecurity risk assessment. It is critical to select a suitable risk assessment approach that may give universities a range of instruments to identify unforeseen events and mitigate the impacts. We conducted extensive literature studies by evaluating existing risk assessment frameworks and related works on risk assessment in HEIs.

Based on our findings, we can conclude that the most dominant risk assessment literature in HEIs utilizes OCTAVE and OCTAVE Allegro framework for risk assessment and ISO 27005 framework for risk management. Hence, our study aims to explore ISO 27005 and NIST SP 800-30 frameworks to establish a risk assessment model for HEIs.

The context establishment and criteria are adapted based on ISO 27005 because it describes how to represent an incident process in risk scenarios. HEIs can assess the likelihood and impact that occurs in the scenarios of information risk to information security with the aid of incident description of risk scenarios. Meanwhile, the risk assessment process is based on the NIST SP 800-30 framework since it includes criteria, scoring, and decision matrices for analyzing risk, whereas ISO 27005 solely focuses on objectives, guidelines and concepts.

V. CONCLUSION AND FUTURE WORKS

This study aimed to establish a cybersecurity risk assessment model for HEIs by modeling the factors associated with HEIs. The method is based on the prominent ISO 27005 and NIST SP 800-30 frameworks. The primary goal of risk assessment in HEIs is to measure the risks and to improve their decision-making in managing the risk within the environment. A proposed cybersecurity risk assessment model was developed, demonstrating that several critical scenarios may arise in the HEIs environment. After evaluating the identified risks, the next step is to identify and determine the next course of action to keep the risks within the organization's risk tolerance level. Future research initiatives could further enhance the proposed model on establishing appropriate countermeasures for risk treatment in the HEI environment.

Acne Classification with Gaussian Mixture Model based on Texture Features

Alfa Nadhya Maimanah, Wahyono*, Faizal Makhrus
Department of Computer Science and Electronics, Universitas Gadjah Mada, Yogyakarta, Indonesia

***Abstract*—This paper presents an acne detection method on face images using a Gaussian Mixture Model (GMM). First, the skin area in the face image is segmented based on color information using the GMM. Second, the candidates of the acne region are then extracted using a Laplacian of Gaussian-based blob detection strategy. Then, texture features are extracted from acne candidates using either a Gabor Filter or Gray Level Co-occurrence Matrix (GLCM). Lastly, these features are then utilized as input in the GMM for verifying whether these regions are acne or not. In our experiment, the proposed method was evaluated using face images from ACNE04 dataset. Based on the experiment, it is found that the best classification results were obtained when GLCM features in the Cr-YCbCr channel are applied. In addition, the proposed method has competitive performance compared to K-Nearest Neighbor (KNN).**

Keywords*—Acne; GLCM; Gabor filter; Gaussian mixture model

I. Introduction

In recent years, the beauty technology industry has experienced significant growth along with increasing public enthusiasm and awareness of skin health. One major concern of skin problems is *acne vulgaris*. Acne occurs when sebum is trapped in the hair follicles and attacked by *Propionibacterium acnes* [1]. Adolescents to adults may experience this problem. It could leave scars that influence the level of confidence of some people. A common method to determine the acne severity is through manual counting by a dermatologist. The process is susceptible to subjectivity factors, both inter-observers—the same patient has different assessments by different dermatologists—and intra-observer—the same patient has different assessments by the same dermatologist on different days [1]. In addition, the technique is not effective in terms of time and effort spent by a dermatologist [2]. Therefore, technology is needed to assist the process of acne severity assessment through face images.

There have been several developed technologies which are employed to assess facial skin. In addition to helping determine the appropriate and accurate type of treatment, the presence of technology can also attract the attention of customers. The types of technology developed are quite diverse, ranging from instruments equipped with skin analysis systems such as VISIA, Internet of Things (IoT) such as LG U+ LTE Magic Mirror, mobile-based applications such as TroveSkin, and Skin Genius by L'Oréal Paris, as well as Software as a Service (SaaS) such as Haut.AI. Facial skin analysis models are developed based on Artificial Intelligence (AI) which is trained using the data, the company had collected.

This research proposes a study of comparison of texture-based feature extraction methods for assessing the acne severity on human face images. To the best of our knowledge, the research related to acne images generally aims to segment and/or classify acne types. However, research that aims to determine the severity of acne suffered by patients is still limited. Research [3] contributed to determining the severity of acne, but it was still based on the area of acne on the right and left cheeks without using appropriate standards. Since there are still few studies on acne images with standardized acne severity, this research used the criteria formulated by Hayashi [4], which was also utilized in the dataset developed by Wu et al [5]. This criterion estimates the acne severity based on the number of papules and pustules detected on a face image captured with an angle of 70° from the front side.

Furthermore, this research utilizes texture-based features, namely GLCM and Gabor Filter. GLCM was chosen because it was inspired by research related to the acne types classification conducted by Ramadhani [6] which achieved an accuracy value of 72%. In addition, research conducted by Chang and Lio [7] successfully detected acne on face images using GLCM features with accuracy of 99.40%. It was proved that GLCM has the ability to extract the features needed for acne detection. On the other hand, Gabor Filter was chosen because research conducted by Jeon and Cheoi [8] could successfully detect abnormal areas on skin images, including small acne and regions with low contrast levels, which open the possibility of implementing this method for acne detection. To classify acne and non-acne areas, this research conducted an experiment to use the Gaussian Mixture Model (GMM) method. This method is usually used as a density estimator so it is suitable for clustering problems. In addition, the GMM has also been proved as a good approach for classification which was implemented by Dey [9] for skin classification as well as Wan et al. [10] for classifying 10 kinds of datasets from the UCI Machine Learning Repository.

The rest of this paper is organized as follows. Section II discusses the research related to this topic. Section III explains the details of the proposed method. Section IV demonstrates the experimental result. Conclusions are given in Section V.

II. Literature Review

Based on the feature extraction method, the research related to acne images is generally divided into two categories: hand-crafted and deep learning-based feature extractions. The features from the hand-crafted strategies can be obtained based on color, shape, and texture [11]. A comprehensive experiment and observation are required to

*Corresponding Author.

determine the best features as the basis for acne detection, unlike deep learning where the model can extract its own features automatically.

Deep learning is the latest research trend regarding images with acne objects. Zhao et al. [12] used a regression model with transfer learning on ResNet-152 to determine the acne severity but it did not achieve a good performance since the data were imbalanced, which is dominated by one class. Arifianto and Muhimmah [13] used transfer learning on ResNet-50 to detect acne and obtained an accuracy of 63.2%. Both studies faced the problem of limited data with good quality which resulted in low accuracy. Junayed et al. [14] also utilized deep learning for classifying five classes of acne with accuracy over 94%, but it required an expensive computation time.

On the other hand, the hand-crafted feature extraction based on either color or texture was also implemented. Acne color features tend to be inconsistent with variations in lighting and skin color on the same type of acne as in [15] and [16]. With the input of the cropped acne area from the face image, the author [6] utilizes feature textures for classification of acne types. Authors in [7] extracted Gray Level Co-occurrence Matrix (GLCM) statistical features on a whole face image which was then divided into blocks. However, the image acquisition process required a special device with standard camera settings, lighting, and shooting distance parameters that had been determined beforehand. It was less flexible to be implemented as a mobile application only has a smartphone camera available. Nevertheless, the hand-crafted approach could achieve a high accuracy of 99.40% with less computation time compared to deep learning approach. Therefore, this research would be conducted to study more on the utilization of hand-crafted texture-based features to detect acne on face images.

The input images used in previous studies related to acne recognition were quite diverse. Some studies used whole human face images with various levels of acne severity, as in the research [12] and [13], while other studies used cropped images on the acne object only, such as [14] which used a dataset from Dermnet consisting of five types of acne.

Furthermore, research related to acne images can be grouped into three objectives: acne segmentation, acne classification, and acne severity assessment. Research conducted by Maroni et al. [2] detected and counted the number of acnes with a sequence of processes starting from body part detection, skin segmentation, heatmap creation, acne extraction, and blob detection. The best skin segmentation was generated by the Random Forest method based on the 15 most informative features explored. Acne extraction was carried out using the adaptive thresholding of heatmap images. After that, acne was detected and counted using the Laplacian of Gaussian (LoG) filter. Research conducted by Jeon and Cheoi [8] aimed to cluster abnormal areas on human skin using the density-based spatial clustering of applications with noise (DBSCAN) algorithm based on the features obtained from the Gabor Filter. In their study, the skin segmentation was not carried out first even though there was an image input in the form of a face. The proposed method had better performance than the [17] method because it could detect small acne and regions with low contrast levels.

Lastly, some researchers classified acne based on texture features. Ramadhani [6] utilized GLCM to obtain texture characteristics including contrast, energy, entropy, correlations, and dissimilarity. Among these characteristics, entropy was the most influential statistical feature since it represents texture irregularities. The overall accuracy value obtained was 72%. Some studies classified acne based on color features, like a research by Darmawan et al. [15] where RGB color intensity was used. Although it had been able to detect types of acne, there were still limitations due to lighting factors during image acquisition resulting in color values discrepancy and accuracy. Gunawan et al. [16] conducted segmentation using Region Growing and classified the acne types using Self Organizing Map (SOM). RGB histogram feature was used as SOM input. The classification accuracy was still not ideal due to acne color variations influenced by diversity of skin color and lighting conditions in each image. Several studies used the segmentation results to classify the types of acne, like in Arora and Sarvani [17] who explored the methods of acne segmentation and machine learning models for acne classification. Compared to color and texture segmentation, the 2-level K-means clustering had the best accuracy at 70%. While the classification of acne and acne scars had an average accuracy of 80% using the Fuzzy C-Means (FCM).

III. METHODS

A. Classification Model Development

A total of 40 images from the ACNE04 dataset—10 images from each Hayashi Criteria—are used for evaluation. These images have non-uniform dimensions therefore they are resized to 320×320. The bounding box coordinates in the Extensible Markup Language (XML) annotation document are also adjusted to the same dimension which is then used for image cropping to obtain acne blocks. On the other hand, for non-acne blocks, a whole image is divided into a uniform block size of 20×20 which is then curated manually to remove the ones with acne. In total, there are 908 acne blocks and 870 non-acne blocks.

The first texture features are extracted from GLCM. The distance and angles chosen are one pixel and (0°, 45°, 90°, and 135°), respectively. For comparison purposes, this feature extraction is carried out on four different channels of color space, i.e. Grayscale, Hue-HSV, Red-RGB, and Cr-YCrCb. There are six features calculated from the GLCM including contrast, dissimilarity, correlation, energy, homogeneity, and ASM, each of which was the average of the four neighboring angles. These features are then normalized to the range of [0,1]. Finally, there will be six GLCM features obtained from each block. The second texture features are extracted from Gabor filtered images. The two-dimensional Gabor filter is a Gaussian kernel function modulated by a sinusoidal wave [18]. The Gabor filter bank is created with the size of 3×3 by adjusting the five variables in formula 1. The first three variables followed the research by [8]: $\Psi=\pi/2$; $\lambda=0.8$; $\gamma=0$. For comparison purposes, the last two variables are set on two different configurations: $\theta=0°$, 30°, 45°, 60°, 90°, 120°, 135°,

150°; σ=1 and θ= 0°, 45°, 90°, 135°; σ=1,2. The visualization of the Gabor filters used is displayed in Fig. 1. After the filtering process, two statistical features, namely, mean and variance are calculated. Finally, there will be 16 Gabor features obtained from each block. After both features are gathered, they are trained for acne and non-acne classification using GMM.

$$g(x, y; \Psi, \lambda, \gamma, \theta, \sigma) = exp\left(\frac{-x'^2+\gamma^2 y'^2}{2\sigma^2}\right) cos\left(2\pi \frac{x'}{\lambda} + \psi\right) \quad (1)$$

The GMM classifier performs acne and non-acne classification using two GMMs, one model for acne features and the other for non-acne features. After training those models, a new testing feature is classified as acne if the log-likelihood value in acne GMM is higher than in non-acne GMM. To determine the optimal number of Gaussian components in the two GMMs, experiments are carried out on the number of Gaussian components in the range of 2-20 so that the lowest Bayesian Information Criterion (BIC) value could be obtained. Below is the pseudocode to create a GMM Classifier.

Input: GLCM/Gabor Features, K_{max} = 20, and C = 2 (acne and non-acne)
Output: K_{opt} for every class c
for c=0:C do
  for k=2: K_{max} do
    Apply GMM−EM with k number of Gaussian components;
    Calculate BIC based on maximum parameters obtained;
  end for
  K_{opt} = arg min k (BIC)
end for

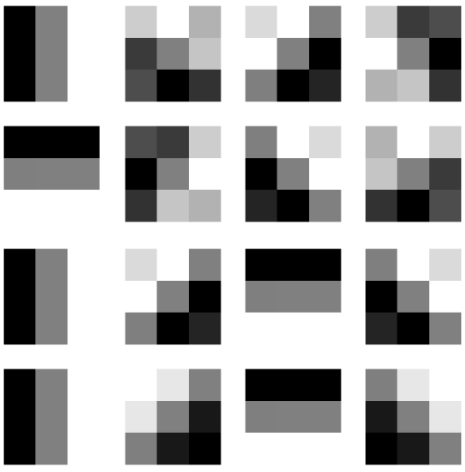

Fig. 1. Gabor Filter Bank: 8 Angles-1 Standard Deviation (Row 1 and 2), 4 Angles-2 Standard Deviations (Row 3 and 4)

B. Skin Segmentation

To evaluate the classification model, skin segmentation steps are implemented as shown in Fig. 2. A total of 20 images from the ACNE04 dataset—five images from each Hayashi Criteria—are used for testing. These images are also resized to 320×320 dimensions. Then an enhancement process is carried out on the a* CIELab channel. The reason behind this is that the a* channel represents the level of pixel redness that is independent of lighting, making it stronger for detecting acne that tends to be redder than the surrounding skin. The enhancement started with the unsharp mask to sharpen the image after going through the resizing step. Then, the Difference of Gaussian (DoG) process is applied by subtracting the unsharp masked image from the Gaussian Blurred image following the research conducted by [19]. The resulting image highlights the pixels that tended to be red. The Gaussian Blur filter parameters use kernel size of 19×19 and σ=13. The next step is skin segmentation. For comparison purposes, two skin segmentation methods are used. The first is GMM segmentation based on BGR skin and nonskin pixel values from the Skin Segmentation Dataset, UCI Machine Learning Repository. The second method is Otsu Thresholding on the median blurred Cr image. This channel is selected since it is a red chromatic channel that could help the process of blurring pixels whose intensity did not resemble the skin—in which the color tends to be reddish. The size of the median blur filter is 21×21. The result of Otsu Thresholding is then used as the mask on the resulting image from a* CIELab enhancement step. Face parts such as the mouth, right eye, left eye, right eyebrow, and left eyebrow could be susceptible to being misdetected as acne, especially those with similar features in terms of color intensity, such as the mouth. Therefore masking is done on these parts. Face parts detection was done with the help of the DLIB library. The resulting image is then being used as a mask. The next step is to do acne candidate thresholding on the already masked a* CIELab enhanced image with the threshold value of 128. To remove the noise, a morphological opening operation is performed with a kernel size of 3×3.

C. Acne Detection

To calculate the number of acne candidates, the blob detection method is used with the Laplacian of Gaussian (LoG) kernel. The parameters used include the minimum standard deviation of the Gaussian kernel = 1, the maximum standard deviation of the Gaussian kernel = 5, the number of intermediate values, standard deviation = 15, threshold = 0.2, and overlap = 0.1. Each detected blob stored the coordinates of the blob's center (x,y) and its radius. They are used to determine the bounding box coordinates of the acne candidates which are then used for the cropping process. The cropping process is carried out by taking the pixels in the bounding box's coordinates range. The cropped pixel blocks are stored for texture features calculation. The features obtained from all blocks of acne candidates are used to predict the acne classification using the GMM Classifier model that had been trained previously. To reduce the number of overlapping bounding boxes while recognizing the same object, the Non-Maximum Suppression (NMS) process is carried out. The output image is the original image with a bounding box on each of the detected acne. In addition, the text of the number of detected acne and the severity are also displayed.

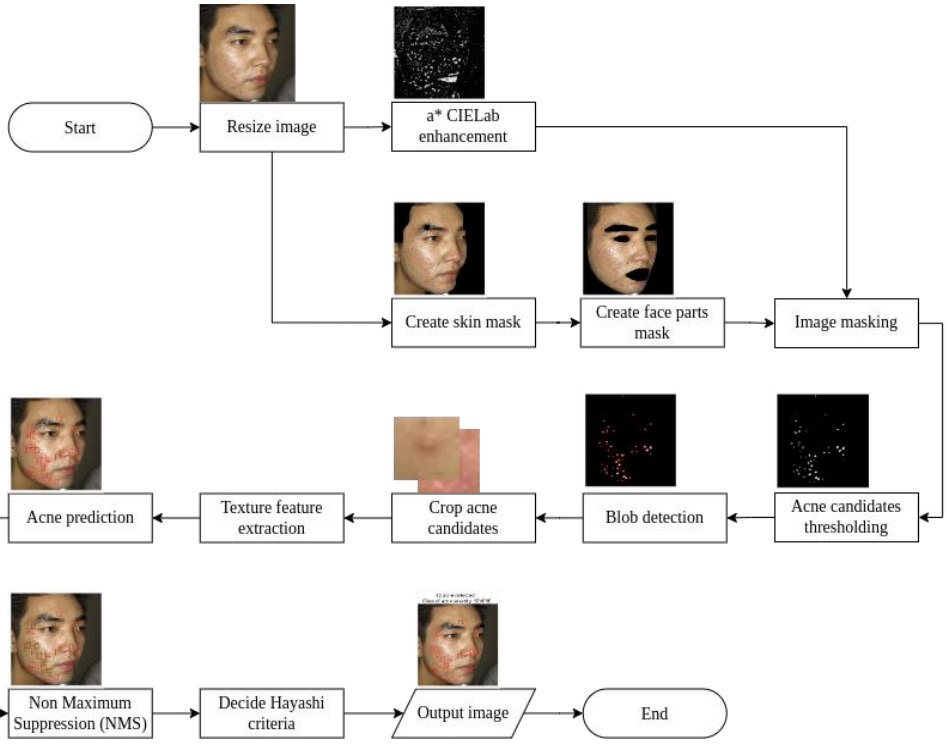

Fig. 2. Flowchart of the Proposed System.

IV. Experimental Results and Discussions

A. Skin Segmentation Result

Skin segmentation using the GMM method can separate facial skin areas in some images although hair, background, and clothing areas are still visible. Based on observations, these non-facial areas occur because of the morphological operation process carried out to remove noise and holes from the initial segmentation results. Several kernel sizes (3×3,5×5,7×7), the number of iterations (1,2,5,7), and the order of operations morphology are tried, however the obtained results still include 20-30% of non-facial regions. Fig. 3 on the left is the result of skin segmentation using the GMM method by performing closing and dilation operations using a kernel size of 5×5 and iterating 7 and 2 times respectively. Fig. 3 on the right is the result of skin segmentation using Otsu Thresholding on Median Blurred Cr Image which is better than the GMM method based on the minimum visible hair area, almost no visible background area, and minimum visible clothing area factors. The computation time of this second method is faster with an average computation time of 0.005 seconds, compared to the GMM method with an average computation time of 0.419 seconds. Therefore, based on the quality of the segmentation results and computational time, the experiments use Otsu Thresholding on Median Blurred Cr Image.

B. Classification Result with GLCM Features

Acne classification using the GMM method with the input of GLCM features is shown in Table I. In addition, Table II presents the details of Table I. Viewed from the prediction accuracy, all channels have accuracies below 55%. The highest total performance is obtained by Red-RGB channel based on the validation and test accuracies and the second place is Grayscale channel. Meanwhile, viewed from the precision value, all channels have relatively low precision in the range of 0.45-0.52, which means that there are still quite a lot of false positives. On the other hand, based on the recall value, Cr-YCrCb channel has the highest value at 0.78 that it becomes the best among the other three channels in correctly predicting acne close to the ground truth. Cr-YCrCb also has the best F1-Score value of 0.56.

Fig. 3. Example of Skin Segmentation Result with GMM Segmentation (Left) and Otsu Thresholding on Median Blurred Cr Image (Right)

TABLE I. Comparison of Testing and Prediction Accuracy with GLCM Features

Channel	K of non-acne	K of acne	Val Acc	Test Acc
Grayscale	10	7	95.22%	48.89%
Red-RGB	6	5	94.38%	53.20%
Cr-YCrCb	11	12	87.92%	45.14%
Hue-HSV	11	15	71.34%	41.75%

TABLE II. MODEL EVALUATION WITH GLCM FEATURES

Channel	Acc	Prec	Rec	F1	Time	IoU	Hayashi Correct
Grayscale	48.89%	0.52	0.58	0.50	1.228	0.466	10
Red-RGB	53.20%	0.53	0.53	0.49	1.209	0.442	10
Cr-YCrCb	45.14%	0.50	0.78	0.56	1.260	0.463	11
Hue-HSV	41.75%	0.45	0.70	0.52	1.236	0.452	12

Based on the number of images where the Hayashi class [4] is determined correctly, Hue-HSV is the best with 12 images. Having the recall value of 0.70, Hue-HSV channel performs below the Cr-YCrCb because more acne was still predicted as non-acne (it has more false negatives). In terms of computation time, the four channels do not differ much in the range of 1.2 seconds since the computational load tends to be the same as seen from the number of calculated features and steps. Based on the Intersection over Union (IoU) values [20], all four channels are above 0.4 which mean that they are quite good at detecting the location of acne. Nonetheless, since the size of the ground truth bounding boxes varies while the size of the prediction bounding boxes is uniform, the IoU value is difficult to approach 1. From all the experiment results, Cr-YCrCb is chosen as the best performance of GMM classification since it has the highest recall value of 0.78 although its accuracy value is low—in third place. An example of the output images can be seen in Fig. 4. The recall metric is chosen since in this problem, it is more important to correctly identify positive acne (the fewer false negatives are the better). Cr-YCrCb still has many errors in detecting non-acne, as indicated by the high number of false positives (low accuracy). Although in this case, this error is not life-threatening, it is much better to reduce it.

C. Classification Result with Gabor Features

Table III shows the comparison of validation accuracy and testing accuracy of GMM classification using Gabor features. The detailed evaluation results are also shown in Table IV. Viewed from the prediction accuracy, all filters do not achieve high accuracy. The highest was obtained by 4 degrees-2 standard deviations (4deg2sd) filter variation at 55.43%. Meanwhile, viewed from the precision value, both still have low values around 0.5 which mean that there are still many false positives. Compared to the recall these two filters do not differ too much around 0.5. Therefore, they are not good at predicting the correct acne. In addition, since both precision and recall from those two filters have small differences then the F1-Score values differ by only 0.02.

These two filters have the same number of images where the Hayashi class is determined correctly. It means that even though the number of detected acne is close to ground truth, the false negative predictions are still a lot. In terms of the computational time, they are both in the range of 0.4 seconds. The reason for the computational load which tends to be similar is because of the similarity in the number of features and steps. Based on the IoU value, the results show that both are above 0.4 which means that they are quite good at detecting the location of acne. Nevertheless, since the size of the ground truth bounding boxes varies while the size of the prediction bounding boxes is uniform; hence the IoU value is difficult to approach 1. Based on these two experiments, the 8 degrees-1 standard deviation (8deg1sd) filter parameter is chosen as the best filter since it has the highest recall value of 0.54.

TABLE III. COMPARISON OF TESTING AND PREDICTION ACCURACY WITH GABOR FEATURES

Filter	K of non-acne	K of acne	Val Acc	Test Acc
4deg2sd	3	3	67.69%	55.43%
8deg1sd	3	3	67.82%	54.27%

TABLE IV. MODEL EVALUATION WITH GABOR FEATURES

Filter	Acc	Prec	Rec	F1	Time	IoU	Hayashi Correct
4deg2sd	55.43%	0.52	0.51	0.48	0.449	0.446	10
8deg1sd	54.27%	0.54	0.54	0.50	0.472	0.411	10

Fig. 4. Example of the Output Images from the Proposed Method (Detected Acnes Represented by Red Bounding Boxes).

D. GLCM Features vs Gabor Filter Features

An important factor that affects the performance of the model is the quality and ability of the features to represent acne and non-acne characteristics. Viewed from the number of features, Gabor Filter [8] has 16 features while the GLCM has 6 features (initially there are 24, but then only the average value of all neighboring directions of each feature is used [7]). Having fewer features, the GLCM has a generally better recall value than the Gabor Filter although they tend to have lower accuracy. Therefore it is concluded that the GLCM features tend to be better at representing acne and non-acne objects even though in terms of computation time it is longer than the Gabor features. Models with GLCM features require computation time around 1.2 seconds while Gabor features only 0.4 seconds. Another factor that affects the model performance is the classification class which is limited to only two classes, namely acne and non-acne. Based on observations, the model detected several blocks as positive with characteristics close to acne but they are not, such as acne scars, spots, moles, and image lighting that make the skin tend to look red. This causes the high number of false positives in the prediction.

E. Color vs Texture

To determine the performance of the texture features in acne detection, some experiments are conducted. One reason to conduct this research is that color features are not good enough to detect acne since it tends to be inconsistent with variations in lighting and skin color during the image acquisition process even for the same type of acne as stated in [15] and [16]. Therefore the use of the texture features is proposed in order to improve the detection results. However, from the results presented in Table V, it shows out that the color features are still better than the texture features. The color features have the highest recall, F1-Score, and IoU values. With a faster computation time due to less computational load, the accuracy values of color features are generally near to the accuracy values of texture features. Therefore, it is concluded that the use of texture features for acne detection is not better than color features.

TABLE V. TEXTURE FEATURES COMPARED WITH COLOR FEATURES

Feature	Acc	Prec	Rec	F1	Time	IoU	Hayashi Correct
Color	44.15%	0.52	0.79	0.58	0.383	0.473	12
GLCM Grayscale	48.89%	0.52	0.58	0.50	1.228	0.466	10
GLCM Red-RGB	53.20%	0.53	0.53	0.49	1.209	0.442	10
GLCM Cr-YCrCb	45.14%	0.50	0.78	0.56	1.260	0.463	11
GLCM Hue-HSV	41.75%	0.45	0.70	0.52	1.236	0.452	12
Gabor 4deg2sd	55.43%	0.52	0.51	0.48	0.449	0.446	10
Gabor 8deg1sd	54.27%	0.54	0.54	0.50	0.472	0.411	10

F. GMM vs KNN (K-Nearest Neighbor)

To determine the performance of GMM as a classification model, a comparison is made with KNN as one of the supervised machine learning models. The inputs of KNN are GLCM features since they produce better performance than the Gabor Filter features in GMM classification. Based on the number of images where the Hayashi class is correctly determined by using KNN classifier, Hue-HSV is the best channel with 14 correct images. KNN with the Hue-HSV channel is good at predicting acne blocks that are quite close to the ground truth given the recall value of 0.69. However, Cr-YCrCb achieved the highest recall value at 0.77. Despite that, both of those channels have equal F1-Score at 0.54. The computational time of four channels is approximately 1.4 seconds for the reason that the computational loads are similar. Based on the IoU values which are approximately 0.4, they are quite good at detecting the location of acne.

Viewed from the overall accuracy values, the KNN model is better than the GMM. However, the overall recall and F1-Score values are still below GMM except using Cr-YCrCb channel which has a high recall at 0.77. The overall computation time and IoU between KNN and GMM do not differ much. GMM Classifier is better in general at predicting Hayashi class correctly. It can be concluded that GMM as a classification model has competitive performance compared to KNN based on the evaluation parameters. The performances of GMM and KNN with the GLCM features can be seen in Table VI.

TABLE VI. GMM CLASSIFIER AND KNN CLASSIFIER EVALUATION WITH GLCM FEATURES

Channel	Acc	Prec	Rec	F1	Time	IoU	Hayashi Correct
GMM Grayscale	48.89%	0.52	0.58	0.50	1.228	0.466	10
GMM Red-RGB	53.20%	0.53	0.53	0.49	1.209	0.442	10
GMM Cr-YCrCb	45.14%	0.50	0.78	0.56	1.260	0.463	11
GMM Hue-HSV	41.75%	0.45	0.70	0.52	1.236	0.452	12
KNN Grayscale	60.12%	0.57	0.39	0.43	1.322	0.358	7
KNN Red-RGB	59.15%	0.58	0.32	0.39	1.434	0.374	7
KNN Cr-YCrCb	41.76%	0.47	0.77	0.54	1.484	0.473	12
KNN Hue-HSV	49.90%	0.52	0.69	0.54	1.422	0.444	14

All experiments with GMM Classifier have low accuracies in the range of 40-50% since there are still many false positives—or in the other word there are still many parts of the skin that are misdetected as acne. Therefore, the number of detected acne is often bigger than the ground truth. The reason behind this is the limited annotation of the dataset—only acne is labeled—causing the model to fail in recognizing non-acne objects such as acne scars, spots, and moles to acne objects. Adding professional annotations by dermatologists for those

objects may improve the classification performance to let the model learn better.

V. CONCLUSION

The best acne classification result based on recall value is achieved by using the GMM classifier with the GLCM features in Cr-YCrCb channel as the input. The recall is 0.78. It also has a faster computation time, which is about 0.3 seconds compared to the worst method using texture features which is about 1.2 seconds. This classification method is also compared to a standard classification method which is KNN and shows that it outperforms all the evaluation criteria (see Table VI). Some suggestions for further research include the using of a face frame during image acquisition to keep the distance and the captured face size to be uniform, trying other classification algorithms to improve the performance, and increasing the number of training images as well as complementing them with a wider variety of colors and skins.

***Abstract*—Finding suitable learning content for learners with different learning styles is a challenging task in the learning process. Hence it is essential to follow some learning taxonomies to deliver learner-centric learner content. Learning taxonomies are used to express various learning practices and learning habits to be followed by the learner for a better learning process. The investigator has already classified the learners based on the 2022 augmented verb list of Marzano and Kendall taxonomy. The main objective of this paper is to minutely classify the tutor-defined learning contents according to the domains as well as the subdomains of the considered taxonomy which is in text format. Providing personalized learning content could help the learners for a better understanding of learning content and their interrelationship which in turn produce better learning outcomes. Mapping the six levels of learning contents into the corresponding learner is a challenging task. Hence the investigator has chosen seven algorithms including Bagging, XG Boost, Support Vector Machine from Machine Learning and four algorithms including Convolutional Neural Network, and Deep Neural Network in Deep Learning algorithm to classify the learning contents. The experimental results indicate that Support Vector Machine performed well in machine learning and Deep Neural Network yields good performance in deep learning in the learning content classification process. These micro contents were organized using a property graph. Further, the micro contents were retrieved from the property graph using SPARQL for mapping the classified contents to the corresponding learners to achieve personalization in the learning process.**

Keywords*—Learning taxonomies; marzano and kendall taxonomy; personalization; XG boost; deep neural network; CNN; property graph; action verbs; content classification

I. Introduction

Learning is a process of adapting changes in personal and professional to ameliorate the quality of life. According to Stephen Hawking, Intelligence is the ability to adapt the change. Acquiring intelligence, absorbing, adapting and storing new information in memory is uneven among the learner. Hence it is the need of the hour to identify different learning characteristics of the learner to achieve a better learning outcome. The resource used to provide knowledge to the learner is known as learning content. According to the learner's preference and learning styles, learning content has to be provided to the learners. This process is called personalization in the learning process [1]. Personalized learning must pass some control over the learners, providing some input into how they progress through their learning activities. This can be achieved by adapting learning taxonomies in the learning process. Various taxonomies were developed by researchers in the field of Education and Learning since from the year 1956 [2].

This research work adapted Marzano and Kendall (MK) taxonomy to determine the learning style of the learners. MK taxonomy model provides better knowledge about certain fundamental processes in learning, such as emotion, memory, motivation and metacognition. This model also provides greater precision while creating learning objectives, having a more specific map of the types of knowledge that can be acquired and how they are acquired. Due to this greater precision, it is also possible to evaluate more easily [3]. MK taxonomy has six domains from lower order of thinking skills to higher order of thinking skills.

The investigator prepared the questionnaire based on the 2022 augmented verb list of MK taxonomy to find the learning style of the learner and classified the learners into six domains and 22 sub-domains of the considered taxonomy To classify the learning contents into micro contents the same taxonomy has to be utilized.

Text-based learning content was pre-processed to provide good interpretation and usage. It can also reduce the redundancy in the text content. After the content were pre-processed, it has to be classified based on the considered taxonomy. To accomplish the classification of learning contents into the micro-content process, the investigator has chosen seven algorithms from Machine Learning models such as

*Corresponding Author.

- Naïve Bayes,
- Support Vector Machine (SVM)
- K-Nearest Neighbor (KNN)
- Decision Trees
- Random Forest
- Bagging
- XG Boosting

and four algorithms from Deep Learning models such as

- Deep Neural Network (DNN)
- Recurrent Neural Network (RNN)
- Convolutional Neural Network (CNN)
- Recurrent Convolutional Neural Network (RCNN)

have been considered based on the verb list of six domains and sub-domains of MK's taxonomy.

The classified micro contents were stored in file format. And these micro contents can be represented using Property Graph also called a labelled property graph since it contains nodes(entities), edges(relationships) and properties(attributes). This research work creates ontology for MK Taxonomy to provide learning contents based on the weightage. In ontology, individuals are created for each micro-content with the annotation properties of learning content, keywords and file size. Once all the terms are arranged, the data can be retrieved using the SPARQL query. The representation in the property graph is visualized using the OWLGrEd Visualization tool.

Further, the researcher evaluated the performance of each model and compared them according to precision, recall, F1 score and accuracy. Classified micro contents obtained from the classifiers were mapped to the synonymous learners based on the maximum score on the accuracy of the model.

The rest of the paper is systematized as follows. Section II provides an overview of the related works. Section III provides the design and methodology of the proposed method. Section IV expresses evaluation and results and discussion. Section V illustrates the way to represent the learning content organization using a property graph and the method to extract the contents using SPARQL. Section VI discusses mapping the learning micro-content into the corresponding learner according to six domains and 22 sub-domains of the considered taxonomy. Section VII presents the conclusion and Section VIII illustrates the case study of the proposed method.

II. Related Works

A. Action Verbs

To express the noticeable behaviour of the learner the learning objective must start with action verbs. Action verbs were used to monitor the learner and the throughput of the learning objectives. Choosing the right verb for different types of the learner is an art [4]. The verb list of Marzano and Kendall Taxonomy was first published in 2007 and it needed an up-to-date update to include the later verbs. This is because the recent education system utilizes new vocabularies as per the current technology. The existing action verb list in the taxonomy may not be fulfilling to achieve the throughput of learning objectives. Hence it is the need of the hour to augment the verb list of Marzano and Kendall Taxonomy.

Augmentation is achieved by gathering suitable verbs from sixteen existing taxonomies and open domains. Hence the researcher has made an exhaustive search to update the verb list from 95 to 360 verbs as shown in Table I.

TABLE I. Augmentation of Verbs in MK Taxonomy

Domain / Level	Sub-domain/Level	No. of Existing Verbs	No. of Extended Verbs	Total Number of Verb List
Self-System Thinking	Examining Importance	01	15	16
	Examining Efficacy	01	14	15
	Examining Emotions	01	17	18
Metacognition	Examining Motivation	01	14	15
	Specifying Goals	02	13	15

	Recalling	12	12	24
	Recognizing	04	11	15
	Total No. of Verbs	**95**	**265**	**360**

B. Adaptive Learning Path and Contents

A learning path is a progression of activities and concepts to be chosen by the learner to construct their knowledge or skills in a specific area. Traditional learning system provides the same content and learning path to all learners. But the learner's knowledge, circumstance, and preference are different, and their performance and satisfaction may decrease if they have been given the same content and learning path [5]. Presenting learner-centric learning content can ameliorate the effectiveness and performance of the learning process. To achieve this goal the researcher presented a new model as shown in Fig. 1.

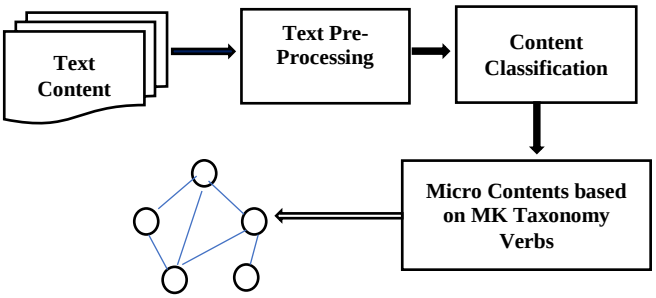

Fig. 1. A Text Content Classification Model.

These micro contents can be represented using Property Graph. Then the micro-content will be retrieved using SPARQL from the property Graph. Further, these micro contents are mapped into the corresponding learners according to six domains and sub-domains of MK taxonomy based on the descending order of the size of the micro contents.

C. Existing Content Classification Approaches

Learning Contents can be in the form of images, text, audio, animations, and video. Text contents can be classified as rule-based, supervised learning-based, and combined classifier-based approaches.

A set of handcrafted rules are utilized in the rule-based approach. In supervised learning text classification approach classification made based on learning past observations. The combined classifier utilized both a machine learning trained base classifier and a rule-based classifier for showing improvement in the throughput [6]. Table II illustrate the various researchers who proposed their model for the classification of questions into Bloom's taxonomy only on a cognitive level. This research work classifies the learning contents into six domains and 22 sub-domains of MK taxonomy.

III. PROPOSED METHOD: DESIGN AND METHODOLOGY

Learning style is the strategy to accommodate receiving and processing the received information which are two phases of learning [17]. The process of recognizing the behaviour of the learner then spontaneously generates a natural learning path, and tailoring the learning contents to an individual learner is known as adaptation in learning which is the prime need for personalized learning [18]. Learning taxonomy can be employed to understand the learning levels of the learners scientifically. Hence this research focused on classifying the learning contents based on a learning taxonomy for better-personalized learning.

This research focused only on text learning contents. These learning contents were preprocessed and classified based on the augmented verb list of MK Taxonomy into micro contents. Then the suitable micro contents were assigned to the corresponding learner to accomplish the personalized teaching-learning process. Fig. 2 depicts the design architecture for text-based content classification. The design contains two main modules a pre-processing module and a Classification module.

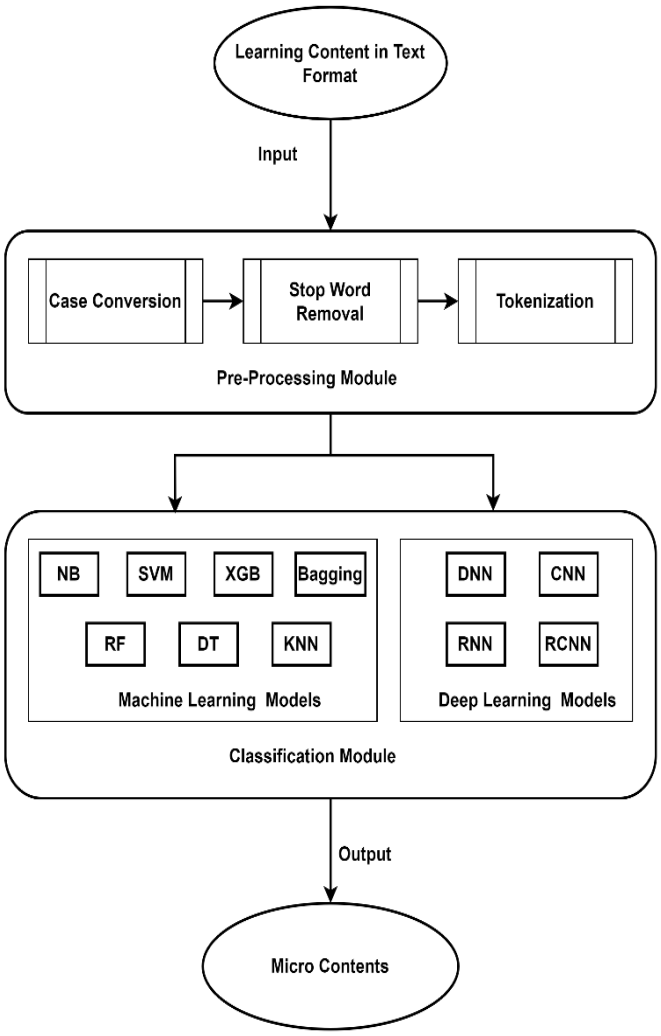

Fig. 2. Design Architecture of Content Classification.

The pre-processing module is the first module of content classification. Text pre-processing is essential for eliminating all the irrelevant objects from the data and making it ready for further processing. This is because raw text data might have insignificant text which makes it difficult to understand and investigate. Hence proper pre-processing must be implemented on raw text data [19]. This research work utilizes three pre-processing techniques as Case Conversion, Stop word removal, and Tokenization.

Case Conversion: Converting all the text content into the lower case is utilized to discard unproductive words [20].

Stop Word Removal: Articles, prepositions, pronouns, and conjunctions in any language are called stop words. "The", "a", "an", "so", and "what" are examples of stop words in English. Removal of such words would help in the size reduction of a dataset and further the training time can also be reduced due to the lesser number of tokens involved in the training [21].

Tokenization: Splitting text contents into smaller units is known as tokenization. The individual units are called tokens. Tokens can be words, phonemes, or maybe full sentences [22]. This research work utilizes sentence tokenization. The learning contents were divided into sentences and considered tokens.

In the e-learning environment, a large volume of learning materials was available in various formats. But it is necessary to provide appropriate learning content to the respective learners according to the six domains and sub-domains of MK taxonomy.

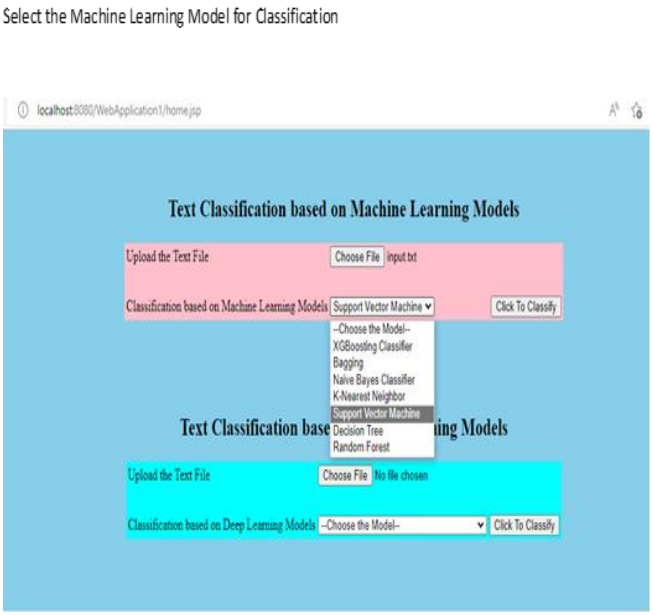

Fig. 3. Text Classification based on Machine Learning Models.

The classification module is the second important module of the design. The preprocessed text contents are classified using seven machine learning models Naive Bayes, SVM, Decision Trees, Random Forest, KNN, Bagging, XG Boosting as shown in Fig. 3, and four deep learning models such as DNN, CNN, RNN, RCNN algorithm based on the action verb list of 2022 augmented verb list of MK Taxonomy as shown in Fig. 4.

This study utilizes NetBeans IDE open-source integrated development environment using Java and libraries such as NLKT, pandas, TensorFlow, NumPy, sklearn, text blob, and seaborn for the classification process.

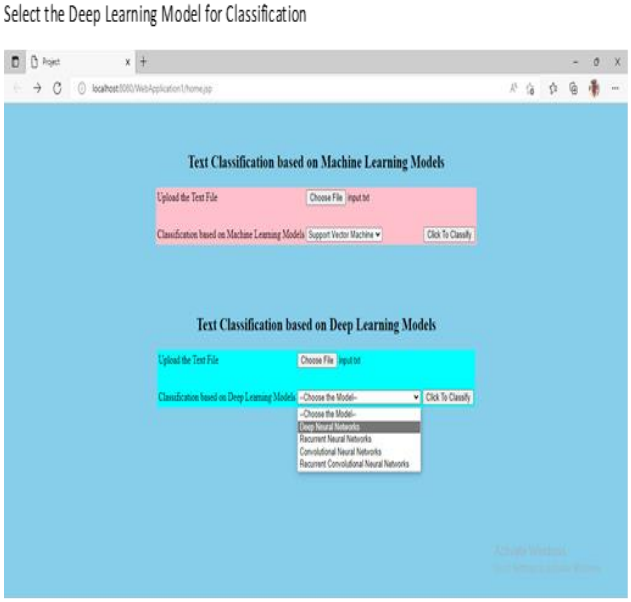

Fig. 4. Text Classification based on Deep Learning Models.

IV. Results and Discussions

For the evaluation process, this study has selected a dataset from the responses received from hundred students for three different learning contents. In a convenient sampling technique analysis on data-set can be carried out either by taking multiple sampling or by repeating the survey. The researcher adapted multiple sampling techniques to produce a reliable result.

A. Evaluation Metrics

Accuracy, precision, recall and f1-score are the measures for evaluation utilized by this study for understanding, measuring relevance and correctness of classification of learning content into micro-contents. Accuracy is used to check the correctness of the model. The exactness of the results is expressed by precision. The completeness of the quality of the results was measured by a recall. F1-score is the weighted average of precision and recall. F1-score is used to evaluate the binary classification system [23].

The evaluation of this study was performed based on the number of keywords classified per domain of MK Taxonomy. A maximum of ten keywords were considered for the classification of learning content into micro-content in each domain of the considered taxonomy.

B. Experiments

The experiments were conducted both on machine learning models and deep learning models and categorized into two.

Experiment 1: Analyze the results of individual Machine learning and deep learning classifier models.

Experiment 2: Results Analysis based on the evaluation metrics.

Experiment 1: Results of Individual Classifier Models

Table III represents the evaluation metric for the XG Boosting classifier in the machine learning model.

TABLE III. EVALUATION METRIC FOR XG BOOSTING CLASSIFIER

Marzano and Kendall Taxonomy Levels	No. of Keywords Classified per level	Accuracy	Precision	Recall	F1-Score
	1	68	0.69	0.7	0.69
Retrieval	2	69	0.7	0.68	0.69
Comprehension	3	71	0.64	0.72	0.68
Analysis	4	78	0.79	0.79	0.79

The evaluation metric for Deep Neural Network is illustrated in Table XI. It is observed that the DNN classifier successfully classified the contents because the accuracy of the classifier is 83% which is high score than the remaining classifiers considered in this study.

The evaluation metrics for CNN and RNN were represented in Tables XII and XIII.

CNN	76	0.76	0.74	0.74
RCNN	78	0.77	0.75	0.76

Table XVII shows the Accuracy measure values obtained for each classifier and arranged in descending order based on the percentage of Accuracy.

According to the results, the SVM classifier performed well toward the correctness of classification and the accuracy is measured as 86 per cent. Further, the F1-score, the weighted

average of precision and recall is also 86% as shown in Table XVIII. The analysis based on accuracy is depicted in Fig. 5.

TABLE XVII. EXPERIMENTAL RESULTS AS PER ACCURACY

Machine Learning and Deep Learning Models	Accuracy %
Support Vector Machine (SVM)	**86**
Naïve Bayes (NB)	83
Deep Neural Networks	83
XG Boosting	80
Random Forest (RF)	79
Recurrent Neural Networks (RNN)	78
Recurrent Convolutional Neural Networks (RCNN)	78
Convolutional Neural Networks (CNN)	76
K-Nearest Neighbor	67
Bagging	65
Decision Tree (DT)	56

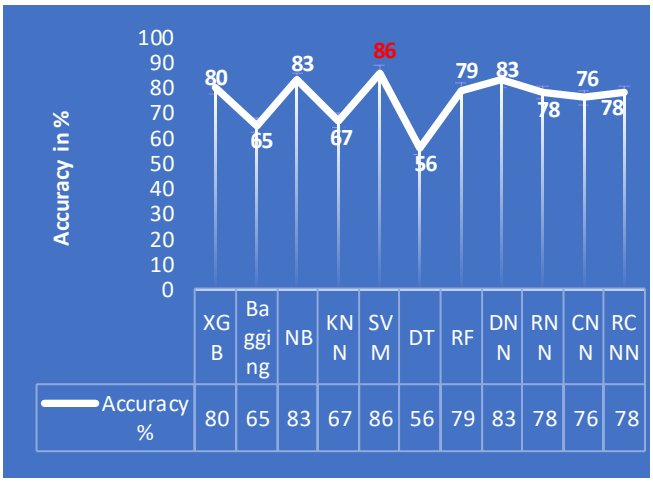

Fig. 5. Analysis based on Accuracy.

TABLE XVIII. EXPERIMENTAL RESULTS AS PER F1-SCORE

Machine Learning and Deep Learning Models	F1-Score
Support Vector Machine (SVM)	0.86
Deep Neural Networks	0.82
Naïve Bayes (NB)	0.8
XG Boosting	0.78
Random Forest (RF)	0.78
Recurrent Neural Networks (RNN)	0.78
Recurrent Convolutional Neural Networks (RCNN)	0.76
Convolutional Neural Networks (CNN)	0.74
K-Nearest Neighbor	0.65
Bagging	0.64
Decision Tree (DT)	0.53

As per the analysis, it is observed that the Naïve Bayes classifier achieved a considerable value in precision. The higher precision indicates that, less false positive measure. It shows the exactness of the classification of learning contents. Table XIX represents the experiment results based on the precision measure.

TABLE XIX. EXPERIMENTAL RESULTS AS PER PRECISION

Machine Learning and Deep Learning Models	Precision
Naïve Bayes (NB)	**0.86**
Support Vector Machine (SVM)	0.85
Deep Neural Networks	0.83
XG Boosting	0.8
Recurrent Neural Networks (RNN)	0.79
Recurrent Convolutional Neural Networks (RCNN)	0.77
Convolutional Neural Networks (CNN)	0.76
Random Forest (RF)	0.75
K-Nearest Neighbour	0.67
Bagging	0.65
Decision Tree (DT)	0.55

The completeness of the quality of the results was measured by a recall. SVM classifier again occupies the top place among other classifiers for the completeness of the classification of learning content according to keywords of MK Taxonomy. Table XX illustrate the experiment results based on recall measure.

TABLE XX. EXPERIMENTAL RESULTS AS PER RECALL

Machine Learning and Deep Learning Models	Recall
Support Vector Machine (SVM)	**0.86**
Deep Neural Networks	0.83
Naïve Bayes (NB)	0.8
Random Forest (RF)	0.8
XG Boosting	0.77
Recurrent Neural Networks (RNN)	0.76
Recurrent Convolutional Neural Networks (RCNN)	0.75
Convolutional Neural Networks (CNN)	0.74
K-Nearest Neighbor	0.64
Bagging	0.63
Decision Tree (DT)	0.57

According to the above analysis, this study concludes that the SVM classifier model provides more accuracy. Hence the micro-contents classified by utilizing the SVM classifier are considered for mapping to the synonymous learner based on the verb list of MK Taxonomy.

V. Learning Content Organization and Retrieval

Information can be represented in the form of tables, charts and graphs to support organizing, analyzing and fetching them when required. Graphs are shines well in representing the connections and relationships among diverse data.

A graph in which the connections between nodes are used to represent the relations along with name and some properties is called Property Graphs. Nodes, labels, relationships, and properties are the components of a property graph. Relationships and connecting nodes of data are capable of storing properties. Appropriate and easy-to-recognize labels are utilized by the property graph for modelling data and its connections. This structured form of data can be easily understood by laymen [24].

This research work utilizes the property graph to represent the classified micro contents according to MK taxonomy. Visualization of six domains and sub-domains and the corresponding micro-content of MK Taxonomy using OWLGrEd is depicted in Fig. 6. OWLGrEd is an editor for OWL to represent graphical notation in an ontology. Ontology becomes common in the fields of artificial intelligence and machine learning, where knowledge plays a vital role. Ontology creates a generic vocabulary which can be shared with researchers and different stack holders. It consists of machine-interoperable definitions of the domain concepts and the relationship between them. It enables the researcher to retrieve data based on knowledge which is known as knowledge-based retrieval. Ontology shares the knowledge to understand the structure of information which can be reused from the domain knowledge. This feature motivates to development of learning content to enhance the learner to gain knowledge of the subject based on their interest and learning ability.

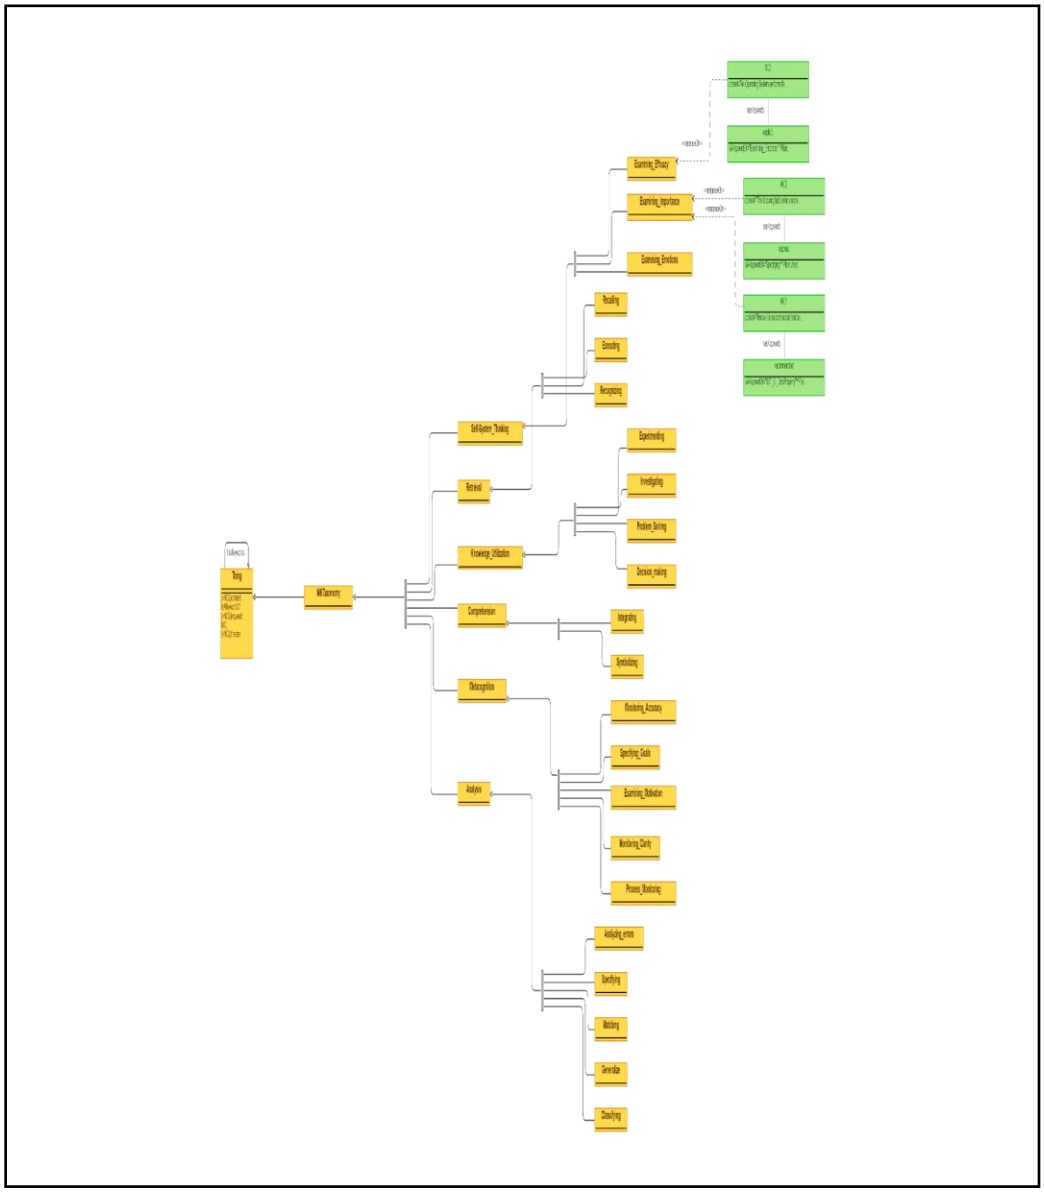

Fig. 6. Visualization of Six Domains and Sub-Domains and the Corresponding Micro-Content of MK Taxonomy using OWL.

Ontology is a collection of classes, properties, instances and axioms. Classes are also known as the concepts of the domain, properties define the relationship between the concepts, instances are the individuals of each class, and axioms denote the restrictions. Ontology can be defined as, a formal explicit specification of a shared conceptualization'. The key terms of a domain are identified and arranged hierarchically and the relationships between the terms are established before developing ontologies.

This research work creates ontology for MK Taxonomy to provide learning contents based on the weightage. The levels and sublevels of the considered taxonomy are arranged as classes hierarchically to frame ontology using the Protégé ontology development tool.

The level/domain of learning is identified through the keywords used in the learning content. Each level of MK taxonomy contains a different set of keywords to group the learning content. The keywords are listed as individuals and the relationship between the classes and keywords is established.

The learning contents were partitioned into micro contents to improve the learning ability of the learner. In ontology, individuals are created for each micro-content with the annotation properties of learning content, keywords and file size.

Micro-content (MC) can be represented as

$$MC_{ij} = \{K_{ij}, C_{ij}, FS(C_{ij})\} \quad (1)$$

Where

i represents domains of MK Taxonomy,

j represents sub-domains of MK Taxonomy,

K is a Keywords,

C is a Learning Content,

FS is the File Size of the learning content.

In this study, MC_{11} represents a micro-content in the sub-domain Recognizing in the domain Retrieval. Each micro-content is defined with these annotation properties to retrieve the content based on the file size given in Fig. 7.

Each micro-content is related to the type of class and object property it belongs. Variable content is created to hold the value of micro-content. Once all the terms are arranged, the data can be retrieved using the SPARQL query.

The SPARQL query to retrieve the micro-content based on the file size in descending order is given below and the result is shown in Fig. 8.

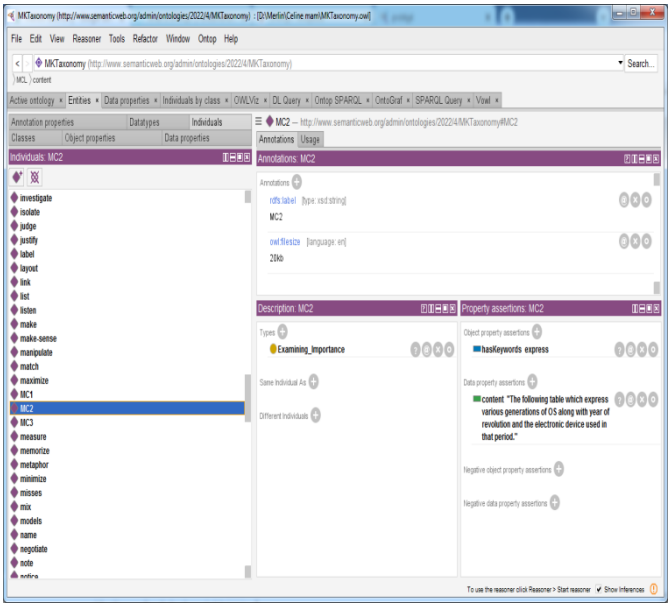

Fig. 7. Creation of Individuals for Micro-contents.

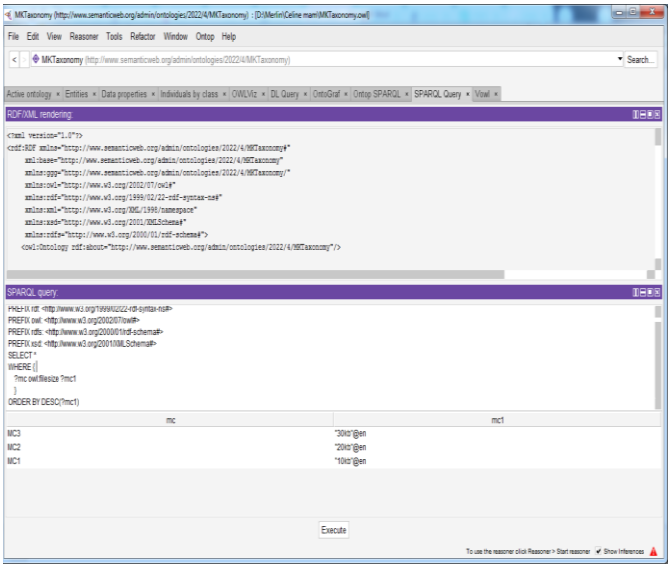

Fig. 8. Retrieval of the Micro-Contents using SPARQL.

SPARQL query to Retrieve the micro-content

```

VI. Mapping the Microlearning Content to the Synonymous Learners

The classified learning contents which are retrieved from the graph were mapped to the corresponding leaner to achieve personalization in the learning process. Each micro-content with learning content, keywords and file size defined with annotation properties was used to retrieve the content. Further, these retrieved micro-contents were arranged in descending order based on the size of the files. Based on the score obtained by the learner, they were classified by the researcher. The micro-content classified based on the keyword under the sub-domain Recognize in domain Retrieval is MC_{11}.

This study proposed a novel method to perform the mapping process. The learners' characteristics were obtained by the response received from them through the tool questionnaire according to the 2022 verb list of MK Taxonomy. Questions were rationalized to 50 according to six levels of MK Taxonomy as 8, 8, 10, 8, 8, 8 which can be considered as weightage (w) for each domain as shown in Fig. 9. Eight questions in D1 in turn sub-dived into 3, 3 and 2.

Dataset has been constructed from the response fetched from the hundred learners. The correct response was represented as 1 and the incorrect response was represented as 0. Further, the total score against each domain was calculated as illustrated in Table XXI. This provides a way to quantify each type of learning style in the learner.

Based on the score (SC) obtained by the learner out of each domain and sub-domains of MK Taxonomy, the number of micro-contents (NMC) retrieved from a graph as per each domain, and file size are the parameters for providing micro contents to the synonymous learner. Equation (2) is utilized for mapping the micro-contents to the corresponding learner.

$$K_{ij} = SC_{ij} / w(SD_{ij}) * NMC_{ij} \quad (2)$$

Where i represent six domains of MK Taxonomy,

j represents sub-domains of MK Taxonomy,

K - Number of micro-contents to be provided to the learner,

SC - Score obtained by the learner,

SD – Sub-Domains of MK Taxonomy,

w – Weightage assigned to SDs as shown in Fig. 9,

NMC – Number of Micro-Contents.

The Pseudo code for the mapping process is illustrated below.

1. Start the process.
2. If (i = 1) then j = 1 to 3
3. {Calculate NMCs for D1
4. $K_{ij} = SC_{ij} / w(SD_{ij}) * NMC_{ij}$
5. }
6. If (i = 2) then j = 1 to 2
7. {Calculate NMCs for D2
8. $K_{ij} = SC_{ij} / w(SD_{ij}) * NMC_{ij}$
9. }
10. If (i = 3) then j = 1 to 5
11. {Calculate NMCs for D3
12. $K_{ij} = SC_{ij} / w(SD_{ij}) * NMC_{ij}$
13. }
14. If (i = 4) then j = 1 to 4
15. { Calculate NMCs for D4
16. $K_{ij} = SC_{ij} / w(SD_{ij}) * NMC_{ij}$
17. }
18. If (i = 5) then j = 1 to 5
19. { Calculate NMCs for D5
20. $K_{ij} = SC_{ij} / w(SD_{ij}) * NMC_{ij}$
21. }
22. If (i = 6) then j = 1 to 3
23. { Calculate N MCs for D6
24. }
25. Stop the process.

The MCs were arranged in descending order based on the file size. Hence as per the above calculation, the MCs were mapped to the synonymous learners to achieve personalization in the learning process according to MK Taxonomy.

VII. Conclusion

The main objective of this paper is to specifically classify the learning contents based on the specific characteristics of the learner and according to the domains as well as the subdomains of the considered taxonomy. The learning contents in text format were represented in a property graph and retrieval of the same is achieved to fulfil the personalization process in the learner-centric environment. The learners were classified according to MK Taxonomy. Hence the classified learning contents were assigned to the synonymous learners to achieve personalization in the learning process.

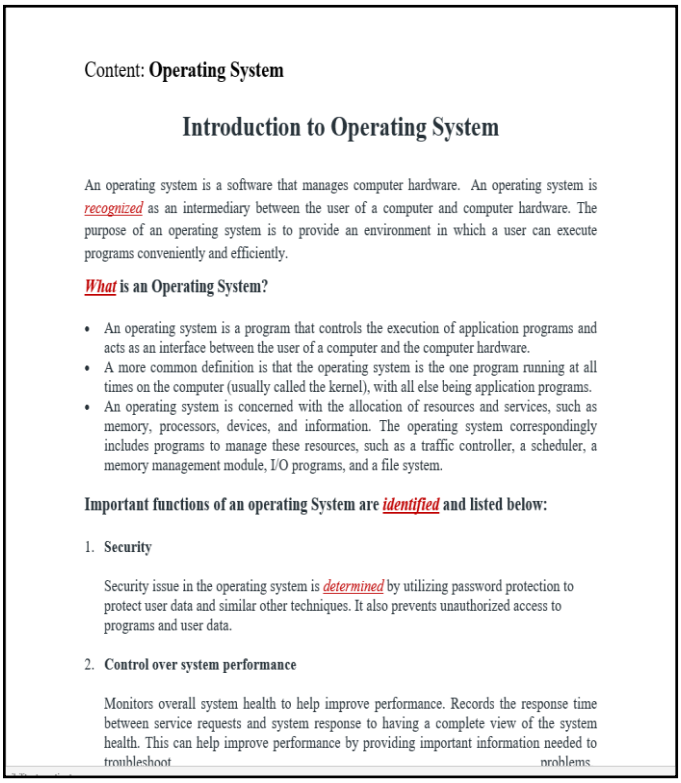
Many researchers classified the learners based on Bloom's Taxonomy's cognitive level. But this research work proposed a novel contribution towards the classification of learning contents into micro contents according to the six domains and 22 sub-domains of MK Taxonomy and represents them using a property graph. Further, these micro contents were retrieved from the graph and mapped to the corresponding learners who were classified according to MK Taxonomy. Hence the learner-centric learning contents were provided to the learners for better learning outcomes.

VIII. Case Study

Learning Contents classification can be carried out by the following steps. Fig. 9 shows the Screenshot of the learning content.

Input: Subject: Operating Systems-Tutor defined Text Contents.

An Operating System is recognized as an intermediate between the user of the computer and computer hardware. Important functions of an operating system are identified and listed below.



Content: **Operating System**

Introduction to Operating System

An operating system is a software that manages computer hardware. An operating system is *recognized* as an intermediary between the user of a computer and computer hardware. The purpose of an operating system is to provide an environment in which a user can execute programs conveniently and efficiently.

***What* is an Operating System?**

- An operating system is a program that controls the execution of application programs and acts as an interface between the user of a computer and the computer hardware.
- A more common definition is that the operating system is the one program running at all times on the computer (usually called the kernel), with all else being application programs.
- An operating system is concerned with the allocation of resources and services, such as memory, processors, devices, and information. The operating system correspondingly includes programs to manage these resources, such as a traffic controller, a scheduler, a memory management module, I/O programs, and a file system.

Important functions of an operating System are *identified* and listed below:

1. **Security**

   Security issue in the operating system is *determined* by utilizing password protection to protect user data and similar other techniques. It also prevents unauthorized access to programs and user data.

2. **Control over system performance**

   Monitors overall system health to help improve performance. Records the response time between service requests and system response to having a complete view of the system health. This can help improve performance by providing important information needed to troubleshoot problems

Fig. 9. Screenshot of Learning Contents.

Step 1: Text content Pre-Processing

Step 1.1: Case Conversion – convert into a lower case

an operating system is recognized as an intermediate between the user of the computer and computer hardware. important functions of an operating system are identified and listed below.

Step1.2: Stop word Removal

the operating system recognized intermediate user computer hardware. Important function operating system identifies list.

Step 1.3: Tokenization (Sentence Tokenization)

Token 1: operating system recognizes intermediate user computer hardware

Token 2: important function operating system identify the list.

Step 2: Verbs are Extracted from the tokens.

Verb list: recognize, identify, list

Step 3: Classification based on the verb list according to MK Taxonomy domains and sub-domains using seven ML models and four DL models as shown in Fig. 2. As per the performance metrics, the SVM model is used to classify this study. Keywords or the action verbs in MK Taxonomy were utilized for the classification of tokens into micro contents.

Action verbs 'recognize' and 'identify' the sub-domain Recognizing in domain Retrieval. Hence the corresponding MCs were assigned to that sub-domain.

Output:

MC 1: operating system recognizes intermediary user computer hardware.

MC 2: Important functions operating System identify list.

Step 4: These MCs were represented in the property graph as illustrated in Fig. 8 and retrieved using SPARQL.

Step 5: Mapping the MCs to the synonymous learners.

The total number of MCs in Sub-domain1 Recognizing in domain Retrieval were 02. These two MCs were to be mapped to the learners who were already classified under the same sub-domain as shown in Fig. 9 and the score obtained by the learners as shown in Table XXI were applied in the equation (2).

The score obtained by learner 1 in SD1 (SC) = 02

$$NMC = 02$$

$w(SD_{11}) = 03$

By utilizing equation (2) $K_{11} = 02/03*02 = 1.33 \approx 02$

Result:

Hence two MCs were provided to the learner in Sub-domain1 Recognizing in domain Retrieval according to MK Taxonomy in a personalized manner.

TABLE XXI. SCORE OBTAINED IN LEVEL 1 (RETRIEVAL) FOR FIFTEEN LEARNERS

AUTHORS' PROFILE

First Author: Mrs S. Celine is currently working as an Assistant Professor in the Department of Computer Science, Government of Arts College for Men, Krishnagiri, Tamil Nadu. She has published four papers in International Journals. Her area of research is e-Learning using Deep Learning.

Second Author: Dr M. Maria Dominic is currently working as an Assistant Professor in Computer Science, at Sacred Heart College. He has published one book and more than 30 Research Articles in International Journals. His area of interest is AI, Machine Learning, and Deep Learning.

Third Author: Dr. F. Sagayaraj Francis is an Associate Professor in the Department of Computer Science and Engineering, Pondicherry Engineering College, Pondicherry, India. He has published more than 65 Research Articles in International Journals. He specializes in Data Management, Data Modeling, Information Systems and e-Learning.

Fourth Author: Dr M. Savitha Devi is currently working as an Assistant Professor and Head, Department of Computer Science, Periyar University Constituent College of Arts & Science, Harur, Tamil Nadu. She has published 30 research articles in various National and International Journals. She has published 2 books. Her area of research is Network Security.

The Hybrid Combinatorial Design-based Session Key Distribution Method for IoT Networks

***Abstract*—Internet of Things (IoT) is currently being used in a range of applications as cutting-edge technology. IoT is a technological platform that connects the physical and digital worlds, allowing us to use things remotely. Various sensor-connected nodes serve as objects that communicate with one another over the internet. Hence security-related problems are more likely to arise in IoT networks. However, due to resource constraints such as power and memory capacity, complex security algorithms cannot be implemented in IoT networks. One of the security measures for IoT networks is to implement the lightweight key distribution algorithm. The lightweight key management process is essential for IoT networks to share the key securely. We presented the new key-distribution approach based on the hybrid combinatorial design that implements lightweight algorithms and describes the analysis functions. The comparison to existing hybrid combinatorial works shows better connectivity, resilience, and scalability.**

***Keywords*—Key distribution; hybrid combinatorial design; IoT networks; resource constraint nodes; symmetric key generation**

I. INTRODUCTION

The Internet of Things (IoT) is a system that allows multiple sensor nodes and wireless nodes to communicate without the need for human involvement. The term "things" in the Internet of Things refers to physical objects such as sensor nodes that monitor or access data from other networked devices. In the research aspect, IoT has been becoming a much-desired area. The security of each node's data is the primary issue in today's rapidly growing IoT networks.The security services are like confidentiality, authentication, and integrity of the data. Cryptographic algorithms and keys are required for encryption, and effective key management is essential for this process to work appropriately. Ineffective key management can make even the strong algorithms useless for any type of network. IoT networks also need to have strong key management procedures.

Even though key management is essential for IoT networks, using conventional key management methods demands more memory. Due to resource-constrained nodes' memory and battery limits, the IoT network requires a lightweight solution.Thus, we discussed about lightweight approaches that are already in use for key management.Basic methods to generate and distribute the keys to nodes in the network are symmetric keys and public keys. Even though the public key approach is widely used for key distribution, it could not be used often in IoT networks since it requires more memory and processing resources to run the code, and in many applications, these approaches are also costly. Hence, the Majority of IoT networks are using symmetric key distribution methods, which require only one key to share as mentioned by Alagheband et al. [1].

There are two methods for sharing keys amongst connected nodes: decentralized and centralized approaches. In the decentralized process, Nodes in the network can share their secret keys directly with one another to provide secure communication. Every node should hold private keys that are unique for communicating with each node in the network. Those private keys are exclusive to committed pairs only. However, as IoT networks grow, devices will be unable to keep as many secret keys in memory due to the restricted memory space of IoT nodes.

Another option for resolving this problem is to use a trustworthy centralized device to distribute private keys to all nodes in the network. Key Distribution Center (KDC) is an example of providing centralized service. Kouicem et al. [2] presented that the KDC is a mechanism that distributes keys to all the users in a network sharing sensitive or confidential information. When two nodes in a network need a connection, they request the KDC to generate a unique session key that end users can use as a secret key for communication. So, the nodes can share the data with other nodes connected to the network using Key Predistributions or KDC.

As a result, using a KDC with symmetric key distribution is the best way to distribute the key to all nodes. One of the best symmetric key generation approaches is combinatorial block designs.It uses a simple calculation to compute the blocks for different nodes. Many Authors have been working on this for determining the keys for multiple nodes.In the introduction, we covered the fundamental ideas of combinatorial block design, how the authors expanded these ideas to implement keys for every node, and a brief discussion on our approach.

Stinson et al.[3] used Balanced Incomplete Block Design (BIBD) which is one of the combinatorial designs to generate the blocks for sharing the keys securely with other nodes. When it is impossible to incorporate all treatments or factor combinations for every block, then BIBD is utilized here.

Assume there are b blocks, each with k keys, and v total number keys can be used, each key replicated r times. Thus,

$$br = vk$$

And also assume that the blocks (b) are just partially complete by confining with the following conditions.

1) $k < v$

2) In any block, the same key doesn't appear more than once.

$\lambda_{ij:}$ i and j are two different keys from the 'v', it gives the occurrences among the blocks.

Example 1: $v = 6, b = 4, k = 3, r = 2$

v={1,2,3,4,5,6}, b=no.of blocks, k=keys in each block,r= each key repitations in blocks.

So the Blocks are

b1:{1,2,3} ,b2:{1,4,5}, b3:{2,4,6}, b4:{3,5,6}

λ_{14}=1, λ_{46}=0 (It gives the pair occurrences in blocks.

In a Balanced Incomplete Block Design: $\lambda(v-1) = b(k-1)$.

Symmetric BIBD:

A BIBD is said to be Symmetric BIBD when $b = v; k = , r, \lambda = 1$

Example 2:

Consider (v,b,k,r,λ)=(7,7,3,3,1) because v=b;k=r

V(keys)={1,2,3,4,5,6,7}

b1:{1,2,3}

b2:{1,4,5}

b3:{1,6,7}

b4:{2,4,6}

b5:{2,5,7}

b6:{3,4,7}

b7:{3,5,6}

Another combinatorial method is the finite projection plane. A Finite Projection plane consists of P points and set of subsets of P called lines. A prime integer q (>=2) and that has four properties.

1) Every line should be having exactly q+1 points
2) Every point occurs on exactly q+1 lines
3) Exactly $q^2 + q + 1$ points used
4) Exactly $q^2 + q + 1$ lines used; then that can be called Symmetric Design with $(q^2 + q + 1, q + 1, 1)$ given by Stinson et al. [4].

Already existing key predistribution methods are mainly followed by three procedures.

1) Probabilistic: Keys are chosen randomly from the pool and assigned to the nodes.
2) Deterministic: Based on pre-defined procedures select the keys and assign them to the nodes.
3) Hybrid Approach: The combination of both approaches is mentioned above.

The KDC implements key predistribution methods to get the keys for all nodes. The pre-key distribution can be acquired based on the key-Matrix approach by Chien et al. [5], So it helped share the key easily. Other pre-key distribution approaches are Blundo et al. [6] and Liu et al. [7], In these, Polynomial-based key pre-distribution was proposed for group key establishment. In Chan et al. [8], Two nodes having q keys should be linked, and the hash value of the q keys would be used for key verification that improved resilience from the attackers. Qian and Sun [9] presented the drawback of the above approach is that resilience increased but wouldn't guarantee to get the common key between two devices. Li et al. [10] was provided threshold value for random key pre-distribution in which each should communicate with its neighbor node with the same key. Catakoglu et al. [11] increased the resiliency of the previous system by adding numerous key rings.

Camtepe andYener [12], first time they presented the symmetric balanced incomplete design(SBIBD) for generating the keys for nodes in the network, however, the disadvantage is the scalability of the network with nodes. In comparison to prior techniques, Lee et al. [13] exhibited improved resilience.Ruj et al. [14] generated the pre-key distribution method using the partial BIBD technique, however, it did not share the keys with every node in the network. Ruj et al. [15], the same authors proposed a combinatorial strategy for improving BIBD and PBIBD resilience. Bechkit et al. [16] employed a new pre-key distribution design, a combinatorial-based way to determine the keys, which improved the scalability and connectivity.Bahrami et al. [17] presented great scalability of the network nodes by using residual key pre-distribution design for key pool generation.

Camtepe et al. [18] presented a combinatorial method for generating keys for network nodes that are connected. And they used SBIBD and GeneralizedQuadrangle (QD), which are the basictwo deterministic key pre-distribution designs. Complete connectivity between network nodes was the improvement of this algorithm. Also provided is the hybrid pre-key distribution method.Chakrabarti et al. [19] and Kavitha et al. [20] enhanced the scalability and connectivity of the previous approach.Dargahi et al. [21] enhanced the hybrid method to get the keys for almost all network nodes, but didn't get the exact number of keys to all network nodes. When compared to prior hybrid techniques, Akhbarifar et al. [22] used a hybrid strategy and provided improved connectivity and resilience. However, the unique keys were not generated for nodes in the network.

Despite the fact that combinatorial designs have been addressed extensively, not all linked network nodes are given the session keys. Every IoT network needs to be able to enable the construction of many nodes and should distribute a session and a unique key for every node.By supplying unique and dynamic keys for each node, we suggested a hybrid combinatorial method that resolves the problems discussed earlier. As a result, our system now supports network scalability.

Our entire method is detailed in a total of six sections:

- Secton 1 gives the introduction part of basic methods for Combinatorial block designs.
- Section 2 explains the existing hybrid approaches and their drawbacks in detail.
- Section 3 is our actual work to be implemented to generate the unique and session keys for every node.
- Section 4 gives the analysis of scalability, connectivity,resilience, and Memory utilization. And also provides the results analysis with graphs.
- Section 5 is a complete discussion.
- Section 6 is a conclusion.

II. Related Works on Hybrid Combinatorial Designs

Camtepe and Yener [12] proposed a first-time pre-key distribution strategy based on the SBIBD technique. It was the basic combinatorial design to get the keys for network nodes.

Assume there are b blocks, each with k keys, and v total number keys can be used, each key replicated r times.The following criteria were used to allocate keys to the nodes in the proposed algorithm.

$q^2 + q + 1 = length\ of\ keypool(v); here\ q\ is\ prime$

$q^2 + q + 1 = number\ blocks(b); here\ q\ is\ prime$

$q + 1 =\ keys\ assigned\ to\ the\ each\ block(k)$

$q + 1 =\ In\ the\ blocks, every\ key\ is\ repeated\ (r)$

The fundamental advantage of this approach is that it identifies the unique keys among the b nodes. This technique had good connectivity and resilience, but it lacks scalability. However, this strategy has the disadvantage of limiting the total number of blocks that meet the before-mentioned criteria. As a result, it was completely reliant on the q value. This approach could not identify the keys for all n nodes in the network; where N is the total number of network nodes, and that was not meet the above condition.Although this method cannot be applied to all of the network's nodes, it accurately delivers the keys for the limited number of nodes.

In Camtepe et al. [18] (HSYM), the previous approach was upgraded by including scalability and resilience properties. It was implemented using a hybrid technique that enhanced the number of nodes in the IoT networks. It could find the b blocks by using SBIBD and this method found the complimentary design for all symmetric blocks then chose q+1 keys and assigns them to the remaining nodes.The author's implementation is described in Algorithm1.The fact that more nodes have a chance of acquiring the same key reduces the probability of obtaining a key share, which is a drawback of this technique.

Algorithm 1: Hybrid Design of HSYM

Input(s): N (Total Number of nodes)
Output(s): K (Block size)
Begin

1. Find largest prime power q such that $k \leq K$;
2. Generate base Symmetric
   - v objects $P = \{a_1, a_2, a_3, \ldots . a_v\}$
   - b blocks B= $\{B_1, B_2, B_3, \ldots . B_b\}$of size k;
3. Generate Complementary Design of the base design: Blocks $\bar{B} = \{\bar{B}_1, \bar{B}_2, \bar{B}_3, \ldots . , \bar{B}_b\}$where $\bar{B}_i = P - B_i$ and $|\bar{B}_i| = v - kfor\ 1 \leq i \leq b$;
4. Generate $N - b$ hybrid blocks $H = \{\bar{H}_1, \bar{H}_2, \bar{H}_3, \ldots . , \bar{H}_{N-b}\}$ of size *k*. For *i*th block $H_i$where $1 \leq i \leq N - b$:
   - Randomly select a block in $\bar{B}$, say $\bar{B}_j$
   - Randomly select a *k*-subset γ of the block B_j where $\gamma \notin H$,
   - Let $H_i = \gamma$ and $H = H \cup H_i$,
   - Use the variable $s_i$to hold index of the block $\bar{B}_j$from which the block $H_i$is obtained;
5. Blocks of the Hybrid Design are $B\ \cup H \Rightarrow K$

End

Dargahi et al. [21] (MHS) proposed an enhancement version of the above hybrid approach. For b blocks, they also used the same BIBD method. For the remaining nodes in IoT networks, they used a different key pool. N-b times, they have chosen q+1 keys from the new key pool that were assigned to additional N-b nodes.The generation of the blocks is described in Algorithm 2.The authors have used more space in the node memory to store the extra keys and new key pool in the nodes, but we all know, that IoT devices have limited capacity.

Algorithm 2: Hybrid Design of MHS

Input(s): N (Total Number of nodes)
Output(s): M Blocks
Begin

1. Find the largest prime number q Where $q^2 + q + 1 < N$
2. Generate the first symmetric $(q^2 + q + 1, q + 1, 1)$-BIBD with the following key pool:
   - $KP_1 = \{K_1, K_2, \ldots . , K_V\}$Containing *v* objects,
3. Generate *b* blocks $B = \{B_1, B_2, \ldots . , B_b\}$ from KP_1;
4. Choose a number *d* where $0 < d \leq q^2 + q + 1$;
5. Generate the second symmetric $(q^2 + q + 1, q + 1, 1)$-BIBD with the following key pool:
   - $KP_2 = \{K'_1, K'_2, K'_3 \ldots . , K'_V\}$ Containing *v* objects
   - KP_2 is generated in a way that *d* keys differ from KP_1 and other keys are the same,
6. Generate *b* blocks $M = \{M_1, M_2, \ldots . , M_b\}$ from KP_2;
7. Assign *b* blocks from *B* to *b* nodes $(b < N)$;
8. Choose$(N - b)$blocks from *M* in a random manner and assign them to $N - b$ remaining nodes

End

Akhbarifar et al. [22] (MHSYM) proposed a new enhancement of the previous proposes. They identified two random blocks in b, combined their blocks data, then extracted the q+1 keys from it. Then allocated each of the remaining nodes with a random selection of q+1 keys.Algorithm 3's detailed explanation of the entire process. The key share probability was increased as compared to Camptepe [18] method, but there is no guarantee that at least one common key would be allocated among the blocks. The complete procedure explained in Algorithm 3.

Algorithm 3: Hybrid Design of MHSYM

Input(s): N (Total Number of nodes)

Output(s): M Blocks

Begin

1. Find the largest prime number q
2. Where $q^2 + q + 1 < N$
3. Generate the first symmetric $(q^2 + q + 1, q + 1,1)$-BIBD with the following key pool:
   - $KP_1 = \{K_1, K_2, \ldots, K_V\}$containing *v* objects,
4. Generate b blocks $B = \{B_1, B_2, \ldots, B_b\}$ from $KP_1$and assign them to *b* nodes;
5. Choose two blocks among *b* blocks randomly;
6. Merging two blocks to construct new key-pool *M*;
7. Select $(N - b)$ blocks among $q + 1$ subsets of M and assign them to $N - b$ remaining nodes.

End

As mentioned above, the Procedures to apply the hybrid combinatorial design won't generate keys for all blocks of nodes.Our method uses a limited memory source to provide session keys for all blocks of nodes.The proposed work covers related algorithms and also provides examples for key generation.

III. Our Proposed Work

The Symmetric BIBD (SBIBD) allows multiple users in the same network to share the same keys without causing any problems. The IoT Architecture has not been supporting for huge capacity of memory inbuilt and high processing devices. Because of the above-mentioned reasons, the IoT node connected to the network is unable to remember all of the keys required for communication with other nodes in the network.

The SBIBD allows for the storage of the smallest amount of keys on the devices themselves, however, scalability is an issue here. If the network grows larger, nodes will be unable to store numerous keys in the tiny size memory. So, we are providing a new solution to this problem, a centralized system called Dynamic Key Generation and Distribution Center (DGDC). And the whole design that we suggest is depicted in Fig. 1.

In the context of IoT, we describe the symmetric key authentication and key management system based on BIBD. In this paper, we present a technique for exchanging the secret key that uses for providing the different security levels to assure scalability and confidentiality. We propose a technique for key agreement between two IoT devices that have never been in contact before, based on trusting the centralized server or using a proxy-based approach.

Fig. 1, describes the overall architecture that we have implemented to generate the session key and distribute it to the host which is requestedto the centralized server. The diagram itself is made up of three different blocks: DGDC, Initiate System (A) which starts to set up the communication connection, and Destination System (B) which accepts data from User (A) after receiving the Session key from DGDC.

The connected systems first exchanged their symmetric key to communicate with the centralized block, which is DGDC. Before implementing this architecture, the symmetric keys (secret keys for authentication) should be shared with DGDC so that other systems already connected to the network can communicate with it. Hence, this step is really important for our design because it is also providing authentication.Key generation and Key Distribution are the two main components of DGDC's actual work.

For Generating the keys, DGDC always works on the below-mentioned algorithms to implement the symmetric keys for all connected nodes. The previous algorithms mentioned in the related works are not implementing unique keys for all connected nodes.It is a pioneering building component for dynamic key implementation and distribution, increasing data security by often changing node keys.

In the DGDC, Data generation block contains all of the modules that have been proposed to create dynamic and unique keys for data transactions carried out by connected nodes. The modules are:

1) SBIBD,

2) Building the remaining nodes,

3) Computing the unique keys for each node in the network using a hybrid combinatorial design approach,

4) Reconstructing the outgoing blocks of nodes to protect the keys that have been compromised.

To create a complete table with unique keys for every node, DGDC executes each module in the order that they are presented.Once the table has been built, DGDC verifies requests using secret keys before sending the session key to the requested nodes.

Here, the architecture also proposed by us gives more security levels to the data because the session keys are not known by each individual connected system in the network. If an attacker compromises one of the systems, the attackers are unable to identify the session keys from the compromised system as it never stores any keys in their systems.

In particular, eight steps must be completed to observe the workings of our model. They are mentioned below in the Fig. 1. The model can generate and distribute the session key for communication between the request systems based on the mentioned processes. One of the most essential features of the proposed approach is the ability to dynamically alter the session keys of each system.

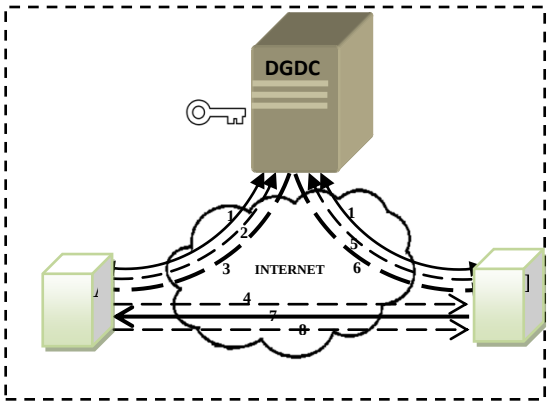

Fig. 1. Proposed Architecture.

1) Both users A and B identified their symmetric keys and exchanged them with DGDC for authentication purposes.

2) User A requests a session key from DGDC to communicate with User B.

3) By using a symmetric key, DGDC completes the authentication process and obtains the common key of both parties. And sends it to User A.

4) Using the Session key provided by the DGDC, User A transfers the data to User B.

5) Using its symmetric key, User B requests the session key from DGDC.

6) Like Step3, DGDC finishes its authentication process and provides the session key (which is already shared with A) to B.

7) User B uses the session key to decrypt the data provided by User A and provides the acknowledgment in an encrypted format.

8) The communication between User A and User B begins with the use of the same session key.

In the Proposed Work, The main required module is DGDC, it is generating the session keys dynamically and distributes them to the systems. First, we have to complete the code for generating the SBIBD with restricted blocks provided in Algorithm 4. The session keys for all nodes in the network could not be generated through the SBIBD procedure.

Where N is the number of network nodes used in communication. Calculate N>=q2+q+1, where q is the largest prime integer that may be used to solve the preceding equation; the result is v and b. Here, The 'N' and the 'v ' may not be the same. That is, the SBIBD algorithm was unable to determinethe keys for each node in the N network. SBIBD can be generated with v blocks and q+1 keys, which are represented by the k in each block.

The input for Algorithm 4 is N which is the number of nodes that need to be connected to the network, where v, k, and r are generated by the above Algorithm 4. The maximum number of nodes (blocks) in a network for generating session keys in SBIBD is represented by b. However, Algorithm 4 provides limited session keys for a few numbers of network nodes, therefore we are improvising by using other Algorithms 5, 6, and 7.

Algorithm 4: Design of SBIBD

Input(s): N (Total Number of nodes)
Output(s): B
Begin

1. Choose the maximum prime number q to compute the below equation
$$q^2 + q + 1 \leq N$$
2. Using the previous equation, generate inputs for producing the blocks.
$v = q^2 + q + 1$; where v is the size of the key pool
$b = q^2 + q + 1$; b is the number of blocks
$k = q + 1$; k is the number of keys allotted to each block
$\gamma = 1$; γ denotes, In SBIBD, each node has only one shared key to communicate to other nodes in the B.
3. Construct blocks B using Symmetric BIBD design
$$B = SBIBD(v, b, k, \gamma).$$
Then assign the blocks in $B = \{B_1, B_2, .., B_b\}$

End

Algorithm 5 completes the generation of remaining blocks of the network nodes. Algorithm4 computes the ' B ' number of blocks, while Algorithm5 will handle the rest.c=N-b; c is the number of blocks to be calculated, where N network nodes and b have already been given in Algorithm 4. Algorithm 5 determines which of the c number blocks should be assigned to the network's other nodes. In Algorithm 5, the R represents the remaining nodes of the IoT network.Select the keys from the key pool, and then place them as keys to generate the blocks by the requirements of Algorithm 5.

Algorithm 5: Design for remaining nodes(R)

Input(s): c,v,k
Output(s): R
Begin

1. Construct the (v,N-b,k,r,γ); here v is the key pool, N-b blocks need to construct, k keys for each node, r repetitions among the blocks, γ = 2 or more; means each block in N-b should share two or more keys among the q+1 keys.
2. As a result, each key from the key pool can only be used at most 3q times in the construction of N-b blocks.
3. Then return R blocks from this Algorithm
$$R = \{B_{N-b,}B_{N-b+1,} \dots, B_N\}$$

End

The final blocks are represented by $H = B \cup R$ which is input for Algorithm 6 and also computed the key pair values for all resource-constrained nodes.

Algorithm 6 is used to generate the v number of keys, however, the remaining keys were not able to be generated directly. The remaining c keys are found and perform an XOR operation on the common keys that existed between the two nodes. At the end of Algorithm6, be able to find the unique session keys between each node in the network. Here, Algorithm6 uses 32 bit (8 bytes) key for computation as the IoT devices could be handled easily with this length.

Algorithm 6: Hybrid Combinatorial Design with Unique keys

Input(s): N,v,b,K,B

Output(s): H(Total no.of blocks), x (The Session Key)

Begin

1. Execute Algorithm1 to get the q^2+q+1 Symmetric block within N blocks.

   $v = q^2 + q + 1$ (Number of keys used)

   $$Key = \{K_1, K_2, .., K_v\}$$

   $b = q^2 + q + 1$ (Number of nodes generated with the length of k by Algorithm1)

   $$B = \{B_1, B_2, .., B_b\}$$

2. Generate N-b blocks using Algorithm2.

   $$R = \{B_{N-b}, B_{N-b+1}, \dots, B_N\}$$

   $$Key = \{K_1, K_2, .., K_v\}$$

3. Hybrid Design's Blocks are $H = \mathrm{B} \cup R$
4. Choose any two blocks from N (BB, BR, and RR) blocks randomly and determine the common key(s) of these blocks that should store in *l*.

   Example: Here we have taken two blocks B_1, B_{N-b}.

   $$l = B_1 \cap B_{N-b}$$

   Get the common keys that are presented in both blocks.
5. (i) If the length of the *l* is one then directly take the key as the secret key for both blocks.

   $$if\ length(l) == 1\ ;$$

   $$then\ x = l\ and\ x\ as\ a\ secretkey$$

   (ii) If the length of the *l* is above one, take the last two keys from blocks and do the XOR operation among those keys.

   $$if length(l) \geq 2$$

   $$then x = l[length - 1] \oplus l[length - 2]$$

   $$x\ is\ a\ secretkey$$

   (iii) If the length of the *l* is null, select the first key-value from each block and calculate XOR between those keys. For example

   $$if\ length(l) == 0$$

   $$then\ x = first\ key(B_1) \oplus first\ key(B_{N-b})$$
6. *x* is the final secret key that is given by the DGDC.

End

The blocks for nodes are generated by DGDC up through Algorithm 6, and those key values in blocks aresent to nodes during transaction time. Once generated, they can be used every time, so there are chances of keys being compromised. Thus, We have also implemented an Algorithm 7 to get a solution for compromised keys by an attacker. Algorithm 7 illustrates how we can avoid attacks by utilizing a technique that shuffles the keys in the blocks in a certain amount of time.

Algorithm 7: Reconstruction of H

Input(s): H (Total blocks with keys)

Output(s): H blocks

Begin

1. For every, Threshold time(T) changes the key values of nodes
2. Shuffle all blocks of the H and assign the values of the block to nodes

   $$H = shuffle(H) \text{ for } \Delta T$$
3. And shuffle each block key value of the H to get the session key from Algorithm3.

   $$Apply\ \forall Bin(H);\ like$$

   $$H(B_i) = shuffle(H(B_i)) \text{ for } \Delta T$$

End

The complete workflow illustrates the DGDCs in Fig. 2.

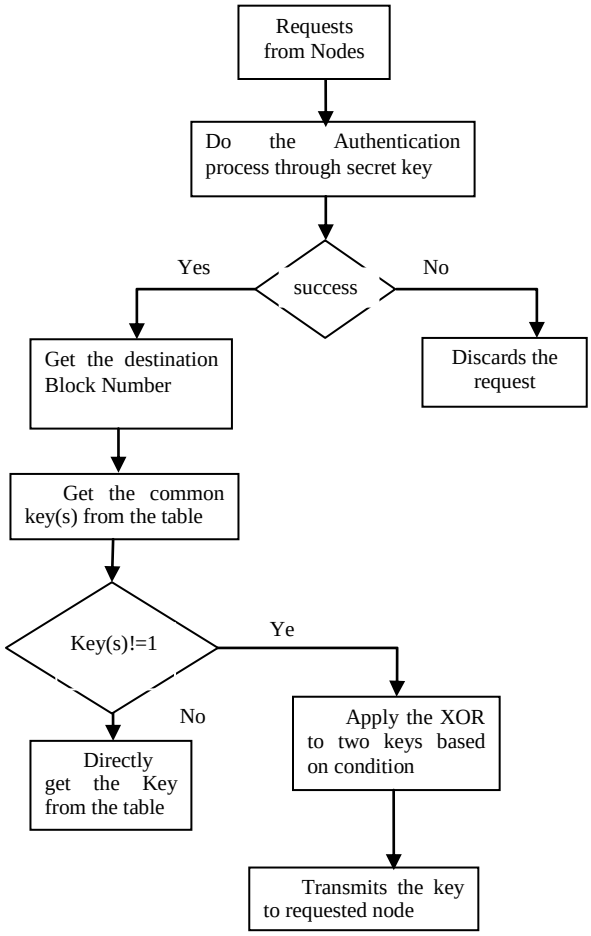

Fig. 2. The Workflow of Dynamic Key Generation and Distribution Center (DGDC).

Example 3: In the Example, We are taking network size as 7 (Select maximum prime number that satisfies q=2, 22+2+1=7). So.

v= 2^2+2+1= 7, k=q+1=4

Such that the total number of blocks (B) designed by the SBIBD=7. Each DGDC module identifies the session key for every block by using Algorithm 4. And below Table I shows the key numbers for each block.

These are the seven keys stored in DGDC before starting the communication.

{1: 31037803, 2: 34051950, 3: 75095512, 4: 67731601, 5: 90790958, 6: 42721930, 7: 56819008}

By using the above network configuration the users can communicate with each other. For example, if User 1(B1) wants to transmit the data to User 6 (B6), DGDC identifies the

common key between B1 and B6 i.e., 3. Then select the '3' Key value from Algorithm 3 that is already given above. Here the value is 75095512. DGDC transmits this Key to User 1 as well as User 6 when it sends a request for communication.

TABLE I. CONSTRUTION OF 7 NODES USING ALGORITHM1

User(s)	Block Number	Key number1	Key number2	Key number3
1	B1	1	2	3
2	B2	1	4	5
3	B3	1	6	7
4	B4	2	4	6
5	B5	2	5	7
6	B6	3	4	7
7	B7	3	5	6

Example 4: Here, We are taking 20 as the input, N (q=3, 32+3+1=13). We could not use the value for q is 2.

$v = q^2 + q + 1 = 13, k = q + 1 = 4$

These blocks are getting from the DGDC from Algorithm4. But the given N value is 20. So, we have to find out the other blocks by using Algorithm 5. Table II shows the key numbers up to block 13.

The below-mentioned keys are the basic keys that are stored in the DGDC and these keys are also used for calculating the other node keys by using Algorithm 6.

{1: 56940651, 2: 83179189, 3: 88850165, 4: 50901991, 5: 95809326, 6: 88046686, 7: 45506527 , 8: 42631960, 9: 36152950, 10: 31237906, 11: 91772959, 12: 87834612, 13: 13247806}

The Remaining nodes are: 20-13=7. Table III shows the key numbers of the remaining nodes.

TABLE II. CONSTRUCTION OF 13 NODES USING ALGORITHM1

User (s)	Block Number	Key Number1	Key Number2	Key Number3	Key number4
1	B1	1	2	3	4
2	B2	1	5	6	7
3	B3	1	8	9	10
4	B4	1	11	12	13
5	B5	2	5	8	11
6	B6	2	6	9	12
7	B7	2	7	10	13
8	B8	3	5	10	12
9	B9	3	6	8	13
10	B10	3	7	9	11
11	B11	4	5	9	13
12	B12	4	6	10	11
13	B13	4	7	8	12

TABLE III. CONSTRUCTION OF REMAINING 7 NODES USING ALGORITHM 2

User (s)	Block Number	Key number1	Key number2	Key number3	Key number4
14	B14	1	2	4	7
15	B15	1	2	4	10
16	B16	2	4	10	13
17	B17	2	4	9	10
18	B18	1	4	7	9
19	B19	4	7	10	13
20	B20	4	7	10	11

Algorithm 5 can generate multiple possibilities to build the tables to address the aforementioned problem.One of the solutions has mentioned in Table III. The DGDC can select any

But, here we can get the duplicate key numbers for identified blocks. We have implemented Algorithm 6 to calculate the accurate key for both parties. For Example, User 1 (B1) wants to send the data to User 17 (B17). So, DGDC needs to identify the key for them by using Algorithm6 itself.

The block key numbers are again mentioned here for reference.

B1-(1, 2, 3,4)

B17-(2,4,9,10)

Two common keys from the above blocks are 2 and 4. The keys values are taken from above dictionary for 2: 83179189 and 4: 50901991. After applying Algorithm 6,the output key-value is D3878818. So, DGDC transmits this common key to both users for further communication.

We shall receive new blocks for nodes after the same table with keys has been used for a time determined by the DGDC.

IV. ANALYSIS

The connectivity, scalability, resilience, and memory utilization of our model are all evaluated.

A. Scalability

The model can be scalable with the maximum number of nodes that were constructed for the IoT network. The model works with all keys in the keyring that correspond to the maximum number of IoT nodes that can be supported. The number of blocks generated with their keyrings determines the network's scalability. The scalability of a proposed approach is

$$q^2 + q + 1 + \binom{n^2 + 2qn + n}{q + 1}$$

here n is an integer value to get the next prime number and$(q^2 + q + 1)$ is identified by Algorithm1.

The following equation is for the calculation of the remaining nodes:

$(q + n)^2 + (q + n) + 1 - (q^2 + q + 1) =$

$n^2 + 2qn + n$

B. Connectivity

The probability of any two IoT nodes sharing only one communication key.

The main advantage of this model is to get the probability of key share at most 1 for maximum all cases.

$$p_{BB} = \frac{\binom{q^2+q+1}{2}}{\binom{N}{2}} = \frac{q^2+q+1(q^2+q)}{N(N-1)}$$

$$p_{BR} = \frac{\binom{q^2+q+1}{1}\binom{N-(q^2+q+1)}{1}}{\binom{N}{2}}$$

$$= \frac{2(q^2+q+1)\left(N-(q^2+q+1)\right)}{N(N-1)}$$

$$p_{RR} = \frac{\binom{N-(q^2+q+1)}{2}}{\binom{N}{2}}$$

$$= \frac{(N-(q^2+q+1)(N-(q^2+q+1)-1)}{N(N-1)}$$

According to the proposed model $p_{BB} + p_{BR} + p_{RR} = 1$, because the connectivity should be 1 in all maximum cases in the proposed approach.

$$p_{keyshare} = p_{BB} + p_{BR} + p_{RR} = 1$$

C. Resilience

Resilience means reliability among the network nodes from the attacker. The capture attack is called by capturing and revealing the key values from the nodes. So, the links which are used by the attacked key that might be compromised then those links are at risk. The proposed approach employs a unique key to communicate across nodes. And at random times, it shuffles all key values of blocks and blocks values as well As a result, if an attacker captures a key, it will not be worked after the shuffle.

$$p(L|C_x) = \sum_{\forall i} p(l_i|l)(p(D_i|C_x)$$

Where L denotes the link, $C_x$is x nodes are captured, l_i is the secure link between devices that already shared the i^{th} key in the pool. $D_i$has identified the key pool that includes key $i$is compromised. In our proposed system, from Algorithm 3, each key appears in the B blocks.

$r = q + 1$. For R blocks, each key repetitions are, $r' = 3q$

$$p(l_i|l) = \frac{\binom{((q+1)+3q)}{2}}{\binom{q^2+q+1+\binom{n^2+2qn+n}{q+1}}{2}}$$

The probability of key$i$, appearing in one or more of the x compromised keyrings is:

$$p(D_i|C_x) = 1 - \frac{\binom{((q^2+q+1)+(N-(q^2+q+1)))-((q+1)-3q)}{x}}{\binom{q^2+q+1+\binom{n^2+2qn+n}{q+1}}{x}}$$

When x keyrings are captured, the probability of a link being compromised can be calculated as.

$$p(L|C_x) = \sum_{i=1}^{q^2+q+1} p(l_i|l)(p(D_i|C_x)$$

$$= q^2+q+1\frac{\binom{((q+1)+3q)}{2}}{\binom{q^2+q+1+\binom{n^2+2qn+n}{q+1}}{2}} p(D_i|C_x) \cong p(D_i|C_x)$$

Our proposed system increases resilience when compared to previous models. The other systems probabilities of resilience are:

In the [18] model:$p(L|C_x) = 1 - \frac{\binom{q^2}{x}}{\binom{q^2+q+1}{x}}$

In the [21] model:

$$p(L|C_x) = 1 - \frac{\binom{2q^2}{x} + 2\binom{q^2}{x}}{\binom{2q^2+2q+2}{x}}$$

In the [22] model:

$$p(L|C_x) = 1 - \frac{\binom{((q^2+q+1)+(N-(q^2+q+1)))-((q+1)+\binom{2q}{q})}{x}}{\binom{q^2+q+1+\binom{2q+1}{q+1}}{x}}$$

Resilience values are provided for 500, 800, and 1700 nodes in Tables IV, V, and VI, respectively. Fig. 3, 4, and 5 show the graphs for the corresponding tables with various nodes. Different methods for hybrid combinatorial design are provided in tables and figures, and it is demonstrated that our approach produces the best results when compared to other ways.

TABLE IV. RESILIENCE VALUES FOR 500 NODES

N	Compromized nodes x	q value	HSYM	MHS	MHSYM	Our Approach
500	20	19	0.669	0.664	0.644	0.639
	40		0.897	0.89	0.87	0.852

TABLE VI. RESILIENCE VALUES FOR 1700 NODES

N	Compromized nodes x	q value	HSYM	MHS	MHSYM	Our Approach
1700	80	37	0.89	0.94	0.87	0.86
	100		0.94	0.9904	0.91	0.9
	120		0.967	0.996	0.95	0.93
	140		0.982	0.998	0.97	0.96
	160		0.9904	0.999	0.99	0.98
	180		0.994	0.999	0.99	0.98
	200		0.997	0.999	0.99	0.98

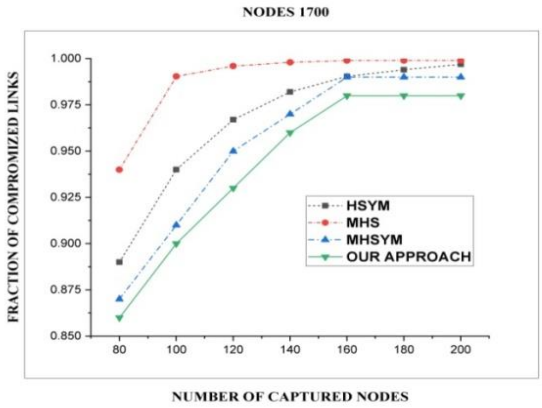

Fig. 5. Resilience Simulationresults of Our Approach Versus HSYM[18], MHS[21], and MHSYM[22] for the 1700 Nodes.

The above graphs and tables prove that our system greatly reduces the probability of compromized network links.Each node receives a different key for its links, and they all also get dynamic keys.

D. Memory Utilization

Here, DGDC is proposed as a centralized key distributor in the proposed system. So, there is no pressure on any network node to maintain all keys in the memory. The IoT node should store only one key that is applied to get the session key from DGDC.

As a result, We can declare that our proposed strategy improves node capture resilience with a combinatorial design.The notations and descriptions of the different parameters used in the article are given in Table VII.

TABLE VII. NOTATIONS OF PARAMETERS

Data related to implementing the Combinatorial designs	Parameter Notation
Blocks (nodes) connected to the IoT network	N
Blocks are generated by SBIBD	B
Remaining Blocks	R
Blocks are generated by HBIBD	H
Number of keys used in each block	k
Key Pool	v
Keys each replicated in the blocks	r
Number of keys intersecting any two blocks	γ

V. DISCUSSION

There is a demand for network security research that is essential due to the upsurge of online transactions. Every user in the transactions believes that the data will be secure and unaltered during transmission. To make secure data and provide reliable keys, a lot of algorithms can be used to provide confidentiality for the data and key-management techniques. In the present work, we are discussing a simple key management algorithm with less time and space complexity compared to the relevant studies on key management algorithms using combinatorial design. We observed that if the network has more than 800 nodes, the

comprised links are reduced when compared to existing techniques. We also mentioned the relevant graphs of resilence in Fig. 3, Fig. 4, and Fig. 5 for various nodes.

VI. Conclusion and Future Work

In this paper, we present a new hybrid combinatorial key distribution scheme for IoT networks that improves the key share probability, scalability, and resilience against capture attacks. In comparison to the other three hybrid methods, our experimental outcomes were better. For all connected nodes, our suggested approach provides the key sharing probability with 1. Every link in the established IoT network can use the same unique key. This paper also provides low resilience values against capture attacks when compared to other schemes. We will also extend this work to reduce the resilience of specific attacks like a man in the middle, Denial of service. We would like to implement it in real networks for better analysis.

Automated Study Plan Generator using Rule-based and Knapsack Problem

Muhammad Amin Mustapa, Lizawati Salahuddin, Ummi Rabaah Hashim
Fakulti Teknologi Maklumat dan Komunikasi,
Universiti Teknikal Malaysia Melaka (UTeM)
Durian Tunggal, Melaka, Malaysia

***Abstract*—Undergraduate students are given the flexibility of arranging courses throughout their study duration especially when they are eligible for credit exemption for the courses taken during their diploma study. Issues arise when students arrange their studies manually. Improper course arrangement in the study plan may be resulting some of the selected courses do not correspond to the courses offered, and imbalance credit hours. Hence, this study aims to propose an algorithm to generate an automated and accurate study plan throughout the study duration. A combination of rule-based and knapsack problem were proposed to generate an automated study plan. A quantitative methodology through expert's reviews and questionnaire survey was conducted to evaluate the accuracy of the proposed algorithm. The proposed algorithm shows high accuracy. In conclusion, the combination of rule-based and knapsack problem is appropriate to generate an automated and accurate study plan. The automated study plan generator can help students generate an effective study plan.**

Keywords*—Knapsack problem; rule-based; study plan; undergraduate; credit exemption

I. INTRODUCTION

Study planning is important to ensure the students carry a balance study load in every semester. The balance of courses and the number of credit hours chosen by the students themselves determine the planning of non-burdensome study sessions. Students need to allocate time (also known as student learning hours) for the implementation of all learning activities to achieve the learning outcomes. The student learning hours includes formal meetings (e.g., lectures), guided learning (e.g., tutorials, seminars, internships, and fieldwork), self-directed learning, and preparations for tests and final exams. A balance study load could influence the student's academic performance. Study planning is becoming more critical for undergraduate students who are eligible for credit exemption for the courses taken during their diploma study. When each student has a different number of total credit exemptions, the difference becomes more pronounced. As a result, different study plan is devised for each student. With a well study plan, students may shorten their undergraduate study depending on the total credit exemption.

Study planning is tied to academic rules. For instance, students are allowed to take minimum of 12 credits (exception on the last semester of study), and maximum of 20 credits per semester. Besides, a prerequisite course must be completed prior to another course. Moreover, not all courses are available in every semester. Some courses are only available in odd semesters, while others are only available in even semesters. Therefore, courses should be arranged according to the curriculum structure, and total credit hours per semester should be divided appropriately. The study plan should not interfere with the learning journey.

The field of artificial intelligence (AI) and knowledge-based system has enormous potential for improving simulation modelling support [1, 2]. Due to recent advances in the field of AI, a knowledge-based system has demonstrated its abilities by providing successful solutions in a wide range of applications including in the field of education [2], agriculture [3], manufacturing [4], and health [5]. The system can be used as an alternative to traditional systems, particularly in advisory tasks and symbolic reasoning [6]. It is a subfield of AI that collects data automatically without the assistance of a human expert to solve problems that normally necessitate human intelligence [7, 8].

Rules can be viewed as a simulation of the cognitive behavior of human experts. A rule-based expert system can mimic the ability of human experts to make decisions [9], [10]. They are programmed to solve problems in the same way that humans do, by using stored human information or expertise. Rule-based structures are created to solve specific problems in a given domain. Every domain has its own set of intelligent and reasoning humans that can be modelled and even replaced by automated rule-based systems. A system generator based on a rule engine that uses an improved Rete algorithm was designed to match data objects to perform certain functions through a system generator using rules set by the user (production) [11]. The rule engine's primary responsibility is to match the data objects submitted to the engine with the business rules, activate the business rules based on the current data state, and trigger the operations in the application based on the execution of logic declared in the ruleset. Reference [12] states that the problem of scheduling by minimizing the amount of flow time has attracted more attention from the research community. This is because the lower the total flow time value, the greater the resource utilization and cost savings. In this regard, today's manufacturing environment is quite practical, as it reduces the amount of flow time. Several tasks comprised of some sequences are utilized to determine optimal values for minimizing overall flow time; to provide good solutions as the problem size expands the development of heuristics and meta-heuristics is essential. In the study, a ruled-based heuristic process for determining the sequence with the least total flow

time is proposed. The experimental results show that the proposed approach makes a major contribution to the exceedingly difficult scheduling problem.

The basic principle of all knapsack problem families is to choose a few objects, each with a benefit and weight value, to be packed into one or more capacity knapsacks. Assume there is a group of elements with known weights and values, as well as a pack or bag with a limited capacity for filling the knapsack. A problem known as the knapsack problem is devised to fill the said pack with the elements in such a way that their aggregate sum is possibly the highest without exceeding the pack's ability [13]. Knapsack Problem 0-1 is a popular form of knapsack problem with a wide range of applications, including capital budgeting, project selection, resource allocation, cutting stock, and investment decision-making. As a result, the issue of Knapsack Problem 0-1 optimization has drawn the attention of an increasing number of researchers [14]. GRASP technique was applied to a nurse-scheduling problem where the goal is to optimize a collection of preferred courses to a set of binding constraints [15]. A critical challenge is striking a balance between feasibility and optimality. Construction heuristics, neighborhood search methods, and evolutionary algorithms have all been effectively utilized to solve real scheduling issues. However, there is a frequent conflict between feasibility and solution quality, as well as difficulties in maintaining an appropriate balance between goals. This is solved by employing a knapsack problem, which ensures that the solutions generated by the construction heuristic are simple to fix. A diversification approach and a dynamic assessment criterion improve the optimum combo even further.

Study in [16] developed an automatic course planning system by using ontology and rule-based. The aim was to create a suitable course plan for a group of students according to the course prerequisite requirement, complexity of the course, teaching method, and the duration of the course. However, the course planning system did not include the course scheduling for a complete study duration from year one until end of study duration. Machine learning techniques were used to group students into similar study pattern according to the CGPA achievement and subsequently determine a feasible study path for the forthcoming semester [17]. Specifically, Neural Network algorithm is used for creating CGPA prediction models, and K-means algorithm is applied to group students according to the similarities of their grades in each course. The evaluation of the proposed system revealed that the students have improved their study performance for their ultimate CGPA in graduation. However, the proposed system does not consider the duration of the study completion, the course prerequisite requirement, and total number of credits in a semester. Moreover, [18] in their research work addressed the issue of determining the ideal set of courses to provide students with in a particular semester, while taking into account the required courses and the availability of teachers to teach those courses. The use of *CourseScheduler*, *IApplet* and *AdmValidatorApplet* function altogether helps the authors to achieve their aim successfully. However, the research focused on the creating a schedule of classes that aid the department administrative in the course scheduling rather than the study plan for students. The method to assist students generating study plan is lacking. Based on these limitations, this study aims to propose and validate an algorithm for compiling study plans throughout the study duration. A more in-depth investigation was conducted to assess the method's accuracy and usefulness.

II. BACKGROUND

A direct entry student is defined as a student who pursues a degree from a particular institution or a university with a particular completed diploma degree. Compared to direct admission students, direct entry students are allowed to make credit exemption. Credit exemption is a provision of the academic regulations under the semester system that aims to facilitate student mobility. For an instance, students must complete a diploma with at least a 3.00 CGPA from an institution and the courses pursued must be recognized by the senate as equivalent and meet the curriculum requirements of the program pursued or in their respective field of study. Credit exemption may be granted to students who have taken equivalent courses and passed with a minimum grade of C using the university's grading system, provided that at least 80% of the learning content is equivalent. The amount of credit exemption allowed should not exceed 30% of the total credits of the graduating requirements.

Academic handbooks have become a reference for students, containing important information about students' curriculum structure according to a specific program. Courses are divided into four categories, namely general module (W), core module (P), specialization module (K), and free module (E). Table I explains the course category. All courses are categorized as W and are not allowed for credit exemption.

TABLE I. COURSE CATEGORY

Component	Code	Meaning	Credits
General Module	W	University Compulsory Courses, which are a group of important Courses determined by the Senate and made compulsories for all students.	14
Program Core Module	P	Mandatory courses to meet the requirement of Bachelor of Computer Science.	45
Final Year Project			6
Industrial Training			12
Specialization Module	K	Specialization courses to a specific major of an academic program.	30
Free Module	E	Elective Courses that are offered to deepen an academic program.	13
Total Credits			120

Table II shows the list of course code and name. Students must meet all components of the code to complete a total of 120 credit hours.

III. ALGORITHM IMPLEMENTATION INTO UNIVERSITY RULE

Rule-based expert system is based on knowledge that collects a range of factual information, and makes actions through interpretation from a set of predefined rules [19]. Certain courses have rules that must be followed to complete the semester. According to the rules, the proposed algorithm will decide whether or not to include the course. For the arrangement of study plans, a new rule is proposed to control the arrangement of schedules according to the selected semester. The selection of courses is based on the current semester offers and availability through the knapsack problem method until the credit hour rate reaches a predetermined limit.

Normal students must complete all 120 credits in a minimum of 7 semesters. However, direct entry students have the option to shorten the semester depending on the total number of credit exemption approved. Alternatively, students can stay with 7 semesters as offered with lower credit hours. The first step is to determine the maximum number of semesters according to the total number of credit exemption approved. Then, the total credit hour in a semester is calculated to ensure a balance credit taken by students in every semester, and to ensure that the total credit hours to be taken do not exceed the stipulated conditions. Fig. 1 depicts the semester calculation step as well as the total credit hours in a semester according to total credit exemption approved.

Equation (1) shows the calculation of total credit hours in a semester (*tch*).

$$tch = \frac{120-\text{tce}-12}{(\text{ts}-1)} \quad (1)$$

where 120 is the minimum graduating credit, *tce* is total credit exemption, 12 is the Industrial Training credit, and *ts* is the total number of semesters.

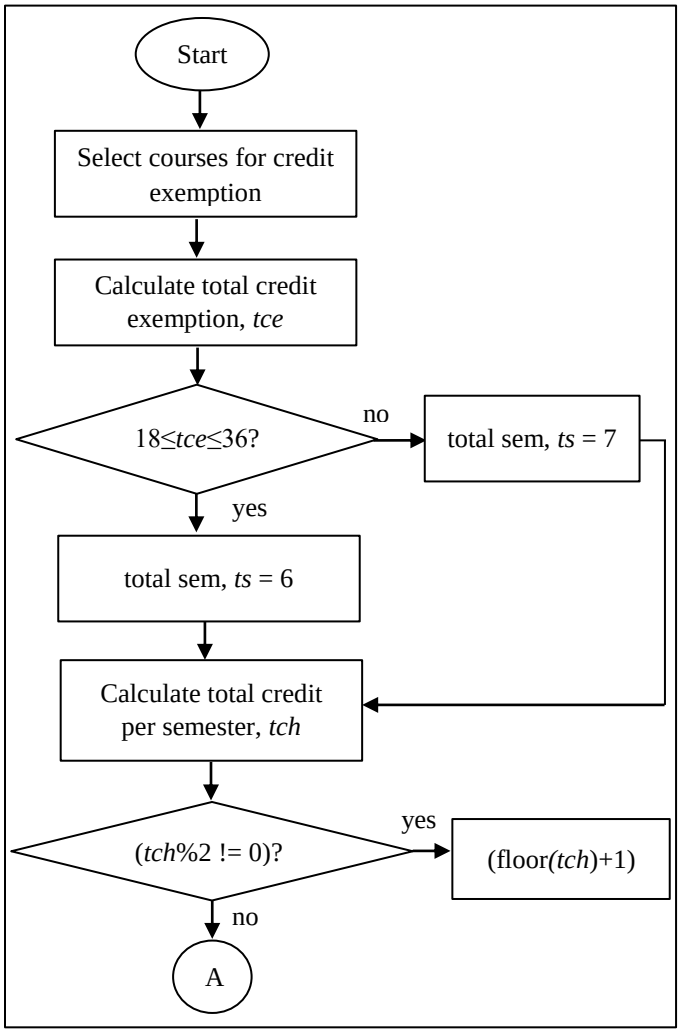

Fig. 1. Total Semester and Credit Hour according to Total Credit Exemption.

Industrial Training is a mandatory requirement for students at the end of the semester before graduation. Hence, the industrial training credit and the semester are deducted to calculate *tch*. To make the calculation method simpler, the maximum amount generated will be added to a value of 1 for the semester when the calculation result produces a decimal number and the decimal part is removed as shown in Fig. 1. This is because the number of available credits offered varies and there are no credit hours in decimal form. Using this formula, the total credit hours will not fall below the semester's minimum total credit of 9 and will not exceed the semester's maximum total credit of 20.

Credit exemption is permitted for program core courses. Not all courses can be exempted, including those courses with W category. Workshop I (P1), Workshop II (K1), Final Year Project I (P2), and Final Year Project II (P3) are project-based courses that cannot be exempted. P1 and P2 is the prerequisite course of K1 and P3, respectively. Moreover, K1 is the prerequisite course of P2. As they are offered once a semester and have pre-requisites, these courses should not be taken lightly. The proposed algorithm has set some rules based on the number of semesters. Each rule has unique characteristics

for each course. The course is thus removed from the list of available courses because it has become a rule that must be followed. Using the proposed rule-based approach, several courses must be prioritized to ensure the planned flow runs smoothly. Overall, rule-based algorithm is applied to:

- determine number of semesters study
- prioritize University Compulsory Courses to be arranged in the semester according to the program curriculum structure.
- prioritize program core courses according to the pre-requisite and semester offered.
- prioritize specialization courses according to the pre-requisite and semester offered
- prioritize English courses according to the pre-requisite and semester offered.

The parameters used for configuring the rule-based algorithm include the total credit hours, exempted courses and their credit hours, course prerequisites, program curriculum structure and course details. The course details including course name, course code, course category, credit hours, and the semester offered according to odd or even semesters.

A. General Rule for Seven Semesters of Study

Students who only receive credit exemption ranging from 3 to 15 credit hours are advised to complete seven semesters of study. This is because the number of exemption hours is insufficient to reduce the study time. However, students can reduce the credit hours for the coming semesters. The rule prioritizes the courses categorized as W and K to be arranged in the semester according to the curriculum structure as depicted in Fig. 2.

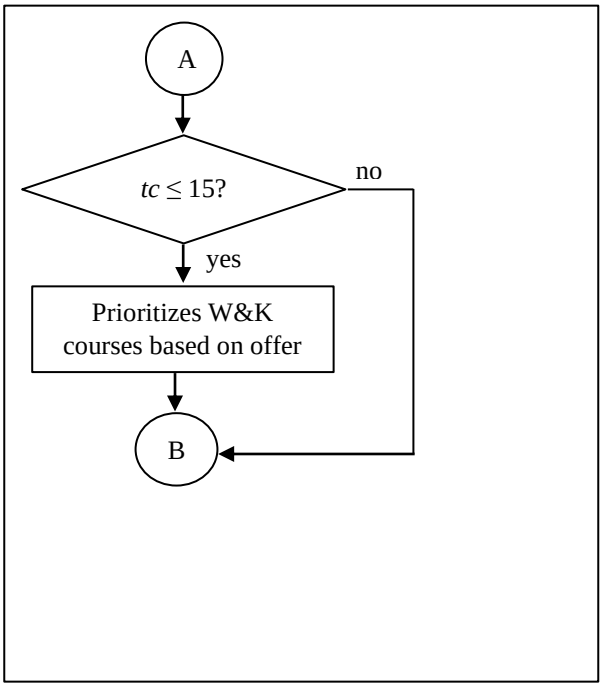

Fig. 2. 7-Semester Rules.

B. General Rule for Six Semesters of Study

Fig. 3 illustrates how the rules for 6 semesters are applied. For all programs offered at the faculty, workshops (P1 and K1) are the main course at the core of the program. The P1 course is available in both semesters, but the K1 course is only offered in the odd semester. Therefore, students are encouraged to take P1 early in the semester so that they can enroll K1 in the subsequent odd semester with 3rd year students. Then, students are allowed to take final project courses in the following semester. Moreover, P4 (Programming Technique) is the pre-requisite course of P1. In this way, planning to shorten the semester is more structured because the core courses can be enrolled in the appropriate semester.

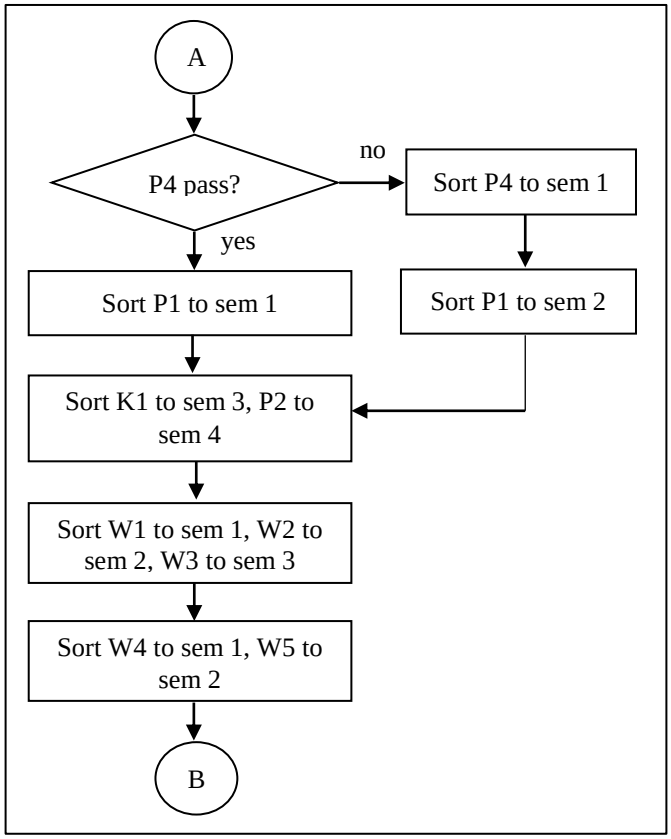

Fig. 3. 6-Semester Rules.

P1 and K1 are given priority because they are the backbone of the study plan and are divided into six semesters. According to the curriculum structure, these workshop courses are only offered in odd semesters. In semester 1, the algorithm will check the pre-condition status of the P1 course first before allocating the course in a semester. If the requirements are not complied with, students will first consider the P4 and change P1 to the second semester. The group for K1 comprises direct entry students and normal entry students. Hence, the course must be offered in semester 3 to ensure the direct entry students can be assigned in groups. This is equivalent to semester 5 of normal students. Next, English courses are placed in the earlier semester such as English for Academic Purpose (W1), sorted to semester 1, English for Academic Purposes (W2), sorted to semester 2, and English for

Professional Interaction (W3) at semester 3. The next rule ensures the selection of co-curriculum courses. The method is the same as the prerequisites by ensuring that co-curriculum courses are not taken in the same semester and Co-Curriculum II (W5) does not precede Co-Curriculum I (W4).

C. Course Specialization Rules

In addition, specialization based on the program taken by the students is emphasized. This is because these courses are only concentrated among the same programs. The students are not permitted to join specialization classes of other programs. Since specialization courses are offered at a particular semester, a rule is made to allow and ensure specialization courses are taken during the semester where the courses are offered. This ensures the students are following the correct guidelines throughout their study. The rules have limited the students to take 3 or 4 courses per semester to ensure that their study schedule is bearable during the semester. Therefore, maximum specialization courses are set based on the proposed rules. There are several additions to the rules for certain programs such as Bachelor of Computer Science (Database Management) with honors (BITD), Bachelor of Computer Science (Computer Networking) with honors (BITC), and Bachelor of Computer Science (Artificial Intelligence) with honors (BITI). For instance, for the BITI program, the P5 (Artificial Intelligence) course is a prerequisite that must be met. The P5 course affects other courses like K2 (Knowledge-Based System), K3 (Natural Language Processing), and K4 (Machine Learning). Fig. 4 illustrates the additional rules of BITI program.

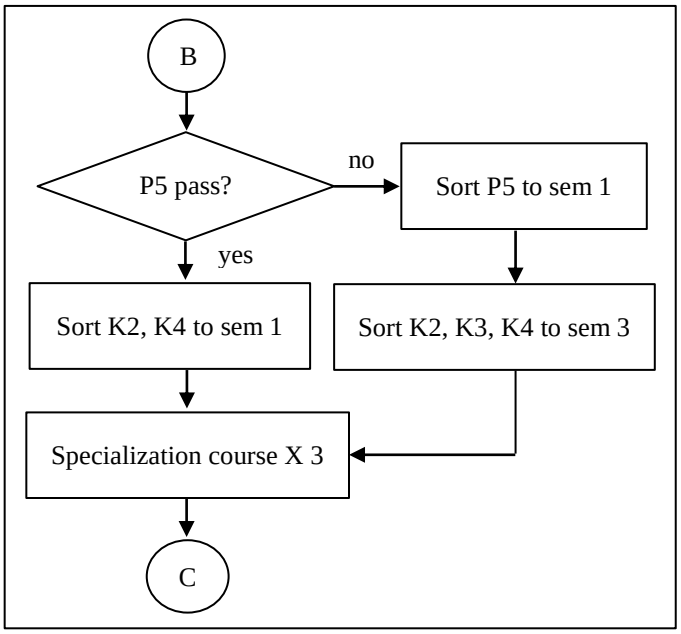

Fig. 4. BITI Specialiazation Rules.

D. Course Availability Rule

The availability of a course should be considered before carrying out this proposed rule. This is because specialization courses need to be sorted accordingly. It is important to offer the courses according to odd or even semesters so that students are not left behind when the courses are offered. If the courses are only offered in odd semesters, they will not be available in even semesters, and vice versa. Some courses are open to other programs in other semesters. Students can plan ahead of time to enter the classes indirectly. This arrangement is based on the lean and the year of the offers to correspond to the students' year of study. This arrangement must be made to ensure that students take a diverse range of courses while also meeting the required credit hours. The proposed algorithm will ensure the availability of a course's semester whether it is in an even or odd semester only or both.

Fig. 5 shows a continuation of the previous compilation of rules. The next rule stipulates that the specialization courses should be included in a particular semester. This is because the semester arrangement is short, and some courses need to be taken first. Specialization courses according to a particular program are usually not offered in other programs; hence should be prioritized in the compilation.

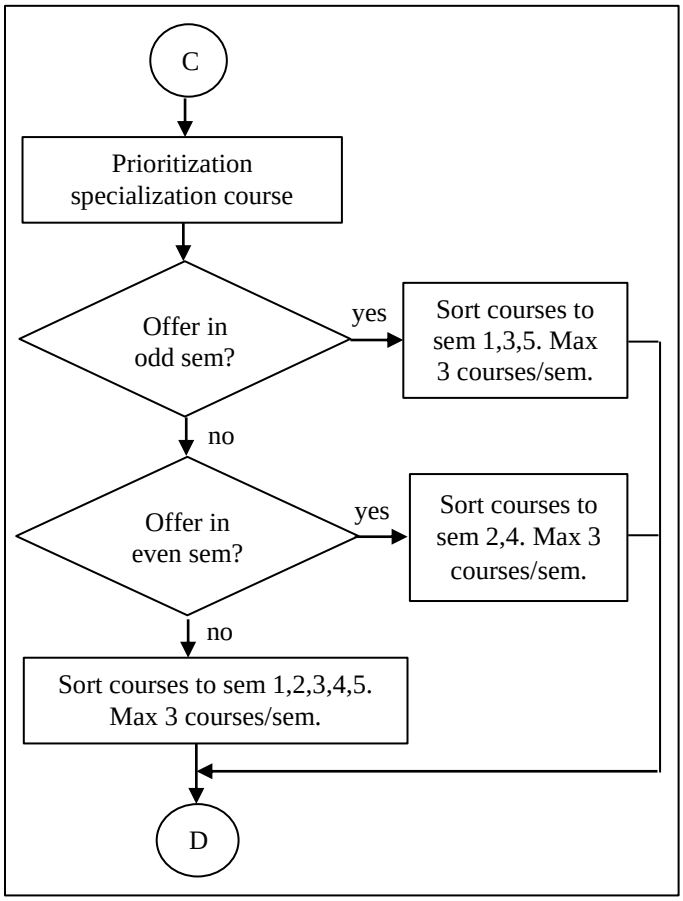

Fig. 5. Specialization Course Flow.

E. Sorting Courses using Knapsack Problem 0-1

The Knapsack Problem 0-1 is applied to fill the remaining number of credit hours from the rule-based algorithm until the total credit hour limit is reached. Equation (2) shows the equation for the Knapsack Problem 0-1.

$$max \sum_{i=1}^{n} xi * pi$$

$$\sum wi\ xi\ \leq c$$

$$xi\ \in \{0,1\}, i = 1, \ldots\ldots, n.$$

$$pi > 0, wi > 0, c > \qquad (2)$$

where i represents course (xi = 1 for selected course, whereas xi = 0 for unselected course), n is a number of total courses, wi is weight, pi is profit which is the credit hour of a particular course, and c is the required remaining credit hours to fulfil the total credit hours per semester. The algorithm will select the highest and most appropriate credit hours that can be adjusted for the number of credit hours remaining. The election results made by the proposed algorithm are entered into the semester. This process is repeated until the total number of credit hours reaches a maximum. This process continues to compile for the next semester. Fig. 6 depicts the flow of the knapsack problem where the process is repeated until the number of hours and courses for each semester reaches the maximum rate.

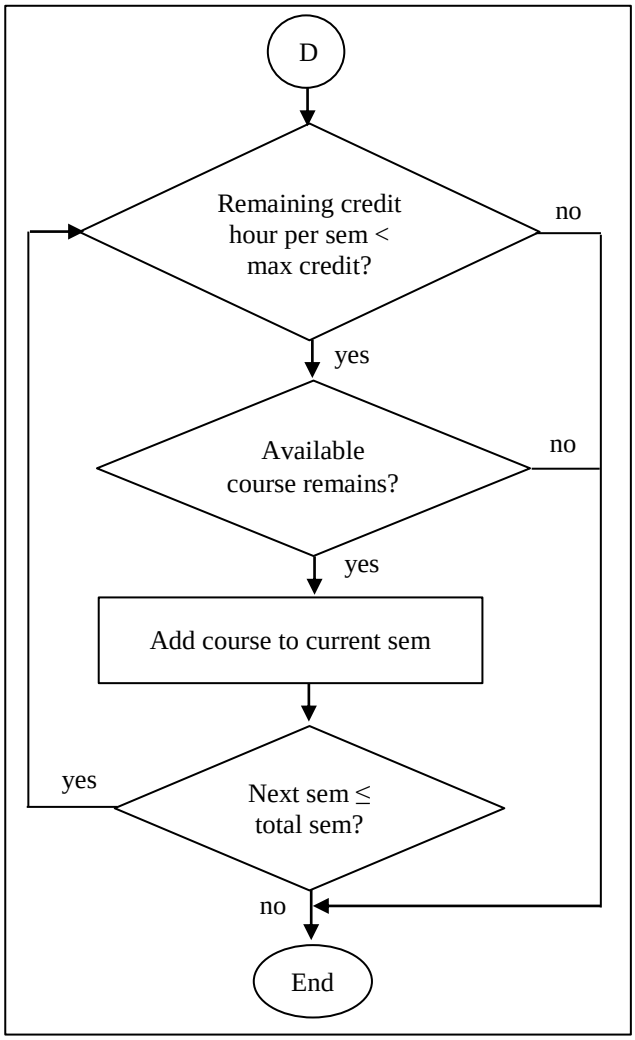

Fig. 6. Sorting Courses using Knapsack Problem 0-1.

IV. Automated Study Plan Generator Prototype

The creation of the courses details for a complete curriculum structure is the first stage in constructing this prototype. The course details include course code, course name, prerequisites course, credit hours, and semester of offering are the required input as shown in Fig. 7.

Fig. 7. Course Details.

The total credit hours exempted is then determined as shown in Fig. 8. This stage is crucial since it serves as the prototype's major support structure. The total credit hours exempted must not exceed the maximum credits set by the university. The prototype shows warning when total credit hours exempted exceed the maximum credits to prevent students from making mistakes.

Fig. 8. Exempted Courses and Credit Hours.

Subsequently, the algorithm will determine the number of semesters and arrange the courses that are appropriate for the student. According to the parameters given by the algorithm, new courses will be substituted for the exempted courses. Fig. 9 shows the example of courses plan generated from the automated study plan generator.

Fig. 9. Example of Courses Plan.

V. METHODS

A. Expert Reviews

Expert review was conducted to evaluate the suitability and accuracy of the proposed algorithm. For this study, experts consist of lecturers who had experience as academic advisors in a faculty. In total, four experts representing various academic program were participated in the review. The experts were contacted in advance to obtain information about their experience as academic advisors and to obtain their consent to become experts. Each expert was chosen from different departments to ensure that the rules established for each program were followed correctly. Then, the test case was sent via email.

The preparation of test cases was planned following the program to be given to experienced academic advisors. Test cases were organized based on the study plan generated from the proposed algorithm. To ensure accuracy, respondents were allowed to test the automated study plan generator prototype at random. The test cases were divided into 3 sections. Section A contains five test cases of total credit exemption between 3 and 15 credit hours which allows students to take 7 semesters of study. Section B contains five test cases of total credit exemption between 18 and 36 credit hours which allows students to take 6 semesters of study. Section C contains 3 test cases based on the random credit exemption course selected by the respondents. The total credit exemption between 3 and 36 credit hours. In total, 32 test cases were distributed to the experts.

B. Testing

Testing was conducted to identify bugs in the proposed algorithm. Testing helps in understanding and refining the given requirements [20]. It is the practice of comparing a piece of software's behavior to the predetermined and expected behavior established during the development phase. This method of testing accuracy was accomplished through the use of a study plan generated by the prototype. This test was run for each program several times to identify any problems that may have arisen. This test was performed independently to ensure that the study plans produced met the study's objectives.

C. Questionnaire Survey

A user acceptance survey was developed with Google Forms and sent through messages to respondents. The survey was distributed to direct entry students who are aware of the direct entry concept and procedures. The questionnaire items were separated into sub-categories to acquire a clear understanding and accountability of evaluations and comments at the next step. The technology acceptance model (TAM) created by Davis was used in this study to evaluate the behavior of persons by using one generally known theory on the actual use behavior of utilizing new technology [21]. The influences on the intention of using the prototype were based on the individual's perceived ease of use (EU). The capability of the prototype (CP) was determined in terms of features and results generated to leverage user needs for study plan activities. Attitude (ATT) was thought to assist in meeting the needs of the users and hence influenced the attitude created toward the prototype. The perceived usefulness (PU) ensured that the developed prototype received a response in terms of use and usage behavior. Lastly, the student intends to use (IU) was created to determine the extent to which prototype requirements were developed to address existing problems. Fig. 10 illustrates the revised TAM model that specifically explains the computer acceptance determinants that are general and capable of explaining user behavior toward the automated study plan generator.

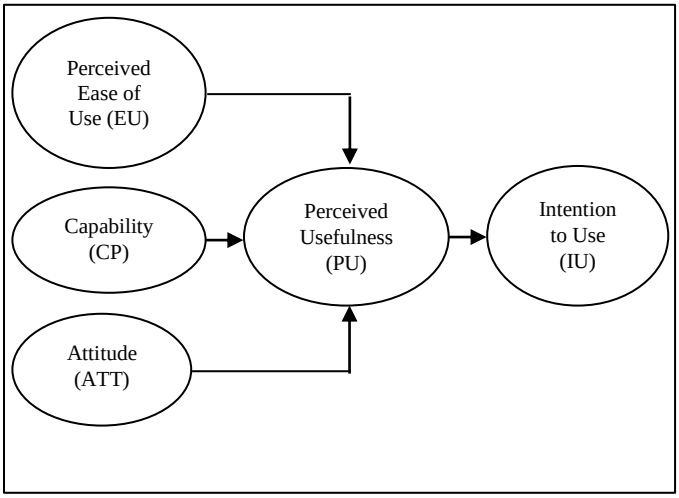

Fig. 10. Revised TAM for Automated Study Plan Generator.

The questionnaire used a five-point Likert scale of 1 to 5, 1 refers to strongly disagree and 5 refers to strongly agree. The questionnaire consists of 19 items. Respondents were instructed to use the automated study plan generator first to provide an overview of the prototype. Next, the respondents were required to answer the questionnaire survey. Each aspect presented was analyzed to gain the respondents' acceptance of the prototype to achieve the objectives.

D. Data Analysis

Test case results from experts and testing were analyzed using a confusion matrix to evaluate the accuracy. Table III shows the aspects to calculate the accuracy of the matrix by taking the average values across the "main diagonal".

The formula to calculate the accuracy based on the confusion matrix is shown in (3).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (3)$$

TABLE III. CONFUSION MATRIX FOR BINARY CLASSIFICATION

		True Class	
		Positive	**Negative**
Predicted Class	**Positive**	**TP**: Expected outcome was YES, and the actual outcome was also YES.	**FP:** The expected outcome was YES, and the actual outcome was NO.
	Negative	**FN:** The expected outcome was NO, and the actual outcome was YES.	**TN**: The expected outcome was NO, and the actual outcome was also NO.

On the other hand, a descriptive analysis (Mean ± SD) and correlation analysis were performed to analyze the data collected form the questionnaire survey.

VI. RESULTS

Table IV shows the results from the expert review. In total, four experts representing various program were participated in the review. Each expert evaluated thirteen cases of a particular program. The results indicate that the automated study plan generator generates highly accurate study plan between 0.99 to 1 accuracy.

According to an expert who evaluated BITI program, the P1 (Workshop 1) course should be scheduled in the second semester so that students can learn how to tackle their studies at UTeM first. If a student successfully exempted for more than 18 credit hours, the algorithm rules place P1 course in Semester 1. They can be changed because the P1 course is available in both, and a new course will be taken. As for the BITC program, the arrangement of courses developed in the automated study plan generator is good, except that there is a problem with the K1 (Workshop II) course that is supposed to be taken before the end of Year 2. This is because the outcome of the arrangement produced depends on the P6 (Data Communication and Networking) course whether it is excluded or not. This plays an important role in compiling the study plan, but it is not stated in the handbook. Human error occurs where the availability of elective courses is incorrectly set causing the accuracy of the program to decrease.

Overall, the study plan generated from the proposed algorithm has high accuracy. It is very useful for new direct entry students to obtain an initial overview of the preparation of study plans at the beginning of the semester. The courses offered also depend on the quota set by the faculty, which forces students to change their study plans in the event of a change.

A. Testing

Table V shows 28 manual testing results from various programs. Random course selection reveals that the automated study plan generator prototype has an accuracy of 0.999 on an average. The accuracy of the manually tested program has given a value of 1 except for the BITE program. This is because when the BITE program is shortened; students must merge three even semesters into two semesters. This causes the generated study plan exceeds the total credit hours. If a student is exempted from 18 credit hours, but the courses provided in the second semester are not reduced, the generated study plan will be unbalanced credit hours.

B. Questionnaire Survey

Forty-four direct entry students have participated in the survey. These students were from Semesters 2 and 6. The female and male respondents were 43.2% and 56.8% respectively. BITS program had the highest percentage of 45.5%, followed by BITI and BITD at 15.9%. Besides, there are 11.4% students from the BITC program and 9.1% from the BITM program. Lastly, there are 2.3% of students from the BITZ program.

TABLE IV. RESULTS FROM EXPERT REVIEW

Program	TP	TN	FP	FN	Total	Accuracy
BITI	539	0	7	0	546	0.99
BITM	546	0	0	0	546	1.00
BITC	538	0	8	0	546	0.99
BITS	544	0	2	0	546	0.99

TABLE V. TESTING RESULTS

Program	TP	TN	FP	FN	Total	Accuracy
BITI	252	0	0	0	252	1
BITS	126	0	0	0	126	1
BITM	210	0	0	0	210	1
BITC	210	0	0	0	210	1
BITZ	168	0	0	0	168	1
BITE	125	0	1	0	126	0.992
BITD	84	0	0	0	84	1
Total	**1175**	**0**	**1**	**0**	**1176**	**0.999**

TABLE VI. DESCRIPTIVE ANALYSIS OF USER ACCEPTANCE CONSTRUCTS

Construct	Mean ± SD
Perceived ease of use (EU)	4.301 ± 0.610
Perceived usefulness (PU)	4.291 ± 0.624
Capability (CP)	4.369 ± 0.561
Attitude (ATT)	4.348 ± 0.618
Intention to use (IU)	4.242 ± 0.619

Table VI shows a descriptive analysis of the acceptance test constructs. All mean values are greater than 4.2, indicating that respondents have a generally positive opinion of the automated study plan generator. A total of 96% of respondents agreed that the automated study plan generator is capable of producing a study plan that meets the specified requirements. The majority of respondents (92%) rated all items under attitude and perceived ease of use constructs on a scale of 4 (agree) to 5 (strongly agree). All respondents also agreed on the automated study plan generator's perceived usefulness. Lastly, the automated study plan generator would be used by more than 90% of the respondents.

Correlation analysis of the acceptance test between constructs is shown in Table VII. The results indicate all the constructs show a positive and strong correlation (exceeding 0.5), with all correlations significant at the $p<0.01$ level. The relationship between capability (CP) and intention of use (IU) is 0.862, indicating that the two are highly correlated. The finding implies that user intention is based on the capabilities of the prototype to assist users in achieving the goal of use.

TABLE VII. CORRELATION ANALYSIS OF USER ACCEPTANCE CONSTRUCTS

Construct	EU	PU	CP	ATT	IU
EU	1				
PU	0.842	1			
CP	0.671	0.743	1		
ATT	0.638	0.774	0.769	1	
IU	0.600	0.753	0.862	0.801	1

Following that is perceived ease of use (EU) concerning perceived use (PU), with a high correlation between the two constructs, demonstrating that the prototype is simple to understand and provides convenience to the user.

VII. Discussion

An algorithm for compiling study plans was proposed and validated in this study. Rule-based and knapsack problem were applied in compiling student learning plans. The rule-based method is utilized to optimize the courses that students must take during the semester as specified by the faculty. These courses have been planned based on the total number of credit hours exempted. There are crucial courses that must be prioritized based on the semester to guarantee that students do not miss out and create a change in the intended number of semesters. Besides, the knapsack problem used in this study is intended to select courses that are not included in the rules and can be put into a table based on credit hours and the desired offer. The courses to be chosen are balanced according to the number of hours allotted. As a result, a study plan that satisfies the prerequisites is created. These two approaches are ideal for dealing with this issue. This is because significant courses can be certain of their offer, while other courses are offered following the correct offer. The planned structure qualifies for making a study plan. The results from expert reviews and testing reveal that the automated study plan generator prototype has an accuracy of 0.999 on an average. Moreover, most of the respondents participated in the user acceptance survey have a generally positive opinion of the automated study plan generator in term of ease of use, usefulness and capability. The automated study plan generator would be used by more than 90% of the respondents.

The results produced from this study could provide valuable contributions to the undergraduate students to plan their course schedule prior to their graduation. The process of organizing learning can be more effectively implemented using the proposed algorithm. Students will not be overburdened and will be able to increase the consistency of their learning output in the coming semester by finding suitable learning arrangements. It has the potential to indirectly improve student learning performance.

This study has certain limits and problems. If the rule is incorrect or not written in the academic handbook, it can disrupt the schedule's arrangement. This is because the rules cannot be followed, resulting in a wild and incorrect arrangement. It will stymie students' planning and make new arrangements difficult. When constructing the study plan, Knapsack Problem 0-1 acts greedily to avoid this problem by using rules to ensure the algorithm obeys the established limitations. Knapsack Problem 0-1 will continue to produce results based on the number of credit hours without following the course codes. Moreover, human error is unavoidable when conducting studies, which reduces the accuracy of the results. The combination ruled-base and knapsack problem algorithm assures that the study schedule can be organized properly. Prerequisites can be met, credit hours can be allocated in a balanced manner, and courses can be arranged according to the offers by the faculty, all in one system. With the study's findings, any desired method can be constructed in the future. To solve this problem, rule-based and knapsack problem are appropriate. This is because each course must follow all rules, and voids can be filled by the knapsack problem with greedily picked courses to fulfil the prerequisite credit hours. It also relies on the availability of courses offered in the semester. The results have a high level of accuracy and can be used by academic advisors and new direct entry students to arrange their schedules.

VIII. Conclusion

This study had successfully proposed and validated an algorithm for compiling study plans by using rule-based and knapsack problem. Based on the results and analysis, it is possible to conclude that the accuracy of the algorithm based on the rule-based and knapsack problem to generate study plan is high. Survey respondents believe that the proposed algorithm can assist them in creating and designing study plans. The majority of respondents are interested in using the automated study plan generator. Finally, it can be seen that both students and academic advisors can benefit from the automated study plan generator to arrange their study plans.

Combining Multiple Classifiers using Ensemble Method for Anomaly Detection in Blockchain Networks: A Comprehensive Review

Sabri Hisham, Mokhairi Makhtar and Azwa Abdul Aziz
Faculty of Informatics and Computing, Universiti Sultan Zainal Abidin, 22000 Terengganu, Malaysia

***Abstract*—Blockchain is one of the most anticipated technology revolutions, with immense promise in various applications. It is a distributed and encrypted database that can address a range of challenges connected to online security and trust. While many people identify Blockchain with cryptocurrencies such as Bitcoin, it has a wide range of applications in supply chain management, health, Internet of Things (IoT), education, identity theft prevention, logistics, and the execution of digital smart contracts. Although Blockchain Technology (BT) has numerous advantages for Decentralized Applications (DApps), it is nevertheless vulnerable to abuse, smart contract failures, security, theft, trespassing, and other concerns. As a result, using Machine Learning (ML) models to detect anomalies is an excellent way to detect and safeguard blockchain networks from criminal activity. Adapting ensemble learning methods in ML to create better prediction outcomes is a viable approach for anomaly identification. Ensemble learning, as the name implies, refers to creating a stronger and more accurate classification by combining the prediction results of numerous weak models. As a result, an in-depth evaluation of ensemble learning methodologies for anomaly detection in the blockchain network ecosystem is applied in this paper. It comprises numerous ensemble methods (e.g., averaging, voting, stacking, boosting, bagging). The review collects data from three established databases, which are Scopus, Web of Science (WoS), and Google Scholar. Specific keywords are employed, such as Blockchain, Ethereum, Bitcoin, Anomaly Detection, and Ensemble Learning, employing advanced searching algorithms. The results of the search found 60 primary articles from 2017 to 2022 (30 from Scopus, 20 from the WoS, and 10 from Google Scholar). Based on these findings, we decided to divide our debate into three primary themes: (1) the fundamentals of Blockchain Technology (BT), (2) the overview of ensemble learning, and (3) the integration and analysis of ensemble learning in blockchain networks for anomaly detection. In terms of awareness and knowledge, the results are also discussed in terms of what they mean and where future research should go.**

Keywords*—Blockchain; Ethereum; Bitcoin; ensemble; anomaly detection

I. INTRODUCTION

Nowadays, most agencies have started evaluating Blockchain Technology (BT) in various sectors such as pharmaceuticals, automotive, agri-food, livestock, supply chain, health, and government digital initiatives [1]. This scenario has an impact in the context of traceability, transparency, and trustworthiness values in distributed and decentralized ecosystem environments [2]. A Blockchain operates based on a data structure storage method consisting of blocks that are interconnected with each other using a cryptography hash mechanism. Technically, each block stores information such as timestamp, Merkle root, nonce, previous hash and difficulty in the block header [3]. From the point of view of decentralized Blockchain applications, the world of cryptocurrency has become popular and dominant. Thus, Bitcoin BT has forged success by producing the first cryptocurrency application. It is different from Ethereum, which introduced smart contracts, and Ether has been declared the second largest cryptocurrency after Bitcoin [4]. Additionally, Ethereum was created to address the Bitcoin protocol's functional insufficiency [5]. Technically, the Ethereum network hosts smart contracts, which are collections of code that run on the Blockchain and carry out a set of instructions. These contracts are what power Decentralized Applications (DApps), which are akin to smartphone apps that operate on Google (Android) or Apple (iOS) operating systems.

In a public blockchain network, all transactions are transparent and are publicly available. Hence, anyone in the network can examine these transactions and may cross-verify any fraudulent behavior. Along with its rapid development, BT has encountered several security issues and shortcomings, including majority attacks, forking, and bugs in smart contracts. Wallet attacks, Ponzi Schemes, Proof of Work (PoW) vulnerabilities, and crypto-jacking are all challenges that need to be addressed. For instance, the Ethereum Blockchain has increased in prominence. Nevertheless, it has been beset by security vulnerabilities such as phishing scam, which has accounted for nearly half of all criminality on the platform since 2017 [6]. Therefore, for an efficient functioning of a blockchain network, it is vital to detect these vulnerabilities in the most precise and timely manner. To enable the successful identification and prediction of such attacks over Blockchain, the field of anomaly detection models in the Machine Learning (ML) method for Blockchain comes into play.

In general, an attempt to detect an anomaly in a pattern or thing that is different from the norm is termed anomaly detection. [7]. This demonstrates that combining ML and BT has a good impact and is widely employed in industries such as automotive, health, decentralized finance (DeFi), supply chain, agriculture, and the Internet of Things (IoT). Both technologies are combined for goals such as detecting suspicious activity, cybercrime and fraud. Besides, a

Blockchain system that can handle massive data sets is compatible with ML approaches to data analysis and can increase data security [8]. Therefore, a huge variety of anomaly detection models are being designed and deployed by researchers for various Blockchains. However, one of the most difficult aspects of detecting fraud on the Blockchain is that it is anonymous [9].

Overall, it is necessary to note that anomaly detection is one of the important areas for protecting future blockchain networks and that a considerable amount of work is being undertaken on this subject from many views, which will be described in this paper. Ensemble approaches are prominent ways of increasing the prediction capacity of an ML model for anomaly detection. In theory, ensemble learning techniques use multiple classifier methods to improve experimental outcomes. Conventional methods that use a single classifier to perform predictive analysis are ineffective. Therefore, combining individual classifiers in an ensemble can produce higher accuracy values [112]. For instance, strategies include stacking, averaging, bagging, and boosting approaches [10].

This research focuses on the fundamentals of BT, ML classification, and the combined contribution of ML and Blockchain to detect irregularities utilizing ensemble techniques. To aid comprehension, the study is divided into three sections: (2) Blockchain principles, (3) an overview of ensemble learning classification, and (4) developing the ensemble learning method for anomaly detection in blockchain networks.

II. Blockchain Technology

A. Overview

Blockchain is presently one of the most promising technology trends, with great possibilities across many useful applications. It is basically a distributed and encrypted variation of a database, which can solve several difficulties connected to online security and trust. As a result, the Blockchain feature of securely and decentralized data management makes Blockchain known in the world of cryptocurrencies such as Bitcoin and Ether (Ethereum). Historically, the goal of producing interference-proof texts led to the development of a cryptographic hash formatting system for storing documents in a chain of blocks [11]. In this endeavour, hash-based cryptographic algorithms are used to store a collection of verified documents in Merkle tree format in each block [12]. Moreover, since it was invented and exploited in cryptocurrencies like Bitcoin, which was presented by Nakamoto [1] in 2008, this technology has become well-known. This has helped popularize Bitcoin as the first digital electronic payment mechanism that operates on a peer-to-peer (P2P) basis and in a decentralized ecosystem. The field of Blockchain has been divided into four categories: Private, Public, Hybrid, and Consortium. Fig. 1 depicts the categorization of Blockchain.

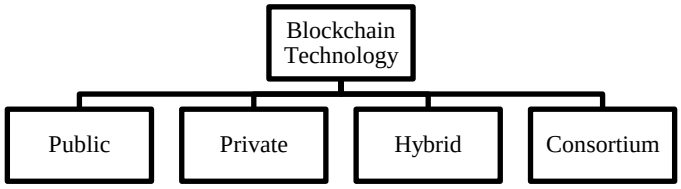

Fig. 1. Blockchain Classification.

A Public Blockchain is non-restrictive and permissionless [13]. This means anyone can do the mining process, and these transactions involve the addition of new blocks settled through a consensus mechanism. This concept has been fundamental to the existence of Bitcoin and other cryptocurrencies in the Distributed Ledger Technology (DLT) ecosystem [1]. As a result, the weakness of the centralized operating system faces challenges in terms of low-security level and no value of transparency (dependence on third parties). Regarding data storage, the DLT ecosystem stores data distributed across nodes linked by a blockchain network, as opposed to a centralized system that stores data in a single location. Technically, the consensus mechanism is an important algorithm in Blockchain operations to ensure that members joining a blockchain network agree on certain conditions before the ledger is updated. Proof of work (PoW) is a common consensus algorithm used in Public Blockchain environments. One of the benefits of this consensus is that as the number of miners grows, attacks can be reduced to 51 percent [16].

In contrast to the Public Blockchain, the Private Blockchain operates based on an organization through access granted only to be allowed to enter the network. Therefore, they are also called "permissioned blockchains" or "business blockchains" [17]. It has the same properties as a Public Blockchain that is distributed, decentralized, and operates in a P2P environment. Typically, a Private Blockchain is used in a network environment with a small organization compared to a Public Blockchain, where anyone has the right to enter a public network. The consensus algorithm used in the Private Blockchain (permissioned) is Practical Byzantine Fault Tolerance (PBFT).

Using both Public and Private Blockchain features in Blockchain development is necessary in the real world. As a result, a Blockchain ecosystem known as Hybrid Blockchain [18] has emerged. Elements from the Private Blockchain (permissioned) are employed in the enterprise context. On the other hand, a Public Blockchain is ideal for practice since the data requirements are open or public (permissionless). The addition of the participation of several organizations from a single organization so that the value of collaboration is higher in a Private Blockchain environment is termed a "blockchain consortium" [18]. It combines features of a Public and Private Blockchain and is very similar to a Hybrid Blockchain. An important goal is to eliminate access gaps limited to a single organization in a Private Blockchain environment.

B. Blockchain Architecture

In a decentralized ledger, all transactions in a Blockchain are stored in interconnected blocks. Each block contains a block header that stores critical information, including the timestamp, nonce, difficulty, block hash, and Merkle root tree, to keep these blocks related. This method guarantees the security of the data within the blocks, and the size of the witness determines the size of each block. One Bitcoin block, for example, is 1 MB in size [1]. Meanwhile, the Merkle tree employs the hash technique for each block transaction, as shown in Fig. 2. From an operational point of view, each block stores the address of the parent block or the previous block in the form of a hash value. This mechanism can help to identify the chain sequence between these blocks. Blocks generated in the early stages of blockchain network construction are termed "block genesis." To ensure the uniqueness of each block, the timestamp information is crucial to store the time differentiation generated on each block. For example, the current block has a more recent timestamp value than the timestamp of the previous block. This mechanism can prevent the occurrence of double-spending cases.

Blockchain environments, especially Bitcoin, are known for mining processes using pseudo-random numbers (nonce) and are used only once throughout the mining process. Note that it is difficult to keep the value of the difficulty level based on a threshold with a specific target. For example, the difficulty level rises when the number of transactions increases. As a result, block formation becomes increasingly complex (mining process) and slower. It also affects cyber attackers and greedy miners who want to take advantage of many transactions and slow the processing. The Merkle tree cryptographically manages the hash mechanism on transactions in blocks. This is described as a tree consisting of leaves as well as twigs. Conceptually, the hash in the brand tree is constructed based on a combination of left and right hashes to produce the parent hash. The generation of interconnected hashes forms a chain called a Blockchain. Therefore, an abnormality in the Merkle tree indicates something is happening in the chain, and appropriate action is taken immediately [19].

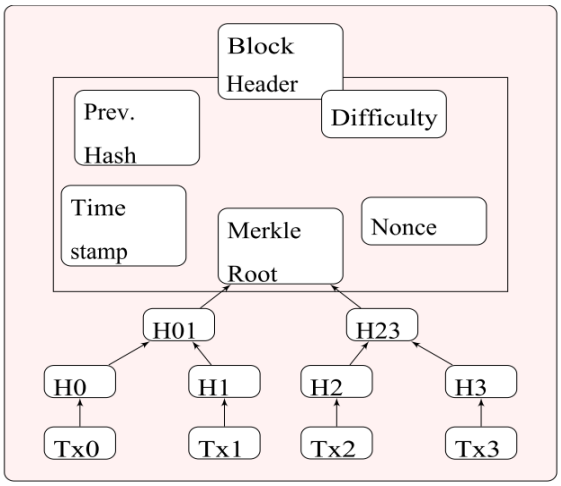

Fig. 2. Block Architecture [2].

C. Blockchain Layers

From the Blockchain Technology (BT) layer perspective, there are six layers in the blockchain network, as depicted in Fig. 3. The blockchain network contains several layers to execute specialized activities [20,21]. The data layer provides cryptographic techniques that store data in the hash, Merkle tree, and timestamp value forms in both on-chain (Blockchain) and off-chain (database) settings. The network layer manages all of the nodes in the blockchain network. At the network layer, this level of security and privacy is made sure to stay in place by a decentralized P2P environment. At the same time, transaction consistency is managed by consensus mechanisms located at the consensus layer. The mining process rewards successful miners. It is managed in the incentive layer. The condition of the smart contract in the Blockchain ecosystem is important to ensure that the security aspects are guaranteed, bug-free, and free from any vulnerabilities. Therefore, the smart contract programme is implemented at the contract layer. The application layer, which connects the end-user to the blockchain network, is the final layer. This layer comprises Blockchain applications (Decentralized Applications (DApps)) that were designed and constructed based on the business case in various sectors.

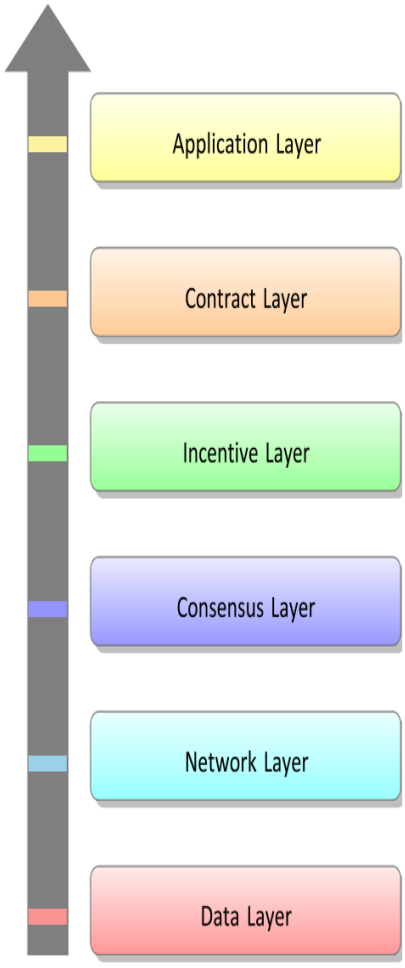

Fig. 3. Six Blockchain Layers [3].

D. Consensus Algorithm

The blockchain network must verify each software's ledger for consistency and clarity. This is performed by a few steps that follow certain rules during the transaction process. The verification process is carried out decentralized, with transactions completed in a distributed environment managed by P2P-connected nodes in the network. The approaches or algorithms utilized to reach a consensus are called consensus algorithms. Fig. 4 shows various widely used consensus algorithms, including Proof of Authority (PoA), PoW, Proof of Stake (PoS), and PBFT. Each node seeking to participate (mining) in the PoW consensus process must contribute resources by completing mathematical problem challenges [14]. This problem has a different level of difficulty. It is a consensus technique used in Bitcoin [1] and Ethereum [22]. In PoS, only one miner can generate new blocks from all participating nodes, while other miners waste incentives and energy resources on the blockchain network [15].

As a result, PoS works better when only those nodes can verify that their shareholders are permitted to participate. It avoids the circumstance where one node owns the network since no single node may hold 51 percent of the network's money[23]. As a result, PoS can efficiently cut energy consumption and reduce the number of miners, and the transaction speed can be boosted compared to PoW. It is critical to obtain mutual understanding in the PoA consensus to ensure the transaction is valid. The node's blocks must be certified by the verified node, and the process continues through the successive rounds as planned [24]. The PBFT consensus refers to a Byzantine military analogy that is difficult to reach consensus if no nodes have reached an agreement. The effort to reach this agreement based on the leaders with the most weight is called the PBFT consensus [25].

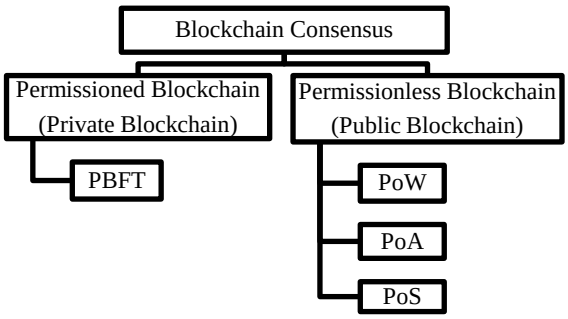

Fig. 4. Blockchain Consensus Algorithm.

E. Bitcoin

Cryptocurrency is one of the most extensively used Blockchain applications today and is used worldwide. Bitcoin and Ether (Ethereum) are two digital currencies commonly used in the crypto realm. Satoshi Nakamoto was the first to introduce Bitcoin, successfully solving the double-spending problem while introducing digital currency use [1]. The Blockchain controls each transaction using a cryptographic process based on hash values on input and output sets from an operational standpoint. Only one input transaction from the whole blockchain network is used to generate the output [26].

Aside from that, Blockchain is linked to a P2P ecosystem for transaction management and network ownership. The decentralization of Blockchain is a clear distinction between traditional databases and Blockchain. This implies that each network node is accountable for storing a copy of the ledger [19]. In the Bitcoin ecosystem, anyone can participate in the network. This feature is why Bitcoin is known by the term "incentive" or "reward" through the PoW consensus given to miners who successfully perform the mining process. As such, this Blockchain operates in a decentralized manner, which means it does not require a centralized body compared to traditional financial systems, which are centralized in nature. In this process, the miner gets paid a few Bitcoins after completing the operation.The mining process is secure because it involves hashed and encrypted transactions using the SHA-256 cryptographic technique. The popularity of Bitcoin as a Blockchain application for managing cryptocurrencies has prompted the development of several other crypto and DApps.

F. Ethereum

Buterin's paper [27] launched Ethereum and solved various problems with Bitcoin's scripting language. Ethereum had added transaction list and state information in the block header compared to before, which only contained information such as nonce, difficulty, and block number. A new state will be formed based on the previous state in the transaction list. The notable difference between Bitcoin and Ethereum is the cryptographic protocol used. Ethereum uses Keccak 256 bits while Bitcoin uses SHA-256. Thus, the header block in Ethereum consists of hashes for gas fee information, timestamp, parent block header, root state, and additional hashes for verification process purposes [28]. Ethereum provides a decentralized ecosystem for developers to develop products using the Solidity language and Ethereum Virtual Machine (EVM). The Solidity language is used to develop smart contract programmes based on business cases to be executed and converted to byte code in EVM [26].

G. Smart Contract

Historically, the idea of contract management has traditionally inspired the introduction of digital smart contracts by the founder of smart contracts, Szabo [29]. The main purpose of digital smart contracts is to automate traditional contract management. This smart contract is referred to as computer technology with the help of writing programme code to be implemented to automate the contract process. For operational purposes, smart contracts are integrated with Ethereum to be executed and stored in a decentralized ledger. Recently, the use of smart contracts has been widely used in conjunction with BT in various fields [61, 62]. Furthermore, the EVM environment and the Solidity programming language facilitate the development of smart contracts within Ethereum. This development has also attracted researchers to explore smart contracts on the Blockchain.

III. Ensemble Method

Machine Learning (ML) algorithms have been widely applied in both supervised learning and unsupervised learning situations to construct systems capable of making realistic decisions in light of past data. Numerous classification-based ensemble methods have been developed to boost the accuracy of supervised Learning Algorithms (LAs). Therefore, ensemble methods are prominent solutions for boosting the prediction capacity of an ML model. In the competition aspect, the ensemble approach has succeeded in several ML model competitions in which it has participated. For instance, the winner employed an ensemble method to create a robust collaborative filtering algorithm in the popular Netflix Competition [30]. Another example is Knowledge Discovery in Databases (KDD) 2009 when the winner also used ensemble methods [31].

Conceptually, the ensemble approach combines several trained individual classifiers to produce a new classifier. Typically, these individual classifiers are termed weak learners, and their ensemble combination aims to make this model stronger in terms of accuracy. However, among the challenges of using the original model individually is exposure to high variance and bias factors. Therefore, the ensemble strategy can reduce the bias and variance gaps to produce new combinations with better performance results, as illustrated in Fig. 5.

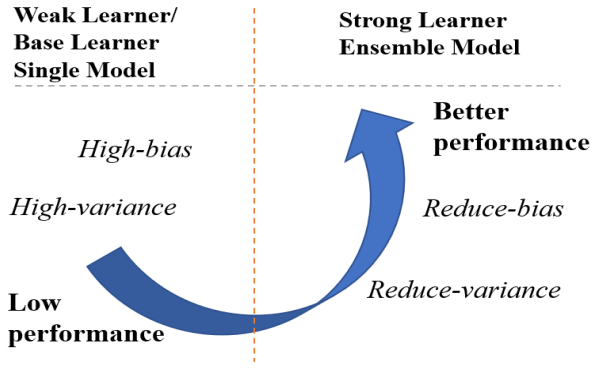

Fig. 5. Weak and Strong Learners.

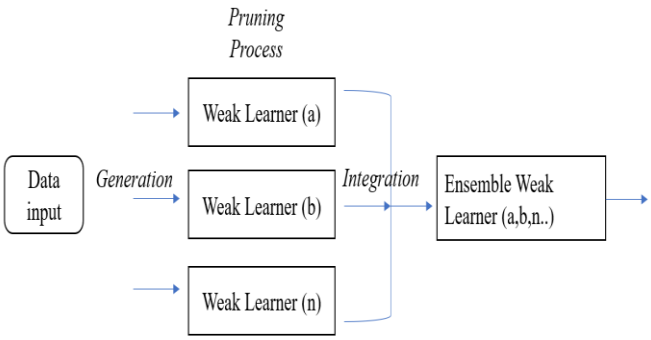

Fig. 6. Typical Process of the Ensemble Method.

With reference to Fig. 6, the process of ensemble generation from data input takes place in the first phase to produce weak learners. Next, the pruning and cleaning process is done for the weak learners. Finally, the combined integration of the weak learners is implemented in the last phase using the selected model. Past research has proven the ensemble approach successfully produces more accurate study results and lower false positive (FP) metrics than individual classifiers. The study also shows that popular ensemble strategies are stacking, bagging, and boosting. The authors [10] has described the ensemble as a variety of combined approaches consisting of the voting method, the averaging method, the stacking method, the bagging method, and the boosting method. According to [32], the ensemble approach can address the shortcomings of traditional ML, such as mathematical, computational, and representation problems. Fig. 7 depicts the ensemble learning methodology and methods. Moreover, the authors explain an ensemble as a model that incorporates the results from numerous other models to remedy the flaws of every situation. Most of this strategy's options can be classified as bagging or boosting [33]. In the averaging approaches, the authors [34] tests with different alternatives of anomaly detection models. The authors believe that choosing a simple average score between different algorithms is a simple and successful solution. Apart from that, the authors define combining the multiple models as needed because they address the problem from diverse aspects [34]. Using ensemble learning, the combination of Random Forest (RF), Extra Trees, and Bagging classifier demonstrated a possible performance by gaining the predictions based on averaging the probabilities derived from these methods [35]. The authors [36] describe how the results generated from the individual classifiers have enhanced their capabilities and have shown improved performance on the study results through the ensemble method. Meanwhile, the study by [113] used a Deep Learning (DL) approach to produce prediction analysis with an ensemble combination for a single classifier based on medical datasets. The study results show that the ensemble technique produces high accuracy values compared to the individual classifiers. Nowadays, more studies lead to new methods or techniques for model optimization compared to before, which is more to developing new models. Among them is a study conducted by the authors [114] using ensemble techniques to develop a new model optimization method for the prediction of taxological applications. The experimental results in this study show that the ensemble technique produces better results than the single classifier.

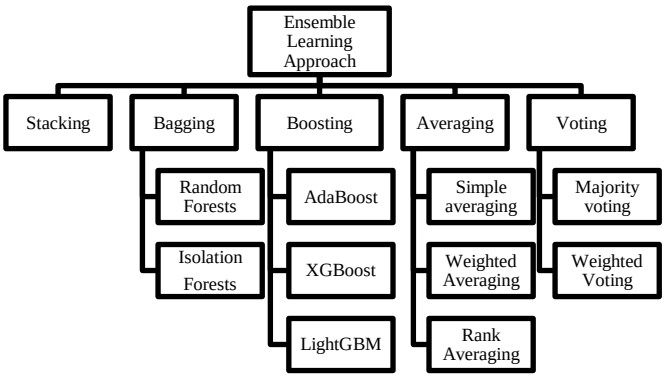

Fig. 7. Ensemble Learning Approach.

A. Voting

Voting is the easiest ensemble procedure. Among the main techniques of the voting ensemble is the majority voting ensemble, sometimes called the max voting ensemble. This is an ensemble strategy that combines multiple different types of individual classifiers. The desire to increase performance from individual models is an essential strategy. For classification and regression, ensemble voting might be used. The mean value of the forecast is derived using the regression approach. In the classification approach, labelling is based on the number of prediction outcomes tagged and the majority of votes. In practice, ensemble voting is appropriate when all individual models show good performance. Fig. 8 illustrates a voting ensemble learning illustration. In a study by [37], the majority voting-based ensemble model method was used. The results successfully detected network traffic as if there had been an attack on the Intrusion Detection System (IDS). In this research, the authors [37] mentioned that many classifiers were employed for training and testing, and final findings were attained utilizing the voting approach. Aside from the majority vote approach, the researchers chose to perform the investigation using the weighted voting method. Repeated calculations on the model prediction are used in the weighted voting method to produce a favourable result from the standpoint of the ballot weights. In the current work, weighted majority voting was used to categorize the data, where Particle Swarm Optimization (PSO) was employed for allocating weights to several classifiers [37].

B. Averaging

Using the averaging method, the simplest strategy for making predictions from dataset inputs is based on average values. In general, this method generates a better regression model and reduces overfitting. Nevertheless, this averaging variant is slightly modified to be a weighted average model. The prediction generated from this model is calculated based on the average value generated from the multiplication operation by the weights on each model. Rank averaging is the process of allocating ranks to individual models based on the weight to be assigned to each model. The method of averaging and determining the maximum score is one of the combination methods that can be used. The findings of the pilot experiment reveal that weighted averaging has been utilized to normalize the anomaly scores. This is done before combining the method to balance the results of unbalanced for different algorithms with different datasets [38]. The weighted average is the result of the study's final output based on the method of grouping the list of scores and assigning a weighting value that is inversely proportionate to the group size possessed by each list of scores, according to [39]. Fig. 9 illustrates the average ensemble learning demonstration.

C. Stacking

Stacking, or layered generalization, is an alternative way of integrating numerous models. In the stacking technique, various individual (multiple) models have been integrated. Among them are logistic regression (LR), Naïve Bayes (NB), and Decision Tree (DT). The learning approach of stacking is for merging the expectations of several classification models into a single meta-classifier [31]. Meanwhile, the authors [40] explained that stacking techniques in the ML approach could produce a more powerful model. This is implemented through training on datasets on individual models to improve accuracy. Basically, the stacking method uses the predictions made by a single model to make another model.

From an operational point of view, the stacking technique is carried out sequentially. The process begins by training several selected individual models using a dataset sample. Subsequently, the production probability results from each individual model go through a fine-tuned process before being combined into a final model. This procedure is performed repeatedly depending on the number of stacking layers you want to use. Finally, the final output is formed based on the final output generated by several individual models in the last layer. Therefore, the individual models generated at this end layer are known as meta-classifiers. According to [41], the learning output at the base layer determines the final output produced by the stacking method. Fig. 10 depicts the usual two-layer stacking modelling approach.

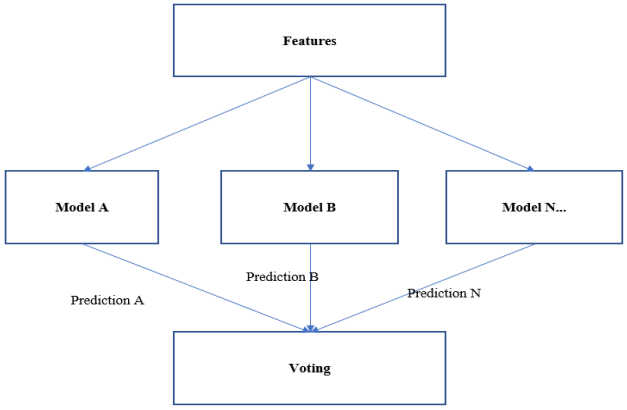

Fig. 8. Voting Ensemble Learning Illustration.

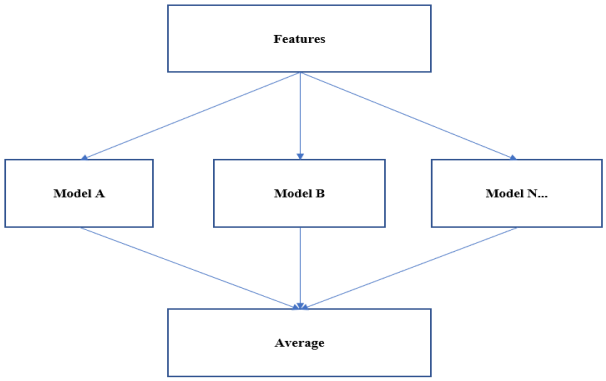

Fig. 9. Averaging Ensemble Learning Illustration.

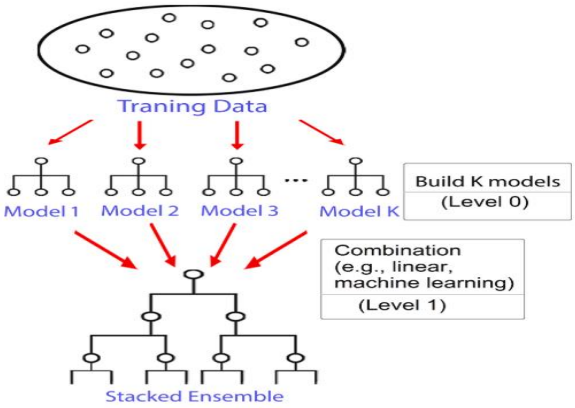

Fig. 10. Stacking Ensemble Learning Illustration[6].

D. Bagging

The bootstrap aggregating (bagging) was first described in [43]. It is one of the simplest ensemble approaches and is best suited for issues involving small training datasets. Sequential and parallel ensemble methods are the two predominant paradigms for constructing ensemble models. Technically, various series of datasets are formed through random extraction from samples of the original data set, and these data sets are used to train different models. Then, voting is used to aggregate the results of the models to form a single output. Bagging is used in regression and classification to improve the precision of ML algorithms. Besides, bagging also utilizes the most prevalent techniques for combining the outputs of base learners, namely averaging for regression issues and voting for classification tasks. Among the algorithms commonly used in the bagging technique is the DT. According to [44], this algorithm can be compatible with weak models and have high variance. However, apart from the DT, other model classifications such as K-Nearest Neighbour (KNN) and NB are also used in the bagging technique. Furthermore, creating a model using a simple method that incorporates large and complex data is impossible. Consequently, bagging approaches are ideal for managing both high-dimensional and large-capacity data. Fig. 11 depicts an illustration of the Bagging algorithm procedure.

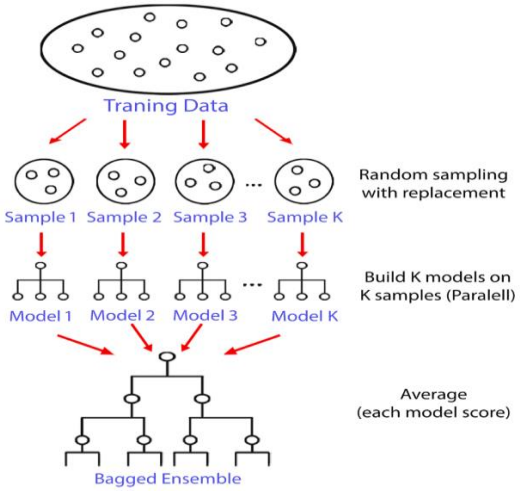

Fig. 11. Bagging Ensemble Learning Illustration[6].

1) Random Forest (RF): RF was introduced in 2002 by Breiman. The Random Forest is, as its name suggests, a forest comprised of numerous trees. In general, RF (Tree-Based) use a DT as an individual model, which generates a set of random parameters as the value of dependence on each tree. Similar to other ensemble algorithms, RF produces predictions by combining numerous separate models. Basically, the RF procedure consists of multiple steps. First, bootstrap samples were randomly generated from the dataset. Then, the prediction results of each tree will be obtained from the construction of the DT based on the data sample. Lastly is the implementation in the voting phase to produce the final output. In this last phase, the model that gives the most accurate prediction results will be selected [45].

2) Isolation Forest (IF): The Isolation Forest (IF) algorithm was first proposed in 2008 [46]. Like any other tree ensemble method, this approach is based on DT. It operates on the premise that an individual who is easier to distinguish from others in a random sub dataset of the feature space must be an outlier. It begins by drawing a random sample from the dataset and selecting a random dimension. Correspondingly, a random value within the range of that dimension is selected to precisely divide the sample into two pieces. Next, the root node of a tree is built using the selected dimension and splitting point. Further nodes are produced recursively for subsamples until a subdivision is impossible or an arbitrary tree depth is attained. In this tree, a point closer to the root node correlates to a situation more likely to be isolated. Nevertheless, this could be due to random chance. Therefore, the entire tree generation technique is repeated for additional samples until the necessary number of trees is achieved. Note that the anomaly score is computed using the mean traversal path length of the trees. The authors of [46] claim that their algorithm is superior to other alternatives for addressing masking difficulties (clusters of anomalies) and swamping problems (mistakenly identifying normal situations as being surrounded by anomalies).

E. Boosting

Boosting is a strategy for enhancing the performance and accuracy of the ML approach by transforming weak base learners into strong ones [47] as shown in Fig. 12. The fundamental premise of the boosting strategy is to sequentially add new models to the ensemble. In general, the boosting technique generates a sample of training data randomly with the replacement of the main dataset sequentially. In this procedure, a sequence of models is learned. The process begins by providing training on the weak model using a training dataset to produce a second model after fixing the weaknesses in the first model. Subsequently, a third model was produced that overcame the weaknesses of the previous two models. This process will continue until all the mistakes are fixed and the final model is made. Last, a technique weighted majority voting was used to build the final model from the weak model [48,49]. Boosting techniques have been proven to increase accuracy and reduce bias and variance. Among the algorithms widely used in boosting techniques are

Adaptive Boosting (AdaBoost), Extreme Gradient Boosting (XGBoost), and Light Gradient Boosted Machine (LightGBM).

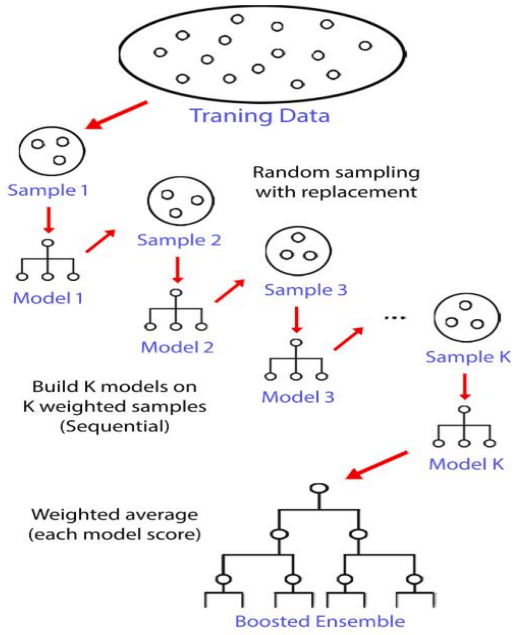

Fig. 12. Boosting Ensemble Learning Illustration [6].

1) Adaptive Boosting (AdaBoost): AdaBoost was the first truly successful binary classification boosting method. It was originally referred to by its inventors as AdaBoost.M1 [50]. Recently, it has been referred to as "discrete AdaBoost" because it is utilized for classification instead of regression. AdaBoost, like other approaches, may be used to increase the performance of any ML model and can be used for learners with low intelligence. This strategy works by turning weak learners into strong ones by getting rid of them by correcting their mistakes over and over again iteratively. The weighted training dataset is used to train weak learners in succession. Subsequently, numerous weak learners are joined to become a single powerful learner. Finally, the weight voting method on the weaker model was used to determine the stronger final model [50]. Besides, one-level DT is the best-suited and, thus, the most popular algorithm employed with AdaBoost. Since these trees are so short and contain only one classification decision, they are often referred to as decision stumps.

2) Extreme Gradient Boosting (XGBoost): Extreme Gradient Boosting, or XGBoost, is a scalable ML approach for tree boosting that was presented by Chen and Guestrin [51]. XGBoost is a gradient boosting-based model that uses additional boosting strategies to produce predictions more accurately compared to other gradient boosting models [52]. Therefore, the advantages of this technique have been acknowledged in various fields of ML and data science. For example, a total of 17 winners used the XGBoost technique out of a total of 29 winners to complete one solution contest as well as be featured in the Kaggle blog [53]. XGBoost uses the advantages of boosted tree algorithms to produce accurate and scalable boosting gradients. Moreover, XGBoost has been designed with fast computer processing and improved ML model performance in mind. In general, XGBoost works in parallel to generate trees. This process is implemented level by level to produce predictions on each iteration from weak learners. As a result, each of these iterations can improve the errors of their predecessors. The final result of prediction with a combination of individual models and these mechanisms is the same as with other ensemble approaches.

3) Light Gradient Boosted Machine (LightGBM): LightGBM, or Light Gradient Boosted Machine, was described by Guolin Ke et al. in 2017 [54]. LightGBM is a gradient boosting implementation aimed to be efficient and possibly more successful than previous gradient boosting implementations. According to the authors [54], the solution includes two main concepts: 1) Gradient-based One-Side Sampling (GOSS); and 2) Exclusive Feature Bundling (EFB). GOSS is a variation on the gradient boosting approach that prioritizes training samples that provide a greater gradient, accelerating learning and minimizing the method's computing complexity. In contrast, EFB is a method for combining sparse (mainly zero) mutually exclusive features, such as one-hot encoded categorical variable inputs. Consequently, this is a form of automatic feature selection. Through this concept, LightGBM has adapted a tree algorithm capable of producing high performance, classification, ranking, and various tasks in ML. Besides, LightGBM is a fast, more efficient, less memory-intensive, more accurate than any other boosting algorithm, compatible with large datasets, and gradient boosting framework. Normally, the DT through the boosting method is determined based on their level or depth. Nevertheless, this approach differs from LightGBM, which divides the tree based on the optimal leaf. Therefore, this approach provides a high level of accuracy by minimizing the level of loss and is an achievement that is rarely achieved by any existing booster algorithm.

IV. Ensemble Anomaly Detection in Blockchain

Nowadays, the development of Blockchain Technology (BT) is not just focused on the world of cryptocurrency but its expansion to Decentralized Applications (DApps) in various fields. Following this, the features available in BT have provided advantages in terms of transparency, immutability, enhanced security level, fast transactions, and high privacy. As a result, we see many applications that use BT in various sectors, namely finance, supply chain, halal products, pharmaceuticals, education, government, etc. In cryptocurrency, Bitcoin and Ethereum are the most popular and widely used applications due to their high market capitalization and trading volume. Apart from that, Bitcoin constitutes about 39.53 percent of the market's entire value [55]. At the same time, Ether is the second-biggest cryptocurrency [3]. Meanwhile, Ethereum is the largest and most widely used decentralized Blockchain platform for smart contract adaptation. The widespread use of Bitcoin, as well as Ethereum, has given rise to some critical issues in the aspects of cybercrime and security. As a result, many have become

victims of various frauds, such as phishing and Ponzi Schemes, after detecting more than 10 percent of Initial Coin Offering (ICO) on Ethereum. Generally, the Ethereum blockchain network is a public distributed ledger with around 1.158 million daily transactions [56] and is categorized as big data. Therefore, manually combing through all of these transactions to find any transactions suspected of exhibiting unusual characteristics would be impracticable and interminable. Based on this scenario, Machine Learning (ML) algorithms would help differentiate between transactions that exhibit normal and abnormal behavior among user accounts by learning the attributes that correspond to either normal or abnormal conduct.Therefore, an approach to detecting transactions that show abnormalities was introduced, known as the abnormal detection method. Nowadays, this method is increasingly used in various fields to detect patterns of abnormalities, especially its role in the Blockchain ecosystem. The detection model developed using the ML model helps detect and predict the initial attacks on the blockchain network. Fig. 13 offers data visualization for normal and anomalous transactions to better understand anomaly transactions. Oddities or unusual occurrences have the same meaning as deviations, noise, novelties, exceptions, and outliers [7]. Clearly, the combination of Blockchain and ML technology positively benefits both parties, as shown in Fig. 14. The Blockchain ecosystem is known for its overly large data storage nature and can be declared big data. There is also data from external sources such as smart devices, the Internet of Things (IoT), and external applications that store data in a database (off-chain). Thus, data from various sources is analyzed using ML techniques to produce analytical dashboards, predictions, visualizations, and others that can help with planning, monitoring, and decisions.

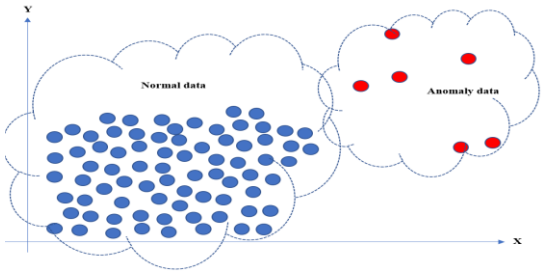

Fig. 13. Data Visualization for Normal & Anomaly.

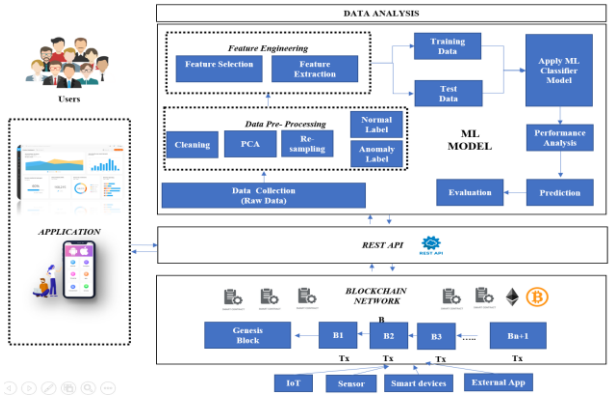

Fig. 14. Connection between Blockchain and ML.

In earlier study, numerous ML algorithms have been applied in supervised [57] and unsupervised learning [58] for anomaly detection in blockchain networks. Random Forest (RF) [59], Decision Tree (DT) (j48) [60], Extreme Gradient Boosting (XGBoost) [61], Adaptive Boosting (AdaBoost) [62], secureSVM [63], Light Gradient Boosted Machine (LightGBM) [64], K-Nearest Neighbour (KNN) [65], Support Vector Machines (SVM) [66], Naïve Bayes (NB) [67] and Isolation Forest (IF) [68] are examples of supervised learning models. Among the models in unsupervised learning that have been utilized are One Class Support Vector Machine (OCSVM) [69], K-means [70], Density Based Spatial Clustering of Application with Noise (DBSCAN) [71] and Long Short Term Memory (LSTM) [72]. This article evaluates the ensemble learning method for detecting anomalous or criminal transactions in blockchain networks. Ensemble learning gave good results and great performance in the experiments for recognizing malicious Ethereum entities [73]. Moreover, the authors execute ensemble learning, a mixture of ML predictors that wins over other classical learning approaches at predicting licit and illegitimate transactions. In the experiment, ensemble learning can be characterized as a classification method based on an average probability ensemble constructed from the collection of best-performing supervised learning methods employed in our experiment [35]. However, individual classifiers are troublesome for processing high-complexity data, according to [74] research. Consequently, this issue has been handled by developing a classification model utilizing the ensemble approach. In a Proof of Concept (PoC) development project for the decentralized unmanned aerial vehicle (UAV), the ensemble stacking method was applied to a variety of individual models to assess its predictive accuracy [75].The completed literature evaluation led to the classification of prior research articles about the addressed applications published from 2017–2022. Publications were divided into four aspects: anomaly detection in cybercrime (see Table I), security (see Table II), information processing (see Table III) and smart devices (see Table IV).

A. An Anomaly in the Aspect of Cybercrime

Cybercrime means using computers, tools or materials with the intent to do illegal things [76]. BT's openness, transparency, and immutability have prompted malicious parties to commit criminal activities. Most cyberattacks are performed for financial benefits. In the cryptocurrency era, hackers are prompted to get their ransoms in cryptocurrencies, as it provides the advantage of anonymity and easy transfer across countries. Therefore, among the effective methods is to use ML techniques to detect abnormalities in blockchain network transactions. Many previous studies have reported detecting transaction abnormalities using the approach of the abnormality detection method. Thus, in this review, we identified 31 publications that apply the cybercrime aspect in the selected papers, as shown in Table I. Referring to Table I, cybercrime aspects are categorized according to the type of application case, namely smart contracts, illicit transactions, scams (pump and dump), fraud detection, ransomware, Ponzi Schemes, money laundering, High Yield Investment Program (HYIP), and phishing, as shown in Fig. 15.

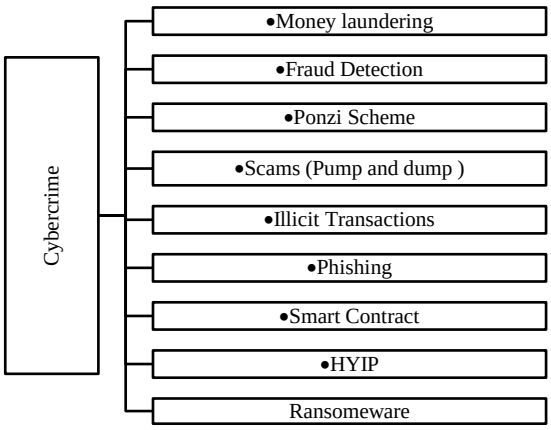

Fig. 15. Classification of Application in the Cybercrime Aspect.

As indicated in Table I, an RF was the most commonly utilized ensemble model (based learner) in the chosen research publications. In addition, 20 research publications utilized bagging as an ensemble approach, and 11 research papers embraced the boosting method. Furthermore, we uncovered 24 research articles utilized in Bitcoin and Ethereum. Since developing an ML model relies on the dataset, we analyzed the data source of ML models for anomaly detection applied in the selected research publications. The analysis of data sources has shown that 30 different types of data sets were used in the experiment. In earlier investigations, it was observed that there are numerous ways employed in the ensemble learning method. Among them is combining ensemble approaches or tactics to produce a good result. The review papers describe numerous techniques for this hybrid scenario, including bagging with voting, bagging with averaging, bagging with boosting and bagging with stacking.

The authors [77] suggested a pre-encryption detection algorithm (PEDA) that seeks to identify ransomware using an ML approach to assess and categorize ransomware using the bagging and voting (majority voting) ensemble learning technique. This research was conducted in Phase 1 and Phase 2 using a dataset created by Resilient Information System Security (RISS) from Imperial College, London. Nevertheless, the focus of this study is the focus on Learning Algorithm (LA) implemented in Phase 1. In general, LA works through an ensemble DT approach. First, the simulations of the LA model were implemented using the Application Programme Interface (API) data generated by suspicious software for inspection. Then, performance measurement analysis was performed by comparing the LA model with three other models, namely NB, RF, and ensemble techniques (RF and NB). Finally, this model was selected using the majority voting method. The results of this experiment have shown that the LA model produces better performance compared to the individual models' RF, NB and the ensemble models (RF and NB). Measurement metrics use detection rate (DR), False Positive Rate (FPR), Under Area the ROC Curve (AUC), and test error values.

TABLE I. SUMMARY OF PREVIOUS RESEARCH USING ENSEMBLE METHOD IN CYBERCRIME ASPECT

Ref.	Year	Blockchain Application	Application	Ensemble method applied	Model/Based learners	Tools/Dataset
[79]	2017	Bitcoin	Fraud detection	Bagging	Random Forest	Public Dataset

[74]	2022	Cryptocurrency	Anomaly Detection	Boosting, Stacking	SVM, KNN Logistic, DT, MLP	Kaggle

Adapting ensemble techniques has also worked well in networking, where they have been used to predict both licit and illicit transactions [35]. In this experiment, the approach of bagging with averaging technique has been applied to anticipate licit and criminal transactions in the blockchain network. The proposed approach of an ensemble (RF, Extra Trees, and Bagging classifiers) has fared the best with a comparison of RF, Multilayer Perceptron (MLP), and Logistic Regression (LR). In an average probability ensemble, the classification is done by employing numerous pre-trained ML models. The final predictions are formed by averaging the summation of the prediction probabilities received from the LAs. Note that the results demonstrate that ensemble learning is able to execute classification with an accuracy (98.13 percent) and F1 score (83.36 percent) to forecast licit and illegal transactions.

The authors [78] gives a comprehensive evaluation of different supervised ML algorithms, such as bagging models (RF), boosting models (AdaBoost), and others, to prevent fraud. This research concluded that utilizing AdaBoost and RF classifier produced the best performance result among the other seven algorithms.

Feature selection in the ensemble approach plays an important role in producing better results. This has been demonstrated by [74], who conducted studies on the use of feature selection and without feature selection. This simulation is performed by comparing the use of feature selection with that without feature selection in the ensemble classifier (boosting, stacking). The final results have shown that there is an increase in the value of F-Score (7 to 9 percent) and accuracy (2 to 3 percent).

B. An Anomaly in the Aspect of Security

BT does not guarantee freedom from security issues. Therefore, there is a need to establish risk management through a comprehensive cyber security framework and undergo security assessment services to protect against attacks and abuse by hackers. This security issue has been researched and has found a total of 31 research papers involved in the study on the aspect of security, as shown in Table II. This in-depth study uses ensemble techniques to find anomalous transactions in a blockchain network. According to Table II, security elements are largely split into backdoor assaults, vulnerability identification, crypto-jacking, under-priced Denial of Service (DoS) attacks, intrusion detection, miner detection, malware, cybersecurity framework, protection of private information, botnet and malicious account detection, and so on, as shown in Fig. 16.

As shown in Table II, an RF was the most commonly utilized ensemble model (based learner) in the selected research publications. In addition, four research publications utilized bagging as an ensemble approach, two research papers adopted the stacking method, and 1 research study applied to boost and to vote. Moreover, we identified four research publications that have been used in Ethereum. The utilization of datasets is the crucial component of ML model construction. Consequently, this study's analysis considers the datasets utilized in prior studies. As a consequence, it was determined that the selected research utilized five distinct types of data sets. In the ensemble approach, a combination of several ensemble (hybrid) techniques is used to achieve better performance in the study. Among them are: In reviewing investigations for security considerations, it was determined that two research publications used combined ensemble methods or strategies to achieve a decent outcome. In addition, there is one research paper that utilized the stacking with boosting strategy and one paper that used the bagging with the voting approach. The authors [73] offered strategies for detecting malicious entities that employ versions of RF, SVM, LR, and ensemble methods with stacking and boosting (AdaBoost Classifier). With an average F1 score of 0.996, the study's findings demonstrate that the ensemble technique yields effective outcomes. This study's strategy is to establish a framework for identifying entities that potentially do harm to blockchain networks.

The conventional Exploratory Data Analysis (EDA) methodology is implemented via data collection, feature extraction, model training, model testing, and final outcomes evaluation to achieve this objective. The study's results also demonstrated that feature extraction is an effective strategy for achieving positive outcomes.The research on under-priced DoS assaults was proposed by the authors [99]. In this study, the simulation method is implemented on the transaction using several input features, namely pending time, value, gas price, and gas. Several ML models were used in this study, such as NB, SVM, KNN, RF, and DT. While the voting technique, which consists of two criteria, namely majority vote (hard) and average confidence (soft), is practiced. This study concluded that the experimental results had shown good performance in detecting under-priced DoS attacks. Conventional UAVs generally depend upon the centralized server to execute data processing with complicated ML techniques. In reality, all classic cyberattacks are relevant to data transmission and storage in UAVs. In this regard, [75] proposes to boost the performance of UAVs with a decentralized ML architecture based on Blockchain. In general, UAV or drone technology uses centralized data processing technology. Unlike a decentralized Blockchain, it is vulnerable to cyberattacks on storage and transactions. Thus, [75] has studied this matter by providing added value using the ML method in Blockchain applications to generate prediction analysis and improve UAV performance. This study also aims to prove that the centralized ML model approach has improved resource utilization and overhead performance. Following this, the decentralization of the ML model is a wise move to produce high-quality forecasting. Therefore, this study conducted two experiments using stacking techniques and without stacking. This study found that using PoC stacking has made forecasting analysis more accurate.

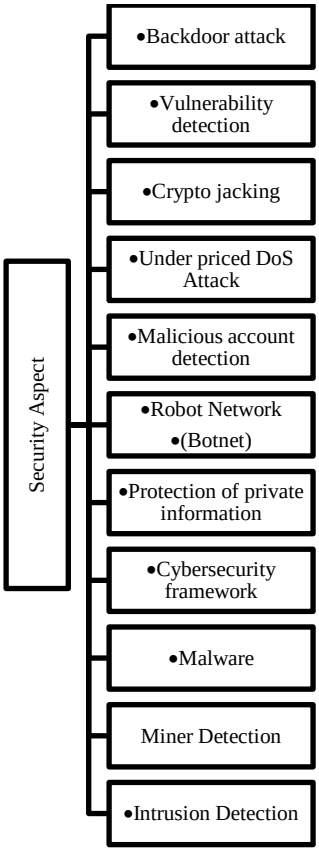

Fig. 16. Classification of the Security Aspect.

C. An Anomaly in the Aspect of Information Processing

Information processing is capturing, recording, organizing, retrieving, displaying, and disseminating information. The word has often been applied to computer-based activities in recent years. In this part, we identified 31 papers that apply the information processing characteristics in the selected publications. The list of these applications shows in Table III. According to Table III and Fig. 17, information processing components are primarily categorized as Blockchain simulator, performance testing, network traffic, social media, data analysis, address identification, performance testing, transaction clustering and behavioural pattern

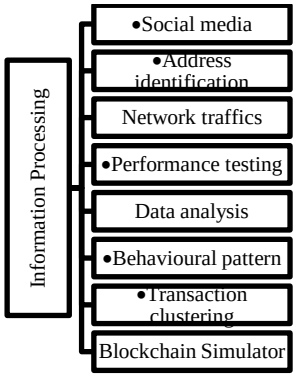

Fig. 17. Classification of Information Processing Aspect.

TABLE II. SUMMARY OF PREVIOUS RESEARCH USING ENSEMBLE METHOD IN THE SECURITY ASPECT

Ref.	Year	Blockchain Application	Application	Ensemble method applied	Model/Based learners	Tools/Dataset
[67]	2019	Ethereum	Vulnerability detection	Bagging	Random Forest	Etherscan API
[73]	2020	Ethereum	Malicious Transaction	Stacking, Boosting	Random Forest, Stacking Classifier, AdaBoost	Ethereum Client, Etherscan API
[100]	2020	Blockchain-based	Crypto-jacking	Bagging	Random Forest	VirusTotal
[101]	2021	Ethereum	Malicious Account	Bagging	Tree-based	Etherscan API
[99]	2021	Ethereum	Under-priced DoS attack	Bagging,Voting	DT, Random Forest,KNN, SVM	Ganache
[75]	2021	Blockchain-based	intrusion detection	Stacking	KNN, NB, SGD, Onevsrest, Logreg	KDD99 attack dataset

TABLE III. SUMMARY OF PREVIOUS RESEARCH USING ENSEMBLE METHOD IN INFORMATION PROCESSING ASPECT

Ref.	Year	Blockchain Application	Application	Ensemble method applied	Model / Based learners	Tools/Dataset
[64]	2019	Bitcoin	Address Identification	Boosting	LightGBM	WalletExplorer, Blockchain.info, BitcoinTalk
[103]	2019	Bitcoin	Network Traffic	Bagging	Random Forest	WalletExplorer
[102]	2019	Bitcoin	Data Analysis	Stacking	Random Forest Gradient Boosting (GB)	WalletExplorer

As indicated in Table III, there are three research articles, and the most commonly employed ensemble model (based learner) in the selected research papers was an RF. In addition, one research paper utilized bagging as an ensemble approach, one research paper adopted the stacking method, and one research paper applied to boosting method. Furthermore, we uncovered three scientific publications that have been utilized in Bitcoin. Finally, note that the development of the ML model depends on dataset input. Thus, this analysis has looked at three different types of data sources used in selected studies. In this study, the authors in [102] employs cascading ML principles—a sort of ensemble learning employing stacking techniques. This study's simulations utilized weak classifiers, GB and RF. As a result, the ensemble stacking method yielded effective classification outcomes based on F1-score, recall, and accuracy values.

The voting-based method developed by the authors [103] aims to improve the level of tracking of Bitcoin performance by labeling addresses controlled by the same user. This study uses Bitcoin datasets taken from previous study publications [104,81] and WalletExplorer. Through simulations on Bitcoin addresses of 200K, we found that the voting method produces better results than the non-voting method in terms of F1 score, recall, and precision. Labeling using supervised learning methods was used to develop a model classification for detecting anomalies in Bitcoin addresses [64]. Therefore, this experiment was conducted using eight main classifiers, namely LightGBM, XGBoost, NN, AdaBoost, RF, SVM, Perceptron, and LR. The experiment showed that the LightGBM classifier produced the best results with a micro/macro score value of F1 (97 percent/86 percent).

D. An Anomaly in the Aspect of Smart Devices

Smart devices are generally IoT gadgets with support for Internet connectivity. They can interact with other devices over the Internet and offer remote access to a user for operating the device as per their needs. In this section, we selected three papers exploring smart device applications. The list of these applications is shown in Table IV. According to Table IV, smart device characteristics are largely grouped, as illustrated in Fig. 18.

As indicated in Table IV, there are two research articles, and the most often employed ensemble model (based learner) in the selected research papers was XGBoost and Adaboost. In addition, two research publications utilized boosting. Furthermore, we located 1 research paper used in the Blockchain-based Blockchain simulator. From the perspective of datasets, the study has identified four distinct dataset categories used in the selected studies. This is because the ML model to be constructed is dependent on the dataset used.

The authors in [61] describe the design and architecture of our Blockchain simulator, BlockEval, which simulates the behaviour of concurrent activities in a real-life Blockchain system. This research confirmed the correctness of our simulator by comparing it with an independent model constructed using genuine Bitcoin transaction data. XGBoost is a non-parametric supervised LA used for classification and regression. The goal value is anticipated by learning simple decision rules inferred from data attributes. Simulation results have been drawn up to 2000 nodes, which have been checked against actual Bitcoin data. However, there is a scope of enhancement to both the simulator and the validation architecture. For instance, adding propagation latency data with a suitable variance will increase the accuracy of simulation findings. IoT-related research has been undertaken

by [42], concentrating on data integrity and security. An important thing to perform is to discover irregularities in data transactions using ML approaches. Hence, the IoTID20 dataset, consisting of 80 characteristics (62578 records), was utilized for training the model to be constructed. This study was conducted by taking 15 traits designated as normal and abnormal. During this investigation, different model classifications were trained based on measurement parameters such as F1 score, recall, precision, and accuracy. The experimental results reveal that the AdaBoost and RF algorithms provide similar results and are among the highest classifiers with good performance.

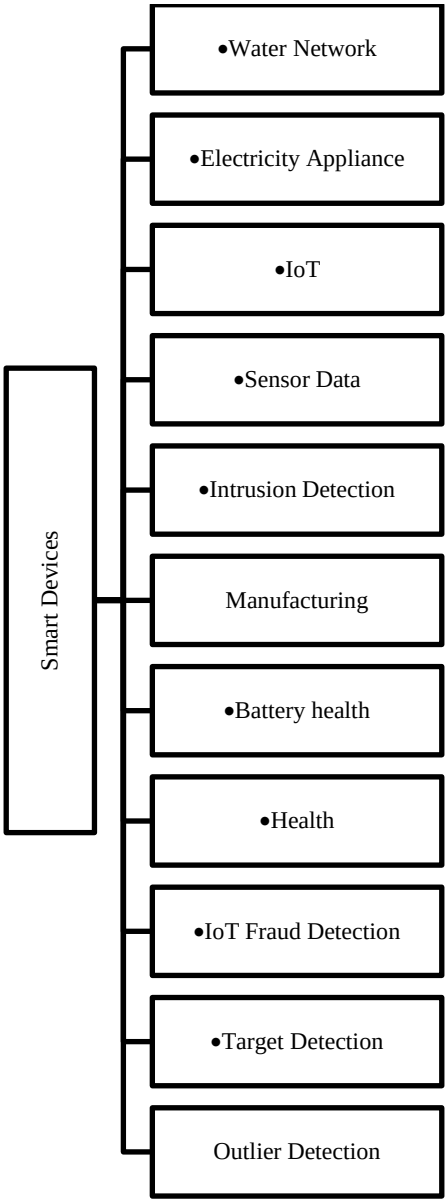

Fig. 18. Classification of Smart Devices Aspect.

TABLE IV. SUMMARY OF PREVIOUS RESEARCH USING ENSEMBLE METHOD IN SMART DEVICES ASPECT

Ref.	Year	Blockchain Application	Application	Ensemble method applied	Model/Based learners	Tools/Dataset
[61]	2021	Blockchain simulator	IoT	Boosting	XGBoost	Bitcoin-transaction, blockchain.info, Bitcoins
[105]	2022	Blockchain-based	IoT	Boosting	Adaboost, Random Forest, DT, NB, KNN	IoTID20

V. Discussion

As demonstrated in Tables I to IV, several studies have been conducted and published since the creation and application of Machine Learning (ML) algorithms in blockchain networks. In this investigation, the researchers' implementation of the ensemble method has demonstrated an improvement pattern. The ensemble strategy is based on combining multiple individual models to generate a model with superior performance compared to a poor classifier. As a result, researchers are continually on the lookout for procedures or processes that provide better results over time than present approaches. Consequently, the strategy of merging multiple ensemble algorithms can give superior results compared to the use of individual ensemble algorithms. Combining stacking and boosting (stacking and boosting) can improve performance, for instance.

According to Fig. 19, 51 percent of the research articles analyzed used the bagging technique, and this technique was used the most in the selected research. Besides, 27 percent utilized the boosting method, while 7 percent applied both the bagging and boosting procedures. In comparison, 5 percent of research articles employed both boosting and stacking. Furthermore, 3 percent employed the stacking and averaging strategy. Lastly, 2 percent of the research studies incorporated both (bagging and voting) and both (bagging and averaging) (bagging and averaging).

According to Fig. 20, we exhibited 17 distinct ML models that academicians have implemented, with the most usually employed being Random Forest (RF) (27 research articles) (27 research papers). On the other side, seven research publications utilized the Extreme Gradient Boosting (XGBoost) model, while four research studies applied Adaptive Boosting (AdaBoost) and Support Vector Machines (SVM) models. In contrast, three of the study articles employed Decision Tree (DT), Naïve Bayes (NB) and K-Nearest Neighbour (KNN).

Analyzing ensemble learning research in cybercrime, security, smart devices, and information processing employing an ensemble approach with distinct techniques (e.g., voting, averaging, stacking, bagging and boosting) for anomaly detection is in blockchain networks. Moreover, we found research in the cybercrime aspect (16 research articles) as the most popular for anomaly identification in the blockchain network. On the other hand, five research publications focused on security aspects, while three research papers focused on information processing. Furthermore, one study paper was applied to the smart device's aspect.

Fig. 21 indicates the fast-increasing tendency of adopting bagging methods in the last four years (from 2017 to 2020) and shows a declining trend in 2021. On the other hand, the research publications utilizing the boosting method show growth from 2017 to 2021. Apart from that, 31 distinct datasets utilized in the experiments of connected papers were found. As depicted in Fig. 22, most experiments utilize real-time datasets retrieved using the Etherscan Application Programme Interface (API).

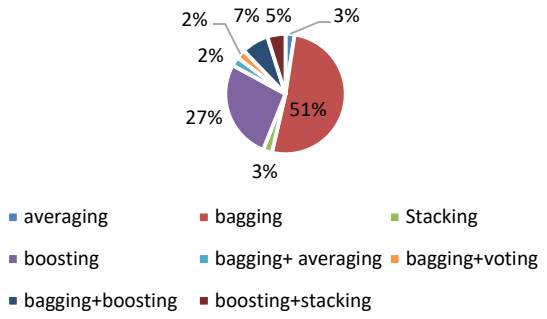

Fig. 19. Percentage of Ensemble Method.

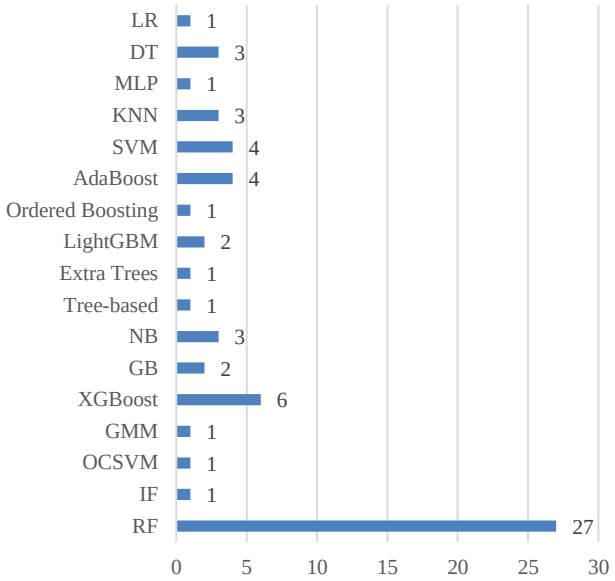

Fig. 20. Frequency of Ensemble Model Base Learner.

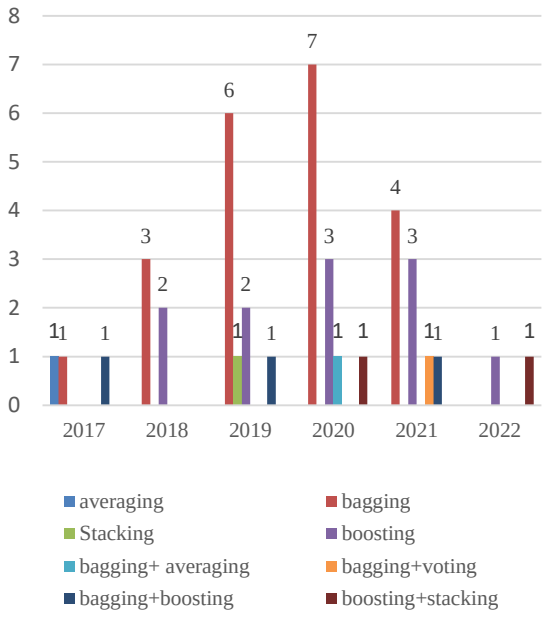

Fig. 21. Anomaly Detection using Ensemble Method Iteration Per Year.

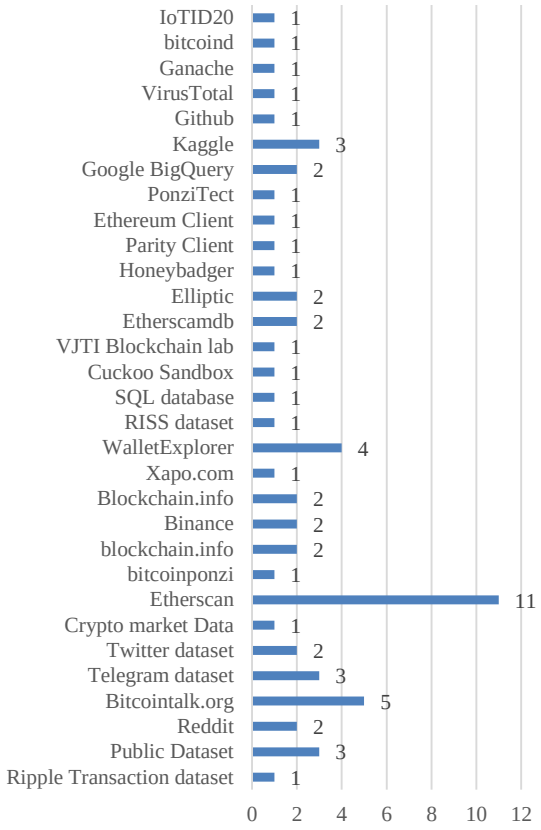

Fig. 22. Utilized Database and Tools in Collected Research Articles.

There are also some prospective challenges in this domain. In addition to analyzing prior studies, several upcoming studies can be highlighted and enhanced. Among these are studies that do not employ feature selection, which has been demonstrated in several prior studies to increase the performance of outcomes. In addition, the majority of studies utilize obsolete data sets. Therefore, it is recommended that researchers regularly update data. This is because scams and cyber assaults contain crucial data in datasets that must be analyzed to develop better trials. This is supported by [106], who concluded that outdated data usage contributed to the efficacy of drop-in attack detection. Furthermore, the authors in [107] concur that researchers should utilize current databases for their studies.

Exploration of new technologies like ML Designer and AutoML affords researchers the option to undertake research. In the study, adapting the strategy of applying feature selection also yielded positive results. This research [74] compared the detection of anomalies using feature selection against those without feature selection. Using synthetic data sources is another way that can aid in the production of more precise research. For example, this strategy was utilized by [108] in employing synthetic credit card data to detect credit card fraud. Additionally, the authors [99] utilized artificial data to imitate network assault activities. Researchers should also look into techniques to automate various preprocessing stages [109], as well as expand and enlarge datasets [110]. In addition, more dedicated preprocessing steps should be adopted for more specific challenges to improve the result of the Ssoft-TeC and give a more appropriate based learner for the co-training scheme [111].

VI. Conclusion

This paper examines the understanding of Blockchain Technology (BT), Blockchain and Machine Learning (ML) integration. It examines previous research on the usage of ensemble approaches as a means of anomaly identification. This investigation demonstrates that assembling strategies can enhance performance and results. The merging of numerous weak models facilitates their unification, resulting in the creation of stronger models. Nevertheless, a mix of ensemble techniques (such as stacking and bagging) can also generate more accurate findings, as demonstrated by several earlier researches.

As demonstrated in Tables I to IV, bagging and boosting are two approaches utilized regularly in the studies over these five years (2017–2020). Nonetheless, we can note that these two strategies are delivering the greatest outcomes largely among research released in 2019 and 2020. In the past two years, we also observed a new trend toward the use of the boosting method. Moreover, from the model employed in the ensemble learning approach, Random Forest (RF) dominated from 2017 to 2020. In 2021, this model declined, whereas Extreme Gradient Boosting (XGBoost) exhibited a growing tendency from 2017 to 2021.

Acknowledgment

This research was conducted to fulfil the requirements for a PhD and with the support of RMIC (UniSZA).

***Abstract*—Arabic language incurs from the shortage of accessible huge datasets for Sentiment Analysis (SA), Machine Learning (ML), and Deep Learning (DL) applications. In this paper, we present MASR, a simple Mobile Applications Arabic Slang Reviews dataset for SA, ML, and DL applications which comprises of 2469 Egyptian Mobile Apps reviews, and help app developers meet user requirements evolution. Our methodology consists of six phases. We collect mobile apps reviews dataset, then apply preprocessing steps, in addition perform SA tasks. To evaluate MASR datasets, first we apply ML classification techniques: K-Nearest Neighbors (K-NN), Support vector machine (SVM), Logistic Regression (LR), and Random Forest (RF), and DL classification technique: Multi-layer Perceptron Neural Network (MLP-NN). From the examination for pervious classification techniques, we adopted a hybrid classification approach combined from the top two ML classifier accuracy results (LR, RF), and DL classifier (MLP-NN). The findings prove the adequacy of a hybrid supervised classification approach for MASR datasets.**

Keywords*—Arabic sentiment analysis; mobile application; hybrid classification model; hybrid supervised classification approach; Google play store; random forest; logistic regression; neural network; multi-layer perceptron neural network; machine learning; deep learning

I. INTRODUCTION

Mobile app stores supply an amazingly wealthy source of information on app specification, characteristics, and utilize, and analyzing these information supplies knowledge and a more profound comprehension of the idea of apps. However, manual analysis of this tremendous measure of information on mobile apps is anything but a basic and clear task; it is expensive as far as human effort and time [1]. There are different mobile app stores, for example, Google, and Apple app store, and others that include free and paid mobile apps [2].

Mobile app classification phase is classified based on a significant category or class. In case users want to investigate and discover an app reasonable for their requirements, it is more helpful to have a special predefined classification scheme by which all apps are classified [3].

Being a significant provenance of data for organizations, the requirement to produce exact SA is a significant issue. Most sentiments accumulated from Arabic resources like social media is in colloquial Arabic, as the utilization of Modern Standard Arabic (MSA) in online is uncommon [4].

A few researches have been directed to analyze English mobile apps [5] [6] [7] [8] [9] [10]. In addition, according to the literature review, few researches have analyzed Islamic Arabic mobile apps and Saudi governmental services mobile apps [1] [11] [12]. However, no previous study has constructed, classified or analyzed Egyptian Dialect Arabic (DA) mobile apps reviews dataset.

The contributions in this research can be summed up as follows:

1) Introduce present MASR, simple Mobile Applications Arabic Slang Reviews of Egyptian reviews dataset for SA, ML and DL applications.

2) Investigate the structure, properties of the dataset, and perform tests on selected attributes for sentiment polarity classification.

3) Apply a various supervised ML, DL classifiers to the simple MASR that we gathered.

4) Adopted a hybrid supervised sentiment analysis classification approach including heterogenous approaches: Machine Learning (ML) approach such as: Logistic Regression (LR), and Random Forest (RF), and Deep Learning (DL) approach: Multi-layer Perceptron Neural Network (MLP-NN) classifiers to enhance the performance models of predicting MASR datasets and accuracy.

5) Compare our proposed model approach performance with various ML, and DL models.

The rest of the paper is organized as follows: Section II presents the literature review. Section III presents the six

phases of our proposed hybrid classification approach methodology. Section IV presents experimental results and discussion. Section V presents conclusion and Section VI presents future works.

II. Literature Review

Slight endeavors have been made to anatomize mobile apps reviews to handle mobile apps requirements evolution, advancement information and significant software. Related previous studies handle many aspects in mining mobile apps reviews for different sentiment analysis purposes such as building lexicons, classifying non-functional requirements, classify buggy apps, recognizing high-rated apps, and hybrid system to find the most similar word in lexicon for Egyptian Arabic tweets.

1) Arabic sentiment analysis tasks: El-Beltagy et al. [13] build a sentimental Egyptian Dialect lexicon. Their tests showed that their proposed methodology gave improved results with regards to twitter even with the poor utilized resources.

Fu et al. [14] dealt with an enormous user reviews dataset including about 13 million mobile apps reviews from google play store. The creators proposed a WisCom framework to recognize the motivations behind why clients dislike specific mobile apps.

Gómez et al. [15] construct mobile apps reviews dataset to evolve a framework that identifies conceivably buggy mobile apps by enforcing a linkage in consent patterns and fault related reviews.

Chen et al. [16] presented a SimApp framework for identifying similar apps utilizing machine learning algorithms. SimApp inspects multimodal different data in app stores. They construct numerous kernel functions to degree app similarity. The outcomes exhibit that SimApp is powerful and promising for use in numerous applications, for example, app categorization, search and recommendation.

Tian et al. [5] research the main factors for recognizing high-rated apps by implementing random forest classifier. The test indicates that the main factors are promotional images numbers appeared on the app page, app size, and app version.

Lu et al. [17] suggest an approach to deal with classify mobile apps reviews automatically in light of non-functional requirements. They gathered 11,096 mobile apps reviews from Apple Store and Google Play.

Hameed et al. [11] explore existing Islamic apps accessible on Google Play app store. They handled the issue of the shortfall classification and the mis-categorization of Islamic apps. Therefore, they recommended another categorization for the Islamic apps' dependent on their common features such as download numbers, app ratings, and languages. They gathered proposed 5 distinct classes for the Islamic apps: Zakat, Qibla/Prayer Time, Quran, Hadith, and Supplications.

Abuelenin et al. [18] proposed hybrid system to find the most similar word in lexicon and increase the accuracy of Egyptian Arabic using the cosine similarity algorithm and the Information Science Research Institute Arabic stemmer (ISRI).

Al-Shamani et al. [12] construct Arb-AppsReview dataset for various research domains, such as gender detection, dialect analysis, sentiment analysis.

2) State-of-arts hybrid models: Heikal et al [19] propose a model which applies a hybrid model consists of CNN, and LSTM on ASTD. This model prediction performance is to 65%.

Al-Twairesh et al [20] suggest a model which applies a hybrid model SF+ GE + ASEH on SemEval. This model prediction performance is to 80.36%.

Mohammed et al. [21] propose a model which applies a hybrid model LSTM+Augmented on Arabic tweets. This model prediction performance is to 88.05%.

Furthermore, few previous works suggested a hybrid classification SA model for classify Egyptian Dialect Arabic mobile apps reviews.

III. A Hybrid Sentiment Analysis Classification Approach for Mobile Apps Arabic Slang Reiews (MASR) Methodology

This paper methodology depends on previous qualitative, quantitative and SLR research methodology [22]. It built according to previous observations after analyzing ASA survey, comparative framework [23] and future relationship hypothesis, user satisfaction surveys and case studies. The proposed methodology will be based on applying Natural Processing Language (NLP) and Data Mining (DM) Tools, Methods and Techniques. It depends on the quality of extracted features that express user opinion and its sentiment for Arabic Mobile Apps'. Finally, the main goal for it is to help developers improve and enhance new releases of Mobile Apps to meet rapidly changing in requirements evolution.

This research adopted a hybrid classification model which consist of six phases for collect, analyze and classify sentimental Arabic Dialect mobile apps reviews on google play store, as shown in Fig. 1.

This paper construct six phases for a hybrid classification Model methodology as indicated by Fig. 1; phase 1 MASR collection phase involves how to scrape and gather the dataset from google play store via Appbo[1] scraper tool and describing the dataset characteristics. The second phase involves the implementing of various pre-processing steps which will be applied on MASR dataset. The third phase is implementing feature extraction using Bag of Words (BOW) and Tf-idf. The fourth phase is implementing famous supervised machine learning classification algorithms such as Support Vector Machine (SVM), Naïve Bayes (NB), Linear Regression (LR), Neural Network (NN), and KNN classifier. The fifth phase proposing hybrid classification techniques according to the results of classifiers which accomplish highly accuracy results from the previous phase to enhance MASR accuracy results.

[1] https://appbot.co/

The last phase is to evaluate and compare the classification results utilizing recall, precision and accuracy.

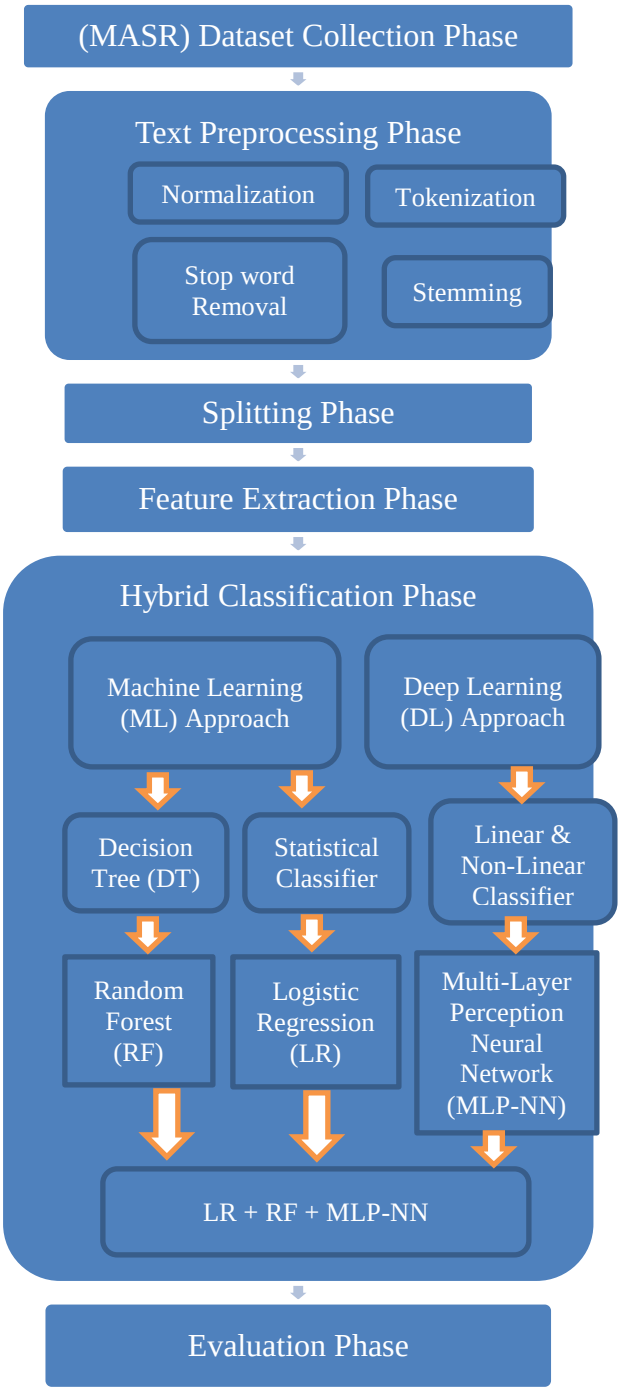

Fig. 1. HSACA-MASR Methodology Phases.

1) First Phase: Mobile Apps Arabic Slang Reviews (MASR) Dataset Collection Phase.

In this research, the Mobile Apps Egyptian DA reviews dataset was extracted using Appbot scraper tool which follows those steps:

- Choose Google Play Store.
- Select 9 various categories of mobile apps as shown in Table I.
- Focus on reviews of Egyptian mobile apps, and another Egyptian reviews for non-Egyptian mobile apps such as: Instagram, as shown in Table I.
- Save extracted attributes and reviews in CSV file: app category, app name, review, rating, and review polarity, as shown in Table II.

TABLE I. APP CATEGORY, APP NAME, APP RATING

	App category	*App name*	*App rating*
1	**Social**	Instagram[2]	4.4
2	**Lifetyle**	ContactCars[3]	4.5
3	**Travel & Locals**	Egypt Air[4]	4
4	**Shopping**	Kazyon[5]	4
		Olx Egypt[6]	4.3
5	**Tools**	Otlob[7]	4
		Shareit[8]	4.1
6	**Medical**	Vezeeta[9]	4.7
7	**Productivity**	Ana Vodafone[10]	4.2
8	**Education**	Aladwaa Education[11]	4
		بنك المعرفة المصرى [12]	4
9	**Maps & Navigation**	Careem[13]	4.2

2) MASR Properties: MASR dataset comprises of 2469 reviews made up of 653 positive, 756 neutral and 1060 negative reviews. A negative review is characterized as a review that has been given a rating of "1" or "2" or "3". A positive review is one where the review has been given a rating of "3" or "4" or "5". At last, Neutral reviews with a rating of "1" or "2" or "3" or "4" or "5". The MASR dataset was made from the gathered data and comprises of the following fundamental attributes as shown in Table II.

3) MASR distribution: MASR dataset covers 2469 mobile apps reviews contributed by various reviewers from 12 mobile apps which covers nine various mobile apps categories such as social, lifestyle, education, maps and navigation, productivity, shopping, travel and tools. The negative reviews comprise 43% of the absolute number of reviews when contrasted with

the 26% of the positive ones. Furthermore, 31% of the reviews are "neutral". As expected, the negative reviews are the greater part class. Fig. 2 presents the classification of ratings for our extracted dataset.

TABLE II. MASR DATASET ATTRIBUTES

Attribute	*Description*
Mobile App Category	Category of mobile app which include various category according to extracted datasets (Social, Lifestyle, Travel & Local, Shopping, Tools, Medical, Productivity, Education, or Maps & Navigation).
Mobile App Name	Name of selected Mobile App.
Review	opinion of reviewer's written in the ED which is mixing between MSA or DA.
Rating	Applies scale from 1 to 5 showing the scope of the reviewer's satisfaction. Positive reviews instead of using the previous scale from 1 to 10.
Review Polarity	Denotes the sentiment of the review with "+1" for a positive review, "−1" for a negative review, and "0" for a neutral review.
