**Abstract**—COVID-19 (Corona) virus has spread across the world threatening lives of millions of people. In India first COVID-19 case was detected on 30th January 2020 in Kerala. To minimize the spread of Corona Virus, countries all over the world implemented complete lockdown. Due to complete lockdown even people who are not exposed to corona virus, have to self-quarantine to keep themselves safe from getting infected by the disease. People (especially Indians) have never experienced such complete lockdown and quarantining situations before. Thus, this creates a space for curiosity that how people are going to react to this situation. The present study aims to analyse how self-quarantined people during COVID-19 lockdown period are reacting to quarantining, what measures they are taking to deal with this situation, and what are their sentiments towards quarantining. The study also aims to measure their Happiness and to identify the factors that are statistically significant to Happiness. For this study, the data is collected through a survey method. Multiple correspondence analysis are performed to analyse the survey data. The happiness score is evaluated by using the GNH (Gross National Happiness) methodology. Proportional Odd Logistics Regression is used to identify factors that are statistically significant in predicting happiness. The study suggests that family factor is related to the happiness of the self-quarantined people during such lockdown situations.

**Keywords**—Correspondence analysis; happiness index; sentiment analysis; proportional odds logistic regression; self-quarantining

## I. INTRODUCTION

‘Quarantine’ is a practice in which restrictions are imposed on the movement of people. Sometimes people may have been exposed to disease but do not show any symptoms of being infected by the disease. In such cases, people are not allowed to go to public places for some period. This period is called as quarantine period. Quarantine period identifies whether someone is being infected by the disease or not. In case of COVID-19, the Corona Virus has spread so rapidly making the situation worse. To deal with this dangerous situation and to minimize the further spread of this deadly virus, many countries were locked down and thus even people who are not infected by this virus or not been exposed to this disease have to Self-quarantine to keep themselves safe from getting infected by Corona Virus. The intensity of a lockdown

depends on the situation in which it is declared. In case of COVID-19 pandemic situation, many countries including India declared a complete lockdown. During a complete lockdown period, people are informed to stay where they are and are not allowed to leave their premises. Many organizations started practising Work From Home. People who are dependent on daily wages are deeply affected due to the COVID-19 lockdown situation. Lockdown has adverse effects on the economy, human life, environment and transport sector of the country that in turn leads to unemployment, inflation and recession [1]-[3]. Thus, lockdown disturbs normal life of people. This adversely affects the psychological well-being of people. There are various researchers who have studied the impact of lockdown on the psychological wellbeing of the human being. The researcher discusses the impact of large-scale quarantine during the early 2003 outbreak of severe acute respiratory syndrome (SARS). The research focuses on the factors that influenced people's willingness to follow quarantine orders [4]. Reynolds and Melanie studied the problems, compliance, and psychological impact of the quarantine experience during the SARS pandemic, and the findings imply that quarantine implementation should be evaluated [5],[6]. Researchers have also studied the psychological impacts of quarantining a city in a review study [7], [8]-[13]. Residents in afflicted areas are socially shunned, face workplace discrimination, and have their property vandalized, according to the article. The author of this research studies "coping with the psychological impact of quarantine".The researcher has also explained how quarantine affects mental health, what are the factors that influence coping, and various ways of dealing with the effects of quarantine. [14]. The author developed a Happiness Index survey tool to measure happiness, wellbeing, as well as features of sustainability and resilience. It can also be used to assess happiness with one's life and living circumstances. Survey Development, Domain and Question Reduction, Survey Standardization, and Survey Honing were the four stages of development for the survey instrument [15]. The research on a mental health survey of the UK population before and during the COVID-19 pandemic. The authors find that being young, a woman, and living with children, particularly preschool-aged children, had a significant impact on the extent to which mental anguish rose during the

pandemic[16]. The impact of assessing the prevalence of depression, anxiety, and mental well-being before and during the COVID-19 pandemic is explored in this work by the author [17]-[19]. A review study on “The psychological impact of quarantine”. The authors of this review find that quarantine has a wide-ranging, significant, and long-lasting psychological impact [20]. The author of this research investigated whether or not being quarantined to stop the spread of H1N1 virus had negative psychological impacts [21].

Thus, the present study is about analysing the state of mind of self-quarantined people by measuring their Happiness, identifying the factors that are statistically significant to happiness and to evaluate their sentiments towards quarantining. This study may help policy makers to decide on measures to cut down the psychological consequences of quarantine and to provide guidelines on what things are to be done to take care of the mental health of those who are undergoing quarantining.

## II. METHOD

The current study has followed the methodology as displayed in Fig. 1

### A. Data Collection and Preparation

The data for this study was collected through a survey method. A structured questionnaire designed and shared with people through online mode during second phase (15<sup>th</sup> April 2020 – 3<sup>rd</sup> May 2020) and third phase (4<sup>th</sup> May 2020 – 17<sup>th</sup> May 2020) of COVID-19 lockdown period in India. For this analysis, samples are collected using Stratified Sampling Method. Stratified Sampling is a type of Probability Sampling. In Stratified Sampling method, the population is divided into strata or subgroups and a random sample is taken from each strata [22]. The structured questionnaire designed for this analysis is shared with people who belong to age group 22 and above. Three age groups are created as 22-40, 41-55, 56 & above. A total of 473 responses to the questionnaire are received. After data collection, the data preparation was done. Data preparation includes the data selection and data cleaning. The happiness score will be calculated separately for respondents staying with family and respondents staying away from their family during lockdown period as some parameters that will be used for calculating the happiness score will be different for these two groups of respondents. Thus the data is divided into two datasets. The variables containing text data are used for Sentiment Analysis. The collected data consisted variables such as ‘timestamp’, ‘name’ that were not required for the analysis. Thus, these variables were dropped from the dataset. The null values were not present in the dataset as all the questions were marked as mandatory.

### B. Exploratory Data Analysis (EDA)

The dataset consists of categorical data. To understand how frequently categories of each variable are occurring, frequency distribution technique is used. ‘countplot()’ function of seaborn library is used for plotting the graphs for better understanding of the distribution of categories. From these plots, the categories with very low frequencies will be

identified. The variable with very low frequency categories will be dropped from the further analysis.

### C. Multiple Correspondence Analysis (MCA)

MCA is a method which is usually used to analyse data acquired through a survey questionnaire [23]. The dataset under study consists of many categorical variables. In this study, instead of using correspondence analysis (CA) that is suitable when there are only two categorical variables, MCA is used to understand the relationships between more than two categorical variables. By performing MCA, the similarities between respondents will be identified based on their category selection pattern. From MCA results, the variables that are contributing the most to define dimensions are identified.

### D. Happiness Score Evaluation

To evaluate the happiness score the dataset was divided into two parts as , People who are staying with family (with family dataset) and People who are staying away from their family (without family dataset) . To measure the happiness, the 5-point Likert Scale along with the score 1-5 was used. Table I shows the responses for indicators and their respective score which were used for the analysis. Table II shows the responses for indicators for Yes/No indicators and their score. For measuring happiness of the people who are staying with family and people who are staying away from family, 11 indicators are used. Thus, the maximum score is 55 (11\*5). The happiness score for each respondent is calculated by taking the sum of the score of each indicator.

Fig. 1. Research Methodology.

TABLE I. RESPONSE CONVERSION TO SCORE FOR 5 POINT SCALE INDICATORS

Response	Score for ‘sleep’, ‘Governance’ and ‘creativity’	Score for ‘boredom’, ‘discomfort’
0-1	1	5
2-3	2	4
4-6	3	3
7-8	4	2
9-10	5	1

TABLE II. RESPONSE CONVERSION TO SCORE FOR 2 POINT SCALE INDICATORS

Response	Score for 'break needed', 'new skill', 'new routine', 'home exercise',	Score for 'recession', 'feeling lonely', 'fear', 'anxiety', 'stress'
Yes	5	1
No	1	5

GNHI (Gross National Happiness Index) methodology, respondents are classified into one of the four categories as follows (Table III) [24].

TABLE III. HAPPINESS CATEGORIES

Happiness Category	Score Range
Deeply Happy	77% - 100% of the maximum score
Extensively Happy	66% - 76% of the maximum score
Narrowly Happy	50% - 65% of the maximum score
Unhappy	0% - 49% of the maximum score

Thus, for example, if the happiness score of the respondent is 42 out of 55 (77%-100% range) then the respondent is classified as Deeply Happy.

E. Proportional Odds Logistic Regression

The objective for using proportional odds logistic regression model is to identify the factors that are statistically significant to predict happiness category (unhappy/narrowly happy/extensively happy/deeply happy). Based on these factors the happiness category (unhappy/narrowly happy/extensively happy/deeply happy) to which the individual respondent belongs will be predicted. This prediction is done based on the factors that are used to evaluate the happiness score. Here, the happiness categories are ordered and thus proportional odds logistics regression method is used. The proportional odds model can be mathematically represented as:

$$\text{logit} [P (Y \leq j)] = \alpha_j - \sum \beta_i X_i \tag{1}$$

Where, j ranges from 1 to J-1

- Here, J refers to the number of categories of the target variable, in this case the happiness category. Since there are four categories, J = 4.
- The happiness categories are coded as unhappy = 1, narrowly happy = 2, extensively happy = 3 and deeply happy = 4. The category 'deeply happy' is the highest category and 'unhappy' is the lowest category.
- $P(Y \leq 2)$  refers to the probability of being unhappy or narrowly happy versus being extensively happy and above category (in this case, deeply happy).
- Logit refers to 'log odds'. Odds can be defined as the ratio of the probabilities of success of an event and failure of an event. Logit  $[P (Y \leq 1)]$  refers to log odds of the probability [25].
- For better understanding, log odds are converted to probability as follows:

$$P (Y \leq j) = \exp (\alpha_j - \sum \beta_i X_i) / (1 + \exp (\alpha_j - \sum \beta_i X_i)) \tag{2}$$

- Model fitting is done using 'polr()' function from 'MASS' package. The summary result of the model provides intercepts, coefficients of regression with values (slopes), and p-values is calculated from this result [25].
- The coefficients (Variables used in the model) with p-value less than or equal to 0.05 are kept in the model.
- Once the model is finalised, prediction is done on the new values. The 'predict()' function returns estimated probability values for all four categories. The category with highest probability is the category predicted for a respondent [25].

III. RESULTS AND DISCUSSION

A. EDA Results

The total number of respondents staying with their family is 422. The total number of respondents staying away from their family is 51. The frequency distribution of different variables is as follows.

The Fig. 2 and Fig. 3 shows that more than 50% of the respondents of both 'with family' and 'without family' dataset wanted such break from their regular routine that they got due to COVID-19 lockdown. More than 50% of the respondents of both 'with family' and 'without family' dataset planned a new routine for the self-quarantined period (Figure 1 & 2). This shows that instead of being worried, people are trying to adjust with the quarantining situation. It is also shows that, for 'with family' dataset, 55% of the respondents are not learning any new skills whereas for 'without family' dataset, more than 55% of the respondents are learning new skills. This shows that, those who are not staying with their families during self-quarantining period are trying to deal with the loneliness and utilizing the free time they got.

In the questionnaire, respondents were asked to rate the quality of sleep they are getting during self-quarantining period. It is observed that the maximum respondents selected categories for quality of sleep as 7, 8, 9, 10 under both the datasets. Categories 7-9 were considered as, having a good quality sleep while category 10 is considered as having an excellent quality sleep.

Fig. 2. Response of Indicators (Break Needed, New Routine and New Skill) with Family.

Fig. 3. Response of Indicators (Break Needed, New Routine and New Skill) without Family.

Fig. 4. Quality of Sleep with and without Family.

Around 70% of the total respondents from both the datasets are getting good to excellent quality sleep. Having a good quality sleep helps in maintaining psychological well-being (Fig. 4).

Fig. 5. Creativity with and without Family.

With reference to the creativity attribute, Fig. 5 shows that, most selected categories for ‘with family’ dataset are 5-8 and for ‘without family’ dataset are 5-8 and 10. This indicates that people are trying to be creative to deal with boredom no matter whether they are staying with their family or not.

The Fig. 6 shows the response of boredom from the respondents on a scale of 0-10 being ‘extremely bored’. This question received mixed responses for all the categories (category ‘5’ being the most selected) from the respondents who were staying with their family. Respondents who are staying away from their family experienced high level of boredom.

Fig. 6. Comparison of Boredom Value Variable with and without Family.

Fig. 7. Comparison Governance with and without Family with Pattern.

Governance is one of the important factor which affects the Happiness of the people. Whether people are satisfied with the strategies adapted by government for handling pandemic is related to the Happiness of population. Fig. 7 shows, the responses of the respondents to the statement ‘The Government is taking the right measures to handle the COVID-19 pandemic situation’. From the graphs it is

observed that from ‘with family’ dataset, 44% of the respondents ‘agree’ and 30% of the respondents ‘strongly agree’ with the above-mentioned statement. From ‘without family’ dataset, 55% of the respondents ‘agree’ and 21% of the respondents ‘strongly agree’ with the above-mentioned statement.

Fig. 8 and Fig. 9 show that, 76% of the respondents from ‘with family’ dataset and 82% of the respondents from the ‘without family’ dataset are worried about the consequences they have to face due to the upcoming recession/inflation. This worry- “about the future”, may affect the psychological well-being of respondents. People may experience anxiety, fear, irritability, stress, depression, fatigue, sadness, panic during quarantining that can impact mental health. From ‘with family’ dataset 62% of the respondents and from ‘without family’ dataset 69% of the respondents experience such feelings (Fig. 8 and Fig. 9). One of the important measures to be taken to stay physically and mentally healthy is to do a regular exercise. Due to lockdown people cannot go to parks or gym. But they can definitely do exercise at home. They can do yoga, meditation, Zumba, home gym etc. Fig. 8 and Fig. 9 shows that, 67% of the respondents of ‘with family’ dataset and 71% of the respondents from ‘without family’ dataset follow home exercise routine.

From ‘with family’ dataset, 95% of the respondents selected category ‘Yes’ for answering whether being with family is helping them to cope with the quarantining situation or not. Also, to answer whether they are satisfied with the quality time spent with their family, 95% of the respondents selected category ‘Yes’ (Fig. 10).

Respondents who are staying with their family during quarantining period may experience discomfort due to extended lockdown (too much togetherness). In response to the statement ‘Extended lockdown (too much togetherness) may cause discomfort with family’, 32% of the respondents selected ‘Disagree’, 29% of the respondents selected ‘Neutral’, 23% of the respondents selected ‘Strongly Disagree’, 13% of the respondents selected ‘Agree’ (Fig. 11).

Fig. 9. Response of Indicators (Recession, Feeling, & Exercise) without Family.

Fig. 10. Response of Indicators (Family\_is\_Helping\_to\_Cope, & Quality\_Time\_with\_Family) with Family.

Fig. 8. Response of Indicators (Recession, Feeling, & Exercise) with Family.

Fig. 11. Response Response of Indicator Discomfort with Family.

Fig. 12. Response Response of Indicator (Feeling Lonely, & People Around are Supportive) without Family.

Respondents who are not staying with their family during quarantining period may experience loneliness. The question ‘Do you feel lonely as you are away from your family during this self-quarantined situation?’ almost equal number of responses for categories ‘Yes’ and ‘No’. In such difficult situations, getting social support is very important especially for those who are staying away from their family. Respondents staying away from their family were asked whether people around them are supportive or not. In response to this question, 92% of the respondents selected category ‘Yes’. From the above frequency distribution plots, it is found that the variables ‘family is helping to cope’, ‘quality time with family’ from ‘with family’ dataset contain categories having very low frequencies as compared with other category of these variables. Thus, these two variables are omitted from the analysis. Also, the variable ‘people around are supportive’ from ‘without family’ dataset contain category (‘No’) having very low frequency as compared with the other category (‘Yes’) of variable. Thus, this variable is omitted from the analysis (Fig. 12).

**B. MCA Results**

In Fig. 13 and Fig. 14, each point on a graph represents the contribution of that particular variable in constructing dimension one and dimension two. From these graphs we can say that for ‘with family’ dataset, creativity contributes the most in constructing dimension one and dimension two. Whereas for ‘without family’ dataset creativity contributes the most in constructing dimension one and dimension two while new\_skill contributes in constructing dimension one and Governance contributes the most in constructing dimension two.

From the Fig. 15 and Fig. 16 the important categories of the variables were identified. For ‘with family’ dataset, categories sleep\_1, sleep\_2, Governance\_2 contributes the most towards

positive direction of the first dimension whereas categories creativity\_1, discomfort\_with\_family\_1 contributes the most towards positive direction of the second dimension. For ‘without family’ dataset, categories sleep\_1, creativity\_2 contributes the most towards positive direction of the first dimension whereas category Governance\_2 contributes the most towards positive direction of the second dimension. The value of cos2 represents the quality of representation of variables and variable categories. The Fig. 17 and Fig. 18 show that for ‘with family’ dataset, feeling\_1, feeling\_5, governance\_5, exercise\_5, exercise\_1, new\_routine\_1, new\_routine\_5 these categories have higher values of cos2 as compared with other categories for dimension one.

Fig. 13. Variable Representation (with Family).

Fig. 14. Variable Representation (without Family).

Fig. 15. Variable Categories Plot (with Family).

Fig. 16. Variable Categories Plot (without Family).

Whereas, for ‘without family’ dataset, categories creativity\_1, Governance\_2, new\_skill\_5, new\_skill\_1, new\_routine\_1, new\_routine\_5 have higher values of cos2 as compared with other categories for dimension one.

In Fig. 19 and Fig. 20 each point on a graph represents an individual respondent. Respondents are grouped together based on their category selection pattern. From the above graphs it is identified that there are similarities among respondents in both the datasets.

### C. Happiness Score Evaluation Result

Happiness Scores of 422 respondents who are staying with their family is evaluated. Table IV shows that, 15.88 % of

respondents are ‘Deeply Happy’, 34.6 % of the respondents are ‘Extensively Happy’, about 37 % of the respondents are ‘Narrowly Happy’ and 12.56 % of respondents are ‘Unhappy’. For respondents staying without family, we can say that, 17.65 % of respondents are ‘Deeply Happy’, 21.57 % of respondents are ‘Extensively Happy’, 41.17 % of respondents are ‘Narrowly Happy’, 19.6 % of the respondents are ‘Unhappy’. During quarantining situations, factors such as working from home, gender, personality, staying with family (or not) may related to happiness. To verify this, statistical analysis was performed.

Fig. 17. Cos2 of Variables (with Family).

Fig. 18. Cos2 of Variables (without Family).

Fig. 19. Individuals Plot (with Family).

are working from home and staying with their family (51%, unhappy and narrowly happy) tend to be happier than respondents who are working from home and staying away from their family (58%, unhappy and narrowly happy).

Fig. 21. Work from Home vs. Happiness (with Family).

Fig. 20. Individuals Plot (without Family).

Fig. 22. Work from Home vs. Happiness (without Family).

TABLE IV. HAPPINESS SCORE

Happiness Score	Count of respondents staying with family	Count of respondents staying without family
Deeply Happy	67	9
Extensively Happy	146	11
Narrowly Happy	156	21
Unhappy	53	10
Total	422	51

1) *Work from home vs. happiness*: From the statistical analysis (Fig. 21 and 22) it is found out that respondents who

2) *Gender vs. Happiness*: From Fig. 23 and Fig. 24, it is observed that male respondents staying away from their family tend to be unhappier (57%, unhappy and narrowly happy) than the male respondents staying with their family (47%, unhappy and narrowly happy).

3) *Personality vs. Happiness*: Fig. 25 & Fig. 26 shows that, there is no relation found between personality (Introvert/Extrovert) of the respondent and happiness. But both Extroverts and Introverts who are staying with their family are happier than those who are staying away from their family.

Fig. 23. Gender vs. Happiness (with Family).

Fig. 24. Gender vs. Happiness (without Family).

Fig. 25. Personality vs. Happiness (with Family).

Fig. 26. Personality vs. Happiness (without Family).

D. Proportional Odds Logistic Regression Result

Proportional odd logistic regression model is created using polr() function. Initially all 11 variables that are used to calculate happiness score are included in model creation. In each iteration, the variables with p-value greater than 0.05 are excluded from the model creation (Table V). Finally, a model is created with seven important variables that are break needed, new routine, new skill, recession, discomfort, exercise, feeling for ‘with family’ dataset and with five important variables that are break needed, new routine, new skill, recession, feeling for ‘without family’ dataset (Table VI).

The summary result of the model created for with-family dataset is as follows:

TABLE V. PROPORTIONAL ODD LOGISTIC REGRESSION SUMMARY RESULT (WITH FAMILY)

Coefficients	Value	Std. Error	t-value	p-value
break_needed5	4.563	0.4799	9.507	0.000
new_routine5	4.311	0.4611	9.350	0.000
new_skill5	4.563	0.4764	9.577	0.000
recession5	4.235	0.4812	8.801	0.000
discomfort2	3.151	0.9342	3.373	0.001
discomfort3	5.199	0.9549	5.444	0.000
discomfort4	5.743	0.9567	6.003	0.000
discomfort5	6.945	1.0082	6.888	0.000
exercise5	4.972	0.5193	9.573	0.000
feeling5	5.342	0.5262	10.152	0.000

TABLE VI. TABLE VI. INTERCEPTS (WITH FAMILY)

Proportion	Value	Std. Error	t-value	p-value
1 2	11.2652	1.2860	8.7600	0.000
2 3	19.3984	1.8702	10.3722	0.000
3 4	25.9091	2.3327	11.1069	0.000

TABLE VII. TABLE VII. RESIDUAL DEVIANCE AND AIC (WITH FAMILY)

Residual Deviance	382.3822
AIC	408.3822

Interpretation:

- The coefficient values correspond to  $\beta$  and intercept values correspond to  $\alpha$ .
- Residual Deviance and AIC values are used to compare different models.
- The categorical variables can be interpreted as follows:
- Variable 'new\_skill' can be interpreted as the respondent who selected category of new\_skill variable as '5' tends to be happier than the respondent who selected category '1'. Other variables are interpreted in the same manner.
- Intercept interpretation:

Table VII shows that the intercept 1|2 (i.e Unhappy|Narrowly Happy) corresponds to  $\text{logit}[P(Y \leq 1)]$ . It can be interpreted as log odds of being 'Unhappy' versus being 'Narrowly Happy', 'Extensively Happy' or 'Deeply Happy'.

The intercept 2|3 (i.e Narrowly Happy|Extensively Happy) corresponds to  $\text{logit}[P(Y \leq 2)]$ . It can be interpreted as log odds of being 'Unhappy' or 'Narrowly Happy' versus being 'Extensively Happy' or 'Deeply Happy'.

The intercept 3|4 (i.e Extensively Happy| Deeply Happy ) corresponds to  $\text{logit}[P(Y \leq 3)]$ . It can be interpreted as log odds of being 'Unhappy' or 'Narrowly Happy' or 'Extensively Happy' versus being 'Deeply Happy'.

The summary result of the model created for without-family dataset is shown in the Table VIII.

The interpretation of this result is same as that of with-family dataset result Table IX and Table X.

The prediction function returns the estimated probabilities for each class (Unhappy/Narrowly Happy/Extensively Happy/Deeply Happy)

For with-family dataset the prediction result is as follows:

For data values break\_needed = 5, new\_routine = 1, new\_skill = 1, recession = 1, discomfort = 2, exercise = 5, feeling =5 the total score is 20 out of 35 (57.14 %) the prediction output is shown in Table XI.

The estimated probability for class 2 (Narrowly Happy) is highest. Thus, the model correctly predicts the class for given data values.

Similarly, for without-family dataset the prediction result is shown in the Table XII.

For data values break\_needed = 5, new\_routine =1, new\_skill =5, recession=1, feeling=1 the total score is 13 out of 25 (52 %) the prediction output is:

Validation:

- In the questionnaire, the respondents were asked to describe self-quarantining in one word. To validate the happiness score calculated for each respondent, this

one word mentioned by the respondent is used to compare it with the happiness category.

- To perform validation, happiness categories 'Unhappy' and 'Narrowly Happy' are coded as 0 and happiness categories 'Extensively Happy' and 'Deeply Happy' are coded as 1. The positive words used to describe self-quarantining are coded as 1 and negative words that are used to describe self-quarantining are coded as 0. Then the number of 1's and 0's for both the happiness categories and one word are counted.
- For with-family dataset, number of 0's for one word is 61 and number of 1's is 131. For happiness categories, number of 0's is 75 and that of 1's is 117. Thus, 89.31 % respondents are correctly categorized as 'Happy'. And 81.33 % respondents are correctly categorized as 'Unhappy'.
- For without-family dataset, number of 0's for one word is 8 and number of 1's is 18. For happiness categories, number of 0's is 13 and that of 1's is 13. Thus, 72.22 % respondents are correctly categorized as 'Happy'. And 61.53 % respondents are correctly categorized as 'Unhappy'.

TABLE VIII. PROPORTIONAL ODD LOGISTIC REGRESSION SUMMARY RESULT (WITHOUT FAMILY)

### E. Discussion

- This study found that respondents who needed break from regular routine, who planned a new daily routine

to follow during quarantine, who utilized the available free time by learning some new skills, who exercise regularly during quarantine to be physically fit, tend to be happier.

- Respondents experiencing anxiety, stress, fear, irritability, frustration, panic tend to be unhappier.
- This study suggested that the family factor is related to the happiness of the respondents.
- Respondents who are staying with their family may feel discomfort due to extended lockdown and this may lead to unhappiness.
- It is also found that the happiness of the respondents who are working from home during the self-quarantining period is related to whether they are staying with their family or not. Also, irrespective of the personality of the respondent, those who are staying with their family during self-quarantining period tend to be happier than those who are staying away from their family.
- Male respondents who are staying away from their family tend to be unhappier.
- The worry about the future consequences such as inflation or recession that the respondents may have to face post lockdown is related to the happiness.
- From the sentiment analysis it is found out that most respondents have a positive attitude towards self-quarantining that leads to respondents being psychologically healthy.

#### F. Limitations

This study has some limitations.

- The sample size is small. Thus, the results are not generalizable.
- The samples are taken during second and third phase of the COVID-19 lockdown period. If samples were taken during fourth phase, then the results might have been different.

#### IV. CONCLUSION

The overall happiness of self-quarantined people is measured. This study identified the factors affecting happiness of those who undergo quarantining. For 'with family' dataset, these factors include 'break needed', 'new routine', 'new skill', 'recession', 'discomfort with family', 'exercise' and 'feeling'. For 'without family' dataset, these factors include 'break needed', 'new routine', 'new skill', 'recession' and 'feeling'. The sentiments of self-quarantined people towards quarantining are evaluated. This study may help to identify the measures that can be taken to mitigate the consequences of Quarantine. According to the results, people who undergo quarantining can be advised to plan a routine, utilize the free time by learning some new skills, to do regular exercise at home. This will keep them happy and mentally healthy which

eventually will help them to cope with the quarantining situation.

# SIBI (Sign System Indonesian Language) Text-to-3D Animation Translation Mobile Application

Erdefi Rakun, Sultan Muzahidin, IGM Surya A. Darmana, Wikan Setiaji

Faculty of Computer Science  
Universitas Indonesia  
Depok, Indonesia

**Abstract**—This research proposed a mobile application prototype to translate Indonesian text into SIBI (Sign System for the Indonesian Language) 3D gestures animation to bridge the communication gap between the deaf and the other. To communicate in sign language, the signer will use his/her hands and fingers to demonstrate the word gesture, and at the same time, his/her mouth will pronounce the word being expressed. Therefore, the proposed mobile application needs two animation generator components: the hand gesture and the lip movement generator. Hand gestures are made using a motion capture sensor. Mouth movements are created for all syllables available in the SIBI dictionary using the Dirichlet Free-Form Deformation (DFFD) method. The subsequent challenging work is synchronizing these two components and adding transitional gestures. A transitional gesture done by the cross-fading method is needed to make a word gesture that can smoothly connect with the next word gesture. The Mean Opinion Score (MOS) test was run to measure the mouth movements in 3D animation. The MOS score is 4.422. There are four surveys conducted to measure user satisfaction. The surveys showed that the animation generated did not significantly differ from the original video. The Sistem Usability Score (SUS) is 76.25. The score means that prototype is in the GOOD category. The average time needed to generate an animation from Indonesian input text is less than 100ms.

**Keywords**—SIBI sign language; sequence generation; visual speech; animation

## I. INTRODUCTION

Sign language is a non-verbal language used to help people with hearing impairment communicate. Sign language represents a word with hand gestures and mouth movements. Communication with sign language uses a combination of hand, finger, and mouth movements representing words [1]. Indonesia has two sign languages acknowledged by the government: SIBI (Sign System for the Indonesian Language) and BISINDO (Indonesian Sign Language).

SIBI is a sign language that the Ministry of Education and Culture officially acknowledged in Indonesia in 1994. SIBI follows the Indonesian language grammar and has been used formally in the School for special needs students. The characteristic of SIBI is that SIBI applies Indonesian grammar

in organizing word gestures in a sentence [2]. Indonesian words are written using the Latin-Roman alphabet and categorized into four elements: subject, verb, noun, and adverb. Indonesian also has inflectional words that attach prefixes, suffixes, and affixes to the root word. With these affixes, the root word has additional meaning.

BISINDO is a sign language that developed naturally through the deaf community in Indonesia. BISINDO does not follow Indonesian grammar and is commonly used in conversation. BISINDO prioritizes the meaning of the gestures carried out rather than the language structure of the gestures.

Unfortunately, not many people master sign language to communicate with the Deaf. This research proposes to bridge the communication gap between the deaf and others by building a mobile application to translate Indonesian text to 3D SIBI gesture animation.

SIBI differs from other sign languages such as American Sign Language (ASL) and British Sign Language (BSL) in terms of their gestures and method of arranging gestures in a sentence. Gestures in SIBI are arranged according to the rules in Indonesian grammar. Another difference lies in how the inflectional gesture is formed. Inflectional gestures are formed by combining the root word and affixes in the inflectional words [3].

Constructing a SIBI sentence gesture that differs from other sign languages needs different ways to generate 3D animation of a SIBI sentence gesture. This research faces several challenges. First, the Indonesian input sentence must be deconstructed into its components according to the SIBI rules to generate animated gestures. Fig. 1 shows an example of how an Indonesian sentence is deconstructed into word components: An inflectional word will be split into components affixes, and the root word ("mengatakan" = claim, will be separated into to prefix "me" + root word "kata" + suffix "kan"); Name will be changed to its alphabets ("William" will be split into w+i+l+l+i+a+m); numbers will be split into their essential number components ("6023" becomes "6"+"thousand"+"20"+3) [4].

Fig. 1. Deconstruction of an Indonesian Input Sentence.

Second, to communicate in sign language, the signer will use his/her hands and fingers to demonstrate the word gesture, and at the same time, his/her mouth will pronounce the word being expressed. Therefore, building a 3D SIBI gesture animation has to be divided into two steps: building hand gestures and mouth movements. After the hand and mouth movement components are completed, two more challenges need to be solved by this research: how to make hand movements synchronize with mouth movements and how to connect the word components in a sentence into a single, smooth movement.

In conclusion, this paper discusses how to solve the four challenges in building an application to translate Indonesian input text into a 3D animation of the SIBI gesture.

The remainder of this paper is organized as follows: Section 2 states other research on generating text-to-gesture translation systems and mouth movement; Section 3 explains the proposed method for Indonesian text-to-3D SIBI gesture animation, dataset, and evaluation metric; Section 4 evaluates and analyzes the evaluation results; Section 5 closes this paper with the conclusion and future works.

## II. RELATED WORKS

This section discusses other research on generating text-to-gesture translation systems and mouth movement. Table I shows some research on gesture generation, while Table II shows the research on mouth movements.

Table I shows that a common way to generate gestures from text is to create a sign language script and then generate gestures based on the script. Sign language scripts commonly used are Sutton SignWriting and HamNoSys notation. Sutton SignWriting notation is sign language that transcribes the signed gestures spatially, in two-dimensional canvas, as they are visually perceived. Furthermore, HamNoSys notation is an alphabetic system that describes a sign, primarily phonetic. HamNoSys notation is designed as a markup language foundation used to transcribe all sign languages worldwide. It does not depend on the conventions of each country, such as gestures for spelling the finger alphabet [5][6][7]. The lack of documentation of the HamNoSys and Sutton SignWriting corpus available for sign language in Indonesia causes the HamNoSys, and Sutton SignWriting cannot be implemented in SIBI's text-to-gesture translation system. SIBI is a sign system that follows Indonesian grammar [8]. The similarity between the SIBI structure and the Indonesian language structure is an advantage that can be used in SIBI's text-to-gesture translation system [4]. This research proposed an Indonesian Language stemming method to find word components in SIBI sentences. Table I also shows that other research focuses on building web-based text-to-gesture translation systems. Meanwhile, this research focuses on developing a text-to-gesture translation system as an Android Mobile Application.

TABLE I. RESEARCH ON GENERATING GESTURES IN SEVERAL COUNTRIES

Author	Sign Language	Platform	Method
(Karpouzis et al., 2007) [5]	Greek Sign language	Web-Based	1. Scripting Technology for Embodied Personal language (STEP) 2. HamNoSys 3. 3D Animation
(Bouزيد & Jemni, 2014) [28]	Tunisian Sign Language	Web-Based	1. SWML (SignWriting Markup Language) 2. Sutton SignWriting notation 3. 3D Animation
(Boulares & Jemni, 2012) [6]	American Sign Language	Web-Based and Android	1. XML based 2. HamNoSys 3. Video Animation
(Efthimiou et al., 2009)[7]	Dicta-Sign: Greek, British, German, and French Sign Language	Web-Based	1. Signing Gesture Markup Language (SiGML) 2. HamNoSys 3. 3D Animation

Table II shows the research on mouth movements. Mouth movement research usually uses the form of viseme, which is a visual form of pronunciation. Three approaches to generating Viseme derived automatically from pronunciation are key-frame interpolation, model-based, and concatenative [9]. The Key-frame interpolation connects through interpolation the pre-define lip shape of all viseme that appear in a word or sentence [10], [11]. The model-based approach creates viseme from each pronunciation done by the human model [12]. The concatenative approach is a combination of key-frame and model-based approaches. Research by [13] and [14] tracks viseme on the human face to create a database of viseme animations. To generate mouth movement animation, all the viseme that appear in a word or sentence will be taken from the database and then connected through interpolation. The concatenative approach creates a realistic speech animation because it uses actual human face data as a model. Therefore, this research uses the concatenative approach for SIBI mouth movement animation.

Research related to text-to-gesture translation systems generally focuses on generating hand movements only. So far, no system has been found to generate hand movements and mouth movements from text input. This research proposes a combined SIBI hand and mouth movements from Indonesian text.

TABLE II. THE GENERATION OF MOUTH MOVEMENTS RESEARCH

Author	Language	Input	Method
(Setyati et al., 2017) [10]	Indonesian	Text	Hidden Markov Model, 2D Animation, key-frame interpolation

(Taylor et al., 2017) [14]	English	Voice	AAM, Concatenative

Note: FACS = Facial Action Coding System, AAM = Active Appearance Model, RBF = Radial Basis Function, DFFD = Dirichlet Free-Form Deformation

### III. PROPOSED METHOD

This section discusses the proposed method to generate 3D animation from Indonesian sentence text. The discussion is divided into six sub-sections: overall system design, how to do SIBI sentence deconstruction, how to make 3D animation for hand and mouth movements, how to synchronize hand and mouth movements, and how to connect each word component in sentences by inserting transitional movements, and evaluations carried out to measure system performance.

#### A. Application Overview

Fig. 2 is the architecture used to build the Indonesian text to SIBI's 3D animation. The application consists of two main modules: text parser and animation engine. Text parser consists of two types: deconstructing Indonesian sentences into word components using hand gesture text parser and deconstructing Indonesian sentences into syllables using mouth movement text parser.

The other process is to generate movement based on the text parser. This process occurs in the animation engine module, resulting a 3D animation. This module is divided into two, namely, hand gestures and mouth movement animation engines. The hand gesture animation engine develops 3D animation of hand and finger movements based on data obtained from sensors placed on the body of the SIBI expert. Meanwhile, the mouth movement animation engine develops mouth movements using the facial data of the SIBI expert model. The two-generation processes will run in parallel. The synchronization process equalizes the speed between the hand gesture and mouth animation movements.

Fig. 2. SIBI 3D Animation Application Architecture.

The previous study (Rakun & Darmana 2020) [15] discusses deconstructing Indonesian sentences into word components and the hand gesture animation engine, so these two topics are discussed briefly here. This paper will discuss the mouth movement text parser, the mouth movement animation engine, and how to synchronize hand and mouth animations.

**B. SIBI Sentence Deconstruction**

This section discusses breaking down Indonesian sentences into the components needed to generate 3D animation for hand movements (1) and mouth movements (2). The text parsing result of both hand and mouth in (3).

1) *Hand gesture text parser*: SIBI uses the standard Indonesian grammar and has two types of gestures: word and finger gestures (Fig. 3). The word components are obtained with the help of a look-up table consisting of all inflectional

words available in the SIBI dictionary. The look-up table contains each inflectional word's affix and root word components [4]. In addition to the look-up table consisting of inflectional words, there is also a look-up table consisting of slang words, which will later be used to correct the input word.

Fig. 4 shows the implementation of the hand gesture text parser [15]. In-text parsing splits sentences into word components. This process starts with the text tokenizer, splitting sentences based on spaces between words. Next is miss-spelling correction using slang word table look-up. This process corrects the slang words into root words. Furthermore, after the sentence is split into word components and corrected, the Word Mapper process will use the look-up table created previously based on the SIBI dictionary to split any inflectional word into its affix and root word.

Fig. 3. Gestures in SIBI.

Fig. 4. Hand Gesture Text Parser Module.

The output of the hand gesture text parser, for example, is the splitting of the inflectional word "mengatakan" (= to say/ to tell) into prefix "me" + root word "kata" + suffix "kan." Meanwhile, the names and numbers in the sentence will be split into finger gestures. Names will be split according to the alphabet in the name; for example, William will be split into "w," "i," "l," "l," "i," "a," and "m." At the same time, the numbers will be split into the essential components of numbers, such as ten, hundred, thousand, and million: for example number "6203" will be split into "6" + "ribu" (= thousand) + "2" + "ratus" (= hundred) + "3" as seen in Fig. 4 [15].

2) *Mouth text parser*: The mouth text parser is a module used to break a sentence input into syllables. There are four steps to breaking the input sentence into syllables:

- Removing symbols and punctuation marks from the input sentence.
- Identifying the words and numbers in the sentence.
- Changing them to lowercase.
- Breaking the word into syllables according to the syllable look-up table (Table III below shows part of the syllable look-up table).

TABLE III. LIST OF INDONESIAN SYLLABLES AND THEIR EXAMPLES

Syllable	Example
V	a-tau, i-kan, u-ang, e-lang
CV	ba-ca, du-ka, ko-ta
VC	an-da, il-mu, ku-il, in-dah
CVC	tam-bah, sam-bal, tum-pah
CCV	pri-a, pu-tra pu-tri, tri-o
VCC	eks-tra, bu-ang
CVCC	teks,
CCVC	Stig-ma
CCCV	In-stru-men
CCCVC	Struk-tur
CCVCC	Kom-pleks, ke-nyang, me-nyang-kut

Note: C = consonant, V = vowel

Forming the mouth movements will use as many syllables as the syllables in the input sentence.

A syllable is a part of a word articulated in one breath. A syllable consists of one or more phonemes combined. Each syllable always contains a vowel phoneme [16][17]. Table III shows some examples of syllables. The actual syllable look-up table consists of all syllables in the SIBI dictionary.

In the previous study (Muzahidin and Rakun, 2020) [18], the respondents gave suggestions and criticisms of the lack of tongue movement. The tongue is essential in pronouncing a word [19]. Therefore, this study improves the mouth movement animation by adding tongue movement. With the addition of tongue movements, respondents can better distinguish words with similar lip movements. Tongue movements are formed separately from the formation of lip movements. The lip movement is formed based on videos of SIBI experts pronouncing words. On the other hand, the tongue movement data was formed according to the rules in the Bina Talk book, as shown in Table IV [20].

TABLE IV. TONGUE MOVEMENT

No	Name	Description	Example
1	Apiko dental	The tip of the tongue at the base of the upper teeth touches the front alveolar (upper gum).	/t/, /d/, /n/
2	Apiko alveolar	The tip of the tongue meets the arch of the tooth (alveolar)	/s/ and /z/
3	Dorso velar	Attach the back of the tongue to the area (soft palate)	/ng/, /g/, /k/, and /x/
4	Fronto platal	The center of the tongue is the articulator, and the palate is the articulation	/j/, /c/, and /y/
5	Lateral	Lifting the tongue to the palate	/l/
6	Vibration	Attaching the tongue to the alveolar (gums) and so on repeatedly	/r/

3) *Module text parser results*: The hand gesture and mouth movement text parser will produce different sentence fragments. Table V shows examples of output from hand gestures and mouth movement text parsers. Next, the output of each text parser will be used to generate hand gesture and mouth movement animations.

TABLE V. TEXT PARSER RESULT

Word	Hand Gesture	Mouth Movement	Represent
Saya	Saya	Sa, ya	Root Word
Surya	S, u, r, y, a	S, u, r, y, a	Fingerspelling (name)
45	Empat, puluh, lima	Em, pat, pu, luh, li, ma	Fingerspelling (number)
Abu-abu	Abu-abu	A, bu, a, bu	Repeated Word
Memakai	Me-, pakai	Me, pa, kai	Prefix + root word
Pakaian	Pakai, -an	Pa, kai, an	Root word + suffix
Memakaikan	Me-, pakai, -kan	Me, pa, kai, an	Prefix + root word + suffix

### C. 3D Animation Generation

This section discusses how to generate hand gesture animation based on a hand gesture text parser (1) and how to generate mouth movement animation based on a mouth movement text parser (2).

1) *Hand gesture animation engine*: Hand gesture data creation begins with hand movement data collection using

sensors from Perception Neuron v2. This study used 25 sensors: 3 upper-body, 1 left-shoulder, 3 left-hand, 7 right-fingers, 1 right-shoulder, 3 right-hand, 7 right-fingers. These sensors attached to a SIBI expert model will record data in coordinates of the position and rotation of the human body joints. All 3,100 words available in the SIBI dictionary were recorded. The recorded sensor data are then stored as skeletal animation. The data generated by the sensor is not perfect. Fig. 5 shows the difference between the hand movements made by the SIBI expert (right image) and the hand gestures generated by the sensor (left image). The AxisNeuron application is used to check and correct every skeletal data generated. In this process, the skeletal animation clip needs to be readjusted with references to the SIBI dictionary. The corrected skeletal animation clips were exported in fbx format and are used by Unity3D to generate hand gesture animation.

Fig. 5. Data Sensor Recording Result.

2) *Mouth animation engine*: The mouth animation movement was created based on SIBI expert facial data detected using the OpenPose<sup>12</sup> library. Then, the Dirichlet Free-Form Deformation (DFFD) uses the coordinate data from the face detection to build mouth movements. The data used in this process is data for mouth movements generation only. In addition, it is also necessary to develop tongue movements based on the Bina Bicara book.

a) *Mouth Movement*: The process of generating mouth movements starts by recording the SIBI expert pronouncing every word from the SIBI dictionary. Using actual video data can produce more realistic lip movements [21]. The steps to obtain the face coordinates to drive the three-dimensional mouth movement animation are as follows (as shown in Fig. 6 and Fig. 7):

Fig. 6. Obtaining Face Coordinate Steps.

★/ red line = outer coordinates ( $po$ ); ●/ orange line = inner coordinates ( $pi$ ); ◆/ Blue line = middle coordinates ( $pm$ )

Fig. 7. Simplification Lip Point.

- Take sign language gesture with its pronunciation video performed by a SIBI expert [Fig. 6(a)].
- Crop the video to focus on the face only [Fig. 6(b)].
- Implement the coordinate detection process on the face using OpenPose [Fig. 6(c)].
- Get coordinates lip point [Fig. 7(a)].
- Cut the lips in half, and take a left part [Fig. 7(b)].
- Discard the right half of the lip and replace it with the mirror of the left lip to form symmetrical lips [Fig. 7(c)].
- Do the lips simplification process by averaging the outer and inner lips [Fig. 7(d)].
- The result of the lips simplification will be used for mouth movement animation [Fig. 7(e)].

The mirroring process is implemented because the shape of the human lips is not symmetrical between the left and right parts, caused by various factors such as teeth, cheeks, and face shape. The lip coordinates are then identified as the outer coordinates ( $po$ ) and the inner coordinates ( $pi$ ). Then, find the middle coordinates ( $pm$ ) using equation 1 [22]. Fig. 7(c) shows the results of the lip point simplification. These lip simplification coordinates will generate lip movement animation [18].

$$pm_x = \frac{(po_x + pi_x)}{2} \quad (1)$$

b) *Dirichlet Free-Form Deformation (DFFD)*: In this study, the Dirichlet Free-Form Deformation (DFFD) method is used to deform the 3D model. The application of DFFD in this research is by the following process:

- Apply the point of mouth movement form [Fig. 7(e)] into the 3D animation.
- Using the DFFD method to make mouth movements.
- Do this process for all the syllables in the SIBI dictionary
- Save this mouth movement into the database

<sup>1</sup><https://github.com/CMU-Perceptual-Computing-Lab/openpose>

The DFFD process changes the coordinates of a control point in an area that affects changes around another control point. Fig. 8 is the result of the deformation of the DFFD where the change in coordinates at one point has a local deformation area that reaches its surrounding points. All coordinate points move each other towards the specified coordinates. The results of these coordinates create changes in the shape of the lips according to the input data.

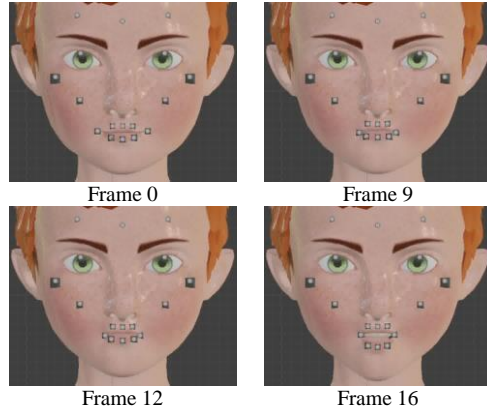

Fig. 8. 3D Animation Mouth Movement Syllable “Bu”.

Next is transferring the lip movement data into a 3D animation. Each lip part that will be moved has to be defined and coded for each syllable. All animation clips of Indonesian viseme syllables will be available after doing this process for all syllables. These visemes syllables animation will be stored as a database that the SIBI application can use.

The determining factor in understanding the word pronounced depends not only on the movement of the lips but also on teeth, tongue, and expression. Until now, no research has proven that people can catch a syllable or a word by looking at lip movements alone. Providing the 3D models with teeth and the tongue movement corresponding to each syllable will make it easier for the deaf to catch each syllable spoken.

#### D. Synchronizing Hand Gestures and Mouth Movement

Hand gestures and mouth movements are called based on the input sentence. The input sentence is deconstructed into words and syllables to generate hand gestures and mouth movements. The hand gestures and mouth movements will be generated simultaneously, but they do not take the same amount of time. So to synchronize hand gestures and mouth movements, it is necessary to accelerate or decelerate the movement of hand gestures. The speed of hand movement will follow the speed of the mouth movements. Generally, humans need 1 to 3 seconds to pronounce a word (depending on the length of the spoken word). Usually, words with only two syllables will be pronounced in one second. The gestures in the hands will follow the speed of the word's pronunciation. A one-second (two syllables) video is converted into frames,

which is 30 frames per second or equal to 15 frames per syllable. So the length of the hand gesture is 15 frames multiplied by the number of syllables of the word input. The algorithm for synchronizing hand gestures and mouth movements can be seen in Algorithm 1 below. The 3D animation will be displayed in a full model with synchronized pronunciation and hand gestures.

---

#### Algorithm 1 Synchronizing Hand and Mouth Movement

---

```

program start
initialize variable word_input
initialize variable mouth
initialize variable handsign
initialize variable frame = 15
start
    call function splittosyllable with word_input
    splittosyllable return value mouth
    output mouth

    handsign = mouth*frame
    output handsign

    call function runanimationmouth withinput mouth
    call function runanimationhandsign withinput
handsign
end
    
```

---

#### E. Insertion of Transition Movement using Cross Fade

This section explains how to create animated hand gestures. Hand gesture data creation begins with collecting hand and fingers movement coordinates for each word in the SIBI dictionary using a sensor, Perception Neuron v2. The coordinates of the hand and fingers are stored in a database. Creating hand gestures from an input sentence is done by retrieving the hand and fingers coordinates of each word in the sentence from the gesture database. Next is to insert transition gestures between words to create smooth, unified 3D animation sentence gestures. Fig. 9 shows the position of transition gestures in a sentence. This research uses the cross-fade method implemented using the Animancer API [15][18] to create transition gestures.

This research uses interpolation to generate a smoother transition movement between word gestures. Linear interpolation, also known as LERP, is the method to interpolate the positions and rotation values from the last frame of a word animation to the first frame of the following word animation linearly. It has the advantages of easy implementation and short execution time as the animation method traditionally used in animation [23]. Linear interpolation is a parametric curve defined as a straight line function can be seen in the following equation 2:

$$Q(u) = P_0 + u(P_1 - P_0) \tag{2}$$

Fig. 9. Transition Motion between Word Gestures.

Equation (2) can also be written as:

$$Q(u) = (1 - u)P_0 + uP_1 \quad (3)$$

The value of  $u$  is used to set the interpolation to be built. If the value of  $u$  is 0, then  $Q(u)$  will be equal to the starting point of  $P_0$ , whereas if the value of  $u$  is 1, then  $Q(u)$  will be equal to the endpoint of  $P_1$ . If the value of  $u$  is between 0 and 1, then it will produce a point on the line  $\overline{P_0P_1}$ . Interpolation occurs if the value of  $u$  is in the interval  $[0,1]$ . If the value of  $u$  is outside the interval, it will not be interpolated.

Cross-fading is used to combine two LERP-based animated clips [24]. This technique can generate a smooth transition between animation clips. Cross-fade works by stacking the timeline of two animated clips, as seen in Fig. 10. The merging process requires a blend percentage  $\beta$  of the clips to be merged.  $\beta$  starts at 0 at time  $t_{start}$ . The meeting time between clip A and clip B is when a cross-fade process occurs. The value of  $\beta$  is then slowly incremented to 1 until time  $t_{end}$ . At that time, only the animation of clip B will appear. The time interval when the cross-fade is in progress is called the *blend time* ( $\Delta t_{blend} = t_{end} - t_{start}$ ).

#### F. Evaluation Metric

There are three tests carried out to measure the performance of the system being built. The first test is intended to measure the mouth movement animation when using syllables. The second test is carried out to measure the usability of this system. The third test is to measure the execution time.

1) *Evaluation of mouth movement*: Evaluation of mouth movement is done by calculating the Mean Opinion Score (MOS). Four online questionnaires (done during the Covid-19 pandemic locked down) need to be filled in by the respondents to check how well the 3D animation works: In Questionnaire 1, the animation pronounces 40 Indonesian words available in the SIBI dictionary; In Questionnaire 2, the animation pronounces 25 sentences long sentences; Questionnaire 3 compares the 3D animation with the original videos; In questionnaire 4, combine the mouth movement with hand gestures simultaneously. MOS respondents consisted of three deaf students and three SIBI teachers from the School for special needs SLB Santi Rama.

The evaluation uses subjective values from the teachers and deaf students because there is still no ground truth to test the correctness of lip movements. This application is intended for the Deaf, so it requires a direct assessment of the intended target. The MOS assessment uses a scale from 1 to 5 [2].

Calculations using MOS can be seen in the following equation 4:

$$MOS = \sum_{i=1}^N \frac{x(i).k}{N} \quad (4)$$

Where:

$x(i)$  = sample number  $i$

$k$  = weight value

$N$  = Number of Respondents

Fig. 10. Smooth Transition on Cross-Fading.

2) *Application survey measurement*: The System Usability Scale (SUS) test, a qualitative research tool, is used to assess and improve the usability of this system. Usability testing is carried out using a usability testing sheet containing tasks and scenarios the respondent must do during the test. In each task and scenario, the respondent will be assessed on whether he/she has succeeded in carrying out the task, the ease and difficulty the respondent faced, things the respondent likes and dislikes, and any suggestions from the respondent [25]. In each question, respondents will be asked to determine their rating on a scale of 1-5 based on their experience after using an interactive system design. A low score indicates disagreement from the respondent, while a high score indicates the respondent's agreement with the questions. SUS Score Assessment using the scoring formula [26]. Table VI is a list of questions of SUS taken from statements from [26] that have been translated into Indonesian [27]. The SUS itself consists of 10 items, the odd numbers are for positive items and the even numbers for negative. For positive items, the score contribution is the scale position minus 1 and for the negative items, the score contribution is 5 minus the scale position. The overall SUS score is the result of the sum of item score contributions multiply by 2.5, range from 0 to 100.

TABLE VI. TEXT PARSER RESULT

No	Question (Indonesian)	Question (English)
1.	Saya berfikir akan menggunakan sistem ini lagi	I think that I will use this system again
2.	Saya merasa sistem ini rumit untuk digunakan	I found the system to be unnecessarily complex
3.	Saya merasa sistem ini mudah untuk digunakan	I found the system easy to use
4.	Saya membutuhkan bantuan dari orang lain atau teknisi dalam menggunakan sistem ini	I think that I would need the support of a technical person to be able to use this system
5.	Saya merasa fitur-fitur sistem ini berjalan dengan semestinya	I found the various features in this system were well integrated
6.	Saya merasa ada banyak hal yang tidak konsisten(tidak serasi) pada sistem ini	I thought there was too much inconsistency in this system
7.	Saya merasa orang lain akan memahami cara menggunakan sistem ini dengan cepat	I feel that most people would learn to use this system very quickly
8.	Saya merasa sistem ini membingungkan	I found the system very cumbersome to use
9.	Saya merasa tidak ada hambatan dalam menggunakan sistem ini	I found no obstacles in the usage of this system
10.	Saya perlu membiasakan diri terlebih dahulu sebelum menggunakan sistem ini	I needed to learn a lot of things before I could get going with this system

#### IV. EXPERIMENT RESULTS

##### A. Mouth Movement Development

This research used deconstruction of words into syllables to generate mouth movements. Each syllable is developed based on lip movements and stored in a database. The lip movement of 3D animation starts from a silent mouth position labeled "idle." Then the lip movements are generated sequentially according to the word's syllables. At the end of the movement of the syllable, the mouth returns to the "idle" position. Fig. 11 shows an example of mouth movement generation. Furthermore, a transition motion that connects one syllable to the next using the cross-fading technique was added. This cross-fading technique is the same technique when generating transitions in hand movements.

Fig. 11. Mouth Movement Generation.

##### B. Text-to-Gesture Application System Analysis

The text-to-gesture application system analysis measures the mean opinion score (MOS) on four questionnaires, System Usability Scale (SUS), and execution time. The MOS testing is used to test how well the mouth movement is in pronouncing words. Usability testing is a test to assess the user interface of the text-to-gesture application. Furthermore, execution time tests the time it takes to run the text-to-gesture application.

1) *Mean opinion score result:* The qualitative testing to measure the performance of the mouth movements generation on syllables was done by distributing four questionnaires to three SIBI teachers and three students from the School for special needs students, SLB Santi Rama. Questionnaire 1, that test the mouth movements animation in word pronunciation,

yields a score of 4.025. Questionnaire 2, which tests the mouth movements animation to pronounce a sentence, got a score of 4.025. Then, questionnaire 3, to test user understanding of the animation when hand gestures and mouth movements were combined, got a score of 4.422. Finally, questionnaire 4 tested the similarity between the animation and the original video and got a score of 4.282.

From the MOS results, respondents found it easier to catch words spoken solely (4.025) than in sentences (3.96). The combination of hand gesture and mouth movement animation can improve animation realism and understanding of the gestures demonstrated in 3D animation (3.96 vs. 4.422).

2) *System usability scale (SUS):* Google Form application is used to help design the questionnaire for SUS. The respondents will answer ten questions by choosing a scale from 1 – 5 for each item. This questionnaire was distributed for seven days and obtained 72 respondents. These respondents consisted of various backgrounds (sign language teachers, deaf people, and ordinary people), ranging from 19 to 61 years, and comprised 28 women and 44 men. The results of the SUS test obtained a score of 76.25 which means that it is categorized as GOOD and considered an application that users generally can accept [26].

3) *Execution time:* In building the Text-to-3D animation application, three processes involve the use of data, namely (1) sentence translation, (2) storage of application settings, and (3) dictionary search. In each of these processes, the execution time was tested 100 times. Furthermore, from the 100 results, a 95% confidence interval was calculated to find the actual execution time value interval. The 95% confidence interval results for each process successfully met the requirements to react instantaneously based on [23], which has an execution time of under 100 ms. The results of the execution time test can be seen in Table VII.

TABLE VII. EXECUTION TIME

Process	Confidence interval 95% execution time	Qualified react instantaneously (< 100 ms) based on research by Nielsen (1993)
Sentence translation	36.5 ± 2.65 ms	Yes
Storage of application settings	0.23 ± 0.039 ms	Yes
Dictionary search	2.21 ± 0.196 ms	Yes

## V. CONCLUSION

This study aims to build a SIBI Text-to-3D animation translator application system. The output of this application is SIBI 3D gesture animation of every input word in an Indonesian sentence. The 3D animation consists of hand gestures and mouth movements' animation. Hand gesture data creation begins with hand movement data collection using sensors from Perception Neuron v2. The recorded sensor data are then stored as skeletal animation. The mouth animation movement was created based on SIBI expert facial data detected using the OpenPose library. Then, the Dirichlet Free-Form Deformation (DFFD) uses the coordinate data from face detection to build mouth movements. Hand gestures and mouth movements are called based on the input sentence. The input sentence is deconstructed into words to generate hand gestures and syllables to generate mouth movements.

It is necessary to accelerate or decelerate the movement of hand gestures to synchronize hand gestures and mouth movements. This research uses Cross-Fade interpolation to generate a smoother transition movement between word gestures. There are three tests carried out to measure the performance of the system being built. The first test is intended to measure the mouth movement animation when using syllables by calculating MOS. The second test is carried out to measure system's usability by using the SUS test. The third test measures the execution time by calculating the time needed by processes involving data. From the MOS results, respondents found it easier to catch words spoken solely (4.025) than in sentences (3.96). The combination of hand gestures and mouth movement animation can improve animation realism and understanding of the gestures demonstrated in 3D animation (3.96 vs. 4.422). The resulting animation is quite similar to the original video (4.282). SUS score is 76.25, which means this application is in the GOOD category. The execution time of all processes that involved data (sentence translation, storage of application settings, and dictionary search) are less than 100ms, which means it met the application requirements to react instantaneously. Hopefully, this application can be used to solve the communication problems between the deaf and the people around them. Because the number of words available in the SIBI dictionary (around 3100 words) is far less than the Indonesian words, some words need to be fingerspelled or replaced by similar words available in the SIBI dictionary. In the future, a synonym table can be added to this application. The synonym table will speed up the process of replacing a word with its synonym from the SIBI dictionary. This synonym table must be updated regularly to cover as many Indonesian words as

possible. Another thing that can be done to improve this application is to add facial expressions to the 3D model. In sign language, facial expressions are used to strengthen the meaning of a sentence, just like intonation in spoken language.

Student, Department of Information Technology, MVGR College of Engineering (A), Vizianagaram, A.P, India<sup>2,3</sup>

**Abstract**—Foreground segmentation in dynamic videos is a challenging task for many researchers. Many researchers worked on various methods that were traditionally developed; however, the performance of those state-of-art procedures has not yielded encouraging results. Hence, to obtain efficient results, a deep learning-based neural network model is proposed in this paper. The proposed methodology is based on Convolutional Neural Network (CNN) model incorporated with Visual Geometry Group (VGG) 16 architecture, which is further divided into two sections, namely, Convolutional Neural Network section for feature extraction and Transposed Convolutional Neural Network (TCNN) section for un-sampling feature maps. Then the thresholding technique is employed for effective segmentation of foreground from background in images. The Change Detection (CDNET) 2014 benchmark dataset is used for the experimentation. It consists of 11 categories, and each category contains four to six videos. The baseline, camera jitter, dynamic background, and bad weather are the categories considered for the experimentation. The performance of the proposed model is compared with the state-of-the-art techniques, such as Gaussian Mixture Model (GMM) and Visual Background Extractor (VIBE) for its efficiency in segmenting foreground images.

**Keywords**—Foreground segmentation; deep learning; Convolutional Neural Network (CNN); Visual Geometry Group (VGG) 16 architecture; Transposed Convolutional Neural Network (TCNN); Gaussian Mixture Model (GMM); Visual Background Extractor (VIBE)

## I. INTRODUCTION

Foreground segmentation [1] is a major part of various applications of computer vision. Foreground segmentation means that segmenting moving information from static information (background). Foreground segmentation is also called as Background Subtraction or Change Detection. Foreground segmentation is widely used in several applications like video surveillance [2], traffic monitoring, shopping malls, airports, etc. It analyzes a video sequence by using a set of techniques and those video sequences are recorded by a stationary camera.

Gaussian Mixture Model introduced by Chris Stauffer et al., [3] works on pixel-based classification. GMM models each pixel with K-Gaussians. It easily copes up with illumination changes. Even though a single Gaussian function is not able to deal with a dynamic background by providing a low updating rate of the background model. It is failed by the camouflage effect. The number of Gaussians here is predetermined as either 3, 4 or 5.

Visual Background Extractor introduced by O. Barnich et al., [4] is a non-parametric method and it works on pixels. This method utilizes the spatial information around the pixel for the background model. First of all, a set of values should be taken for each pixel at the same location in the neighborhood. Later, it compares this set to the current pixel value to determine whether it is background or foreground and adapts the model by choosing randomly among values to substitute from the background model. This approach differs from classical approach and belief that the oldest values should be replaced first. Finally, when the pixel is found to be part of the background, its value is generated into the background model of a neighboring pixel. Visual Background Extractor (VIBE) applied to color values of pixels of background training sequences as samples of observed backgrounds. Visual Background Extractor (VIBE) shows the best performance because it using samples as background models to represent the background changes. However, Visual Background Extractor (VIBE) has a major disadvantage that it uses color values of pixels to build the background model but color values are found to be sensitive to noise and illumination changes.

This article concentrated on developing a foreground segmentation model based on Deep Learning technique called Convolutional Neural Networks. The Convolutional Neural Network (CNN) is associated with Transposed Convolutional Neural Network (TCNN) for extracting the feature maps to identify foreground image. A thresholding technique is utilized to filter out the feature maps which distinguishes foreground object from a background object in an image. The main contributions of this article are:

- Detecting foreground objects in an image with improved accuracy.
- Design and implementation of a model using Deep Learning technique for effective segmentation of foreground objects.
- Evaluation of the proposed model using Gaussian Mixture Model (GMM) & Visual Background Extractor (VIBE) techniques.

The reminder of the paper is further organized as follows: Section II discusses related work, Section III presents the proposed methodology, Section IV of the article illustrated the experimental setup, and Section V illustrates the performance evaluation and experimentation results. Section VI gives out the conclusion and future work.

## II. RELATED WORK

In the past few years, eminent researchers experimented on foreground object segmentation techniques such as, Midhula Vijayan et al., [5] proposed a deep-neural network architecture using temporal and spatial information from background images and current processing images. Their experimentation obtained a better performance model when compared with existing background subtraction methods both qualitatively and quantitatively. Tsung-Han Tsai et al., [6] elucidated an unsupervised segmentation technique using distinct thresholding techniques by sorting of changed pixels ratio for precise decision. They obtained satisfactory results in generic images. Patrick Dickinson et al., [7] addressed the problem of foreground segmentation, when there is a varying background over time using Adaptive Gaussian Mixtures model (AGMM). Their experimentation resulted in better performance than the per-pixel and Markov Random Field-based Models and achieved a Jaccard coefficient of 0.59.

Jaime Gallego et al., [8] experimented by combining pixel-wise and region-based model for foreground segmentation using one Gaussian per pixel. This improved the performance of the system having similar colors to those of the background. Jaime Gallego et al., [9] proposed a method for monocular static camera sequences and indoor scenarios using Gaussian pixel color, Modified Mean Shift algorithm, and by Bayesian framework. Their methodology yielded robust segmentation and tracking of objects than the state-of-art methodologies. Jaime Gallego et al., [10] illustrated the reduction of false positive and false negative by using region-based models for modeling foreground and background region. Their model surrounds the foreground by Maximum A Posteriori and Markov Random Field model which uses pixel-wise color GMM for background sequence classification.

Jiayu Liang et al., [11] constructed a new method using Genetic Programming for feature construction by incorporating subtree technique. The simultaneous construction of multiple features and parsimony pressure techniques are introduced to improve the proposed techniques bloat control. Xuchao Gong et al., [12] developed a method using the GMM for modeling static background regions and inter-frame change detection and Scale-Invariant Feature Transform (SIFT) feature analysis is used for boundary identification of foreground regions. The Grab cut methods are used for segmentation of foreground moving objects. Yizheng Guo et al., [13] illustrated the segmentation of pigs in group-housed environments by combining a mixture of Gaussians using prediction mechanism and threshold segmentation algorithm.

Nikolaos Katsarakis et al., [14] considered Stauffer and Grimson's algorithm as a baseline algorithm and enhanced their algorithm by changing the learning rate and combining the Gaussian mixture if they are similar. They yielded good results than the baseline algorithm.

As per the literature review, many models proposed by eminent researchers have failed to obtain efficient results for foreground segmentation. This paper focuses on the implementation of foreground segmentation methodology using deep learning techniques for enhanced segmentation results.

## III. PROPOSED METHODOLOGY

The proposed methodology uses the VGG-16 model for foreground segmentation. It comprises two sections namely Convolutional Neural Network (CNN) and a Transposed Convolutional Neural Network (TCNN).

Each frame is extracted from video data and moved onto the following Convolutional Neural Network (CNN) and Transposed Convolutional Neural Network (TCNN).TCNN networks, where, the Convolutional Neural Network (CNN) network extracts the features from the input frame which are related to the foreground object by moving the frame onto different layers which are described in section A. The extracted features from the Convolutional Neural Network (CNN) network are fed into Transposed Convolutional Neural Network (TCNN), where the feature maps are unsampled to obtain original input size. By applying the thresholding technique based on probability to the unsampled features, the foreground objects are segmented from the background objects in a frame and hence for all the frames.

The proposed model is highlighted in Fig. 1. The Convolutional Neural Network and Transposed Convolutional Neural Network are described as follows:

### A. Convolutional Neural Network (CNN)

The actual VGG-16 model contains 5 blocks with 16 layers. The feature extractor section uses 5 blocks and each block contains a set of  $3 \times 3$  kernels like a stack with a max-pooling layer. The filters used in each convolutional layer are 64, 128, 256, 512, and 1024.

Our proposed model contains only 4 blocks as a feature extractor section and each block having  $3 \times 3$  kernels as a smaller kernel size. Two receptive fields of  $3 \times 3$  kernels are equal to a  $5 \times 5$  receptive field. The three  $3 \times 3$  kernels are equal to the  $7 \times 7$  receptive field. Due to this, the parameters are reduced to 30%. The input is a  $W \times H$  RGB image. The four convolutional layers of  $3 \times 3$  kernels are followed by a max-pooling layer with stride 2. This first section produces the feature maps of size  $W/8 \times H/8$  with 512. Doing this input by half, we get fine features from each frame, so it will have minute information from frame. The feature extraction section is done well because the Visual Geometry Group (VGG) 16 architecture, network is pre-trained. It is already trained on millions of images. It uses the CDNET-2014 dataset as input. The obtained feature maps are fed as input for the Transposed Convolution Neural Network (TCNN) part.

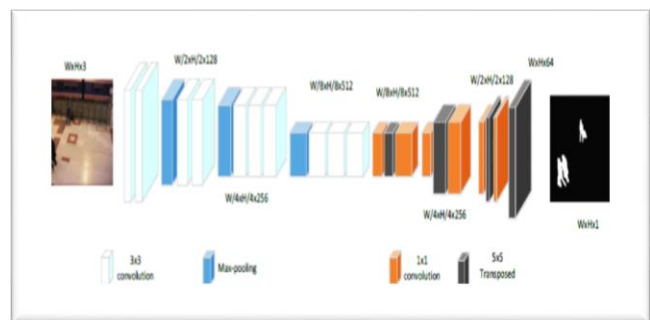

Fig. 1. Architecture of the Experimented CNN.

### B. Transposed Convolutional Neural Network (TCNN)

The feature maps in the CNN section will be unsampled by Transposed Convolution Neural network (TCNN). It unsamples the features into original input by performing the multiplication of output by transposing the kernel or padding output to reconstruct the input. It down samples the feature maps by decreasing them from 512 to 64.

In this TCNN section, we have four blocks each block contains two 1x1 convolutions followed by 5x5 transposed convolutions with stride 2. These 1x1 convolutions are used to shrink the feature maps to get the original input size. After that thresholding technique is applied for the segment the foreground object.

### IV. EXPERIMENTAL SETUP

The overall experimentation was carried out on a 64-bit Windows 10 operating system having Inter® core™ i5 processor clocked at 2.24 GHz, 8 GB RAM, and 1 TB hard drive installed with Anaconda, Python platform with Tensor flow as backend and supporting image processing packages.

The CDNET-2014 benchmark dataset is used for experimentation. The dataset comprises of 11 categories and each category has 4 or 5 videos. For the experimentation, only four categories are namely: baseline, camera jitter, bad weather, and dynamic background to validate the performance of the model.

### V. PERFORMANCE EVALUATION AND EXPERIMENTATION RESULTS

To evaluate the performance of the proposed model different quality metrics are considered such as: Precision, Recall, Accuracy, F-Score, mean Squared Error (MSE), Root Mean Squared Error (RMSE), False Negative Rate (FNR), False Positive Rate (FPR), Peak Signal to Noise Ratio (PSNR), and Pair Wise Correlation (PWC) coefficient which are defined as follows:

$$Precision = \frac{True_{pos}}{False_{pos} + True_{pos}} \quad (1)$$

$$Recall = \frac{True_{pos}}{False_{neg} + True_{pos}} \quad (2)$$

$$Accuracy = \frac{True_{pos} + True_{neg}}{True_{pos} + False_{pos} + True_{neg} + False_{neg}} \quad (3)$$

$$F - Score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (4)$$

$$MSE = \frac{1}{n} \sum_{i=1}^n (Actual\ Values - Predicted\ Values)^2 \quad (5)$$

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (Actual\ Values - Predicted\ Values)^2} \quad (6)$$

$$FNR = \frac{False_{neg}}{True_{pos} + False_{neg}} \quad (7)$$

$$FPR = \frac{False_{pos}}{True_{neg} + False_{pos}} \quad (8)$$

$$PSNR = 10 \log_{10} \frac{R^2}{MSE} \quad (9)$$

$$PWC = 100 * \frac{False_{neg} + False_{pos}}{True_{pos} + False_{neg} + True_{neg} + False_{pos}} \quad (10)$$

To validate the performance of the proposed model, GMM and VIBE are considered as reference model. The graphical illustration of experimental results is shown in Fig. 2 and their corresponding results are given in Tables I to IV.

## VI. CONCLUSION AND FUTURE WORK

This paper focused on the enhancement of foreground object segmentation using deep neural network model viz., VGG-16 which comprises of CNN and TCNN. To evaluate the performance of the proposed model, comparison with the traditional methods such as GMM and VIBE is done. The results showcased that the proposed VGG-16 model has proven its supremacy in obtaining the highest accuracy of 99.99% in - comparison to the state-of-the-art techniques such as GMM and VIBE. Hence, the proposed model performed better in segmenting the foreground image with improved accuracy. Exploring other advanced deep learning techniques for improved segmentation of foreground objects in images is considered as the future work.

**Abstract**—Personal identity has become an important asset in today's digital world for any individual in society. Biometrics offers itself as a reliable and secure guarantor of our identities, so it has become essential to build efficient and robust recognition systems. In this orientation, we propose a fusion approach, which aims to optimally exploit the dividing block dimensions in the case of local methods to reduce similarities. We will use the compound local binary model (CLBP) for local features extraction, a robust operator descriptor that exploits both the sign and the inclination information of the differences between the center and the neighbor gray values. The reliability of the proposed approach was evaluated on the PolyU Finger Knuckle Print (FKP) database. We presented several experimental results that show the detailed path of our approach, explain the choices made for each step and illustrate the significant improvements compared to other existing recognition systems in the literature. The recognition rate of the proposed global approach is one of the highest among the other methods. Optimal final approach recognition rates vary between 99.70% and 100%.

**Keywords**—Biometrics; Finger Knuckle Print; local features; fusion; compound local binary pattern

## I. INTRODUCTION

The security of personal identity has become a major asset in the development of the world we live in. This era has a wide spectrum of daily transactions that are in the billions, given the number of the world's population involved in the digital world and its applications. This digital world is committed to the development of many services, the main purpose of which is to facilitate this mass of interaction between the population and the services, and to ensure the efficiency of all the transactions that can be judging sensitive; such as finance and communication. These needs are generally linked to many risks, particularly security. The implementation of mechanisms and efficient applications to ensure personal identity has become important and urgent given the daily risks. To overcome these risks, the use of biometrics is an effective way to solve security difficulties in various fields and services [1].

During the last decades, several research works have been conducted to build reliable recognition systems. Researchers have exploited and experimented with various biometric modalities including face, voice, fingerprint, palm print, iris, [2-6], etc. Some types of these biometric descriptors show an intrusive nature [7]. It should be noted that the acceptance and ease of use of biometric identifiers play a key role in the success of recognition systems. To ensure these two points, the thinking of the researchers was drawn to the hand-based

descriptors. There is a lot of research and promising results in the literature on hand-based biometric modalities, e.g. hand [8], [9], palm print [10], [11], fingerprint [12], [13], and hand geometry [14], [15], which have been widely studied. These studies have allowed the construction of a large set of recognition systems to ensure the identity authentication function and which operate successfully in several areas.

The most common identification systems in the real world are based on the use of fingerprint recognition, moreover it is the most used system in the field of access control, the police etc. Moreover, the most reliable systems are based on the use of the iris as an identification modality. Except that, these two descriptors represent drawbacks, which can hinder their success, iris sensors represent high intrusiveness, which makes them not very acceptable by users and extraction of small unique features called minutiae from damaged fingerprints is difficult [16]. It is added to the two drawbacks cited, the fact that fingerprints are vulnerable to spoofing attacks which consist in the creation of biometric artefacts. Matsumoto et al. [17] found that gummy fingers were accepted with high recognition rates by the 11 different fingerprint systems they used. These forged fingerprints are easily achievable with readily available devices and materials. This vulnerability is due to the anatomical structure of the hand and the mechanisms of its movements; in fact, the use requires a contact surface between the hand bottom and the object used, this interaction will keep traces of fingerprints and palm prints on this object. To overcome this problem, one of the proposed solutions is to employ the back side of the hand. In recent years, researchers have observed that the skin pattern of the outer surface of the fingers, especially in the area around the phalangeal joint, has a rich texture due to the lines and folds of the skin. This texture shows a distinctive character given the uniqueness it represents; therefore the finger knuckle print can be used as a biometric descriptor [18], [19].

In the literature, researchers have begun their work to create recognition systems based on finger knuckle print FKP, with approaches based on the use of global characteristics such as: principal component analysis (PCA), independent component analysis (ICA) and linear discriminant analysis (LDA) [20]. Subspace analysis approaches are methods whose concept is suitable for large devices; they are rather effective for large areas such as facial recognition, which reduces their performance for systems that use descriptors with smaller surfaces such as FKP images [21]. Subsequently, researchers turned to multi-algorithm or multimodal approaches [22-24]. The mechanisms based on these approaches have shown

\*Corresponding Author.

satisfactory results in the majority of cases. Based on this observation, we directed our work towards FKP recognition systems using local and not global characteristics, given the nature of the descriptor. Also, our orientation to ensure maximum reliability was to continue work towards the construction of a multi-instance biometric system, based on a reliable and robust extraction algorithm.

The response to these established expectations was the motivation we set ourselves to propose an efficient approach, which relies on the use of local characteristics to build a reliable multi-instance recognition system and which allows reducing the complexity of the calculations, as well as the implementation cost will be optimized. The proposed approach is based on the use of the compound local binary model (CLBP) [25] for the assurance of the local feature extraction phase. In this phase, we experimented and evaluated this method on several block sizes and also the nature of the block (square or rectangular), which is often neglected in other works, to produce optimal histograms and achieve the best possible results. The classification phase will be oriented towards classifiers based on the use of distances, this kind of classifiers can produce good results in the case of low resolution images, which we will use. We have opted for three variants of measurements: Euclidean distance, Jeffrey divergence and city block, which we will study their performance with our extracted characteristics and choose the most suitable to work in a real-time environment and produce effective results.

This paper is organized as follows: in Section 2, we will describe the proposed approach and the methods used. In Section 3, we will report and discuss the experimental results conducted on the PolyU FKP database [26] and finally, in Section 4, we will draw our conclusions.

## II. PROPOSED APPROACH

The construction of recognition systems in the real world is based on several factors. The reliable recognition rates, the reduction of the calculation time and the robustness are decisive assets. In the approach we propose, we aim to satisfy these factors. This work is divided into three phases:

In the first phase, we will address two major points that will later be used to build our final system. The first point during this phase is to show that the recognition system based on local feature extraction with a compound local binary pattern (CLBP) can provide reliable results.

The second point concerns the matching phase, which is a very important step and can be costly in computation time. To satisfy this constraint, we will proceed with distance-based classifiers to reduce the computation time. We are going to test three classifiers during the first phase and take the most appropriate one in relation to the local extraction method used (recognition rate and computation time). The system used for this evaluation is shown in Fig. 1.

Fig. 1. FKP Recognition System Adopted for Evaluation.

During the second phase, we will proceed to an analysis and a comparison of the results obtained with other methods, in order to demonstrate the efficiency of the method to be used in our system.

In the end, the last phase consists in using the results and the conclusions obtained in the two previous phases to test the effectiveness of our global system, which is based on the concept of fusion at score level. The results obtained in the last phase will be analyzed and compared with phase 2. The proposed FKP recognition system is shown in Fig. 2.

### A. Local Feature Extraction Process

Recognition systems generally satisfy two overriding conditions: high recognition rates and low computational cost. Note that the capture phase may be affected by environmental conditions. To overcome this problem, the local feature extraction phase will be ensured by a robust variant of Local Binary Patterns (LBP), this variant is called Compound Local Binary Patterns (CLBP) [25]. Ojala and Ai [27] introduced the local binary pattern method for the first time as an efficient method for feature extraction from images. The features extracted by this process have provided an efficient means for texture segmentation and classification.

The local binary pattern is recognized by a gray scale texture operator characterizing the local spatial structure of the image texture [28]. Given a central pixel in the image, a pattern code is calculated by comparing it to its neighbors. This procedure is illustrated in Fig. 3.

The LBP operator takes the form:

$$LBP(x_c, y_c) = \sum_{n=0}^7 2^n S(i_n - i_c) \tag{1}$$

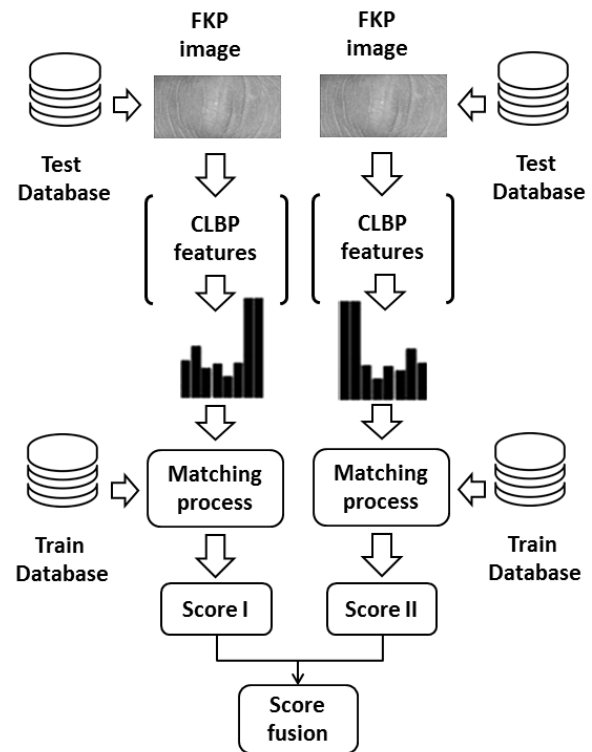

Fig. 2. The Proposed FKP Recognition System.

Fig. 3. Local Binary Pattern Operator.

where in this case  $n$  runs over the eight neighbors of the central pixel  $c$ ,  $i_c$  and  $i_n$  are the gray-level values at  $c$  and  $n$ . Function  $S(x)$  is shown below,

$$S(x) = \begin{cases} 1 & \text{if } x \geq 0 \\ 0 & \text{if } x < 0 \end{cases} \quad (2)$$

The LBP operator employs a process that relies solely on the use of the sign of the difference between two gray values, which often leads to a failure to generate binary codes consistent with the texture properties for local region. To overcome this problem, we will use an extension of this operator. This extension assigns a 2P bit code to the central pixel based on the gray values of the local neighborhood comprising P neighbors; this extension is the Compound Local Binary Pattern method (CLBP) [29]. The CLBP operator employs two bits for each neighbor in order to encode the sign as well as magnitude information of the difference between the center and the neighbor gray values, unlike the LBP that uses only one bit for each neighbor by representing the sign of the difference between the center and the corresponding neighbor gray values. In this case, the first bit is representing the sign of the difference between the center and the corresponding neighbor gray values as the basic LBP encoding. The second bit is for encoding the magnitude of the difference with respect to a threshold value, which is the average magnitude  $M_{avg}$  of the difference between the center and the neighbor gray values in the local neighborhood of interest. This CLBP operator chooses the value of 1 for the second bit if the magnitude of the difference between the center and the corresponding neighbor is greater than the threshold  $M_{avg}$ . Other way, it takes the value of 0. Thus, the indicator  $s(x)$  of equation 2 is replaced by the following function:

$$s(i_p, i_c) = \begin{cases} 00 & i_p - i_c < 0, |i_p - i_c| \leq M_{avg} \\ 01 & i_p - i_c < 0, |i_p - i_c| > M_{avg} \\ 10 & i_p - i_c \geq 0, |i_p - i_c| \leq M_{avg} \\ 11 & \text{otherwise} \end{cases} \quad (3)$$

where  $i_c$  and  $i_p$  are the gray values of the central pixel and the neighbors, and the average magnitude of the difference between  $i_p$  and  $i_c$  in the local neighborhood is  $M_{avg}$ . The illustration of the CLBP operator is shown in the Fig. 4.

Fig. 4. Compound Local Binary Pattern Operator.

In Fig. 4, it can be observed that the CLBP operator discriminates the neighbors of the northeast, east and southeast directions because they have higher gray values than the other neighbors, thus producing a consistent local model.

### B. Matching Process

Our choice of classifiers that can be used in our system was based on two important points. The first concerns the computation time, which is an important asset for the success of a recognition system, which directs us towards distance-based classifiers. The second point concerns the resolution of our images, which is not high, so we avoid classifiers such as SVM, which is rather oriented for high resolutions [30], [31]. Taking into account the guidelines already mentioned, we opted for a set that includes three distance-based classifiers, which we will experiment with the extraction method employed and see their performance for recognition rates generation. These classifiers are based on the Euclidean distance, Jeffrey Divergence and City-block.

The Euclidean distance is the most common distance metric used for low dimensional data sets, examines the root of square differences between the coordinates of a pair of objects. This is most generally known as the Pythagorean Theorem. For testing we used this classifier, for calculating the minimum distance between the test image and train image. Euclidean distance  $d$  is presented as follows:

$$d(x, y) = \sqrt{\sum_{i=1}^n (x_i - y_i)^2} \quad (4)$$

The Jeffrey divergence is a modification of the Kullback-Leibler (KL) divergence, if  $P = (p_1, \dots, p_N)$  and  $Q = (q_1, \dots, q_N)$  are two discrete distributions, the Jeffrey divergence between  $P$  and  $Q$  is defined as:

$$D(P, Q) = \sum_i (p_i \log \frac{p_i}{m_i} + q_i \log \frac{q_i}{m_i}) \quad (5)$$

$$\text{Where } m_i = \frac{(p_i + q_i)}{2}$$

The city-block distance classifier, Manhattan distance classifier, also called, rectilinear distance, L1 distance, L1 norm, Manhattan length. It represents the distance between points in a city road grid. It examines the absolute differences between the coordinates of a pair of objects as follows:

$$d(x, y) = \sum_{i=1}^n |x_i - y_i| \quad (6)$$

## III. EXPERIMENTAL RESULT

In this section, we will proceed with various experiments to prove the reliability of the proposed recognition scheme. For a comparative evaluation of our recognition system, we will conduct experiments on the PolyU database [26]. This database is part of the databases, which can be described as referential databases in this field.

### A. FKP PolyU Database

The PolyU FKP database is identified as a reference in biometrics research work (Fig. 5). This benchmark is used for evaluating the performance of the majority of FKP recognition systems that have been studied. The database construction was made thanks to the participation of 165 volunteers, including 40 women and 125 men. Among them, 143 individuals aged

between 20 and 30 years old and the rest between 30 and 50 years old. Two separate sessions have been designed to collect FKP images. During these two sessions, the volunteer is asked to provide six images for each of the right index finger, left index finger, right middle finger and left middle finger. All the original FKP images used have a resolution equal to 220x110. In the end, each subject is determined by  $12 \times 4 = 48$  images, 12 FKP images of each finger. Thus, the database total is 7920 images from 660 fingers.

Fig. 5. Finger Knuckle Print PolyU Database.

### B. Evaluation and Analysis of Results

In order to validate our recognition system, we have established an evaluation process divided into three different phases. The first step concerns a single finger knuckle print evaluation of our scheme, this step aims to determine the classifiers able to provide reliable results, and then we choose the most efficient ones. During this step, we will perform detailed experiments for each finger. The object of these experiments will be to determine the most suitable classifiers for our case study (recognition rate), the overall time taken by the matching phase for all the classes which are of the order of 165 classes, each class uses 6 test images which will be compared to  $6 \times 165$  images = 990 images, we will call later in the experiments this computation time: Matching Process Time MPT. We will also introduce the division of the image into sub-images according to the type of resolution (square or rectangular) and conclude whether it is possible to introduce this kind of rectangular division, which is generally absent in the literature. In the second step, after having obtained the results and their analysis, we will proceed to a comparison with the other mechanisms already cited in the literature, which have used finger knuckle prints for the creation of recognition systems and conclude on the obtained performance. Finally, in the last part, we will use the directives obtained in our global approach, see its impact on performance and demonstrate the reliability of the proposed approach.

Single finger knuckle print evaluation in this first step, we will apply the same experimental protocol used by the others systems cited in literature. The 6 images captured during the first session are used to create the training database and the 6 images captured in the second session for the testing database. Therefore, for each volunteer, there are six training samples and six testing samples (Fig. 6). Our approach is based on local methods. The performance of scheme is evaluated with different sizes of sub images for each FKP image.

Fig. 6. Standard Protocol used for FKP Experiment.

We have categorized block sizes into three divisions: large division, medium division and small division. Large division is defined by two type of size block: 110x110 and 64x64, for medium size: 48x48 and 32x32 pixels, and for small size: 24x24 and 16x16. In order to increase Classification Process Performance of our approach, we have inspected many classifiers based on the squared Euclidean distance, the divergence of Jeffrey and City-Block. The recognition rates for each finger with the different divisions of sub-images are presented in the comparative Tables I, II, III, IV, V, VI, VII and VIII. This comparative evaluation is made with the intention of showing the most adaptive classifiers in our case.

1) *Result of experiment on left index finger:* The Table I shows the adequacy of classifiers based on distance city-Block and Jeffery divergence compared to the classifier based on Euclidean distance. The city-block classifier gives the best recognition rate value 98.18% for divisions (sub-images) of 16x16 pixels. We also notice that the Matching Process Time MPT increases proportionally with the decrease of the dividing block size. This observation is normal, since the smaller the block size, the more the number of sub-images increases (for image), and therefore the histogram of the image too. As we can also notice that even if the recognition rates can be equivalent between city-block and Jeffrey divergence, the MPT with the Jeffrey divergence classifier is much higher, we can cite the case of the 16x16 pixel block where the MPT for city block equal to 21.30s while that obtained with Jeffrey divergence equal to 852.96s.

It should be noted that these divisions (16x16, 24x24, 32x32, 48x48 and 64x64) are the most used in the literature. Nevertheless, we must not limit ourselves to this rule often used by researchers; we can extend the division with blocks of rectangular sub-images and not only square ones. In our case, we have an image whose size is 220x110 pixels; it would be wise to choose a division, which participates in an optimal construction of the histograms of each sub-image. In this sense to verify this proposal and based on the analysis of the optimal results obtained with blocks, which vary between 16x16 and 24x24 pixels and the shapes of the lines in the FKP images, we will extend the experiment to the 11x22 pixels blocks. This block division has exact multiples for the size of our FKP (220x110) images  $11 \times 20 = 220$  pixels and  $22 \times 5 = 110$  pixels, which gives for the division  $(220 \times 110) \setminus (11 \times 22) = 100$  sub-images.

TABLE I. RECOGNITION RATE FOR LEFT INDEX WITH TYPICAL BLOCKS

		Table Recognition rate RR (Left index)		
Block size	RR/MPT	Euclidian distance	Jeffrey divergence	City-Block
110x110	RR	78,69%	<b>88,79%</b>	87,07%

	MPT	1,932484 s	273,279155 s	7,005333 s
24x24	RR	96,16%	97,37%	<b>98,08%</b>
	MPT	2,615035 s	422,307223 s	10,967445 s
16x16	RR	96,26%	97,98%	<b>98,18%</b>
	MPT	3,784349 s	852,959212 s	21,302479 s

TABLE II. RECOGNITION RATE FOR LEFT INDEX WITH RECTANGULAR BLOCK

		Table Recognition rate RR (Left index)		
Block size	RR/MPT	Euclidian distance	Jeffrey divergence	City-Block
11x22	RR	96,56%	97,98%	<b>98,48%</b>
	MPT	3,613546 s	877,053453 s	21,665596 s

In the Table II, we notice that the division of the image into sub-images with blocks size 11x22 pixels gives an optimal recognition rate with a value of 98.48%, this value rivals that obtained by the 16x16 block whose value is 98,18%. We are going to opt for this additional experience for the rest of the fingers (right Index, left middle and right middle).

2) *Result of experiment on right index finger:* In Table III, the obtained results affirm once again the adequacy of the resulting recognition rate with the classifiers based on the Jeffrey divergence and the City-block. We note that the value of the high recognition rate obtained is 98.48% with city block for a size block 24x24 pixels. As we mentioned before we are going to continue the complement of the experiment with the block whose size is 11x22 pixels. For MPT, we observe the same remark as before.

In the Table IV, we still notice the same remark and that the division of the image into sub-images with block of size 11x22 pixels gives optimal recognition rate with a value of 98.69%, this value remains equivalent or higher than that obtained by the 24x24 block whose value is 98.48%. It should be noted that even if we have equivalence in terms of recognition rates for the 11x22 pixels blocks with Jeffrey divergence and City-block, there remains the MPT factor, which gives a considerable advantage for City-block. The operation with Jeffrey divergence is more cost in computation time, MPT equal: 570, 16 s.

3) *Result of experiment on left middle finger:* Table V still shows the results superiority of the obtained recognition rates with the classifiers based on the Jeffrey and City-block divergence. We note that the value of the highest recognition rate is 99.29% with city-block for size 16x16 pixels. We will continue our experiments with the complement concerning the 11x22 pixels blocks.

TABLE III. RECOGNITION RATE FOR RIGHT INDEX WITH TYPICAL BLOCKS

		Table Recognition rate RR (Right index)		
Block size	RR/MPT	Euclidian distance	Jeffrey divergence	City-Block

TABLE IV. RECOGNITION RATE FOR RIGHT INDEX WITH RECTANGULAR BLOCK

		Table Recognition rate RR (Right index)		
Block size	RR/MPT	Euclidian distance	Jeffrey divergence	City-Block
11x22	RR	96,46%	98,69%	98,69%
	MPT	2,451808 s	570,162648 s	14,020781 s

TABLE V. RECOGNITION RATE FOR LEFT MIDDLE WITH TYPICAL BLOCKS

		Table Recognition rate RR (Left middle)		
Block size	RR/MPT	Euclidian distance	Jeffrey divergence	City-Block
110x110	RR	82,12%	<b>91,41%</b>	90,61%
	MPT	0,942734 s	14,488085 s	1,122162 s
64x64	RR	91,81%	<b>95,86%</b>	<b>95,86%</b>
	MPT	1,035171 s	47,818859 s	1,788124 s
48x48	RR	94,24%	<b>97,07%</b>	<b>97,07%</b>
	MPT	1,163299 s	95,044139 s	2,828460 s
32x32	RR	96,76%	97,68%	<b>98,48%</b>
	MPT	1,359258 s	175,401198 s	4,502957 s
24x24	RR	97,58%	98,59%	<b>98,89%</b>
	MPT	1,726323 s	287,939161 s	7,067663 s
16x16	RR	97,17%	98,89%	<b>99,29%</b>
	MPT	2,704647 s	550,270049 s	13,806499 s

TABLE VI. RECOGNITION RATE FOR LEFT MIDDLE WITH RECTANGULAR BLOCK

		Table Recognition rate RR (Left middle)		
Block size	RR/MPT	Euclidian distance	Jeffrey divergence	City-Block
11x22	RR	96,87%	<b>98,99%</b>	98,89%
	MPT	2,508779 s	569,049885 s	14,005159 s

The results obtained in the Table VI show that the division of the image into sub-images with 11x22 pixels always gives optimal recognition rates with a value of 98.89% in the case of city-block. This value still remains near to that obtained by the 16x16 pixels division, which has a value equal to 99.29% and equal to that obtained by the 24x24 pixels division.

4) *Result of experiment on right middle finger:* Table VII keeps the same conclusion made in the three previous experiments, the superiority of the recognition rates obtained with the classifiers based on the Jeffrey divergence and City-block is maintained. We see that the value of the most optimal recognition rate is 98.89% with city-block for the size 24x24 pixels. We are going to finish the experiments of this first part with the complement concerning the 11x22 block as before.

The block sizes of 11x22 pixels still ensure optimal recognition rates in Table VIII with a value of 98.89% for the 11x22 pixel block. This value is equal to the highest obtained in Table VII by the 24x24 pixel block with a value of 98.89%. In the end, we can conclude that dividing the sub-images into rectangular blocks can give results as optimal as square blocks.

TABLE VII. RECOGNITION RATE FOR RIGHT MIDDLE WITH TYPICAL BLOCKS

		Table Recognition rate RR (right middle)		
Block size	RR/MPT	Euclidian distance	Jeffrey divergence	City-Block
110x110	RR	83,23%	<b>92,63%</b>	90,71%
	MPT	0,950980 s	14,532302 s	1,141061 s

16x16	RR	96,77%	<b>98,38%</b>	98,18%
	MPT	3,809532 s	843,720436 s	21,210157 s

TABLE VIII. RECOGNITION RATE FOR RIGHT MIDDLE WITH RECTANGULAR BLOCK

		Table Recognition rate RR (right middle)		
Block size	RR/MPT	Euclidian distance	Jeffrey divergence	City-Block
11x22	RR	97,37%	98,48%	<b>98,89%</b>
	MPT	3,584845 s	868,403304 s	21,696460 s

### C. Comparison and Analysis of Results

As we have already mentioned, we have set ourselves as objectives, the construction of a robust recognition system which offers a high recognition rate and a reduced computation time. The results obtained confirm our choice of distance-based classifiers with the method used for the extraction of local characteristics. Our choice thereafter to ensure the comparison of our mechanism with others in the literature will be based on the use of the city-block distance. The optimal results are in the following table:

TABLE IX. OPTIMAL OBTAINED RECOGNITION RATE

Table optimal Recognition rate				
Block size	Left index	Right index	Left middle	Right middle
11x22	<b>98,48%</b>	<b>98,69%</b>	98,89%	<b>98,89%</b>
16x16	98,18%	97,88%	<b>99,29%</b>	98,18%
24x24	98,08%	98,48%	98,89%	<b>98,89%</b>

We notice on the Table IX, that the block which shows the highest rates on average is the 11x22 block; we will take its results and compare them with those of the literature to remove the performance of the adopted mechanism.

TABLE X. COMPARATIVE STUDY

Table optimal Recognition rate				
Methods	Left index	Right index	Left middle	Right middle
PCA+LDA [22]	50.64 %	47.00%	51.08 %	54.68 %
CLPP [24]	86.58 %	86.43 %	85.89 %	86.16 %
OCLPP [24]	87.87 %	87.49 %	86.94 %	87.38 %
MSLBP [23]	93.80 %	94.70 %	92.20 %	94.80 %
LGBP [33]	94.14%	94.24%	97.27%	94.75%
LBP+DCT [32]	98.2%	98%	98.7%	97.1%
<b>Our work</b>	<b>98,48%</b>	<b>98,69%</b>	<b>98,89%</b>	<b>98,89%</b>

Table X shows that the preliminary results of the adopted process claim to be reliable, however there are still other aspects that we want to address to study and improve the support of our approach. This is what we will see in the next phase.

### D. Global Evaluation of Proposed Approach

In this section, we will conduct our experiments to evaluate the proposed approach. These experiments consist in exploiting the sizes of the blocks, which have shown their performance previously, with a single finger knuckle print (24x24, 16x16, and 11x22). In this evaluation, we will use the approach with a fusion at the score level, with the city-block distance for the set of multi-instance combinations: left index with left middle (LI, LM) and right index with right middle (RI, RM). This choice is due to the fact that these combinations belong to the same hand, which facilitates the use and creation of sensors in a real recognition system. We will use the Cumulative Matching Characteristics (CMC) curves for each fusion case to measure the identification accuracy. CMC curves demonstrate the ability of a recognition system to identify a given user in a set of data. As the CMC

curve decreases, this represents an increasing amount of impostor images that are more similar than images of the required class, otherwise performance increases.

1) *Results of fusion left index and left middle results for block size 24x24 pixels:* In Fig. 7, we notice that the resulting curve for the fusion of the LI+LM instances is much higher than the other curves and it quickly tends towards 1. The higher recognition rate obtained with the approach equal to 99.90%, this rate is higher than the best rate obtained for studied systems with single instance, in this case left and right middle with 98.89%.

Fig. 7. CMC Curve for Fusion LI+LM with 24x24 Blocks.

a) *Results for block size 16x16 pixels:* In Fig. 8, we will report the same remark in the case of the block equal to 16x16. The recognition rate obtained with the approach is equal to 99.90%; this rate is higher than the best rate obtained for the systems studied previously.

Fig. 8. CMC Curve for Fusion LI+LM with 16x16 Blocks.

b) *Results for block size 11x22 pixels:* In Fig. 9, we used the 11x22 pixel blocks and the resultant is a perfect curve with a score of 100% which outperforms all the curves.

Fig. 9. CMC Curve for Fusion LI+LM with 11x22 Blocks.

2) *Results of fusion right index and right middle*

a) *Results for block size 24x24 pixels:* In Fig. 10, despite the recognition rate that the approach offers and which is equal = 99.80% for the fusion between Right Index and

Right Middle instances (RI, RM), but we notice the Right Index (system with single instance) curve overlaps with the (RI, RM) curve and it reaches values 1 well before the melting curve and this is due to the inter-class similarities.

Fig. 10. CMC Curve for Fusion RI+RM with 24x24 Blocks.

b) *Results for block size 16x16 pixels:* In Fig. 11, despite the recognition rate offered by the approach and which is equal = 99.70% for the fusion between the instances Right Index and Right Middle (RI, RM) with the 16x16 blocks, but we notice that the curve (RI, RM) on the first 100 ranks it does not reach the values 1 and that it is exceeded by the Left Index curve and the Left Middle curve towards rank 24.

Fig. 11. CMC Curve for Fusion RI+RM with 16x16 Blocks.

c) *Results for block size 11x22 pixels:* In Fig. 12, we notice that the resulting curve for the fusion of the right index and right middle instances, in the case where the block size equal to 11x22 pixels is much higher than the other curves. The recognition rate obtained with the approach is equal to 99.70%, and reaches quickly the value 1 quickly before others curves.

Fig. 12. CMC Curve for Fusion RI+RM with 11x22 Blocks.

3) *Comparison between fusion curves (LI, LM) and (RI, RM):* The results obtained show that the choices do not depend on the size of the block but also on its most suitable shape for

the subdivision of the source images. The performance of the results is shown in the Table XI. To confirm these hypotheses, we will obtain the CMC curves of all the mergers (LI, LM) and (RI, RM) with the 16x16, 24x24 and 11x22 blocks.

TABLE XI. RESULTS OF OUR APPROACH

	Recognition rate		
	Block size		
Instances	24x24	16x16	11x22
LI+LM	99,90%	99,90%	100%
RI+RM	99,80%	99,70%	99,70%

a) Results for fusion(LI, LM): In Fig. 13, The curve that represents the LI+LM fusion with the 11x22 block is a curve that surpasses the 2 other fusion curves with the 16x16 and 24x24 blocks. We notice that the fusion curve with the 24x24 blocks is more efficient and its convergence is faster towards the 1 than the 16x16 curve.

Fig. 13. CMC Curves for Fusion LI+LM.

b) Results for fusion(RI, RM): In Fig. 14, although the RI+RM fusion curve with the 24x24 block begins with a higher recognition rate compared to the RI+RM fusion curve with the 11x22 block, the latter tends towards ones more quickly than the curve 24x24 and 16x16.

Fig. 14. CMC Curves for Fusion RI+RM.

All the experiments show very satisfactory results with the fusion approach adopted. The curves in Fig. 7, 8, 9, 10, 11 and 12 support these results. The introduction of the notion of the "block size \ image resolution" ratio in the experiments has shown its effectiveness and its ability to improve the results already obtained. The CMC curves Fig. 13 and Fig. 14 clearly demonstrate this improvement.

#### IV. CONCLUSIONS

In this paper, we evaluated the performance of the local CLBP descriptor, the influence of the block size parameter and its shape on the recognition rate. To improve efficiency and accuracy, we proposed an approach based on multi-instance fusion at the score level. The experimental results on the PolyU FKP reference database clearly show that the proposed approach increases the recognition rates (between 99.70% and 100%) and that it reduces the influence on the variance of the rates by taking charge of the adequate divider block according to the resolution of the image for the optimal construction of the histograms. Thus, we can conclude that this approach provides a noticeable performance improvement and can be usefully used for FKP recognition systems. The future works will focus on improving the security side of the recognition systems construction based on hand modalities. This improvement will aim to reduce the possibility of personal identity theft, while reducing the complexity of the mechanism to be built.

# Detection of Credit Card Fraud using a Hybrid Ensemble Model

Sayali Saraf<sup>1</sup>, Anupama Phakatkar<sup>2</sup>  
Department of Computer Engineering  
SCTR's Pune Institute of Computer Technology  
Pune, India

**Abstract**—The rising number of credit card frauds presents a significant challenge for the banking industry. Many businesses and financial institutions suffer huge losses because card users are reluctant to use their cards. A primary goal of fraud detection is to identify prior transaction patterns to detect future fraud. In this paper, a hybrid ensemble model is proposed to combine bagging and boosting techniques to distinguish between fraudulent and legitimate transactions. During the experimentation two datasets are used; the European credit card dataset and the credit card stimulation dataset which are highly imbalanced. The oversampling method is used to balance both datasets. To overcome the problem of unbalanced data oversampling method is used. The model is trained to predict output results by combining random forest with Adaboost. The proposed model provides 98.27 % area under curve score on the European credit cards dataset and the stimulation credit card dataset gives 99.3 % area under curve score.

**Keywords**—Credit card; hybrid ensemble model; bagging; boosting; data imbalance

## I. INTRODUCTION

There is a growing issue of financial fraud in the government, businesses, and financial sector with significant implications [1]. In credit card fraud, purchases occur on a cardholder's account without the cardholder's knowledge or consent. It is crucial to prevent fraud by taking all necessary precautions when carrying out these transactions. Bank regulators must also employ snipping technology to anticipate these thefts. Predicting the transactions that account holders will make but which will be completed by other people with access to the account is a fraud detection method for our dataset. It is a complex issue that needs to be resolved by both the account holder and the bank so that other customers don't face the same issue. However, there is a problem of class inequality with this issue. An individual consumer will complete many more legitimate transactions than fraudulent ones, or even none at all. A transaction that differs from a customer's previous purchases might be considered fraud. As credit card transactions increase in popularity for payment, academics are focusing on several strategies for fighting credit card fraud. The most common yet challenging issue is credit card fraud detection. As a result of the limited amount of credit card data, it is challenging to match a pattern for a dataset. Second, many records in the collection could include fraudulent transactions that follow a pattern of honest activity [2]. There are also some limitations to the issue. Firstly, study results are often classified and regulated, making them

unavailable. Additionally, classified data sets are not readily available to the general public. Due to this, benchmarking specific models may be challenging. It is also difficult to develop solutions due to the security issue, which limits the exchange of concepts and techniques for detecting fraud, particularly credit card fraud [3]. The last point is that data sets are continually changing and evolving. It produces profiles of legitimate and fraudulent behavior separate from current valid transactions that may have been fraudulent in the past. In this paper, we will use a variety of machine learning algorithms, including logistic regression, random forest, and AdaBoost, to evaluate the performance of our proposed model. Two credit card datasets are used in the experiment, one of which is very skewed and unbalanced. The hybrid ensemble model is used to differentiate between fraudulent and legal transactions.

The work presented in the paper can be summarized as follows:

- 1) A hybrid ensemble model is proposed to classify fraudulent and legitimate transactions. The system uses an Adaboost, random forest, and Logistic regression to build a classifier.
- 2) The oversampling method and the removing outliers' approach are two methods used to address the problem of imbalanced data.
- 3) The train and test datasets are used to conduct the experiments on the proposed model.

The structure of the paper is organized as follows: The related work of existing algorithms is described in section II, while section III refers proposed hybrid model for fraud detection. Experimental credit card fraud detection, results, and discussion are presented in Section IV. The paper's conclusion is discussed in Section V in the final part.

## II. RELATED WORK

The performance of machine learning and data mining to prevent credit card fraud has been examined by the authors in [1]. On the other hand, most researchers used some classification measures to assess the solutions. A credit card detection model was used to extract the right attributes from transactional data. The aggregate approach was utilized to observe the customer's spending behavioral pattern. The author of this research proposes to construct a new set of features based on the periodic behaviors of transaction time

using an aggregation technique. An actual credit card fraud detection dataset from a large European cardholder company was used by the author. To examine the results, the author compared state-of-the-art credit card fraud models and weighed the pros and cons of various feature sets.

Credit cards are becoming more widely used in financial transactions, and at the same time, fraud is also increasing. The author presented a convolutional neural network framework to capture the pattern of fraud data in this research [2]. The author has proposed a trading entropy model to identify more complex consuming behaviors. Aside from that, the author merges the trending features into feature matrices for convolutional neural networks. As a result, the CNN model outperforms state-of-the-art approaches.

Supervised fraud classification algorithms for credit card fraud detection were proposed in [3]. The author has used two bank datasets to test these methods. Aggregation methods were suitable in many situations, but not all. SVM, logistic regression, random forest, and KNN were some of the classification algorithms used by the author. Out of this, the random forest gives better accuracy. Credit card transactions, as well as the fraud linked with them, are becoming more popular today. When credit card information is obtained unlawfully and used to make purchases, credit card fraud occurs. If credit card data is available and sufficient for a company or service, the author used a different machine learning technique to tackle the problem.

In [4], several popular methods in supervised, unsupervised, and ensemble classification were evaluated. The authors have applied different algorithms to identify fraudulent and legitimate transactions. Because unsupervised algorithms handle the skewness of datasets better than supervised algorithms, they outperform supervised algorithms in terms of performance measures. In future work, the author wants to contribute to the re-sampling techniques that will help us to balance data.

In [5], the authors have proposed a method to identify fraudulent and legitimate transactions. Because of the rapid progress of e-commerce and online banking, the usage of credit cards has increased dramatically, resulting in a large number of fraud instances. The author proposed a novel fraud detection method that has three stages. The first phase involves initial user authentication and card details verification. After the initial state, the transaction proceeds to the following step, where a fuzzy c-means clustering method was applied to determine the new pattern of credit card users based on their previous transactions. The authors used fuzzy c-means clustering algorithms to group similar datasets and a neural network to reduce misclassification based on the amount, timing, and kind of items purchased. For analyzing the proposed model, the author used stochastic models. The authors concluded that the application of fuzzy clustering and learning was the solution to a real-world problem based on the findings.

The main objective is to determine whether a transaction is legitimate or fraudulent. Various techniques, such as supervised and unsupervised procedures, were used to detect fraud [6]. Numerous methods identify fraud when utilizing

supervised techniques. The author combined supervised and unsupervised techniques to classify credit card fraud to build a hybrid approach to improve system accuracy. This based on the results using the hybrid model gives better accuracy.

In [7], the authors have proposed long short-term memory networks as a method to aggregate the new pattern of data purchase behavior of cardholders, to improve the accuracy of the credit card fraud system. The comparison of baseline random forest to long short-term memory in this research improves the detection of accuracy as offline transactions, where the cardholder was physically present at the merchant. The author looks at both sequential and non-sequential learning systems that benefit from aggregation strategies in this paper.

The authors have used different algorithms on real-time datasets such as nearest neighbors, random forest, naive Bayes, multiple Perceptron, ad boost, quadrant discriminative analysis, pipelining, and ensemble learning [8]. The sample consists of European cardholders who were present for two days in September 2013. The dataset is highly unbalanced, so the ADASYN method has been used to correct it. As for performance measures, the author used precision, recall, accuracy, F1-measure, Matthew's correlation coefficient, and Balanced Classification Rate. Depending on a variety of parameters the pipelining gives better accuracy.

The authors have proposed Fraud-BNC, a customized Bayesian Network Classifier (BNC) algorithm on a real-time credit card fraud dataset in [9]. The Hyper Heuristic Evolutionary Algorithm was used to create BNC automatically (HHEA). A categorization dataset provided by Pag Seguro, a well-known Brazilian online payment provider, caused this difficulty. The author deals with two issues: a skewed dataset and misclassified fraud costs. As a result of Fraud-BNC, the method's economic efficiency was evaluated and tested against seven alternative classification algorithms. When it comes to accuracy, Fraud-BNC outperforms other algorithms.

In business and banking, credit card fraud has become an issue. Credit card fraud occurs when a fraudster employs modern techniques and technology to complete credit card information without the owner's permission. The author proposed an intelligent approach for detecting credit card fraud using an upgraded light gradient boosting machine to address this issue (OLightGBM) in [10]. The author goes through numerous stages to establish this framework, including data collection, data pre-processing, model development, and model evaluation. The researcher had to use a Bayesian-based hyperparameter to maximize the parameter in the suggested approach. To assess the performance of the intelligent technique, the author employed two real-time datasets for detecting credit card fraud transactions. The first dataset comes from credit card fraud transactions made by European Cash Holders in 2013. The second dataset came from the UCSD-FICO Data Mining Contest in 2009. To compare with the provided technique, the author used a variety of machine learning algorithms. As a result, OLightGBM exceeds confusion matrices, accuracy, precision, and recall, among other performance metrics.

In today's technology world and internet banking, credit card usage is rapidly increasing. Credit cards have become the most frequent payment method for online purchases. As a result, the number of cases of fraud increased. Stopping fraud was critical since it hurts the economy. To solve this problem, the author [11], has employed several techniques, including logistic regression (LR), Naive Bayes (NB), Support Vector Machines (SVM), decision tree (DT), and K-nearest neighbors (KNN), as well as random forest (RF). The author proposed a new deep learning architecture based on Spark to detect fraud. After that, the author compared the proposed deep learning architecture and the machine learning algorithm. The author used accuracy, precision, and recall performance metrics to classify fraudulent and legitimate transactions. As a result, random forest generates more precise outcomes.

In [12], the authors have proposed a novel fraud detection system that evaluates customers' previous transaction records and extracts pattern behavior. At the start, the authors used the clustering method to separate the cardholders into groups. To determine cardholder behavior, researchers employ the sliding window method to organize transactions. The dataset contained the European cardholder dataset. To balance the credit card fraud dataset, the author applied SMOTE techniques. Another option for dealing with unbalanced datasets is to employ the single class SVM. The authors used a variety of algorithms, both with and without statistical methodologies, to determine the dataset's correctness. Local Outlier factor, Isolation Forest, Support vector machine, logistic regression, decision tree, and random forest are some of the algorithms used. The main objective of this paper is to classify fraud and legitimate transactions.

In [13], has developed a deep learning and machine learning method to detect credit card fraud transactions. For developed a model author performed data pre-processing, normalization, and under-sampling techniques using a European cardholder imbalanced dataset. Then compare the machine learning methods such as Support Vector Machine and K-Nearest neighbors. After that, to train, the model artificial neural network was used by the author. As a result, the artificial neural network gives better accuracy.

In [14], the authors have focused on a new ensemble learning algorithm that combined bagging and boosting. As a result, detecting credit card fraud is a difficult task. The author proposed an ensemble hybrid model with the bagging and boosting method. The authors perform steps like pre-processing and feature engineering with ad-boost divide the data between train and test groups, classify the test data set using bagging-based ensemble classifiers like random forest and extra tree approaches, and generate results. The dataset UCSD-FICO was used as an input, and it is a severely unbalanced dataset. As a result, the author of the balancing data set utilized various strategies. The original feature space to the next feature space mapping approach was utilized in the first step, followed by the generation of the feature space. The next step is to use a tree-based classifier to solve the classification and regression problems. The author employed false negative and false positive rates, detection rates, and accuracy rates in the proposed model.

To detect credit card fraud, the authors [15] have used a different machine learning method. The results of a benchmark and a real-world dataset were compared by the author. A hybrid method combining ad boost and majority voting has also been developed by the researcher. The author compared the performance of a single model and a hybrid model on the same dataset. Researchers used naive Bayes, random forest, Decision tree, Neural Network, Linear Regression, Deep Learning, Logistic Regression, SVM, and Multilayer Perceptron as machine learning techniques. As a result, the methods were utilized to assess using ad boost and majority voting, which improved the accuracy with benchmark and real-time datasets.

In [16], a semi-supervised technique to detect credit card fraud, in which user profile clusters were created and used to construct classifiers. Users were profiled and grouped based on their patterns of conduct. Consumer segments were spread and further divided based on transaction factors such as volume, frequency, and distance. Random forest and XGBoost classifiers were trained on the total sample and compared to transaction-level classifiers in each cluster. This study finds that classifiers trained at the cluster level need not improve classifiers trained in the sample group in terms of overall weighted performance. The clustering method was used to identify groups of account holders. Moreover, some classifiers trained in specific groups do significantly better than the baseline, whereas classifiers learned in other groups do not perform as well. The optimum classifier for a given cluster varies by cluster and demonstrates the potential for new classifiers to perform well on groups that currently use underperforming models.

For credit card fraud detection, a Decision tree and random forest are used [17]. The author has used public data as sample data to test the model's efficiency. The finding was similar to a set of real-world credit card data obtained from a financial institution. Furthermore, some clutter was introduced to the data samples as a secondary check on the system's endurance. The study's methods were significant in that the first method created a tree against the user's activity, and frauds were detected using this tree. A user activity-based forest will be generated in a second way, and an attempt will be made to identify the suspect using this forest.

Artificial intelligence techniques were used to classify a fraudulent transaction as a routine transaction [18]. The author was to compare and contrast the results of several machine learning algorithms in detecting credit card fraud. The algorithm's rank and performance are of primary interest to the author. The model for identifying bad transactions in the e-commerce dataset was analyzed using the UCSD-FICO Data mining content 2009 dataset; Performance measures used by the author, such as classification accuracy and fraud detection rate.

To deal with anomalous transactions and develop a cardholder behavior model was proposed in [19]. To classify fraudulent and legitimate activities, the author used classification algorithms such as naive Bayes, Bayes Net, random forest, j48, libSVM, and MOLEM, as well as the Weka tool. Initially, the data was created and tested using the

random forest and j48 models. The author used a real-time dataset to test the efficacy, and random forests performed better.

In [20], the authors have proposed decision trees, random forests, and logistic regression as machine learning algorithms for fraud detection. The analytical model was put to the test using the benchmark dataset. The most accurate models are the random forest and decision tree. A confusion matrix was employed to assess accuracy Table I.

TABLE I. LITERATURE SURVEY

Sr.no	Title	Dataset	Methodology & tools	Advantages and limitation
1	Feature engineering strategies for credit card fraud detection.	European cardholder dataset	Decision Tree, Logistic Regression, Random Forest	The author proposed a method to improve the performance results of credit card fraud. The author has a problem with the system it takes a long time to make a decision.
2	Credit card fraud detection using convolutional neural networks.” In International conference on neural information processing	Real-time credit card dataset	Convolution Neural network cost Estimation method	The advantage of implementing a convolutional neural network is to capture neural patterns of fraud activity discovered from a labeled dataset. Because there are far fewer fraud transactions in real life than in non-fraud situations, the major drawback when implementing it is the issue of an unbalanced dataset.
3	Transaction aggregation as a strategy for credit card fraud detection	Bank A and Bank B	SVM, logistic regression, Random Forest and KNN, Cart,	The advantage of aggregation is data do not need to be properly classified, it may be more resistant to the impacts of population drift.
4	Performance Evaluation of Machine Learning Algorithms for Credit Card Fraud Detection	European cardholder dataset	NB, RF, KNN LR, XGBT, SVM ANN, DL	The main advantage of unsupervised algorithms performs better throughout all measures both in absolute terms and in comparison, to other approaches since they are better at handling the dataset skewness.
5	Credit Card Fraud Detection: A Hybrid Approach Using Fuzzy Clustering & Neural	Real-time credit card dataset	Fuzzy Clustering and Neural Network	In this paper, fuzzy clustering is used to decrease the misclassified rates of transactions and also find new patterns based on past transaction data. The authors further

	Network			used the different attributes to correctly classify the transactions.	
6	Combining Unsupervised and Supervised Learning in Credit Card Fraud Detection	Credit card fraud detection dataset		K-means clustering, ensemble learning,	In this paper main advantage is a combination of supervised techniques and unsupervised techniques to improve accuracy.
7	Sequence Classification for Credit-Card Fraud Detection	Real-world fraud detection dataset.		Random Forest, long short-term memory	The advantage of implementing a neural network to identify credit card fraud is that it can identify credit card activity and use patterns in a significant amount of customer and transactional data.
8	Credit Card Fraud Detection using Pipeline and Ensemble Learning	European cardholder dataset		Logistic Regression, Naive Bayes, K nearest neighbors, Multi-Layer Perceptron, Ada Boost, Quadrant Discriminant Analysis, Random Forests, Pipelining, and Ensemble Learning	The author compared different algorithms in which pipelining works best as compared to another algorithm. The benchmark dataset was highly imbalanced so the author was able to the balanced dataset.
9	A customized classification algorithm for credit card fraud detection	Pag Seguro dataset		customized Bayesian Network Classifier (BNC) algorithm for a real credit card fraud detection problem	In this paper, the authors were given High processing and detection speed on the Pag Seguro dataset for credit card fraud detection.
10	An Intelligent Approach to Credit Card Fraud Detection Using an Optimized Light Gradient Boosting Machine	Real-world credit transaction		Optimized light gradient boosting machine (OLightGBM), light gradient boosting machine (LightGBM), KNN, SVM, NB, DT.	In this paper, OLightGBM gives better accuracy than other machine learning algorithms. The proposed model identifies a useful pattern of credit card fraud.
11	An Enhanced Secure Deep Learning Algorithm for Fraud Detection in Wireless Communication	European cardholders		Logistic regression (LR), Naive Bayes (NB), Support Vector Machines (SVM), decision tree (DT), and K-nearest	The credit card fraud dataset is highly imbalanced but in this system that imbalanced problem was solved. Credit card fraud prevention was a very important task but the author was unable to achieve it.

			neighbor (KNN) as well as random forest (RF)	
12	Credit card fraud detection using machine learning.	European cardholder dataset	DT, Local Outlier factor, Isolation forest, LR, RF	The advantage is that the author balanced the dataset using SMOTE techniques. In this paper, the authors need a balanced dataset for achieving high precision and recall.
13	Credit card fraud detection using artificial neural network	European cardholder dataset	SVM, KNN, and ANN	Using an artificial neural network model turns out to be the best for detecting fraud. The author was also unable to balance data using normalizing, under-sampling, or pre-processing methods.
14	Credit Card Fraud Detection by Modelling Behavior Pattern using Hybrid Ensemble Model	Brazilian bank data and UCSD-FICO data.	Ensemble learning techniques such as boosting and bagging.	Combination of Bagging and boosting ensemble learning method for distributing credit card detection. Dataset is highly imbalanced. For analyzing the behavior of the customer drift method
15	Credit card fraud detection using AdaBoost and majority voting	Benchmark Dataset. Real-time dataset	AdaBoost and majority voting methods	In this paper author used Majority and AdaBoost. The majority voting gives better accuracy. The author wants to use online learning methods where online learning methods prevent fraud it informs before fraud happens.
16	Improving Credit Card Fraud Detection by Profiling and Clustering Accounts	Credit card bank dataset	Random forest and XGBoost, k-mean clustering,	In this paper, k means clustering used for the effective and fast result of data. The disadvantage of k means is selected k values. The authors used Clustering to improve the detection of credit card fraud
17	A Novel Approach for Credit Card Fraud Detection using Decision Tree and Random Forest Algorithms	Credit card fraud Dataset	Bayesian network, Gaussian network, Random Forest, Decision Tree	The advantages of decision trees and random forests where random forests are utilized for preventing overfitting problems. The disadvantage of a decision tree, it gives the problem of overfitting.

18	An Evaluation of Computational Intelligence in Credit Card Fraud Detection	UCSD-FICO Data Mining Contest 2009 dataset	This paper analyses and compares various popular classifier algorithms that have been most commonly used in detecting credit card fraud	Classification accuracy and fraud detection rate are high in an evaluation of computational intelligence in credit card fraud detection. For credit card, and anomaly detection author want to propose a reliable expert system.
19	Credit Card Fraud Detection Based on Transaction Behavior	Real-time dataset	Random Tree and J48	Random forest gives the highest accuracy on the real-time dataset. The author had been unable to solve a random forest problem due to the slowness of the algorithm in a large number of trees.
20	Predictive Modelling for Credit Card Fraud Detection Using Data Analytics	German credit card fraud dataset	Logistic Regression, Decision Tree, Random Forest, Decision Tree.	The author compares various algorithms and concludes that random forest gives better accuracy. The author occurred a problem during the testing of random forest speed during the predictive model.

### III. PROPOSED HYBRID MODEL FOR FRAUD DETECTION

Fig. 1 shows the primary steps of the proposed models, which include data preparation, EDA, and a hybrid ensemble model. For the credit card fraud system, the result has been given as a categorization of genuine and fraudulent transactions. Data preparation employs the Smote technique, outlier removal, and null value deletion. After preprocessing, the hybrid ensemble model has been proposed for differentiating between legitimate and fraudulent transactions. A hybrid model reduces the risk of fraudulent transactions compared with a single model before applying SMOTE.

#### A. Data Preprocessing

Data pre-processing is an essential step because without it, the model can generate inaccurate results and it helps to preserve the integrity of the data. Data distribution, outlier identification, and noise reduction have been part of the data preprocessing stage.

Fig. 1. Proposed Model of Credit Card Fraud Detection.

Anomaly detection is a method for finding outliers or odd patterns that deviate from anticipated behavior. In the proposed model Interquartile range (IQR) has been used to remove the outliers [21]. The interquartile range, or IQR, is the space between the first and third quartiles, or Q1 and Q3:

$IQR = Q3 - Q1$ . Outliers are data points that are either below or above the median ( $Q1 - 1.5 IQR$  or  $Q3 + 1.5 IQR$ ).

Q1 is the median.

Q2 is the average of the n smallest data points.

Q3 is the average of the n highest data points.

### B. Bagging-Based Ensemble Learning

Bootstrap aggregation, sometimes known as "bagging," is a common strategy applied in ensemble learning-based models that integrate both classification and regression techniques, hence increasing accuracy and other associated metrics. The principle of bagging is the combination of weak learners with a strong learner [14]. For our experimentation, we implemented decision tree-based bagging classifiers such as random forest-based classifiers.

In bootstrap sampling, replacement sampling is used to produce a bootstrap sample  $B_{Si}$  that is equal to  $D$ , where  $D$  is the input data. When  $D$  is big enough,  $B_{Si}$  acts as an independent version of  $D$ , and the assumed empirical distributions resemble  $D$  [15]. Therefore,  $B_{Si}$  might be viewed as a distinct and comparable variant of  $D$ . At bagging, in the  $i_{th}$  iteration, the model's predictions are averaged to suit the bootstrap sample  $B_{Si}$ .

In the end, bootstrap sampling wants to remove a classifier's potential for overfitting.

1) *Random forest*: A supervised machine learning approach based on ensemble learning is known as a random forest. To create a more efficient prediction model, you can combine several algorithms or use the same technique more than once in ensemble learning [3, 4]. The term "Random Forest" comes from the fact that the random forest method mixes several algorithms of the same type or different decision trees into a forest of trees. Both regression and classification tasks may be performed using the random forest approach.

The basic steps of the random forest method are as follow [21]:

- a) Choose  $N$  records at random from the dataset.
- b) Based on these  $N$  records, construct a decision tree.
- c) Repeat steps 1 and 2 after choosing how many trees you.
- d) Want in your algorithm.
- e) Each tree in the forest can forecast the category to which the new record belongs in a classification issue. The category that receives the majority of the votes is finally given a new record.

2) *Adaboost algorithm*: Adaboost is one boosting technique, which is similar to Random Forest Classifier. The

Ada-boost classifier combines weak and strong classifier algorithms to create a large classifier [8]. A single algorithm may incorrectly categorize the items; however, by combining many classifiers, selecting the training set at each iteration, and assigning the appropriate amount of weight in the final vote, we can achieve a high accuracy score for the entire classifier. It keeps the algorithm repeatedly by selecting the training set depending on prior training accuracy. At any iteration, the weighting of each trained classifier is determined by the accuracy achieved. Adaboost provides weight to each training item after training a classifier at any level. The weight of a misclassified item is increased so that it is more likely to appear in the training subset of the Adaboost classifier. The basic steps of the Adaboost algorithm [21] are:

a) Initialize  $M$ , the maximum number of models to be fit, and set the iteration counter  $m=1$ .

b) Initialize the observation weights  $w_i = 1/N$  for  $i = 1, 2, N$ . Initialize the ensemble model  $\hat{f}_b = 0$ .

c) Train a model using  $\hat{f}_m$  observation weights that minimize the weighted error  $ECM$  defined by summing the weights for the misclassified observations is shown in (1).

d) Add the model to the ensemble:

$$\hat{f}_m = (\hat{f}_{m-1}) + (\hat{\alpha}_m)(\hat{f}_m) \quad (1)$$

$$\text{Where } (\hat{\alpha}_m) = \frac{\log(1-e)m}{e_m} \quad (2)$$

e) Update the weights  $w_1, w_2, w_3, \dots, w_N$  so that the weights are increased for the observations that were misclassified. The size of the increase depends on  $(\hat{\alpha}_m)$  with larger values  $(\hat{\alpha}_m)$  leading to bigger weights as mentioned in (2).

f) Increment the model counter  $m=m+1$  if  $m_i=M$ , go to step 1. The boosted estimate is given below:

$$\hat{f} = (\hat{\alpha}_1) (\hat{f}_1) + (\hat{\alpha}_2) (\hat{f}_2) + \dots + (\hat{\alpha}_m) (\hat{f}_m) \quad (3)$$

g) The factor  $(\hat{\alpha}_m)$  has a lower error and higher weight.

### C. Logistic Regression

One of the most widely used Machine Learning algorithms, within the category of Supervised Learning, is logistic regression. The categorical dependent variable is predicted using a collection of independent factors. In a categorical dependent variable, the output is predicted using logistic regression [3]. As a result, the result must be a discrete or classifying value. Instead of providing the exact values of 0 and 1, it gives the probabilistic values that fall between 0 and 1. It can be either Yes or No, 0 or 1, true or false. Except for how they are applied, logistic regression and linear regression are very similar [4]. While logistic regression is used to solve classification difficulties, linear regression is used to solve regression problems. In logistic regression, we fit an "S" shaped logistic function, which predicts two maximum values, rather than a regression line (0 or 1) is shown in Fig. 2. The logistic function's curve shows the possibility of several things, like whether or not the cells are malignant, and whether or not a rat is fat depending on its weight [11]. Because it can classify new data using both continuous and

discrete datasets, logistic regression is a significant machine learning approach.

Fig. 2. Comparison between Linear Regression and Logistic Regression.

The equation of logistic regression of straight line written as [22]:

$$y = a_0 + a_1 * x_1 + a_2 * x_2 + \dots + a_k * x_k \quad (4)$$

In logistic regression, y can be between 0 and 1 only, so divide the above equation by (y-1):

$$\frac{y}{y-1} | 0 \text{ for } y = 0 \text{ and } \infty \text{ for } y = 1 \quad (5)$$

As a result, the logistic regression equation is defined as:

$$\log \frac{y}{y-1} = a_0 + a_1 * x_1 + a_2 * x_2 + \dots + a_k * x_k \quad (6)$$

#### D. Hybrid Ensemble Model

Fig. 3 shows how the hybrid ensemble model works. In a hybrid ensemble model, the first step is to train the model, and once it has generated individual results, the hybrid ensemble combines those outcomes with the help of majority voting to produce the final predicted results. The hybrid ensemble model is a combination of the bagging and boosting models. There are two well-known types of ensemble learning; bagging and boosting [14]. The widely used ensemble learning model for bagging is a random forest. Another well-liked ensemble learning approach that comes under the boosting category is AdaBoost. While the boosting models use the complete dataset, the bagging models only use a portion of the datasets. Random forest and Adaboost are employed as weak learners to create a hybrid ensemble model.

Fig. 3. Hybrid Ensemble Model.

#### IV. EXPERIMENTAL DETECTION OF CREDIT CARD FRAUD DETECTION

This section explains the specificity and stability of our proposed models and compares them with the most recent research-based models. Our main objective is to increase the model's capacity for fraud detection. A better understanding of the data is required to do this. The experimental study was conducted on a simple Windows computer with a quad-core processor and 8 GB of RAM, and the results on the European credit card dataset and the Credit card stimulation dataset were acceptable. The proposed system has implemented the hybrid ensemble model for classification of the credit card fraud detection using python programming on a Jupyter Notebook. This system, primarily apply smote technique for data imbalanced problem. Further implementation of the hybrid ensemble model is on credit card fraud dataset. For checking the performance of the model, precision, recall, F1- score, and ROCAUC are calculated for every test case.

##### A. Data Description

Table II shows the instances, columns, and fraudulent and non-fraudulent cases of the European credit card dataset and credit card fraud stimulation dataset. Datasets are used to train and validate the efficacy of proposed approaches and hence play an essential part in research motivation. In this section, we'll go through two different datasets that have been used in our suggested approach's experiments.

1) *European dataset:* The first dataset, collected from www.kaggle.com, consists of credit card transactions performed by European cardholders within two days in September 2013, with 492 fraudulent transactions out of 284,807 as shown in Fig. 4. It has 31 features, including the time when a transaction occurred, the number of transactions, and 28 other qualities labeled V1 to V28, as well as the target label 'Class,' which uses a binary value of '1' or '0' to determine if a transaction is fraudulent or not [13].

TABLE II. THE CREDIT CARD DATASET DESCRIPTION

Name	Instances	Features	Normal	Fraudulent
European Credit Card Dataset	284,807	31	248,315	492
Credit Card Stimulation Dataset	594,643	10	587,443	7200

Fig. 4. European Credit Card Dataset.

2) *Credit card bank stimulation dataset*: The second dataset includes 594,643 transactions made across 180 simulated days, 7200 of which are considered fraudulent (1.2 percent). This dataset is a synthetic dataset developed with BankSim software, which is a simulation tool meant to simulate fraud data in Fig. 5, BankSim uses a multi-agent simulation methodology that is based on a sample of aggregated real-time transaction data provided by a Spanish bank. Thousands of transactional data records from November 2012 to April 2013 make up the initial bank data. To simulate this genuine bank data, BankSim employs many agents from three main categories: traders, customers, and fraudsters. These agents interact with one another for a duration of a few days, establishing a purchasing transaction log that strongly matches the original bank.

step	customer	age	gender	zipcodeOri	merchant	zipMerchant	category	amount	fraud

**B. Performance Parameter**

The learning algorithm's performance measure showed unbalanced behavior in the imbalanced distribution of the classes. So, it is necessary to select suitable measures to assess the effectiveness of the categorization system. Precision, recall, F1 Score, and accuracy have been chosen as performance evaluation metrics for the proposed work because the learning algorithm exhibits an accuracy phenomenon in unbalanced scenarios.

True Positive (TP) - How many safe cases did our model properly predict.

False Negative (FN) - How many cases of our model incorrectly predicted.

False Positive (FP) - How many fraud cases are classified incorrectly.

True Negative (TN) - How many fraud cases are classified correctly.

Precision -  $TP / (TP + FP)$

Recall -  $TP / (TP + FN)$

F1 Score - Harmonal mean of precision and recall

F1 Score =  $(2 * precision * recall) / (precision + recall)$

**C. Data Imbalanced**

In this paper, two benchmark datasets have been used. In the given datasets there are few fraudulent incidence which makes data imbalanced. The Fig. 6 and Fig. 7, represents percentage ratio of fraudulent transaction of the European credit card dataset and the credit card stimulation dataset

respectively. To increase the fraudulent cases Synthetic Minority Oversampling Technique (SMOTE) technique is used. The Fig. 8, represents the number of increases the fraudulent cases after applying smote approach for the European credit card dataset and the Credit card stimulation dataset.

**D. Exploratory Data Analysis**

Exploratory data analysis is a data analysis process used to properly understand the data and discover its many characteristics, frequently using visual methods. Data analysis allows us to better understand and identify meaningful patterns in it.

Fig. 6. European Credit Card Dataset before Applying Smote Technique.

Fig. 7. Credit Card Stimulation Dataset before Applying Smote Technique.

Fig. 8. European Credit card and Credit Card Stimulation Dataset after Smote Technique.

To analyze the time and amount in this paper, exploratory analysis is performed. Fig. 9 and 10, show how the time and number of transactions during the day and at night differ.

Fig. 9. Transaction Time of European Cardholder Dataset.

Fig. 9 shows the low peak value in the time distribution because there is a significant difference between the night and day transactions. In the density plot to x-axis shows the time of transaction and the y-axis shows the density of attributes.

Fig. 10. Transaction Amount of European Cardholder Dataset.

Fig. 10 represents the total amount of money transacted. The majority of transactions are small, and just a few come close to reaching the maximum transaction value.

Fig. 11. Transaction Amount of Credit Card Stimulation Dataset.

Fig. 11 represents the total amount of money transacted. It shows that number of fraudulent transactions is less than a non-fraudulent transaction.

### E. Result and Discussion

Hybrid ensemble modeling is proposed to categorize fraudulent and legal transactions. The experiment is done on the European credit card and credit card stimulation dataset. The 70:30 % ratio is used for training and testing classifier. In both, the dataset fraudulent instances are less compared to non-fraudulent transactions. So, this is a serious issue that has been found with the dataset. In the European dataset 495 fraudulent transactions out of 284,807 non-fraudulent transactions, so the number of transactions needs to be increased. Same as credit card stimulation dataset 7200 fraudulent transactions out of 594,643. Our approach provides non-fraudulent transactions more weight when applied to an imbalanced dataset. Ensemble models are used to solve the main issue in credit card fraud detection, which is predicting future transaction behavior and finding the right solution.

The initial comparison between the single model and the original dataset is carried out in this study. But the single model has obtained less True positive value and more false positive value which indicates that more fraudulent transactions are presented in datasets because of unbalanced datasets. In order increases true positive value and handle unbalanced dataset oversampling strategies is used. To increases performance of the model hybrid ensemble model is proposed. The hybrid ensemble model is constructed by combining an Adaboost and random forest. This will improve the performance parameters of the system.

In this paper, the performance of the proposed hybrid ensemble model is compared to the machine learning algorithms, including logistic regression, random forest, and Adaboost. Table III and Table V shows the performance measure of European credit card and credit card bank stimulation on the imbalanced dataset. As we observed that the single model and ensemble model did not improve the true positive rate and true negative rate with the imbalanced dataset. So, we applied smote technique to the balanced dataset. Smote technique is used to increase fraudulent instances. After applying Smote oversampling method, the datasets are much more balanced.

The balanced dataset is added and tested with an ensemble model such as bagging and boosting and a predictive model such as logistic regression. Table IV is showing an improvement in precision, recall, and F1 score for the European dataset. Same for Credit card fraud detection dataset precision, recall, and F1 score slightly increased is observed in Table VI precision-recall (AUPR) curve is being used to analyses the performance measure of the proposed model. Table VII shows the comparison results of the European cardholder dataset and Credit card stimulation dataset, which show the AUPR score for boosting, LR, and Adaboost (+) random forest. Fig. 12 and Fig. 13 show the AUPR curve for random forest + Adaboost. On the European cardholder dataset and Credit card stimulation dataset, the proposed method shows a Random Forest +Adaboost which means the hybrid ensemble model gives better results than the single model.

Fig. 12. Recall and Precision Curve for European Credit Card Dataset.

Fig. 13. Recall and Precision Curve for Credit Card Stimulation Dataset.

Table III and Table V shows the performance measure of classification algorithms on the European dataset and Credit card stimulation dataset before applying smote technique. So, we observed that after applying smote technique value of precision, recall, and F1 Score is improved rather to the without applying smote technique. Here hybrid ensemble model with random forest and Adaboost gives better precision, recall, and F1 Score.

Table IV and Table VI show the performance of measure of classification algorithm on European cardholder dataset and credit card stimulation dataset after applying smote technique. Here, the hybrid ensemble model with a combination of random forest and Adaboost gives better precision, recall, and F1- score than other algorithms.

TABLE III. BEFORE SMOTE TECHNIQUE ON EUROPEAN CREDIT CARD FRAUD DATASET

Algorithms	Precision	Recall	F1 Score
Logistic Regression	0.88	0.62	0.73
Adaboost	0.78	0.66	0.72
Random Forest	0.94	0.77	0.85
Random Forest+Adaboost	0.94	0.78	0.85

TABLE IV. AFTER SMOTE TECHNIQUE ON EUROPEAN CREDIT CARD FRAUD DATASET

Algorithms	Precision	Recall	F1 Score
Logistic Regression	0.96	0.90	0.93
Adaboost	0.97	0.94	0.95
Random Forest	0.97	0.98	0.95
Random Forest+Adaboost	1.00	0.94	0.97

TABLE V. BEFORE SMOTE TECHNIQUE ON CREDIT CARD FRAUD STIMULATION DATASET

Algorithms	Precision	Recall	F1 Score
Logistic Regression	0.88	0.62	0.73
Adaboost	0.78	0.66	0.72
Random Forest	0.94	0.77	0.85
Random Forest+Adaboost	0.91	0.78	0.84

TABLE VI. AFTER SMOTE TECHNIQUE ON CREDIT CARD FRAUD STIMULATION DATASET

Algorithms	Precision	Recall	F1 Score
Logistic Regression	0.92	0.99	0.97
Adaboost	0.97	0.99	0.98
Random Forest	0.98	0.97	0.98
Random Forest+Adaboost	0.99	0.99	0.99

The Predictive behavior of the proposed model is analyzed concerning the area under precision and recall curve. The result shown in Table VII is the area under precision and recall score for LR, boosting Adaboost +random forest. Here we observed that a hybrid ensemble model with random forest +Adaboost gives a better AUC Score than other algorithms.

TABLE VII. AREA UNDER CURVE SCORE ON EUROPEAN CREDIT CARD DATASET AND CREDIT CARD STIMULATION

The area under curve score (AUC Score)	European credit card dataset	Credit card bank stimulation dataset
Logistic Regression	95.10	95.80
Adaboost	96.79	98.43
Random Forest	97.32	98.09
Random Forest+Adaboost	98.26	99.37

## V. CONCLUSION

In this paper, a hybrid ensemble-based model is proposed to classify fraudulent and legitimate transactions. At the beginning of the project, the data analysis technique is used to map the original feature. To overcome the imbalanced problem oversampling smote method is used to balance the dataset during data pre-processing. After pre-processing, logistic regression, random forest, and Adaboost are used to check whether a transaction is legitimate or fraudulent. The hybrid ensemble model before applying the smote technique gives 0.85 % F1-Score and after applying smote technique it gives 0.97% on the European credit card fraud dataset. So, the F1 -score of Smote technique with the hybrid ensemble model

gives more results. For the Credit card stimulation dataset before applying smote technique F1 score gives 0.84% and after applying smote technique F1 Score gives 0.99%. It is observed that a hybrid ensemble model that combines random forest and Adaboost gives better results. From Table VI, the hybrid ensemble model for the European dataset achieves 98.27 % area under the curve score, whereas the Credit card fraud stimulation dataset achieves 99.37 % area under the curve score. In future work, apply the under-sampling method to check the performance of the algorithm and also use deep learning techniques for the classification of fraudulent and legitimate transactions.

# Covid-19 and Pneumonia Infection Detection from Chest X-Ray Images using U-Net, EfficientNetB1, XGBoost and Recursive Feature Elimination

Munindra Lunagaria, Vijay Katkar, Krunal Vaghela  
Department of Computer Engineering  
Marwadi University  
Rajkot, India

**Abstract**—The pandemic caused by the COVID-19 virus is the most serious current threat to the public's health. For the purpose of identifying patients with Covid-19, Chest X-Rays have proven to be an indispensable imaging modality for the hospital. Nevertheless, radiologists are needed to commit a significant amount of time to their interpretation. It is possible to diagnose and triage cases of Covid-19 effectively and rapidly with the assistance of precise computer systems that are powered by Machine Learning techniques. Machine Learning techniques such as Deep Feature Extraction can help detect the disease with improved precision and speed when used in conjunction with X-Ray images of the lung. This helps to alleviate the problem of lack of testing kits. Using the U-Net for Semantic image segmentation for lung segmentation and deep feature extraction-based strategy that was suggested in this research, it is possible to differentiate between patients who have contracted the Covid-19 virus, pneumonia and healthy people. XGBoost and recursive feature extraction based proposed methodology is evaluated using 20 different Pre-Trained deep learning based models including EfficientNet variations and it is observed that the maximum detection accuracy, precision, recall specificity, and F1-score are achieved when EfficientNetB1 is used to extract deep features. The respective values for these metrics are 97.6%, 0.964, 0.964, and 0.982. These findings lend credence to the efficiency of the proposed methodology.

**Keywords**—Covid-19; u-net; efficientnet; semantic image segmentation; XGboost; recursive feature extraction

## I. INTRODUCTION

The recently found Coronavirus pneumonia, which has been given the name Covid-19 ever since it was found, is both extremely contagious and highly pathogenic [1]. The symptoms may advance to a more unadorned form of pneumonia, which can lead to serious health problems and the failure of multiple organs. There is also the risk that pneumonia will prove fatal to the patient. Covid-19 has spread to 223 nations and is blamed for over 6.4 million deaths around the earth; additionally, quantity of deaths caused by virus is steadily rising [2] (see Fig. 1). In any region of the world, medical professionals, governments, organizations, and countries face a noteworthy impediment in the form of need to diagnose Covid-19 patients as early as possible.

Even though immunological tests are offered in a number of countries, the RT-PCR i.e., Real-Time Reverse Transcription-Polymerase Chain Reaction is the process that is employed majority of the time to identify Covid-19. Early treatment can be ensured by recognizing the detrimental effects of Covid-19 by assessing photographs of patients' lungs rather than relying on RT-PCR, which has limited sensitivity (60–70%) and is also a technology that requires a significant amount of time.

Care for patients with Covid-19 necessitates careful tracking of their condition's evolution over time. When used in conjunction with other diagnostic tests, medical imagery practices like Computed Tomography (CT) and X-Rays of Chest can help to confirm a diagnosis of Covid-19 pneumonia and keep tabs on how the disease is progressing. These photos demonstrate the rapid progression of ground-glass opacities with irregular patterns after the onset of Covid-19 symptoms [3].

The term “Artificial Intelligence” (AI) refers to an assorted methodologies intended at imitating human cognition and deeds. Algorithms that consent high end processors to comprehend intricate patterns and associations from empirical information are the focus of the discipline of Machine Learning (ML), a subfield of AI. While traditional ML approaches are limited in their ability to deal with complicated problems like medical image categorization, Deep Learning (DL) takes cues from biological neural networks to attain greater power and flexibility [4].

Fig. 1. Number of Worldwide Deaths Due to Covid-19.

Having access to a big dataset that contains images that have been labeled is essential to the success of a detection or classification system that is based on DL. Deep feature extraction (DFE) and transfer learning (TL) are two of the most successful alternatives to using a small sample size of images when there is not a big sample size of images available. TL refers to the process of making use of previously taught models to tackle unanticipated obstacles. TL is not an individual category of ML algorithms; rather, it is a process that can be utilized in the development of a new ML model. Model will be able to put the knowledge and abilities that it has gained in previous training to use in brand new situations [5]. In a manner analogous to the activity that came before it, this one will need organizing data according to the type of file. Another application of TL is the extraction of deep feature information. It is possible to extract feature vectors by making use of pre-trained CNN models rather than manually adjusting the activation layers of the CNN. The deeper layers, which are triggered by the activations of the lower-level layers, include the higher-level features that are essential to the classification of images [6].

Using U-Net, EfficientNetB1, XGBoost and Recursive Feature Elimination (RFE), this paper provides a DFE-based technique for discriminating healthy individuals and those infected with pneumonia from those infected with Covid-19. The remaining paper is structured as follows. The relevant work is briefly described in Section II, and use of U-Net model is explained in Section III. Brief introduction of Pre-Trained models employed in the study is provided in Section IV. The proposed approach is explained in Section V whereas dataset utilized for the experiment along with experimental findings is described in Section VI. Section VII briefly describes the significant contributions of the research work whereas section VIII concludes the research work.

## II. LITERATURE SURVEY

CNNs are constructed by first adding a sequence of layers that are known as convolutional, then adding layers that are known as normalization, and finally adding layers that are known as pooling. Feature extraction is the responsibility of the convolution layers, whereas feature normalization and feature down sampling are the purview of the normalization and pooling layers, respectively. In a manner analogous to that of more traditional approaches to machine learning, training of the CNN is carried out by use of an optimization strategy like Stochastic Gradient Descent [7].

A DL-based framework with fuzzy enhancements was presented by Cosimo Ieracitano et al. [8] under the name CovNNet for the purpose of classifying Chest X-Rays of Covid-19 patients and recognizing those of other patients with pneumonia. The CovNNet model was given X-Rays of the chest as well as fuzzy images that were created using a fuzzy logic based edge detection method. Experiments have shown that using fuzzy features in conjunction with chest X-Rays can result in enhanced classification performance.

Emtiaz Hussain et al. [1] have introduced a 22-layer deep CNN model named CoroDet with the purpose of being utilized in the process of recognizing Covid-19 cases in chest CT and X-Ray images. Their methodology is validated for its

usefulness utilizing a five-fold cross-testing procedure. Patient detection method using X-Ray pictures that is based on a faster RCNN-based object detection methodology was proposed by Fátima A. Saiz and Iñigo Barandiaran [9].

To develop a concatenated neural network, Mohammad Rahimzadeh and bolfazi Attar [10] merged features extracted with ResNet50V2 and Xception, then transmitted the aggregated data to a convolutional layer. The convolutional layer is responsible for the extraction of features, and it uses 1024 filters with a Kernel size of 1x1. This layer is introduced in order to provide assistance to the network in better learning characteristics from the combined data. They demonstrated the viability of their approach by utilizing a procedure known as three-way cross-testing.

Arman Haghanifar et al. [11] compiled a significant number of different chest X-Ray images from a variety of sources into a single extensive database that is open to the public. The TL paradigm is used in conjunction with the CheXNet model to generate a model that is referred to as COVID-CXNet. This model is effective at detecting pneumonia caused by the coronavirus and pinpointing its exact location.

Mohammad Shorfuzzaman et al. [12] describes an ensemble-based DFE approach as a means of determining the existence of Covid-19 in X-Ray of chest images. This technique takes the weights that were determined by a large number of models that have been pre-trained and turns them into a single band that represents X-ray characteristics. After that, these traits will be utilized in the process of making a diagnosis of the ailment.

M. D. Kamrul Hasan et al. [13] suggest a two-stage, DFE-based process that makes use of VGG16 Net and patient lung X-Ray photos in order to sense COVID-19-induced pneumonia. When evaluating their methodology, the scores for precision, specificity, and sensitivity are taken into consideration.

Junfeng Li et al. [14] developed COVID-GATNet with the intention of identifying Covid-19 patients with the assistance of Graph Attention Network. The results of the X-Ray input can be interpreted as normal, as having Covid-19 +, or as having pneumonia. They used the information from three different open-source datasets to produce a more extensive training data pool for their studies.

Debabrata Dansana et al. [15] proposed a three-stage approach by utilizing CNN, Pre-Trained CNN models, and Decision Tree. The first step in the process is to use CNN to clean up the input images by removing any noise that isn't wanted and building composite feature maps. The performance of the pre-trained CNN models that are used to extract image features is improved with the help of these Composite feature maps, which are used in the second step. Second stage extracts image features to use for training a Decision Tree, which will be used for categorizing the disease.

According to research that was carried out by Karim Hammoudi et al. [16] who optimized four different Pre-Trained CNN models (specifically ResNet50, InceptionResnetV4, Densenet, and VGG-19), InceptionResnetV2 had the lowest

false negative rate. Abdullahi Umar Ibrahim et al. [17] showed that optimizing the Alexnet Pre-Trained model for patient detection in X-Ray pictures led to the discovery that the model is capable of providing good detection precision. Asif Iqbal Khan et al. [18] developed a TL-based model utilising Xception Net and gave it the name CoroNet. Xception Net's base layers are connected to the dropout layer, which is in turn coupled to fully-connected layers for classification task. A DFE-based approach employing the VGG-19 Pre-Trained Model was presented by Harsh Panwar et al [19]. The original VGG-19 model's foundational layers were expanded with fully connected layers, and they were then fine-tuned for patient detection.

Eduardo Luz et al. [20] presented DFE based method of hierarchical classification with the help of EfficientNet models. Target categories are positioned at leaves of the tree, whereas classifiers are located in the in-between nodes of the tree. At the root node, one classifier was used to segregate between the Normal and Pneumonia patients, while at a higher level, another classifier was used to segregate between the Pneumonia patients themselves.

Two-stage DFE based model for Covid patient detection using U-Net and Pre-Trained models was presented by Sivaramakrishnan Rajaraman and Sameer Antani [21]. After using U-Net to identify and extract the lung region in a chest X-ray, the resulting cropped pictures are fed back into the Pre-Trained model to be fine-tuned for improved detection accuracy.

Numerous studies have adopted a mixed-method approach, employing both traditional Data Mining based models like Support Vector Machine (SVM) and Pre-Trained DFE-based models for feature extraction in order to identify Covid-19 infected patients. Sara Hosseinzadeh Kassani et al. [22] presents a DFE based hybrid for computer-assisted decision of Covid-19 pneumonia. Several ML algorithms were trained on deep features extracted by well-known Pre-trained CNNs architectures. Their results suggests that hybrid approach is effective for computer-assisted detection.

#### A. Research Gap

Researchers put forth a lot of time and effort studying how best to detect Covid-19 using deep learning methods. A few research gaps remain, though, as can be seen below.

- Deep learning-based models trained for differentiating pneumonia from Covid-pneumonia fall into the category of Black box models.
- Existing methodologies use complete X-Ray images for detection of disease. X-Ray image contains many body parts other than lung which makes model less reliable.
- Researchers have not considered False Discovery Rate, Negative Predictive Value, False Negative Rate and False Positive Rate while evaluating their proposed model.

This paper resolves these research gaps with the help of U-Net model and Local Interpretable Model-agnostic Explanations methodology.

### III. U-NET

U-Net was originally developed and used in 2015 to process biomedical images; it is an evolution of the conventional convolutional neural network [23]. The network's architecture was improved and expanded from the fully convolutional network to allow it to function with less training images and produce more accurate segmentations. The key concept is to add on more layers to a standard contracting network, with up sampling operators replacing pooling functions. This is because these layers improve the output's resolution. Later convolutional layers can use this data to fine-tune their outputs. U(up sampling) Net's section, which has been modified to include several feature channels, is what allows the network to convey contextual information to finer-grained nodes. This results in a u-shaped layout, with the expanding section mirroring the contracting one.

In this paper, the U-Net architecture is utilized for lung segmentation in patient Chest X-Rays. U-Net model's output for lung segmentation is displayed in Fig. 2. Raw X-Ray image is displayed in Fig. 2(a), while the result of the segmentation process is displayed in Fig. 2(b).

Fig. 2. (a) Original X-Ray Image, (b) Output of U-Net.

From Fig. 2, it is clear that the segmentation process eliminates a great deal of inessential data from the X-Ray image.

### IV. DEEP LEARNING-BASED PRE-TRAINED MODELS

DFE has been widely implemented in the arena of medical imaging in current years. When compared to a CNN that has just been taught, a CNN that has undergone prior training and has undergone appropriate fine-tuning may perform better or on par with the latter. DFE has been vigorously explored for the goal of identifying Covid-19 in chest X-Rays, but there is a dearth of sufficient training data. This section briefly describes the most widely used Pre-Trained models for DFE by researchers.

#### A. MobileNet

It is extremely tiny CNN, making it ideal for integration into small form factors and embedded systems. By using depth-wise distinguishable convolution, a more lightweight architecture is built. Additionally, trade-off hyperparameters are introduced in order to find a fair equilibrium between accuracy and latency [24].

#### B. DenseNet

The term "Densely connected convolutional network" (also known as "DenseNet") refers to the architecture of a network in which every layer is capable of communicating directly with every other layer. Instead of simply adding the feature maps

from each level that came before it, they are now concatenated and added to the most recent layer. As a result of this, DenseNets are able to reuse features while still necessitating a smaller number of parameters than a standard CNN would require to achieve the same level of performance [25].

### C. VGG

The VGG object recognition model is at the bleeding edge of technology and can have as many as 19 layers. VGG, which is a deep CNN, performs better than the baseline on a variety of tasks and datasets, not just ImageNet. The name of the network, VGG, gives away the fact that it is a deep neural network consisting of between 16 and 19 layers [26].

### D. ResNet

Deep residual networks (ResNets), like ResNet-50, are 50-layer CNNs. Using shortcut connections, a residual neural network transforms a plain network. Comparatively, ResNets have fewer filters than VGG Nets [25].

### E. Inception

Inception is a network with a modular architecture made up of recurrent components called Inception units. It gives the inner layers the freedom to determine which filter size is necessary to acquire the necessary knowledge. So the layer adapts to recognize the object no matter what size it is in the image [27].

### F. Xception

By exchanging the traditional Inception components for depthwise Separable Convolutions, Xception augments the inception Style. As with Inception V3, it has large number of parameters [28].

### G. NASNet

ResNet integrated residual learning into the conventional CNN framework. The RU, or residual unit, is made up of a standard layer connected via a skip link. By linking the input of one layer directly to its output, the skip connection facilitates the propagation of signals across the network. That's why it is able to train a super-deep model with the help of RUs [29].

### H. EfficientNet

All three dimensions of depth, width, and resolution are scaled equally using a compound coefficient in this convolutional neural network design and scaling method. The rationale for the compound scaling approach is the intuitive understanding that a larger input image necessitates a more complex network with more layers to broaden the approachable field and additional channels to pick up the finer details in the larger image [30].

## V. PROPOSED ARCHITECTURE

Fig. 3 depicts the proposed architecture. Besides the lungs, Chest X-Rays often show other sections of the body, which might complicate the DFE process and reduce the accuracy of the classifier's predictions. U-Net is applied to the issue of X-Ray image segmentation in order to find a solution. The image of the lungs is kept intact during the segmentation process, but the rest of the picture is completely blacked out as shown in Fig. 2.

Fig. 3. Proposed Architecture.

Segmented Chest X-Ray images undergo a two-step feature extraction technique. In the first step, a set of segmented X-Ray images is sent to a Pre-Trained model to extract features. As soon as the features have been extracted, they are ranked using Recursive Feature Elimination. At last, it is decided to retain only those features with a ranking of one. This two-step process is described by Algorithm 1 (Deep Feature Extraction).

#### Algorithm 1: Deep Feature Extraction

**Input:** Pre-Trained Model (i.e. M), Set of 'N' Images  $I_1 \dots I_N$ , Required Image Size (i.e.,  $K \times K$ )

**Output:** Matrix Representing Deep Features after RFE, class\_labels

**Procedure:**

$M_R \leftarrow \text{Remove\_Non\_Conv\_Layers}(M)$

$DF = []$

for  $i=1$  to  $N$  do

    Resize image  $I_i$  to size  $(K \times K)$

    features  $\leftarrow M_R(I_i)$

    features  $\leftarrow \text{Flatten}(\text{features})$

$DF \leftarrow DF \cup \text{features}$

Feature-rank  $\leftarrow \text{Feature-Ranking}(DF)$

selected-features =  $DF[\text{feature-rank} == 1]$

In RFE, given an external classifier that assigns weights to features, the primary goal is to determine features by recurrently considering progressively reduced sets of features. The classification model is pre-trained on a limited number of features, and their relative credibility is then established through inspection of a predefined attribute or the execution of a user-defined function. Next, the current set of features is culled to remove the extraneous ones. At last, features are eliminated one by one until only a handful remain.

RFE is a method that relies on a classification model to determine how features should be ranked. Features that aid the classification model in increasing accuracy are ranked higher, whereas features that decrease accuracy are ranked lower. The proposed approach employs the use of REF to guarantee that the output of Pre-Trained models is used to determine the most suitable set of tuning parameters for each variant of the XGBoost classifier model.

The Gradient Boosted decision trees algorithm has been implemented in XGBoost. Here, decision trees are crafted in a logical order. In XGBoost, weights serve a crucial function. All

of the independent variables are given weights, and this information is then used to feed into the decision tree, which makes predictions. Variables that the first decision tree incorrectly predicted are given a higher weight in the second tree's analysis. The ensemble of these separate classifiers/predictors yields a robust and accurate model [31].

Adjustments to the XGBoost Classifier need to be made for a wide range of parameter values so that a precise estimate of inference may be made. In all 29 different parameter values can be tuned for obtaining the best performance of XGBoost model [32]. However, this tuning process requires extremely high processing power in terms of time and computation. Thus, we selected three most widely tuned parameters namely Learning Rate (LR), the number of estimators (classification trees), and the Maximum Depth (MD). The XGBoost Classifier Tuning Algorithm 2 goes into detail about the tuning process. An XGBoost classifier allows the user to modify aspects, including LR, the number of estimators, and MD of each tree.

**Algorithm 2:** Tune XGBoost Classifier

```
Input: Matrix Representing Deep Features after RFE, class_labels  
Output: XGBoost Classifiers' Finest Tuning Parameters  
Procedure:  
Accuracy-Array = []  
for max-depth = 3 to 5 do  
  for learning-rate = 0.1 to 0.5 (step-size 0.2) do  
    for n-estimator = 300 to 800 (step-size 50) do:  
      accuracy-XGB ← XGBoostModelEvaluation  
        (max_depth, learning_rate, n_estimators)  
      Accuracy-Array[n_estimators, learning_rate, max-depth]  
        ← accuracy-XGB  
  Select combinations of Parameters from Accuracy-Array which  
  gives highest accuracy
```

Having a firm grasp on how our machine learning model operates is becoming increasingly crucial. Merely looking at the model's accuracy as a metric of its efficacy is insufficient, though, because it can mislead you. Black-box models, such as deep CNN, are notoriously challenging to interpret. Local Interpretable Model-agnostic Explanations (LIME) aids in comprehending the operation of classifier model. It denotes the visual features that the model employs to classify the images.

Fig. 4(a) shows features derived from an X-Ray image without lung segmentation, while Figure 4(b) shows features extracted from an X-Ray image with the lungs segmented using U-Net. These images demonstrate how features retrieved from segmented images are superior to those extracted from unsegmented images for training a model.

Fig. 4. (a) Feature Extracted from X-Ray Image without Segmentation by Pre-Trained Model, (b) Feature Extracted from X-Ray Image after Segmentation by Pre-Trained Model.

VI. EXPERIMENT DESIGN AND RESULTS

In this section, the data utilized for experimentation along with experimental results is discussed. The April 2021 edition of the COVID-19, Pneumonia and Normal Chest X-ray Dataset is drawn upon for this experimentation [33]. In the first step of data collection process, 613 X-ray images of COVID-19 patients were obtained from the following online resources: GitHub [34] [35], Radiopaedia [36], The Cancer Imaging Archive (TCIA) [37], and the Italian Society of Radiology (SIRM) [38]. Then, rather than the data being individually supplemented, a dataset from Mendeley [39] including 912 photos that had previously been augmented was acquired. Finally, 1525 images of pneumonia cases and 1525 X-ray images of normal cases were retrieved from the Kaggle repository [40] and the NIH dataset [41], respectively. The dataset contains 4575 photos, with 1525 images in each of three distinct groups. The dataset's developer gathered these photographs from a wide range of available web resources.

In order to acquire the utmost precise deep feature, which is decisive to ML, the networks MobileNet, MobileNetLarge, MobileNetSmall, DenseNet121, DenseNet169, DenseNet201, Xception, ResNet50V2, ResNet101V2, ResNet152V2, InceptionV3, InceptionResNetV2, VGGNet16, VGGNet19, NASNet, and EfficientNetB0 through EfficientNetB7 were chosen. Effectiveness of model trained for patient classification based on X-Ray images is evaluated using metrics specified in equations 1 to 5.

$$Precision = \frac{TP}{(TP+FP)} \tag{1}$$

$$Recall = \frac{TP}{(TP+FN)} \tag{2}$$

$$Specificity = \frac{TN}{(TN+FP)} \tag{3}$$

$$Accuracy = \frac{(TP+TN)}{(TP+FP+TN+FN)} \tag{4}$$

$$F1 = 2 * \frac{Precision*Recall}{(Precision+Recall)} \tag{5}$$

For validation of proposed approach, experimentation dataset is divided into two parts namely Training Set and Testing Set. Training Set contains randomly selected 70% images (i.e. 3202) where as remaining 30% images (i.e. 1373) are used to test effectiveness of proposed approach. Evaluation metric for every Pre-Trained model are calculated by taking average of 10 iterations of Training-Testing evaluation in which different set of randomly selected images are used for training and testing the proposed approach.

Fig. 5 depicts the precision of tuned XGBoost models that make use of features retrieved by algorithm 1 as well as a variety of pre-trained models. Evidently, the tweaked XGBoost model that was trained using the features that were retrieved by Algorithm 1 and EfficientNetB1 obtains the best precision of 0.964. Results for precision and other evaluation metrics used in this expropriation for EfficientNetB4 to EfficientNetB7 are less compared to any other models. Thus, we have not presented these results in Fig. 5 to Fig. 9.

Fig. 5. Precision of Tuned XGBoost Models Trained using Features Extracted by Algorithm 1 (Deep Features Extraction) and Assorted Pre-Trained Models.

Fig. 6 depicts the recall of tuned XGBoost models that make use of features retrieved by algorithm 1 as well as a variety of pre-trained models. Evidently, the tweaked XGBoost model that was trained using the features that were retrieved by Algorithm 1 and EfficientNetB1 obtains the best recall of 0.964.

Fig. 7 depicts the specificity of tuned XGBoost models that make use of features retrieved by algorithm 1 as well as a variety of pre-trained models. Evidently, the tweaked XGBoost model that was trained using the features that were retrieved by Algorithm 1 and EfficientNetB1 obtains the best specificity of 0.982.

Fig. 6. Recall of Tuned XGBoost Models Trained using Features Extracted by Algorithm 1 (Deep Features Extraction) and Assorted Pre-Trained Models.

Fig. 7. Specificity of Tuned XGBoost Models Trained using Features Extracted by Algorithm 1 (Deep Features Extraction) and Assorted Pre-Trained Models.

Fig. 8 depicts the accuracy of tuned XGBoost models that make use of features retrieved by algorithm 1 as well as a variety of pre-trained models. Evidently, the tweaked XGBoost model that was trained using the features that were retrieved by Algorithm 1 and EfficientNetB1 obtains the best accuracy of 0.976, which is equivalent to 97.6%.

Fig. 9 depicts the F1-Score of tuned XGBoost models that make use of features retrieved by algorithm 1 as well as a variety of pre-trained models. Evidently, the tweaked XGBoost model that was trained using the features that were retrieved by Algorithm 1 and EfficientNetB1 obtains the best F1-score of 0.964.

Fig. 8. Accuracy of Tuned XGBoost Models Trained using Features Extracted by Algorithm 1 (Deep Features Extraction) and Assorted Pre-Trained Models.

Fig. 9. F1 of Tuned XGBoost Models Trained using Features Extracted by Algorithm 1 (Deep Features Extraction) and Assorted Pre-Trained Models.

Additional set of trained model’s (evolution) metrics are provided in table 1 for fine-tuned XGBoost model that was trained using the features that were retrieved by Algorithm 1 and EfficientNetB1. Equations for these metrics are given below in equation 6 to equation 9. These metrics are provided for individual categories i.e. Covid-19, normal and Pneumonia and well as overall testing dataset.

$$\text{False Discovery Rate} = \frac{FP}{(FP+TP)} \tag{6}$$

$$\text{Negative predictive value} = \frac{TN}{(TN+FN)} \tag{7}$$

$$\text{False Negative Rate} = \frac{FN}{(FN+TP)} \tag{8}$$

$$\text{False Positive Rate} = \frac{FP}{(FP+TN)} \tag{9}$$

TABLE I. EVALUATION METRICS FOR FINE-TUNED XGBOOST MODEL THAT WAS TRAINED USING THE FEATURES THAT WERE RETRIEVED BY ALGORITHM 1 AND EFFICIENTNETB1

Metric	Covid-19	Normal	Pneumonia	Micro-Average
Accuracy	98.4%	97.1%	97.3%	97.6%
F1	0.977	0.954	0.961	0.964
Precision	0.971	0.943	0.979	0.964
Recall	0.983	0.966	0.944	0.964
Specificity	0.985	0.973	0.989	0.982
False Discovery Rate	0.029	0.057	0.021	0.036
Negative Predictive Value	0.991	0.984	0.971	0.982
False Negative Rate	0.017	0.034	0.056	0.036
False Positive Rate	0.015	0.027	0.011	0.018

TABLE II. COMPARISON OF PROPOSED METHODOLOGY WITH RELATED WORK

Reference	Method	Dataset	Accuracy
[1]	22-Layer CNN	Merged Publicly Available Datasets	94.2%
[9]	VGG16 + CLAHE	Merged Publicly Available Datasets	88.8%
[10]	Xception + ResNet50V2	Merged Publicly Available Datasets	91.4%
[11]	DenseNet-121	Merged Publicly Available Datasets	81.04%
[12]	ResNet50V2 + VGG-16 + InceptionV3	Merged Publicly Available Datasets	95.49%
[13]	VGG16	Publicly available Dataset	91.69%
[14]	COVID-GATNet	Merged Publicly Available Datasets	94.1%
[15]	VGG16	Publicly available Dataset	91.0%
[16]	DenseNet169	Publicly available Dataset	95.72
[17]	AlexNet	Merged Publicly Available Datasets	94.0%
[18]	Xception	Merged Publicly Available Datasets	89.6%
[20]	EfficientNetB3	Merged Publicly Available Datasets	93.9%
Proposed	U-NET + EfficientNetB1 + XGBoost	Merged Publicly Available Datasets	97.6%

Table II details how the proposed architecture and experimental results compare to the state-of-the-art. Because there is no universally accepted reference dataset, it is clear that all researchers are making use of data that is already available publicly.

## VII. DISCUSSION

Significant research contributions of this paper are as follows:

1) Proposed use of U-Net model to segment lung part from X-Ray image and then segmented image to extract deep features.

2) Proposed model is trained on reduced features set using XGBoost classifier model, thus it can be easily deployed on low-end cost-efficient devices like Raspberry-pi easily.

3) Use of Explainable AI: Local Interpretable Model-agnostic Explanations (LIME) methodology is used to explain the decision-making process of Deep Learning Model (Explained in section V).

4) Performance of 20 different Pre-Trained models is evaluated against 9 different metrics specified in Table I.

Limitations of the Research work carried out are as follows:

1) As discussed in Section V, the XGBoost model has 29 parameters that can be adjusted to optimize performance. This study, however, relied on only three variables. This allows for

additional investigation into how the remaining XGBoost classifier parameters affect performance.

2) Using the U-Net model for segmentation does not result in any image enhancement of the lung segment area. Pre-Trained models for deep feature extraction can be used after various image enhancement techniques on lung segmented images have been performed.

### VIII. CONCLUSION

In this study, a Deep Feature Extraction-based method for detecting individuals infected with Covid-19 and pneumonia by analyzing Chest X-Rays is provided. U-Net is used to split the lung region of the chest from the image so that the Pre-Trained model may concentrate on the relevant area of the image and extract more meaningful features. In this article, following the segmentation of the lung part, a two-stage technique to the extraction of deep features from X-Ray images is provided. After that, the XGBoost classifiers are trained to exploit these features in order to differentiate between patients infected with Covid-19 and healthy individuals and patients infected with pneumonia. When the performance of 20 different Pre-Trained models is analyzed, it is discovered that the maximum detection accuracy, precision, recall, specificity, and F1-score are achieved when EfficientNetB1 is used to extract deep features. The respective values for these metrics are 97.6%, 0.964, 0.964, and 0.982. These findings lend credence to the efficiency of the strategy that was proposed.

# Analysis of Privacy and Security Challenges in e-Health Clouds

Reem Alanazi

Faculty of Engineering and Information Technology  
University of Technology Sydney, Australia

**Abstract**—Electronic Health Records (EHR) techniques are being used at an increasingly faster rate to store the patient data making it easier to retrieve, share and utilize it efficiently. This data can be used for research purposes, clinical trials and for studying epidemiology to come up with strategies for epidemic control. With a huge global inflation, the increasing costs of healthcare and the shortage of medicine, it becomes convenient for the healthcare organizations to migrate from the traditional healthcare system to a more sophisticated, cost effective and efficient cloud-based e-Health model. To optimize the full potential of an ICT-based e-Health system, it is imperative for the existing healthcare systems to be implemented in a full-fledged cloud environment. However, with numerous benefits of technology, it might pose some privacy and security threats as well. Therefore, the security and access control of such information is of vital significance. Nonetheless, with the increasing interest of healthcare organizations to migrate from the conventional healthcare systems to the modern cloud-based e-Health systems, not much care is being taken to address security and privacy issues effectively towards the protection of sensitive data.

**Keywords**—HER; e-health; security; privacy; cloud

## I. INTRODUCTION

With the advancements in Information and Technology, services all across the globe have improved, in all fields in general, and around healthcare in particular, all due to several provisions like flexible processes and low-cost treatments. When healthcare is integrated with the internet it is termed as e-Health [1] [2]. This e-Health is the biggest innovation of technology and its implementation in a cloud-based environment is necessary to maximize the benefits. Despite all the benefits that e-health has been providing, it nevertheless still gets affected by certain challenges of privacy and security [1]. Since its conception, cloud computing has garnered enough popularity around the health sector. The cloud-based e-health makes the sharing of this health data with its stakeholders easier [3]. Although the internet by making use of technologies like cloud computing has made the concept of centralized healthcare possible, it has however brought in with it certain bugs and loopholes in the system. There are certain issues concerning security and privacy that remain unaddressed and unresolved even today [3].

The services that the e-health cloud offers are preventive care, keeping an account of patient satisfaction, a continuous vigil and AI supported detection. All these services are prone to privacy breach, and it needs to be taken care while rules regarding privacy measures are implemented. With the growth

of use of technology among people, the awareness regarding privacy of their medical data has grown as well. Patients fear leak of their private medical history that they might be embarrassed of, to social media. It's important to maintain the trust of patients in health services providers, thus the e-health cloud needs to be highly secured [2] [9]. The centralization and digitization of the data in the health sector has made the sharing of medical data easy. However, this sharing might lead to data attacks and cause loss of confidential data. To tackle this, several government bodies have taken initiatives to ensure better security and proper privacy of data. Instances from the US healthcare industry show the progress that's been made in securing the e-health systems. The Health Insurance Portability and Accountability Act (HIPAA), which had guidelines set for security and privacy requirements of US healthcare, ensured proper utilization of e-health [1]. A secure e-health system ensures the system has these attributes; Authenticity, Integrity, Availability, Access control, Anonymity [4].

## II. LITERATURE REVIEW

Several articles have been written and read about e-Health and its merits and demerits. The research has been done about what challenges are being faced in the pursuit of better security and maintaining privacy of data, and how these drawbacks can be addressed. Security models developed in relation with healthcare applications, targeted the information loss and ways to combat it. A security model, Role Based Access Control (RBAC) was deployed to find solutions for the already identified security challenges in electronic health [31]. An extended version of RBAC known as u-healthcare, was designed to carry out four vital functions: what meal should the patient take, exchange of information related to health, management of the same health information on smart devices that the records are accessed through. These studies however concluded not much could be resolved about these security issues. The model had several drawbacks, and it was not suitable for disturbed environment. The solution offered had limited application. It was not scalable to any number of users.

Another model developed by [32] demonstrated the working of a comparatively lightweight framework that was based on Transport Layer Security/Secure Sockets Layer (TLS/SSL) to secure the data shared between the server and client. This framework was called Secure Health and it had many security features like proper authentication, and authorization for the transmitted and stored data. It protected the system from unidentified and unauthorized access minimizing alien access to confidential health data. It also

helped the administrator in identifying wrongly stored information [33]. Despite all the benefits that the system offered, some challenges remained unresolved, the main one being its platform dependency and no or less scalability. In cloud computing, scalability is the most sought feature. The systems based on cloud should have provision for an expansion in future. In the need to minimize the cost of maintaining the health data and for keeping it available but secure, another security mechanism with a different concept of hierarchy was given by Barua, et al. This model adopted the theory of Attribute Based Encryption (ABE). It had provision for access control, which was framed at the central level. However, even this approach failed at addressing a large number of requests from the client side because of the centralized manner in which the health data was stored in [34]. In case of many users accessing the system at once, the requests needed to be sorted out depending on their priorities. To overcome the challenges caused due to the centralization of data, other attributes like collaborative and distributive nature of the e-health systems were taken in consideration by Guo et al. [35]. They brought about a change in the way requests were being addressed and servers being accessed. They suggested authorization from both the patients and the doctors, and not from the centralized server itself. Clients were given access only on the basis of priorities concealing their identities and characteristics. Hamid et al. worked on the confidentiality of patient's multimedia data in the cloud. They proposed a bilinear pairing cryptography based triparty one-round authenticated key agreement protocol. This protocol helps in secure communication by generating a session key. Also, a decoy technique with a fog computing facility has been implemented so that the private healthcare data can be accessed and secured securely. This approach induces computational expenses in communication for strong security [10-15]. Marwan et al. proposed a new method to enhance the reliability of cloud storage and used Shamir's Secret Share Scheme (SSS) and multi cloud concept. This was done to meet security requirements, avoid data loss, and prevent unauthorized access and privacy disclosure. To prevent medical records from getting leaked and revealed, this technique allows division of the data into small shares. Also, data is spread among various cloud storage systems. Medical Data is encrypted using SSS technique and split into shares to ensure confidentiality and privacy. This article has not discussed any aspect of the optimal number of shares aroused to tradeoff between efficiency and security [16, 17]. Galletta et al. have proposed a system developed at Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) claiming to address security and privacy of patient's data [18]. This system works on two software parts: the splitter and anonymizer. The anonymizer collects anonymized clinical data and the splitter obscures and stores health data in multiple cloud storage providers. This data can be accessed by only authorized clinical operators. Moreover, the performance of the system has been assessed by magnetic resonance imaging (MRI) data. Alexander et al. proposed anonymization techniques and privacy-aware systems in order to publish data on the cloud. This system used Advanced Encryption Standard (AES) and k-anonymity [19-21]. Smithamol et al. proposed a novel architecture to address data confidentiality. This model

constructed the group-based access structure and Ciphertext-Policy Attribute-Based Encryption (CP-ABE) by making use of the partially ordered set, thereby providing medical records access control. This approach reduced overall encryption time and computational overhead [22] [23]. Ibrahim et al. provided a solution to access securely the privacy-sensitive EHR data through: 1) a cryptographic role-based technique for the distribution of session keys with the help of Kerberos protocol, 2) location and biometrics-based process for user authorization, and 3) a wavelet-based steganographic technique for embedding EHR data securely. This approach showed resilience to man in the middle attack and replay attacks. However, it did not show resilience to other security threats and did not analyze its scalability [24]. Shah and Prasad deployed a novel structure with cloud-based privacy-aware role-based access control (CPRBAC) model. This model presented a list of different methods of encryption and various privacy, and security challenges were addressed. Its goal was to minimize computational complexity. However, no qualitative analysis was carried out to check the efficiency of the approach [25]. Supriya and Padaki surveyed various lapses in health care security particularly concerned with non-repudiation, CIA model. They studied and discussed some already proven operational strategies and methodologies related to risk management. This way they were able to perceive what the health industry must follow to reduce security and privacy threats [26]. Lohr et al. tried to establish privacy domains in e-health infrastructures by presenting a security architecture based on Trusted Virtual Domains (TVDs). This architecture, however, did not address other research challenges like anonymity, non-repudiation, incapacity of the patient to authenticate [27, 28]. Kumar et al. proposed a model based on encryption technique called Attribute Based Encryption (ABE). All the users have been divided into two domains: personal and public. This is done to control key management complexity. In the personal domain, a user can encrypt data that is allocated to him whereas in the public domain, a user can adopt and utilize multi-authority ABE. Scalability and flexibility are the two challenges associated with this approach as integrating ABE into the EHR system gives rise to serious and key management challenges [29]. Zhu et al. proposed a model that utilized re-encryption and Attribute Based Encryption (ABE) with proxy encryption which is enabled by Rivest Shamir and Adleman (RSA). The whole purpose of using proxy encryption was to induce a separation mechanism to validate the patient's data. Write privilege keys were given to professionals whereas read privilege keys were given to patients. Using this model, computation overhead was minimized. The healthcare worker can be easily stopped from getting the read keys and this does not need to be approved from both ends. Moreover, this framework can be accessed by only a few users [30].

### III. WHAT IS E-HEALTH

The concept of conventional healthcare has been narrowed down to virtual healthcare. The integration of technology with healthcare has emerged as a new concept termed as e-health. In an era like today time management is the need of the hour. Going to doctors for consultations and waiting in queues for hours is an obsolete scene now. With the internet and

technology being used in all walks of life, people prefer a virtual way of seeking medical treatment. The process of having consultations online, using desktops and laptops is e-Health [5]. This cloud-based e-health system can be created specifically according to the needs of the patient. Also, healthcare accessed via mobile phones is m-health which is mostly for self-management of chronic diseases. The e-Health systems have been of great help in dealing with patients who had prolonged diseases and needed to be kept constant vigil. These e-Health systems keep a track of health-related information and provide help with symptom checking, finding a suitable doctor, managing financial records, self-monitoring, and filling prescriptions. This information is available and accessed by a large population [5]. E-health has now become a vital part of the healthcare system due to its efficient services and accurate results, and error free unlike the traditional healthcare systems. In a traditional way of treatment, a patient could get a particular dose of medicine twice due to manual handling of records. This is not the case with health where electronic medical records are maintained, which store all the information about the patient's treatment and medicines given, thus avoiding any errors with the medication of the patient [6]. A country's success of e-Health is derived from many factors like what type of management and infrastructure is being used, how much is the user involvement, if the system is scalable to adapt to as many users as possible or not. The medical data in the cloud is of importance to its healthcare professionals, patients, entrepreneurs, and businesses which deal with health insurances or such policies. E-health strategies like norms, laws and regulations must be created to implement cloud technology in healthcare effectively. It is not just another

progress in the field of technology, it is a way of thinking, state of mind, to increase the reach of healthcare, improving local, regional and global healthcare by making use of ICT (Information and Communication Technology).

As the name suggests the e-Health uses electronics which can be mobile phones or computers along with cloud technology for storage purposes. The eHealth is mainly of two types: Personal Health records (P-HR) and Electronic Health Records (E-HR). The P\_HR is used by patients to update their health records themselves and for seeking consultations online by using mobile phones. Whereas E-HR is of use to healthcare professionals. This E-HR is very beneficial in providing the right treatment to the patient and for secure sharing medical records or patient medical history, medicine details and prescriptions. E-health provides an effective and real time treatment for the patient.

#### IV. CLOUD BASED E-HEALTH MODELS

1) *Private cloud*: Model given in Fig. 1 is the most secured model. It is usually operated and managed by the same organization that uses it, making it highly secured and hence security issues are limited. It is located on premises, over the intranet and behind the firewall. In this, the public internet is completely restricted. Only recognized personnel from the healthcare institution are able to access the electronic medical record (EMR). Only these personnel are considered to be trustworthy and reliable. A good example is VMware [1] [4].

Fig. 1. Private Cloud.

2) *Public cloud*: This model given in Fig. 2 is totally in control of the third-party provider as the services of the cloud system are provided by them only. They are known as cloud service providers (CSPs). It is located off premises, over the internet controlled by CSPs. In this, EHRs are held between various organizations and these EHRs are highly vulnerable to malicious attacks. It has many security challenges associated with it and to avoid them, efficient cryptographic mechanisms and fine-grained access control frameworks need to be applied. It is considered less secure than the private cloud. Some good examples are Dropbox, Amazon EC2, Microsoft Azure [1] [4].

3) *Hybrid cloud*: Model given in Fig. 3 is a combination of public and private cloud servers where both works

individually but unitedly. The deployment of this model combines the benefits of both the models and multiple cloud services can be used. This model is highly advantageous to e-health and plays an important role in integration, composition and organizational impact and housing big medical data. Health care providers that have restricted and limited resources can easily deploy this model which makes use of third-party services. There is a huge importance of hybrid cloud in health care but at the same time there is a need of effectively implementing hybrid cloud in e-health as it has trust and confidentiality issues because of the public part. An important example is Rackspace [1] [7].

Fig. 2. Public Cloud.

Fig. 3. Hybrid Cloud.

## V. PRIVACY AND SECURITY REQUIREMENTS

It is a known fact that transition of conventional health care systems to e-health care has brought with it a lot of benefits and has made health care systems easier and affordable but there are a lot of challenges associated with it like confidentiality, privacy and security of patients' records. Cloud computing is highly acceptable in digital technology which is being used in the healthcare industry extensively [8]. In order to increase the confidence of patients and organizations, the cloud service providers and other government organizations have formulated a range of security measures and guidelines. Cloud servers have been broadly classified into three categories: trusted, semi-trusted, and untrusted. A trusted server can be defined as the one that can be trusted completely. It doesn't lead to any information leak and threats to the health data. Semi trusted servers are those that are considered to be honest but curious servers. They conspire with malicious users to acquire health data. Untrusted servers cannot be trusted and are highly vulnerable to attacks.

In e-health system there is a need of security and privacy in the following ways:

- 1) *Data integrity*: It is a mechanism which ensures health data is not being altered by an unauthorized entity.
- 2) *Data confidentiality*: It is a mechanism which ensures that the sensitive health information does not reach unauthorized users. Data confidentiality is achieved by data encryption.
- 3) *Authenticity*: It is a mechanism that ensures sensitive health data is accessed by only authorized and authentic authority.
- 4) *Accountability*: It is a mechanism to justify the actions and decisions of organizations and individuals.
- 5) *Audit*: It keeps the track of any kind of activity on the health data and is continuously monitored and protected. It also ensures data privacy and security.
- 6) *Non-repudiation*: It refers to the sender and receiver's non denial of authenticity. It means, neither patients nor doctors can repudiate health data after its theft.
- 7) *Anonymity*: It is a mechanism which keeps the identity of the users anonymous so that the cloud servers are unable to access the stored health data.

## VI. CONCLUSION

The security and privacy of patient data in e-Health systems is quite a demanding task. Researcher is being carried out internationally to provide and protect the Electronic Health Records (EHR) data. To mitigate the hurdles of security and privacy challenges, it is essential for health organizations to migrate from the traditional e-Health systems to the advanced cloud-based e-Health systems. While migration towards the cloud-based infrastructure protects the patient data in EHRs to a larger extent, it, however, does not guarantee the full-proof security and protection against data theft and other type of

threats and vulnerabilities. An in-depth analysis has been done in this perspective. Firstly, an attempt has been made to understand the requirement of shifting from traditional e-Health systems to cloud-based infrastructure. A survey has been carried out to highlight the privacy and security considerations prevalent in the cloud-based e-Health systems [8]. More than 30 research papers were analyzed to highlight the underlying security and privacy issues in various cloud-based e-Health systems across the globe. Some security techniques with their pros and cons have also been presented. Finally, some recommendations have been made for enhanced privacy and protection in the cloud-based e-Healthcare infrastructure. For the future research, we are looking forward to exploring the state-of-the-art techniques for preserving privacy especially in terms of EHR data in the cloud infrastructure scenarios.

## VII. FUTURE DIRECTIONS

There has been a tremendous development and progress in security and privacy in e-health clouds. Still, there is a need to enhance and enforce certain security and privacy measures in the e-health system. This can be done by enhancing and maintaining efficiency of all the initiatives regarding security and privacy.

Some of the strategies for security purpose in e-health are mentioned below:

- 1) Auditing is the first thing in assuring security and privacy in e-health. This approach greatly helps in locating and identifying any kind of wrongdoing in the e-health system. Hence, auditing can be regarded as a new research direction for e-health.
- 2) Encryption schemes can also help in achieving security and privacy. Encrypting information that has the data regarding e-health users will in no way lead to insecurity of data. This is an excellent procedure as the other parts of information remain unencrypted.
- 3) RBAC is a model that has been put into use in order to address the issues of security and privacy in e-health. Also, Attribute Based Access Control (ABAC) model is widely used to ensure remarkable scalability and flexibility for authorizations and authentications.
- 4) Attribute Based Encryption (ABE) is an exceptional way to ensure privacy in e-health. But the performance is affected while decrypting data because of bi-linear pairing operations. These bi-linear operations require a solution to strengthen the efficiency of ABE.
- 5) General enforcement needs to be adopted to ensure privacy. Privacy must be incorporated in e-health that benefits all the parties. Also, research must be done to know about the security and privacy violations.
- 6) Most of the solutions adopted RBAC, MAC, and DAC. These models can ensure better results of security and privacy when applied collectively or hybridized into a single model.

Assistant Professor and Research Advisor in Computer Science,(Ref.No:05526/Ph.D.K 10/Dir/Computer Science/R.A) P.G and Department of Computer Science, J.J.College of Arts and Science (Autonomous), Sivapuram, Pudukkottai, Tamil Nadu, India<sup>2</sup>

**Abstract**—Infections of the retinal tissue, as well as delayed or untreated therapy, may result in visual loss. Furthermore, when a large dataset is involved, the diagnosis is prone to inaccuracies. As a consequence, a completely automated model of retinal illness diagnosis is presented to eliminate human input while maintaining high accuracy classification findings. ODALAs (Optimal Deep Assimilation Learning Algorithms) are unable to handle zero errors or covariance or linearity and normalcy. DLTs (Deep Learning Techniques) such as GANs (Generative Adversarial Networks) or CNNs might replace the numerical solution of dynamic systems (Convolution Neural Networks), in order to speed up the runs. With this objective, this study proposes a completely automated multi-class retina disorders prediction system in which pictures from the Fundus image dataset are upgraded using RSWHEs (Recursive Separated Weighted Histogram Equalizations) to boost contrast and noise is eliminated using the Wiener filter. The improved picture is used for segmentation, which is done using clustering and the optimum threshold. The suggested EFFCM is used for clustering (Enriched Fast Fuzzy C Means). The suggested AOO (Adaptive optimum Otsu) threshold technique is used for clustering and picture optimal thresholding. This work suggests AMF-RCNNs (anchor-free modified faster region-based CNNs) that integrate AFRPNs (anchor free regions proposal generation networks) with Improved Fast R-CNNs into single networks for detecting retinal issues accurately. The performances of Accuracy is 98.5%, F-Measure is 96.5%, Precision is 99.2% and different Subset features are 98.5 % show better results when compared with other related techniques or models.

**Keywords**—Retinal disease; fundus image dataset; contrast enhancement; segmentation; Fast Fuzzy C Means; adaptive optimal OTSU; faster region-based convolutional neural network

## I. INTRODUCTION

Human's vision is a crucial sense and lack of which impacts independence and productivities in humans. Retinal illnesses affect millions of humans resulting in visual losses when not identified or treated in early stages of vision loss. DRs (Diabetic retinopathies), glaucoma and other eye defects are macular degenerations which crop up as humans age [1] where early therapies can arrest or eliminate the disease's progressions. Despite the fact that there are many hospitals and eye clinics in India's cities, the doctor-to-patient ratio remains low. There is a paucity of both infrastructure and ophthalmologists in rural locations [2]. Even community outreach activities are hampered by a lack of qualified professionals in remote locations to appropriately assess

patients. With advancements in technology and image processing, it is feasible to automate disease identification and refer patients to doctors for additional evaluation. Ophthalmologists can use retinal fundus imaging to diagnose retinal abnormalities. Early detection can boost treatment chances and avoid blindness [3].

Medical specialists can use retinal fundus images to identify retinal diseases including DRs and retinitis pigmentosa. Studies using MLTs (Machine learning techniques) have been recently focusing on identification of retinal disorders including DRs by categorizing fundus images based on extracted features [5]. The main aspire of this paper is to differentiate automatically abnormalities in the retina without segmentations or feature extractions from their images and use DLTs to automatically categorize retinal images as healthy or sick. Many of these models use the retinal picture to identify, extract, and evaluate disease-specific characteristics. This necessitates a thorough understanding of the illness as well as considerable work in developing the characteristics for the classifiers. Without being taught where to look, MLTs utilize data to uncover hidden patterns and have gained traction in disease diagnostics. These algorithms identify patterns and qualities in images at multiple levels and relate them to recognized disease classes. Guided learning have assisted in early detections and categorizations of eye disorders including cataract, conjunctivitis, and DRs. Various MLTs have been found equivalent to that of human specialists for certain eye conditions in studies. ANNs (Artificial Neuronal Networks) are mathematical models that reproduce neuronal organizations of cerebral cortex [6]. Layers of neurons make up NNs (Neural networks) and these layers are made up of fully connected 'nodes,' each with non-linear 'activation functions,' which reduce errors in executions of GDs (gradient descents) using BPs (back propagations).

Input layers are followed by one or more hidden layers where patterns are processed using system of weights 'connections' for recognizing patterns. These hidden layers get connected to output layers, creating patterns of retinal images. Most ANNs include learning rules which alter weights of neurons in response to input patterns. A typical neural network, on the other hand, is incapable of analyzing patterns in different positions. Specifically, unlike traditional ANNs, the layers of DLTs, such as CNNs and DNNs (Deep Neural Networks) [7], contain neurons organized in three dimensions: width, height, and depth. Certain neurons may sense the

margins while others detect the centre. Using a certain stride and ensuring that various neurons acquire distinct data on pattern localization. Thus, unlike standard NNs, these networks learn more about patterns in images instead of plain detections. Information obtained by first layer's neurons is forwarded to corresponding hidden layers, with neurons contributing vital information about distinct image parts. The last layers use multi-class classification functions that count number of units as output class counts. This research work's contributions include developing DLTs based on CNNs for identifying retinal eye diseases from fundus images and are listed below: RSWHEs are used to boost the contrast of input pictures. Detecting diabetes-related eye disorders areas early

and automatically using cluster-based segmentation is a difficult challenge. The EFFCM-based approach was applied in the described methodology for disease area localization. The findings suggest that combining EFFCM with AOO leads in accurate localization of the afflicted regions, ensuring exact illness detection in an automated way.

The motivation suggested AMF-RCNNs can identify illness symptoms, including early warning indications, and have no difficulty learning to recognize an image of a healthy eye. Finally, we compared the strategy to the most recent cutting-edge methodologies and obtained better performance results.

Fig. 1. Examine Method Smart Art.

The overall research technique displayed in Fig. 1, research work summarizes various DLTs techniques applied for detection and classification of eye diseases (Section II). Implementation methodology describes the clustering method and proposed classification method for classifying the retinal disease (Section III). Then the results of the experiment with discussion is projected in experimental and results (Section IV). Finally concludes the paper with future study in conclusion and future work (section V).

## II. RELATED WORK

This section provides a thorough examination of the principles and applications of DLTs in retinal image processing. Machine learning, particularly DLTs, has lately been successfully utilized in this field. This section examines current developments in DLTs approaches for retinal image processing. Pan et al. [8] use DLTs to identify and categorize DRs Lesions in pictures of FFAs (fundus fluoresce in angiographies) by comparing three CNNs: DenseNet, ResNet50, and VGG16. In [9] developed a DLTs-based DC-Gnets (disc cup segmentation glaucoma networks) for glaucoma diagnosis using structural characteristics like cup-to-disc ratios, probability scales of disc damages, inferior/superior nasal temporal regions using RIM-One and Drishti-GS datasets for segmentations. In [10] present a method for detecting the existence of neovascularization that includes image resizes, filtering green channels, Gaussian filters, and morphological methods like erosions and dilations in processing of images. The several layers of CNNs were employed and modelled combined in a VGG-16 net architecture for classification. The method was tested and trained on over 2200 photos from the Kaggle database. In [11] suggested a two-stage approach for detecting and localizing

the optic disc before classifying it as healthy or glaucomatous. The first stage utilizes Regions of CNNs to locate and extract optic discs from fundus images while in the second stage DCNNs (Deep CNNs) classify extracted discs as healthy or glaucomatous. Unfortunately, none of the publicly obtainable retinal fundus image datasets could provide much needed bounding boxes localization of discs.

In [12] offered modified U-Net topologies that included block squeeze and excitations as well as usages of attention gates in datasets to segment demarcation lines/ridges and vessels. These changes were verified and confirm by ROP experts. All three networks (AG U-Net, U-Net and SE U-Net) showed good results with ranges in the dice coefficients ranging from 1 to 6% for the HVDROPDB datasets. In [13] suggested architecture employs a dilated convolution filters to obtain bigger receptive fields, resulting in near-human accuracy in segmenting retinal blood vessels. The popular datasets were used to train the CNNs. In [13] introduced the DL-CAEF (DLT Assisted Convolution Auto-Encoders Frameworks) to diagnose glaucoma and recognize AVPs (Anterior Visual Pathways) from retinal fundus pictures. In [15] identified CWS, HE on retinal images using super iterative clustering approach which comprised of CNNs and encoders with encoder structures. To convert red, blue and green images into ideal grayscale images devoid of noises, FBMIR dataset's data were combined with histogram filters and subsequently categorized using DALAs (deep assimilation learning algorithms). Through the investigation of retinal fundus color photographs, in [16] proposed presenting a mixture of losses in DNNs model to enhance recognition performances in biomedical data for classifiers. Table I show the literature review method with advantages and disadvantages.

TABLE I. THE LITERATURE REVIEW METHOD WITH ADVANTAGES AND DISADVANTAGES

Authors	Method	Advantages	Disadvantages	Evaluation result
Juneja et al., [9-8]	DC-Gnet	Reducing the computational complexity.	It is susceptible to interference from uneven lighting in fundus pictures, resulting in low precision and poor robustness.	Dice, Jaccard, and recall coefficients
Bajwa et al., [10-11]	Deep CNNs	This strategy avoids the necessity for the creation of dataset-specific empirical or heuristic localizations.	However, if glaucoma is detected early enough, it is feasible to delay the progression of the disease.	95% accuracy
Agrawal et al., [12]	U-Net architectures	As a result, trained models were generic and robust to data fluctuations or heterogeneities.	However, U-net-based segmented discs are extremely sensitive to segmentation accuracy, and even little errors in eye disease delineation can have a major impact on diagnosis.	AUC obtained for all three networks was above 0.94, AG U-Net sensitivity of 96% and specificity of 89%
Biswas et al., [13]	CNNs	Obtaining appropriate contexts for items extending beyond filter sizes	However, because to the convolutional filters' restricted receptive field, this approach frequently fails to effectively segment the retinal blood vessels and introduces extra noise.	AUC) of 0.9794 and an accuracy of 95.61%
Saravanan et al.,[14]	DL-CAEF and CNNs	It used multi-model learning for reducing image reconstructions or classification errors.	However, if ambient light enters the picture as it is being captured, it might appear brighter than the optic disc.	IOU greater than 50%
Sikkandar [15]	DALA	The ability to learn discriminative depiction of eye illness performed much better.	However, there may be additional bright areas in the picture owing to illness or poor image capture settings, which can impair the DALA method's efficacy.	accuracy ratio of 98.5%

### III. PROPOSED METHODOLOGY

The suggested AMF-RCNN for classifying retinal fundus pictures was examined. BDR Backgrounds for PDR stands for Proliferative DRs, CRVOs stand for Central Retinal.

Vein Occlusions, CNVs stand for Choroidal Neovascularizations, HISTs stands for Histoplasmoses, and Normal stand for Normal eyes. Fig. 2(a) depicts the normal anatomical features of the retina, whereas Fig. 2(b) depicts an eye illness complication in a retina.

In Fig. 3 depicts the broad framework of the primary sequential procedures for classifying DR pictures in the suggested technique. To begin, DR pictures were acquired,

graded, and tagged. The STARE (Structured Analysis of the Retina) web-database was used to obtain the dataset. The collection contains 400 raw fundusoscopic pictures from various instances, including 13 illnesses and normal cases [17]. After that, the appropriate image pre-processing techniques were used to capture images for better training for the planned learning. The improved picture is used for segmentation, which is done using clustering and the optimum threshold. The suggested method gathered features from multiple sample photos with ground truth labels and automatically changed its hyper parameters to get the greatest classification accuracy. The identification outcome might help ophthalmologists decide whether or not to refer patients.

Fig. 2. (a) The Normal Anatomical Structures of the Retina. (b) Illustrates a Complication of Eye Disease in a Retina: A. Microaneurysms, Narrow Bulges (DRs), B. Optic Nerve Damage (Glaucoma), C. Exudates with Retinal Thickening (Diabetic Macular Edema), D. Degeneration of Lens (Cataract) [4].

Fig. 3. The General Framework of Proposed Methodology.

### A. Image pre-processing

The suggested approaches aid in the identification of eye diseases by enhancing picture quality and clarity. Here, two ways for improving the contrast and quality of retina fundus pictures have been developed: RSWHEs boost picture contrast, whereas Wiener filters reduce noise. RSWHEs: RSWHEs work by recursively segment input histograms into sub-histograms and modify sub-histograms with weights based normalized power law function procedures and histogram equalizations on weighted sub-histograms separately. It improves the contrast of a picture in three phases [18]: First, take the picture  $I$  and calculate the histogram  $H(I)$ , which is then split into the number of sub-histograms. A second histogram weighting is used to modify the sub-histograms using a normalized power law. Finally, histogram equalization is performed, in which the weighted sub-histograms are equalized separately over the modified sub-histograms. Wiener filters: Wiener filters are non-adaptive additional predefined patterns that incorporate linear approximations of predicted signal organization on or after a non-adaptive extra predetermined pattern. A typical Wiener filter is a convolution filter that computes the shape and size of the neighborhood using only a frame. It may be more effective to filter with more really large Viennese masks and fewer blurry masks. A fundus photograph of size  $(ij)$  must have each pixel representing the strength of a single stationary point in front of the camera. The Wiener filter is used to remove noise from a signal that has been tampered with by statistical analysis. The Wiener filter is a type of filter that is used to reduce assuming that signal and noise processes are second-order picture derivatives. Consider the following equation-1 to demonstrate and transform to 2D:

$$ob(i, j) = ir(i, j) * I(i, j) + un(i, j) \quad (1)$$

Where  $*$  represents  $I$  is the unknown real ovarian cyst picture with  $ij$  pixel value,  $ir$  is the impulse response of a linear, time-invariant filter,  $un$  is incremental unknown noise independent of  $I$ , and  $ob$  is the observed image. Then, as given in equation-2, a de-convolution filter  $dc$  must be found to evaluate  $I$ :

$$\hat{I}(i, j) = dc(i, j) * o(i, j) \quad (2)$$

where  $\hat{I}$  indicates the value of  $I$  that reduces the mean square error. The transition function of  $Tr$ , in the frequency domain, given in equation-3,

$$Tr(x, y) = \frac{ir^*(x, y)PS(x, y)}{|ir(x, y)|^2PS(x, y) + NSP(x, y)} \quad (3)$$

$Tr(x, y)$  is the Fourier transform of the probability mass equation,  $PS$  is the power spectrum of the signal process used to acquire the Fourier transform of the signal collinearity, and  $NSP(u, v)$  is the power spectrum of the noise ( $N$ ) practise acquire by generating the Fourier transform of the noise autocorrelation.

### B. Segmentation Process using EFFCM Clustering and AOO Method

The improved picture is used for segmentation, which is done using clustering and the optimum threshold. The suggested EFFCMC Algorithm is used for clustering, while the proposed AAO threshold with ALOs is used for optimum thresholding (Ant Lion Optimizations). Real-time photos are used to collect materials for processing. FCMC is a widely used approach for picture segmentation since it is more efficient than other machine learning algorithms. The biggest disadvantage of this approach was its slowness. The Fast Fuzzy C Means Clustering technique was applied to increase the speed of this technique. The primary distinction in this approach was that an image histogram was employed instead of raw picture pixels. The objective function OF of the Fast Fuzzy C Means Clustering method is given by,

$$OF = \sum_{i=0}^n \sum_{c=1}^c hist_i * \mu_{ic} * dis(i, \theta_c)$$

Here,  $hist_i$  refers to the histogram,  $\mu_{ic}$  refers to the fuzzy membership between pixel  $x_i$  and histogram of cluster with center  $\theta_c$ ,  $dis(i, \theta_c)$  refers to the distance between pixel  $x_i, i = 1, 2, \dots, n, \forall n = 255$  and histogram of cluster with center  $\theta_c$ , Let  $C = 1, 2, \dots, c$  represent each centroid. Then, the mean of the pixels in every centroid is given as  $v_c$ . The mahalanobis distance between the data point  $x_i$  with each  $v_c$  is then calculate. This term is added to the objective function in the present EFFCMC plan. Thus, the new objective function is given as

$$OF = \sum_{i=0}^n \sum_{c=1}^c hist_i * \mu_{ic} * dis(i, v_c) * mahalan(x_i, v_c)$$

Otsu thresholds are common image segmentation techniques that use global thresholds to divide images into two categories: foreground and background. Pixel values in images are compared using thresholds. When values of pixels exceed threshold values they are classified as foregrounds; else they are classified as backgrounds. The initial threshold determines Otsu algorithm's efficacy. As a result, the authors suggest an adaptive Otsu thresholding method (AOTA) in which optimal threshold selection is performed using ALOs that adaptively select best starting threshold values. In this part, the variable threshold influences the AOTA output, and the goal of any optimizer is to find values for these variables that provide the best segmentation rate and accuracy. The Ant Lion Optimizer (AOO) is used to increase the performance of AOTA. AOO is a strategy that disallows the local minima and maxima in order to obtain an optimal solution. To compute the input for the AOO method, the ALO [17] algorithm is employed. The suggested algorithm AOTA system is adjusted utilizing the ALO optimizer using the provided fundus image pre-processed data set. This raises the bar for learning from the model. ALO is used to modify the incidence of local minima and maxima. The AOTAs through ALOs is illustrated in Fig. 4.

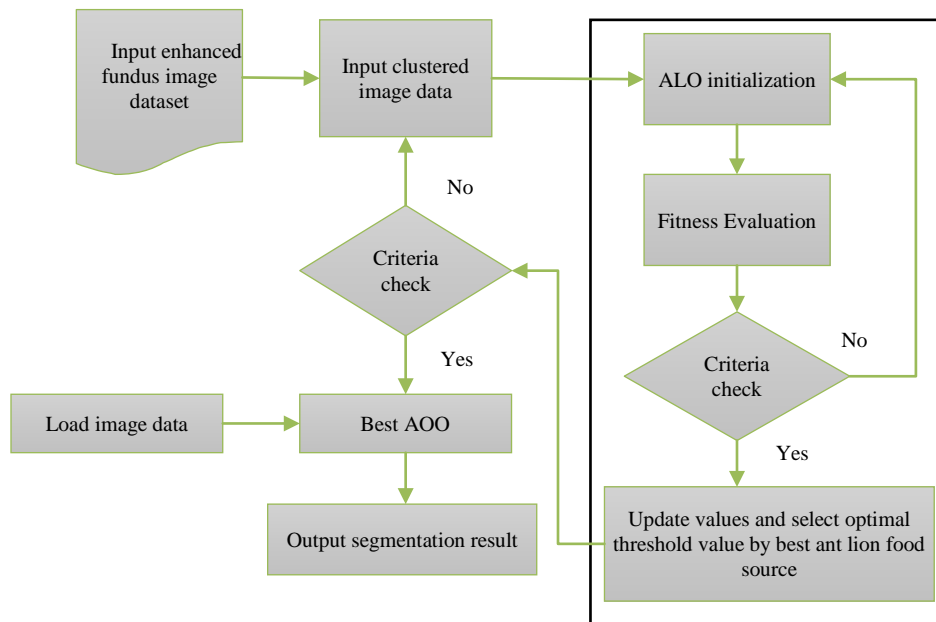

Fig. 4. Flowchart of Proposed AOO Method.

Early data quality segmentation is a necessary step since classifying early phases of eye illnesses includes uncertainties that govern disease predictions, and progressions caused by aspects of image data which necessitate strong models to reliably predict outcomes and the segmentation region of eye disease. In this study, AOO is used for segmentation with the weaker domain identification among the major four domains.

- Step 1. Initialize: random initialization of the positions of input variables of the features as Ant lion selected from preprocessed image dataset.
- Step 2. Calculate the cumulative total of a maximum number of iterations, where iteration represents the steps in a random walk. One matrix stores the position of each input's value. Another matrix stores the relevant objective values. Another matrix is generated in order to save the position and fitness value as accuracy.
- Step 3. Use a random threshold value to update the location of the input value.
- Step 4. Create Traps: Make two vectors, one with a minimum of all variables from a single input source and the other with a maximum of all variables from the same input source. This provides the input weight for the fitter for the intended output value.
- Step 5. Entrapment of Ants in Traps: If it gets fitter, replace the position of all input variables with the appropriate fit of the other input variables.

- Step 6. Finally, change the threshold value based on Ant Lion's location.
- Step 7. Rebuilding Traps: Check the termination requirements; if the termination conditions are met, return the ideal solution; otherwise, proceed to updating Ant Lion's location.

Following inference is used to provide automated threshold selection for segmentation. Elitism, or remembering the best solution discovered, is an important feature of a nature-inspired algorithm that allows for the preservation of the best solution achieved at any point of the optimization process. The best result generated in each iteration is kept and considered Elite in this investigation. Because the Elite is the fittest output, it will influence the movements of all other variable thresholds throughout iteration.

### C. Eye Disease Image Detection Model using AMF-RCNN Model

As illustrated in Fig. 5, the proposed eye disease image detection model, AMF-RCNN, consists of eye disease images. Area of interest extraction network, a features extraction network, and an eye illness picture detection network are all examples of networks. To begin, CNNs are used to extract characteristics and get fusion features from an image of an eye ailment. Second, the AFRPN receives the fused feature map produce by the feature fusion methods and creates a series of eye sickness image suggestions. The top sorted are reduced to the similar size ROI vector using the ROI Align layer [12]. The classification layer predicts the image category of an eye condition, and the bounding box regression layer refines class-specific suggestion box offsets, using these fixed vectors.

Fig. 5. Block Diagram of AMF-RCNN.

**Feature Extraction Network:** Automatically extracting target features from eye disease pictures and integrating feature depiction and goal for "joint learning" were accomplished using the CNN-based approach. Depending on the optimization goal, the parameters of eye sickness picture features can be changed adaptively during network training. The feature extraction network is made up of four layers: convolution, pooling, activation, and feature fusion. In conclusion, the new feature fusion module creates a more compact feature map with strong semantic characteristics and fine-grained details ideal for micro item identification. AFRPNs are full convolution networks that enable compute sharing with multi-class detection networks. This tiny network employs a 33 spatial window on the input feature map, and the feature extract by every sliding window is translated to a 512-dimensional feature vector using a 33kernel convolutional operation with 512 channels, which is then transmitted to two simultaneous complete convolutional networks. For classification, one branch generates two probabilities of being objects or not, while another generates four box coordinates for localizations.

This study integrates AFRPN and modified Fast R-CNNs into one network, i.e. AMF-RCNN, to identify the multi-categories eye illness picture, where AMF-RCNN is trained end-to-end via back-propagation and stochastic GDs (SGD), allowing for shared convolutional layers. Each SGD mini-batch is created for AMF-RPN training from a single eye illness imaging image containing 256 data. Positive and negative samples are chosen at random for each mini-batch, so that the ratio of positive to negative samples is 1:1. The regression layers and classification start with a zero-mean Gaussian distribution with standard deviations of 0.01. Backward propagation occurs as normal, and the backward propagated signals for the shared convolutional layer originate from a mix of AFRPN loss and modified Fast R-CNNs loss. The fundus image scale varies substantially during the real eye disease detection procedure. The original quicker RCNN typically uses a set size for all training pictures. As a result, the generalization performance of object identification with varying sizes is low. This work employs multi-scale training;

before being uploaded to the network, the photographs will be scaled at random. After that, the various scale photographs will be taught. For joint training, loss function LF is widely used. Furthermore, enhancing localization exactness can get better the overall finding rate of airports. As a result, we get better the classification loss, which is defined as the integral of the classification loss  $Loss_{cl}$  under IoU threshold  $th$ . The final loss function is:

$$\int_{50}^{100} Loss_{cl}(pr_{th}, clp_{th}) \approx \sum_{50}^{100} \frac{Loss_{cl}(pr_{th}, clp_{th})}{n}$$

Where  $n = 4$ ,  $th \in \{50,60,70,80\}$ , the predicted probability of the final output of the network model is the average value of different thresholds. The feature map corresponding to the suggestion box is input to the full connection layer, and finally, output from two same output layers. One output is the set of predicted probabilities for the background and  $k$  classes objects, namely,  $(pr_0, pr_1 \dots pr_k)$ ,  $clp_{th}$  represents the class prediction value when the threshold value is  $th$ .  $pr_{th}$  Represents the prediction probability and  $n$  is the equal number in definite integral interval. The final loss function can be rewritten as:

$$LF(pr, clp, v) = Loss_{cl}(pr, clp) + [clp \geq 1] \frac{Loss_{cl}(pr_{th}, clp_{th})}{n}$$

When many types of eye illness images are detected during the testing stage, duplicate boxes are frequently predicted for the same eye disease image. Traditionally, a recommendation box SB with the highest score is chosen, but its adjacent boxes are suppressed depending based on a preset overlap threshold. If the suppressed boxes include extra items, however, the suppression will cause some items to be overlooked. To solve this problem, instead of forcing class scores to be zero, give them penalty weight. The following is an example of how a Gaussian penalty function (GPF) is used:

$$GPF = cs_i e^{-\frac{IoU(SB, nb_i)^2}{th}}$$

$$IoU(SB, nb_i) = \frac{area(SB \cap nb_i)}{area(SB \cup nb_i)}$$

Where  $cs_i$  is the confidence score for the  $i$ -th detection box,  $IoU(SB, nb_i)$  denotes IoU (Intersection over Unit) ratio between boxes with highest scores  $SB$  and their neighboring boxes  $nb_i$  and  $th$  is threshold is set to 0.5. Following the above stages, sharper eye disease image identification results will be obtained. When we find multi-category pest items during the testing stage, duplicate boxes are frequently anticipated for the same bug. To suppress these redundant boxes, a class specific NMS is traditionally used: picking a bounding box with the highest score but suppressing its nearby boxes depending on a pre-defined overlap level (Dalal and Triggs, 2005). However, if the suppressed boxes include additional items, the suppression will result in some things being missed. To remedy this issue, we provide penalty weight to class scores instead of forcing them to be zero. A Gaussian penalty function is used specifically:

$$cs_i = e^{-\frac{IoU(SB, nb_i)^2}{\delta}}$$

Where  $\delta$  is set to 0.5 and after the above soft-NMS suppression method, can obtain finer eye disease detection results.

#### IV. RESULTS AND DISCUSSION

To validate the effectiveness of the proposed approach, the proposed AMF-RCNN method is used to identify eye diseases and is compared to several current detection methods based on CNNs [8, DL-CAEF [14], and ODALAs. The fundus pictures were arbitrarily divided into training (70%) and test (30%) (30%). There were 650 training photos and 280 validation images from five illness categories used. The results showed that the outputs provided by the proposed single CNNs model, which was meant to categorize pairs of distinct retina diseases BDRs (Background DRs), CRVOs CNVs, HISTs: PDRs: Proliferative DRs and Normal were accurate, sensitivity, and specificity. In the context of classification presentation, a true positive value (TP)" is a result that properly predicts the positive class. A true negative value (TN) is a result that forecasts the negative class appropriately. False negative (FN) and false positive (FP) values are used to reflect misclassified samples. Using accuracies, precisions, F1-scores, and MCCs as parameters (Mathew Correlation-coefficients), specificities, and sensitivities, their equations may be represented as follows:

Accuracies of models show overall performances of models and computed by the formula given below:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} * 100$$

Precisions are ratios of actual positive scores and positive predicted scores by classification models/algorithms. Precisions are computed by the following formula:

$$Precision = \frac{TP}{TP + FP} * 100$$

F1-scores are weighted measures of both recalls and precisions. They range between 0 and 1 where 1 implies good performances of classification algorithms while 0 stands for bad performances.

$$F1\ score = \frac{2 * Precision * Recall}{Precision + Recall}$$

MCCs are correlation coefficients between actual and predicted results. MCCs give resultant values between -1 and +1. Where -1 represents completely wrong predictions of classifiers while 0 implies classifiers generate random predictions and +1 represents ideal predictions of classification models. The formula for calculating MCCs are given below:

$$MCC = \frac{TP * TN - FP * FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}$$

Specificities are ratios of recently classified healthy people to total counts of healthy people. It implies the predictions are negative and persons are healthy. The formula for calculating specificity is given as follows:

$$Specificity = \frac{TN}{TN + FP} * 100$$

Sensitivity is the ratio of recently classified heart patients to the total patients having heart disease. It means the model prediction is positive and the person has heart disease. The formula for calculating sensitivity is given below:

$$Sensitivity = \frac{TP}{TP + FN} * 100$$

From Fig. 6, it gives the accuracy of proposed and existing models for the amount of features in a given database. The AMF-RCNN increases the accuracy while reducing the processing time. The AMF-RCNN attains the accuracy of 98.5% compared to all other models since the high quality generated by the proposed AFRPN can be applied to improve the disease detection. The results of existing methods such as DL-CAEF, CNNs and ODALAs are 94%, 96% and 98% respectively. Thus the proposed algorithm is greater to the existing algorithms in terms of better good validation results for predicting DR disease.

Fig. 6. Accuracy Performance of Methods on different Subsets of Feature.

Fig. 7. Precision Performance of Methods on different Subsets of Feature.

From Fig. 7, it indicates the precision of proposed and existing models for the amount of features in a given database. As increasing the amount of features, the precision is also maximized. The AMF-RCNN attains a recall of 99.2%. This may be due to the benefit of our sample selection approach, which is based on an effective region of RFs and allows more tiny objects to participate in training the eye illness detection module. Existing approaches such as DL-CAEF, CNNs, and ODALAs achieve 93 per cent, 95 per cent, and 99 per cent accuracy, respectively. Existing approaches cannot yield good detection findings when blood vessels are thickly scattered. In comparison to these three approaches, the suggested method is capable of successfully overcoming blood vessel interference and obtaining the best eye disease detection result.

From Fig. 8, it indicates that the F1-score of proposed and existing models for the amount of features in given databases. While maximizing the amount of features, the f-measure is also maximized. For e.g., the AMF-RCNN provides an f-measure of 96.5% compared to the all other models such as DL-CAEF, CNNs and ODALAs. The results of existing methods such as DL-CAEF, CNNs and ODALAs are 91%, 95% and 96% respectively. The DL-CAEF approach clearly fails to capture the limits of the eye illness adequately, resulting in a fitted ellipse that deviates significantly from the ground truth. The CNNs approach is sensitive to weak edges and produces the lowest results for detecting eye diseases. The ODALAs approach detects the brightest section of the eye illness zone, resulting in incorrect detection findings. Instead, the suggested technique, which takes use of the deep features recovered from the pretrained AFRPN, is a smaller amount influenced by blurred eye disease borders and poor contrast and achieves the desired eye illness identification results.

From Fig. 9, it indicates the MCC of proposed and existing models for the amount of features in a given database. As increasing the amount of features, the MCC is also maximized. For e.g., the AMF-RCNN attains a recall of 98.5% compared to the DL-CAEF, CNNs and ODALAs. The performance of existing approaches is as follows, based on the examination of experimental findings. The available

approaches are substantially hampered by the interference of lesions. When the intensities of the eye illness region and lesions are near, the system cannot identify them accurately. In comparison to the preceding techniques, the suggested method may resist the impact of lesion interference to a assured amount and take out the eye disease borders more precisely using an efficient clustering method.

From Fig. 10, it indicates the recall of proposed and existing models for the amount of features in a given database. As increasing the amount of features, the recall is also maximized. For e.g., the AMF-RCNN attains a recall of 98% compared to the DL-CAEF, CNNs and ODALAs. By observing the results, the proposed method has attain alike results and is superior than the other methods, because of effective EFFCM and adaptive OTSU threshold with ALO segmentation method could achieve prior eye disease detection.

Fig. 8. F1-score Performance of Methods on different Subsets of Feature.

Fig. 9. MCC Performance of Methods on different Subsets of Feature.

Fig. 10. Specificity Performance of Methods on different Subsets of Feature.

Fig. 11. Sensitivity Performance of Methods on different Subsets of Feature.

From Fig. 11, it gives the accuracy of proposed and existing models for the amount of features in a given database. The AMF-RCNN increases the accuracy and attains the accuracy of 98% compared to DL-CAEF, CNNs and ODALAs. Thus the proposed algorithm is greater to the existing algorithms in terms of better good validation results for predicting DR disease. Because this proposed method tends to focus on detection efficiency with including the detection accuracy of targets, also benefiting by the feature fusion module.

## V. CONCLUSION AND FUTURE WORK

In this work, we describe a novel unsupervised learning strategy for detecting eye diseases in retinal fundus pictures using AMF-RCNN and EFFCM-AOO segmentation. In addition, pay attention to the precise extraction of the illness region in the presence of vascular structures, lesion regions, and intensity in homogeneity. The EFFCM-AOO-based segmentation detection approach is used first to pre localize the eye disease region. On this premise, the AMF-RCNN model is developed to extract the correct optic disc area by

including the deep features generated from pre-trained AFRPNs into the original framework. The experimental findings and quantitative analysis show that the suggested technique is capable of precisely detecting eye disease areas and outperforms several current methods. AMF-RCNNs have shown promising results in the identification of eye diseases, but the complexity of regulating is unknown and regarded a black box. In the future, for example, research should focus on fine-tuning the restrictions of the existing AMF-RCNN approach in order to improve classification efficiency. As a result, determining the efficient model and ideal values for the number of hidden layers and modules in various levels remains difficult.

**Abstract**—The challenge of proving autonomous landing in practical situations is difficult and highly risky. Adopting autonomous landing algorithms substantially minimizes the probability of human-involved mishaps, which may enable the use of drones in populated metropolitan areas to their full potential. This paper proposes an Unmanned Aerial Vehicles (UAV) vertical safe landing & navigation pipeline that relies on lightweight computer vision modules, able to execute on the limited computational resources on-board a typical UAV. In this work, a grid-based mask technique is proposed for selecting the safe landing zones where each grid is parameterizable based on the size of the UAVs, which is implemented using OpenCV. A custom trained YOLOv5 model is the underlying building block for safe landing algorithm which is trained for aerial views of pedestrians, cars & bikes to identify as obstacles. The nearest obstacle-free zone algorithm is applied over the YOLOv5 output where boundary box locations are identified using Hue Saturation Value (HSV) filtering and then split into grids for safe landing zones where maximum coverage is taken into account while analyzing each scene. It performs a 2-level operation to prevent collisions while descending at different altitudes. Since UAV is expected to be processing only at predetermined altitudes, which will shorten the processing time, generating a PID signal for UAV actuators to navigate to the required safe zone with utmost safety and accuracy.

**Keywords**—Autonomous UAV system; computer vision algorithm; YOLOv5; safe landing site selection; Haversine equations

## I. INTRODUCTION

Unmanned Aerial Vehicles (UAVs) is that uses navigation and control software powered by artificial intelligence (AI) and do not need a human pilot to fly them. These aircraft carry out activities and make decisions on their own, from takeoff and landing to conducting aerial site inspections and surveys. The utility of an autonomous UAV hinges on its ability to navigate with acceptable positional inaccuracy. The term "autonomous UAV" means a UAV that can fly without external guidance with help of onboard sensors and processors. The main problem is to build UAVs strong enough to fly independently and land safely in open fields without harming people, as in automated package delivery applications [17].

The law prohibits UAV operation over a crowd, but in practice, UAVs may fly over an unwary crowd, compromising

people's safety in the event of a failure, such as a communication loss, a power shortage, or a human error. Providing every UAV with safety rules to prevent injuring people in an emergency and to select landing zones autonomously is vital. If every UAV had an emergency autonomous landing system [15], it would minimize harming people during drone accidents and enhance their urban deployment potential, especially in crowded circumstances.

Different drones use obstacle avoidance sensors such as stereo vision, ultrasonic (Sonar), time-of-flight, lidar, infrared, and monocular vision, either singly or in combination, thus fusing data for complex computations [18]. The data from these numerous obstacle avoidance sensors is fed back to the flight controller, which further uses algorithms and software to detect obstacles. The role of the flight controller is diverse, one of which is the real-time processing of visual data from the environment that is scanned by the obstacle detection sensors that will be employed in our model.

UAVs' limited processing capability owing to weight and battery power limits is one major challenge and developing UAV-compatible algorithms is difficult too. Also, Deep Neural Networks (DNNs) attaining state-of-the-art computer vision results demands a lot of processing resources for real-time operation. Utilization of single-stage object detection algorithm [8] like YOLOv5 along with OpenCV functions in the proposed architecture aids in surpassing the above concerns thus maximizing the desired outcome with minimal resources.

This paper is organized as follows. Section II described the related work for this study. In Section III, a proposed architecture for autonomous UAV safe landing algorithm is discussed. Simulation results are described in Section IV and Section V concludes the paper.

## II. RELATED WORK

Human recognition based on live input is crucial to the safety of autonomous UAV flying [1]. In order to avoid hurting people in the event of a failure, UAV safe landing demands that the UAV visually detect people [2] nearby the landing place; airspace above/near humans should be treated as a no-fly zone. Such detectors place a properly sized rectangular bounding box around each item they find on the image feed and assign it a discrete class label.

\*Corresponding Author.

Early deep neural techniques [3] on human detection employed CNNs or R-CNN [4] object detection architecture, achieves a high-quality externally offered recommendations to attain good performance. In later efforts [5], such YOLOv2, employ single-stage detectors model. While speed is significantly increased by these detectors end-to-end construction in comparison to Faster R-CNN, accuracy is slightly decreased [6]. RetinaNet [7] is a different single-stage detector with detection performance relatively as good as to two-stage methods. A Feature Pyramid Network acts as the backbone on top of a ResNet architecture. Two separate sub-networks classify anchor boxes and modify values in relation to the default anchors. In this study [8], most effective model for identifying the kind of vehicle, each algorithm went through a training dataset of cars and then examined its performance. According to a study, YOLO v3 has advantages in detection speed while maintaining certain MAP i.e. 80.17% MAP (Mean Average Precision) surpasses competing approaches such as Faster R-CNN, SSD where frames per second (FPS) was more than eight times than that of Faster R-CNN. In [9], the author has conducted an experiment to check the viability of utilizing object detection methods to identify safe landing spots in case the UAV suffers an in-flight failure and compared different versions of YOLO model and it shows that YOLOv5 algorithm outperforms YOLOv4 [11] and YOLOv3 in terms of accuracy of detection while maintaining a slightly slower inference speed also a light-weight algorithm to execute worry-free procedure for power-limited UAVs.

This paper [10] inspired the idea of employing HSV color space masking to avoid water bodies and dense vegetation. This technique has no restrictions compared to prior studies. The aerial photos are segmented using color and texture cues to determine acceptable landing places.

#### A. Motivation

The abundance of commercial camera drones served as the motivation for this study. These drones are capable of "return to home" (RTH) and vertical landing. A number of environmental conditions, such as a sudden break in connection between the drone and the controller, instability brought on by a strong wind when the drone is in flight, or lack of power between drone parts, can cause emergencies. In this research, a model is employed for landing camera enabled drones securely without using a target as a reference landing or flying the drones back to their home location, which would be difficult and power intensive. A drone can do a vertical landing using the suggested architecture. According to the survey, YOLOv5 appears to be the most appropriate for real-time processing with a lightweight model for object detection in case of power-limited applications and using grid-based architecture maximizes the area coverage for site selection, as opposed to SLZ candidates, which are obtained as circular regions [15], where valuable portions of an obstacle-free zone may be missed. Our main objective was to offer most commercial drones a stable dynamic landing approach without the use of additional hardware or sensors.

### III. METHODOLOGY

In this paper, an architecture is proposed for autonomous UAV safe landing algorithm. In the event when drone is unable to reach its home location due to low power or emergency, the purpose of our algorithm is to choose a safe landing zone inside populated areas so that it does not cause injury to any of the people within vicinity of drone and also minimal impact to the drone. Specifically, a UAV with a camera mounted on it is being considered. First, the camera is used to detect obstacles using YOLOv5 model. Second, the location of the closest safe landing zone is determined using grid-based architecture. These decisions are then relayed to the PID control block, which generates PID signals for the drone actuators so that they can navigate to the desired location as shown in Fig. 1.

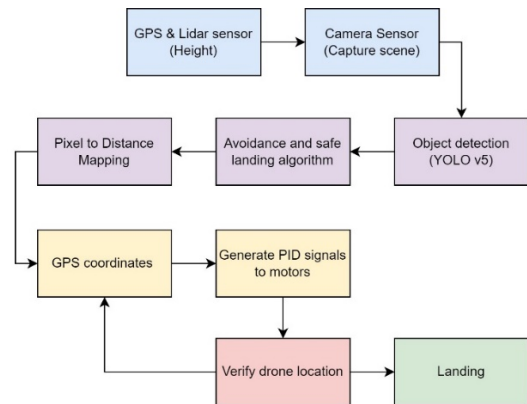

Fig. 1. Block Diagram of Overall Safe Landing Algorithm.

#### A. Camera FOV Distance Calculation

To calculate aerial view coverage of drone using fixed Field of View (FOV) camera is given below.

$$\tan\left(\frac{FOV}{2}\right) \times D \times 2 = N \quad (1)$$

The coverage, denoted by "N," is obtained by using the field of view (FOV) of the camera and the working distance of the drone, "D". Keeping image formats as 1:1 aspect ratio, this results in a 1:1 ratio for the working distance and coverage as shown in Fig. 2(a). The fundamental highlight is the ability to determine the coverage distance based on the height of the drone. Scene 1 in Fig. 2(b) indicates that level-1 operation is being considered at an altitude of 27 meters, and coverage is 27m × 27m. Similarly, at level-2 operation at an altitude of 9m is considered will have a coverage of 9m × 9m shown as scene 2. The aforementioned equation (1) is verified using the practical specifications of a drone camera listed in Table I.

#### B. Object Detection – YOLOv5

Object detecting methods like the single-stage detectors YOLOv5 model are utilized to avoid people, cars, and bikes on metropolitan areas. This model is trained using VisDrone datasets [12] and the Stanford Drone Dataset (SDD) [13]. Basically, YOLO models have three architectural blocks [14].

- YOLOv5 Backbone: It is used to extract image features. YOLO v5 uses CSP (Cross Stage Partial Networks) to obtain useful features from an input image.

- YOLOv5 Neck: It is used to construct feature pyramids. Feature pyramids help scaling models generalize. It helps identify objects in different sizes and scales. Feature pyramids help models perform well on new data. FPN, BiFPN, and PANet use feature pyramids. PANet generates a feature pyramids network to aggregate features and passes it to Head for prediction.
- YOLOv5 Head: Responsible for final detection. It employs anchor boxes to construct class probabilities, objectness scores, and bounding boxes.

Fig. 2. (a) Drone Representation of Working Distance, (b) Working Distance Calculation.

TABLE I. PARAMETERS FOR DRONE CAMERA

Parameters	Value
Image sensor	1/4"
Image format	1:1 aspect ratio (square)
Image Pixel	1024x1024
FOV	$53^\circ$
Focal length	3.2 mm
working distance	27m
Converge	27m x 27m

### C. Avoidance and Identification of Safe Landing Location

The YOLOv5 output image is then provided to the avoidance system after object detection is done. Here, the image is converted to the HSV format in order to identify YOLO boundary boxes, green vegetation, water bodies such as pool, lake etc. HSV green threshold is then applied as a mask to represent the green vegetation and boundary boxes, while HSV blue represents the water bodies. The HSV range is fine-tuned using threshold of dominant color of image. The area within the boundary boxes is filled to represent an obstacle and then the image is inverted to show obstacles as being black.

The flow diagram as shown in Fig. 3, to determine the safe landing zone, a  $3 \times 3$  grid is applied over the inverted image (scene-1), and at an altitude of 27 meters, each grid has a sufficient area of  $9m \times 9m$  for level-1 operation as show in Fig. 2(b). After a set of safe landing zones (SLZ) are determined and stored in LUT for subsequent use. Therefore, the nearest safe landing area is considered. The geolocation is then determined by doing a pixel to distance mapping and then converting the distance to GPS coordinates. The PID control block receives these GPS coordinates and uses them to provide the necessary signals for the drone actuators to navigate to the specified safe landing site. After descending to 9m from an altitude of 27m, the above set of steps are repeated to locate a sub-zone for the drone to land securely. At altitude 9m with a  $3 \times 3$  grid applied over the scene-2, the drone still has a sufficient space of  $3m \times 3m$  for each grid to land safely. This can be dynamically modified depending on the size or class of the drone.

The below Table II shows that the algorithm is flexible enough to reconsider the decisions while descending to verify if the SLZ selected are truly obstacle free at lower altitudes.

TABLE II. SAFE LANDING DECISION MODES

Mode	No. of SLZ <sub>27m</sub> (At level - 1)	No. of SLZ <sub>9m</sub> (At level - 2)	Response
1	SLZ == 0	Don't care	TRAVERSE to New Site
2	SLZ == 1	SLZ == 0	ASCEND to Level -1; Then TRAVERSE to New Site
3	SLZ > 1	SLZ == 0	ASCEND to Level -1; Then TRAVERSE to Next nearest SLZ
4	SLZ > 0	SLZ > 0	LANDING

### D. Pixel to GPS Coordinates

- Considering the captured scene is of 1:1 aspect ratio selected for computation. Firstly, a distance of 27 meters is mapped onto an image of 1024 pixels by using the map function in Python. Secondly, find the distance from the reference point (center of image) to the desired safe landing zone and calculate the destination GPS coordinate based on the distance to be travelled.

- For distance to GPS coordinates, GPRMC was utilized from the GPS NEMA sentence to obtain coordinates (longitude and latitude information) which decimal degree (DD) format.
- The following formula can be used to convert GPS data in the form of degrees, minutes, and seconds (DMS) to signed decimal degree (DD).

$$\text{GPS coordinate} = \text{degrees} + \frac{\text{minutes}}{60} + \frac{\text{seconds}}{3600} \quad (2)$$

The GPS waypoint distance is calculated using distance module in python using Algorithm 1.

**Algorithm 1** Distance to GPS coordinate Mapping

**Input:** origin: latitude and longitude of current location

D: Distance from origin to destination

sel: To select latitude or longitude

dir: Direction in either West/East or North/South

**Output:**

1: Find destination GPS coordinate lat2 or lon2.

2: Set radius of earth in km, radius = 6371

3: Compute central angle,  $c = D/\text{radius of earth}$

4: **if** (sel is longitude) **then**

5: Compute,

$$dlon = \text{degrees} \left( \cos^{-1} \left[ 1 - \frac{2 \times \tan\left(\frac{c}{2}\right)^2}{\cos(\text{lat}1)^2 \left[ 1 + \tan\left(\frac{c}{2}\right)^2 \right]} \right] \right)$$

6: **if** (dir == North)

7:  $\text{lon}2 = dlon + \text{lon}1$

8: **else if** (dir == South)

9:  $\text{lon}2 = \text{lon}1 - dlon$

10:  $\text{coordinate} = \text{lon}2$

11: **else if** (sel is latitude) **then**

12: Compute,

$$dlat = \text{degrees} \left( \cos^{-1} \left[ 1 - \frac{2 \times \tan\left(\frac{c}{2}\right)^2}{\left[ 1 + \tan\left(\frac{c}{2}\right)^2 \right]} \right] \right)$$

13: **if** (dir == East)

14:  $\text{lat}2 = dlat + \text{lat}1$

15: **else if** (dir == West)

16:  $\text{lat}2 = \text{lat}1 - dlat$

17:  $\text{coordinate} = \text{lat}2$

18: **return** coordinate

This algorithm is inspired using the Haversine equations [16]. This helps to create pre-defined points in grid to send drone to desired location as the scene captured is static.

$$\text{origin} = [\text{lat}1, \text{lon}1] \quad (3)$$

$$\text{destination} = [\text{lat}2, \text{lon}2] \quad (4)$$

$$\delta\text{lat} = \text{radian}(\text{lat}1) - \text{radian}(\text{lat}2) \quad (5)$$

$$\delta\text{lon} = \text{radian}(\text{lon}2) - \text{radian}(\text{lon}1) \quad (6)$$

Using haversine formula,

$$\alpha = \sin^2(\delta\text{lat}/2) + \cos(\text{lat}1) * \cos(\text{lat}2) * \sin^2(\delta\text{lon}/2); \quad (7)$$

$$\phi = 2 * \text{atan} \left( \sqrt{\frac{\alpha}{1 - \alpha}} \right) \quad (8)$$

$$\delta = \text{radius} * \phi \quad (9)$$

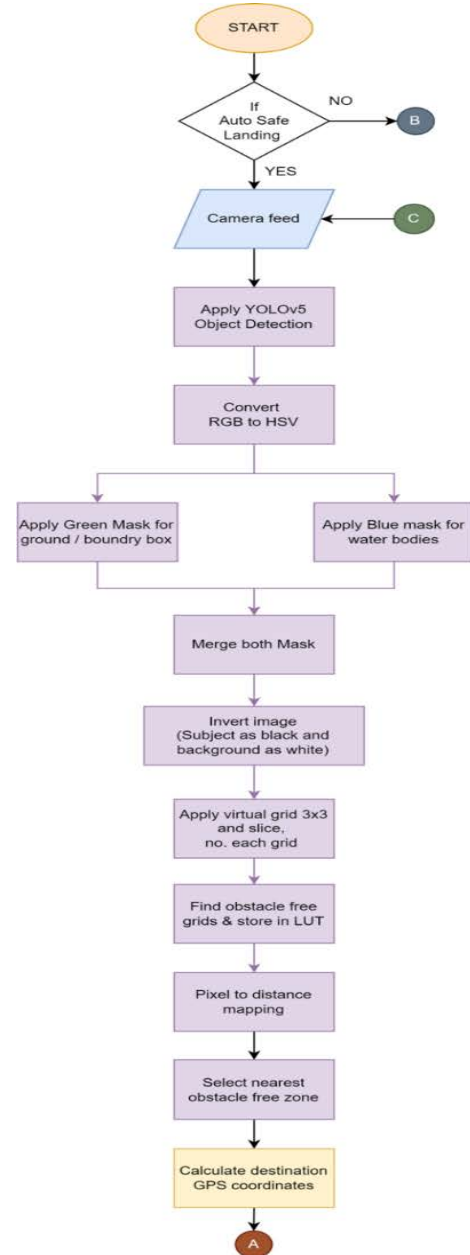

Fig. 3. Functional Flow Diagram of Safe Landing Algorithm.

**E. Generate PID Signals**

The command to send the drone to the desired location is done using only roll (x) and pitch (y) parameters. The current GPS location is assumed and motor control command is initiated upon receiving the safe landing zone GPS coordinates as shown in Fig. 4. In practice, drone angle is calculated from

the gyro rates of the IMU sensor and sent to the PID module to check the angle error to be corrected in the (x,y) region and calculate motor input speed. Then, PWM signals sent to the appropriate drone motors to perform actions such as roll or pitch to cruise to the desired location until the GPS coordinates latitude and longitude matches with destination coordinates. Once the drone reaches the target point, it descends to level-2 height (9m) and repeats the avoidance and location operation for scene 2.

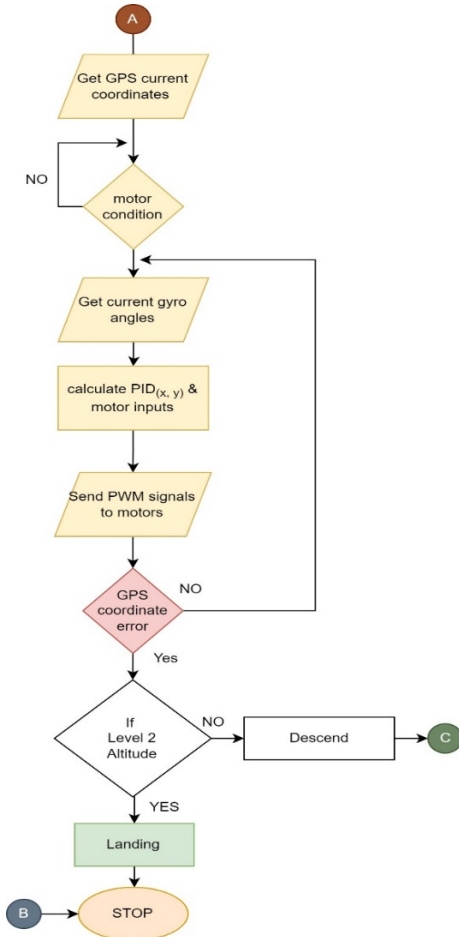

Fig. 4. Functional Flow Diagram of PID Control Block.

#### IV. RESULTS

Utilizing test datasets from VisDrone and SDD pictures as input feed, the proposed safe landing technique is simulated on PC. The following figures illustrate the intermediate results for achieving the safe landing control signals generated for the drone:

##### A. Simulation Results of Avoidance and Safe Landing Location Algorithm

The raw image is fed into YOLOv5 model such that the objects can be identified, and the output of YOLO is shown in Fig. 5 for the objects identified with boundary boxes(green).

Fig. 5. YOLOv5 Output.

In Fig. 6, it shows the output of YOLO is then converted from RGB to HSV image using OpenCV for further image processing. Later, to mask the range of green color a threshold set for HSV image to identify the YOLO's Boundary boxes as well vegetation as shown in Fig. 6(b) where white indicates the masked colors which identifies the boundary boxes and vegetation locations within the captured scene.

Fig. 6. (a) RGB to HSV Color Space (b) Identify Boundary Boxes.

The next step is that identified contours of the boundary boxes are filled. Then image is inverted, such that to identify the obstacles in black color as shown in Fig. 7.

Fig. 7. (a) Fill in Objects Identified (b) Invert Image.

As shown in Fig. 8 the image is applied with grid such that to indicate each grid is sufficient area for drone to land in that select grid for safe landing area/zone. In this model, 3x3 grid is considered and size of each grid is dependent on the altitude of UAVs. At 27m altitude (level 1 scan), each grid will have as sufficient as 9mx9m grid space. And at 9m altitude (level 2 scan), grid size of 3m x 3m is given for safe landing zone.

Fig. 8. (a) Apply Grids (b) Safe Landing Zone.

Each grid is split to identify if obstacles are present and is it safe to land. Here all the grids are taken individually and find if any obstacles are there by capturing the black pixels in each grid space and accordingly store all safe landing zones (SLZ) in LUT (Look-up-table). In Fig. 8(b) identifies the nearest SLZ indicated by blue spot which is the shortest distance from the reference point (red cross; resides at the center of image).

### B. Simulation Results of PID Control Signals

The dimensions of image are taken as  $1024 \times 1024$  and assuming that the drone is at 25m height and according to focal length to working distance ratio set to 1:1 ratio the Field of View will be  $25m \times 25m$ , and these values are mapped using map () function. A set of pre-defined values are given for roll/pitch angle (here, roll\_angle =  $12^\circ$ ) which determines the speed of drone, and set until reaches destination waypoint. The below Fig. 9 shows output of each PID for drone motors i.e. roll (x) and pitch (y) plot which indicates that the drone will be navigated to desired safe landing zone location.

Fig. 9. PID Control Signal – (a) x-axis(roll) (b) y-axis (Pitch).

## V. CONCLUSION

In this paper, the proposed vision-based safe landing algorithm for UAVs intended for urban regions is simulated in Spyder IDE and has been verified using a real-life scene which is taken from SDD and VisDrone test datasets instead of a virtual environment. The custom YOLOv5 is trained for an aerial view of tiny objects such as humans, cars, and bikes and is carried out on a PC with an i9 processor and RTX 3060 GPU specification, which is identified successfully, especially for human detection. The grid-based decision nature of the algorithm for a safe landing will enable maximum coverage of area without missing valuable portions of obstacle-free zone.

By feeding the real-life scenes, the model is verified and successfully works for all possible situations as shown in Table II where the algorithm is flexible enough to make re-decisions if unexpected obstacles occur while descending.

Since the YOLOv5 object detection model allows for the differentiation of objects, this model has a lot of potential for the future, as it can be implemented with a more intelligent system to choose and prioritize where the drone can land without creating any hazards to living beings. In addition, adequate data for tiny object detection allows the decision to be taken from higher altitudes, facilitating the selection of a suitable location for detection and landing.

**Abstract**—Outlier detection or simply the task of point detection that are noticeably distinct and different from data sample is a predominant issue in deep learning. When a framework is constructed, these distinctive points can later lead to model training and compromise accurate predictions. Owing to this reason, it is paramount to recognize and eliminate them before constructing any supervised model and this is frequently the initial step when dealing with a deep learning issue. Over the recent few years, different numbers of outlier detector algorithms have been designed that ensure satisfactory results. However, their main disadvantages remain in the time and space complexity and unsupervised nature. In this work, a clustering-based outlier detection called, Random Projection Deep Extreme Learning-based Chebyshev Reflective Correlation (RPDEL-CRC) is proposed. First, Gaussian Random Projection-based Deep Extreme Learning-based Clustering model is designed. Here, by applying Gaussian Random Projection function to the Deep Extreme Learning obtains the relevant and robust clusters corresponding to the data points in a significant manner. Next, with the robust clusters, outlier detection time is said to be reduced to a greater extent. In addition, a novel Chebyshev Temporal and Reflective Correlation-based Outlier Detection model is proposed to detect outliers therefore achieving high outlier detection accuracy. The proposed approach is validated with the NIFTY-50 stock market dataset. The performance of the RPDEL-CRC method is evaluated by applying it to NIFTY-50 Stock Market dataset. Finally, we compare the results of the RPDEL-CRC method to the state-of-the-art outlier detection methods using outlier detection time, accuracy, error rate and false positive rate evaluation metrics.

**Keywords**—Outlier detection; clustering; Gaussian random projection; deep extreme learning; Chebyshev distance; temporal; reflective correlation

## I. INTRODUCTION

Outliers are nothing but considered as data points or observations that plunge extraneous of an anticipated distribution or pattern and hence considered as the most-hottest topics as far as data mining is concerned. For example, if we were to perform data approximation with a Binomial distribution, then the outliers are the findings that do not emerge to go along with the pattern of a Binomial distribution. It discover anomalous data objects and are said to be of high use in several applications like detecting network intrusion, detecting fraudulent activities concerning credit card

management, outlier detection in stock market to mention few. In the area of outlier detection, the ground truth is found to be seldom missing and hence machine learning techniques are extensively utilized in outlier detection research.

Most of the prevailing research works concentrates on outlier detection for categorical or numerical attribute data. A fuzzy rough set (FRSs) was proposed in [1] to detect outlier in mixed attribute data based on fuzzy rough granules. Initially, the granule outlier degree (GOD) was designed with the objective of characterizing the outlier degree of fuzzy rough granules via fuzzy approximation accuracy.

Followed by which, the outlier factor on the basis of fuzzy rough granules was designed by integrating GOD and respective weights to measure outlier degree of objects using fuzzy rough granules-based outlier detection (FRGOD) algorithm. With this both precision and recall were said to be improved. Despite improvement observed in terms of precision and recall, the time and space complexity were relatively high. To address on this aspect, Gaussian Random Projection-based Deep Extreme Learning-based Clustering model is first designed and then the outliers are detected. With this process, the time and space complexity involved in outlier detection will be reduced to a greater extent.

Iterative ensemble method with distance-based data filtering was proposed in [2] based on an iterative approach with the purpose of detecting outliers present in unlabeled data. The ensemble method was utilized in clustering the unlabeled data. Then, with the clustered data potential outliers were filtered in an iterative manner employing cluster membership threshold. This was performed in an iterative manner until Dunn index score for clustering was said to be maximized.

On the other hand, the distance-based data filtering eliminated the prospective outlier clusters from post-clustered data on the basis of the distance threshold utilizing the Euclidean distance measure from majority cluster as filtering factor. With this the improvement were found to be observed in terms of both precision and f-score value. Despite improvement observed in terms of both precision and f-score, by detecting possible outlier clusters based on weighted method, the false positive rate can be reduced to a greater extent. With this objective, Chebyshev Temporal and Reflective Correlation-based Outlier Detection model is

designed so that using Chebyshev distance based temporal factor obtains highly correlated data points, therefore reducing the false positive rate to a greater extent.

#### A. Objective and Contributions

The main objective of this research is to propose a novel cluster-based outlier detection method that performs clustering process and outlier detection separately in a significant manner. This clustering-based outlier detection method addresses the limitations of the earlier outlier detection methods by its multi-factor i.e., deep clustering and correlative outlier detection model. Further, the contributions of this paper include the following.

- To propose a novel Gaussian Random Projection-based Deep Extreme Learning-based Clustering algorithm to minimize a composite objective function, i.e., outlier detection time along with the improvement in error rate. The model minimizes the outlier detection time and reduces error rate during outlier detection via two different functions, Gaussian Random Projection and square gradient function.
- To design a new Chebyshev Temporal and Reflective Correlation-based Outlier Detection algorithm based on Chebyshev Temporal function and Reflective Correlative function that ensures accurate outlier detection.
- The proposed Random Projection Deep Extreme Learning-based Chebyshev Reflective Correlation (RPDEL-CRC) method has provided improved results for outlier detection time, accuracy, error and false positive rate as performance evaluation measures.

#### B. Organization of the Paper

The rest of the paper is organized as: The discussion about the obtainable modern outlier detection techniques is presented in Section II. In Section III, the proposed Random Projection Deep Extreme Learning-based Chebyshev Reflective Correlation (RPDEL-CRC) method has been discussed. In Section IV, Chebyshev temporal and reflective correlation-based outlier detection model is discussed. The discussion about the experimental setup and comparative analysis with an elaborate discussion is described in Section V and finally, the conclusions are presented in Section VI.

## II. RELATED WORKS

The issue of outlier detection consists of detecting and eliminating malicious inferences from data. This problem is found to take place in several applications. However, outliers are frequently equipped by data stream that in turn influence the accuracy of data-based predictions. Hence, there arises an acute requirement to identify the outliers so as to enhance the data reliability.

A novel method to identify trajectory outlier group from large trajectory database using different types of algorithms was proposed in [3]. First, algorithms based on data mining were designed to identify the correlations between trajectory data and identify abnormal trajectories. Second, machine learning algorithms were applied to identify the group of

trajectory outliers. Finally, convolution deep neural network were used to learn distinct different features to determine group of trajectory outliers, therefore enhancing runtime and accuracy performance.

Conventional outlier detection method however does not take into consideration the subset occurrence frequency and hence, the outliers being detected do not fit the definition of outliers. To address on this aspect, a two-phase minimal weighted rare pattern mining-based outlier detection method, called MWRPM-Outlier [4] was proposed to efficiently detect outliers based on the weight data stream.

A novel methodology to identify conjunct unusual human behaviors from large pedestrian data in smart cities was proposed in [5]. First, data mining was used followed by which convolution deep neural networks was explored that in turn identified distinct features to determine collective abnormal human behavior. With this both runtime and accuracy were said to be improved.

Despite several outlier detection algorithms are said to exist for scenarios necessitating numerical data, only a few prevailing methods can control categorical data. Moreover, the methods outlined for categorical data severely endure from two issues, low detection precision and high time complexity. Two novel outlier detection mechanisms for categorical data sets were proposed in [6]. First an entropy based method using Outlier Detection Tree (ODT) was designed followed by which second simple if-then rules were utilized for outlier detection. With these two integrated mechanisms both precision and computational complexity were improved to a greater extent.

Outlier detection has received paramount significance in the domain of data mining owing to the requirement to detect unusual events in different types of applications, to name a few being, fraud detection, intrusion detection and so on. Different types of outlier detection algorithms have been proposed in the recent past for utilization on static data sets employing a finite number of samples.

Probabilistic deep autoencoder was proposed in [7] with the objective of reconstructing measurements of power system that in turn can be employed in outlier detection. First, nonparametric distribution estimation method was utilized for obtaining information pertaining to uncertainty. Second, confidence intervals were acquired from estimated distribution and were further utilized as input. Finally, based on the multilayer encoding and decoding processes, the measurement intervals were reconstructed, with which outlier detection were made in an accurate manner.

Outlier detection methods employing machine learning are said to be receiving greater attention in the past few years in several domains. But, an ensemble of such outlier detection methods could improve the overall detection performance. An algorithm called, Average Selection and Ensemble of Candidates for Outlier Detection (DASEC-OD) was proposed in [8] for high dimensional data. A review of unsupervised outlier detection methods focusing on multi-dimensional data was investigated in [9].

With the exponential requirement in analyzing high speed data streams, the job of outlier detection becomes more

demanding as the conventional outlier detection method can no longer presume all data for processing. In [10], a Memory-efficient incremental Local Outlier (MiLOF) was proposed for large data streams, therefore ensuring accuracy to a greater extent.

Nowadays, there prevail very huge types of outlier detector methods that bestow satisfactory results. But their major disadvantage remains in their unsupervised characteristic in conjunction with the hyper parameters that has to be appropriately assigned for acquiring better performance.

An improved content-based outlier detection method was proposed in [11]. In [12], a novel supervised outlier estimator was designed. This was performed by pipelining an outlier detector in such a manner that the targets involved in the outlier detector were obtained in an optimal manner. However, these methods did not perform in a satisfactory manner in case of utilization of the complex datasets and hence suffer from noise introduced by outliers, specifically when the ratio of outlier was found to be high. To address this aspect, a framework called, Transformation Invariant AutoEncoder (TIAE) was proposed in [13] that in turn attained not only stability but also ensured high performance on outlier detection. A comprehensive review of outlier detection techniques were investigated in [14].

In several practical classification issues, a portion of outliers are said to exist in datasets that in turn would have heavy influence on the constructed model performance. A group method of data handing (GMDH) using neural network in outlier detection was proposed in [15]. A novel robust outlier detection method (RiLOF) based on Median of Nearest Neighborhood Absolute Deviation (MoNNAD) was designed in [16] that employed median of local absolute deviation of the samples to attain high detection performance.

Monitoring data including the significant information of monitored object forms the fundamentals for data mining and analysis. However, the data being monitored suffers from outlier pollution therefore causing negative influence on corresponding data processing. To address on this aspect, an outlier detection method based on stacked autoencoder (SAE) was proposed in [17]. The proposed SAE had the significant potentiality of feature extraction and heavily maintained the indigenous information of data to a greater extent.

Accuracy and time involved in outlier detection was not focused. To address this aspect, a Neighbor Entropy Local Outlier Factor was presented in [18] that with the aid of self organizing feature map not only improved accuracy but also reduced the execution time to a greater extent. Moreover, semantic information was focused on [19] for outlier detection employing meta path based outlier detection. Outlier detection based on the multivariable panel data was designed in [20] via correlation coefficient that in turn indicated high accuracy detection ability.

Motivated by the above mentioned techniques in this work, a novel cluster-based outlier detection method called, Random Projection Deep Extreme Learning-based Chebyshev Reflective Correlation is proposed (RPDEL-CRC). The

elaborate description of RPDEL-CRC method is presented in the following sections.

### III. RANDOM PROJECTION DEEP EXTREME LEARNING-BASED CHEBYSHEV REFLECTIVE CORRELATION (RPDEL-CRC)

The proposed Random Projection Deep Extreme Learning-based Chebyshev Reflective Correlation method concentrates on the detection of outliers based on clustering. Methods designed based on cluster detect the outliers by placing data objects into distinct clusters. Here, the data objects in a data set are initially clustered. To design cluster-based outlier detection, the RPDEL-CRC method is split into two parts. Fig. 1 shows the block diagram of RPDEL-CRC method.

As illustrated in the figure below, the first part models robust cluster by means of Gaussian Random Projection-based Deep Extreme Learning. Here, the clustering based outlier detection initiates the outlier detection process by clustering the given input dataset, Nifty 50 Stock Market Data (2000 – 2021). Hence, to be more specific outliers are considered as data points within deviating clusters or the data points that deviate to the formed clusters. The second part uses the Chebyshev Temporal and Reflective Correlation-based Outlier Detection algorithm to detect outlier with minimum falsification. In this section, we first explain all prerequisites of the proposed method with a system model, and then finally we describe the proposed method.

#### A. System Model

Let  $P \in R^{(m*n)}$  represent a matrix with 'm' rows and 'n' columns of real numbers  $P_{ij} \in R$ . The matrix 'P' denotes a dataset 'DS' that includes the data for outlier analysis. The 'n' columns are called features and on the other hand, the 'm' are referred to as data points. Then, vector  $[DP]_i \in R^n$  refers to the data point, which is a row in 'P'. The matrix 'P' then consists of 'm' data points  $DP = \{ [DP]_1, DP_2, \dots, [DP]_n \}$ . Then, with the aid of the outlier detection algorithm the outliers present in the dataset 'DS' are detected. Finally, the overall feature space represents the vector space defined by the given features that in turn estimates the characteristics of the examined occurrence or event. Inliers are detected in subsets of the overall feature space and referred to as normal regions or normal data points. To be more specific, inliers are considered to as the data points in the normal regions. On the other hand, an outlier is a data point that does not belong in the normal region.

Fig. 1. Block Diagram of Random Projection Deep Extreme Learning-based Chebyshev Reflective Correlation Method.

### B. Case Analysis of Outlier Detection Accuracy

To detect outliers based on the cluster in a given dataset, the data has to be initially clustered. In this paper, Gaussian Random Projection-based Deep Extreme Learning model is first employed for clustering. The objective behind the design of Gaussian Random Projection-based Deep Extreme Learning model remains in training feed forward network from a raw training data set with ‘N’ samples, ‘{P,Q}={P<sub>i</sub>,Q<sub>i</sub> }<sub>(i=1,2,3, … ,N)</sub>’, with ‘P<sub>i</sub> ∈ R<sup>d</sup>’ and ‘Q<sub>i</sub>’ represents ‘M-dimensional’ binary vector where one entry denotes ‘1’ representing the cluster that ‘P<sub>i</sub>’ belongs to. Fig. 2 shows the block diagram of Gaussian Random Projection-based Deep Extreme Learning-based Clustering model.

Fig. 2. Block Diagram of Gaussian Random Projection-based Deep Extreme Learning-based Clustering Model.

As shown in the above figure, the training process of GRP-DEL includes two steps. In (1), the hidden layer with ‘K’ nodes employing distinct numbers of neurons are constructed. Next, for the ‘i-th’ hidden layer node, a ‘d-dimensional’ vector ‘x<sub>j</sub>’ and a metric ‘y<sub>j</sub>’ are generated in an arbitrary manner. Then, for each input vector ‘P<sub>i</sub>’, the pertinent output on the ‘i-th’ hidden layer node is obtained by utilizing Sigmoid activation function. This is mathematically stated as given below.

$$g(P_i, x_j, y_j) = \frac{1}{1 + \exp[-(x_j^T * P_i + y_j)]} \quad (1)$$

Then, using the resultant value of the above Sigmoid activation function, the hidden layer outputs the matrix as given below.

$$H = \begin{bmatrix} g(P_1, x_1, y_1) & \dots & g(P_1, x_K, y_K) \\ \dots & \dots & \dots \\ g(P_N, x_1, y_1) & \dots & g(P_N, x_K, y_K) \end{bmatrix}_{N \times K} \quad (2)$$

In (2), an ‘M-dimensional’ binary vector ‘α<sub>j</sub>’ represents the output weight that associates the ‘j-th’ hidden layer with the resultant output node. Here, a random projection is applied that states that if points associating the ‘j-th’ hidden layer in a vector space are of sufficiently high dimension, then the ‘j-th’ hidden layer may be projected into a lower-dimensional space in such a manner that it preserves the distances between points (therefore minimizing dimensionality). With original input vector being ‘P<sub>i</sub> (K\*M)’, using a random ‘K\*d’ matrix dimensional matrix ‘R’, then the projection of data on to a

lower dimensional subspace is mathematically formulated as given below.

$$P_{K \times M} = R_{K \times d} P_{d \times M} \quad (3)$$

Then, with the above lower dimensional subspace random projection dimensionality of set of points and output matrix ‘Q’ is mathematically stated as given below.

$$H \cdot \alpha = Q \quad (4)$$

$$\alpha = \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \dots \\ \alpha_K \end{bmatrix}_{K \times M}; Q = \begin{bmatrix} Q_1 \\ Q_2 \\ \dots \\ Q_N \end{bmatrix}_{N \times M} \quad (5)$$

Next, with the resultant matrices ‘H’ and ‘Q’, the objective of GRP-DEL model remains in solving the output weights ‘α’ by reducing the losses of prediction errors, leading to the following equation.

$$\alpha_i(n) = \alpha_i(n-1) - \beta_i(n) \frac{MA_i(n)}{\sqrt{G_i(n)}} \quad (6)$$

From the above (6), ‘[[MA]]<sub>i</sub>(n)’ symbolizes the moving average of feature or attribute ‘i’ at iteration ‘n’, with square gradient denoted by ‘G<sub>i</sub>(n)’ and learning rate ‘β<sub>i</sub>(n)’ respectively.

$$MA_i(n) = \gamma_n MA_i(n-1) + (1 - \gamma_n) \quad (7)$$

$$G_i(n) = \theta_n G_i(n-1) + (1 - \theta_n) \quad (8)$$

$$\beta_i(n) = \beta_i(n-1) \frac{\sqrt{(1-\theta_n)^n}}{(1-\gamma_n)^n} \quad (9)$$

From the above (7), (8) and (9) the factors ‘γ<sub>n</sub>’ and ‘θ<sub>n</sub>’ are utilized in fine tuning the decay rates of moving averages close to one (i.e., ‘γ<sub>n</sub>=0.85’ and ‘θ<sub>n</sub>=0.9’). The pseudo code representation of Gaussian Random Projection-based Deep Extreme Learning-based Clustering is given below.

Algorithm 1: Gaussian Random Projection-based Deep Extreme Learning-based Clustering

---

**Input:** Dataset ‘DS’, data points ‘DP = {DP<sub>1</sub>, DP<sub>2</sub>, …, DP<sub>n</sub>}’  
**Output:** obtain cluster ‘Q<sub>i</sub>’ corresponding to ‘P<sub>i</sub>’ in computationally efficient and precise manner

---

- 1: **Initialize** ‘m’ rows and ‘n’ columns
  - 2: **Begin**
  - 3: **For** each Dataset ‘DS’ with data points ‘DP’ and input vector ‘P<sub>i</sub>’
  - 4: Obtain pertinent output on the ‘i-th’ hidden layer employing Sigmoid activation function as in (1)
  - 5: Obtain output matrix via hidden layer as in (2)
  - 6: Evaluate Gaussian Random Projection as in (3)
  - 7: Estimate hidden layer output and calculate the output matrix as in (4) and (5)
  - 8: **Repeat** (training of neural networks)
  - 9: Solve output weights by minimizing prediction loss error as in (6)
  - 10: Treat each row of ‘Q’ as a point and cluster them into ‘K’ clusters
  - 11: Estimate learning rates for cluster parameter as in (7), (8) and (9)
  - 12: **Until** (first-order gradients for neural networks is arrived at)
  - 13: **Return** ‘Q’
  - 14: **End for**
  - 15: **End**
-

As given in the above Gaussian Random Projection-based Deep Extreme Learning-based Clustering algorithm, with the objective of reducing the outlier detection time along with the improvement in precision, two different functions are employed. First, by employing Gaussian Random Projection the dimensionality of data is said to be reduced by projecting original input space (i.e., the raw data) with the aid of a sparse random matrix. Second, by estimating the learning rate by means of square gradient minimizes the error involved during the process of clustering to a greater extent. As a result, with these two function, clusters are formed both in a computationally efficient and precise manner.

#### IV. CHEBYSHEV TEMPORAL AND REFLECTIVE CORRELATION-BASED OUTLIER DETECTION MODEL

Outlier detection remains to be one of the primary step in data mining tasks. The motive behind the outlier detection strategy here is to identify the features or parameters that are counterfeit from several other features. Different types of outlier detection models are said to exist. In order to determine the perpetual temporal outliers, we obtain outliers based on distance measures by analyzing temporal values of the objects employing Chebyshev Temporal and Reflective Correlation-based Outlier Detection model. Fig. 3 shows the block diagram of Chebyshev Temporal and Reflective Correlation-based Outlier Detection model.

Fig. 3. Block Diagram of Chebyshev Temporal and Reflective Correlation-based Outlier Detection Model.

As shown in the above figure, with the obtained clusters for the given dataset ‘DS’, in a ‘d-dimensional’ vector, with data point denoted by ‘DP={DP[1],DP[2],...DP[d]}’ at time instance ‘T’, distance between two points ‘[[DP]]\_i’ and ‘DP\_j’ employing Chebyshev distance is mathematically, expressed as given below.

$$Dis(DP_i, DP_j) = Max(|DP_i - DP_j|) \quad (10)$$

From the above (10), by employing the Chebyshev distance measure ‘Dis ([[DP]]\_i, DP\_j)’, the greatest difference between two vectors (i.e., the data points) along any coordinate dimension (i.e., the cluster) is evaluated based on the maximum ‘Max(|[[DP]]\_i- [[DP]]\_j|)’ distance along one axis. To be more specific, based on the principle of chessboard distance as the minimum number of moves required by a king to go from one square to another is utilized; by means of Chebyshev distance, the overall outlier detection accuracy is said to be improved. Next, with the assumption of ‘m’ clusters

‘[[CI]]\_1, [[CI]]\_2,..., [[CI]]\_m’ the centroid data point ‘CP’ is then measured as given below.

$$Cl_i CP [i] = \frac{\sum_{P \in Cl_i} DP[i]}{|Cl_i|} \quad (11)$$

With the above determination of the centroid (11), with the assumption that in a cluster ‘CI’ most of the normal data points are hardly encircling the centroid data point of cluster ‘CI’, the abnormal data points or the outlier are those generally farther from the centroid data point. Then the updated weight of a centroid data point is mathematically stated as given below.

$$W(DP) = \frac{Dis(DP, Cl_i CP [i])}{\sum_{S \in Neigh(DP)} Dis(S, Cl_i CP [i])} \quad (12)$$

From the above (12), the weight of data point ‘DP’ in cluster ‘[[CI]]\_i’ is estimated based on the neighbors of ‘Neigh(DP)’ in ‘[[CI]]\_i’. Finally, to reflect the robustness and direction of linear correlation between two data points and minimizing the false positive cases, Reflective Correlation Coefficient is applied. RCC function is employed to evaluate the amount of dependency between two distributions of normalized scores ‘G\_i^Norm (DP), G\_j^Norm (DP)’ and is mathematically stated as given below.

$$RCC(DP_i, DP_j) = \frac{W(DP_i)W(DP_j)}{\sqrt{(\sum DP_i)^2 (DP_j)^2}} \quad (13)$$

From the above (13), reflective correlation coefficient ‘RCC’ is obtained based on the weighted data points ‘W([[DP]]\_i)’ and ‘W([[DP]]\_j)’ respectively. The final form of the objective function for minimizing the false positive cases of the ‘j-th detector’ is mathematically stated as given below.

$$Res_j = [G_j^{Norm}(DP)] - [G_j^{Norm}(DP_o)] \quad (14)$$

From the above (14) ‘G\_j^Norm’ forms the normalized score function of the ‘j-th detector’, ‘DP’ denoting the data points with contaminated dataset and ‘[[DP]]\_o’ denoting the outliers. The pseudo code representation of Chebyshev Temporal and Reflective Correlation-based Outlier Detection is given.

#### Algorithm 2 Chebyshev Temporal and Reflective Correlation-based Outlier Detection

<b>Input:</b> Dataset ‘DS’, data points ‘DP = {DP <sub>1</sub> , DP <sub>2</sub> , ..., DP <sub>n</sub> }’
<b>Output:</b> Accurate Outlier Detection
1: <b>Initialize</b> time instance ‘T’
2: <b>Begin</b>
3: <b>For</b> each Dataset ‘DS’ with data points ‘DP’ and cluster ‘Q <sub>i</sub> ’
4: Evaluate distance between data points ‘DP <sub>i</sub> ’ and ‘DP <sub>j</sub> ’ as in (10)
5: <b>For</b> each cluster ‘Q <sub>i</sub> ’
6: Evaluate centroid data point as in (11)
7: Evaluate weight of data point as in (12)
8: Estimate Reflective Correlation Coefficient as in (13)
9: Obtain final form of the objective function of the ‘j – th detector’ as in (14)
10: <b>Return</b> (outliers ‘DP <sub>o</sub> ’)
11: <b>End for</b>
12: <b>End for</b>
13: <b>End</b>

As given in the above Chebyshev Temporal and Reflective Correlation-based Outlier Detection algorithm, with the objective of improving the outlier detection accuracy with minimum falsification, two different functions are employed. First with the obtained clusters based on the data points, Chebyshev distance function is applied to estimate the difference between two data points along any cluster. Based on the minimum number of positioning between clusters, according to time, results are obtained, therefore ensuring outlier detection accuracy. Second by employing the Reflective Correlation Coefficient function dependency between two distributions or data points are obtained therefore reducing the false positive rate to a greater extent. Finally, the outliers are obtained.

### V. EXPERIMENTAL SETUP

In this section, experimental analysis of the Random Projection Deep Extreme Learning-based Chebyshev Reflective Correlation (RPDEL-CRC) method for outlier detection in data mining is presented. In this section, the performance of the proposed RPDEL-CRC is compared with the state-of-the-art methods, fuzzy rough granules-based outlier detection (FRGOD) [1] and Iterative ensemble method with distance-based data filtering [2] using NIFT-50 Stock Market Dataset (<https://www.kaggle.com/datasets/rohanrao/nifty50-stock-market-data>). Simulations are performed in R Programming language. Fair comparison between proposed RPDEL-CRC method and existing fuzzy rough granules-based outlier detection (FRGOD) [1] and Iterative ensemble method with distance-based data filtering [2] are made for evaluating different parameters like, outlier detection time, outlier detection accuracy, false positive rate and error for different iterations.

#### A. Case Analysis of Outlier Detection Time

The first metric significant for cluster based outlier detection is the time consumed in detecting the outlier. To be more specific, outlier detection time refers to the time consumed in detecting the outliers. Lower the outlier detection time more efficient the method is said to be because earlier the time consumed in detecting the outlier is more efficient the method is. The outlier detection time is mathematically stated as given below.

$$OD_{time} = \sum_{i=1}^n Samples_i * Time [Res_j] \tag{15}$$

From the above (15), the outlier detection time ‘[[OD]]\_time’ is measured based on the samples involved in the simulation process ‘[[Samples]]\_i’ and the time consumed in detecting the outliers ‘Time [[Res]]\_j’. It is measured in terms of milliseconds (ms). Table I given below shows the results of outlier detection time observed for three different methods, RPDEL-CRC, FRGOD [1] and Iterative ensemble method with distance-based data filtering [2].

Fig. 4 illustrated above shows the outlier detection time with respect to 50000 different numbers of samples obtained at different intervals from different companies stock values between years 2007 and 2021. These curves are plotted with increasing cardinality of training samples ranging between 5000 and 50000. With the increasing cardinality, the number of

samples involved in analysis for outlier detection increases and therefore an increase in the outlier detection time is observed. However, simulations with 5000 samples observed ‘250ms’ for detecting outliers with respect to single stock sample using RPDEL-CRC, ‘350ms’ for detecting outliers with respect to single stock sample using [1] and ‘450ms’ for detecting outliers with respect to single stock sample using [2]. From this analysis it is inferred that the outlier detection time using RPDEL-CRC is comparatively lesser than [1] and [2]. The reason behind is the incorporation of Gaussian Random Projection-based Deep Extreme Learning-based Clustering model. By applying this model, dimensionality of data or data points are said to be reduced using Gaussian Random Projection based on projecting original input space (i.e., the raw data) with the aid of a sparse random matrix. With this, data points considered to be outliers are obtained that in turn assist in detecting the outliers altogether. Therefore, the outlier detection time using RPDEL-CRC method is found to be reduced by 20% compared to [1] and 37% compared to [2].

TABLE I. TABULATION FOR OUTLIER DETECTION TIME

Samples	Outlier detection time (ms)		
	RPDEL-CRC	FRGOD	Iterative ensemble method with distance-based data filtering
5000	250	350	450
10000	295	395	555
15000	355	435	635
20000	410	485	680
25000	435	535	745
30000	485	625	795
35000	525	685	835
40000	595	745	890
45000	685	800	920
50000	735	835	955

Fig. 4. Graphical Representation of Outlier Detection Time.

#### B. Case Analysis of Outlier Detection Accuracy

The second parameter of significance for cluster based outlier detection is the accuracy rate. In other words, the outlier detection accuracy is measured based on percentage ratio

between the samples involved in simulation process ‘ $\llbracket$  Samples $\rrbracket_i$ ’ and the actual samples accurately detected with outliers ‘ $\llbracket$  Samples $\rrbracket_{ODC}$ ’. This is mathematically stated as given below.

$$OD_{acc} = \sum_{i=1}^n \frac{Samples_{ODC}}{Samples_i} * 100 \quad (16)$$

Table II given shows the results of outlier detection accuracy observed for three different methods, RPDEL-CRC, FRGOD [1] and Iterative ensemble method with distance-based data filtering [2].

Fig. 5 illustrates the outlier detection accuracy for 50000 different stock samples obtained from the NIFTY-50 stock dataset at different time instances. From the figure it is inferred that the outlier detection accuracy is found to be inversely proportional to the stock samples involved in the simulation process. In other words, increasing the stock samples for detecting the outlier causes an increase in the overall data points involved in the process and this in turn minimizes the outlier detection accuracy. However, sample simulations performed with 5000 samples 4845 samples were accurately detected with outliers as it is using RPDEL-CRC, 4755 samples using [1] and 4695 samples using [2]. With this the overall accuracy using the three methods were found to be 96.90%, 95.1% and 93.9% respectively. The overall accuracy was found to be improved using RPDEL-CRC upon comparison with [1] and [2]. The reason behind the outlier detection accuracy improvement was owing to the application of Chebyshev distance function. By applying this distance function, the difference between two data points along any cluster was first evaluated. Then, on the basis of the minimum number of positioning between clusters, according to time, results were obtained, i.e., outliers were detected, therefore ensuring outlier detection accuracy. This in turn improved the outlier detection accuracy using RPDEL-CRC method by 3% compared to [1] and 7% compared to [2].

### C. Case Analysis of False Positive Rate

False positive rate is measured as the ratio between the numbers of negative events (i.e., negative outliers) wrongly categorized as positive (i.e., outliers) and the total number of actual negative events (i.e., actual outliers). This is mathematically stated as given below.

$$FPR = \frac{FP}{FP+TN} \quad (17)$$

From the above (17), the false positive rate ‘FPR’ is measured based on the false positive samples ‘FP’ (i.e., actually the data are not outliers) and the true negative samples ‘TN’ (i.e., outliers detected as outliers) respectively. Table III given shows the results of false positive rate observed for three different methods, RPDEL-CRC, FRGOD and Iterative ensemble method with distance-based data filtering [2].

TABLE II. TABULATION FOR OUTLIER DETECTION ACCURACY

Samples	Outlier detection accuracy (%)		
	RPDEL-CRC	FRGOD	Iterative ensemble method with distance-based data filtering
5000	96.9	95.1	93.9
10000	95.35	94.35	91.15
15000	94.15	92.85	90.35
20000	94.05	91.55	88.15
25000	93.85	91	88
30000	93.25	90.85	87.35
35000	93	90.25	86
40000	92.55	89.85	85.25
45000	92.15	89.15	84.35
50000	92	89	83

Fig. 5. Graphical Representation of Outlier Detection Accuracy.

TABLE III. TABULATION FOR FALSE POSITIVE RATE

Samples	False positive rate (%)		
	RPDEL-CRC	FRGOD	Iterative ensemble method with distance-based data filtering
5000	0.007	0.015	0.025
10000	0.015	0.018	0.026

50000	0.038	0.042	0.048

Fig. 6. Graphical Representation of False Positive Rate.

Fig. 6 given depicts false positive rate for different stock samples. From the figure, it is inferred that the false positive rate also increases with the increase in the number of stock samples involved in the simulation and hence the false positive rate is found to be directly proportional to the stock samples or samples. However, simulations conducted for 5000 samples show a false positive rate of 0.007 using RPDEL-CRC, 0.015 using FRGOD [1] and 0.025 using Iterative ensemble method with distance-based data filtering [2]. From this, it is observed that the false positive rate is comparatively lesser using RPDEL-CRC when compared to [1] and [2]. The reason behind is the application of Chebyshev Temporal and Reflective Correlation-based Outlier Detection algorithm. By applying this algorithm, dependency between two distributions of data points or data are separated. First, according to different weight of data points, i.e., based on the neighbors or data points in cluster, updated weight of a centroid data point is obtained. Next, with the identified updated weight of a centroid data point, outliers are detected based on the linear correlation between data points. Hence, by applying different updated weight of a centroid data point for each cluster, false positive rates are significantly reduced using RPDEL-CRC method by 24% compared to [1] and 36% compared to [2].

D. Case Analysis of Error Rate

Finally, the error rate involved in outlier detection is discussed in this section. The error rate is one of the significant parameters involved in the outlier detection process. This is owing to the reason that while clustering certain data points are said to be misplaced in the adjoining clusters, therefore resulting in error. This error rate is mathematically stated as given below.

$$ER = \left( \frac{V_{actual} - V_{expected}}{V_{expected}} \right) * \% \tag{18}$$

From the above (18), the error rate ‘ER’ is measured based on the actual value ‘V\_actual’ or the actual data point positioning and the expected value ‘V\_expected’ or the expected data positioning. It is measured in terms of percentage (%). Finally, Table IV lists the error rate obtained using the (18).

Finally, Fig. 7 illustrates the error rate observed during the process of outlier detection. From the figure, an increasing

trend is found to be observed using all the three methods, RPDEL-CRC, FRGOD [1] and Iterative ensemble method with distance-based data filtering [2] increasing the stock samples. This is due to the reason that with the increase in the stock samples provided as input obtained during different time instances from different companies, first, clusters are performed. While performing the clustering based on data points certain data points due to temporal instances cause a small shift in the positioning of clusters. This in turn results in the deviation and therefore error. However, simulations conducted with 5000 samples with actual data positioning observed to be 53, the expected data positioning using the three methods were observed to be 48, 45 and 43. Hence, the error rate were found to be 9.4%, 15.09% and 18.86% respectively using the three methods, therefore reducing the error with RPDEL-CRC method. The reason behind the minimization of error using RPDEL-CRC method was due to the application of Gaussian Random Projection-based Deep Extreme Learning-based Clustering algorithm. By applying this algorithm, the learning rate for solving the output weights were estimated by means of square gradient. As a result, the error rate using RPDEL-CRC was said to be reduced by 28% compared to [1] and 45% compared to [2].

TABLE IV. TABULATION FOR ERROR RATE

Samples	Error rate (%)		
	RPDEL-CRC	FRGOD	Iterative ensemble method with distance-based data filtering
5000	9.4	15.09	18.86
10000	9.75	16.15	21.32
15000	10.35	16.35	22
20000	10.85	17.25	22.85
25000	11.35	17.85	24.35
30000	13.15	18.35	24.85
35000	15.25	20	25
40000	17.35	21.35	28
45000	19.55	22.45	29.35
50000	21.25	23	30

Fig. 7. Graphical Representation of Error Rate.

## VI. CONCLUSION

In spite of the fact that there has been an improvement in outlier detection, nevertheless mushrooming outliers are still found in its disastrous intents. In this day and age, it has become a big ultimatum that the behavior of outliers has to be monitored in many data mining tasks. In this paper, we proposed a new outlier detection method, called, Random Projection Deep Extreme Learning-based Chebyshev Reflective Correlation (RPDEL-CRC). The main contributions of our proposed RPDEL-CRC method is to the field of outlier detection that reduces the outlier detection time, error and false positive rate involved with maximum accuracy. The proposed method reduces the outlier detection time and error for operating the outlier detection via Gaussian Random Projection-based Deep Extreme Learning model that initially performs the clustering process by means of Gaussian Random Projection function. Next, with behavior grouping and clustering using Deep Extreme Learning, false positive rate is reduced in a timely manner. Third, the actual outlier detection process based on the clustering results is performed by means of Chebyshev Temporal and Reflective Correlation-based Outlier Detection model. Simulations were performed to evaluate the performance of RPDEL-CRC, FRGOD and Iterative ensemble method with distance-based data filtering method. Simulation results revealed that the proposed RPDEL-CRC method outperforms, FRGOD and Iterative ensemble method with distance-based data filtering method implementations, in terms of outlier detection time, accuracy, error rate and false positive rate.

# Efficient Decentralized Sharing Economy Model based on Blockchain Technology: A Case Study of Najm for Insurance Services Company

Atheer Alkhamash, Kawther Saeedi, Fatmah Baothman, Rania Anwar Aboalela, Amal Babour\*

Information Systems Department, Faculty of Computing and Information Technology  
King Abdulaziz University, Jeddah 21589, Saudi Arabia

**Abstract**—Blockchain is an emerging technology that is used to address ownership, centrality, and security issues in different fields. The blockchain technology has converted centralized applications into decentralized and distributed ones. In existing sharing economy applications, there are issues related to low efficiency and high complexity of services. However, blockchain technology can be adopted to overcome these issues by effectively opening up secure information channels of the sharing economy industry and other related parties, encouraging industry integration and improving the ability of sharing economy organizations to readily gain required information. This paper discusses blockchain technology to enhance the development of insurance services by proposing a five-layer decentralized model using Ethereum platform. The Najm for Insurance Services Company in Saudi Arabia was employed in a case study for applying the proposed model to effectively solve the issue of online underwriting, and to securely and efficiently enhance the verification and validation of transactions. The paper concludes with a review of the lessons learned and provides suggestions for blockchain application development process.

**Keywords**—Blockchain; decentralized; Ethereum; multichain; Najm; sharing economy

## I. INTRODUCTION

Blockchain is a new technology that is defined as “a distributed database, which sequentially stores a chain of data packaged into locked blocks in a safe and unchanging way” [1]. Traditionally, most of the electronic service providers are centralized entities that are required to be validated and verified, and they need to be trusted by their stakeholders. By utilizing the concept of platform cooperation with peer-to-peer (P2P) rather than centralized services, blockchain technology offers the infrastructure for decentralized security, verifiability, and trust [2]. However, several blockchain designs and implementations resulted in principally different governance structures, such as hierarchy over meritocracy, necessitating comprehensive communication among all involved stakeholders [3]. To ensure a balance in sharing economy settings, a trusted platform in centralized architectures should be replaced with blockchain technology and associated protocols to ensure trust, security, and privacy [4]. The design of such decentralized platforms based on blockchain technology and its practical implications regarding security, privacy, and trust is extremely reliant on the type of blockchain technology used [5].

Along with the advancement of blockchain technology, sharing economy is another IT-mediated development that is growing rapidly. Sharing economy can be defined as: “the sharing activity of underutilized assets with the help of IT-based technology” [6]. It is an umbrella term related to activities of sharing goods and services such as exchanging or renting them via IT, without the need to change their ownership. It enhances efficiency and effectiveness by minimizing the cost of transactions and raises the utilization and exchange of goods and services. It also enhances competition between competitors within a marketplace and minimizes the complacency of suppliers [7], [8]. Integrating blockchain into sharing economy would improve the sharing economy in terms of security and privacy, and it might increase the distribution of P2P businesses due to the provision of a high level of data integrity and nonexistence of third parties; consequently, data security would be ensured.

Therefore, in this study, a new model for integration of blockchain and sharing economy was proposed as a five-layer decentralized model and it was applied to the Najm for Insurance Services Company as a case study. The main contributions of this study are the following:

- A model for car accident report application was designed for the Najm for Insurance Services Company using a blockchain platform.
- The proposed model was developed.

The remainder of this paper is organized as follows: Section 2 discusses related works; Section 3 details existing car insurance services; Section 4 discusses the design of the proposed car insurance application based on blockchain; Section 5 covers the implementation of the proposed model; and Section 6 presents the conclusions and discusses directions for future work.

## II. RELATED WORK

### A. Blockchain Concept

Blockchain is a new technology that is operated without the need for third parties to exchange their transaction data. Blockchain can also be defined as “an appending only, ever-growing chain of blocks, which are linked sequentially using the hash pointers as a linear linked list” [9]. Specifically, as shown in Fig. 1 the block header contains a hash pointer that is linked directly to the previous block, called the parent

\*Corresponding Author.

block, and this linkage extends all the way back to the first block, called the genesis block. Further, all transactions are ordered based on Merkle trees. As a result, data on the blockchain cannot be changed unless all the subsequent blocks are altered.

Fig. 1. Structure of Blockchain.

Blockchain can be one of three types: public blockchain, private blockchain, and consortium blockchain. The core components of the blockchain architecture are described below [10]:

- Node: the blockchain transaction that represents a user or a computer. It is the smallest construction unit of any blockchain system.
- Block: a data structure utilized to control a sequence of transactions disseminated to other network nodes.
- Chain: a series of blocks in a specific order.
- Miners: a collection of rules and agreements to conduct blockchain operations; these are unique nodes that conduct block verification processes.
- Consensus mechanism: it is called the consensus protocol and is the core of blockchain platforms. Its algorithm is used to validate the blocks, order them, and ensure agreement between nodes across the distributed P2P network. There are two main types of consensus mechanisms: proof-of-work (PoW), which is trusted and has a strong history, and proof-of-stake (PoS), which requires relatively fewer computations, less energy-consumption, and is more reliable and scalable.

The main driving features of the blockchain technology include: decentralization, transparency, security, immutability, and privacy. These are explored below [11]:

- Decentralization refers to governing the transactions to be updated from the ledger through transmission of the responsibilities to regional nodes that independently verify the transactions and then transmit them for computation with high throughput such as by employing the longest chain rule. Under decentralized consensus, no central authority or integration point is needed to receive the transactions and verify set rules. Further, no failure or trust is possible at a single point.

- Transparency refers to auditing of records by a predefined set of participants that can either be less or more open. These records are traceable and transparent, and the participants have the choice to combine their individual weighted rights.
- Security is a blockchain feature that takes the form of irreversible records stored in shared, replicated, and tamperproof ledgers. Additionally, the records cannot be forged because of the use of one-way cryptographic hash-functions. Blockchains are secure to some extent; however, security is a relative feature and having a private key allows data to be transferred throughout a blockchain.
- Immutability refers to the features of non-repudiation and irreversibility of records that control blockchain function. The data recorded in the ledger, which is tamper-resistant, cannot be secretly altered unless the alteration is done with the knowledge of the network, thereby making blockchains immutable.

Blockchain infrastructure is defined and implemented using interconnected devices in the hardware layer. The infrastructures of two major blockchain platforms are discussed below [12]:

'Ethereum' blockchain is a decentralized, open-source, generic and public blockchain network in which the transactions are validated through the PoS consensus. Its business model is used for business-to-consumer (B2C) activities. Every node has equity and can participate in creating new blocks. In contrast, the 'Hyperledger Fabric' blockchain is a decentralized, open-source, modular and private blockchain network in which the transactions are validated by different types of consensus. Its business model is used for business-to-business (B2B) activities. Further, each node in this blockchain does not have equity and thus, it cannot participate in creating new blocks.

### B. Blockchain-related Application

Blockchains may be used in different fields. The following are some examples where blockchain is used to enhance different functionalities [13]:

Gem is a Central Disease Control system that uses blockchain to provide effective disaster relief by inputting outbreak information onto a blockchain having an immutable ledger to help researchers collect and analyze data, and make the circumstances of the disease spread evident. The Ethereum platform has been used in Gem [14].

Abra is a cryptocurrency wallet that employs the Bitcoin blockchain network to control balances saved in different regions. It operates an interest-earning service for stable coins and cryptocurrencies, a trading service for buying and selling cryptocurrencies, and lending services. The Ethereum platform has been used in Abra [15].

Augur is a market prediction system that uses blockchain technology for financial services and it is based on a decentralized ecosystem. The main purpose of creating the Augur platform was to serve as a warning system in all matters. It also allows people to invest and profit through their

expectations and opinions, which enables Augur to provide more accurate forecasting of upcoming events. The Ethereum platform has been used in Augur [16].

Skuchain is a control goods and services system based on blockchain that is used to track the services provided through a supply chain. It assists businesses in overcoming the difficulties and expenses associated with their inventory and help to advance the concept of "collaborative commerce." The Hyperledger platform has been used in Skuchain [17].

OpenBazaar was a blockchain-based decentralized trading market where no middlemen were needed to trade goods and services. It also utilized Bitcoin, which is a censorship-resistant, decentralized, and inexpensive digital currency. The Ethereum platform has been used in OpenBazaar [18].

Blockchain is used to enhance the functionality of car reporting systems in different ways. For instance, the blockchain-based reporting system proposed in [19] provides a new mechanism to provide indisputable accident forensics by guaranteeing verifiability and trustworthiness of information. The proposed mechanism is used to verify and validate a new block of event data in a trusted manner without any central ownership. In addition, the model proposed in [20], called (IV-TP), is used to communicate between intelligent vehicles using blockchain technology. The data shared between the intelligent vehicles are secure and reliable. The (IV-TP) model provides trustworthiness for vehicles' histories (i.e., behavior) and their actions (legal or illegal). Blockchain is used to store all the details of each vehicle.

The present paper proposes an architecture of a car accident reporting application for the Najm for Insurance Services Company using the blockchain platform. Najm is a Saudi company started in 2007 to implement an effective platform for facilitating, overcoming, and resolving accident-related transactions and formalities [21]. This organization has obliged itself to offer hassle-free and smooth processing among insurance companies. Najm initially had only 13 insurance agencies as its core shareholders but now, it works with more than 26 Saudi insurance companies.

### III. EXISTING CAR INSURANCE SERVICES

This section demonstrates the existing accident reporting systems for the Najm for Insurance Services Company [21].

As shown in Fig. 2, the process begins when the insured party first records the accident on an application or contacts the car accident reporting company. Second, the company appoints a surveyor located close to the accident spot. Third, the surveyor arrives at the accident spot. Fourth, the surveyor examines and evaluates the accident. Fifth, the insured party receives a report from the surveyor. Sixth, the insured party goes to the traffic police to get a repair paper in the report stamped. Seventh, the insured party gets the estimated damage cost from the authorized assessment Center. Eighth, the insured party goes to the insurance company. Finally, the insured party obtains a final clearance or written approval from the insurance company to get the vehicle repaired.

Fig. 2. Existing Accident Procedure in the Najm for Insurance Services Company.

Therefore, the existing accident reporting systems such as that of the Najm for Insurance Services Company, are suffering from various challenges, including the need to enhance user security, increase service availability, and provide service flexibility at the lowest cost. Moreover, the accident report data must not be changed after they are inputted into the database. Further, accident reports should be shared and distributed among different stakeholders such as the insured party, reporting company, surveyor, traffic police, assessment centers, and insurance company in a consistent and secure manner. These issues should be addressed to provide a trusted accident reporting system.

### IV. DESIGN OF THE PROPOSED CAR INSURANCE APPLICATION BASED ON BLOCKCHAIN

After conducting a thorough synthetic analysis about the use of blockchain technology in sharing economy applications, this study combined the blockchain technology with sharing economy applications to create a decentralized P2P sharing economy model for a car accident reporting application. In general, the sharing economy for businesses connects service providers and consumers, and enables people to offer services through online platforms in a private and secure manner. As mentioned hereinabove, the blockchain technology facilitates decentralization of data storage and communication. The decentralized processes can be automated when deploying 'smart contracts' that are a part of the blockchain technology.

To build a decentralized sharing economy using the blockchain technology, several design elements should be considered, including the features of blockchain and its main components, as well as decentralized infrastructures and platforms. As previously stated, the blockchain architecture presents benefits for businesses in gaining several features such as improved security and privacy.

The proposed model is adapted from the 'Blockchain Market Engineering Framework' [22]. The Ethereum platform was selected for implementation in the proposed model because it is an open-source, public, and generic blockchain architecture in which the transactions are validated by the PoS consensus. The proposed blockchain architecture is independent of any specific platforms and it consists of five main layers, as shown in Fig. 3.

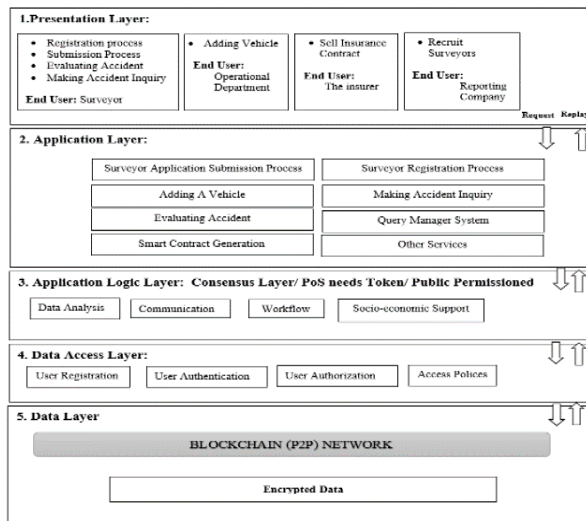

Fig. 3. Five-layer Architecture of the Proposed Model.

The blockchain platform (BaaS) provider manages the setup, maintenance, and support of the blockchain infrastructure. A node is any electronic equipment that is linked to the internet and has an IP address, such as a computer, mobile phone, or printer. The node can copy the blockchain and process transactions.

The data layer manages encrypted data that are maintained in a standard form to ensure compatibility and inter-sectoral communication requirements.

The data access layer integrates the data generated from various sources to enable user registration, user authentication, user authorization and accessing of policies. Effective access control is required to ensure that only the involved actors (i.e., legal users) have access to the relevant transaction data. The implementation of a role concept is critical in this context. Furthermore, a precisely designed role concept combined with effective access control makes illegal data alteration more difficult. Furthermore, the integration of related organizational parties and relevant metadata is supported by a metadata repository.

The application logic layer manages data analysis, communication, socioeconomic support, and workflow of the integrated applications and systems. Therefore, the processed and retained data are available for all purposes. This predominantly concerns research trends and allows to conduct statistical assessments.

The application layer represents the platform features, business services and user-controlled services that are given to the users of sharing economy organisations, such as the surveyor application submission process, surveyor registration process, addition of a vehicle, making an accident inquiry, evaluation of an accident, querying the manager system, smart contract generation, and other services.

Lastly, the presentation layer enables the services provided by the system to be displayed to stakeholders such as the surveyor, insurer, reporting company and operational department. The functions and features provided to each user differ depending on their role and permission. For instance,

the registration process, submission process, accident evaluation, and making an accident inquiry are available for the surveyor; addition of vehicles is available to the operational department; selling of insurance contracts is available to the insurers; and recruitment of surveyors is available to the reporting company. Note that it is vital to ensure responsiveness in the proposed model by allowing access through web or desktop applications supported by various operating systems. Also, the model can be further extended by applying security mechanisms in smartphones, such as fingerprint and iris scanning.

To demonstrate the effectiveness of the proposed model, it was adapted in the Najm for Insurance Services Company [21].

## V. IMPLEMENTATION OF THE PROPOSED APPLICATION

To implement the prototype, the following steps were undertaken:

- Creating a blockchain for data storing: A multichain platform was used with the Windows 10 OS; the chain consisted of only one computer and all data about stakeholders were saved in the chain as bytecode that was then converted to the JSON format to be read. Further, any stakeholder computer could be added, and the command prompt (CMD) scripts were used to create the chain.
- Connecting with the chain: To connect with the chain and cover its complexity, an API was created using the Python programming language. The created API offers data storage and retrieval from the chain. Further, the Flask web server was used to allow a client to connect to the chain.
- The application: To create a GUI app for users, an android app was used to connect with the API.

### A. Code and Functions for Computer Program

The system consists of a mobile application and a computer program. The computer program consists of two elements: one is responsible for the blockchain and the other is responsible for the web server. The blockchain and web server functions are listed in Tables I and II, respectively.

### B. Proposed Mobile Application

The proposed application contains different screens for executing different functionalities. Fig. 4 represents the pre-step of using the system. The user needs to enter their IP address to link the application to the blockchain and then, select one of three options: 'Create New User', 'Login', or 'Report an Accident'.

The surveyor is provided two options: 'Create New User' and 'Login'.

Create New User: When the surveyor chooses to create an account, the screen contains fields to receive information about the user. The surveyor should enter their name, email, password, form number, car plate, identification number and mobile number and then, click on the 'Create User' icon, as shown in Fig. 5.

TABLE I. BLOCKCHAIN FUNCTIONS

Functions	Description
Create	It is used to create a new blockchain.
Start	It is used to start a blockchain activity.
Storage	It is used to create a stream on blockchain to start writing on it and give permission for commuters who are connected to the blockchain to write on it.
add_data	It is used to take (chain, stream, path) of blockchain to write on it and publish.
converter	It is used to take the existing data and convert it to hexadecimal.
find_data	It is used to find data inside a blockchain.
distance	It is used to calculate the distance between the surveyor and the insured party.
find_ac	It is used to store all the data in the JSON file and search for the existing data.

TABLE II. WEB SERVER FUNCTIONS

Functions	Description
app.route(users)	It is used to add a new user to the company.
app.route(acid)	It is used to report an accident.
app.route(Log)	It is used to log in to the user account and locate the nearest accident.
app.route(Select)	It is used to the nearest accident for serving.

Fig. 4. Initial Registration.

Fig. 5. Create an Account.

After the surveyor account creation process is completed, the screen shown in Fig. 6 is presented to the surveyor, which contains the message “Your Req Has been sent, wait for a phone call”.

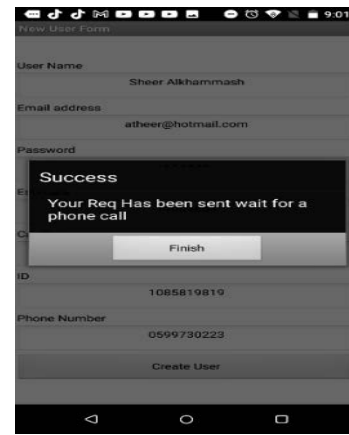

Fig. 6. Request Message.

Login: When the surveyor selects the “Login” option, they will be allowed to login. This screen contains two fields: email and password. After providing this information, the surveyor is logged into the application, as shown in Fig. 7.

Fig. 7. Login.

After the surveyor login process is successfully executed, the screen shown in Fig. 8 appears which contains longitude and latitude coordinates of the nearest accidents.

Fig. 8. Nearest Accidents.

On the other hand, the insurer has one option:

Report an Accident: When the insurer chooses the third option, a screen appears containing information about the

accident, mobile number of the insured party, car plate number, username, and accident degree. There are three different accident degrees: "small no injury", "medium no injury", and "With injury", as shown in Fig. 9 and 10.

Fig. 9. Report an Accident.

Fig. 10. Accident Degree.

After determining the accident degree, the insurer presses submit and the screen shown in Fig. 11 appears for the insurer, which contains the message "Accident Data Has been Received".

CMD scripts are used for interacting with blockchain. Fig. 12 shows how the user information is saved in blockchain. Fig. 13 shows how the accident report is stored in blockchain.

Fig. 11. Submit Accident Report Form.

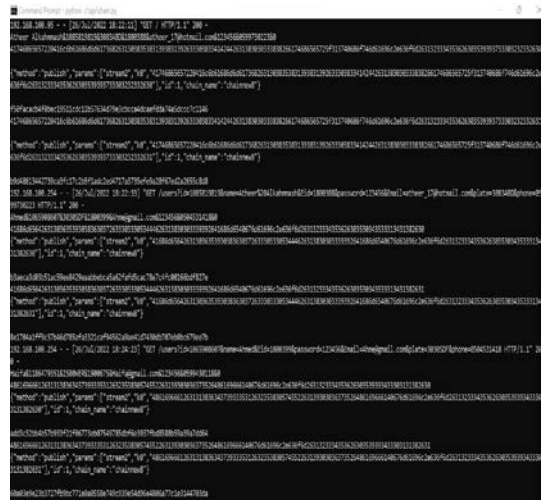

Fig. 12. User Information.

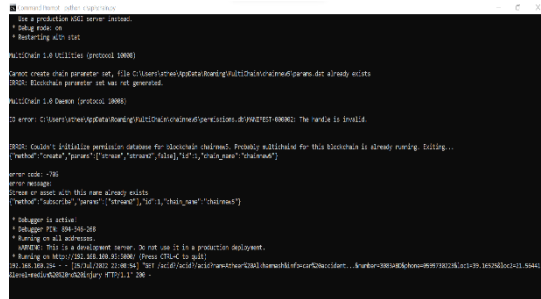

Fig. 13. Accident Reporting Information.

## VI. CONCLUSION AND FUTURE WORK

Blockchain plays an important role in increasing data security and integrity in sharing economy applications. Therefore, proposing a blockchain-based framework to enhance sharing economy application is important to solve the issues related to existing accident reporting systems, including the need for significant data harvesting, providing secure storage, and enabling frequently updated transactions. Moreover, the old reporting data must not be changed after inputting it into the database. Also, accident reports should be shared and distributed among different stakeholders in a consistent and secure manner. These issues should be addressed to provide a trusted accident reporting system. In this paper, a new business method is proposed for sharing economy using the blockchain architecture. The proposed model features a software architecture that was used to develop the sharing economy application based on blockchain and the identified business pattern and architectural model of a car accident reporting application was adopted as a prototype of the proposed blockchain platform and subsequently implemented for the Najm for Insurance Services Company in Saudi. With regards to future work, we need to add new functions and evaluate the adaptation of the architecture and business pattern identified through the case study.

**Abstract**—Virtual Communities of Practice (VCoPs) are networks of people who share a common interest and a desire to learn together in the same domain via ICT. The limitations of the existing concepts for developing VCoPs in general contexts are not explained in terms of the integration between virtual learning technologies and digital learning strategies used to promote expected learning outcomes in the agricultural sector. This research aims to propose the conceptual framework for developing the Virtual Communities of Practice through Digital Inquiry (VCoPs-DI Model) to promote digital agriculturists' learning competencies and engagement. The research methodology was divided into three stages: the first stage involves a literature review for document analysis and synthesis, the second stage involves constructing the conceptual framework, and the third stage involves evaluating the content validity index. The key results showed that the developed conceptual framework has three parts: (1) The fundamentals of concept formation were divided into four concept bases: (1.1) Communities of Practice (CoPs), (1.2) Virtual Learning Environments (VLEs), (1.3) Digital Learning Resources (DLRs), and (1.4) Critical Inquiry Method; (2) The identification of the manipulated variable was divided into two compositions: (2.1) VCoPs and (2.2) Digital Inquiry (DI); (3) The identification of the dependent variable was divided into two compositions: (3.1) Digital agriculturists' learning competencies, and (3.2) learning engagement. Findings from an expert's review show that the scale levels of the content validity index (SCVI) were 0.958. We anticipate that our conceptual framework could be used for reference as part of the design and development of the VCoPs model to promote learning in the agricultural sector.

**Keywords**—VCoPs; digital inquiry; digital agriculture; learning competencies; learning engagement

## I. INTRODUCTION

Many global issues, such as climate change, lack of natural resources, demographics, and food waste, are putting pressure on the overall sustainability of agricultural systems. In this digital age, traditional agricultural management approaches need to be radically transformed so that smart technologies can contribute to innovation and redesign the entire value chain to maintain the sustainability of the agricultural sector. Current advances in advanced digital technology tend to lead to the

fourth phase of the revolution in the agricultural sector, known as "Agriculture 4.0" [1].

Agriculture 4.0 in developing countries is characterized by low technological levels of technology. The main reasons for this are the high cost of advanced digital technology (e.g., 5G, cloud computing, Internet of Things, blockchain, data mining, artificial intelligence, augmented reality, virtual reality, etc.) and the dynamics of today's business environment. However, these types of systems are becoming increasingly important, especially for achieving the Sustainable Development Goals (SDGs), which are related to three specific goals: Zero Hunger (Goal 2), Clean Water and Sanitation (Goal 6), and Life on Land (Goal 15). One alternative to achieving this goal is to adopt Logistics 4.0 technologies and educational technology. This is because these technologies can address issues such as nutrition, food safety, and soil and water conservation [2].

Information and communication technologies (ICT), such as the Internet, e-mail, and videoconferencing, have made the human learning process more efficient and productive in terms of daily operations. However, ICT not only improves people's daily productivity but also supports the ability to share that information and tacit knowledge with both internal and external organizations as well as social networks. One of the most popular ways to share large amounts of information and tacit knowledge is through an informal learning environment such as a Community of Practices (CoPs) [3] or Virtual Community of Practices (VCoPs) [4].

Digital learning resources are characterized by being virtual spaces that learners can access through information and communication technology. Managing learning resources in a virtual space requires consideration of the media exposure and lifestyle of digital learners. Digital learning resources can be classified into five categories [5–7]: 1) search engines and translation tools; 2) data and storage management tools; 3) content creation, presentation, and publishing tools; 4) distance learning tools; 5) social networking tools.

The limitations of existing concepts for the development of VCoPs in general contexts are not explained concerning the integration between virtual learning technologies and digital

\*Corresponding Author.

learning strategies used to promote expected learning outcomes in the agricultural sector for digital learners of all ages, regardless of their background and geographical location [3–4]. Thus, this research paper focused on proposing the conceptual framework for the development of the Virtual Communities of Practice through Digital Inquiry (VCoPs-DI Model) to promote digital agriculturists’ learning competencies and learning engagement that can be used for reference in the design and development of the VCoPs model by integration between virtual learning technologies and digital learning strategies used to promote learning in the agricultural sector in the future.

## II. RESEARCH OBJECTIVES

1. To synthesize the conceptual framework for the development of the Virtual Communities of Practice through Digital Inquiry (VCoPs-DI Model) to promote digital agriculturists’ learning competencies and learning engagement.
2. To construct the conceptual framework for the development of the VCoPs-DI Model to promote digital agriculturists’ learning competencies and learning engagement.
3. To validate the conceptual framework for the development of the VCoPs-DI Model to promote digital agriculturists’ learning competencies and learning engagement.

## III. RESEARCH METHODOLOGY

Stage I: Synthesis of the conceptual framework for the development of the VCoPs-DI Model to promote digital agriculturists’ learning competencies and learning engagement. This stage was a qualitative research method based on a literature review. The researchers conducted studies, analyzed, and synthesized research papers that included Communities of Practice (CoPs), Virtual Learning Environments (VLEs), Digital Learning Resources (DLRs), the Critical Inquiry Method, Digital Agriculturists’ learning competencies, and learning engagement from ERIC, Scopus, and Web of Science online databases published during 2015–2021 using content analysis [8] of text data in research papers.

Stage II: Construct the conceptual framework [9] for the development of the VCoPs-DI Model to promote digital agriculturists’ learning competencies and learning engagement was developed by conducting studies, analysis, and synthesis through content analysis in stage I.

Stage III: Validation of the conceptual framework for the development of the VCoPs-DI Model to promote digital farmers’ learning competencies and learning engagement was an expert judgement by five educational technology experts on a four-point Likert scale for the Content Validity Index (CVI) [10] The scale used in this study was used and responses included 1 = Not Relevant, 2 = Somewhat Relevant, 3 = Relevant, and 4 = Highly Relevant. Researchers recommend that a scale with excellent content validity should be composed of I-CVIs of 0.78 or higher and S-CVI/UA and S-CVI/Ave of 0.8 and 0.9 or higher, respectively.

## IV. RESEARCH FINDINGS

### A. The First Stage

- The results of the synthesis of components of Communities of Practice (CoPs) as shown in Table I [11-18]:

TABLE I. RESULTS OF THE SYNTHESIS OF COMPONENTS OF CoPs

Components of CoPs	Reference							
	[11]	[12]	[13]	[14]	[15]	[16]	[17]	[18]
1. Purpose/ Vision/ Mission	✓	✓	✓	✓	✓	✓	✓	✓
2. Participant/ Members/ People	✓	✓	✓	✓	✓	✓	✓	✓
3. Perspective/ Paradigm/ Shared values/ Negotiation	✓	✓	✓	✓	✓	✓	✓	✓
4. Processes/ Methods/ Activity	✓	✓	✓	✓	✓	✓	✓	✓
5. Platforms/ Technology	✓	✓	✓	✓	✓	✓	✓	✓
6. Products/ Productivity	✓	✓	✓	✓	✓	✓	✓	✓

According to the result of the synthesis indicated in Table I, it can be summarized that the CoPs comprise six components: 1) purpose, 2) participants, 3) perspective, 4) processes, 5) platforms, and 6) products.

- The results of the synthesis of components of Virtual Learning Environments (VLEs) as shown in Table II [19-26]:

TABLE II. RESULTS OF THE SYNTHESIS OF COMPONENTS OF VLEs

Components of VLEs	Reference							
	[19]	[20]	[21]	[22]	[23]	[24]	[25]	[26]
1. Learning aims and objectives	✓	✓	✓	✓	✓	✓	✓	✓
2. Learning contracts			✓	✓	✓	✓		
3. Learning issues/ Topic / Agenda	✓	✓	✓	✓	✓	✓	✓	✓
4. Learning activities/ Task	✓	✓	✓	✓	✓	✓	✓	✓
5. Learning technologies	✓	✓	✓	✓	✓	✓	✓	✓
6. Learning assessments	✓	✓	✓	✓	✓	✓	✓	✓

According to the result of the synthesis indicated in Table II, it can be summarized that the VLEs comprises six components: 1) learning aims, 2) learning contracts, 3) learning issues, 4) learning activities, 5) learning technology and 6) learning assessments.

- The results of the synthesis of components of Digital Learning Resources (DLRs) as shown in Table III [5, 7, 27-29]:

TABLE III. RESULTS OF THE SYNTHESIS OF COMPONENTS OF DLRs

Components of DLRs	Reference				
	[5]	[7]	[27]	[28]	[29]
1. Search engine and translation tools	✓	✓	✓	✓	✓
2. Data and storage management tools	✓	✓	✓	✓	✓
3. Content creation, presentation, and publishing tools	✓	✓	✓	✓	✓
4. Distance learning tools	✓		✓	✓	✓
5. Social networking tools	✓	✓	✓	✓	✓

According to the result of the synthesis indicated in Table III, it can be summarized that the DLRs, comprise five components: 1) search engine and translation tools, 2) data and storage management tools, 3) content creation, presentation, and publishing tools 4) distance learning tools, and 5) social networking tools.

- The results of the synthesis of components of the critical inquiry method as shown in Table IV [30-32]:

TABLE IV. RESULTS OF THE SYNTHESIS OF COMPONENTS OF CRITICAL INQUIRY METHOD

Components of critical inquiry method	Reference		
	[30]	[31]	[32]
1. Observing/ Exploring and questioning	✓	✓	✓
2. Information seeking/ Information searching/ Problem-posing	✓		✓
3. Knowledge building/ Knowledge gathering/ Knowledge construction/Taking action	✓	✓	✓
4. Creative communicating	✓	✓	✓
5. Knowledge sharing/ Knowledge exchange	✓	✓	✓

According to the result of the synthesis indicated in Table IV, it can be summarized that the critical inquiry method comprises five components: 1) exploring and questioning, 2) information searching, 3) knowledge building, 4) creative communicating and 5) knowledge sharing.

- The results of the synthesis of components of the digital agriculturists' learning competencies as shown in Table V [33-38].

According to the result of the synthesis indicated in Table V, it can be summarized that the digital agriculturists' learning competencies comprise six components: 1) seeking lifelong learning opportunities, 2) self-concept of being an effective digital learner, 3) initiative, creativity, and independent learning concerning digital agriculture learning issues, 4) self-responsibility in digital agriculture occupations, 5) optimistic about agriculture's evolution in the digital era, 6) problem-solving and decision-making concerning agriculture practices in the digital era.

TABLE V. RESULTS OF THE SYNTHESIS OF COMPONENTS OF DIGITAL AGRICULTURISTS' LEARNING COMPETENCIES

Components of Digital agriculturists' learning competencies	Reference
1. Seeking lifelong learning opportunities	[33], [34], [35], [36], [37]
2. Self-concept of being an effective digital learner	[33], [34], [36]
3. Initiative, creativity and independent learning concerning digital agriculture learning issues	[33], [34], [35], [38]
4. Self-responsibility in digital agriculture occupations	[33], [34], [35], [36], [37], [38]
5. Optimistic about agriculture evolution in the digital era	[33], [34], [35], [36], [37], [38]
6. Problem solving and decision-making concerning agriculture practices in the digital era.	[33], [34], [35], [36], [37]

- The results of the synthesis of components of the learning engagement as shown in Table VI [39-41]:

TABLE VI. RESULTS OF THE SYNTHESIS OF COMPONENTS OF LEARNING ENGAGEMENT

Components of learning engagement	Reference		
	[39]	[40]	[41]
1. Behavioral engagement	✓	✓	✓
2. Emotional engagement	✓	✓	✓
3. Cognitive engagement	✓	✓	✓

According to the result of the synthesis indicated in Table VI, it can be summarized that learning engagement comprises three components: 1) behavioral engagement, 2) emotional engagement, 3) cognitive engagement.

*B. The Second Stage*

- The results of the construction of the conceptual framework for the development of the Virtual Communities of Practice through Digital Inquiry (VCoPs-DI Model) to promote digital agriculturists' learning competencies and learning engagement are in Fig. 1.

Fig. 1. Conceptual Framework.

From Fig. 1, this conceptual framework consists of the following three parts: (1) The fundamentals of concept formation were divided into four concept bases: a) Communities of Practice (CoPs), b) Virtual Learning Environments (VLEs), c) Digital Learning Resources (DLRs), and d) Critical Inquiry Method. (2) The identification of the manipulated variable was divided into two compositions: a) Virtual Communities of Practice (VCoPs), which has six elements: i) desire and passion for learning, ii) digital learning platforms, iii) decentralized learning contracts, iv) deep learning issues of practice, v) dynamic learning processes, vi) developmental learning assessments and b) Digital Inquiry (DI), which has five elements: i) exploring and questioning, ii) information searching, iii) knowledge building, iv) creative communicating, v) knowledge sharing. (3) The identification of the dependent variable was divided into two compositions: a) Digital agriculturists' learning competencies, and b) Learning engagement.

C. The Third Stage

The results of the validation of the conceptual framework for the development of the VCoPs-DI Model to promote digital agriculturists' learning competencies.

3) Cognitive engagement	4	4	4	4	4	5	1.00	Valid	
<b>S-CVI/Ave</b>							0.958	Excellent content validity	

From Table VII, based on the experts' review, the results of the validation of the conceptual framework for the development of the VCoPs-DI Model to promote digital agriculturists' learning competencies found that the item levels of the content validity index (I-CVI) were in the range of 0.80–1.00.

In addition, the scale levels of the content validity index (SCVI) also showed excellent content validity (S-CVI/Ave ≥ 0.90).

## V. CONCLUSION AND DISCUSSION

The proposed conceptual framework for developing the Virtual Communities of Practice through Digital Inquiry (VCoPs-DI Model) to promote digital agriculturists' learning competencies and learning engagement has three parts as follows:

1. The fundamentals of concept formation are divided into four concept bases: *a*) Communities of Practice (CoPs), *b*) Virtual Learning Environments (VLEs), *c*) Digital Learning Resources (DLRs), and *d*) Critical Inquiry Method.

2. The identification of the manipulated variable was divided into two compositions: *a*) Virtual Communities of Practice (VCoPs), which has six elements: *i*) desire and passion for learning, *ii*) digital learning platforms, *iii*) decentralized learning contracts, *iv*) deep learning issues of practice, *v*) dynamic learning processes, *vi*) developmental learning assessments and *b*) Digital Inquiry (DI), which has five elements: *i*) exploring and questioning, *ii*) information searching, *iii*) knowledge building, *iv*) creative communicating, *v*) knowledge sharing.

3. The identification of the dependent variable was divided into two compositions: *a*) digital agriculturists' learning competencies and *b*) learning engagement. The five educational technology experts evaluated the validity of the conceptual framework for developing the VCoPs-DI Model to promote digital agriculturists' learning competencies and found that the validity of the proposed conceptual framework has excellent content validity.

From the findings, we anticipate that our conceptual framework could be used for reference in the design and development of the VCoPs model to promote learning in the agricultural sector. We expect that our framework will lead to practical ways to incorporate agricultural communication to increase participation in VCoPs among the agricultural workforce, including for all ages in the digital transmedia era, towards the Digital Agriculturists' learning competencies, which include six expected learning outcomes: 1) Seeking lifelong learning opportunities, 2) Self-concept of being an effective digital learner, 3) Initiative, creativity and independent learning concerning digital agriculture learning issues, 4) Self-responsibility in digital agriculture occupations, 5) Optimistic about agriculture's evolution in the digital era, 6) Problem-solving and decision-making concerning agriculture practices in the digital era.

## ACKNOWLEDGMENT

The researchers would like to thank the Faculty of Industrial Education and Technology, King Mongkut's University of Technology Thonburi (KMUTT), and Thailand Cyber University Project (TCU), Ministry of Higher Education, Science, Research, and Innovation for supporting this research.

# Deep Q-learning Approach based on CNN and XGBoost for Traffic Signal Control

Nada Faqir, Chakir Loqman, Jaouad Boumhidi

Department of Computer Science, Faculty of Sciences Dhar El Mehraz  
Sidi Mohammed Ben Abdellah University of Fes, Fes, Morocco

**Abstract**—Traffic signal control is a way for reducing traffic jams in urban areas, and to optimize the flow of vehicles by minimizing the total waiting times. Several intelligent methods have been proposed to control the traffic signal. However, these methods use a less efficient road features vector, which can lead to suboptimal controls. The objective of this paper is to propose a deep reinforcement learning approach as the hybrid model that combines the convolutional neural network with eXtreme Gradient Boosting to traffic light optimization. We first introduce the deep convolutional neural network architecture for the best features extraction from all available traffic data and then integrated the extracted features into the eXtreme Gradient Boosting model to improve the prediction accuracy. In our approach; cross-validation grid search was used for the hyper-parameters tuning process during the training of the eXtreme Gradient Boosting model, which will attempt to optimize the traffic signal control. Our system is coupled to a microscopic agent-based simulator (Simulation of Urban MObility). Simulation results show that the proposed approach improves significantly the average waiting time when compared to other well-known traffic signal control algorithms.

**Keywords**—Convolutional neural network; extreme gradient; traffic control; traffic optimization; urban mobility

## I. INTRODUCTION

Congestion causes serious social problems such as long distance travel, fuel consumption, and air pollution. Factors that contribute to traffic congestion include the proliferation of vehicles, poor road infrastructure, and poor signal control. But it doesn't stop people from buying cars, and building new road infrastructure is expensive. A relatively simple solution is to improve the efficiency of traffic light control. Approaches to reduce congestion are still priority topics for researchers from different disciplines. There have been several technological developments to help solve these problems; but there is a real need for further study and analysis of the impact of this problem on the daily lives of millions of people.

According to World Bank statistics released in 2017, 64% of the world's oil is consumed in the transportation sector. The sector also contributes 27% of his CO<sub>2</sub> emissions globally. According to the same source, according to 2022 statistics, domestic and international transport already accounts for 20% of global greenhouse gas emissions. It could rise as much as 60% by 2050 [1].

Artificial intelligence plays a very important role in this topic; agent-based simulations have attained a sufficient degree of complexity and scalability and have shown their ability to

manage traffic in the urban environment with other means to improve the quality of life of users.

Some researchers have proposed an optimization method for dynamic routing systems. Although this technique has proven effective in improving computation time, it is rarely used nowadays. Another technique for improving dynamic routing systems is to predict traffic conditions, like in [2] where, a machine learning approach for short-term traffic forecasting was proposed. This approach uses common conditions such as traffic volume, speed, and road segment occupancy to forecast short-term traffic volumes.

Our work presents a contribution to this line of research; and more precisely we will study a simple and always interesting situation: an isolated intersection regulated by traffic lights, which we want to manage by means of an agent capable of exploiting the experience acquired from its learning, possibly representing the admissible traffic conditions. We describe a Convolutional eXtreme Gradient Boosting (ConvXGB) algorithm as a deep reinforcement learning algorithm that automatically extracts all useful functions for adaptive traffic light control from raw real-time traffic data and learns the optimal policy for traffic light control instead of using human-crafted functions. We model the control problem as a reinforcement learning problem. A deep convolutional neural network is then used to extract useful features from the raw real-time traffic data (vehicle positions, velocities, waiting times of each vehicle on the road, traffic light status, etc.) to output the optimal traffic signal control decision. ConvXGB combines the performance of a Convolutional Neural Network (CNN) and eXtreme Gradient Boosting (XGBoost). A key feature of ConvXGB is a systematic strategy for choosing between these two models: XGBoost, widely used by data scientists, is a scalable machine learning system for tree boosting that avoids overfitting. It works well on its own and has proven its prowess in many machine learning competitions. Adding machine learning with CNN, a deep learning class that involves hierarchical learning at multiple different levels, brings clarity.

The simulations are carried out using SUMO (urban mobility simulation tool) of [3] in which we can see the results of the potential regulation of the actions carried out. A considerable reduction in waiting times and vehicle delays is achieved by using the proposed method.

The paper morphology will be as follows: the second section provides a literature research on the applications of Reinforcement Learning (RL) algorithms dedicated to traffic

light control. The third section, we briefly present an explanation of the different techniques used. In the fourth section, we present the studied environment and its concepts. The fifth section describes the structure of the proposed model architecture. The simulation results and performance compared to other reference models are presented in the sixth section and the concluding remarks are given in the last section.

## II. RELATED WORK

In general, traffic signals are based on repeated "cycles", where a cycle is a full rotation of all information provided at the intersection, and consisting of a number of phases. According [4] the "phase" is a group of traffic movements through the intersection; undergoing a "green" time interval, followed by "yellow" time and then "red" time. The dedicated time for each phase follows a fixed plan according to [5] method, or by adopting an adaptive green time scenario for each phase according to the traffic dynamics. The RL method applied to adaptive traffic light control has been proven effective in many papers. Multi-agent systems for solving many traffic management and control problems as in [6] research, a challenge in multi-agent environments is whether to approach traffic control as a collaborative problem/domain. In other words, the local optimum usually competes with the global optimum (the entire road network). Dimensional problems related to learning in multi-agent systems. Each implicitly influences the decisions of other agents. Co-evolution and the role of driver behavior in transport networks. The reference [7] introduced Q-learning algorithm for a single isolated intersection, we know that it is a tabular algorithm dealing with a restricted modeling of the environment based on a finite number of states and actions, which only works for this kind of problem and which will suffer from the curse of dimensionality if we ever think of expanding the state space and giving more details on the traffic state. The reference [8], the authors introduced a RL method with context detection for traffic signal control optimization, the detection of the change of context requires the installation of very sophisticated sensors, which is not at all acquired in various road networks throughout the world. The authors of [8] used a variety of RL algorithms to define the impact of the representation of state and action spaces, as well as the choice of actions and the definition of rewards on traffic models for a real-world intersection, and proved the effectiveness of the phasing variable, especially in large and dynamic traffic models. Most of the works deal with the problem of traffic signal control based on human-designed characteristics such as vehicle queue length and average vehicle delay. Human-designed features are abstractions of raw traffic data that ignore useful traffic information and result in suboptimal signal control. For example, vehicle queue length does not take into account vehicles that are not in the queue but are due to arrive soon. This is also useful information for traffic light control. Average vehicle delay reflects only historical traffic data, not real-time traffic demand.

In this work, we draw on the work of [9] and [10] by establishing a more detailed representation of the state space of the studied environment in order to provide more information of the intersection state. In addition, in this paper we propose a new deep learning model for reinforcement learning problems,

called "ConvXGB" which is a combination of CNN and XGBoost.

The ConvXGB model does not use human features, nor does it use vehicle queue lengths, instead it automatically extracts all useful features from the raw traffic data. Our algorithm works efficiently at realistic intersections. Our ConvXGB consists of several stacked layers of convolutions that learn the properties of the input and can learn the properties automatically. Then XGBoost predicts the class labels in the last layer. The ConvXGB model is simplified by reducing the number of parameters under suitable conditions, as it does not require readjusting the weight values in the backpropagation cycle.

## III. METHODOLOGY

### A. Deep Reinforcement Learning

The treatment of a problem by reinforcement learning (RL) using Deep Neural Networks (DNN) is called deep reinforcement learning (DRL). RL is a goal-oriented machine-learning algorithm aimed at achieving it by interacting with the environment. For a problem handled by RL, the environment is iteratively observed by the agent (in our case the road network), and it takes an action (by changing the phase or the duration of the phase of the signal). As a result, it receives from the environment a reward (in the case of traffic light control: waiting time ...) for the chosen action, the reward will be cumulated with its long-term goal (minimize delay, minimize stops ...). Then according to its rules and the state transition probability, the environment switches to the next state.

The RL agent tries to optimize the correspondence between the state space and the action space called policy, by analyzing the rewards discounted, and accumulated in the long run, and from the application of different action sequences. The agent's policy can be adjusted to converge to an optimal policy, by maximizing the expectation of the long-term reward during the learning process. Fig. 1 shows an RL-agent for traffic signal control.

The value function of the reinforcement-learning problem is the estimate of the reward of each pair of state-action in the long run. The value of environment state is the estimated long-run reward discounted by a factor following the policy, as defined in the Bellman equation as follows:

$$v(s) = \sum P(s', r|s, a)[r + \gamma V_{\pi}(s')] \quad (1)$$

Fig. 1. Reinforcement Learning Agent for Traffic Signal Control.

Where  $s$  represent the environment state,  $a$  the chosen action,  $r$  the reward received from the environment,  $P$  the state transition probability,  $\gamma$  the discount factor,  $\pi$  the agent policy and  $s'$  the next state according the probability  $P$ .

### B. Q-learning

Tabular Q-learning according to [11] is a widely used off-policy RL algorithm. Where the chosen action  $a \in A$  corresponds to the largest Q-value taken from a grid called Q-table. All discrete values of states and actions  $s \in S$  and  $a \in A$  will match in this grid. At each time step, Q-learning improves its policy according to the following equation:

$$Q_t(s, a) = (1 - \alpha)Q_{t-1}(s, a) + \alpha(r + \gamma \max_{a' \in A} Q_{t-1}(s', a')) \quad (2)$$

At time step  $t$  when the agent chooses to execute action  $a$  on states it receives a reward  $r$ , the parameters  $\alpha$  and  $\gamma$  represent respectively the learning rate and the discount factor defining the importance of the upcoming state.

Tabular Q-learning needs a grid to store the Q-values of all pairs  $(s, a)$ . The learning process suffers from the curse of dimensionality using [11], [12] and [13] approaches, if the sets of states  $S$  and actions  $A$  increase and if, in addition, the representation of the state is very detailed, so that the grid of Q values becomes giant. Therefore, the function approximation  $Q(s, a; \theta)$  introduced (where  $\theta$  is the hyper-parameter of the approximator) aimed at the generalization of the function from an example to estimate the correspondence. In this paper, we used this method by convolutional neural networks while adopting a continuous state representation.

### C. Deep Q-Network

The Deep Q-Network (DQN) is a RL algorithm that uses Deep Neural Networks (DNN) as function approximators. Its effectiveness in handling the large state-action space in RL problems as in [14] and in [15] is very significant. In addition, it uses two very important mechanisms to solve instability and divergence problems: experience replay and target network as introduced in [10]. At each learning step, the agent stores the quadruplet  $(s, a, r, s')$  in the replay memory, then it takes a random samples as a mini-batch from the memory to update the weights  $\theta$ . Thus, it eliminates strong correlations between consecutive states. The target network mechanism, which is a neural network identical to the original one, but where weights are updated less frequently, also reduces the correlation problem.

### D. XGBoost

XGBoost (Extreme Gradient Boosting) as explained in [16] is a trendy model widely used in several machine-learning challenges. Indeed, it runs faster than other model and is popular for its scalability in all scenarios discussed in [17]. There are many other boosting algorithms such as parallel boosting, regression tree boosting, stochastic gradient boosting, but in [16], the XGBoost model is one of the leading boosting algorithms.

The performance of many machine-learning algorithms depends on their hyper parameter tuning, it is important to tune a hyper-parameter; we used the cross-validation grid search

technique to tune the hyper-parameters of XGBoost in this paper. Our results show that this step helped our model achieve impressive scores and consequently beat older methods.

### E. Cross-validation Grid Search Tuning Hyper-parameters

XGBoost is a powerful and flexible machine learning algorithm and also it performs very well in general, but there are some problems. Notably the large number of hyper-parameters it has, as well as the fact that different combinations of parameters generate different evaluation scores. Hence it is essential to find the optimal hyper-parameters to get the most out of it. Grid search is method to find optimal hyper-parameters by testing every combination of them. In our case, we choose to tune three common parameters to prevent over fitting: learning rate, minimum child weight and maximum depth.

### F. ConvXGB Model

As a fresh deep learning model for categorization issues, we introduce the Convolutional eXtreme Gradient Boosting (ConvXGB) technique. ConvXGB combines the strengths of a Convolutional Neural Network (CNN) with eXtreme Gradient Boosting (XGBoost) [16], resulting in a state-of-the-art performance and high accuracy, as we will demonstrate. The ConvXGB architecture consists of three sub-CNN-networks each containing three stacked convolutional layers, the outputs of which are merged and reshaped, thus serving as the input to the XGBoost which is the final layer of the model. They differ from conventional CNN in that there is neither a pooling couch nor a fully connected (FC) couch. This adds simplicity and reduces the number of calculation parameters because it is not necessary to adjust the weight in the FC couches in order to adjust the weight in the preceding couches.

## IV. DESCRIPTION OF THE REINFORCEMENT LEARNING ENVIRONMENT FOR TRAFFIC LIGHTS CONTROL

### A. Intersection Model

The environment, on which the agent operates, is a four-armed intersection shown in Fig. 2. Each arm is 500 meters long, the maximum speed is 70km/h and the adopted traffic scenario handles an average of 1000 vehicles per hour. There are three lanes on each arm defining the possible directions of a vehicle: the rightmost lane allows vehicles to turn strictly right, the middle lane allows the driver to go straight only, while on the leftmost lane the driver can turn left or make a U-turn.

In the center of the intersection, the agent controls an adaptive traffic light system. Pedestrians, pavements and pedestrian crossings are not included in our environment.

Fig. 2. Intersection Model.

### B. State Representation

A detailed representation of the state of the environment is provided for the RL agent. The state is provided in the form of three matrices on each incoming road: a matrix of the vehicle's position and the matrix of the vehicle's speed used in [10], [18], [19] and [20]; and a waiting time matrix of the vehicle's, and also the last traffic lights status [21]. To create the three matrices  $P_i$ ,  $V_i$  and  $W_i$ , we will need to consider two parameters the segment length  $l$  and the cell length  $c$  for each road  $i = 0, 1, 2, 3$ ; Fig. 3.

In this paper hot coding has been used to define the position matrix of the road  $i$ , the result is the matrix  $P_i$ . The speed matrix  $V_i$  is calculated by normalizing each vehicle's speed by the edge maximum allocated speed. In our case, we consider the waiting time from the moment the vehicle enters the incoming route  $i$  of the network, and the result is recorded at the corresponding entry in the matrix  $W_i$ . The waiting time of a vehicle is defined as the amount of time during which a vehicle has been in the "waiting" state.

From the state of the last activated traffic lights, a matrix  $L$  is generated, where:  $L = [1, 0]$  is a value that defines green lights on horizontal roads whereas  $L = [0, 1]$  represents green lights on vertical roads as used in [10]. In this way, the state representation of the intersection at each time step  $t$  provided to the RL agent will be  $S_t = (P, V, W, L) \in S$ , where  $S$  is the entire state space.

### C. Action Definition

In Fig. 4, at each time step the agent observes the state of the intersection then chooses and executes either action ( $A_t = 0$ ): "0" setting green lights on for horizontal roads or action ( $A_t = 1$ ): "1" setting green lights on for vertical roads. A transition phase is required if the action taken at time step  $t$  is different from the one chosen at time step  $t+1$ , it will be executed as follows:

- 1) Switching the lights for straight ahead vehicles to yellow.
- 2) Switching the lights for straight ahead vehicles to red.
- 3) Switching the lights for left-turning vehicles to yellow.
- 4) Switching the traffic lights for vehicles turning left to red.

The times allocated for the yellow and green lights are fixed and are worth six seconds and ten seconds respectively.

### D. Reward Definition

In reinforcement learning, the feedback that the agent receives from the environment as a result of his choice of action is called a reward. This crucial concept of the training process is used to measure the effectiveness of the choice of action and thus allows the RL agent to improve future choices of his actions.

The reward can generally take positive or negative values. The positive value is the result of the right choice of actions; whereas a negative value is due to the wrong choice of actions. In our case, the objective is to minimize the total waiting times of all vehicles in the intersection. So that the RL agent can measure the effect of the action taken on the effectiveness of

the adaptive control of traffic lights at the intersection in terms of reduction or increase, the reward must be derived from a performance measure of traffic efficiency, so the goal will be met. The intersection is observed for two times, once at the beginning of the time step and then at the end of the time step.

The waiting times in the arrival lanes are noted for each observation and for all vehicles present in the intersection. The formula for the total reward  $R_t$  also used in [10] is therefore:

$$R_t = r_1 - r_2 \tag{3}$$

The values of  $r_1$  and  $r_2$  are respectively the sum of the waiting times recorded at the beginning and at the end of the green light interval according to [10]. The agent will only be rewarded if the value of  $r_2$  decreases; in case a transition phase is mandatory ( $A_t \neq A_{t+1}$ ), the two values  $r_1$  and  $r_2$  will be saved at the end of the execution of the transition phase discussed in section IV.C.

Fig. 3. Illustration of One Arm of the Intersection and the Three Matrices Position (a), Speed (b) and Waiting Time (c) of each Vehicle in the Incoming Lane.

Fig. 4. Chronological Sequence of Events of the Agent: State Observation, Action Choosing, Executing, Getting Rewards and Training Model According.

V. ADAPTATIVE SIGNAL CONTROL ALGORITHM DESIGN  
BASED ON CONVXGB

The ConvXGB agent, which is a RL agent, long-term objective is to reduce congestion at the intersection. After making a series of decisions (actions) in accordance with a policy, we consider  $S_t$ , the intersection's status at the start of time step  $t$ , into consideration. A sequence of rewards  $R_t, R_{t+1}, R_{t+2}, R_{t+3}...$  is given to the agent, after taking a sequence of actions by adopting a policy  $\pi$  for a state  $S_t$  of the environment at the beginning of each time step  $t$ . The action  $A_t$  should maximize the reward  $R_t$  shown in equation (4) to allow the agent to reduce the total waiting times of all vehicles at the intersection at time step  $t$ . The agent is supposed to find an optimal policy for choosing actions, denoted  $\pi^*$  defined in (5) that maximizes the cumulative future reward (Q-values) and that helps it achieve its goal.

$$Q_{\pi}(s, a) = E[\sum_{k=0}^{\infty} \gamma^k R_{t+k} | S_t = s, A_t = a] \quad (4)$$

$$\pi^* \text{ argmax}_{\pi} Q_{\pi}(s, a) \text{ for all } s \in S, a \in A \quad (5)$$

To avoid infinite returns in cyclical processes, rewards must be discounted. Thus at each time step the reward is weighted by a reduction (or discounting) factor  $\gamma \in [0, 1]$ . This discount factor means that the further into the future one is, the less important the rewards become. We denote the optimal values of Q under policy  $\pi^*$  as  $Q^*(s, a) = Q_{\pi^*}(s, a)$ . Our model extract useful traffic features, and predict the Q-values while trying to find the optimal policy  $\pi^*$  and thus find the optimal Q-values  $Q^*(s, a)$ . Bellman's optimality equation (6), gives a recursive relation for the optimal Q-values  $Q^*(s, a)$ .

$$Q^*(s, a) = E[R_t + \gamma Q^*(S_{t+1}, A_{t+1}) | S_t = s, A_t = a] \quad (6)$$

In order to calculate (6), we would need to have complete knowledge of the underlying system mode (state transition probabilities and associated rewards), which is actually not feasible. Due to the complexity and size of the intersection traffic space, ConvXGB model is used to approximatively determine the optimal Q-values. It receives as input the state representation  $S_t = (P, V, W, L)$ . Based on this traffic data, the CNN sub-networks extract useful features, which they then

input to XGBoost to forecast the estimated  $Q(S_t, a)$  for all actions  $a \in A$  given the observed condition  $S_t$ .

A. Proposed ConvXGB Architecture

Our paper is based on a new deep learning model, dedicated to reinforcement learning problems called "ConvXGB". It is a hybridization between convolutional neural network and an XGBoost model. The architecture of ConvXGB is shown in Fig. 5. The model has five layers: 1) input layer, 2) three identical CNN sub-networks each containing three stacked convolutional layers, 3) reshape layer, 4) Q-values prediction layer and 5) output layer. These layers, each of which has unique talents and duties, are crucial to the model's success. Further, the model can be divided into two parts: one for feature learning and the other for Q-values prediction.

These three identical sub-networks having respectively as inputs the matrices (P, V, W). The outputs of these three sub-networks is flattened, and then we merge them with the vector L (last state of the traffic lights) to provide the result to the third layer for reshaping, Table I shows all the CNN parameters.

The second part of the ConvXGB model is an XGBoost model, with tuned parameters using GridSearchCV technique, to predict the Q-values. XGBoost are optimized by a cross-validation grid search.

The performance of the hybrid ConvXGB model is compared to the classical DQN model using only convolutional networks to show its robustness. ConvXGB effectively uses features learning and predicts Q-values, thus significantly reducing the total waiting times for all vehicles in the intersection, which will be detailed in the results section.

TABLE I. PARAMETERS OF THE CNN LAYERS

CNN Layers	Number of filters	Stride	Activation function
Conv1	16 of 4x4	2	ReLU
Conv2	32 of 2x2	1	ReLU
Conv3	64 of 2x2	1	ReLU

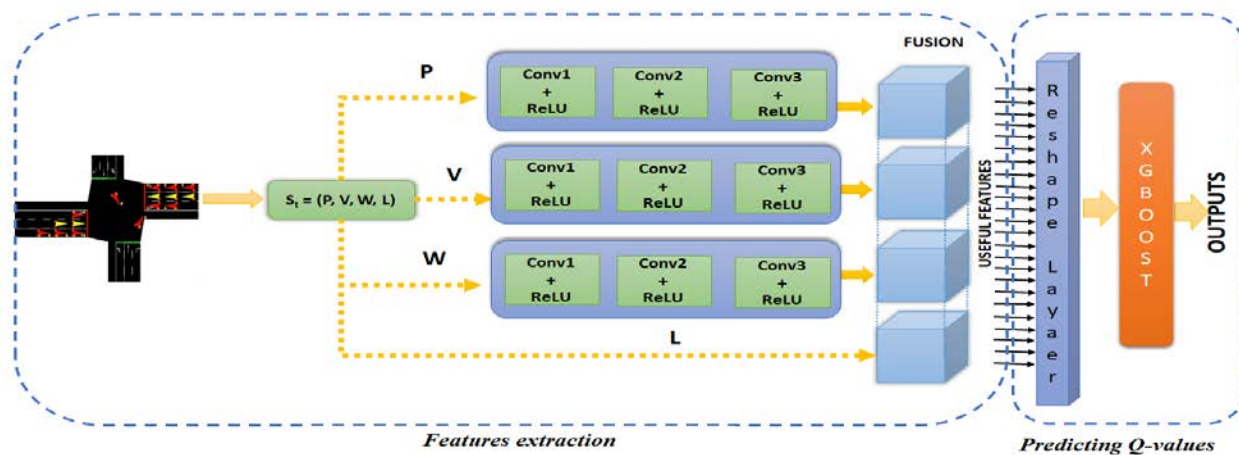

Fig. 5. Architecture of the ConvXGB Model.

## B. Algorithm and Training Process

The algorithm in Fig. 6 summarizes the process of forming the ConvXGB model used. We use a hybrid model composed of three identical CNN sub-networks to extract useful features from an environment representation (state). In the prediction phase, we use XGBoost to make Q-values predictions given the features extracted by CNN sub-networks. We also used the experience replay used in [10] to break correlations and improve agent performance during the training phase. The replay memory provides to the RL agent a set of random experiences for its learning, called a mini-batch. Each experience is represented as a quadruplet  $\{S_t, A_t, R_{t+1}, S_{t+1}\}$ , collected and stored in memory M during the learning phase, after choosing and applying the action  $A_t$  from the state  $S_t$ , the agent receive  $R_{t+1}$  as reward.

The environment undergoes a transition from the state  $S_t$  to the state  $S_{t+1}$ . This is why the observations extracted from this environment are correlated. This correlation can limit the learning capacity of the RL agent and prove the need to use the replay memory. The oldest experiments are erased if the memory is full during learning. The agent needs training data: input data set  $X = \{(S_t, A_t) : t \geq 1\}$  and the corresponding targets  $y = \{Q^*(S_t, A_t) : t \geq 1\}$ . For input data set,  $(S_t, A_t)$  can be retrieved from replay memory M. However, target  $Q^*(S_t, A_t)$  is not known. This formula  $R_t + \gamma \max_{a'} Q(S_{t+1}, a')$  is used to estimate the optimal Q-values. Thus, targets  $y = \{R_t + \gamma \max_{a'} Q(S_{t+1}, a') : t \geq 1\}$ .

The RL agent randomly takes 32 quadruples ( $\{S_t, A_t, R_{t+1}, S_{t+1}\}$ ) of the replay memory used to form training data  $X = \{(S_t, A_t) : t \geq 1\}$  and also to tune and update XGBoost parameters using GridSearchCV technique to efficiently estimate optimal Q-values ( $Q^*$ ).

Fig. 6. ConvXGB Algorithm for Adaptative Traffic Light Control using Q-Learning.

The exploration / exploitation problem is a frequent problem facing the policy of choice of actions in reinforcement learning; exploration, where we seek more information to improve future decisions; or exploitation, where the decision is made based on current information. In this paper, we have adopted a  $\epsilon$ -greedy exploration policy as used in [18]; given in equation (7). For the current episode  $e$  we have the probability  $\epsilon$  of an exploratory action, and the probability  $1 - \epsilon$  of an exploiting action.

$$\epsilon_e = 1 - \frac{e}{Total\_episodes} \quad (7)$$

At the start of his training, the agent only explores his environment, which is logical and obvious; he begins to use the information received during his training; an exclusive exploitation of the knowledge acquired by the agent takes place towards the end of his training.

## VI. EXPERIMENT AND EVALUATION

### A. Simulation Settings

In this study, we used the SUMO simulator [1], to generate urban traffic simulations. It allowed us to implement and customize road infrastructure functionalities. Moreover, subsequently extract useful data during the traffic simulation.

1) *Intersection*: We have an intersection of four roads, each road having three lanes, as shown in Fig. 2. The length of the road is 500 meters, the maximum speed is 19.44 m/s (i.e. 70 km/h), and the length of the vehicles is 5 meters with a minimum distance between vehicles of 2.5 meters. Moreover, the flow of vehicles (an average of 1000 per hour) is uniformly distributed.

2) *Traffic*: Vehicles, while selecting their route in advance make the choice of entry routes randomly. Horizontal roads will be heavily used while vertical roads, which will be less frequented, we also increase the frequency for left deviating roads compared to right deviating roads. Specially,  $P_1 = 1/7$  (for horizontal roads),  $P_2 = 1/11$  (for vertical roads),  $P_3 = 1/30$  (for roads deviating to the right),  $P_4 = 1/25$  (for roads deviating to the left). The setting of the traffic lights and the transition phase used in this paper are detailed in Section IV.

3) *Agent parameters*: The training process takes place over 2000 episodes. Where each episode corresponds to two hours of traffic and 7000 time steps, simulating the same traffic load at peak hours. For  $\epsilon$ -greedy method in Algorithm 1, parameter  $\epsilon$  is set to be 1 and the discount factor  $\gamma = 0.95$ . Learning rate of RMSProp  $\alpha$  is set to 0.0002 and the replay memory can store the experiences of 200 episodes. The training of the hybrid agent took a few days non-stop high-end laptop.

4) *Simulation data*: The time (in seconds) that a vehicle takes to cross an intersection (between entering and exiting the lanes) defines the delay that it can make. Therefore, the waiting (stopping) time of a vehicle is closely related to its delay. During the simulations, the total waiting time of all vehicles at the intersection is recorded in a file for all episodes.

Fig. 7. ConvXGB Agent Improvement.

Our approach is based on a hybrid model as detailed in Section V according to an architecture defined in Fig. 6 and inputs (P, V, W, L) explained in Section IV. The results of our contribution using used a tuned ConvXGB approach, shown in Table II, are compared to the fixed time policy, in which the phase cycle is fixed throughout the day, however the timing of each phase is designed by an expert to accommodate traffic volume ratios and to prioritize arterial traffic for green-waves, and also compared to the approach of [10] that we simulated for our intersection. Approach of [10] showed a clear improvement over the fixed traffic light configuration, but the hybrid ConvXGB agent we developed was able to outperform the fixed time policy and the mentioned approach very well. Fig. 7 presents the performance of the mentioned methods.

Using our agent, we obtain approximately 192k seconds as average waiting times for all episodes, while for the agent in [10] it was approximately 285k seconds. This proves that our ConvXGB hybrid model with XGBoost hyper-parameter tuning has significantly improved the problem of reducing traffic congestion.

TABLE II. TOTAL WAITING TIMES OF ALL VEHICLES FOR THE IMPLEMENTED APPROACHES

	Mean of total WT of all vehicles in seconds	Best total WT of all vehicles in seconds	Improvement over the static scenario
DQN agent [10]	285503	231444	54%
ConvXGB agent	<b>192213</b>	<b>145425</b>	<b>72%</b>
Fixed time policy	505850		

B. Training Evaluation Results and Discussion

The problem of this study was as follows: can a hybrid model "Convolutional Neural Network-Extreme Gradient

Boosting" statistically outperform the "DQN" model in optimizing the control of traffic lights in the urban environment?

The quantitative and complete description of the traffic situation provided to the agent helped a lot. It is clear that the states are more complex but the agent gains in performance. The inputs of our model were designed in a suitable way, in contrast to [22] where the authors used binary position matrices. They defined the binary matrix to cover the entire rectangular area around the intersection instead of just covering the area of the street relevant to traffic light control. Most entries in the binary matrix are null and redundant, making the binary matrix inefficient because the vehicle can't travel on non-road areas. In our case the vehicle position matrix covers only intersecting roads. This reduces the cost of training computation. We were able to boost the performance of our ConvXGB model by using the GridSearchCV technique for fine-tuning the XGBoost model. And since the tests we were able to do this step really helped our model to show better results.

Based on the evaluation and comparison of the two models, the results clearly showed the performance difference of the ConvXGB hybrid model. As shown in Fig. 7, the results obtained are significantly larger than the approach of [10]. The ConvXGB-based Q-learning algorithm is an effective choice over traditional traffic control methods, solving the problem of traffic congestion in large cities.

In the future, a better prediction model could be developed by using a heuristics methods for fine-tuning of the XGBoost and experimenting with new hybrid algorithms is recommended for future work.

VII. CONCLUSIONS

We have developed a new deep learning model for traffic light control problems using reinforcement learning. ConvXGB has two parts: one for useful feature extraction based on

detailed traffic situation definition and one for predicting Q values according to Q learning algorithm. We evaluated ConvXGB, on a single intersection, by adopting a traffic scenario illustrating clear peak hour congestion. ConvXGB was simplified by reducing the number of parameters needed and did not require back-propagation in the fully connected layer. ConvXGB based on CNN and XGBoost, was improved by tuning the most common XGBoost hyper-parameters. Our experimental results show that our model is significantly better than the classic DQN model, which also performed well when comparing it to the fixed time policy, but its performance is clearly inferior to our ConvXGB.

# Automatic Text Summarization using Document Clustering Named Entity Recognition

Senthamizh Selvan.R, Dr. K. Arutchelvan

Assistant Professor, Department of Computer and Information Science  
Annamalai University, Chidambaram, Tamil Nadu, India

**Abstract**—Due to the rapid development of internet technology, social media and popular research article databases have generated many open text information. This large amount of textual information leads to 'Big Data'. Textual information can be recorded repeatedly about an event or topic on different websites. Text summarization (TS) is an emerging research field that helps to produce summary from a single or multiple documents. The redundant information in the documents is difficult, hence part or all of the sentences may be omitted without changing the gist of the document. TS can be organized as an exposition to collect accents from its special position, rather than being semantic in nature. Non-ASCII characters and pronunciation, including tokenizing and lemmatization are involved in generating a summary. This research work has proposed an Entity Aware Text Summarization using Document Clustering (EASDC) technique to extract summary from multi-documents. Named Entity Recognition (NER) has a vital part in the proposed work. The topics and key terms are identified using the NER technique. Extracted entities are ranked with Zipf's law and sentence clusters are formed using k-means clustering. Cosine similarity-based technique is used to eliminate the similar sentences from multi-documents and produce unique summary. The proposed EASDC technique is evaluated using CNN dataset and it shown an improvement of 1.6 percentage when compared with the baseline methods of Textrank and Lexrank.

**Keywords**—Named entity recognition; text summarization; k-means clustering; Zipf's law

## I. INTRODUCTION

Internet technology paves the way for information resources. Excessive data is in text form and contains a lot of hidden information. Natural Language Processing (NLP) is one of the basic techniques used to extract hidden information from large amounts of textual data. Social media such as news channels and Facebook play an important role in generating high level text information. Reading huge amount of information is difficult task for human. Text summarization (TS) is the interesting research field that helps to generate summary from the text documents. Due to the data deluge and public consumption, information in the social media has redundant information in all normal dialects. For generating the summary, it is sometimes conceivable to delete words, expressions, rules and complete sentences without disrupting the significance of the message.

TS is the process of creating only brief outlines of the text without redundancies. Statistical analysis has its own limitations with the use of traditional ontological methods for deriving summary [1]. The content writers have different

perspective and use their own writing styles. Hence, traditional ontology does not support to find the cognisance of the knowledge in the documents. This makes more complex for extracting the summary from the documents. Also, the text summary cycle may require an alternative overview of the information. Homogeneous depiction empowers a single representation to gather information from different form of resources using primary integration. This will help in summary productivity. In general, text summarization process is based on finite state automation [2].

These days, a huge number of research articles, news articles, blogs and forums are distributed in every field of study. It represents a great challengeable task for industry experts and researchers to know the latest developments in their specific fields. A new report reveals that many logical articles are copied at regular intervals [3]. The solution of logical essays overcomes this challenge by providing significant findings and commitments to the essay. In the scientific document summary generation, the summary generated by experts have help them to reduce the data collection (secondary research articles) work. It also reduces the work and time required to review any logical article. This was the essential inspiration to run this work.

In general, the text summarization can be done in two ways to get a summary of single or multiple documents. In the primary way, the paper's theory is considered an outline, although the problem with the theory is that it does not reveal the immeasurable significant commitments and findings of an article as a result of length limitations. The findings and confirmations made by the author of an article may be essential from the writer's point of view, but it may not be relevant to the local area. In addition, there is no data from all parts of the theoretical article [4]. The next method overcomes the weaknesses of the main system. Given a note sheet (sheet to be compressed), a note-based summary is generated using the notes in the note sheet. This approach has negative pages based on various authors composing reference texts, and any misconception by them may present mistakes in the last outline; As a result, facts, findings, and basic structure of the reference sheet may be missed. Reference Ecology [5] can take care of this problem. Here every sentence referring to the note-taking notes will be removed first. This arrangement of sentences is called reference systems. It can create the last summary using extracted sentences.

As it is discussed above, two methods are used to obtain the outline of the text: extractive and abstractive [6]. The Extractive Text Summarization (ETS) technique combines the

deletions obtained from the corpus to the frame outline. The Abstractive Text Summarization (ATS) technique creates new sentences from the data obtained from the corpus. The ETS technique is inapt for multiple document resolution. The cause is the likelihood of creating a one-page summary of a few sources [7]. Again, little effort has been made to summarize the evaluation records and differentiate between the components that affect the presentation of each method. Valuation logs contain ratings and preferences, e.g., websites or client surveys.

The goals of this research work are as follows:

- Proposing an entity ranking method to rank the important entities.
- To find the sentence similarity using Cosine similarity.
- Grouping the sentences of multi-document using k-means clustering.
- Generate the text summary using entity aware and document clustering.

The organization of this research article is as follows: the detailed overview of text summarization and its methods are discussed in this introduction Section I. The literature review of previous work on text summarization on various applications such as clinical summary generation, news articles summary generation and scientific article summary generation are discussed in the Section II. The proposed EADSC method is given with a big picture in the Section III. Results of the proposed work is discussed in the Section IV. Finally, this research article is concluded with the future work in section V.

## II. BACKGROUND STUDY

The introduction of the Transformer encoder-decoder models briefly sparked [8], [9] news [10] and logical articles [11] and significant improvements. By the way, their application for summary of medical notes has not been satisfactorily examined. A prototype in the light of Pointer-Generator-Networks [10], [12] has been proposed for a concise outline of radioactivity by combining materials in the medical specifications of UMLS [13] and RadLex [14]. They use inventions and impression pairs for abstract work, where inventions form communications and create objective definitions for creating records.

Sotudeh et al. [15] have proposed a two-level model that includes material selection and abstract summary for medical abstraction. Selector is ready to distinguish ontological terms from discoveries through medical metaphysics (Radlex) and create concise records. Two-LSDMs are used to encrypt inventions and LSDMs are used to create solutions following the LSDM-based decoder. Liang et. al [16] have developed a model for differentiating clinical symptoms in patients with diabetes and hypertension and developing obvious contractions of the disease. They examined a database of 3,453 medical records collected for 762 patients, outlining the difficulty in determining age as a punishment. The authors [17] have proposed a model that incorporated the syntax-based misdiagnosis and approval of the syntax medical idea for extracting the medical message. They conducted their experiments on the MIMIC-III [18] database.

Text report outline is the focus of much research in the research field of NLP. Different kind of methods have been used to solve this problem, such as passive semantic investigation [19], object visualization and poison models [20] and the meta-heuristic method [21]. The essence of live models is the control of information, because a lot of coded information is needed to solve a brief task [22]. In recent days, many researchers involved in developing graph-based models for generating summary from multi-documents. Sentences are considered as vertex or nodes, and the margins between the vertex indicate the similarity between the sentences. The key aspect of the graph-based approach is to determine the most focal sentence in the record. Part of the graph-based models are LexRank [23] and TextRank [24]. The logical solution from the bat made by Duffel et al is correct. [25].

The benefit of using the reference method to create the exterior of a research paper has been demonstrated by Elkis et.al. [26] and Hernandez et.al. [27]. Hong et.al. [28] have developed logical outline practices using various stabilized material wood. Cohen et al. [29] proposed a search-organized approach to separating significant sections of the reference sheet. Most experts are involved in reference contextualization to create a logical solution to the dissertation. The shared tasks in the TAC 2014 database, CL-SciSumm 2016 and the 2017 Logical Report solution [30] provided databases for local education for select reason. Although the CL-SciSumm 2016 and 2017 datasets compile the logical articles of the Computational Semantics section, the TAC database is linked to the Biomedical Article solution.

In a research work, the authors [31] have developed a group-based methods. The important notes are compiled first and more focused phrases are selected from different clusters to create the exterior. Li et al. [32] SVM classifiers are used to outline vocabulary and sentence proximity. The authors [33] have published a semi-ethnic model using similarities based on brain structure and tfidf, which scores relevant text that can be memorized for abstraction. The developers [34] proposed a revised TextRank calculation called TextSentenceRank to sort the sentences; here, a solution is designed in view of the stabilized sentences.

Baki et al. [35] Cosine similitude was used using the term frequency-inverse document frequency vector and a subgroup using SVM (Support vector Machine) [36]. The SVM is combined with Decision Tree (DT) to identify the reference length. The outline is created by removing the sentences considering the average notch in each quote. In another research work, the authors [37] have used TF as a vector space model that uses a characteristic approach to the representation of text and a non-negative structure. Lapalme G et al. [38], used similitude ability to identify reference text, including tips and very serious small fit to create the solution. Cao et al. [39] was used SVM model to rank the reference text for each reference, and the final solution was prepared by complex stabilization [40]. The authors [41] have worked on the tfidf comparison, jacquard similitude and proximity system were used to differentiate the reference length, which is further applied to the outline.

Chiruzzo et al. [42] have experimented the ACL Collection Note that uses a variety of embeds, such as Corpus Word Matching [43] and Google Newsword Installation. Jacquard used similarity [44], LDA [45] and more, with less emphasis on reference identity intimacy and outline age. Glavas et al. [46] the design of the reference summary used element-based features, level-based content, vector space likeness and unigram to obtain text-range. Dipankar et al. [47]. The cosine proximity was used to differentiate the reference length for the solution from the point of view of the scoring system.

The author proposed a work that, [48] reference length was extracted using a standard language model [49], printed content [50] and basic writing learning [51], which are additionally used to relate to the abstract design score. Cohen et al. [52] proposed a logical abstract technique. In another work, similar authors [5] proposed a technique for applying the reference context using question correction, word formation and direct learning. In another work, the researchers [53], have a separate reference structure using cosine likeness and jacquard comparison, and selects phrases in the light of different highlights from the note sheet to create a summary that is closely linked to the notes.

In another research work, authors have proposed a framework for logical resolution [54] to recognize the reference system using the mover's distance and the LDA model; also, they used a set age process (DPP) for the abbreviated age. The authors have proposed a framework [55] and used weighted democratic classifiers to extract the citation system. Clustering method was used to generate the summary. The researchers [56] have used the open NMT an application for the TS. Nghiem et al. [57] an adjusted two-way transformer was used to differentiate the reference system. Furthermore, they have proposed a semi-ethnic outline technique for the compression age. The table I represents the scope and drawbacks of the different automatic text summarization approaches.

TABLE I. SCOPE AND RESTRICTIONS OF THE CONVENTIONAL ATS APPROACHES

Reference	Year	Description	Limitations
[58]	2009	important ways to summarise the content and a taxonomy of summarising techniques	Missing from NLP is extractive, abstract, machine learning, and deep learning.
[59]	2014	Reviewed works from 2000 to 2013 and suggested a statistical approach.	excludes cognitive components
[60]	2014	A hybrid strategy can effectively use both extractive and abstractive Techniques	avoided difficult procedures
[61]	2016	Introduces the concepts of abstractive and extractive summarization.	only describe strategies and procedures
[62]	2017	Extractive approaches for summarising multilingual texts are presented.	There is a lack of a definite classification and concept of feature score.
[63]	2021	to manage several materials for comparison and summary based on recent research work	does not constitute a quick conversation

Li et al. [64] have distinguished between the Word 2 reference system for the CNN model and the determining point processes (DPP) for the text summarization. Cagliero et al. [65] have used a writing model for the reference system for individual sources. The short path amongst the selected text length is predicted and the summary is generated. The authors [66] have used a variety of classification and ballot systems to identify the reference system. To format the summary, they compile phrases and select high-quality phrases from each encounter. Researchers [67] have diagnosis of the use of intermediate brain systems and how to monitor the reference system; for a long time, abstraction was designed by selecting phrases such as notes.

### III. MATERIALS AND METHODS

Extracting a summary from multi-documents are created by cutting key pieces of text from the collected documents. Statistical analysis is involved to find the important of sentences. The overall process involves in the proposed EASDC technique is given in the Fig. 1.

Fig. 1. Research Process of Proposed EASDC Work.

The proposed EASDC technique works using the following components: pre-processing, entity extraction, entity ranking, similarity filtering and EAS clustering. These components are well explained in the following sub-sections.

#### A. Pre-processing

In the text mining, preprocessing plays a major role to provide the documents in structured representation. Multi-document is defined by the following equation (1).

$$\left\{ \begin{array}{l} \{d_1, d_2, d_3, \dots, d_n\} \in MD \\ \text{if } d > 1, MD \text{ is true} \\ \text{if } d > 0 \text{ and } d \leq 1, MD \text{ is false} \end{array} \right\} \quad (1)$$

From the equation 1, d resembles document and MD resembles collection of documents. If d is lesser and equal to one, then it is single document. In English language, each sentence is identified by the full stop (.) at the end of a word. In preprocessing step, each sentence is tokenized using the regular

expression. The sentence tokenization is given in the equation (2), if number of sentences is lesser than five then the summarization process is not needed.

$$\left\{ \begin{array}{l} \{sen_1, sen_2, sen_3, \dots, sen_n\} \in S \\ \text{if } sen \geq 5, S \text{ is true} \\ \text{else, } S \text{ is false} \end{array} \right\} \quad (2)$$

The preprocessing phase involves the following technical process:

1) *Tokenization*: Each word is classified by a token in the sentence. As it is given in the equation 2, each sentence is classified by a token in a document. The sentences are tokenized and store into a desired format. In this proposed work, the tokenized sentences are stored in the array format and resembled as a sequence of tokenized-sentences. Removing non-ASCII characters are essential before proceeding the tokenization process. The non-ASCII characters are meaningless and it is not necessary for the text mining process.

2) *Removal of stopwords*: After tokenization, stopwords are important to remove the useless word in the sentences. For generating the summary, the subjective words are sufficient to find the important sentences. Hence the useless words such as the, of, a, an, in can be removed and generate new tokens.

### B. Entity Extraction

Entities are the key terms that helps to identify the important sentences. The word ambiguity is the important challenge in the entity extraction. Named Entity Recognition (NER) is the important task in NLP to extract the important keywords. For example, consider the following sentence, Chennai super kings won the T20 match that was held in Chennai. In the given sentence, Chennai is location and Chennai super kings is an organization. The output of the entity extraction must be as follows: Chennai super kings (Organization) won the T20 match that was held in Chennai (location). The ambiguous words can be identified by the human easily, whereas the human generated computational application needs lot of training.

For this research work, the fastest Spacy 3.0 library is used to extract the entities. The extracted entities are converted into numerical using token-2-vector model that is present in the spacy library. Conditional Random Field (CRF) technique is used to tag the ambiguous word with its identified entities. The CRF can be calculated using the following equation (3).

$$p(y|X) = \frac{1}{Z(X)} \prod_{n=1}^N \exp\{\sum_{m=1}^M \delta_m f_m(y_n, y_{n-1}, X_n)\} \quad (3)$$

where y is the part-of-speech of the current token and X is the observed entity. The weight of the words are resembles using  $\delta_m f_m$  and  $y_n, y_{(n-1)}, X_n$  resembles the features of the sentences. Z(X) is the total quantity of the named entities (NE). The weight estimation of the NE token is calculated using the maximum-likelihood estimation.

### C. Entity Ranking

NE ranking is used to identify the importance of a NE present in the documents. In general, the frequency of NE across the document gives the importance of a NE (i.e., number of appearances of NE in the document). The actual frequency of word has to be calculated using the inverse proportional of entity in the whole document. Zipf's law is one of the popular methods to identify the rank of the word in the given document. Zipf's law states that, the rank frequency of word is inversely proportional to the rank in the frequency table. The Zipf's law is defined in the equation (4) given below,

$$Z(r, \beta) \propto \frac{1}{r^\beta} \quad (4)$$

where  $\beta \approx 1$ , r denotes the rank of word and Z(r,β) represents the frequency of entity in documents. The identified entities are ranked and organized using the above equation 4.

### D. Similarity Filtering

Cosine similarity is calculated with the following equation (5) given below. It is used to find similarity in the sentences. From the equation (4), if the rank value is lesser than 0 is not considered for the document summary and it is eliminated from the tokenized entities. For the proposed EASDC work, the threshold value for the similarity index is set to greater than 75 percentage to get perfect similarity [68].

In the equation (5), sentence similarity is evaluated by comparing a sentence with all other sentences. The similarity matrix is created based on the values. The highly identical sentences based on the cosine value are removed from the documents. This reduced the redundant information from the multiple documents.

$$\cos(s_i, s_j) = \frac{\sum_{k=1}^n s_i * s_j}{\sqrt{\sum_{k=1}^n s_i^2} \sqrt{\sum_{k=1}^n s_j^2}} \quad (5)$$

where S is sentences and si and sj denotes the current and next sentence respectively.

### E. EAS Clustering

Sentences in multiple documents are ranked based on the presence of entities. The entities are ranked by using the equation 4. The duplicate sentence is eliminated using the equation 5. The unique sentences are embedded using the Doc2Vec mechanism. It is the extension of word embedding. For sentence embedding, this research work uses the Distributed Memory version of Paragraph Vector (PVDm) technique. The embedded sentence is represented with a unique token and stored in a matrix format.

The document clustering is one of the popular methods that is used to group the documents. In the proposed EASDC research work, it used k-means clustering mechanism to grouping the sentences based on the cosine similarity. Cosine distance method is applied to find the distance between the similar sentences. The equation for the cosine distance is given in the equation 6.

$$\cosine_{distance} = \frac{\sum_{n=0}^N s_n - p_x}{\sum_{n=0}^N (s_n)^2 * \sum_{n=0}^N (p_x)^2} \quad (6)$$

where  $s_n$  is the sentence with the position  $n$ , where  $n$  is 1, 2, 3...,  $N$ .  $N$  is the total number of sentences.  $p_x$  is the next sentence with point of observed  $x$ . The pseudocode of  $k$ -means-clustering pseudocode is given below.

---

**Pseudocode 1:**  $k$ -means clustering

---

**Input:** embedded sentences  
**Output:** grouped sentences  
Set number of  $k$   
Set centroids  $p_1, p_2, \dots, p_x$  randomly  
Repeat steps 4 and 5 till the end of iterations  
for  $n$  in  $p_x$ :  
find the nearest centroid  
assign the point to that cluster  
for  $j$  in cluster\_ $k$ :  
find new centroid by calculating the mean of centroids  
End

---

The clusters are pre-defined based on the length of summary that has to be created. The vector of the sentences is used to find the distance between the sentences. The number of clusters is set based on the entities and the chosen topic.

The clustered sentences may have different topics, because, the cluster is formed based on the entities and topics that has discussed in the documents. Therefore, each cluster may have a higher probability of being different topics. The top sentence in each cluster is considered and helps to form the summary. Each sentence from a cluster is sufficient to exaggerate the important of the topic. If there is one cluster, then the sentences in the cluster is extracted to form the summary. In another situation, if similarity is found between the topics, the top sentence of each cluster is taken and the similarity of the sentences is calculated. The redundant sentence from those clusters is eliminated and summary can be generated. The summary generation is given in the pseudocode below.

---

**Pseudocode 2:** Summary Generator

---

**Input:** clustered sentences  
**Output:** Summary  
Load the clustered sentences as  $C$   
Set  $T\_C = [ ]$  //list of topics, i.e., cluster head.  
Set  $summary = [ ]$   
For  $j$  in  $C$ :  
If  $[T\_C(j)]$  and  $[T\_C(j+1)] > 0.75$  : #  
 $T\_C(j)$  denotes,  $j$ th sentence of a cluster  $C$  under topic  $T$   
For  $s$  in  $j$ :  
Summary.append( $s$ )  
Break  
If  $[T\_C(j)]$  and  $[T\_C(j+1)] < 0.75$  :  
Eliminate the redundant sentence  $T\_C(j)$   
End

---

#### IV. RESULTS AND DISCUSSIONS

The proposed EASDC method generates summary using document clustering and named entity recognition. The identified entities are ranked and create the cluster using the equation 5 and 6. The clustered sentences are involved in generating the summary. The summary of the multi-documents

is restricted based on the required length. The sentence similarity plays major role in eliminating the redundant sentences. The sentences are embedded and it helps to diminish computational sparsity.

To evaluate the recital of the proposed EASDC research work CNN dataset is used. The entity extraction played a major role in the proposed research process. It turned out to be more difficult than we had anticipated. The DUC dataset looks to have a perfectly functioning XML structure, but we were unable to load it using numerous Python modules because of errors in the XML format. After that, we had to separate the lengthy text dumps into sentences. Our initial, basic implementation simply divided the text into paragraphs using periods. To speed up the loading of data, this data was saved to disc. This process can take over an hour to perform from scratch, but once finished, it doesn't need to be repeated.

The entities are extracted using the python spacy library. The named entities such as person, organization, location, GPE (geographical place), date, time and money. These entities are ranked based on their occurrences using Zipf's laws. The document-clustering using  $k$ -means cluster helps to grouping the sentences and generate the summary.

ROUGE (Recall-Oriented Understudy for Gisting Evaluation) is used to measure the efficient of proposed summarization technique, which is given in the equation 7.

$$ROUGE - N(c, r) = \frac{\sum_{r_i \in r} \sum_{n-gram} r_i Count(n-gram, c)}{\sum_{r_i \in r} numNgrams(r_i)} \quad (7)$$

Where  $N$  is the grams or tokens or words,  $c$  and  $r$  is candidate and reference respectively.

In this article, the following metrics are tested to evaluate the efficiency of the proposed EASDC technique:

- ROUGE - 1
- ROUGE - 2
- ROUGE - L

Table II denotes the outcome of comparison between EASDC with TextRank and LexRank methods. The proposed EASDC method outperformed well.

The comparative outcomes of the tested strategies for graphical representation are shown in Fig. 2. The LexRank algorithm yielded an average of 38.3%, compared to 39.06% for the TextRank algorithm. The proposed EASDC method performed better and generated 40.73%. It demonstrated a 1.67 percent improvement over the TextRank algorithm. The ROUGE scores improved with entity extraction-based extractive summarization.

TABLE II. SCOPE AND RESTRICTIONS OF THE CONVENTIONAL ATS APPROACHES

	LexRank	TextRank	EASDC
Rouge - 1	36.6	37.6	39.2
Rouge - 2	37.4	38.4	39.9
Rouge - L	40.9	41.2	43.1

Fig. 2. ROUGE Scores of Proposed EASDC Technique and Existing Works.

## V. CONCLUSION

The size-sensitive expansion of the World Wide Web has created better access to textual information. This work presents a technique for generating literary information that solves the problem of repetition and error in one of these ways. Implementing the proposed framework is not significantly different from business text summaries. The entity ranking and sentence similarity calculation helps to extract the unique sentences from the multiple documents. The extracted NE are then passed to the document clustering methods. By estimation, k-implies are a group calculation and high-level cluster calculations are used for incomparable effects. Similarly, the tendency to extract the sentence from each group is not based on random correlation rather to develop a particular calculation. The proposed EASDC technique shown an improvement of 1.67 percentage and 2.3 percentage compared to TextRank and LexRank algorithm respectively.

In order to further enhance the summary quality in the context of multidocument summarizing, we would like to investigate more strategies in the future, such as methods based on reinforcement learning. We also want to use our approach for additional tasks, such as answering multidocument questions.

**Abstract**—Pneumonia is a type of acute respiratory infection caused by microbes, and viruses that affect the lungs. Pneumonia is the leading cause of infant mortality in the world, accounting for 81% of deaths in children under five years of age. There are approximately 1.2 million cases of pneumonia in children under five years of age and 180 000 died in 2016. Early detection of pneumonia can help reduce mortality rates. Therefore, this paper presents four convolutional neural network (CNN) models to detect pneumonia from chest X-ray images. CNNs were trained to classify X-ray images into two types: normal and pneumonia, using several convolutional layers. The four models used in this work are pre-trained: VGG16, VGG19, ResNet50, and InceptionV3. The measures that were used for the evaluation of the results are Accuracy, recall, and F1-Score. The models were trained and validated with the dataset. The results showed that the InceptionV3 model achieved the best performance with 72.9% accuracy, recall 93.7%, and F1-Score 82%. This indicates that CNN models are suitable for detecting pneumonia with high accuracy.

**Keywords**—Neural networks; transfer learning; pneumonia; detection; Convolutional

## I. INTRODUCTION

Pneumonia is a type of acute respiratory infection caused by bacteria, viruses, or fungi that affects the lungs. Pneumonia is the leading cause of child mortality worldwide, with pneumonia killing an estimated 920136 children under five years of age in 2015, accounting for 15% of all deaths in children under five years of age worldwide [1]. Pneumonia is more prevalent in underdeveloped countries, where the lack of basic conditions is notorious, pollution worsens the situation and, at the same time, medical resources are increasingly scarce [2]. Therefore, early diagnosis and treatment play a very important role in preventing the disease from becoming fatal. Chest radiographs (X-rays) are most often used for the diagnosis of pneumonia. However, X-rays are prone to subjective variability [3][4]. Therefore, this paper presents four CNN models to detect pneumonia from chest X-ray images, which can be used by medical centers to detect pneumonia in their patients. The four deep CNN models were trained to classify the X-ray images into two types: normal and pneumonia.

The CNN-based transfer learning (TL) models used for this research work are: VGG16, VGG19, ResNet50, and InceptionV3, these models have been trained with the ImageNet database, a database with millions of images, and have obtained very satisfactory results, considered as successful. However, for this work, we used the Kaggle dataset, which is a less extensive dataset, basically due to computational resources. The four classification models were developed using CNNs for the purpose of detecting pneumonia from chest X-ray images. It is important to note that none of the four models used in this work have the same number of convolutional layers, so there is no direct relationship with the accuracy of the model [5]. Therefore, each of the models delivers different results with respect to accuracy. Each of the models follows its training architecture. To obtain the best accuracy in each model, at first, it is trained with a certain amount of convolutional combinations, dense layers, dropout, and other optimizers evaluating each model after each iteration, later, the complexity was increased to obtain a better model accuracy. The aim of this work is to classify and detect pneumonia from chest X-ray images, using CNNs with TL. If the model manages to achieve high accuracy, but with low recall values, it is considered an unreliable, ineffective, or even unsafe performance, since high false negative values represent a higher number of cases where the model predicts an output as normal, but in reality, the output is not normal. Therefore, to avoid this, we consider only the models with the highest recall and accuracy values [6] [7]. This is why, in the case of medical image processing, retrieval is preferred over other performance evaluation parameters.

This paper is organized as follows: Section 1 provides an introduction to the subject, addressing the problems, importance, purpose, and objective for undertaking this work. Section 2 explores the main works related so far. Section 3 describes the work methodology, the architectures of the models to be trained, the process diagram, and the data set to be trained. Section 4 presents the results obtained by the four CNN models and discusses the results. Finally, Section 5 provides the conclusions of the work.

## II. RELATED WORK

Academic researchers and scientists in the medical sciences have published research papers addressing the problem of pneumonia detection with neural networks.

The authors in [5] presented a CNN model to detect pneumonia with high accuracy from chest images. The experiment worked with chest X-ray images, achieving an accuracy of 89.67%. Similarly, in [8][9] they developed work to automatically detect bacterial pneumonia, through the TL, for which they used 5247 chest X-ray images. Classifying in three groups: normal, bacterial, and viral pneumonia, obtaining results in classification accuracy of 98%, 95%, and 93%, respectively. Similarly, in [10] they developed four models: CNN, VGG16, VGG19, and InceptionV3, where they used TL techniques with CNN. They used 9992 normal chest radiographs and 2972 pneumonia. The results were tested with 854 pneumonia and 849 normal chest images, obtaining an accuracy higher than 97% in all four models. As well as, in [11] applied an automated TL approach with CNN using four pre-trained models (VGG19, DenseNet121, Xception, and ResNet50), to identify pneumonia. the performance of the four models provided an accuracy higher than 83.0%. Also, in [12] they trained different CNNs to classify X-ray images into two types, normal and pneumonia. As well as, in [13] they proposed a learning framework combining residual thinking and convolution to diagnose childhood pneumonia.

CNNs have the function of automatically extracting features. Currently, it is the area of choice for disease diagnosis related to radiographic image analysis, the purpose of which is to aid in the early detection of symptoms and risk factors of the Covid-19 virus. Also, [14] explored the effectiveness of AI to quickly and accurately identify COVID-19 from a set of images with different deep learning (DL) models and adjust them to achieve better detection accuracy of the best algorithms. Also, in [15] they evaluated the performance of CNN architectures for X-ray image classification, concluding that the procedure called TL produces the best results for the detection of various anomalies. Similarly, in [16] they proposed a DL technique based on object detection, CNN, and TL, combined with the pre-trained VGG19 model. For this, they used 1583 healthy samples and 5273 with pneumonia. The proposed model achieved an accuracy of over 99%.

## III. METHODOLOGY

Convolution is the main element in the construction of a CNN. The convolution is composed of several layers of convolutional filters, to which activation functions and optimizers are added to achieve a better result. The work involves a series of steps, starting with the import of the dataset from Kaggle, and then the processing of the dataset is performed. Next, the dataset was trained with the following models: VGG16, VGG19, ResNet50, and Inception-v3 for classification. A total of 5216 chest X-ray images with Pneumonia were used for training and 624 for validation. The following sections describe the above steps in more detail. The phases of this work are shown in Fig. 1.

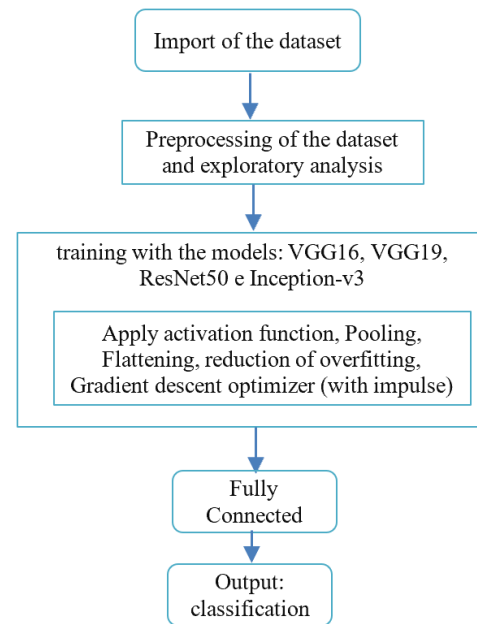

Fig. 1. Diagram of the Process that Follows the Work.

### • Dataset Processing

For preprocessing, a total of 5840 images were used, divided into 5216 chest X-ray images for training and 624 for experimental validation. At this stage, we assigned the parameters and standardized the channel numbers, image dimensions, Batch size, validation size, regulation, and early stopping techniques, and applied the data for training and validation as shown in Fig. 2.

### • Training with the Models

The images are classified into two types: normal and pneumonia, as shown in Fig. 3. In addition, fine-tuning is applied to match the outputs to the classes according to the problem. This consists of four densely connected layers; the first and second are assigned 4096 neurons respectively, the third is reduced to 1000 neurons, and finally, two neurons are used for the output, one for each class. Then the function to generate the model is applied, and with that, the training is started by defining the number of epochs, the batch size, the number of images to train, the number of test images, and the validation steps.

```
# Training
train_image_cogenerator = image_generator.flow_from_directory(
    train_path,
    target_size=image_shape[:2],
    color_mode='rgb',
    batch_size=batch_size,
    class_mode='categorical')

# Test
test_image_cogenerator = image_generator.flow_from_directory(
    test_path,
    target_size=image_shape[:2],
    color_mode='rgb',
    batch_size=batch_size,
    class_mode='categorical')
```

Fig. 2. Training and Test Code.

Fig. 3. Chest X-Ray Images Include Two Types of Images: Normal and with Pneumonia.

#### A. CNN Architecture

CNN is a type of multilayer artificial neural network. As shown in Fig. 4, it is composed of four convolutional layers and among other reduction layers, these are assigned alternately, and at the end, total connection layers are added, similar to a multilayer perceptron network. In the following, each of the layers is discussed.

Fig. 4. CNN Architecture.

#### B. Convolutional Layer

The convolutional layer is in charge of processing the output of the neurons that are connected in the local input areas, calculating the product to be scaled between their weights. One of the functions of this layer is to reduce the dimensions of the images, facilitating their processing. However, this leads to the loss of some information, but the integral part of the image features is preserved since it is retained by the detector [17]. Also, in this layer filters, and attribute detectors were applied to the input matrix. Then a clustering process is applied to obtain our first convolutional layer.

#### C. Activation Functions

The activation function (AF) is the one that returns an output that is generated by the neuron given an input. Each of the layers that make up a neural network has an AF that allows prediction. The AF is divided into two types: linear and nonlinear. The linear function allows the input data to be equal to the output data, it is also applied when linear regression is required as output. Meanwhile, the nonlinear function is applied when you want to classify or when you have categorical outputs.

#### D. Pooling Layer

This layer is applied between the two convolution layers, as input, it receives the feature map formed at the output of the convolution layer; its main function is to reduce the size of the

images while preserving their most resolving features [18]. Finally, in the output of each Pooling layer, the same number of features is obtained as in the output, but considerably compressed [16].

The most commonly used clustering techniques with the different models are Max Pooling and Average Pooling. Also, max Pooling is used to create a feature map with reduced sampling. Average Pooling is used to calculate the average value of the filter size. The application of these two pooling techniques provides the ability to learn invariant features and also acts as a regularizer to reduce the overfitting problem. In addition, they significantly reduce the computational cost and training time of the networks, which are important criteria to consider.

#### E. Fully Connected Layer

This layer allows the feature maps generated from the neural network to be processed in a very facial way. Next, the image to be trained (input) passes through the convolution and clustering layer then enters the fully connected (FC) layer. In this way, the input image continues forward by calculating the weights. An FC neural network is composed of a set of FC layers and, connects to each neuron in a layer. The FC layer also functions as a classifier in the CNN. This layer has a behavior similar to a traditional network. For this case study, the FC layer is implemented through a convolutional operation. The FC layer is FC to the previous layer and, the convolution layer is used to replace the FC layer. Usually, a 1x1 convolution kernel is used. This type of CNN does not include an FC layer; thus, it can be converted into a full convolution of a neural network [19]. In Fig. 2, the first two layers are used to manage the features, while the last two layers are FC, and are used for classification.

#### F. Reducing Overfitting

The dropout technique was applied to reduce the overfitting in the VGG16, VGG19, and ResNet50 models. Dropout is a regulation technique based on the elimination of neurons in the neural network layers that are applied based on the probability given by the distribution [20]. The main objective of this technique is to mitigate the possible occurrence of phenomena known as overfitting. This phenomenon is very characteristic of neural networks and occurs in most training. There are multiple ways to reduce overfitting. Increasing the volume of data is one way to reduce overfitting, however, this leads to an increase in computational resources and training time.

#### G. Transfer Learning

With new advances in CNNs, the margins of error in image classification have been reduced. Models such as ResNet and DenseNet were developed to improve image classification, achieving exceptional performance in large-scale visual recognition. In recent years, TL has been used very successfully in different fields, such as manufacturing processes, medicine, and baggage screening, among others [21][8]. This has allowed eliminating the requirement of large amounts of data for training, it also allows reducing the training time, hence less computational resources. Fig. 5 shows the model from large volumes of data, and how it can be used for smaller data.

Fig. 5. Transfer Learning Behavior.

H. Model Architecture

Four models were trained with the normal and pneumonia images used in this work. The following is a detailed description of the models presented in this work.

1) *VGG16*: VGG16 is a CNN model that achieved 92.7% accuracy among the top five in the ImageNet dataset containing more than 14 million images divided into 1000 categories [22]. The main reasons for using this model are a) its architecture is easy to understand as well as its implementation; b) it contains relatively few convolutional layers: 13 convolutional and 3 dense layers; c) it has been trained with the ImageNet database.

This model starts with an input image of dimensions (224,224,3), as shown in Fig. 6. The first two layers are composed of 64 channels with a filter size of (3,3), then, after a layer (2,2), there are two convolutional layers with 256 channels and with a filter size of (3,3). After that, there are two sets of three convolution layers and a maximum group layer, with 512 channels and filter size (3,3). And so on, successively, until the dense layers are reached.

Fig. 6. Architecture of VGG16.

2) *VGG19*: The VGG19 model is very similar to VGG16, they follow the same logic, with the difference that VGG19 has a greater number of layers, but the objective of both models is common: to filter the image keeping only the discriminant information. The VGG19 model has five blocks as shown in Table I. The first two contain two convolutional layers with filter sizes of 64 and 128; the middle block contains four convolutional layers with a filter size of 256, and the last two contain two convolutional layers with a filter size of 512 each [23].

This model, in its first phase, freezes the entire network, except for the fully connected layer. In a very similar way, as in the VGG16 model, the same connected layer has been used in the VGG19 model. Then, in the second layer, the last four convolutional layers are unfrozen to learn new features. The architecture of the model is shown in Table I.

TABLE I. VGG19 MODEL ARCHITECTURE

Type	N° Filters / Parameters			
2 Conv2D	64	64		
Max Pool	N/A			
2 Conv2D	128	128		
Max Pool	N/A			
4 Conv2D	256	256	256	256
Max Pool	N/A			
4 Conv2D	512	512	512	512
Max Pool	N/A			
4 Conv2D	512	512	512	512
Max Pool	N/A			
3 layers Fully-Connect	4096	4096	1000	
Softmax	N			

3) *ResNet50*: ResNet is classified in the residual networks category. It was developed by Microsoft Research and managed to win first place in the IRSVRC 2015 competition, obtaining a 3.57% margin of error in the top five [12]. It is mainly used for image classification. In this type of network, instead of waiting for the layers to conform to the desired mapping, it is left to conform to a residual mapping. Residual learning is adopted for every certain number of stacked layers. Formally, a building block described in equation 1.1 is considered.

$$y = F(x, w_i) + x \tag{1.1}$$

Where x is the input y, y is the output of the considered layer group, and F (X, Wi) represents the residual mapping to be learned. There are two types of blocks for residual networks [24]. The building block is composed of two convolutional layers with a 3x3 size filter; and the bottleneck building block is composed of three convolutional layers, the first and third layers with 1x1 filters, the second with a 3x3 filter as can be seen in Fig. 7.

Fig. 7. Representation of the Building Block and the Bottleneck Building Block.

4) *Inception-v3*: Inception -v3, is a deep CNN with 42 layers, developed by Google, has a high image classification performance, and is integrated by: convolution layers, avg Pool, MaxPool, Concat, DropOut, Fully Connected and softmax, as shown in Fig. 8. The network has multiple versions from Inception -v1, Inception -v2 and Inception -v4, each version has been presenting significant improvements for

a better adaptation of the model [25]. This version is much more complex to train; it takes more time, even days. However, this problem is solved with TL [26], since the last layer of the model is preserved for the new classes and, the Inception-v3 model is undone by removing the last layer through the TL technique.

Fig. 8. Architecture of Inception-v3.

#### IV. RESULTS AND DISCUSSIONS

This section presents the results of the four models trained and validated with a dataset of 5840 chest X-ray images with pneumonia and, is organized as follows: 5216 chest X-ray images for training and 624 images for model validation. The same processing technique, the same amount of data, and the same number of partitions were used for all four models. With the predicted values, the confusion matrix was constructed for all models, where the predictions are synthesized and compared with the real values. For example, Fig. 9 shows the confusion matrix of the VGG19 model, where the true positives (correct positive predictions), true negatives (correct negative predictions), false positives (incorrect positive prediction), and false negatives (incorrect negative prediction) can be observed.

Similarly, to measure the performance of each of the models, the Accuracy function was used to evaluate the overall correct predictions (true positives and true negatives) among the total predictions (true positives, false positives, true negatives and false negatives). Loss, this function calculates the incorrectly classified predictions (false positives and false negatives), among the total predictions (true positives, false positives, true negatives, and false negatives). This gives us a clearer picture of how well the model is performing. Recall allows us to determine how many of the predicted positives were found to be correct.

The recall or sensitivity to measure the quality of a machine learning model is extremely important in classification tasks. Recall, which is responsible for calculating the percentage of hits, is also known as sensitivity. F1-Score allows the combining of both Accuracy and Recall into a single weighted measure. If the F1-Score is high, this means that false positives and false negatives are low.

Fig. 9. Confusion Matrix of the VGG19 Model.

Graphs were also constructed to evaluate the performance of each of the models as the epochs developed. As shown in Fig. 10, 11, 12, and 13, the performance of the models presented in this work is analyzed below.

Fig. 10, 11, 12, and 13 show a comparison between Accuracy and loss, i.e. the error with training and validation data. The error with the training data is much smaller as we increase the number of epochs. In contrast, in the validation data, Loss differs a lot from its real value as the number of epochs increases, thus it is very unstable. Regarding the accuracy, the blue line indicates that the accuracy percentage of the model is very close to one as the number of epochs increases, unlike the accuracy in the validation data, where it is very high for some cases.

Fig. 10. Accuracy and Data Loss of the VGG16 Model.

Fig. 11. Accuracy and Data Loss of the VGG19 Model.

Fig. 12. Accuracy and Data Loss of the ResNet50 Model.

Fig. 13. Accuracy and Loss of Data from Inception-v3.

In the evaluation of the results, the two types of patients were taken into account: normal patients and patients with pneumonia. The confusion matrix in Table II shows the error generated by each model. This helps us to know the performance of each model in the classification of the validation images. Table II shows the confusion matrix of the four CNN models.

TABLE II. CONFUSION MATRIX OF THE MODELS UNDER STUDY

Model	Predicted	
VGG19	71	194
	40	319
VGG19	73	189
	41	321
ResNet50	63	178
	18	365
Inception-v3	86	144
	25	369

Concerning the performance values for each model, the recall and F1-Score are calculated based on the above-described confusion matrices. A comparison of the training and data validation results for each model is presented below.

With the results in Tables III and IV, it is resolved that the VGG16 model in training managed to obtain an accuracy of 62.5% and a loss of 41%, respectively. Similarly, for the VGG19 model, the level of accuracy in training shows a slight improvement, reaching 63.1% and a 41% loss in validation. With the ResNet50 model, the training accuracy shows a significant improvement, reaching 68.6% accuracy, and a 37% loss in validation. Finally, the InceptionV3 model evidences a better performance, achieving 72.9% accuracy in training and a 23% loss in validation. Therefore, it can be concluded that the InceptionV3 model has outperformed the VGG16, VGG19, and ResNet50 models, given that it has achieved the best values in each performance measure, both in accuracy and F1-score, demonstrating that it is a coherent and effective model obtaining a score of over 93% in the recall, although ResNet50 also obtained an excellent recall score of 95.3%. Inceptionv3 is superior in accuracy with 72.9% and F1-Score with 82%. Models VGG16, VGG19, and ResNet50 did not achieve the best score, as can be seen in Fig. 10, 11, and 12, which show the accuracy and loss value of each model.

TABLE III. VALUES OF MODEL PERFORMANCE MEASURES

Model	Accuracy	Recall	F1
VGG16	62.5%	88.9%	73.4%
VGG19	63.1%	88.7%	73.8%
ResNet50	68.6%	95.3%	79.8%
InceptionV3	72.9%	93.7%	82%

TABLE IV. PRECISION AND LOSS VALUES FOR EACH MODEL

Model	Training		Validation	
	Accuracy	loss	Accuracy	Loss
VGG16	70%	31%	62.5%	41%
VGG19	72%	32%	63.1%	39%
ResNet50	69%	36%	68.6%	37%
InceptionV3	83%	24%	72.9%	23%

In the TL models, the confusion matrices represent the margin of error in the classifier models. The results obtained from the training and validation data are shown in Table IV. Note that models VGG16, VGG19, and ResNet50 show relatively high overfitting concerning InceptionV3 because the difference between the accuracy obtained in the training and the accuracy obtained with the validation data is very noticeable. These three models have high losses and their accuracy is also low, therefore, these three models have poor performance, and little efficiency could be improved or trained with more data volume. In general, the VGG19 model performs better than the VGG16 model; the ResNet50 model outperforms the VGG16 and VGG19 models in all metrics (accuracy, recall, and F1-score), respectively. The accuracy obtained in the training and the loss value can be seen in Fig. 10, 11, and 12, where the variations of the accuracies are shown according to the number of epochs that are increased. The models used in this work correspond to deep CNNs, each model with a certain number of layers. Their accuracy can improve with a higher volume of data for training.

## V. CONCLUSION

This paper presents four high-performance CNN models for application in real medical cases. All four models have high training accuracy rates. Recall is an important factor in measuring performance since it is important to reduce the number of false negatives in the image processing to be trained. While the ResNet50 model achieved the best recall of 95.3%, the Inceptionv3 model also achieved a recall of 93.7%, and the two models with the best F1-Score of 79.8% and 82% respectively.

The Inceptionv3 model is the best performing model in terms of accuracy and F1 score; therefore, it is the model that achieved the highest training efficiency. This model can be used by clinicians to detect pneumonia early in both children and adults. This model can be taken to an automated process to process a large number of X-ray images automatically and provide accurate diagnostic results, helping healthcare facilities to provide better patient services and thus reduce the mortality rate from this disease.

For future work, they seek to improve the accuracy of the models with new tuning parameters and optimizers. In [27] they presented a model based on Xception for the detection of breast cancer in real-time. The InceptionV3 model, which is the best performing model in this work, can be extended to classify other diseases as [27] has done with good results. The performance of the models can be improved with a larger amount of data.

# A Monadic Co-simulation Model for Cyber-physical Production Systems

Daniel-Cristian Crăciunean  
Computer Science and Electrical Engineering Department  
Lucian Blaga University of Sibiu  
Sibiu, Romania

**Abstract**—The production flexibility required by the new industrial revolutions is largely based on heterogeneous Cyber-Physical Production Systems models that cooperate with each other to perform complex tasks. To accomplish tasks at an acceptable pace, CPPSs should be based on appropriate cooperation mechanisms. To this end a CPPS must be able to provide services in the form of functionalities to other CPPSs, and also to use functionalities of other CPPSs. The cooperation of two CPPS systems is done by co-simulating the two models that allow the partial or total access of the functionalities of one system, by the other system. Requests from one CPPS to another CPPS create connection moments of the two models that can only be performed in certain states of the two models. Also, the answers to these requests create connections between the two models in other subsequent states. Optimal aggregation of the behaviors of the two models, by co-simulation, is essential because otherwise it can lead to very long waiting times and can cause major problems if not done correctly. We will see in this paper that the behavior of such a simulation model can be represented by a category, and the co-simulation of two models can be defined by a monad determined by two adjoint functors between the simulation categories of the two models.

**Keywords**—Models; metamodels; co-simulation; adjoint functors; monads; cyber-physical production systems

## I. INTRODUCTION

The new industrial revolutions ("Industry 4.0", "Industry 5.0"), respond to the needs of individualization of production by the widespread introduction of Cyber-Physical Production Systems (CPPS) as central elements in making production flexible at all levels. In essence, CPPSs are complex systems made up of heterogeneous entities and subsystems that cooperate with each other depending on the context in which they evolve at all levels of production.

CPPSs are composable systems, that is, they are systems of systems. The composition operation is determined by the interactions between the subsystems in all the phases of the life cycle of the production process. CPPSs are of overwhelming importance in the production process because they implement the interaction between physical and cybernetic components in distributed networks and therefore represent the fusion between the real and the virtual world as a whole.

In this context, it is obvious the importance of approaches for the optimal design and implementation of CPPS. Modeling and simulation are the most common approaches in the process of designing these systems. Modeling makes it possible to

simulate and analyze production processes as well as make decisions before the actual construction of the manufacturing line [7] [8]. Also, after the construction of the production line, the models can be used for its optimization and diagnosis.

The primary artifact in the process of designing and implementing a CPPS is the model. In such a model the emphasis falls, most of the time, on the interaction and cooperation between the heterogeneous components of the system, and not on the internal functionality of these components [20]. Therefore, classical approaches, from systems theory, cannot satisfactorily respond to these interaction modeling requirements [9,22]. Our approach is motivated by the finding of a deficit of sufficiently strong mathematical mechanisms to be an adequate support for such models [14]. This vacuum of remarkable results is even more accentuated in the field of coupling simulators in dynamic structure scenarios at the level of states [21].

We will see further in this paper that category theory, which, unfortunately, is not used enough in modeling, provides all the ingredients needed to specify such models. Thus, in section 2 we will specify a categorical model of a CPPS, in section 3 we will specify the behavior of a model through a category we call Model Simulation Category, and in section 4 we will see that the co-simulation of two models can be defined by a monad determined by two adjoint functors between the simulation categories of the two models. The paper ends with conclusions.

## II. CATEGORICAL MODELING OF CPPS

An essential phase of the process of developing a model is the conceptualization of the domain [4]. A model is an artifact recognized by an observer as an abstract representation of a real system [1]. This artifact is a syntactic and semantic specification of the real system from the point of view pursued.

The conceptualization of the modeling domain begins with the identification of the generic atomic concepts of the domain that will represent classes of entities in the modeling domain [5]. The state of these atomic concepts is generally specified by the values of some associated attributes. This process continues with the specification of the interaction rules of these atomic concepts in models. We will consider in the following that the models are structured as graphs that have as nodes atomic concepts and as arcs interactions between these atomic concepts. The elementary components of the modeling domain will become atomic concepts in models. The behavior of

atomic concepts is dependent on the state in which they are and the context in which they evolve, i.e., the graph structure in which they are integrated.

The specification of a model involves two specification mechanisms, namely a model specification paradigm through the hierarchical assembly of components and a mathematical model that mimics the behavior of the system. The first mechanism must reflect the static dimension of the model and the second the behavioral dimension of it. Therefore, both the syntax and the semantics of a model are characterized by two dimensions, namely a static dimension and a behavioral dimension.

### A. The Static Dimension of CPPS Models

To specify the syntax of the static dimension of CPPS models we use the categorical sketch (Fig. 1.) which is defined as a tuple  $\mathcal{S}=(\mathcal{G}, \mathcal{C}(\mathcal{S}))$ , where  $\mathcal{G}$  is a graph with typed nodes and arcs, and  $\mathcal{C}(\mathcal{S})$  is a set of constraints on the elements of the graph that specify in categorical terms the conditions that a model must meet. Thus, the categorical sketch becomes a metamodel of the static dimension of our model.

The atomic concepts identified in the conceptualization phase of the domain become nodes of the graph  $\mathcal{G}$  of this sketch. Thus, the metamodel that specifies the static dimension of CPPS models is the graph  $\mathcal{G}$ , which respects the constraints  $\mathcal{C}(\mathcal{S})$ , and which has as nodes the atomic concepts and as arcs the rules of aggregation of these concepts in models.

Therefore, in the metamodel  $\mathcal{S}$  of the static dimension of CPPS models,  $\mathcal{G}$  is a graph whose nodes specify the types of atomic concepts they represent and whose arcs specifies the types of connections between these concepts.

The  $(\mathcal{S})$  component is defined at the metamodel level by a diagram predicate signature [13,15], which maps a set of predicates to a set of special graphs called shape graph arity. These special graphs, called shape graph arity, are then mapped by a set of functors, called diagrams, to the components of the graph of the sketch and therefore receive the types of these components. The set of models of the sketch  $\mathcal{S}$  is represented by the set of functors defined on the graph  $\mathcal{G}$  of the sketch  $\mathcal{S}$ , with values in the category of sets and functions (Set), and which respects the constraints defined by  $\mathcal{C}(\mathcal{S})$  (Fig. 1.). These models are, from a syntactic point of view, also graphs that inherit from the graph of the sketch the type of components.

The components, of the graph  $\mathcal{G}$  of the sketch  $\mathcal{S}$ , are endowed with attributes that are mapped to data domains. The semantics of the static dimension of a model is given by the graph structure of the model and by the values of the attributes of the atomic components.

In our approach, the set of static models represents the set of states in the behavioral model. Such a state is characterized by the graph structure of the model and the values of the attributes.

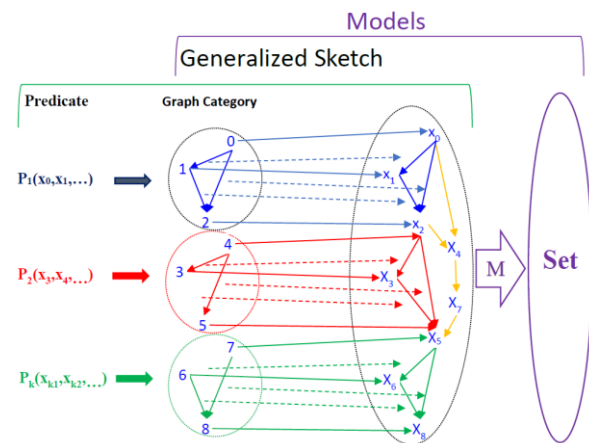

Fig. 1. Generalized Sketch and Models.

### B. The Behavioral Dimension of CPPS Models

The behavior of a CPPS is shaped by the multitude of states in which the CPPS model can be found and by the multitude of transitions that ensure the transition from one state to another. In our approach, the set of states is represented by the set of static models and the set of transitions by a set of transformations of the model that we have called behavioral rules. We associated these behavioral rules with the dynamic components of the model, such as workstation or transport machine components.

We defined the behavioral rules by a tuple  $\tau=(p,\sigma)$ , formed by a graph transformation  $p$  and a behavioral action  $\sigma$ . A behavioral action  $\sigma$ , is a mathematical function that modifies the values of the attributes associated with the graph components in a certain area of the graph structure of the static model. The role of the graph transformation  $p$  is to locate the definition area of the behavioral action and to transform the graph structure from this area of the graph model into another graph structure, provided that the resulting graph structure is also a static model of the categorical sketch.

The syntax of a behavioral rule  $\tau$ , is composed of the syntax of the two components, namely the syntax of the graph transformation  $p$ , and the syntax of the behavioral action  $\sigma$ .

Syntactically a graph transformation is a tuple  $p = (L, R)$ , where  $L$  is a source graph to be transformed and  $R$  is the target graph in which the graph  $L$  is to be transformed. To define the semantics of a graph transformation we used the categorical mechanism called double-pushout (DPO) [16,17,18,19]. The DPO mechanism defines a graph transformation as a span  $p=(L\leftarrow K\rightarrow R)$ , where  $K$  is a common part of the graphs  $L$  and  $R$ , and therefore there are two total inclusion morphisms  $p_L:K\rightarrow L$  and  $p_R:K\rightarrow R$ .

We defined the syntax of a behavioral action by a signature of a behavioral rule that maps a mathematical function to the components of the  $L$  and  $R$  graphs of the graph transformation. Thus, a signature of a behavioral rule is a tuple  $\sigma=(p,C_L,Act,C_R,\alpha)$ , where  $p$  is a graph transformation,  $Act$  is a mathematical function,  $C_L$  is a precondition,  $C_R$  is a postcondition and  $\alpha:\{C_L,Act,C_R\}\rightarrow p$  is an application that

maps the parameters of the Act action and of the preconditions  $C_L$  and  $C_R$  to the nodes of the graphs  $L$  and  $R$ .

The  $L$  and  $R$  components of the graph transformation play in this case the role of shape graphs for the signature of the behavioral action and will be mapped, by means of diagrams, to the graph components of the categorical sketch, mechanism by which they will receive the types of these components. The semantics of behavioral actions will be defined by mathematical functions that recalculate the values of the attributes associated with the graph components  $L$  and  $R$ .

The application of a behavioral rule is preceded by the finding of a total morphism, called a match, from shape graph  $L$  to the static model. If a match is found, the precondition  $C_L$  is checked. If this precondition is verified, the corresponding graph transformation is performed using the DPO algorithm and then the Act action is executed. Finally, the postcondition is checked. If the post-condition is not verified, the behavioral rule cannot be applied and, therefore, we will have to cancel all the effects produced by the partial execution of the behavioral rule. As we can see, a behavioral rule must be applied by an indivisible instruction. We must also note that the behavioral rule must be endogenous, i.e., it must transform a static model of the categorical sketch into another static model of the same sketch. It is obvious that the application of behavioral rules can be done in parallel as long as this application is not conflicting [Ehrig2015].

### III. MODEL SIMULATION CATEGORY

The problem of CPPS optimization is a complex, multi-objective problem, which involves dynamic behavior accompanied by elements of their uncertainty, and therefore cannot be solved by optimization models from classical mathematics. The saving solution to this problem is simulation, which allows the study of the behavior of these complex systems in order to optimize them and eliminate deficiencies from the design phase.

We will understand by simulation the process of imitating the behavior of a materialized system through a multitude of possible trajectories through which it can evolve. Therefore, the simulation can be described as a language on the set of states through which the system can pass. We define an execution of the behavioral model as a word of this language.

In our approach, a state of the behavioral model is represented by a static model of the categorical sketch  $\mathcal{S}=(\mathcal{G},\mathcal{C}(\mathcal{S}))$ , and the transition between these states is made by the behavioral rules. A static model of the sketch  $\mathcal{S}$  is the image of a functor  $\mathfrak{F}:\mathcal{S}\rightarrow\text{Set}$  that maps the nodes of the typed graph  $\mathcal{G}$  of the sketch to sets of components in the category  $\text{Set}$  and the arcs of the graph  $\mathcal{G}$  to functions in  $\text{Set}$ . Next, we will call the image of the sketch  $\mathcal{S}$  by a functor  $\mathfrak{F}$ , instance and we will also denote it with  $\mathfrak{F}$ . The component  $\mathcal{C}(\mathcal{S})$  of the sketch imposes restrictions on the image  $\mathfrak{F}(\mathcal{S})$  in  $\text{set}$ , which will also be respected. Each node  $x$  of the graph  $\mathcal{G}$  represents a type of component of the system, and  $\mathfrak{F}(x)$  is a set of components of type  $x$ . We will consider that these components also contain values for the associated attributes. Also, each arc of the graph  $\mathcal{G}$ , represents an operator of the sketch and is mapped to a

function in the  $\text{Set}$  category. These functions are constitutive elements of the constraints  $(\mathcal{S})$ .

If we have an instance  $\mathfrak{F}_1$  and a behavioral rule  $\tau$ , which transforms  $\mathfrak{F}_1$  into  $\mathfrak{F}_2$ , then  $\tau$  must be endogenous, i.e.,  $\mathfrak{F}_2$ , must also be a static model of the same sketch  $\mathcal{S}$ , this is a condition that must be respected by any behavioral rule. We will denote this by  $\mathfrak{F}_1 \xrightarrow{\tau} \mathfrak{F}_2$ .

With these notations, an execution of a behavioral model, in an initial state  $\mathfrak{F}_0$ , is a chain of behavioral rules:  $\mathfrak{F}_0 \xrightarrow{\tau^0} \mathfrak{F}_1 \xrightarrow{\tau^1} \dots \mathfrak{F}_n \xrightarrow{\tau^n} \dots$ , where  $\mathfrak{F}_k$ ,  $k \geq 0$  are instances and  $\tau^k$ ,  $k \geq 0$  are behavioral rules.

We can introduce a partial operation of composing two behavioral rules. If we have two behavioral rules  $\tau_1=(p_1,\sigma_1)$  and  $\tau_2=(p_2,\sigma_2)$  then the behavioral rule  $\tau=\tau_1 \circ \tau_2$  is defined by composing the components  $(p_1 \circ p_2, \sigma_1 \circ \sigma_2)$ . Since,  $\sigma_1$  and  $\sigma_2$  are mathematical functions, their composition is specific to these functions. For graph transformations, we have a theoretical result that demonstrates that any two sequential graph transformations can be composed into a single equivalent graph transformation that accumulates the effect of both transformations.

Therefore, the set of behavioral rules is endowed with a composition operation. Obviously, this composition operation is associative and to the set of behavioral rules we can add the identity transformation which does nothing. It follows from these considerations that the set of instances together with the set of behavioral rules form a category that we call category of instances and behavioral rules (CIBR). The objects of this category are instances and its arrows are behavioral rules.

Now we can define an execution of a behavioral model, also as the image of the category  $\Omega: 0 \xrightarrow{\alpha_0} 1 \xrightarrow{\alpha_1} \dots k \xrightarrow{\alpha_k} \dots$  through a functor  $\Gamma:\Omega \rightarrow \text{CIBR}$  that specifies the evolution of the model over time:  $\Phi(i)=\mathfrak{F}_i$  for all  $i \geq 0$ ;  $\Phi(\alpha_i)=\tau^i$  for all  $i \geq 0$  as can be seen in Fig. 2. Any execution of a model starting from an initial state  $\mathfrak{F}_0$  produces a simulation trace that is a word in a language defined on the set  $\text{ob}(\text{CIBR})$  of objects of the CIBR category, through the set of behavioral rules.

Thus, if  $\mathfrak{F}=\text{ob}(\text{CIBR})$  then the set of simulation traces, relative to the initial state  $\mathfrak{F}_0$ , form a language  $L(\mathfrak{F}) \subseteq \mathfrak{F}^*$  defined as follows:  $L(\mathfrak{F})=\{ \mathfrak{F}_0 \mathfrak{F}_1 \dots \mathfrak{F}_n \in \mathfrak{F}^* \mid \mathfrak{F}_k = \tau(\mathfrak{F}_j) \text{ for } k \geq 1, k \geq j \geq 0 \text{ and } \tau \text{ is a behavioral rule} \}$ .

If  $L(\mathfrak{F})$  is the language of simulation traces over the vocabulary  $\mathfrak{F}=\text{ob}(\text{CIBR})$ , and  $\beta=\mathfrak{F}_0 \mathfrak{F}_1 \dots \mathfrak{F}_n \in L(\mathfrak{F})$ , we will denote by  $v(\beta)$  the set of instances involved in this trace,  $v(\beta)=\{ \mathfrak{F}_0, \mathfrak{F}_1, \dots, \mathfrak{F}_n \}$ .

We now define a subcategory of the CIBR category, which we call model simulation category (MSC), which has the objects  $\text{ob}(\text{MSC})=\{ \mathfrak{X} \mid (\exists) \beta \in L(\mathfrak{F}) \text{ so that } \mathfrak{X} \in v(\beta) \}$ , and as arrows the corresponding behavioral rules. The PSC category contains all the trajectories on which the CPPS model can evolve. We denote this category by  $\text{MSC}(\mathfrak{F})$ .

#### IV. MONADIC CO-SIMULATION

The essential role of CPPS in the production processes is to make these processes more flexible in order to realize a lot of individualized products or in small batches, adapted to the customers' requirements. These CPPS must also cover many aspects of the production process. Therefore, there cannot be a single CPPS, which can deal with this variety of requirements. In order to carry out the tasks at an acceptable pace, the CPPS must contain adequate cooperation mechanisms.

A CPPS is a fundamental component of a smart factory and therefore must monitor the status of all participants in the production process and be able to automatically react to any event in order to achieve the objectives. For this purpose, a CPPS must be able to offer services, in the form of functionalities to other CPPSs, and also to use functionalities of other CPPSs.

The cooperation of two CPPS systems is done by co-simulating the two models, which allows partial or total access to the functionalities of one system, by the other system. The co-simulation control is realized by an orchestrator that coordinates the system components according to a co-simulation scenario.

However, in order to achieve a good cooperation, each CPPS must know about the functionalities of the other CPPSs with which it collaborates and how to extract and use the knowledge from the specifications of these CPPSs with which it cooperates in order to achieve the goal. This means that it must encapsulate knowledge about the state and evolution of the other CPPS with which it could cooperate.

The requests of a CPPS to another CPPS create moments of connection of the two models that can only be carried out in certain states of the two models. Also, the answers to these requests create connections between the two models between other subsequent states. This type of interaction between two models is realized between the simulation categories of the two models through co-simulation. The optimal aggregation of the behaviors of the two models, through co-simulation, is essential because, otherwise, it can lead to very long waiting times and can cause major problems if it is not done correctly [25]. We will further introduce a categorical modeling model of this type of connection based on the notion of monad specified by the adjunction of two functors.

On the set  $\mathfrak{S} = \text{ob}(\text{MSC})$ , we introduce a relation  $\preceq$ , defined as follows,  $\mathfrak{S}_i \preceq \mathfrak{S}_j$ , if and only if in the category  $\text{MSC}(\mathfrak{S})$ , there is a path from  $\mathfrak{S}_i$  to  $\mathfrak{S}_j$ , i.e. if  $\mathfrak{S}_j$  can be obtained from  $\mathfrak{S}_i$  through the successive application of a series of behavioral rules. Obviously, this relation is a partial preorder relation and therefore the set  $\mathfrak{S}$  is a preordered set in reference to this relation. We observe that if  $L(\mathfrak{S})$  is the language of simulation traces over the vocabulary  $\mathfrak{S} = \text{ob}(\text{MSC})$ , then all simulation traces  $\beta = \mathfrak{S}_0 \mathfrak{S}_1 \dots \mathfrak{S}_n \in L(\mathfrak{S})$ , respect the condition:  $\mathfrak{S}_i \preceq \mathfrak{S}_j$  if and only if  $i \leq j$ .

We now consider two model simulation categories  $\text{MSC}_1, \text{MSC}_2$  with  $\mathfrak{S} = \text{ob}(\text{MSC}_1), \mathfrak{L} = \text{ob}(\text{MSC}_2)$ . The connection points between the states of the two models, relative to the first model, can be specified by two monotone functions; a request function  $\varphi: \mathfrak{S} \rightarrow \mathfrak{L}$  and a response function  $\psi: \mathfrak{L} \rightarrow \mathfrak{S}$ . To ensure a correct collaboration between the two models, without deadlock situations in the co-simulation flow, it is necessary that any two simulation traces  $\beta_1 = \mathfrak{S}_0 \mathfrak{S}_1 \dots \mathfrak{S}_n \in L(\mathfrak{S})$  and  $\beta_2 = \mathfrak{L}_0 \mathfrak{L}_1 \dots \mathfrak{L}_m \in L(\mathfrak{L})$ , where  $m, n \geq 0$ , to respect the conditions: for each pair of states  $(\mathfrak{S}_i, \mathfrak{L}_j), \mathfrak{S}_i \in v(\beta_1), \mathfrak{L}_j \in v(\beta_2)$  with the property,  $\mathfrak{L}_j = \varphi(\mathfrak{S}_i)$ , there is a state  $\mathfrak{L}_k \in v(\beta_2)$ , such that  $\varphi(\mathfrak{S}_i) \preceq \mathfrak{L}_k$ , and  $\mathfrak{S}_i \preceq \psi(\mathfrak{L}_k)$ . This condition is necessary to avoid deadlock situations, in which the two simulations block each other, because each is waiting for a response from the other.

This type of cooperation between two models in the simulation process requires, therefore, that the functions  $\varphi$  and  $\psi$  form a Galois connection [24]. A Galois connection between the sets  $\mathfrak{S}$  and  $\mathfrak{L}$  is a pair of monotone mappings  $\varphi: \mathfrak{S} \rightarrow \mathfrak{L}$  and  $\psi: \mathfrak{L} \rightarrow \mathfrak{S}$  with the property:  $\varphi(\mathfrak{S}_i) \preceq \mathfrak{L}_j$  if and only if  $\mathfrak{S}_i \preceq \psi(\mathfrak{L}_j)$  where  $\mathfrak{S}_i \in \mathfrak{S}$  and  $\mathfrak{L}_j \in \mathfrak{L}$ . The two applications,  $\varphi$  and  $\psi$  are the left adjunct and, respectively, the right adjunct of the Galois connection.

A theoretical result [23,24] tells us that the condition in the above definition of the Galois connection can be replaced by the condition:  $\mathfrak{S}_i \preceq \psi(\varphi(\mathfrak{S}_i))$  and  $\varphi(\psi(\mathfrak{L}_j)) \preceq \mathfrak{L}_j$ . We will see, next, that this condition has a generalization in category theory and is called adjunction.

Since  $\text{MSC}_1$  and  $\text{MSC}_2$  are categories, we can replace the applications  $\varphi$  and  $\psi$  with two adjoint functors,  $\Phi: \text{MSC}_1 \rightarrow \text{MSC}_2$  and  $\Psi: \text{MSC}_2 \rightarrow \text{MSC}_1$ , and thus obtain an adjunction between two functors, where  $\Phi$  and  $\Psi$  are the left adjunct and, respectively, the right adjunct of the adjunction. The adjunction of two functors  $\Phi$  and  $\Psi$  is denoted by  $\Phi \dashv \Psi$ , where  $\Phi$  is the left adjunct and  $\Psi$  is the right adjunct. The necessary and sufficient condition for two functors to be adjoint is that between the two-variable functors  $\text{Hom}(\Phi, -): \text{MSC}_1 \rightarrow \text{Set}$  and  $\text{Hom}(-, \Psi): \text{MSC}_2 \rightarrow \text{Set}$ , there must be a bijective natural transformation, i.e. we have the natural isomorphism  $\text{Hom}(\Phi, -) \cong \text{Hom}(-, \Psi)$ , where we have denoted with "-" the place of a variable. This condition generalizes the condition from the Galois connection. In other words, in the  $\text{MSC}_1$  and  $\text{MSC}_2$  categories, for each pair of objects  $\mathfrak{S}_p \in \mathfrak{S}$  and  $\mathfrak{L}_q \in \mathfrak{L}$ , there is a behavioral transformation from  $\Phi(\mathfrak{S}_p)$  to  $\mathfrak{L}_q$  in the  $\text{MSC}_2$  category if and only if there is a transformation from  $\mathfrak{S}_p$  to  $\Psi(\mathfrak{L}_q)$  in the  $\text{MSC}_1$  category. But this condition is exactly the necessary and sufficient condition to be able to carry out a

co-simulation without deadlock on all the simulation traces defined by the  $MSC_1$  and  $MSC_2$  categories.

Therefore, the necessary and sufficient condition for the functors  $\Phi$  and  $\Psi$  to form an adjunction is for the natural isomorphism  $\text{Hom}(\Phi(-),-) \cong \text{Hom}(-,\Psi(-))$  to exist. From here it follows that in order to define the functors  $\Phi$  and  $\Psi$  so that they form an adjunction  $\Phi \dashv \Psi$ , it is enough to define a one-to-one relationship between the traces from the categories of simulation models  $MSC_1$  and  $MSC_2$ . This correspondence between the simulation traces is reduced to a bijective natural transformation defined on components  $f: \text{Hom}(\Phi \mathfrak{S}_p, \mathfrak{L}_q) \rightarrow \text{Hom}(\mathfrak{S}_p, \Psi \mathfrak{L}_q)$ , between the behavioral rules of the two behavioral models. Thus if  $\tau_2 \in \text{Hom}(\Phi \mathfrak{S}_p, \mathfrak{L}_q)$  then  $\Psi(\tau_2) = f^{-1}(\tau_2)$ , and if  $\tau_1 \in \text{Hom}(\mathfrak{S}_p, \Psi \mathfrak{L}_q)$ , then  $\Phi(\tau_1) = f(\tau_1)$ . Also, if in the state  $\mathfrak{S}_p \in \mathfrak{S}$  of the  $MSC_1$  model, we have a request to the  $MSC_2$  model, which is in the state  $\mathfrak{L}_r$ , and we need an answer in the  $\mathfrak{S}_r \in \mathfrak{S}$  state, from the  $MSC_2$  model, in the  $\mathfrak{L}_q \in \mathfrak{L}$  state, then we define  $\Phi \mathfrak{S}_p = \mathfrak{L}_r$  and  $\Psi \mathfrak{L}_q = \mathfrak{S}_r$ .

In the context of two adjoint functors we can define two special natural transformations called unit and counit. [10, 12]. For the two adjoint functors  $\Phi \dashv \Psi$ , there is a natural transformation  $\eta: id_1 \rightarrow \Phi \circ \Psi$ , where  $id_1$  is the identity functor from the  $MSC_1$  category, so that for any object  $\mathfrak{S}_k \in \mathfrak{S}$  and  $\mathfrak{L}_1 \in \mathfrak{L}$  and any arrow  $\tau_1^{kt}: \mathfrak{S}_k \rightarrow \Psi(\mathfrak{L}_1) = \mathfrak{S}_t$ , there is a unique arrow  $\tau_2^{tl}: \Phi(\mathfrak{S}_k) = \mathfrak{L}_t \rightarrow \mathfrak{L}_1$  so that the diagram in Fig. 3 commutes [10, 12]. The natural transformation  $\eta$  is called unit adjunction.

Also, the adjunction property of the functors  $\Phi$  and  $\Psi$  assumes the existence of a dual natural transformation  $\varepsilon: \Psi \circ \Phi \rightarrow id_2$ , where  $id_2$  is the identity functor from the category  $MSC_2$ , so that for any arrow  $\tau_2^{tl}: \Phi(\mathfrak{S}_k) = \mathfrak{L}_t \rightarrow \mathfrak{L}_1$ , there is a unique arrow  $\tau_1^{kt}: \mathfrak{S}_k \rightarrow \Psi(\mathfrak{L}_1) = \mathfrak{S}_t$ , so that the diagram in Fig. 4 commutes. The natural transformation  $\varepsilon$  is called counit adjunction.

The adjunction of two functors  $\Phi \dashv \Psi$  is unambiguously specified by the tuple  $(\Phi, \Psi, \eta, \varepsilon)$ , where  $\eta$  is the adjunction unit and  $\varepsilon$  is the adjunction counit.

The adjunction unit  $\eta: id_1 \rightarrow \Phi \circ \Psi$  is also called the insertion of generators and has the role of transforming each object  $\mathfrak{S}_k \in \mathfrak{S}$  into the format of an object  $\Psi(\Phi(\mathfrak{S}_k))$ . This function is executed in the  $MSC_1$  model and can be calculated on components starting from the adjunction condition which says that there is a natural isomorphism  $f: \text{Hom}(\Phi \mathfrak{S}_p, \mathfrak{L}_q) \rightarrow \text{Hom}(\mathfrak{S}_p, \Psi \mathfrak{L}_q)$ . If in this natural isomorphism we make  $\mathfrak{L}_q = \Phi \mathfrak{S}_p$ , then we have the natural isomorphism  $f: \text{Hom}(\Phi \mathfrak{S}_p, \Phi \mathfrak{S}_p) \rightarrow \text{Hom}(\mathfrak{S}_p, \Psi \Phi \mathfrak{S}_p)$  and therefore we can calculate  $\eta$  on the  $\mathfrak{S}_p$  component, according to the formula:  $\eta_{\mathfrak{S}_p} = f(id_{\Phi \mathfrak{S}_p})$  where  $id_{\Phi \mathfrak{S}_p}: \Phi(\mathfrak{S}_p) \rightarrow \Phi(\mathfrak{S}_p)$  is the identity functor in  $MSC_2$ .

Similarly, we have the natural isomorphism  $f: \text{Hom}(\Phi \Psi \mathfrak{L}_q, \mathfrak{L}_q) \rightarrow \text{Hom}(\Psi \mathfrak{L}_q, \Psi \mathfrak{L}_q)$  and therefore we can also calculate the adjunction counit  $\varepsilon: \Psi \circ \Phi \rightarrow id_2$  on components according to the formula:  $\varepsilon_{\mathfrak{L}_k} = f^{-1}(id_{\Psi \mathfrak{L}_k})$  where  $id_{\Psi \mathfrak{L}_k}: \Psi(\mathfrak{L}_k) \rightarrow \Psi(\mathfrak{L}_k)$  is the identity functor in  $MSC_1$ . This function is executed in the  $MSC_2$  model and represents, in our

case, the process of generating the response of the  $MSC_2$  model to the request of the  $MSC_1$  model.

The adjoint of two functors defined by the tuple  $(\Phi, \Psi, \eta, \varepsilon)$ , where  $\Phi$  and  $\Psi$  are adjoint functors,  $\eta$  is the adjoint unit and  $\varepsilon$  is the adjoint counit, determines a monad [11]. An endofunctor  $T: MSC_1 \rightarrow MSC_1$ , together with two natural transformations  $\eta: id \rightarrow T$ , called "return", and  $\mu: T^2 \rightarrow T$ , called "join", which make the diagrams in Fig. 5 and Fig. 6 commutative is a monad in category  $MSC_1$ , which is specified by a tuple  $(T, \eta, \mu)$ .

Based on the adjunction  $(\Phi, \Psi, \eta, \varepsilon)$ , we can calculate the monad components as follows: the endofunctor  $T = \Phi \circ \Psi$ ,  $\eta$  is the adjunct unit, and  $\mu = \Psi \varepsilon \Phi$  [11]. Monads are frequently used in functional languages that offer in this way facilitates for inserting imperative code into the functional code. Therefore, in a similar way, mechanisms for specifying monads can be introduced in domain specific modeling languages [6].

Fig. 3. Definition of Unit Adjunction.

Fig. 4. Definition of Counit Adjunction.

Fig. 5. First Constraint.

Fig. 6. Second Constraint.

Most of the time, the co-simulation control is realized by an orchestrator that coordinates the system components according to a co-simulation scenario [3,25]. In this case, the two models must be encapsulated in software units that implement a standard interface [2]. The interaction between two CPPS models can be specified by defining shared variables between the two models or by passing data to the orchestrator. In the case of our approach, the adjunction unit  $\eta$  is executed in the  $MSC_1$  model and has the role of preparing the data, in the appropriate format, to be transmitted to the orchestrator. The  $\mu$  application is executed in the  $MSC_1$  model, and specifies the operations to be executed by this model. Connecting the models through monads makes it possible to analyze the composite system resulting from co-simulation.

#### V. ORIGINAL CONTRIBUTIONS AND CONCLUSIONS

The most important finding, in our proposal, is simplicity and conceptual clarity. Thus, the static dimension of a model is the image of a categorical sketch through a functor. The behavioral dimension of a model is specified by a set of functors and a set of behavioral rules. The simulation space of a model is defined by a category. The co-simulation space of two models is specified by a monad induced by two adjoint functors. All the mechanisms involved in these definitions are generic and can be implemented at the metamodel level. Mechanisms for specifying monads can be included in the modeling language at the metamodel level, as happens in functional languages that offer such mechanisms especially to allow imperative specifications. Most of the times the interaction between two CPPS models can be specified by defining shared variables. Connecting the models through monads makes it possible to analyze the composite system resulting from co-simulation. To our knowledge, co-simulation through monads, which is the main objective of this work, has not been addressed until now.

# A Machine Learning Model for Predicting Heart Disease using Ensemble Methods

Jasjit Singh Samagh, Dilbag Singh  
Department of Computer Science and Engineering  
Chaudhary Devi Lal University, Sirsa, India

**Abstract**—There is the continuous increase in death rate related to cardiac disease across the world. Prediction of the heart disease in advance may help the experts to suggest the preemptive measures to minimize the death risk. The early diagnosis of heart disease symptoms is made possible by machine learning technologies. The existing machine learning models are inefficient in terms of simulation error, accuracy and timing for heart disease prediction. Hence, an efficient approach is needed for efficient prediction of heart disease. In the current research paper, a model based on Machine learning techniques has been proposed for early and accurate prediction of heart disease. The proposed model is based on techniques for feature optimization, feature selection, and ensemble learning. Using WEKA 3.8.3 tool, the feature selection and feature optimisation technique has been applied for irrelevant features elimination and then the pragmatic features are tested using ensemble techniques. Further, the comparison of the proposed model is made with the existing model without feature selection and feature optimisation technique in terms of heart disease prediction effectiveness. It is found that the results of proposed model gives the better performance in terms of simulation error, response time and accuracy in heart disease prediction.

**Keywords**—Heart disease; diagnosis; ensemble; optimization; prediction

## I. INTRODUCTION

Globally, coronary disease is the main cause of death. 15% to 20% of fatalities were thought to be caused by ischemic heart disease and strokes. Investigations including ECGs, chest radiographs, and echocardiograms are typically done at the patient's bedside for the diagnosis of these disorders, although more involved procedures like cardiac catheterization, nuclear scanning, CT scans, and MRIs may also be done. The data that are gathered as a result of these examinations take a long time to analyse, and it takes a long time to deliver medications, which could be harmful to the patient. Doctors, pathologists, and other medical professionals may find that machine learning can shorten test times while improving test accuracy. Data mining and machine learning facilitate quick extraction and helps in fast extraction of results from a large size data in comparison with manual analysis [1].

Data mining plays vital role in health care systems using machine learning. Data mining is regarded as a crucial work that must be carried out precisely and competently since it aims to address real health issues in the diagnosis and treatment of disease. Heart disease prediction model, an electronic approach for detecting the heart illnesses based on

earlier data and information, can be used to determine the sickness and its impact on patients. In order to aid medical professionals in making early forecasts of heart disease, this research aims to replace the time-consuming method with a quick one. Early diagnosis, prompt treatment, and decreased likelihood of casualties [2].

The objective of the present study is to develop and improve ML model which may help medical workers to extend accurate and quick medical help to the needy. For the said purpose different machine learning ensemble algorithms are compared using optimization algorithms. Due to their adaptability, optimization algorithms are frequently employed in numerous research domains. These algorithms are created by simulating or illuminating specific natural processes. GA and PSO are employed for this purpose. GA resolves the given process by replicating the natural process of evaluation. While PSO, a computer method, optimises the problem by iteratively attempting to enhance an optimal solution with regard to a specific number of features. The key features are produced by applying these optimising strategies one after another [10]. The drawbacks of using a single optimization algorithm to solve complicated problems include limited accuracy and generalizability.

In the research, GA and PSO are integrated, which means that exploitation and exploration capabilities are merged for binary and multi-class heart disease in order to further explore the application of optimization in bioinformatics. The wrapper-based feature selection approach is utilised in the study to eliminate redundant and unnecessary features, the GA optimization results are taken into account as the PSO's initial values, and finally the classification model for heart disease is built. Ensemble algorithms including Bagging, Boosting, Randomization, and Hybrid (Integration of Bagging, Boosting, and Randomization) are utilised to conduct the research. For the prediction and classification of the heart disease dataset, it has been found that randomization and hybrid models are better algorithms.

The remaining part of the paper is organized as follows: The problem statement for the research is covered in Section II. The relevant literature is discussed in Section III. The proposed methodology employed for the current study endeavor is described in detail in Section IV. The data mining tool used to conduct the research is discussed in Section V. The dataset for heart disease is presented in Section VI. The experimental findings of the proposed model for the prognosis of heart disease are presented in Section VII. The conclusion and Future Scope is covered in the final part.

## II. PROBLEM STATEMENT

It has been observed in earlier studies that the research is only used to predict and categorise cardiac disease using machine learning approaches. However, the research does not focus on improving these techniques using optimisation techniques, simply on the unique consequences of various machine learning algorithms.

To carry out the work the wrapper-based feature selection method is applied as an initial step, which is also called the pre-treatment step. The mining-relevant attribute selection attributes are chosen from among all the original attributes once all continuous attributes have been discretized. The pre-processing stage of feature selection in machine learning is extremely successful at reducing dimensionality, removing irrelevant data, boosting learning accuracy, and enhancing comprehension of outcomes. The best attributes of the data set are chosen in the following stage by using PSO and GA. The classification will be more accurate thanks to these ideal features. The last phase, which diagnoses heart disease using ensemble approaches, assesses the performance of the suggested procedures by measuring classification accuracy.

## III. LITERATURE REVIEW

Dilbag Singh [11] et al. compared and reviewed already existed models and extracted some major key attributes which are highly useful in creating and building an effective model. The effective model will therefore aid in the early diagnosis of cardiac problems, which will aid medical professionals in the patient monitoring process.

Jasjit Singh Samagh [10] et al. suggested a machine learning model for the heart disease prediction. The model is an integration of wrapper-based feature selection and GA and PSO based feature optimisation technique which is tested on ensemble machine learning techniques. Ensemble techniques itself being the combination of two or more classification techniques resulted in predicting an efficient and more effective model.

Youness Khourdifi [12] et al. associated the algorithms with different performance metrics with the help of machine learning. Different methods were used for prediction. Artificial Neural Networks, Random Forest, and K-Nearest Neighbor provide the greatest outcomes in this investigation. Then the research combines the algorithms and attempted to test the model effectiveness to see if it would be more effective or not. The results were later applied to a data set of heart disease, and his suggested models produced greater accuracy.

K.Vembandasamy [13] et al. analysed some parameters and suggested a data mining-based technique for predicting cardiac disease. Naive Bayes is utilised in the study since it has a strong independence principle for the diagnosis. 500 patients' worth of data from Chennai's premier diabetes research institute were utilised in the study. The tool used WEKA and achieved accuracy of 86.419%.

Vikas Chaurasia [14] et al. suggested the use of data mining tools for heart disease detection. Due to its open source nature and inclusion of machine learning techniques for mining, the author believes WEKA to be the greatest tool. The J48, bagging, and Naive Bayes techniques were applied in the current investigation. The author employed only 11 of the 76 features in the UCI data set, which was used to predict heart disease. Naive is accurately documented with 82.31%. J48 is recorded with an accuracy of 84.35%, and bagging records accuracy at an accuracy of 85.03%.

On the basis of literature review, it can be concluded that to build an effective model for the heart disease prediction it should be an integration of feature selection, feature optimisation and ensemble method.

## IV. PROPOSED METHODOLOGY

The research is carried out in stages for heart disease prediction. The process begins with the collection of data for the dataset. The creation of dataset for the heart disease prediction is the crucial part as ML techniques performance depends upon it. The raw data is collected from electronic source present in form of patient's medical history, observations and laboratory tests. Redundancy is eliminated during pre-processing, which follows data collection, in order to get the information ready for heart disease prediction. The dataset is entered into the data mining tool after it is prepared to assess performance.

The Fig. 1 explains the proposed method for the heart disease prediction. In Proposed method, heart disease training dataset will go through feature selection and feature optimisation technique which will eliminate the low ranked attributes and will result in providing the predominant features. The performance of these predominant features for heart disease prediction is assessed using ensemble approaches [9]. The results predicted by this method are exceptionally best.

### A. Feature Selection

An attribute of a data collection that is used in machine learning is called a feature. Some machine learning experts hold the belief that features should only be applied to attributes that have relevance to a given machine learning problem, although this belief should not be taken at face value. A branch of feature engineering that has attracted a lot of research attention is the selection of the subset of useful features for machine learning. The most important pre-processing step in any machine learning project is probably feature selection. It aims to choose a subset of system information or attributes that contributes most significantly to a machine learning activity [3].

Fig. 2 explains the process of the feature selection that is the internal structure of subset evaluation and resulting in getting the best features.

Fig. 1. Proposed Method (with Feature Selection and Feature Optimization).

Fig. 2. Process of Feature Selection.

**B. Feature Optimization**

The goal of optimization is to achieve the best outcomes possible in any situation. We use optimization to either maximise the expected benefit or reduce the amount of effort needed. Decision variables can be stated as a function of the

work necessary or the intended benefit. Discovering the circumstances that maximise or reduce a function is, thus, optimization. The highest value of the negative of the function is at point  $x$ , which corresponds to the smallest value of the function  $f(x)$ . As a result, since finding the minimum of a function's negative allows us to find its maximum, optimization can be thought of as a minimization problem. Any optimization problem cannot be solved with a single technique. Consequently, we employ several techniques [4].

- Particle Swarm Optimization (PSO)

Every member of the population is referred to as a particle in particle swarm optimization. Particles in typical PSO update their velocity and location at each iteration based on their own experience, which is their personal best (best), and with the best experience of all the nearby particles, which is the global best (best), after the population has been initialised [7, 16].

A workflow diagram makes it simple to comprehend particle swarm optimization. Fig. 3 depicts this. It demonstrates in detail how PSO operates [8].

Fig. 3. Workflow of Particle Swarm Optimization (PSO) for Feature Optimization.

- Genetic Algorithm (GA)

The genetic algorithm, an evolutionary computational technique that has gained popularity recently, was created by Holland in the early part of 1975 and later improvised by Goldberg [9]. It is a method of searching that resolves a specific issue by simulating the course of evolution. An algorithm that uses the idea of "survival of the fittest" and is based on Darwin's theory is known as a genetic algorithm [5]. The use of fresh and better optimal solutions by a genetic algorithm is non-presumptive like continuity. The genetic algorithm as a method has enormous potential, and as a result, it has been applied in a variety of industries, including gaming and financial research. The Genetic Algorithm has grown to be highly sought-after in various industries since it can manage a variety of characteristics. Instead of taking a lifetime to solve the problem, it has an ideal solution or one that is very close to the ideal [9].

GA execution can easily be understood with the help of a workflow diagram. Fig. 4 shows the flowchart of GA, and it explains the steps it takes in execution [6].

Fig. 4. Workflow of Genetic Algorithm (GA) for Feature Optimization.

### C. Ensemble Techniques

An ensemble is a strategy that combines various models with varied strengths. Ensemble methods combine weaker learners to create stronger ones. Ensemble learning models are used to improve the predictive performance of statistical learning techniques by constructing a linear mixture of the simpler base learner. Ensemble learning models use decision trees as the base learner; in the case of random forest, many boosting and bagging implementations have been proposed [17].

One of the earliest and the most popular ensemble models is bootstrap aggregating or bagging. Bagging uses bootstrapping to generate multiple training datasets, and utilizing the same learning process, a collection of models are created using these training datasets [15].

Boosting is another crucial ensemble-based approach, similar to bagging. With boosting, weaker learning models are trained on resampled data, and the results are blended based on the performance of many models and a weighted voting mechanism. A specific type of boosting algorithm is adaptive boosting, often known as AdaBoost. Another well-liked ensemble learning strategy for creating prediction models is randomization [15, 17].

### V. DATA MINING TOOL

When doing numerous experiments on datasets for machine learning, the data mining tool is crucial. WEKA 3.8.3 is the data mining tool utilised to carry out the current study. Waikato Environment for Knowledge Analysis is abbreviated as WEKA. It is created in the New Zealand's University of Waikato. Its platform is Java-based [21].

WEKA is a collection of AI algorithms used for data mining jobs. There are two ways to apply an algorithm when using WEKA, either directly on a dataset or by calling it from Java code. Numerous built-in features in WEKA allow for the prediction of the model's correctness [19].

### VI. HEART DISEASE DATASET

Data could be gathered for the research's objective from a variety of sources. The UCI machine learning repository and Kaggle are the two most frequently used sources. In 1987 at

Irvine, David Aha and a few other students founded the UCI repository [22], whereas the Kaggle is Google Subsidiary founded by Anthony Goldbloom in April, 2010 at United States.

Both UCI machine learning repository [18] and Kaggle contains number of datasets related to healthcare sector. Machine learning enthusiasts, from novices to experts, frequently use the dataset available from these sources to comprehend data empirically.

Further, to carry out the present research the dataset from Staglog (heart) dataset from UCI repository is used which is provided by university hospital, Basel, Switzerland by Matthias Ptisterer, M.D. The data is then pre-processed to check for missing attributes and to eliminate duplication. Machine learning is used to forecast heart disease using a later dataset. The heart disease dataset utilised in the study has features that can number in the tens of thousands, but it also contains 14 attributes that are listed below [20].

TABLE I. HEART DISEASE DATASET

Attributes	Types	Explanation
Age	Numeric	Age in years (29 to 77)
Sex	Numeric	Sex (1 = Male, 0 =Female)
Chest Pain Type (cp)	Numeric	Chest pain type (1: typical angina, 2: atypical angina, 3: non-angina pain, 4: asymptomatic)
Rest Blood Pressure (restbtps)	Numeric	Resting blood pressure ( in mm Hg on admission to the hospital) [94, 200]
Serum Cholesterol (chol)	Numeric	Serum cholesterol in mg/dl [126, 564]
Fasting Blood Sugar (fbs)	Numeric	Fasting blood sugar > 120 mg/dl (1 = True, 0= False)
Resting Electrocardiographic (restecg)	Numeric	Resting Electrocardiographic(ECG) results values(0: normal, 1: having ST-T wave abnormality, 2:showing probable left ventricular hypertrophy)
Maximum Heart Rate (thalach)	Numeric	Maximum heart rate achieved [71, 202]
Exercise Induced (exang)	Numeric	Exercise induced angina (1: Yes, 0: No)
Oldpeak	Numeric	ST depression induced by exercise relative to rest [0.0,62.0]
Slope	Numeric	The slope of the peak exercise ST segment (1: upsloping, 2: flat, 3: downsloping)
Major Vessels (ca)	Numeric	Number of major vessels values(0-3) colored by flourosopy
Thal	Numeric	Defect types: value 3: normal, 6: fixed defect, 7: irreversible defect
Class	Nominal	Prediction of heart disease (1: Absence, 2: Presence)

Table I is the Heart disease dataset used in predicting the heart disease. It consists of the 14 attributes with its explanation used for predicting the model.

**A. Feature Selection Feature Optimisation and Ensembling**

The databases for cardiac disease can contain up to tens of thousands of features. However, only roughly 14 qualities are necessary to forecast cardiac problems because a large number of irrelevant and redundant attributes frequently produce unreliable results, incur expensive costs, and take a lot of time. The performance in predicting heart disease would be better if the qualities were less. On the other hand, Feature Optimization techniques [25] used to identify the optimal solution by minimising or maximising the objective function without going against resource limitations.

By adjusting parameters, optimization methods can be used to enhance the performance of classifiers in the prediction of heart disease. GA and PSO are employed for this purpose [8]. While PSO, a computer method, optimises the problem by iteratively attempting to enhance a candidate solution with regard to a specific number of features, GA resolves the given process by replicating the natural process of evaluation. These optimization strategies are repeatedly used to produce the key features [17].

After applying the wrapper, Genetic Algorithm and Particle swarm optimisation to the heart disease dataset following features got extracted:

- Chest Pain Type (cp).
- Resting Electrocardiographic (restecg)
- Maximum Heart Rate (thalach).
- Exercise Induced (exang).
- Oldpeak.
- Major Vessels(ca).
- Thal.
- Class.

The number of features reduced from 14 attributes to the 8 predominant features. These features are then tested on ensemble techniques that is Bagging, Boosting, Random Forest and Hybrid (a combination of Bagging, Boosting and Randomization) methods of machine learning to evaluate the results regarding prediction of heart disease.

**VII. EXPERIMENTAL RESULTS**

To evaluate the performance, comparison of various ensemble machine learning techniques is made on various criteria.

The Results are calculated on the basis of following norms:

- Results without using Feature selection and Feature Optimization Techniques.
- Results after using Feature Selection and Feature Optimization Techniques (Proposed method).

**A. Simulation Error of Ensemble's**

Simulation error is also taken into consideration in the study's execution to enhance the ensemble learning model's performance. The prediction model's effectiveness is described by simulation errors. The five aforementioned evaluation criteria are used in the current study to assess the simulation error, as indicated in Table II and III, respectively.

Table II describes the simulation error for the heart disease prediction model using ensemble technique. Simulation error tell us how effective the model is in predicting the accuracy. In this, result evaluated is computed without using feature selection and feature optimisation technique.

Table III is the simulation error table for the heart disease prediction model using ensemble technique. In this table the results are computed using feature selection and feature optimisation technique. It is seen that the error rate of the simulation model are reduced after using feature selection and feature optimisation technique that is proposed method.

**B. Confusion Matrix**

The confusion matrix reveals how a predictive model operates internally. It provides insight information on classes that are accurately predicted, classes that are wrongly forecasted, and also about the different forms of faults. The confusion matrix produced for a two-class classification issue with negative and positive classes is the most basic type of confusion matrix. Each cell in the figure has a distinct and clear display, as illustrated. [23].

Fig. 5 explains the insight of the confusion matrix, that how the internal functional of the predictive model are classified in following classes.

TABLE II. SIMULATION ERROR WITHOUT USING FEATURE SELECTION AND FEATURE OPTIMISATION

Evaluation Criteria	Bagging	Boosting	Randomization	Hybrid
KS	0.58	0.595	0.6244	0.6694
MAE	0.2934	0.2374	0.2696	0.2668
RMSE	0.3774	0.3807	0.3587	0.362
RAE (%)	59.4167 %	48.0607 %	54.5794 %	54.0189 %
RRSE (%)	75.956 %	76.6224 %	72.1837 %	72.8601 %

TABLE III. SIMULATION ERROR WITH FEATURE SELECTION AND FEATURE OPTIMISATION

Evaluation Criteria	Bagging	Boosting	Randomization	Hybrid
KS	0.7657	0.6772	1	0.7963
MAE	0.2271	0.2121	0.0867	0.1753
RMSE	0.3001	0.3296	0.1346	0.2474
RAE (%)	45.9852 %	42.9527 %	17.5484 %	35.4954 %
RRSE (%)	60.3894 %	66.3318 %	27.0926 %	49.7841 %

Where KS- Kappa Statistic, MAE- Mean Absolute Error, RMSE- Root Mean Squared Error, RAE- Absolute Error and RRSE- Root Relative Squared Error.

Fig. 5. Insight of Confusion Matrix.

- True Positive (TP): When both the truth and the test's prediction of a positive are true, the class is true positive. For instance, when a patient is ill and the test also detects this.
- True Negative (TN): When the test also predicts a negative outcome and the truth is negative, the class is true negative. For instance, when a test accurately detects that a person is healthy.
- False Negative (FN): When the truth is positive but the test predicts a negative outcome, the class is considered false negative. For instance, when a test falsely indicates that someone is healthy when they are actually ill. In statistics, this is also known as Type II mistake.
- False Positive (FP): The term "false positive" refers to a situation in which the test anticipates a positive result even though the reality is different. If a test falsely indicates that a person is ill even when they are not ill. In statistics, this is known as Type I mistake. [23, 24].

The Table IV indicates the Confusion Matrix of the Ensemble Machine learning models for prediction of the heart disease. The table shows detailed confusion matrix of machine learning ensemble model when created without using feature selection and feature optimisation technique that is the traditional method the proposed method that is using feature selection and feature optimisation techniques. This matrix depends upon four factors namely TP, TN, FP and FN [23, 24]

C. Accuracy Factors

The factors on which the accuracy of model is based are TP rate, FP rate, Precision, Recall and F measures [24].

Fig. 6 is about the calculations of accuracy factors. It shows the formulas used to calculate the accuracy factors Such as TP rate, FP rate, Precision, Recall and F-measure.

Following model creation, its accuracy is assessed by contrasting it against the following criteria.

- True positive rate: that a real positive will test positive is known as the true positive rate. It is calculated as TP/TP+FN and is often referred to as sensitivity.

- Precision: is the ratio of examples that genuinely belong to a class to all instances that are categorised in that class.
- Recall: a class's true total is equal to its actual fraction of instances classed as that class (equivalent to TP rate).
- F-Measure: is a composite measure for recall and precision that is calculated as 2 \* recall / (precision + recall).

The Table V indicates the Accuracy factors of the Ensemble Machine learning models for prediction of the heart disease. The table shows detailed accuracy measures of factors with class of machine learning ensemble model when created without using feature selection and feature optimisation technique, that is, the traditional method (the proposed method) to use feature selection and feature optimisation techniques.

depicted from the line chart that the model with feature selection and feature optimisation techniques have better results than the model without feature selection and feature optimisation technique. Moreover, an increase in accuracy in all the stated ensemble techniques, after the use of feature selection and feature optimization, is observed.

### VIII. CONCLUSION AND FUTURE SCOPE

One of the leading causes of death in the modern world is heart disease. However, if it can be predicted beforehand, it can give clinicians crucial information for diagnosis and treatment. In order to prevent cardiac diseases, it is essential to keep track of any health issues. The effectiveness of machine learning in making these predictions has been demonstrated, and the dataset can be used to derive some interesting conclusions. Though there are many existing machine learning models, whose performance needs to be improved in terms of accuracy, consumes more time and are more prone to simulation errors. The prediction behaviour of the model depends upon these factors. A machine learning model built on ensemble learning and using feature selection and feature optimization techniques is suggested to reach this goal.

The experimental findings for the prediction of heart disease utilising ensemble machine learning approaches are presented in this work. To carry out the current study, exploratory, experimental, and applied research approaches were employed. Data about the patient is gathered from the UCI repository. Experiments are conducted using heart disease dataset which are applied on Weka3.8.3 a data mining tool to predict results. Experiments are conducted on two methods, one without using feature selection and feature optimisation method and another on proposed method, using feature selection and feature optimisation technique and later these methods are tested on Ensemble techniques to evaluate the results.

Fig. 7. Comparison of Performance of the Models with and without Feature Selection and Feature Optimisation.

Fig. 7 illustrates the comparison of performance of the model with and without feature selection and feature optimisation technique in heart disease prediction. It is

It is seen that results are better with the proposed technique. Thus, the method can be utilised by medical professionals to forecast and detect cardiac illness early on, which helps to avoid problems.

In future, the same approach might be applied to various datasets of various diseases gathered from various sources.

**Abstract**—Effective screening and early detection of COVID-19 patients are highly crucial to slow down and stop the disease's rapid spread at this time. Currently, RT-PCR, CT scanning and Chest X-ray (CXR) imaging are the diagnosis mechanisms for COVID-19 detection. In this proposed work radiology examination by using CXR images is used for COVID-19 detection due to dearth of CT Scanners and RT-PCR testing centers. Therefore, researchers have developed various Deep and Machine Learning systems that can predict COVID-19 using CXR images. Out of which, few are exhibited good prediction results. However, Most of the models are suffered with over fitting, high variance, memory and generalization errors which are caused by noise as well as datasets are limited. Therefore, a Convolutional Neural Network (CNN) with the leveraging Efficient Net architecture is proposed for COVID-19 case detection. The proposed methods have an accuracy of 99% which gives the better results than the present available methods. Therefore, the proposed model can be used in real-time covid-19 classification systems.

**Keywords**—COVID-19; x-ray images; deep learning technique; CNN; efficient net

## I. INTRODUCTION

SARS-CoV-2 has never been discovered in people before December 2019, is the virus that causes the unique Coronavirus Disease 2019 (COVID-19), an infectious and lethal disease that has never been seen before in the world [1]. Finding infected individuals through efficient screening is a crucial responsibility in halting the rapid spread of COVID-19 so that they can be separated and given prompt medical attention. The RT-PCR test is now the most widely utilised screening method for COVID-19 case detection [2]. There are still a number of difficulties with RT-PCR testing, despite it being acknowledged as the "gold standard" for identifying infected cases of the disease. Tahamtan et al recent study [3] found that the detection sensitivity is highly varied and can lead to both FN and FP i.e. False-Negative & False-Positive results. The Radiograph imaging and CT Scan are performed and analysed by radiologists to determine whether or not a suspected person was Infected by Covid-19. This alternative effective screening method to RT-PCR is for the quick identification of COVID-19. All three of these tests are typically used to diagnose COVID-19. The RTPCR test, which is used to diagnose viral infection, can identify viral RNA in sputum or nasopharyngeal swabs [4]. Using CT scans, a 3D radiographic image is examined from various perspectives as part of a CT-based examination. The main drawback in the CT

scan is that, it requires lots of time and the equipment is not readily available all the time and in all the areas and high radiation. Although CT scans are more sensitive to pulmonary disorders, they have a number of drawbacks that prevent them from being used in COVID-19 case detection on a broader scale. These drawbacks include non-portability, prolonged scanning, and the potential for patient exposure. In compared to CT scans, CXR imaging offers an adequate level of accuracy in the detection of COVID-19 cases while being portable, quicker, and more widely accessible and less expensive. Due to these advantages, CXR image analysis for COVID19 case detection has become the focus of numerous recent investigations [5, 6]. With the pandemic's rapid spread, certain studies, in particular, advise using portable CXR imaging as a reliable tool for finding COVID-19 cases.

Many writers recommended combining the RT-PCR test with additional clinical procedures like the CT & CXR (chest X-ray). A few recent studies provide estimates of the sensitivity of professional radiologists to diagnose COVID-19 using CT scans, RT-PCR, and CXR. A research on 51 individuals who had a chest CT and RT-PCR performed within three days found that the CT had a sensitivity of 98% and the RT-PCR had a sensitivity of 71%. Similarly RT-PCR will require at least 12Hrs of time, which is not ideal as COVID19 +ve patients should be identified and tracked as soon as feasible, and it requires specialised materials and equipment that are not readily available [7][8].

A sensitivity of 69% for CXR was found in a different study on 64 patients. An analysis of 636 ambulatory patients revealed that the majority of patients with confirmed coronavirus who visit urgent care facilities have normal or barely abnormal CXR results. The professional eye accurately diagnoses only 58.3% of these cases. Although CXR imaging is fairly quick, COVID-19 case detection must be done manually by qualified radiologists, which takes professional knowledge and is a laborious process. However, there are many fewer radiologists than there are people who are being monitored. These scenarios will all broaden the application of AI-driven algorithms for detecting COVID-19 from chest radiographs.

## II. PREVIOUS WORK

Thus, a diagnostic system powered by artificial intelligence (AI) is required to help radiologists screen COVID-19 cases in a more quick and reliable manner. Without such a system, it is

likely that infected individuals may not be promptly identified, isolated, and treated. Based on the AI[17] aided diagnosis many authors proposed different approaches in diagnosing Covid-19 which are based on CT-scan and radiographs along with the technology end depends on transfer learning and machine learning etc.

CNN based data driven deep learning methods have shown promising performance for the classification challenge of COVID-19 case detection with CXR pictures, which is essentially a machine learning problem. As a result, there are numerous recent research that seek to train new deep learning models for infected case detection with CXR images by reusing or changing existing deep neural networks on top of gathered CXR image datasets. Although several research in their articles indicate considerably higher prediction accuracy for their proposed deep learning models with their own datasets, in practice, noise and restricted training data size may cause a deep learning model to suffer from over fitting, excessive variance, and generalization mistakes.

Deep learning (DL) methods for automated image processing have the potential to significantly improve the role of CXR pictures in the rapid diagnosis of COVID-19[20]. A reliable and accurate DL model could enhance medical decision-making and be used as a triage tool. Recent investigations claim to have achieved outstanding sensitivities > 95%, which is much higher than expert radiologists. Numerous deep learning & Transfer Learning based AI-assisted detection techniques have been proposed to lessen the load of detection from radiography pictures (e.g., CT and CXR images) for radiologists [09][10].

CXR pictures are evolving into a well-liked and often used data source for COVID-19 case detection due to its many advantages over CT images, including mobility, availability, accessibility, and quick testing. When AlexNet, ResNet18, DenseNet201, and SqueezeNet were used to identify two classes (i.e., COVID-19 and Normal) for CXR images, Wynants, L. et al. [11] came to the conclusion that SqueezeNet performed better than the other neural networks. Instead, Narin et al.'s [18] comparison of various CNN models trained on CXR images for COVID-19 case detection, including ResNet-50, Inception V3, and Inception-ResNetV2, revealed that ResNet-50 surpasses the other two models with 98 percent accuracy.

A three class prediction with the help of transfer learning was proposed by E. H. Chowdhury et al. and attained an accuracy of 99% by implementing it in the CNN environment [12]. Farooq et al. [13] provided a COVID-ResNet by fine tuning a pre-trained ResNet-50 architecture with a reported accuracy of 96.23%. A semi-supervised few-shot segmentation for the detection of Covid-19 was proposed by Mohamed Abdel-Basset et al. [14] which is a Deep learning based architecture and the implementation was based on CT scans, the limitation of less data set availability overcomes by this approach. In the similar manner with the DL and TL approaches in the diagnosis of COVID-19 from the X-ray and CT images have been implemented in Halgurd S. Maghdid et al. approach [15]. Linda Wang et al. [16] came up with a huge chest X-ray dataset based approach by a DCNN design and

attained good accuracy with the model with this huge dataset system can encounter technical issues [19].

### III. PROPOSED METHOD

#### A. Datasets

The dataset of 15000+ of (512x512pixel) images are collected from Kaggle which are used to train and test the model. The dataset consists of properly labeled radiograph images by radiologists. When a lot of patients need to be examined in a short amount of time, a model like this can help medical practitioners diagnose COVID-19 cases considerably faster than a radiologist having to go over each scan one by one. The sample images are shown in Fig. 1.

#### B. Learning Rate

Learning rate plays an important role in defining the accuracy of the model. In general convergence can be improved by Low Learning rate but the accuracy will be not as expected. Similarly overshooting can be possible with higher learning rate, therefore choosing learning rate properly will improve the performance there by accuracy. In proposed method the model experience with  $10e-4$  rate which led the model with low error rates on test dataset.

#### C. Batch Size

With reference to the literature article [22] batch size in association with learning rate plays a vital role in accuracy. Increase in batch size like 256 or 128 or 64 might lead the system into memory issues. Therefore depends on system performance and other factors in proposed method tested with 32. Hence proposed model trained with a batch size of 32 and learning rate of  $10e-4$ .

#### D. Epochs

The EfficientNet b3 model consists of 12 Million parameters and the images used in the proposed model have chosen for the training instance is around 15k+ images. With the dataset trained model attained accuracy of 99% at 7th epoch. And the system used about 10 epochs with different batch sizes and learning rate combinations.

Fig. 1. Images taken as Sample for Covid & Non-Covid.

E. Pre-Trained Model

In the current quickly evolving technology era, applying this technology to the medical diagnosis will leads to better outcome. Computer Vision is one of the fields where we make a use of diagnosing Covid-19. With reference to the Google AI Blog [21] in our proposal we have chosen EfficientNet in which b3 version has chosen to overcome issues in system configuration instead of using VGG16 or Resnet50. In general most of the architectures are too wide, deep or with high resolution therefore while increasing these characteristics will initially help the model but later it leads to saturation and there by become in-efficient, where as in the chosen EfficientNet model these are scaled in a more principled way [23].

Coming to the architecture representation of EfficientNet-B3 will be shown in Fig. 3.

The difference that we can observe between different EfficientNet models will be the number of feature maps i.e. channels, which leads to increase in number of parameters.

The proposed model initially trained on Google Colabs environment which is an effective tool for learning and quickly creating machine learning models in python with pytorch. Later, implemented the same model in the system environment (Fig. 2).

Fig. 2. Model Scaling.

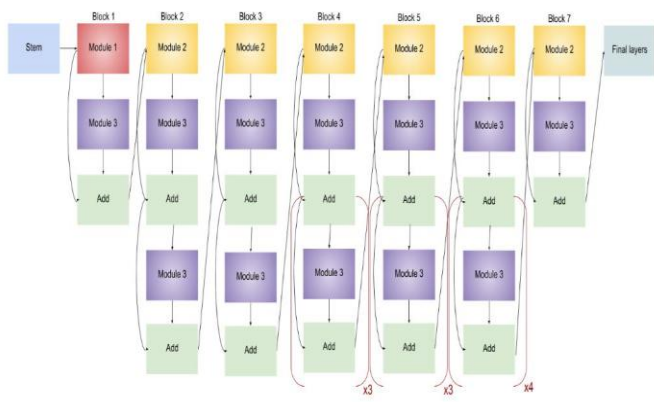

Fig. 3. Architecture for EfficientNet-B3.

Development of the proposed work implemented with the help of PyTorch which will be well suited for the Computer vision applications. When we give radiograph image as input the trained model has to detect the provided image was COVID-19 positive or Negative.

F. Flowchart

The proposed model flow of implementation can be seen in Fig. 4. The existing Dataset consist of the images for training and testing. By applying the transformation method to resize the images and this transformation will be helpful in data augmentation. If more than 90% of the photos in the training dataset belong to the non-Covid class, the training dataset is markedly unbalanced. A naive learning method that just outputs the class of the majority class as the output would achieve high accuracy with severely unbalanced sets, which is a problem. In other words, even though only 10% of people truly have Covid, it will classify everyone as being Covid-free and achieve a "accuracy" of 90%. For the training images with the help of this transform method we can up sample the minority class which is Covid, so that in both the classes we can have same number of images which will be quite helpful improving the accuracy of the model. Now these newly created images can be split into training and validation at a ratio of 80:20. These images are given as input to the system. Across the preprocessing with the help of Data loader Batch size of 32 applied on the training dataset and shuffled them to ensure approximately equal representation of both classes in all the batches. While this process is taking place it's always best practice to save the weights generated at the time of training process to ensure that even though the model got crashed due to any technical reason, instead of starting from the scratch we can call the saved weights and reinitiate the process. Initially while doing the training in the Google colabs the model got crashed because of the number of training images are huge in number and it cannot support these many iterations on the training data as well as testing. Therefore saving the weights will always the best way. And that's why developed model implemented on system environment.

Fig. 4. Flow Chart Representation of Proposed Model.

#### IV. EVALUATION AND RESULT

There are various methods we can apply for the Loss calculation. Here in the proposed method cross-entropy loss is used for the calculation of the losses because of the chosen classification. In the similar manner for the weight update Adam optimizer has chosen which is well suited for deep learning applications. Proposed network trained with above mentioned parameters and the number of epochs is set to 10, out of which the network attained an accuracy of 99%. Training model attained the accuracy for both the classes as 99%-100%.

Fig. 5 shows the Graph between Accuracy and Loss. There is over 7000+ batch iterations taken place and the plot showcases these changes occurring in the values with respect to the batch iterations.

After the training is performed now the trained model has to be applied for the testing samples. Now the transforms are composed and applied to the test dataset to make it conform to the same distribution as the training dataset. Proposed model performed prediction of the test image with an accuracy of 99%. With the proposed model, a medical practitioner can identify Covid accurately in 99 out of 100 people rapidly.

Comparison of the proposed model results with the few of the existing models are shown in Table I.

Fig. 5. Plot between Accuracy and Loss.

TABLE I. COMPARISON OF DIFFERENT MODEL ACCURACIES

Authors	Imaging Type	Dataset Size (No. of Images)	Model Used	Accuracy
Boran Sekeroglu et al.	CXR	6100	CNN	98.5%
Thiyagarajan Padmapriya et al.	CXR & CT	650 349	Multimodal covid network	99.75%
Yu-Huan Wu et al.	CT	3855	JCS	95.9%
Guangyu Jia	CXR & CT	7592	Dynamic CNN	99.3%
Bhawna Nigam	CXR		EfficientNet	93.4%
Dandi Yang	CT	2481	VGG 16	99%
Proposed Method	CXR	15000+	Efficient b3	99%

#### V. CONCLUSION

The most important factor in life is health; therefore early diagnosis of any disease is required. In this current pandemic kind situations early and accurate diagnosis of Covid-19 from radiological examinations like CT scan and Radiograph images is very important for Doctors as well as patients. Proposed model implemented with Deep learning approach based on X-ray images to reduce the financial cost and radiation effect to the patients as well as to diagnose in less time. The proposed model is capable of classifying the radiograph images as Covid positive or negative in less time with an accuracy of 99%. The model trained on huge data samples and attained an accuracy of 100% in training and 99% in testing. This way the proposed approach constructed with CNN architecture on EfficientNet can provide desired assistance in diagnosing Covid-19 for radiologists.

# Machine Learning based Electromigration-aware Scheduler for Multi-core Processors

Jagadeesh Kumar P, Mini M G  
Department of Electronics Engineering  
Government Model Engineering College  
Thrikkakara, Cochin 21  
India

**Abstract**—The rising performance demands in modern technology devices see the need to pack more functionality per area and are made possible with the advent of technology scaling. The extremely down-scaled, high-density processors used in such technology devices functioning at high frequencies and greater temperatures expedite various aging effects which impact the reliable lifetime of computing systems. Electromigration is considered to be an important intrinsic aging effect that reduces the useful lifetime of modern microprocessors. The objective of this work is to use machine learning methods to develop an electromigration-aware scheduler for assigning workloads to cores based on reliability and performance requirements. Aging estimation of the processor cores is performed based on the proposed computationally efficient and accurate regression-based thermal prediction models. According to experimental findings, the suggested technique can significantly extend the lifetime of multi-core architectures while allowing performance to degrade gracefully. The maximum error in the prediction of the lifetime of the cores using the proposed methodology is estimated to be 2.85%.

**Keywords**—*Electromigration aware scheduler; useful lifetime; multi-core processor reliability; machine learning model*

## I. INTRODUCTION

The computing requirements of modern embedded systems in application areas including automotive, storage, networking, and 5G, among others, necessitate the use of high-performance processors. To deliver higher functionality per area demand for such applications, manufacturers create dense integrated multi-core processor chips operating at higher speeds [1]. Increased power density and operating temperature of processor cores can expedite aging phenomena including electromigration, lowering the processor's quality and reliability [2]. Runtime task execution management is a pressing research topic to minimize such aging effects in processor cores [2], [3], [4]. A rise of 10 - 15°C in the operating temperature could reduce the processor lifespan to half [5]. The lifetime of multi-core processors can be improved by estimating the aging effects of tasks that are ready for execution. The workload assignment to cores and frequency adjustments can be done at runtime to minimize the effect of aging of the cores. Such strategies need to be computationally precise and quick for real-time implementation.

Transistor aging is considered an important phenomenon that affects the reliability and lifetime of modern CMOS integrated circuits [6]. Time-Dependent Dielectric Breakdown

(TDDB), Hot Carrier Injection (HCI), and Negative Bias Temperature Instability (NBTI) are the key aging effects that challenge the reliable operation of modern integrated circuits. The intrinsic effects, Electromigration (EM) and Stress migration (SM), which are due to the interconnect aging, are also significant in present CMOS technology devices [7]. New methods for investigating and predicting degradation effects are important for enhancing the lifetime reliability of modern CMOS technology devices.

The suggested method to increase the multi-core processors' lifespan reliability is presented in two sections. In the first section, machine learning models based on regression to predict the processor cores' steady state temperature for the incoming jobs are proposed. A fine-grained approach is followed in this work for predicting the thermal properties of the cores' processing components. The fine-grained approach is more suitable for understanding the localized characteristics of the cores. In the second section, a scheme for mitigating the aging effects of processor cores by implementing a runtime frequency control policy is presented, which takes the temperature estimates of the proposed machine learning models as input. The operating speeds of the cores are decided to take into account the aging effects and the performance requirements. Our experimental results show that the proposed aging-aware scheduler, which is guided by the developed machine learning models could predict the core's lifetime with a maximum error of 2.85 %. The average error in temperature estimation is assessed, for each of the proposed models, and the maximum value is observed as 0.492 °C.

The rest of the paper's contents are arranged in the order mentioned below. A number of the significant efforts on thermal prediction and the regulation of thermal challenges of the processor cores are discussed in Section II. Linear regression and polynomial regression schemes for the estimation of the core temperature and the concept of the proposed aging-aware scheduler for enhancing processor core lifetime reliability are presented in Section III. An analysis of the results obtained for the proposed schemes are mentioned in Section IV. Finally, Section V concludes the work and mentions the possibilities for further research in the field.

## II. LITERATURE REVIEW

The increasing performance demands of current technology gadgets have prompted various studies to concentrate on optimal job scheduling methods in multi-core systems

operating under real-time constraints. A significant body of published works focuses on techniques for a better performance-power trade-off of multi-core processors [8], [9], [10]. The effect of using different styles of coding for balancing between performance and energy consumption of the processing cores is presented in [11]. A core allocation technique to lower the energy usage of mobile devices by engaging the LITTLE cores to a maximum extent and ensuring the performance of the device is proposed in [12]. The execution time of complex programs can be minimized and thus the performance of the applications can be improved by the use of today's high-performance computing systems employing multi-core processors. Parallelization schemes [13] can be employed for converting the serial execution of programs into a hybrid parallel mode to take the advantage of the processing capability of multi-core processors. Reliability-aware scheduling techniques [14] can be used to reduce soft errors of heterogeneous chip-multiprocessors. The performance and power efficiency in heterogeneous multi-core CPUs can be enhanced with smart workload schedulers [15].

An aging-aware scheduler needs an accurate thermal estimate of the various logical components to make run-time decisions when a workload gets executed in a processor core. Several research works have looked into the feasibility of using model-based methodologies to determine the CPU core temperature characteristics [16], [17], [18]. An architectural level thermal behavioral modeling technique known as Thermsid [19] builds temperature models from the observed temperature and power statistics. Multiple scheduling schemes based on the efficient and simple thermal model are used [20] for managing the operations of homogeneous processor platforms. Thermal Estimation Accelerator (TEA) [21], a processing element level monitoring scheme for the temperature at runtime using hardware accelerators can serve as a benchmark for Dynamic Thermal Management (DTM) methods.

For the development of thermal models, it is required to estimate thermal profiles of the benchmark tasks executing on selected cores at defined operating frequencies. HotSpot [22] is a popular tool used in the temperature estimation of processor cores and is helpful in architectural studies. Various logical components in the processor architecture are represented as its equivalent thermal resistor and capacitor values along with the thermal package information [23]. Information about the floor design and power estimations for the logical components are supplied to HotSpot to determine the temperature profile. The power estimation of the logical components can be done with the tool McPAT (Multi-core Power, Area, and Timing) [24]. Based on high-level data, such as the frequency of operation of the core, McPAT can predict the architectural level power usage of the processor core containing caches and memory controllers. A McPAT-monolithic framework is presented in [25] for the architecture modeling of 3-D hybrid monolithic multi-core systems. The work in [26] proposes a micro-architectural framework to estimate the performance and energy consumption of cores in a multi-core processor. A detailed validation of McPAT's power models done with the help of a toolchain used in industrial practice is presented in [27]. In this study, McPAT is utilized to calculate the dynamic

power of the core's logical subsystems. McPAT requires the operation statistics of the applications and micro-architectural characteristics as its inputs to calculate the power consumption of every system component. The operation statistics of the tasks can be evaluated using the gem5 simulator [28]. CPU models with different types of memory configurations and cache organizations can be defined for the analysis. The current generation of widely used commercial Instruction Set Architectures (ISAs) including ARM and x86 are supported by gem5. A significant number of these simulators are utilized in the relevant fields of research since they are useful in analyzing the performance and power consumption of various processor models and can be used to validate various design options. A study of the basics of several multiprocessor simulation methodologies and a summary of the correctness of six architecture simulators including gem5 are presented in [29]. Gem5-X, a framework for system-level simulation based on gem5 [30] may be employed to assess the potential benefits of the architectural extensions for many image processing-related applications.

Computer architecture simulators can be used to closely examine the execution properties of applications that run in a processing core. Regression-based models with high computational efficiency and accuracy may well be constructed by relating the thermal figures estimated with HotSpot to the application characteristics estimated using gem5. Representative applications in open-source benchmark MiBench [31] can be used to develop and validate thermal models of typical workloads running in embedded processors. MiBench presents a collection of 35 embedded programs organized in six categories, each of which focuses on a specific segment of the embedded market. Workloads belonging to the application areas: network, security, telecommunication, and consumer from MiBench suite are used in this work. The characteristics of the tasks jpeg encode/decode, 32-bit Cyclic Redundancy Check (CRC), Dijkstra, and Secure Hash Algorithm (SHA), representing the mentioned application areas, running on x86 architecture-based processing cores are analyzed using gem5 and are used to train the regression models. The MiBench suite's consumer device benchmarks are designed to simulate the consumer device applications found in products including Personal Digital Assistants (PDAs), scanners, and digital cameras. This category largely focuses on image processing, and one of the representative image compression and decompression technologies is JPEG encoding/decoding. The telecommunications category of applications stands close to consumer applications because of the increased demand for consumer devices with wireless communication capability. Cyclic redundancy checks (CRC) are often used in data transmission for the detection of errors. A 32-bit cyclic redundancy check is performed on a sound file from the adaptive differential pulse code modulation benchmark as part of the CRC32 test.

Devices such as switches and routers have embedded applications that fall under the network category. Finding the shortest path through a graph is one of the methods used to illustrate the networking category. The Dijkstra benchmark determines the shortest route across each set of nodes of a graph by repeatedly applying Dijkstra's algorithm. In

applications related to e-commerce, data security is a key factor. Security applications frequently employ a variety of hashing, encryption, and decryption algorithms. The Secure Hash Algorithm (SHA) is frequently used to create digital signatures and transfer cryptographic keys in a secure manner. The secure hashing method, SHA benchmark in MiBench, generates a 160-bit code for an input.

Estimating the temperature and power at runtime using the tools HotSpot and McPAT is computationally expensive and limits their implementation in real-time schedulers. A regression-based model can be developed based on the thermal and power profiles of the workloads estimated using HotSpot and McPAT. Such trained and created regression-based models can quickly and accurately estimate the temperature of the logical components, and they are suitable for the successful application of aging-aware scheduling methods. A method for constructing a compact machine learning-based thermal prediction system appropriate for fast decision-making is presented in [32]. A temperature control strategy based on machine learning to determine the appropriate core frequency and encoder configuration for High-Efficiency Video Coding (HEVC) is proposed in [33]. A machine learning and simulation-based approach can be employed [34] to estimate the temperature map of a chip using the power consumption, utilization of the core, and recorded sensor temperatures. As discussed, a significant amount of the related research works published in recent years propose different approaches for determining the critical parameters associated with the workloads using software tools. Many of these works emphasize the increasing need for runtime techniques to regulate the processor temperature by changing its operating behavior. Such recent research works propose many techniques for better performance-power trade-offs. But, in our understanding, the use of scheduling techniques to reduce aging with the help of computationally efficient runtime temperature estimation methods for high-performance applications running on multi-core processors is a largely unexplored topic.

### III. PROPOSED WORK

The first part of the proposed work deals with thermal profile modeling problems. Here, a regression-based model is employed to predict the steady-state temperature of the processing elements in a multi-core architecture. The temperature estimation model is driven by the properties of the workload. In the second part, an aging-aware scheduler is presented, whose scheduling activities are based on the thermal estimates of the regression model proposed in the first part of the work. The scheduler utilizes the thermal estimations and the performance need of the workloads taking into account the operating speed of the cores and trying to minimize the effect of processor aging.

#### A. Development of Regression-based Models

Regression analysis is one of the powerful multivariate statistical techniques to infer and form a functional relationship in a population [35]. In this work, regression analysis is used to relate the workload characteristics with the thermal effects of the processing elements. Workloads in embedded applications are suitable for implementing the suggested scheme because

they typically have high levels of predictability in their execution characteristics, such as the instruction execution behavior, memory operations, and the kind of information processing. The execution patterns of the MiBench applications running on a Hexa-deca homogenous multi-core architecture are analyzed using the gem5 simulator. The gem5 can be set up to operate in either Syscall Emulation (SE) mode or Full System (FS) mode. In SE mode, gem5 can imitate system calls made by applications. When configured in the FS mode, gem5 creates a bare-metal context for executing an operating system. In this work, gem5 is configured in the SE mode for analyzing the patterns of execution of the benchmark applications. The cores of the multi-core processor are selected as having x86 architecture. The cache hierarchy is defined to be of two levels, with level 1 private cache and level 2 shared cache. A subset  $j$  of the workload parameters is employed in this study, which directly affects the thermal profiles of the various logical components of the core. i.e.,  $j \in \{W\}$ , where  $W$  represents the complete set of workload characteristics analyzed using gem5.

The above-mentioned workloads from the MiBench suite, which cover several embedded application areas, are used for model development and analysis. The selected applications are analyzed using the gem5 simulation tool and the characteristics are determined. The power usage of the various functional parts of the CPU architecture is calculated using McPAT. The thermal model of HotSpot is driven by the estimated power traces, and the chip and package characteristics. The configuration file specifies the parameters of the processor core for the HotSpot tool, which are shown in Table I.

Linear Regression (LR) and Polynomial Regression (PR) are the two regression models used in this work for estimating the thermal values of the functional elements of the CPU. In the Linear Regression (LR) model, the steady-state temperature of a functional element is represented as a weighted sum of the selected workload characteristics. In the LR model, the predicted temperature is represented as in (1).

$$\hat{y}(w, x) = w_1 x_1 + \dots + w_p x_p + b \quad (1)$$

TABLE I. HOTSPOT CONFIGURATION PARAMETERS

HotSpot Parameters	Value
Thickness of the chip (in meters)	0.00015
Specific heat of Silicon (in J/(m <sup>3</sup> -K))	1.75 x 10e6
Thermal conductivity of Silicon (in W/(m-K))	100.0
Resistance (Convection) (in K/W)	0.1
Capacitance (Convection) in J/K (Heat sink)	140.4
Thickness (Heatsink) (in meters)	0.0069
Heatsink side (in meters)	0.06
Thermal conductivity of Heatsink (in W/(m-K))	400
Specific heat (Heatsink) (in J/(m <sup>3</sup> -K))	3.55 x 10e6
Side (Heat spreader) (in meters)	0.03
Thickness (Heat spreader) (in meters)	0.001
Thermal conductivity (Heat spreader) in W/(m-K)	400

where  $X = (x_1, x_2, \dots, x_p)$  represents the features used to train the models,  $w_1, w_2, \dots, w_p$  are the coefficients and  $b$  represents the bias. To reduce the sum of the squared estimate of errors between the measured values of the data, linear regression fits a linear model using weights  $W = (w_1, w_2, \dots, w_p)$ . The loss function which indicates the adequacy of the fit is given by (2).

$$L(\hat{y}, t) = \frac{1}{2}(\hat{y} - t)^2 \quad (2)$$

where  $\hat{y}$ ,  $t$ , and  $(\hat{y} - t)$  represent the prediction, target, and residual values respectively. The coefficients  $w_1, w_2, \dots, w_p$  and  $b$  are selected in a manner to reduce the loss function as represented in (3) and (4).

$$E(w_1, w_2, \dots, w_p, b) = \frac{1}{N} \sum_{i=1}^N L(y^i, t^i) \quad (3)$$

$$= \frac{1}{2N} \sum_{i=1}^N (\sum_j w_j x_j^i + b - t^i)^2 \quad (4)$$

In this study, the Python-based Scikit-learn machine learning package [36] is used, which is regarded as an effective and reliable tool for predictive data analysis.

In the development of the Polynomial Regression (PR) models of steady state temperature, polynomial regression needs to be performed on the data set, which are the workload characteristics, to fit a polynomial equation to it. This work extends linear regression by building polynomial features from the coefficients. For instance, the features in the second-order polynomials are utilized to fit a paraboloid to the data rather than a plane, giving the model represented in (5):

$$\hat{y}(w, x) = w_0 + w_1 x_1 + w_2 x_2 + w_3 x_1 x_2 + w_4 x_1^2 + w_5 x_2^2 \quad (5)$$

The above model can be considered as a linear model creating a set of features given in (6).

$$z = [x_1, x_2, x_1 x_2, x_1^2, x_2^2] \quad (6)$$

This renaming of the data allows for the formulation of the problem as in (7).

$$\hat{y}(w, x) = w_0 + w_1 z_1 + w_2 z_2 + w_3 z_3 + w_4 z_4 + w_5 z_5 \quad (7)$$

The derived polynomial regression belongs to a similar category of linear models as those previously mentioned, which can be evaluated using the same methods. The model is flexible enough to accommodate a broader range of data by taking into account the linear fits in a higher-dimensional space constructed with these basis functions. To transform an input data matrix into a new data matrix of a specific degree, the polynomial properties converter in the Scikit-learn Python machine learning toolkit is used. The parameters of  $X$  have been converted from  $[x_1, x_2, \dots]$  to  $[x_1, x_2, x_1 x_2, x_1^2, x_2^2, \dots]$  and are now applicable to any linear model.

Linear and polynomial regression are used to model the temperature profiles of the processing units of the core. Fig. 1 represents the architecture of the processor core considered in this work. The models thus developed are used to predict the steady-state temperature of the various processing elements in the architecture. The regression models presented in this work are most appropriate for multi-core systems executing embedded tasks since their task characteristics are often highly predictable. The proposed model-based prediction logic is

computationally efficient and is more suitable for real-time thermal estimation. The estimated data can be used by an aging-aware scheduler to determine the best course of action for controlling the temperature below threshold levels while maintaining performance goals and extending the useful lifetime of processor cores.

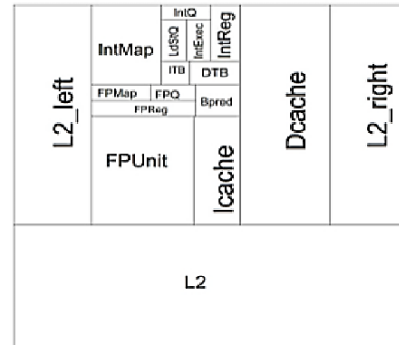

Fig. 1. Core Architecture.

### B. The Aging-aware Scheduler Design

With the advancements in integrated circuit design and fabrication technology, more transistors can now fit into a square millimeter of a silicon wafer. When clocked at higher speeds to address the execution constraints, such densely integrated processors have increased power and heat dissipation, which has a negative impact on lifetime dependability. The major challenge is to develop algorithms that can forecast device-level degradation behavior based on the application features. This work presents a strategy for extending the useful lifetime of multi-core processors. A fine-grained approach is followed for estimating the aging effects of the various processing components of the multi-core processor. The data available for the recent industrial-grade embedded processors manufactured by Texas Instruments [37] is taken as the reference. Referring to [37], the operational lifespan of the semiconductor core is taken as ten years, when the junction temperature  $T_j$  is  $105^\circ\text{C}$ . The crucial factor affecting silicon lifespan is the junction temperature  $T_j$  when the circuit is functioning within the limits of voltage and frequency stated in the data sheet.

Due to continual operation at high temperatures, wear-out processes begin to develop in semiconductor products during their useful life. The wear-out processes commonly considered in the design of integrated circuits include Gate Oxide Integrity (GOI) [38], Electromigration (EM) [39], [40], and Time-Dependent Di-electric Breakdown (TDDB) [41]. Additionally, the lifespan of the present semiconductor devices is affected by processes such as Negative Bias Temperature Instability (NBTI) [42] and Channel Hot Carriers (CHC) [43]. Among these, electromigration is a major aging effect in present integrated circuits. The primary factor that influences electromigration is the junction temperature  $T_j$ . The junction temperature  $T_j$  is thus the critical factor affecting silicon lifespan under electrical bias when the chip is operating within the prescribed data sheet conditions, and the lifetime can be represented using an Acceleration Factor (AF). The Arrhenius equation, which links the chemical reaction rate to temperature,

can be used to analyze the damage that occurs in electronic devices over time for various working temperatures. The accelerating factor (AF) [37] can be represented as in (8).

$$AF = \exp\left(\frac{E_a}{K} \left(\frac{1}{T_{use}} - \frac{1}{T_{stress}}\right)\right) \quad (8)$$

where AF represents the Acceleration Factor,  $E_a$  is the Activation energy in eV, K is the Boltzmann's constant ( $8.63 \times 10^{-5}$  eV/K),  $T_{use}$  is the use temperature in Kelvin and  $T_{stress}$  is the stress temperature in Kelvin.

This work proposes a methodology for improving the useful lifetime of the processor cores by considering electro-migration as the primary failure mechanism. The aging-aware scheduler estimates the temperature of the processing elements of the core when a job is ready, by using the workload characteristics as input to the developed models. Our goal is to allocate the tasks to cores based on the aforementioned inputs to maximize chip lifetime while meeting the performance requirement bounds. For the reliability-aware scheduler design, two types of frequency adaptations are proposed in this work, where the processor clock can either be controlled in discrete values or in a continuous manner. Based on the workload characteristics, the performance requirement, and the end system reliability requirement, the aging-aware scheduler selects a core from the pool of feasible cores and decides its frequency of operation. The architecture of the proposed aging-aware scheduler is represented in Fig. 2.

Fig. 2. The Aging-aware Scheduler.

The proposed aging-aware scheduler supports two types of clocking schemes for the processor core, i) cores whose operating frequencies can be selected from a discrete set of values and ii) cores whose frequency of operation can be varied continuously within a defined range. For the discrete frequency selection scheme, the scheduler will select the maximum possible operating frequency from a set of possible values, such that the lifetime reliability requirement can be met. In the continuous frequency selection scheme, the scheduler will have fine control of the operating frequency. In this case, the scheduler will use interpolate functions to estimate the closest frequency of operation that meets the lifetime reliability requirement with graceful performance degradation. For the specified workload characteristics, the data set includes known frequency and related temperature values of the logical components of the core.

Linear Interpolation (LI) and Spline Interpolation (SI) are the two types of interpolation schemes attempted in this work. To build a function utilizing fixed frequency datasets for linear interpolation, the `interp1d` class from the "scipy.interpolate" package is utilized. SciPy [44] is a free and open-source

Python library used for scientific and technical computing. When using linear interpolation for curve fitting, additional data sets are generated inside the boundaries of a finite collection of existing datasets using linear polynomials. In applications where smoothing is necessary, the piecewise-defined spline function is employed instead of polynomial interpolation because it produces good results for low-degree polynomials while minimizing Runge's phenomena for higher degrees.

Algorithm I illustrate the aging-aware scheduler's pseudo code. The scheduler, based on the workload characteristics, forms a feasible set of cores  $\{C_1, \dots, C_m\}$ , from the set of available cores during the scheduling interval. The temperature patterns of the logical components are predicted using the prediction models developed in the first part of this work, and using these parameters, the aging factor AF of each core  $C_i$  related to the lifetime reliability is determined. Based on the workload's performance requirements, the lifetime reliability requirement of the cores, and the type of frequency control supported by the architecture, i.e., either a discrete frequency control or fine frequency control, the frequency of operation of the core is determined.

---

#### Algorithm I. Aging Aware Core Selection

---

Inputs: workload characteristics, performance constraints, lifetime reliability requirement

1. **while** (true) {
2.   **for** each schedule window  $T_s$ , perform {
3.     **for** each task  $\{T_1, T_2, \dots, T_n\}$  in the process queue Q perform {
4.       a. analyze the characteristics of  $T_i$  and form the feasible set of cores  $\{C_1, \dots, C_m\}$ .
5.       b. estimate temperature characteristics of the processing elements  $\{L_1, \dots, L_p\}$  of the feasible cores  $C_i$ .
6.       c. estimate aging factor AF of each core  $C_i$  related to the lifetime reliability.
7.       d. select a core based on the lifetime reliability and performance requirements.
8.       e. determine the core's operating frequency  $f$ :
  - i. if discrete frequency control  
 $f = f_c$  where  $f_c \in \{f_1, \dots, f_s\}$
  - ii. else  $f = f_i$  where  $f_{min} \leq f_i \leq f_{max}$
9.     } //end for each task
10.   } //end for each schedule window
11. } //end while

Outputs: i) Mapping of the tasks  $\{T_1, \dots, T_n\}$  to cores  $\{C_1, \dots, C_m\}$  if  $n \leq m$ ; stall the remaining  $n-m$  tasks if  $n > m$ , ii) frequency of operation of the selected cores.

---

The regression models for predictive modeling need to be updated if the error in prediction is more than a threshold value because of the change in the data. The accuracy of the prediction logic is verified periodically with an updating interval. The updating interval, a customizable parameter, is kept substantially greater than the scheduling interval to reduce the computational overhead for the assessment of the actual temperature levels. The model updating process is represented in Algorithm II.

Algorithm II. Model Updation

Inputs: workload characteristics, core id, maximum allowable error in prediction (threshold)

1. **while** (true) {
2. **for** each updating interval,  $T_u$  do {
  - a. **for** each core  $\{C_1, \dots, C_m\}$  do {
    - compute the actual temperature of the processing elements (with on-chip sensors and/or software tools).
    - }//end** for each core
    - if** (prediction error > threshold)
      - update the prediction models.
    - end if**
  3. **}//end** for each updating interval ...
  4. **}//end** while

Output: updated prediction models.

IV. RESULTS AND DISCUSSION

The experiments of this research work were conducted using the application benchmarks belonging to consumer, telecommunications, network, and security categories taken from the well-known MiBench suite as represented in Table II.

Multiple instances created by altering the data set handled by the tasks are used to model the temperature characteristics of the logical components. As a result,  $n$  versions of a task  $w$  are created and evaluated its execution on  $m$  number of cores of the multi-core processor. Using new instances of the workloads derived from MiBench, the per-logical unit temperature is estimated to evaluate the developed models. The integer ALU, integer register file, floating-point unit, floating point register file, Data Translation Lookaside Buffer (DTLB), Instruction Translation Lookaside Buffer (ITLB), and load/store queue are characterized as the key power-consuming processing elements of the cores. Fig. 3 illustrates the validation of the developed models for the task CRC. The Steady State Temperature (SST) of the logical elements which are having significant power consumption is evaluated using the developed LR and PR models and is compared with the values estimated using the tool HotSpot. The operating frequency of the core is defined as 3400 MHz. The difference in estimation using the two methods is represented as a percentage error and is shown in Fig. 4. With a maximum prediction error of 0.008 percent for linear regression and 0.826 percent for polynomial regression-based models, the suggested regression-based models exhibit good consistency with HotSpot.

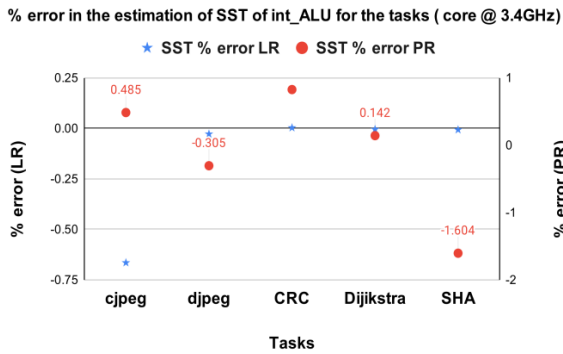

Fig. 6. Differences in the Estimation of Steady-state Temperature of Integer ALU.

The proposed aging-aware scheduler uses predicted SST of the logical components to estimate the degradation in the lifetime of the processor core during the scheduling of workloads. The lifetime of the critical components is represented using the Acceleration Factor (AF) while considering the junction temperature ( $T_j$ ) of silicon as the primary variable impacting the lifetime of the cores. Fig. 7 shows the validation of AFs of the principal power-consuming processing elements of the core for the task djpeg where the AFs are computed using the SST values estimated using HotSpot, LR, and PR models. Fig. 8 represents the validation of the AF estimation of int\_ALU for the different tasks. The processor core is set to operate at a frequency of 3400 MHz.

Fig. 7. Acceleration Factor of the Processing Elements Estimated using HotSpot, Linear Regression, and Polynomial Regression Models.

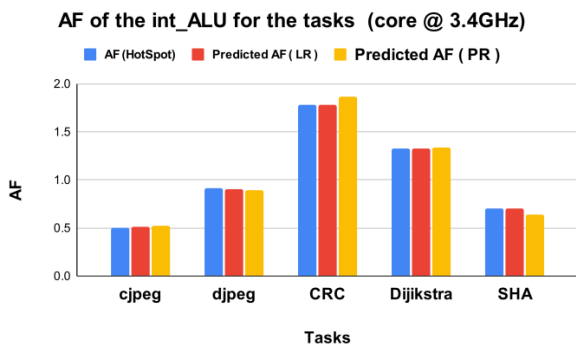

Fig. 8. Acceleration Factor of the Tasks Estimated using HotSpot, Linear Regression, and Polynomial Regression Models.

The proposed aging-aware scheduler estimates the temperature profiles of the logical components of the feasible cores based on the characteristics of the task in the service queue and decides the appropriate frequency of operation of the core. The lifetime reliability requirement of the core and the workload's performance requirements are used to determine the core operating frequency. In this work, the performance of the workloads running on a core clocked at 4000 MHz is taken as the reference, and the performance of the cores executing workloads with different operating conditions is represented relative to the reference performance. Fig. 9 represents the lifetime improvement of the cores and the corresponding relative performance degradation of the tasks when implementing a discrete frequency control scheme. In this case, the lifetime reliability requirement is taken as ten years, corresponding to an AF of 1. The core operating frequency is selected from the set {4GHz, 3.4GHz, 2.4GHz, 1.4GHz} based on the lifetime reliability requirement. Fig. 10 shows the corresponding values for AF = 1.5. The scheduler uses the thermal profile of the logical component having the highest value, for the estimation of AF of the core. This work assumes that the CPU core is designed to function for ten years when the junction temperature is at 105°C.

When the reliability-aware scheduler functions in the continuous frequency mode, the core operating frequency can assume a value within the defined range of 1400MHz to 4000 MHz. Linear Interpolation (LI) and Spline Interpolation (SI) are the two interpolation schemes employed, for estimating the closest frequency required for meeting the reliability and performance requirements. The frequency values for interpolation are determined based on the estimated temperature of the cores. Thermal estimation is performed using HotSpot, the standard method, and with the proposed LR and PR methods. The frequencies estimated by the scheduler for these temperature values are shown in Table III. The frequencies are determined for meeting the lifetime reliability requirement of ten years (corresponding AF = 1). Lifetime reliability of ten years corresponds to a threshold value of the silicon junction temperature,  $T_{qual}$  of 105 Degree Celsius.

Useful lifetime improvement and relative performance of tasks for AF = 1

Fig. 9. Useful Lifetime Improvement and Relative Performance of Tasks (Discrete Frequency Control with AF = 1).

Useful lifetime improvement and relative performance of tasks for AF = 1.5

Fig. 10. Useful Lifetime Improvement and Relative Performance of Tasks (Discrete Frequency Control with AF = 1.5).

TABLE III. CORE OPERATING FREQUENCIES FOR AF=1

Fine Control of Operating Frequency (AF = 1 T <sub>qual</sub> = 105 Degree Celsius)						
Case	Case 1	Case 2	Case 3	Case 4	Case 5	Case 6
Temp Estimation scheme	Hot-Spot	Hot-Spot	LR	LR	PR	PR
Freq estimation scheme	LI	SI	LI	SI	LI	SI
Tasks	Estimated Frequencies of the cores (in GHz)					
cjpeg	2.7127	2.7128	2.7357	2.7356	2.7381	2.7377
djpeg	3.2871	3.2872	3.2852	3.2851	3.2663	3.2663
CRC	4.0	4.0	4.0	4.0	4.0	4.0
Dijkstra	3.7752	3.7752	3.7750	3.7749	3.7876	3.7876
SHA	3.0191	3.0195	3.0192	3.0191	2.9254	2.9253

Validation of the proposed scheme is carried out for the case where there is a lifetime reliability requirement of ten years. In this case, the aging-aware scheduler will adjust the operating frequency to limit the core temperature to 105°C. The actual temperature of the cores for the frequencies of operation mentioned in Table III is computed using HotSpot and is shown in Table IV. It can be seen that the proposed algorithm is adjusting the core frequencies in such a way that the temperature of operation of the cores is very close to the required value of 105°C. The average prediction error of the proposed scheme in the estimation of the core temperature is compared with the results reported in recent publications and is shown in Table V.

The lifetime of the cores, when operating with the temperatures shown in Table IV, is computed using (8). The theoretical lifetime corresponding to AF=1 is ten years. Table VI shows the lifetime of the cores corresponding to the steady state temperature values mentioned in Table IV. In this case, the algorithm is driving the operating frequency of the cores in such a way as to meet the lifetime requirement of ten years. The lifetime of the cores when operating with the frequencies estimated by the algorithm is having a maximum deviation of 2.85 % from the required lifetime.

Using the methodology proposed, embedded application developers can perform a fast design space exploration between the lifetime reliability of the processor cores and the performance requirement of the tasks. Fig. 11 depicts the compromise between AF and the performance of the benchmark applications when linear regression is employed for temperature estimation along with linear interpolation for frequency estimation. At higher values of AF, processing cores have better lifetime reliability but at the expense of application execution performance. Fig. 12 represents the corresponding trade-off when polynomial regression is employed with continuous frequency assignment.

The concept suggested in this paper, where the aging-aware scheduler selects a task from a predetermined list of tasks to assign to a core, works well enough to extend the lifespan of multi-core systems running embedded workloads. A task might run at multiple scheduling points with a varying level of computational load because the complexity of the jobs that get executed on the cores may change over time. It is possible to account for these diverse computational costs at various execution times by building the regression model utilizing the heat profiles of logical units carrying out activities of varied computational costs at various execution times.

V. CONCLUSION AND FUTURE WORK

The aging-aware scheduler proposed in this work uses the developed computationally efficient models to estimate the steady-state temperature of the processing elements in multi-core processor architecture. Temperature values estimated with the models are used to predict electromigration-induced aging. The scheduler performs an aging-aware application mapping strategy for enhancing the lifetime reliability of the cores. The suggested scheduler will estimate the operating frequency of the processing cores for satisfying the lifetime reliability constraints with a gentle decline of the performance as opposed to a no-aging aware scheduler, where the workloads are distributed to the cores based on the performance need. Results from simulations show that the suggested approach can increase the lifespan of the operation of multi-core processor systems.

The algorithm proposed in this work is extensible and configurable. The proposed framework is configurable, as it is possible to use on-chip thermal sensor data for estimating the temperature and aging effects of the logical components along with the temperature data computed using the software tools. In the future, the framework may be extended to take into account the impacts of aging brought on by Hot Carrier Injection (HCI), Positive-Bias Temperature Instability (PBTI), and Negative-Bias Temperature Instability (NBTI), along with electromigration.

Kampus Kuala Terengganu, 21080 Kuala Terengganu, Malaysia

**Abstract**—The COVID-19 pandemic has such a significant impact and causes difficulties in many aspects that the new normal rules should be implemented to reduce the effects. New normal rules have been implemented by governments worldwide to break the virus chain and stop its transmission among the society. Even if the COVID-19 outbreak is under control, governments still need to know whether society could adapt and adjust to their new daily lifestyles. Many precautions still must be addressed as the transition to endemic status does not mean that COVID-19 will naturally eventually disappear. The World Health Organization also has warned that it is too early to treat COVID-19 as an endemic disease. Since the pandemic, many interactions have been done online, leading to the increasing social media usage to express opinions about COVID-19. The objective of the study is to explore the capability of the Naïve Bayes algorithm in the sentiment classification of the public's acceptance on the new normal in the COVID-19 pandemic. Naïve Bayes has been chosen for its good performance in solving various other classification problems. In this study, Twitter data were used for the analysis and were collected between March and June 2022. The evaluation results have shown that Naïve Bayes could generate excellent and acceptable performance in the classification with an accuracy of 83%. According to the findings of this research, many people have accepted the new normal in their daily lives. The future works would include scrapping more data based on geolocation, improving the feature extraction technique, balancing the dataset and comparing Naïve Bayes performance with other well-known classifiers. The subsequent study could also focus on detecting the emotions of the public and processing non-English tweets.

**Keywords**—Sentiment analysis; COVID-19; new normal; acceptance; naïve bayes

## I. INTRODUCTION

The term "sentiment" refers to a topic that includes subjective and objective aspects and factual and non-factual factors. It transcends the difference between a positive or negative subject [1]. Sentiment analysis is an analytical technique to analyze a text that identifies the level of public sentiment or opinion on a product or service and a person, such as politicians or celebrities [2]. The new normal is the new order, habits, and behavior based on adaptation to encourage clean and healthy living [3]. The Corona Virus Disease 2019 (COVID-19) pandemic has changed people's livelihood around the globe.

Consequently, COVID-19 causes so many difficulties to deal with in people's lives, that the governments need to implement new protocols to reduce the spread of the COVID-

19 infection among communities. The guidelines have become the new normal in the community's daily lives when people have suddenly been forced to adapt to all the protocols. Therefore, to mitigate the damaging effect of the COVID-19 pandemic, everyone is required to follow the Standard Operational Procedures set by the authorities in most countries. The new normal requires everyone to practice social distancing, use face masks, regularly wash hands with water and soap or sanitizer, stay at home unless necessary to go out, work from home or online learning for schools and universities [4]. Even after the infections have become less severe, people still have to take the precautions seriously.

It is necessary to break the virus chain and stop its transmission among the communities. Initially, the community was still ignorant of the virus's seriousness and was indirectly forced to adjust quickly and adapt to the new normal rules in daily life. Some people oppose the new normal life and still want to continue their old lifestyle without following health protocols and restrictions [5]. This kind of mentality may also influence others in embracing a new normal in their lives. Violations of health protocols will lead to an increase in COVID-19 cases. Implementing a new defence mechanism against a pandemic is quite challenging since it requires public engagement and acceptance of the policy required by the government [6]. In addition, due to the pandemic, any interaction was severely limited, resulting in increased digital use to obtain information about COVID-19. Therefore, social media sites such as Twitter have become essential platforms for expressing opinions, needs, and preferences. Nowadays, the community often responds to the current issues worldwide through Twitter by using tweets, retweeting others' posts, leaving a comment, or using a hashtag to spread something. A community has used Twitter to express their opinions over the increase of COVID-19 cases. The Twitter post can be a valuable source for understanding the community's acceptance towards new normal guidelines in making these new practices part of everyday habits.

As in Malaysia, after nearly two years of the pandemic, the country has entered the "Transition to Endemic" phase of COVID-10 starting from April 1, 2022, amid thousands of infections [7]. Endemic could be referred to as the constant presence, and usual prevalence of disease or infectious agent in a population within a geographic area. The transition to endemic can be considered an exit strategy.

Align with the announcement made by the Malaysia Government, this study proposes a sentiment analysis on the acceptance of the new normal in society. The tweet regarding

the transition phase will be used. The Naïve Bayes algorithm has been chosen as the machine learning method for sentiment classification. The Naïve Bayes algorithm would help to classify the level of sentiments of society's responses into two categories which are negative and positive. This study aims to explore the capability of the Naïve Bayes algorithm in the sentiment analysis on the acceptance of the new normal in the COVID-19 pandemic. The Naïve Bayes classifier has the advantage of requiring less training data to determine the estimated parameters needed in the classification process. Furthermore, the Naïve Bayes classifier is an algorithm frequently used for data mining because it is simple, fast to process, and easy to use with a simple model and a high-efficiency level [8].

This paper is structured as follows: Section I contains the Introduction; Section II discusses the Literature Review and Section III explains the Methodology. Section IV presents the Results and Discussion, while Section V presents the paper's Conclusion.

## II. LITERATURE REVIEW

### A. Similar Works

Several similar works are related to accepting the new normal in the COVID-19 pandemic. Table I describes the works, presenting the algorithms to solve the classification problems.

The first similar work used the Random Forest and Naïve Bayes algorithm to measure the people's sentiment toward government appeal in facing the COVID-19 pandemic [9]. Another work has implemented the Support Vector Machine Algorithm to analyze Twitter data and identify the Canadians' feelings regarding social distancing in relation to COVID-19 [10]. Research by [5] has analyzed the public's perception of social media towards the new normal during the COVID-19 pandemic in Indonesia. The study found that most Instagram users who follow religious accounts are against the new normal. The study [11] has implemented a Recursive Neural Network in analyzing the Twitter data to evaluate people's attitudes towards public health policies and events in the era of COVID-19. The tweet data analysis showed that many people's sentiments toward the stay-at-home approach were shifted because of the policy's negative consequences. Further, [12] has adopted the Latent Dirichlet Allocation (LDA) algorithm to perform sentiment, emotion, and content analysis of tweets regarding social distancing on Twitter. This research has indicated that most Twitter users supported the social distancing strategy.

In most works, the machine learning algorithms have solved the sentiment classification problems with reasonable accuracy. In this study, Naïve Bayes has been chosen due to its good performance in solving various other classification problems [13-15]. Although Naive Bayes has some drawbacks in the probability technique, it is worth exploring the algorithm's performance in solving another classification problem [16].

TABLE I. SIMILAR WORKS

	Title	Algorithm	Objective	Result	Ref
1.	Community Understanding of the Importance of Social Distancing Using Sentiment Analysis in Twitter	Random Forest Algorithm and Naïve Bayes algorithm	To measure people's sentiment toward government appeal in facing the COVID-19 pandemic.	Random Forest Algorithm had the best accuracy of 95.98%	[9]
2.	Sentiment Analysis on COVID-19-Related Social Distancing in Canada Using Twitter Data	Support Vector Machine algorithm	To analyse Twitter data and identify Canadians' feelings regarding social distancing.	SVM algorithm generated 87% of accuracy	[10]
3.	Public's Perception on social media towards New Normal during Covid-19 Pandemic in Indonesia: Content Analysis on Religious Social Media Accounts	Neuro-Linguistic Programming (NLP) method.	To discover about the public's perceptions of the government policies	The technique succeeds in solving the problem	[5]
4.	Analyzing Twitter Data to Evaluate People's Attitudes towards Public Health Policies and Events in the Era of COVID-19	Recursive Neural Network (RNN)	To track people's opinion regarding the public health policies and events during a COVID-19 pandemic.	The performance RNN is good.	[11]
5.	Understanding public perception of coronavirus disease 2019 (COVID-19) social distancing on Twitter	Latent Dirichlet Allocation (LDA)	To perform sentiment, emotion, and content analysis of tweets regarding social distancing on Twitter during the COVID-19 pandemic.	The algorithm able to generate good result	[12]

### B. Naïve Bayes Algorithm

The Naive Bayes classifier is a simple probabilistic classifier that calculates a set of probabilities by adding up the frequencies and value combinations from a given dataset. The algorithm uses the Bayes theorem and assumes that all variables are independently provided by the value of the class variable. The Naïve Bayes classifier can be trained very

effectively in supervised learning and can also be used in complicated real-life situations. The Naïve Bayes algorithm is simple to understand, requires training data to estimate the parameters, is unresponsive to unrelated features, and performs well when dealing with actual data and unique data source [17]. Below are the equations that calculate the probability categories in Naïve Bayes theorem.

$$P(c | x) = \frac{P(x | c)P(c)}{P(x)} \quad (1)$$

Equation (1) shows that variable c is class and variable x represents the attribute applied. P (c | x) is the posterior probability of class given attribute, P (x | c) is the likelihood, which is the probability of attribute given class, P (c) is a class prior probability. Lastly, P (x) is the predictor prior probabilities of the attribute [18].

### III. METHODOLOGY

#### A. Data Collection

The data collection were conducted from March to June 2022. The data were scrapped by using the Twitter API. A total of 7659 observations (rows) and three variables (columns) were obtained. This data collection process used English tweets comprising sentences or popular hashtags related to the new normal. The search keys were; “face mask”, “hand hygiene”, “Sejahtera scan”, “new normal COVID-19”, “stay at home”, “work from home” and “social distancing”. Table II shows the sample of a raw dataset from the scrapping process. The dataset contains three columns which represent Time, User and Tweet. However, only the Tweet column was used in this study.

#### B. Data Pre-processing

Data cleaning is the terms that refer to the process of identifying and correcting, removing, duplicate or invalid records from a database. Data inconsistency can occur in a variety of ways. For example, it might occur due to data corruption during transmission or storage or user entry errors [19]. Therefore, it is essential to clean up data so it can be used in models and produce better results.

Fig. 1. Steps in Pre-processing.

Fig. 1 shows the steps of the data pre-processing for this study. Firstly, the tweets are converted into lowercase, while symbols and numbers are ignored. The website links such as “https” or “www”, retweets (rt), the hashtag symbol (#), user handles (@), and non-letter characters are also eliminated from the tweets. These are replaced with a blank string. After case folding, all the duplicate rows are removed to prevent redundancy in the dataset. Then, stopword removal is applied to the clean dataset, which removes stopwords listed in the NLTK package. To remove the stopwords, the lambda function is used. After stopwords removal, the tweet is tokenized. In tokenization, all text sentences are broken down into smaller parts called tokens. The Part-Of-Speech (POS) is applied after the data has been tokenized. The POS tagging determines the word class based on the word's placement in the sentences, indicating whether the word is a noun, adjective, verb, etc. and also enables future use of lemmatization.

The pos tags of a word are important to obtain the word's lemma properly. The final step in the process involves lemmatization steps being applied to the dataset. This is done because lemmatization has the potential to give meaningful root words. Lemmatization is preferred over stemming because it produces better results by performing an analysis based on the word's part and producing true dictionary words. After the preprocessing, the datasets were reduced to 2807 data. This is mainly because the pre-processing steps have eliminated all the noisy and unnecessary data.

#### C. Labelling

After the pre-processing, the processed tweets data must go through the labelling process. The labelling process is intended to label the data according to the sentiment classes, which is negative and positive [3]. Text Blob, a python library, has been used in this process. The positive tweets is represented by the number (+1), negative is represented by the number (-1) and neutral is represented by (0). In this study, only positive and negative classes are used. Table III shows an

example of tweets labelled with positive and negative sentiments. After the labelling, there are 2095 positive tweets, while the negative tweets obtained are 712.

TABLE III. EXAMPLE OF TWEETS LABELLED WITH POSITIVE AND NEGATIVE SENTIMENT

Tweet	Label
Keep hands clean, wear a mask for no more than a couple of hours and dont touch your face is the best advice.	1
I am sick of having to wear masks and have no face anymore. I don't want to wear a mask.	-1

D. Feature Extraction

Bag-of-Words is a method that has been used for feature extraction. Bag-of-Words is the most used technique for natural language processing. In this process, the bag-of-word extracts the words or the features from a tweet, and then the frequency of each term is calculated. It is called a “bag” of words because any information about the order or structure of words in the document is discarded. The model is only concerned with whether known words occur in the document, not where in the document [20].

As in this study, the bag of words model calculates the number of tokens collected in each document. Fig. 2 shows the output for the bag of words process. It displays the frequency table that counts how many times the term appeared. It contains three columns: the index representing the words, the count representing the occurrence of the terms, and the label representing each word's positive and negative labels.

E. System Architecture

The proposed system architecture is shown in Fig. 3. The first step is collecting the tweets from Twitter by using the Twitter API. The collected tweets are stored in the database and will go through the pre-processing steps. Then, the data is labelled with the positive or negative tag. Next, the data will be split into training and testing data. The training data will be used for feature extraction. The data is then passed to the Naive Bayes classifier model to categorize the data into positive or negative classes. The output result will show the accuracy of the proposed algorithm. Finally, the sentiment analysis result will be displayed to the user through the graphical user interface [21].

index	count	label

Fig. 2. Bag of Words Model.

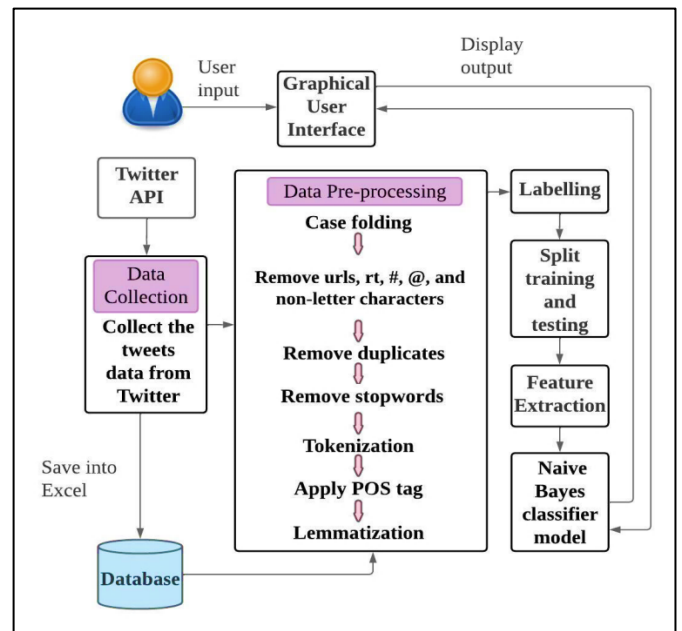

Fig. 3. Proposed System Architecture.

F. Performance Evaluation

Holdout method and Confusion Matrix have been used to evaluate the performance of the Naïve Bayes classifier. The holdout method is the simplest method to evaluate the performance of classifier where the data will be randomly split into two sets, which are training and testing set. The training data set is used to train the Naïve Bayes classifier and the testing dataset is used to test the performance of the classifier. Three sets were used in this study which are 90:10, 80:20 and 70:30. The first number for example for 90:10, indicates the percent of data used for training and the latter is for testing.

In addition, a confusion matrix is a matrix that comprises information on the actual and predicted classification achieved by classifier. It is often used to measure the performance of a classification algorithm. It includes the measurements of accuracy, precision, recall, F1-scores and ROC curve. The confusion matrix gives us a better picture of the algorithm's performance [22].

Table IV illustrates the confusion matrix for two classes which is for actual and predicted. The terms TP and TN indicate the True Positive and True Negative, which are referred to the accurately classified data. Meanwhile, FP and FN represent False Positive and False Negative, indicating incorrectly classified data [23].

TABLE IV. CONFUSION MATRIX

	Actual Positive	Actual Negative
Predicted Positive	TP	FP
Predicted Negative	FN	TN

The classifier accuracy can be calculated by applying the formula in (1). The accuracy presents the ratio of correct prediction over the total data. For the precision, it is indicated as the measure of the correctly identified positive cases from

all the predicted positive label. Next, for the recall, it measures the correctly classified positive from the total of the actual positive. As for the F1-score, it is the combination of precision and recall of a classifier into a single metric by using the harmonic mean [24]. The formulas to calculate the accuracy, precision, recall and F1-score are presented in the (1) to (5) respectively.

The accuracy obtained from (2) below:

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \quad (2)$$

The Precision obtained from (3) below:

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

The Recall obtained from (4) below:

$$Recall = \frac{TP}{TP+FN} \quad (4)$$

The F1-Score obtained from (5) below:

$$F1\ Score = 2 \times \frac{precision \times recall}{precision + recall} \quad (5)$$

Another classifier performance evaluation is the Receiver Operating Characteristic (ROC) curve. The ROC curve is a graph that summarizes the model's performance by integrating the confusion matrices at all threshold values [25]. Therefore, the ROC curve could provide an overview of the model's performance at different threshold values [26]. It is a graphical representation of the paired classifier with the bend indicating a trade-off between positive and false positive.

#### IV. RESULT AND DISCUSSION

There are two main analyses that have been conducted in this study. The first analysis conducted was the exploratory data analysis on the collected tweets data. Then, the second analysis was on the performance of the Naïve Bayes Classifier. In addition, the prototype to be used with the classifier model was proposed at the end of this section.

##### A. Exploratory Data Analysis

The first analysis is by analyzing the most common word obtained from the tweet. Fig. 4 shows the bar chart which is plotted to obtain the common words for the topics of acceptance of new normal in the COVID-19 pandemic. This chart provides an overview of which words frequently appear in the dataset. It reveals that the most common terms are new, home, normal, work, social, distancing, mask, wear, and stay. These top 10 common words have shown that people are aware of the pandemic's new normal lifestyle.

Then the analysis continues by analyzing the dataset according to its label which are positive and negative sentiment. The analysis conducted were word cloud and unigram analysis. A word cloud is one of the most common techniques for displaying and analyzing qualitative data. It is a graphic consisting of keywords found in the body of text, with the size of each keyword indicating the frequency with which it appears in the body of text [27].

Fig. 5 shows the word cloud for positive dataset, The most prominent words are "social", "distancing", "new", "normal",

"hand", "hygiene", "mask", "job", and "home". These words indicate the most discussed topic during the pandemic. It is used to represent positivity and actions during the pandemic. On the other hand, Fig. 6 the word cloud for negative dataset. We can observe some of the negative words such as "ill", "don't", "sick", "hate", "shit", and "pandemic" from the word cloud.

The count of word in positive and negative dataset using unigram analysis were also identified. The unigram is the single word representation in the dataset. Fig. 7 shows the positive dataset's top 10 words: new, normal, home, social, work, mask, get, distancing, wear, and hand. The most used phrase is "new". While Fig. 8 shows the top 10 words in the negative dataset: home, work, mask, get, normal, new, people and hand. The words in both unigrams mostly are the same, but the count for all words is different. For example, the term "new" in the positive Data Frame is more than 400, while the word "new" on the negative side is less than 100.

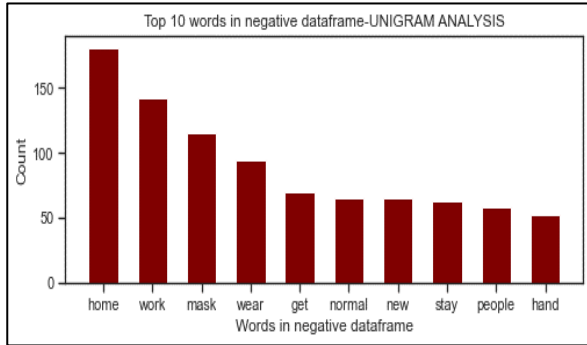

Fig. 8. Unigram Analysis for Words in Negative Dataset.

### B. Naïve Bayes Classifier Performance Evaluation

This section discussed the performance of the Naïve bayes classifier. The first performance was evaluated by looking at the accuracy of the classifier to classify the sentiment of the tweet data. It is done by comparing the actual label in testing data with the predicted label provided by the classifier. In this study, the accuracy was calculated by using the sklearn library in python. Table V presents the accuracy results. Based on the testing, the best accuracy is 83%, and the minimum is 79%.

To better understand the classifier performance, a confusion matrix was used. The analysis is focused on the 90:10 dataset, which obtained the best accuracy result. In this dataset, 281 data were tested. The confusion matrix obtained is shown in Fig. 9. The figure shows that there are 180 positive data and 54 negative data that the model has correctly predicted. However, the Naïve Bayes model cannot predict the remaining 47 data.

The confusion matrix can calculate the accuracy, precision, F1-score and recall of the Naïve Bayes model. Fig. 10 shows the detailed result of the classifier performance. The weighted average for precision, recall and F1- Score is 0.85, 0.83 and 0.84, respectively. Based on these values, even though the dataset contains an imbalance number of positive and negative data, the Naïve Bayes classifier can do the classification with 84% as indicated by the F1-score. In addition, all the parameters show a consistent value, such as the accuracy of the model.

Fig. 11 shows the ROC curve for the Naïve Bayes model. The true positive rate (TPR) is plotted against the false positive rate (FPR) to create a ROC curve (FPR). The actual positive rate (TP/ (TP + FN)) is the proportion of positive

observations that were correctly expected to be positive out of all positive observations. The closer the ROC curve approaches the upper left corner of the plot, the more effectively the model classifies data. To determine how much of the plot falls under the curve, the AUC (area under the curve) is used. The AUC value for Naïve Bayes model is 0.82. The greater the AUC, the better the model's ability to distinguish between the positive and negative classes of data [28].

TABLE V. ACCURACY OF THE CLASSIFIER FOR EACH DATASET

Split dataset	Train data	Test data	Accuracy
90:10	2526	281	83%
80:20	2245	562	81%
70:30	1964	843	79%

Fig. 9. Confusion Matrix for 90:10 Split Dataset.

	precision	recall	f1-score	support
-1	0.62	0.79	0.70	68
1	0.93	0.85	0.88	213
accuracy			0.83	281
macro avg	0.77	0.82	0.79	281
weighted avg	0.85	0.83	0.84	281

Fig. 10. Classification Report.

Fig. 11. ROC Curve.

This study also compares the accuracies of the Naïve Bayes algorithm implemented in other similar works. Table VI shows the accuracies of Naïve Bayes in each of the studies. Based on Table VI, the Naïve Bayes algorithm has generated good accuracies of more than 80% in all similar works. A Naïve Bayes algorithm could produce good and acceptable performance in sentiment classification problems. It is proven that Naïve Bayes is a reliable classifier due to its capabilities in solving various classification problems.

TABLE VI. COMPARISON OF NAÏVE BAYES ACCURACY BETWEEN SIMILAR WORKS

Authors	Accuracy
[3]	80.37%
[9]	80.65%
[29]	84.1%
Proposed Naïve Bayes Classifier	83%

### C. The Proposed Prototype

A prototype has been proposed for the implementation of the classifier. Fig. 12 displays the main user interface for the sentiment analyzer system. The user prototype was developed using the Python library's Tkinter framework. In the system, the user needs to input the sentiments first and then click on the "Check Sentiment Result" button to obtain the sentiment results. The result will then show the category of the tweets, whether it is Positive or Negative. The user needs to click on the "Clear" button to analyze the following statements. In this initial development, the system could only process one tweet at a time. The next improvement would enable the system to process several tweets simultaneously.

Fig. 13 shows the model's accuracy interface. If the user wants to see the model's accuracy in predicting the sentiment, the user must click the "Check Accuracy" button. It will navigate the user to a new window that shows the accuracy. The "Exit" button is used to close the system.

Fig. 12. Main Interface.

Fig. 13. Model's Accuracy Interface.

### D. Research Limitation

Several limitations of this study have been identified during the project's development. The first one is the quantity of data that has been scrapped is quite small. It is due to the time constraints of the project. Also, the standard API only allowed to retrieve tweets up to seven days and has a limited number to retrieve the data. This is because of the restriction on the Twitter developer account. In addition, the distribution of negative and positive tweets is also unbalanced. This might affect the performance of the classifier [30].

The next limitation is emotion analysis, which is not considered in this project. This project cannot indicate the public's emotion toward the new normal issues in the COVID-19 pandemic. The emotions are such as the people feel angry, surprised, happy or sad about accepting the new normal in their daily life. Lastly, the scrapped tweets are limited to English tweets and are not filtered by specific locations. The insight could not be generalizable to non-English speaking populations if only English tweets are used as the dataset. In addition, since most tweets do not have geolocation, it could be lacking in making conclusions based on certain countries or regions [31].

### V. CONCLUSION

This study has successfully explored the capability of the Naive Bayes algorithm in solving the sentiment classification on the acceptance of new normal in the COVID-19 pandemic. A total of 2807 tweets have been processed, which consisted of 2095 positive and 712 negative tweets. Based on the evaluation results, Naive Bayes has generated good and acceptable performance with 83% accuracy and 84% of F1-score. In addition, the developed Naïve Bayes classifier can distinguish between positive and negative tweets as indicated by AUC value of 0.82.

The significance of this study is in demonstrating the capability of the Naïve Bayes classifier in sentiment analysis. The proposed conceptual framework shown in Fig. 3 can be used as a guideline in conducting similar works. As for the study on the acceptance of the new normal in the COVID-19 pandemic, exploratory data analysis on the tweets showed more positive sentiments than negative ones. This indicates that most people could accept the new normal in their daily life during the COVID-19 pandemic. The government could use the results of this study as a resource for consideration in developing policies and campaigns and making approaches to the people to implement the new normal. This study could help the ministry of health deliver the necessary messages to the public while also addressing public concerns and encouraging positive behaviour in response to the COVID-19 pandemic.

Future works would be to include the public's emotions and to process non-English tweets. The next scrapped Twitter data would also be based on geolocation, so that data could be analyzed based on particular countries or regions.

### ACKNOWLEDGMENT

Special gratitude goes to Universiti Teknologi MARA Cawangan Terengganu for the continuous support given

towards the completion of this project. This research is funded under the UiTM Geran Penyelidikan Myra Lepas PHD (600-RMC/GPM LPHD 5/3 (068/2021)).

**Abstract**—A hybrid filter is developed by combining smoothing and edge preservation properties of anisotropic diffusion (AD) filters and noise reduction features of median filtering. Mixed Gaussian Impulse noise and speckle noise are considered for analysis. The performance of this hybrid filter is verified using ultrasound images. The effectiveness of this filter is assessed with Point of Care Ultrasound (POCUS) images to verify whether the algorithm developed is applicable to them. POCUS refers to a handheld portable ultrasound instrument that can be used at patient bedside. Quantitative analysis with COVID-19 POCUS images, in terms of SNR, SSIM and MSE is performed. Results demonstrate that for all test images, the proposed filter has the best SNR, least MSE, and highest SSIM. Significant improvement in image quality is thus observed both qualitatively and quantitatively. The novelty of suggested technique is its effectiveness in reducing both mixed Gaussian impulse noise and speckle noise in ultrasound as well as POCUS images without the need for separate filters. POCUS has played a significant role in the diagnosis and management of pulmonary, cardiac and vascular pathologies associated with COVID-19. Automatic segmentation of these images and subsequent automatic detection and diagnosis are becoming increasingly popular due to the rapid development of artificial intelligence technologies. These results are useful in implementing better pre-processing prior to segmentation of ultrasound images to facilitate improved patient care.

**Keywords**—Anisotropic diffusion filter; POCUS; mixed Gaussian impulse noise; speckle noise

## I. INTRODUCTION

The use of ultrasound imaging for medical diagnosis is widely accepted due to its non-invasiveness, no risk factor, and efficiency. However, the acquisition process introduces noise in the signal, which has an impact on subsequent processes like segmentation, quantitative analysis, etc. The granular interference called, speckle noise is inherent in Ultrasound images. Impulse noises are yet another sort of noise present in ultrasound imaging. Another common type of noise found in medical images is Additive White Gaussian noise. Several different kinds of filters must be designed in order to effectively remove these noises. A median filter is a good choice for eliminating impulsive type noises. But it cannot suppress median tailed noise distributions like Gaussian. If linear filters are used to process such noise, they tend to blur the edges of the image [1]. Also, they cannot remove mixed Gaussian impulse noise and speckle noise adequately [2].

Studies show that various types of nonlinear filters [3] can be effectively used to remove such noises. Partial Differential equation based Anisotropic Diffusion (AD) filters are known for their ability to preserve edges in an image during denoising. AD approaches are being used in image processing since 1987 when Perona and Malik [4] introduced a non-linear method of edge preserving smoothing that outperformed the existing traditional linear methods [5]. Since ultrasound images are mostly affected by speckle noise and impulse noises [6], a combination of filter structures, which can filter out all types of noises, need to be derived. Median filter is usually employed for suppressing impulse noises like salt and pepper noise. However, it is not effective for reducing Gaussian noise or speckle noise [4]. Anisotropic Diffusion filters are the best choice in removing Gaussian noise and speckle noise. This paper introduces a new hybrid form of median and AD filters combining the advantages of median filters in removing impulse noise and AD filters in rejection of Gaussian and speckle noise. This hybrid form is found adequate for the removal of both mixed Gaussian impulse noise and speckle noise. The results are verified qualitatively and quantitatively.

In 1987, Perona and Malik proposed Nonlinear Anisotropic diffusion [4]. It is a filtering technique based on partial differential equation (PDE). It performs nonlinear smoothing and effectively reduces the image noise. The salient feature of AD filtering is that it can preserve important image features such as edges. While smoothing the rest of the image, it can maintain crisp texture detail at all viewing orientations [7]. It implies that blurring of edges and thus loss of information can be avoided. [8] Provides a derivation of AD filters for speckle reduction. Speckle noise is a form of multiplicative noise, usually present in medical ultrasound images and Synthetic aperture radar (SAR) images. Nonlinear means of removing speckle noise is vital in such cases. Some of the classical speckle removing filters like Lee filter or Frost filter tends to remove some important data also. Recent developments based on anisotropic diffusion filtering overcome the major drawbacks of conventional spatial filtering [8][9], and significantly improve image quality and provide better results than above mentioned filters[9][10].

Motivated from the work of Perona and Malik, various additive as well as multiplicative noise removal algorithms have been developed. A speckle reducing anisotropic diffusion (SRAD) method was proposed by Yu and Acton [8] which handles various noise distributions, especially, speckle. Further

improvement of the SRAD was presented by Karl et al. with the oriented speckle reducing anisotropic diffusion (OSRAD) method [11], incorporating local directional variance of image intensity. Both these methods have the drawback of producing over smoothed images. This problem was solved by anisotropic diffusion with memory based on speckle statistics (ADMSS) method [12] by Ramos, Zhou et al. [13] proposed a doubly degenerate nonlinear diffusion (DDND) model by using the diffusion equation theory. It guides the denoising process with the aid of the gradient information and the grey level information. In [14] speckle noise suppression and image segmentation of ultrasound image using AD filters with an improved diffusion coefficient is discussed. In [15] the drawbacks of SRAD filter are eliminated using an optimization algorithm for diffusion coefficient. The algorithm well removes speckle and is more suitable for image segmentation. However, no other noise than speckle is considered [16][17][18]. In [21], Mei Gao et al. proposed a filtering scheme for ultrasound images, which the noise at the edge is processed during denoising process. This is achieved by analyzing the divergence term. Most of the above mentioned developments and research, aided in speckle noise removal of ultrasound images. Such an extensive research has been done in the area of AD filters viewing its selective smoothing and edge preserving capability and speckle denoising property [19][20][22][23][24]. But almost all of them works on speckle removal only and doesn't mention about the other relevant noises.

However, in addition to speckle noise, impulse noise is present in ultrasound images and Gaussian noise is common in medical images. None of the above works consider the removal of such noises. In [2], Meenavati and Rajesh proposed a method to remove mixed Gaussian impulse noise from images using volterra filters. But the analysis does not consider ultrasound images or reduction of speckle noise. Since speckle is an important consideration in US images, AD with removal of speckle as well as mixed Gaussian impulse noise is significant. All these discussions clearly demand the development of a filter which can eliminate both speckle and mixed Gaussian impulse noise.

The uniqueness of proposed work is that the same filter can be used for reduction of both mixed Gaussian impulse noise and speckle noise. In this paper, the emphasis is given to the analysis of POCUS (Point of Care Ultrasound) images to verify whether the algorithm developed is applicable to POCUS images. Analysis with parameters like SNR, MSE, and SSIM is done to quantitatively verify the performance of the proposed filter for POCUS images. Results are found to be better than using median and simple AD filters for noise removal.

Significances of the work are listed below:

- Addresses the removal of almost all kinds of noise such as mixed Gaussian impulse noise and speckle noise, whereas the previous literature on AD primarily discusses speckle noise.

- No prior work has considered the denoising of POCUS images.
- Qualitative and quantitative analysis gave better results with high PSNR, least MSE and improved SSIM compared to the existing methodologies.

This paper is organized as follows. In Section II, a brief review of POCUS is given. The design features of median and nonlinear AD filters are analyzed in Section III. In Section IV, the features of the proposed filter are discussed. Methodology of work is presented in Section V. Experimental results and Quantitative analysis using these images is given in Section VI. Concluding remarks are presented in Section VII.

## II. A REVIEW OF POCUS

Point-of-care ultrasonography (POCUS) refers to handheld portable ultrasound instrument that can be used at patient bedside. In the midst of COVID-19 pandemic, such hand-carried ultrasound devices emerge as a tool that can simplify the imaging process [25]. These devices are perfect for COVID-19 scans because they are small enough to be covered completely with a probe cover and due to its small size, the decontamination process is also simplified. Several studies have indicated that wrapping the whole device in plastic or using single-use plastic sterile probe covers is enough to condense the decontamination process. In addition, a trained healthcare provider requires only 5 to 10 minutes to conduct a lung POCUS study [25]. Experts from China have specifically advocated for the use of hand-held POCUS in COVID-19 due its clinical and economic value [26]. The utility of these devices in continuous monitoring COVID-19 patients managed at home have also been reported. The salient features of POCUS such as its ability to connect to smartphones and tablets, artificial intelligence-assisted diagnosis, wireless feature, rechargeable batteries, and low cost make them a convenient and practical imaging option suitable even in remote areas [25][26][27]. Research has shown that point-of-care ultrasound device can help manage infectious diseases, as well as abdominal cardiac and pulmonary pathologies [25]-[29]. Images of some of the POCUS instruments available in market are shown Fig. 1

### III. FILTERING TECHNIQUES

#### A. Anisotropic Diffusion Filters

As presented by Perona and Malik in [4], the basic PDE equation of anisotropic diffusion can be represented as

$$\frac{\partial I}{\partial t} = \text{div}(c(x, y, t)\nabla I) = \nabla c \nabla I + c(x, y, t)\Delta I \quad (1)$$

Here original Image is  $I_0(x, y)$ .  $I(x, y, t)$  is the smoothed image via anisotropic diffusion method as the solution of equation (1).  $\Delta$  is the Laplacian operation,  $\nabla$  is the gradient of the image.  $\text{div}(\dots)$  denotes the divergence operator and  $c(x, y, t)$  is the diffusion coefficient.  $c(x, y, t)$  is a function of the image gradient which preserves edges and controls filtering process by controlling the rate of diffusion. The Diffusion coefficient can be evaluated by the two functions:

$$c(\|\nabla I\|) = e^{-\left(\frac{\|\nabla I\|}{k}\right)^2} \quad (2)$$

$$c(\|\nabla I\|) = \frac{1}{1 + \left(\frac{\|\nabla I\|}{k}\right)^2} \quad (3)$$

where  $k$  is the edge magnitude parameter.

A four-neighbourhood discrete form of (1) is given by

$$I(x, y, t + \Delta t) = I(x, y, t) + \frac{\Delta t}{4 \sum_{\rho \in Z} G(\nabla I(\rho, t))} \quad (4)$$

where  $Z$  is the set of the four neighbourhoods of pixel  $(x, y)$ , denotes a neighbourhood of  $(x, y)$ , and  $\nabla I(\rho, t) = I(\rho, t) - I(x, y, t)$  is the image gradient at current time  $t$ . The above equation is recursive over time until it meets the stopping criterion. Perona and Malik suggested that a desirable diffusion coefficient should satisfy the basic condition that it diffuses more in smooth areas and less around high-intensity transitions. By this technique, noise or unwanted texture is smoothed, while edges are sharpened [30]. The function  $G$  is a monotonically decreasing function, the edge magnitude parameter. Depending upon the value of the monotonically decreasing function  $G$  and the  $|d|$  which is the absolute value of

gradient, the anisotropic diffusion filtering can be formulated as follows:

- The range of  $G$  is  $[0, 1]$ . For any given parameter  $k$ , Monotonically decreases with  $|d|$ . If  $|d| \rightarrow 0$  then  $G \rightarrow 1$  is isotropic diffusion (Gaussian filtering); if  $|d| \rightarrow \infty$  then  $G \rightarrow 0$  the diffusion flow is arrested and the edges are preserved.
- For any given  $|d|$ ,  $G$  monotonically increases with parameter  $k$ , which means that  $k$  controls the generosity of the anisotropic diffusion filter. For higher value of  $k$ , the diffusion process is more likely to smooth the image and reduce the noise; while for lower value of  $k$ , the diffusion process is more restricted and is more likely to preserve image features [31].

The advantage of this technique is that it reduces noise and preserves the edges so that crisp edge features will be obtained.

#### B. Median Filter

Median filter is a nonlinear filter used for noise reduction in images. Each pixel value is obtained by taking the median value of neighboring pixels under the window. Thus, the result is the middle value after the input values have been sorted. When an image is considered, each pixel of the filtered image is replaced by median brightness value of its neighbourhood pixels in the original image.

Median filtering is a kind of smoothing technique like Gaussian filtering. Almost all the smoothing techniques including Gaussian filter adversely affect edges since they blur the image. Preserving edges is critically important for visual appearance of the image. For moderate levels of Gaussian noise (medium tailed distribution), median filter performs better than Gaussian filter and preserve edges. However, its performance is not significantly improved for high noise levels [32]. For removing salt and pepper noise (impulsive noise) median filters are more effective.

#### C. Proposed Hybrid Filter

The proposed filter is developed by combining the ability of median filter to remove impulsive noises with capabilities of AD filters to filter out Gaussian noise and speckle noise. Designing process involves two steps. The first step is to determine the median value of each and every pixel in the image being analysed. In the second step, these median values are used to design discretised form of anisotropic diffusion equation given in (5). To incorporate advantages of median filter, each pixel of the noised image used in the anisotropic diffusion process is replaced by median value its neighbourhood pixels and further processing is done. As described in [9], the discretised form of Perona –Malik Anisotropic diffusion equation is

$$I_{t+1}(s) = I_t(s) + \frac{\lambda}{\eta_s} g_k(|\nabla I_{s,p}|) |\nabla I_{s,p}| \quad (5)$$

Where  $I$  is the discretely sampled image,  $s$  the pixel position in the 2D grid,  $t$  denotes iteration step,  $g$  denotes conductance function and  $k$  is the gradient threshold parameter [7]. Constant  $\lambda \in (0,1)$  determines the rate of diffusion and  $\eta_s$

denotes the spatial 4-pixel neighborhood of  $s$ ,  $\eta_s = \{ N,S,E,W \}$  are the neighboring pixels of  $s$  in North, South, East and West directions. Visualization of 2D discrete diffusion is given in Fig. 2. The degraded image with each pixel replaced by its median value is given to the AD filter so that better removal of noise can be achieved.

Fig. 2. Eight Neighborhood Visualisation of 2D Discrete Diffusion.

#### IV. METHODOLOGY

This work consists of four steps. They are

- Design of filters
- Implementation
- Qualitative Comparison
- Quantitative Comparison

Design is based on the design equations discussed in Section III. The work is implemented using Matlab R2018b.

Fig. 3. Filter Response for Kidney Cut Ultrasound Image and Ben1 Image Corrupted by a Noise of Standard Deviation  $\sigma = 0.02$  and Impulse Noise Density  $\rho = 0.02$ . (a) Original Image (b) Mixed Gaussian Impulse Noised (c) Simple AD Filter (d) Median Filtered (e) Proposed Hybrid Filter.

#### A. Response of POCUS images to Mixed Gaussian Impulse Noise

POCUS images are collected from the dataset of [https://github.com/jannisborn/covid19\\_pocus\\_ultrasound](https://github.com/jannisborn/covid19_pocus_ultrasound) are used for the evaluation of noise filtering process. 50 POCUS images of COVID-19 are used from this dataset. Gaussian

The images used are degraded by mixed Gaussian impulse noise of standard deviation = 0.02 and impulse noise of density = 0.02 in order to assess how different filters respond to noise. Zero mean speckle noise with variance 0.04 is used for speckle noise analysis. In the proposed algorithm, the US image contaminated with mixed Gaussian impulse noise is decomposed into mask images considering 8-pixel neighborhood. The median filtered mask images are used to evaluate the diffusion coefficient in equation (3), which is further utilized for calculating AD algorithm. Initially, 15 iterations are done for simple AD and the proposed hybrid AD filters.

The qualitative analysis and comparison is performed by visually analyzing resultant images. By comparing SNR, MSE and SSIM, using the equations given in Section 4.2, quantitative analysis is done.

#### V. EXPERIMENTAL RESULTS

Kidney-cut ultrasound image of size 522X469 and Ben1 ultrasound image of size 538X317 are used for initial verification of noise filtering process. Gaussian noise of standard deviation  $\sigma = 0.02$  and impulse noise density  $\rho = 0.02$  are added to the image. The proposed hybrid filter output is compared with simple AD filter and median filter outputs. The output of kidney\_cut and Ben1 US images to simple AD filter, proposed hybrid filter and median filter are shown in Fig. 3. It can be seen that though simple AD filter is not good for eliminating Gaussian impulse noise, the performance is robust for the proposed hybrid AD filter. For median filter, visual quality seems comparatively far better than simple AD filter. But from quantitative analysis we can see that proposed hybrid filter outperforms median filter in SNR, MSE and SSIM.

noise of standard deviation  $\sigma = 0.02$  and impulse noise density  $\rho = 0.02$  are added to the image and the output is analysed. COVID-19 POCUS image, Cov\_severe, of size 367X367 is used for initial verification of noise filtering process. The proposed filter output is compared with simple AD filter and median filter. Results are shown in Fig. 4 and Fig. 5

Fig. 4. Response of Various Filters (a) cov\_severe POCUS Image (b) Image Corrupted by Mixed Gaussian Impulse Noise (c) Response of Median Filter (d) Output of Proposed Filter.

Fig. 5. Response of Simple AD Filter to cov\_severe POCUS Image.

Performance of the filter is evaluated using various POCUS images. A sample set of 10 images is shown in Fig. 6. Images used are degraded by mixed Gaussian impulse noise of standard deviation  $\sigma = 0.02$  and impulse noise of density  $\rho=0.02$

Fig. 6. Test Images used in Experiments.

Output for pneuLung image is shown in Fig. 7 and Fig. 8 respectively. For all the POCUS images, proposed filter provided better results. Visual quality of the proposed filter also seems better.

Fig. 8. Filter Response for pneuLung POCUS Image (a) Original Image (b) Mixed Gaussian Impulse Noised (c) Median Filter o/p (d) Proposed Filter Output.

### B. Response to Speckle Noise

The proposed hybrid AD filter performance is analyzed with an input corrupted by speckle noise. Results show that speckle removal can be efficiently achieved if the image is processed using the proposed hybrid filters.

Speckle noise is the major type of noise present in an ultrasound image. It limits contrast resolution of images by affecting the edges and fine details and make diagnostic more difficult. Anisotropic diffusion filters are efficient in removing speckle noise. Combining the advantages of median as well as AD filter, the performance of the proposed filter to POCUS images corrupted with zero mean speckle noise with variance 0.04 is analysed.

Fig. 9 compares outputs of simple AD filter, median filter and proposed hybrid filter responses for kidney\_cut US image for speckle noised image.

Fig. 10 and 11 compares outputs of simple AD filter, median filter and proposed hybrid filter responses for Cov\_severe POCUS image for speckle noised image. Here, the same zero means speckle noise with variance 0.04 is used. Here also, the visual quality is improved and noise removal is achieved.

Fig. 10. Various Filter Responses for cov\_severe POCUS Image for Speckle Noise.

Fig. 11. Various Filter Responses for pneuLung POCUS Image for Speckle Noise. (a) Original Image (b) Speckle Noised (c) Median Filter o/p (d) Proposed Filter Output.

Simple AD filter response for pneuLung POCUS Image using zero mean speckle noise with variance 0.04 is shown in Fig. 11. For all these experiments, 15 iterations are done initially and verified the process using 20 and 30 iterations.

### C. Quantitative Analysis

A quantitative analysis is done to evaluate the performance of the proposed anisotropic diffusion filter by comparing the parameters such as Signal to Noise Ratio (SNR), Mean Square Error (MSE) [6] and structural Similarity Index (SSIM).

The SSIM is a method for measuring the similarity between two images. The SSIM index can be viewed as a quality measure of one of the images being compared while the other image is considered as of perfect quality. Maximum value of SSIM is 1, reachable only in the case of two identical sets of data [33].

The SNR and MSE are computed using the formula [2]:

$$SNR = 10 \log_{10} \frac{\sum_{p=1}^N \sum_{q=1}^N v(p,q)^2}{\sum_{p=1}^N \sum_{q=1}^N (u(p,q) - v(p,q))^2} \quad (6)$$

$$MSE = \frac{1}{N \times N} \sum_{p=1}^N \sum_{q=1}^N (u(p,q) - v(p,q))^2 \quad (7)$$

Quantitative analysis results with parameters SNR, MSE and SSIM for Ben1 and kidney\_cut US images are shown in Table I. Table II shows SNR, MSE and SSIM values for five sample COVID-19 Lung US images corrupted with mixed Gaussian impulse noise. The parameters were measured after 15 iterations using Simple AD filter, median filter and the proposed filtering method. Results are sketched in Fig. 12. A comparison of SSIM values are plotted in Fig. 13. From these sketches, it is clear that the proposed method outperforms the other methods and turns out to be the most robust scheme, as it yields better SNR, minimum MSE and highest SSIM for all the images.

TABLE I. QUANTITATIVE ANALYSIS OF BEN1 AND KIDNEY\_CUT US IMAGES ON MEDIAN, AD & PROPOSED FILTERS FOR MIXED GAUSSIAN IMPULSE NOISE

Image	Parameters	Mixed Gaussian Impulse noise		
		Median Filter	Simple AD filter	Proposed filter
Ben1	SNR (dB)	18	8	19.35
	MSE	28.16	31	2.96
	SSIM	0.52	0.25	0.65
Kidney cut	SNR (dB)	10.05	8	22.49
	MSE	25	32	1.4
	SSIM	0.52	0.19	0.69

TABLE II. QUANTITATIVE ANALYSIS OF POCUS IMAGES ON MEDIAN, AD & PROPOSED FILTERS FOR MIXED GAUSSIAN IMPULSE NOISE

Image	Parameter s	Mixed Gaussian Impulse noise		
		Median filter	Simple AD filter	Proposed filter
Cov_severe	SNR (dB)	10.5	8.7	25.9
	MSE	22.76	33.8	0.65
	SSIM	0.51	0.15	0.76
Pneu_lung	SNR (dB)	10.7	5.8	28.4
	MSE	18	19	0.36
	SSIM	0.4	0.1	0.6
Cov_5A	SNR (dB)	10.6	9	26.4
	MSE	22	30.8	0.58
	SSIM	0.59	0.2	0.74
Cov_15A	SNR (dB)	10	9.4	27
	MSE	21.8	30	0.5
	SSIM	0.53	0.15	0.73
Sub_pleu	SNR (dB)	10	8	27
	MSE	19.5	28	0.49
	SSIM	0.45	0.12	0.6

Fig. 12. Comparison of SNR, and MSE using 5 Sample Images with Mixed Gaussian Impulse Noise. Results of Median, Simple AD and Proposed Filtering Schemes.

Fig. 13. Comparison of SSIM Values.

Table III shows the same parameters for images degraded with speckle noise. SNR and MSE plot is shown in Fig. 14 and SSIM plot in Fig. 15. From these plots, we can see that Simple AD filters are better in performance than median filters in speckle filtering process, while they perform poor in reducing Gaussian impulse noise. The proposed filter gives more satisfactory results for all the three parameters for all images with highest SNR value of 19.8, minimum MSE of 3 and maximum SSIM of 0.896.

TABLE III. QUANTITATIVE ANALYSIS OF PROPOSED FILTER, SIMPLE AD & MEDIAN FILTER FOR SPECKLE NOISE

Image	Parameters	Speckle Noise		
		Median Filter	Simple AD filter	Proposed filter
Cov_severe	SNR (dB)	7.5	13	19.2
	MSE	44	40	3
	SSIM	0.56	0.4	0.78
Avi_005	SNR	9.5	13	19.8
	MSE	28	5.5	2.6
	SSIM	0.73	0.82	0.84
Cov 15A	SNR (dB)	9.5	13	19

Fig. 14. Comparison of SNR and MSE using Four Sample Images with Speckle Noise. Results of Median, Simple AD and Proposed Filtering Schemes.

Fig. 15. Comparison of SSIM Values for Median, Simple AD and Proposed Filtering Schemes when Speckle Noise is Added to 4 Different Covid POCUS Images.

## VI. CONCLUSION

This paper introduces a new method of noise filtering of POCUS images based on hybrid anisotropic diffusion filters. The smoothing and edge preservation properties of AD filters and the noise reduction features of median filtering are combined to optimize the performance. Both mixed Gaussian Impulse noise and Speckle noise are considered. The resultant images are analysed quantitatively using parameters SNR, MSE, and SSIM. For mixed Gaussian impulse noise, the proposed filter yields a maximum SNR of 28.4 while median and simple AD filters gave only 10.7 and 9.4 respectively. Similarly, the proposed filter has the highest SNR value of 19.8 with speckle noise. The maximum MSE is 0.58, 30.8 and 21.8 for proposed, median and simple AD respectively, with proposed filter scoring minimum MSE for all images. With speckle noise, these MSE values are 3, 44 and 40 respectively. SSIM values are also the highest with 0.76 and 0.896 with mixed Gaussian impulse noise and speckle noise respectively. These findings show that the proposed filter delivers maximum SNR, least MSE, and highest SSIM for all test images. The results were uniform and consistent across all the test images after 20 and 30 iterations.

Due to its low cost, quick diagnosis, and non-exposure to radiation, Ultrasound is recommended in many clinical

scenarios, including respiratory, cardiovascular, and thromboembolic elements of COVID 19, obstetrics, etc. The development of artificial intelligence technology has made automatic segmentation and further diagnosis and detection excellent. A pre-processing stage prior to segmentation is inevitable in all these cases due to the presence of speckle and other noises, poor contrast, and acoustic shadows in US images. These robust software tools, when used in conjunction with point-of-care technologies, are well-suited to replace X-ray and CT scan on patient triage and immediate care.

**Abstract**—Food security is one of the major rising issues as the human population is larger and the land available for cultivation is smaller, as well unassured affairs happened often in society especially in the current CoVID-19 rapidly spread days. To mitigate this condition, further improve the yields and quality of food, this paper proposed a smart and low-cost greenhouse monitoring and control system, which mainly consists of sensors, actuators, LCD display and microcontrollers. DHT22 sensor is used to get the surrounding temperature and humidity in the greenhouse, and NodeMCU is used as the main microcontroller. Some other facilities such as fan and heater are used to adjust the inside environment. The system could monitor the growth environment continuously with Internet-connected, the monitoring data is transmitted and stored in the ThingSpeak cloud, the users can visualize the live data through a webpage or phone APP in real-time. If the environment condition is out of the predefined level, the environment is monitored continuously, and the system can be adjusted automatically. This system can be deployed in the greenhouse simply and maintain the greenhouse environment in a normal range dynamically and continuously.

**Keywords**—Smart greenhouse; ThingSpeak cloud; NodeMCU

## I. INTRODUCTION

As urbanization is continuously expanding, resulting in a huge decrease in arable land, the rapid growth of human population has increased the demand for food as well. The traditional agriculture method is not satisfied with current demands [1]. The problem of food for humans is becoming more and more serious. Food security is still a main issue in current days, it is an integrated and long-term task to deal with not only for agriculture but also for political will [2]. Climate change has resulted in severely damaging agroecosystems of the Loess Plateau in China, further aggravating the loss of soil and crop yields [3]. The living standards of people are greatly affected. The traditional farming model requires more land and manpower to manage, so traditional farming along could not be sufficient and resolve food security problems, it requires to apply of modern technology especially the Internet of Things (IoT) to improve it in this digital age.

In nowadays, the greenhouse is applied widely in the countryside to plant crops or vegetables for the whole year regardless of the seasons. It has heat-keeping, anti-coldness, and transparency characteristics. The main significance of greenhouse is the climate inside can be controlled at a suitable level constantly of the specific plant favorable. Some important nursery factors such as temperature, humidity, soil moisture,

pH, light intensity et al [4]. Along with the yield prediction character, the most efficient production of the greenhouse could be possible with the help of advanced technology. Researchers and Engineers use Internet of Things (IoT) and other modern technologies to make it realize. With the popularity of smartphones, farmers could use phone to monitor and control the greenhouse in real-time without extra human intervention [5]. IoT technology applied in agriculture is a developing trend, the potential benefits not only expand the yields and quality of the planting crops but also reduce farmers' burden and improve income.

It is important to apply smart greenhouse technology in urban areas. An Arduino uno based smart greenhouse prototype was designed and implemented, the greenhouse environment is monitored in real-time and can be accessed through an Android application. The user also could use the Android phone to manually control the inside environment remotely. The prototype was examined and highlighted that it could improve the yields of plants [6]. An STM32-based temperature monitoring and control system was developed; this development proved that smart agriculture could ease the management burden and increase the yields of crops [7]. Artificial intelligence (AI) technology is playing an important role in the smart greenhouse as well. An improved fuzzy neural network algorithm was designed to fit the intelligent greenhouse development. It is a trend that different technologies such as 5G, AI, NB-IoT, and Cloud should be applied to make the greenhouse more sustainable and smarter [8]. The greenhouse can be designed and implemented in a modern way by using different kinds of technologies.

The rest of this paper is divided into sections mentioned below: Section II is about the literature review, it summarizes the corresponding works of the smart greenhouse. In Section III, the proposed system and experimental setup are presented in detail. In Section IV, the results of this research project are described. Finally, the conclusion is summarized in Section V.

## II. LITERATURE REVIEW

Though IoT technology is widely used in different fields, such as smart parking systems, smart healthcare and so on, it still does not apply in large-scale agriculture in many countries especially developing countries. A Lora-based small-scale smart greenhouse was developed; the system could monitor soil moisture, light strength and temperature; the data was transmitted to the Tata server; and the data could be retrieved

from Microsoft Azure Cloud and displayed on the developed webpage through the network [9]. In order to further efficient management of farming, a camera was deployed not only to monitor the growth conditions of plants, but also to check which disease the crops have by using image processing technology [10]. An Esp8266-based smart and automated controlling agriculture system was designed, four parameters: temperature, humidity, light and soil moisture were monitored in real-time, the data was transferred to the customized webpage through a wireless network, the system also could adjust its environment conditions automatically if one factor was out of the predefined threshold so that it could maintain the optimum environment for the crops to grow rapidly [11]. A data analysis platform based on docker technology was designed and implemented; this platform was deployed simply regardless of the underlying operating system [12]. Data analysis is an important process after data gathering in IoT technology.

The yields of outside crops are mostly influenced by severe weather such as rain, and storm. The change of temperature and humidity could result in different diseases for the crops. An Arduino Nano-based smart agriculture system was developed to realize monitoring and controlling of the greenhouse in real time, in this study, compared with traditional monitored parameters: temperature, soil moisture and light intensity, one more rain sensor was used to detect the weather conditions, and to trigger the top of the greenhouse open or close automatically to irrigate the crops. Users not only could see the monitoring environment values on a 16X2 LCD display, but also access the data through the designed phone application remotely [13]. An intelligent supervisory fuzzy controller (ISFC) was developed to control and adjust the greenhouse environment remotely [14]. Soil is the base for plants to grow, so an intelligent soil management system is designed and developed, it is more convenient for farmers to manage and maintain their crops in the greenhouse [15]. Farmers could observe the monitoring data through a blynk application. In order to quickly identify the vegetable disease, deep learning algorithms were integrated into the smart greenhouse monitoring system to avoid loss in the early stage [16]. With the help of machine learning technology can make the whole smart greenhouse system more intelligent [17]. Solar power could be used as a renewable resource to provide electricity for the whole smart greenhouse monitoring system. It not only reduces the cost, but also no pollution to the environment. And the extra power was stored in the rechargeable battery to save cost [18]. A smart greenhouse system can be integrated with hydroponics planting, the soil is saved in this way, and it could provide rich nutrients to make the vegetables grow freely and rapidly [19]. With the help of advanced technology, the smart greenhouse is executable and efficient.

### III. PROPOSED SYSTEM

Internet of things (IoT)-based technology applications are a tendency to make everything intelligent and facilitate. In this project, a low-cost and sustainable smart greenhouse monitoring and controlling system for agriculture is designed and developed. The architecture and experimental prototype setup of this research project are presented in this section.

#### A. System Architecture

In this project, the greenhouse environment not only can be monitored in real-time, but also it can adjust the environment conditions: temperature and humidity at a suitable level automatically and continually. If the temperature is lower than the predefined threshold, the heater would turn on, if the temperature is higher than the preset temperature or the humidity is outside the threshold, the fan would turn on, otherwise, the fan and heater are turned off. Users can remotely access the monitoring data by phone or webpage through the network wherever the users are. The proposed architecture of the smart greenhouse system is illustrated in Fig. 1.

Fig. 1. System Architecture.

#### B. Experimental Setup

This project is developed based on a NodeMCU microcontroller coupled with other electric devices. NodeMCU is a low-cost and open-source Internet of Things developing platform. Arduino IDE is used as the programming tool; the firmware development is based on the ESP8266 environment. The NodeMCU diagram is shown in Fig. 2.

Fig. 2. NodeMCU Microcontroller.

HT22 sensor is used as the humidity and temperature detecting node. It has 4 pins: VCC, DATA, NC, and GND. The normal voltage range of VCC is from 3v to 5v. The working principle of DHT22 is through a built-in capacitive humidity sensor and thermistor to measure. The data is transmitted to the controller through the DATA pin. The maximum working current is 2.5mA [20]. The picture of the DHT22 sensor is shown as Fig. 3.

Fig. 3. DHT22 Sensor.

According to the proposed system architecture, a small-scale and easy-installed smart greenhouse monitoring and controlling system prototype is designed and implemented. In this system NodeMCU is applied as the main microcontroller to collect and transfer the monitoring data, a DHT22 sensor is used to get the temperature and humidity of the environment, the collected data is stored in the ThingSpeak cloud, the data can be visualized through a mobile application or ThingSpeak website through specific channel ID. A two-channel relay is used as the actuator to connect the heater and fan. The diagram of the relay is shown as Fig. 4.

Fig. 4. 2-Channel Relay.

A 16x2 LCD is used to display the current monitoring environment values. The connection of the hardware modules is shown as Fig. 5.

Fig. 5. Connection of Hardware Modules.

The prototype of the proposed system is designed and implemented, and is shown as Fig. 6. LCD display, DHT22 sensor, 2-channel relay, switch and NodeMCU microcontroller are deployed on the top of the printed circuit board (PCB) board. Two 18650 batteries are used to support power for this system and put on the back of the PCB board. The relays connect to the fan and heater. The LCD display screen is connected to the microcontroller via an I2C interface. The real-time monitoring data can not only be displayed on the LCD display screen but also can be visualized by phone APP and webpage through network.

Fig. 6. Implementation of Proposed System.

#### IV. RESULTS

The data also can be assessed through a mobile application called ThingView or ThingSpeak website remotely with an Internet connection. The monitoring data from the ThingSpeak webpage is shown as Fig. 7. From the platform, users can monitor the greenhouse environment in real-time. The live data is accessed through the smartphone application with a specific channel ID and is shown as Fig. 8. The data is updated every 15 seconds. The greenhouse environment is adjusted at a predefined suitable level dynamically.

Fig. 7. Real-Time Monitoring Data through Webpage.

Fig. 8. Real-Time Monitoring Data through Phone APP.

## V. CONCLUSION

Based on the research question, data analysis is a useful way; from the simple test demonstration we can conclude that there is a negative relationship between temperature and humidity. In the future, machine learning technologies such as clustering and classification algorithms can be applied in this system, based on the big data and machine learning technology the expected model could be constructed accurately, and the model can decide whether to activate the specific instrument to predict and adjust current condition for the whole greenhouse system. It adjusts the environment in a normal range dynamically and automatically, to avoid big losses and reduce human intervention.

## ACKNOWLEDGMENT

The authors would like to thank to the support of Information Engineering School, Henan Vocational University of science and technology, for their efforts to conduct this research project. The authors would like to thank to Professor Dr. Omar Ismael Ibrahim for his valuable suggestions.

**Abstract**—This study aims to determine the implementation of System Application and Product in Data Processing (SAP) in a company to provide solutions for companies to obtain reliable reports and improve performance in a company. This study uses the mixed method through interviews with resource persons who have work in well-known company. The data obtained were analyzed by the method of literature study from data on the internet. The results of this study indicate that many companies still apply manual systems in reporting, one of them is the lack of adequate technological facilities within the company so that companies cannot fulfill their business processes optimally due to not using integrated system that connected with each other.

**Keywords**—Accounting; information systems; SAP; ERP; implementation of SAP

## I. INTRODUCTION

The world is currently growing in the world of technology is needed by companies to increase efficiency and achieve maximum accuracy. In the current era of digitalization, technological developments in the world are increasingly advanced, where these developments are increasingly modern and lead to the digital world, so that this has a major impact on various fields and sectors of activity [1]. Many companies especially in the business sector have grown and expanded, giving rise to a drastic increase in business competition. In its development, several companies demand to obtain accurate and relevant data and information in their business processes [2].

In the past, before the company technology used a manual recording system, the drawback of this manual system is that fraud and human error often occur, so that it is considered less effective and efficient. In addition, companies are often found that they cannot fulfill their business processes optimally [3],

so that their records still often occur. The problem that occurs is because there are still many companies that do not have a system that is not connected to each other to get relevant reports [4].

According to Rosenbom there are five strategies in increasing company productivity that are effective and efficient that can be applied [5], namely changing management rules, changing the nature and composition of inputs, increasing new technology, increasing new products, and expanding new markets. Information systems can support two of the five methods above, namely multiplying new technologies and expanding new markets. The solution is to apply System Application and Data Processing (SAP) software which combines the two systems, namely accounting and management information systems that can meet the needs of all parts of the company. Over the last few years, several companies have switched to using applications or software known as System Application and Data Processing (SAP) which are considered to be able to meet business needs more efficiently and effectively so that it is easier for all departments to run the company.

System Application and Data Processing (SAP) is an enterprise resource planning (ERP) software. ERP is an application that can integrate to meet the company's operational needs efficiently which consists of various sets of modules such as manufacturing, finance, HRD, material management, sales, and distribution that are connected into one database. Therefore, System Application and Data Processing (SAP) has developed and is recognized by manufacturing companies, because it is considered to greatly increase effectiveness and efficiency in various matters related to company operations because it is only integrated in one

software so that the settings will also be easier compared to using manual way [6]. This system is expected to provide solutions for companies to deal with all problems that occurred previously and can help employees to work more efficiently. In addition, SAP has other uses such as being able to improve corporate governance data to provide confidence to investors by looking at overall performance through a real time transaction system [7].

In recent years, it is being discussed that many companies have applied SAP to help meet their business needs. According to data from reference sites, there are many ERP systems emerging, but as many as 80% of companies in Indonesia have applied SAP as their ERP system to facilitate their business processes [8]. Several leading companies in Indonesia have applied ERP including PT Pertamina, Starbucks, Astra International, Erafone, Bank Mandiri, PT Garuda Indonesia, Telkomsel, Blue Bird and many others. Digital transformation is not just an alternative but a must for all lines of the company [9].

Three phenomena of applying SAP in the company: First, in about 50 years ago, the most phenomenal technological development was the emergence of the internet, where the internet is a technological development that combines telecommunications and computer technology [10]. Therefore, many companies are now applying SAP in their companies to be able to compete nationally and internationally. So that all companies are required to keep up with global developments by adopting more capable technology such as using SAP as a new breakthrough so that the company can maintain its existence and be able to compete at the national or global level [11]. Second, according to Billyan and Irawan the phenomenon of applying SAP has begun to spread throughout Indonesia, both from service and manufacturing companies, because the use of ERP itself can be used to analyze the consequences that hinder all processes within the company can be investigated [12]. Third, the phenomenon of the application of SAP has been applied to companies in Indonesia and outside Indonesia. This happens because there are some problems in receiving information so far it is considered less than optimal because it is considered less effective, one of which is the application of information technology that is less than optimal. In a company, the company needs information that can be used to make good and fast decisions. Therefore, through this background the researcher trying to find a solution for companies that combine data and technology to record systemically to get reliable reports.

Based on the description above, this research intends to study "Design of Accounting Application Information System and Product in Data Processing in Indonesia Company". Researchers want to examine whether the application of SAP in the company can help productivity and efficiency in the company's operational processes.

- a) Is SAP really needed by the company?
- b) Is SAP able to reduce fraud and human error and increase efficiency in companies that apply SAP
- c) Is the costs incurred to install SAP be balanced with the results obtained by the corporation in terms of accuracy.

## II. LITERATURE REVIEW

### A. Grand Theory

The researcher raised one of the theories that could underlie the formulation of the problem, namely by using the Agency Theory [13]. Agency Theory is a theory that explains the relationship between the two parties, namely the company management (agent) and company owner (principal). Under certain conditions, the owner of the company, namely the principal, always needs information related to the company's activity processes. Through reports that have been prepared by the agent, the company owner (principal) can also receive the information need and provide an assessment of performance within a certain time. In research, there is a discussion that is under agency theory, that statements regarding understand the problems that occur between company owners and agents in giving reports in a company [14].

### B. Accounting Information System

Accounting Information System is the root to obtain information quickly and reliable. Fast means that the information obtained is proven to be really actual and accurate the time. While accurate is based on adequate and reliable evidence accountable for the truth. The presence of an accounting information system can help company to obtain reliable information, and obtain information which is useful in making a good decision under certain conditions. The following describes the notion of an accounting information system based on the opinion of some experts, namely:

a) Bodnar and Hopwood [15], an accounting information system is a combination of resources, such as individuals and equipment, designed to convert financial and other data into useful information to various parties in making a decision.

b) Widjajanto [16], the accounting information system is a layer of various documents, communication tools, personnel implementers, and various reports designed to transform data financial report into financial information.

Based on the above definition, it can be concluded that the accounting information system is combination of resources such as individuals and equipment designed to manage financial data and other data into useful information in making decisions in controlling, planning, and managing the organization.

According to Azhar Susanto listed in his book consists of 6 (six) Accounting Information System indicators [17], namely:

a) Hardware is hardware that is used to combine, process, store, enter, and produce data processing things to provide information some information.

b) Software is a combination of various programs that are used to process data application on the computer.

c) Database is a system used for data collection or writing by using computer media to support information so that it is always available in real time.

d) Procedures are various activities that are carried out repeatedly with techniques use the same method. Consistency is the main key in the process of an organization.

e) Brainware is a human resource that participates in the process of making a product information system, which consists of combining, processing data, distributing data to the use of data for the needs of an organization or company.

f) Communication Network is the use of electronic means to transfer both information and data from one location to another.

### C. Enterprise Resource Planning (ERP)

According to Chofreh et al. [18], Enterprise Resource Planning (ERP) is an information system designed to integrate all company activities both internally and externally to the company that allows access to data quickly and reliably. This system includes manufacturing, distribution, personnel, project management, payroll, and finance. ERP is also a shortcut from technology information to assist companies in managing company operations by implement a shared database. So that the presence of ERP can support the productivity and operating efficiency of business processes by integrating business transaction management activities such as sales, manufacturing, marketing, finance, accounting, logistics, and resources. They also argue that there are three reasons why ERP systems are developing very rapidly lately, including the development of globalization, the era of the 2000s, and the need for information integration better.

Fig. 1. ERP.

The success of applying ERP in the company, according to Pabedinskaite [19] on the research he did in his book entitled "Factors of successful implementation of ERP systems". He revealed that there are 16 (sixteen) indicators in determine the success of ERP implementation, Fig. 1. Here are 16 factors in determining ERP implementation success:

- a) There is good communication from one department to another.
- b) Conduct optimal job training.
- c) There is support from the company's superiors.
- d) There is an equivalence between the company's business and the application of technology.
- e) There is employee involvement in the project.
- f) Reorganizing business processes.
- g) Good organization in transferring data.

- h) Competent external consultant.
- i) Organizational change management.
- j) Develop an organized and measurable plan.
- k) Conduct periodic and tight control on the implementation of ERP within the company.
- l) Involvement from management.
- m) Employee engagement.
- n) Measurable company targets.
- o) In accordance with the needs analysis of the organization.
- p) There is a good relationship with suppliers.

### D. System Application and Products in Data Processing (SAP)

According to Gunawan and Ikhsan [20], System Application and Products in Data Processing (SAP) is an ERP software that is integrated between its various modules such as SD (Sales Distribution), MM (Material Management), FICO (Financial and Controlling), HR (Human Resource Management), CO (Controlling), PP (Production Planning), and PM (Plant Maintenance) and others. Because the system supports integration, making software This is often used by many large companies in order to achieve their goals company, but by installing SAP in the company has a weakness, namely: requires a large amount of money, starting from taking care of the license, SAP training, software etc. SAP (System Application and Products in Data Processing) was first discovered in 1972 in Walldorf, Germany, by Dietmar Hopp, Hans-Werner Hector, Hasso Plattner, Klaus Tschira and Claus Wellenreuther who were former employees at IBM. SAP generally has three functions, namely: Functional (for background in finance, accounting, HR, ABAPer (for programmers), Basis (for admin work). The use of SAP is one of the most famous ERP software in the world and reliable by companies in the world including Indonesia because it has been recognized that SAP is the one of the most superior media and can be configured according to needs business. Here are the facts about SAP ERP:

Distribution of companies using SAP ERP by Country

Fig. 2. Top Countries that used SAP ERP.

Based on the picture, Fig. 2, it shows that 36% of SAP ERP users are in the United States, 9% in India and 5% in the UK.

Fig. 3. Distribution of SAP ERP.

Based on the graph, Fig. 3, it shows that of all those who use SAP ERP, 25% are small customer (<50 Employees), 40% are middle, and 35% (>1000 employee).

Fig. 4. Distribution of SAP (Revenue).

Based on the graph, Fig. 4 shows that customers who use SAP ERP, 47% are small customers (<\$50 Million), 10% are middle, and 33% are large (>\$1000 million).

#### E. Theoretical Framework

##### The Effect of SAP/ERP Implementation on the Company

SAP/ERP needs to be implemented by the company. As we know that when the world is now leading to the digitalization era, which means that everything has turned to technology sophisticated, so that it requires many companies to switch use technology to maintain its existence. In addition, it is often found that. Many companies still do not have a system that is connected to each other. So, it has weaknesses, one of which is the difficulty of connecting between one department to another, recording reporting is still common errors due to human error, inefficient, and so on. To that end, the application of SAP/ERP is very necessary to overcome problems in the business world because through. This platform is making a big impact for companies such as increasing productivity, efficiency, reliability, punctuality and so on. On the other hand, if the

company does not use existing technology such as SAP/ERP then the company will allow frequent errors and result in the company being unable to compete on a global level. According to Jacobs and Whybark [21], “ERP is the technology e-business, an enterprise-wide transaction framework with links to processing sales orders, inventory management and control, planning and finance production and distribution”. ERP is a direct result and extension of manufacturing resource planning and as such, covers all MRP II capabilities. ERP is superior because:

- a) Implement a set of resource planning tools across all companies.
- b) Presents real-time system integration of sales, operations, and financial data.
- c) Linking resource planning approaches to extended supply chains customers and suppliers.

### III. RESEARCH METHODOLOGY

According to Saunders et al. [22], the object of research is an attribute that explains about what and who is the object, where, and when the research is carried out. According to Sekaran and Bougie [23], the object of research is the names of research variables, refers to the identification of problems, hypotheses, and definitions contained in the previous chapter. The object of research here includes the SAP software. Method is derived from the Greek, namely *methodos*, which means way. Besides it's a method that comes from the Greek, *metha* (to pass or through), which means the way or way that must be traversed to achieve a goal. Whereas research which examines the problem by collecting facts. Method that researchers used for this research is qualitative method. Qualitative method is research that aims to understand the phenomena experienced by research subjects for examples of behavior, perceptions, motivations, actions and including in the type of qualitative method that uses data results in the form of sentences that can answer the problem formulations such as “what”, “how”, and “why”.

This type of research is casual research. Casual research aims to knowing the causal relationship that occurs from each variable to get facts from a phenomenon and seek factual information about the application of the SAP. According to Lind, Marchal, and Wathen [24], the general environment in the organizational environment is a broad external condition that can affect the organization and affect indirectly to organizational performance. According to Nurunnabi [25], the macro external environment includes several factors including economic, political and legal conditions, socio-culture, demography, technology and global conditions that affect the organization. General environmental changes may not have a major impact on environmental change; however managers still have to pay attention when planning, organizing, directing and controlling business activities:

Fig. 5. The Star Model.

In the Star Model, Fig. 5, it is shown that there are several variables related to the implementation of SAP. These include Human Resources Management related to the Reward System and then connected to the Business Processes and Structures generating Strategy. The components in SAP include the following:

- 1) SAP Financial Accounting
- 2) Controlling (CO)
- 3) Human Capital Management (HCM)
- 4) Production Planning (PP)
- 5) Project Systems (PS)
- 6) Sales and Distribution (SD)
- 7) Materials and Management (MM)
- 8) Quality Management (QM)
- 9) Plant Maintenance (PM)

#### IV. DISCUSSION

The author conducted module research in SAP to see if this system has been appropriate in the organization. The example below is one of the modules in SAP Hana where there are CO and FI modules in the finance module. Master data must pre-set according to company needs. After the master data has been completed is set, the accounting party does a business mapping and the output is universal journal, Fig. 6.

Fig. 6. Central Finance System Landscape.

We can see more about the FI posts as shown below that the activities manufacturing can be recorded in a system to be processed into information. For example, when the warehouse receives physical inventory, this must be recorded properly in SAP. GR (MIGO) must be made when the goods have been received in good condition. This has an effect when the invoice arrives, the accounting will call the PO number to verify payment. In the initial setup stage of the SAP system, we must ensure that the cost element, cost center, orders, and profit center are correctly summarized in SAP. Consistency is required in this is because we need to ensure that historical data can be used as a basis for do the analysis.

Likewise with the initial settings on the manufacturing side, we need to ensure that the physical stock and stock in SAP is correct and suitable. From the accounting side, we need ensure that the initial settings for tax calculations are in accordance with tax regulations that apply in Indonesia. It's better if the initial SAP settings are conditioned to be able to load supporting documents systemically. This will avoid a long time to search hardcopy documents.

The next stage is to determine the user in each SAP module. This is important because Segregation of Duties needs to be prioritized, meaning that everyone has a responsibility Answer each according to their job role. Therefore, access to SAP too tailored to the needs of each user. Not everyone is granted access as "superusers". A review of the Segregation of Duties should be carried out once a year. This is to avoid fraud. The company's advantages in using SAP as an ERP are as follows:

- a) There are various types of modules in SAP that have the ability to: supports all transactions and each of these modules will work in conjunction with one another with the others.
- b) SAP is also supported by a NetWeaver platform that supports development and logistics software.
- c) SAP has a programmed, which will make it easier for developers to implementation of business logic.
- d) All data in SAP can be stored in 1 server for a long period of time and can be accessed by various parties when needed.
- e) SAP can be modified according to company needs. This means that the modules in SAP are not a locked module but a module that can be modified.
- f) Allows integration globally.
- g) Reducing the level of complexity of applications and technology.
- h) Helping the smooth supply chain and integrating the results into one with financial reports.
- i) Reducing the need to update data continuously.
- j) Facilitating communication relationships internally and externally, inside and outside company.

In field practice, we can find that there are still many users who do not understand how to use the SPA. Usually, SAP will provide a session training and training so that users can be more familiar with using SAP. The following preparations need to be done before going live:

- a) Project Preparation, team formed for SAP project initial planning.
- b) Business Blueprint, establish a shared understanding of how the company intends to implement SAP in support of their business.
- c) Realization, in this phase, the implementation of the standard SAP methodology is carried out in two ways: packages base configuration (main scope) and final configuration (remaining scope). During this phase the solution is also tested.
- d) Final Preparation, the goal is to complete the final preparations including technical testing, final user training, system management and migration activities.
- e) Go Live Support, this phase is moving from the pre-production environment to the production phase.

However, the SAP system also has drawbacks, including:

- a) The implementation time and costs are not small.
- b) If careful preparation is not made, then the implementation process will become delayed.
- c) Users are not necessarily prepared to receive and operate SAP in time short

## V. CONCLUSION

Based on the description above regarding the application of SAP in the company, show that SAP can optimize business processes so that it can obtain information with fast and easy because it only has one integration that connects one with the others. SAP can help companies to reduce fraud and errors, so employee productivity increases. SAP will have a positive and significant impact on decision making. Looking at the current state of development, it shows that the world is getting more advanced and using very advanced technology. For this reason, the application of SAP in the company is a reliable solution for companies because it is only integrated in one system. SAP presence also provides many benefits for businesses, such as being able to help overcome unresolved business problems, get information in real time, reduce fraud or errors, and can obtain information quickly.

Ramapuram Campus, Chennai, India

**Abstract**—Massive Open Online Courses (MOOCs) are a transformative technology in digital learning that incorporates new techniques through video sessions, exams, activities, and conversations. Everyone leads a successful life in their professional and personal skills learning courses during COVID-19. The research concentrated on employing video interaction analysis to characterize crucial MOOC tasks, including predicting dropouts and student achievement. Our work consists of merely generating and picking the best characteristics based on the learner behavior for evaluating the dropout measure. To locate the frequent objects for feature creation, an association rule-FP growth approach is applied. The neural network is implemented using frequent itemset-3, which is used for feature selection. The evaluation metrics are calculated by using the Multilayer Perceptron (MLP) method. The metric values were then compared to the proposed model and some base supervised machine learning models namely Logistic Regression (LR), Decision Tree (DT), Random Forest (RF), K-Nearest Neighbor (KNN), and Naive Bayes (NB). The FIAR (Feature Importance Association Rule)-ANN(Artificial Neural Network) dropout prediction model was tested on the KDD Cup 2015 dataset and it had a high accuracy of over 92.42, which is approximately 18% better than the MLP-NN model. With the optimized parameters, we are solely focused on lowering dropout rates and increasing learner retention.

**Keywords**—Dropout prediction; data analytics; association rule mining; machine learning; artificial neural network

## I. INTRODUCTION

Massive Open Online Courses are the result of the blending of learning and the online world. It broadens the educational system by providing knowledge via modern internet technologies [1]. Moreover, an innovative instructional environment would assist learners in saving their learning time.

Billions of individuals utilize MOOCs for a variety of purposes, including professional growth, career transition, syllabus formation, secondary education, skills training, [2] and more. Courses are created by institutions for MOOC providers such as Coursera, edX, Udacity, and Swayam. Coursera, on the other hand, has done a far better job of preserving the pandemic boost than its closest MOOC competitors. From 31% in 2020 to 39% in 2021, Coursera's proportion of non-university courses expanded.

Learner enrollment in online classes has increased during the last decade. Simultaneously, learner dropout rates should

be raised. It's essential to consider the elements that contribute to inadequate retention rates [3]. The elements have to do with a learner's logs, access to materials, activities, and willingness to execute required actions in order to complete the program. Along with low dropout rates, course completion rates will rise.

This work has become focused on the analysis of learners' behaviors. In effective learning behavior, while the learner watches the video within the duration and submits the assessment on time. Moreover, analyzing the behavior of learners [4] with specific features such as accessing materials, discussion, course forum, and so on is significant.

Analytics has been popularized in recent years. The analytical approaches that extract relevant and meaningful enormous volumes of data and apply them to the educational system have revolutionized research [5] and it indicates as "Education Data Mining" (EDM), "Academic Analytics" (AA), and "Learning Analytics" (LA).

EDM has proven to be a good resource for revealing hidden information [6] and paradigms in data sources. Most educational institutions are being carried on e-learning platforms [7]. The huge amount of educational information recorded has laid the foundation for new research and analysis to better understand and increase learning performance.

Learning analytics is defined as the use of intellectual facts, learner-generated data, and models developed [8] to find knowledge and community interactions for prediction. To enhance learning progress and outcomes, learning analytics is associated with the gathering, processing, and interpretation of data sources. Learning Analytics predictive models employ any data mining, machine learning, or artificial intelligence technique, including classification, regression, prediction, and others, to evaluate the skills of learners, instructors, and universities.

Even though all attributes may be valuable in some circumstances, just a preferred number of attributes [9] are frequently used for identifying targets. In the KDD CUP 2015 dataset, an activity log is often used to collect several sorts of information regarding learners' behavior. In our research, behavioral variables were utilized to value the regularity of various learner behaviors, and we obtained the learners' parameters and used a variety of machine learning and

\*Corresponding Author.

artificial neural network classifiers to produce a significantly high prediction rate.

Establishing feature extraction and selection methods[10], as well as applying an artificial neural network to develop the model in learning analytics. The following are some key aspects of the proposed work:

For effective learning analytics, we proposed the FIAR-ANN model in our research. When association rule mining is utilized for feature selection, the efficiency of the process can be increased.

The relevance of the features is measured using an FP-Growth technique, which then brings them back to the highest values in the features.

The results of our FIAR-ANN model's examination on the KDD CUP 2015 datasets indicate that it is effective. Furthermore, we compare different metrics to the baseline models. Experiments were carried out to verify the research approach.

The layout of successful work in regards discusses past research that focuses on learner behavior to alleviate the problem of learner dropout and details the many aspects of the KDD CUP 2015 dataset in the third part, which includes our processes for cleaning and transforming the raw data to make it suitable for the analysis. In the subsequent sections, we evaluate the gathered data in terms of forecasting learner dropout and compare it to some baseline approaches. Finally, summarize the key achievements and suggest some simple directions for future research.

## II. LITERATURE REVIEW

Learners' performance prediction, behavior modeling, conversations, and retention have all been explored using data mining applications in online learning systems. Depending on the research setting, various studies have investigated multiple feature engineering strategies to extract additional sets of features.

The method of identifying a subset of relevant or essential features from raw data is known as feature selection, whereas feature extraction is the process of constructing a new variable from a collection of raw data.

On the KDD Cup 2015 dataset, Yafeng Zheng et al. [11] used the FWTS-CNN (Feature Weighting Time Series—Convolutional Neural Network) dropout prediction model, which used a decision tree to extract attributes out of a learner's record with a time series matrix [12] and then built a model from the weighted features using a convolutional neural network, and it had a better accuracy of over 87 percent.

Jing Chen and colleagues [13] developed DT-ELM (Decision Tree-Enhanced Learning Machine), a novel hybrid method that combines decision trees with extreme learning machines (ELM) that does not depend upon recurrent training. The first module, in particular, creates and extracts a number of attributes from learners' learning behavior records. The decision tree chooses features that can be classified well. It also gives the specified features more weight in order to

improve their categorization abilities. MATLAB R2016b and Python 2 are used to carry out the tests. The success of DT-ELM is proved by experimental results on the benchmark KDD2015 dataset, which show that it outperforms various basic ML models on several metrics by a percentile.

Cong Jin et al.'s[14] work starts with a feature extraction approach based on the students' behavioral content. Based on the Support Vector Regression parameters, an improved quantum particle swarm optimization (IQPSO) technique [15] is used to estimate the SDP (student dropout prediction) model. MATLAB 7.0 was charged with supporting the analysis with a 2:1 ratio of training and test subgroups at 10-fold cross-validation. The suggested SDP model outperforms benchmark models such as logistic regression (LR), back propagation (BP), and others, according to experimental results using public data.

As compared to earlier feature selection approaches, Anwar UIHaq et al. [16] designed a unique approach to anticipate greater results utilizing similarity multi-filter feature selection (MFFS). The feature ranking module discovers relevant characteristics, while the clustering module minimizes redundant features. Empirical results from a range of real-time data sources support the hypothesis that merging a feature picked using diverse distributed approaches leads to more resilient extracted features and improves the accuracy rate.

Bo Wei and colleagues [17] suggested a new optimization method assigned to particle swarm optimization with learning memory (PSO-LM). The learning recall policy's goal would be to get significant insights into those who are fitter and develop faster, although the genetic operation is frequently employed to reconcile on a small and large scale. By using the Weka tool to test the model's efficacy, each attribute must be scaled between 0 and 1, and the quality of each component must be assessed using the k-nearest neighbor classifier with 10-fold cross-validation. When compared to wrapper-based feature selection algorithms based on global standard datasets, the analysis revealed that they were more efficient.

Anupam Khan et al. [18] state that the most familiar educational data mining technique for determining pedagogical components of learning and assessing student achievement is association rule mining.

The classification algorithm may be used rigorously to establish a forecast connection, and the interactivity allows learners to correlate behavioral characteristics of their actions to program accomplishments.

In the field of educational data mining, Shaveen Singh et al. [19] explores the use of feature selection approaches combined with association rule mining to identify essential course activities and locate more notable links within these parameters. The task at hand is to come up with the right combination of learning activities that use various methodologies to achieve the course's intended learning results. Subsection formation, subgroup analysis, terminating condition, and outcome checking are the four basic phases included in it. The Communication and Information Literacy dataset UU100 enrolled 2,172 students and included a variety

of online actions. There had been no null data in the preprocessed dataset, which had 2172 occurrences with 19 features. To find valuable patterns and correlations among the features, an association rule mining technique is applied. The WEKA tool has been used to do data mining tasks by analyzing acquired data with various algorithms such as Naive Bayes, C4.5, and RBF Network, all of which have high prediction accuracy.

Abeer et al.[20]present a blended strategy for decreasing the high-dimensionality of DNA methylation data and extraction via the Kernel Density Estimation method, resulting in a considerably more accurate and quick-calculating method. The usefulness of the given hybridization technique is evaluated by the metrics of the proposed classifiers such as Naive Bayes, Random Forest, and SVM.

### III. MATERIALS AND METHOD

This section delves into the framework of the proposed model for predicting online learning dropouts. Feature extraction and selection techniques are used alone or in combination [21] to improve performance, such as projected accuracy, visualization, and concision of learned content. The benefit of feature selection is that crucial information about a particular feature is preserved. However, only a small number of qualities are needed, and the distinctive features are diverse. Some of them attempt to forecast a learner's performance in binary classes such as dropout or continue the Programme and so on.

#### A. Problem Definition

The learner dropout rate is the largest myth in MOOC development. Our work identifies the best attributes for predicting dropouts based on a learner's activity and uses a multilayer perceptron to measure accuracy. The available dataset for the KDD CUP 2015 originates from "XuetangX," China's largest MOOC platform[22] and a popular tool for predicting MOOC attrition. As displayed in Table I, the collection contains four catalogs from 79,186 students enrolled in 39 courses.

TABLE I. DATA ENACTMENT

Catalog	Depiction
Date	Timespan of each course
Object	Module in a course
log_train	Behavioral record
true_train	Insight into the actual data of the training set's enrollments.

#### B. Dataset Revelation and Preprocess

The KDD CUP 2015 public dataset, which contains 72,142 records with information about seven learning behaviors, as shown in Table II, including observing visual aids, retrieving objects, learner interaction, laying the course, closing the pages, analytical thinking, and surfing the web, is the exploratory data file used in this article. The binary classifier is used in the outcome analysis, with "0" indicating that students will complete their studies and "1" indicating that they will drop out.

#### C. Framework

The paper provides a strategy for dropout prediction using a FIAR-ANN model that integrates feature importance and neural networks. As illustrated in Fig. 1, the general stages of this approach are database cleaning, character separation, parameter estimation, and comparison.

The analysis begins with preprocessing the public dataset, then using association rules for feature selection to generate a frequent itemset based on behavioral attributes. The ultimate estimated values are then obtained using multilayer perceptron in the ANN model, and it was assessed using a variety of evaluation criteria.

1) *FIAR-ANN approach*: Fig. 2 displays the technical aspects of the FIAR-ANN model design, which are divided into two sections in this article: identifying and grading the characteristics in the activity log; deploying the ANN model; and evaluating the performance metrics.

#### D. Identification and Grading of Features

Our research features were derived from learners' learning activity logs. In an online-learning scenario, association rules can be useful since they can find correlations among distinctive characteristics in a dataset. It is being used to link learners' actions to their results in order to figure out what is influencing their learning chances favorably or adversely.

#### E. Association Rules

The goal of association rule learning is to establish significant relationships between items in huge datasets [23] using a rule-based machine learning system. Let  $Ar = (ar_1, ar_2...ar_n)$  denote a group of n elements, and  $Tr = (tr_1, tr_2...tr_m)$  denote a repository of m transactions.

Each transaction  $tr_i$  contains a subset of Ar's available items. A rule is defined as  $X = Y$ , where X, Y I, i.e., X and Y (also known as itemsets) are subsets of the accessible items. The precedent and subsequent rules are typically referred to as X and Y, respectively.

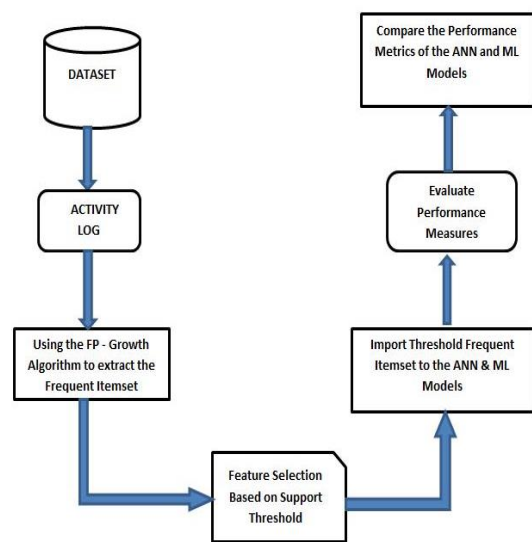

Fig. 1. The Layout of the Proposed Model.

Fig. 2. Architectural Design of FIAR – ANN.

### F. Frequent Pattern (FP)-Growth Algorithm

The frequent pattern growth algorithm is an optimized and reliable substitute for the Apriori algorithm, which additionally searches the transaction database for frequent items.

To produce the association rules, this method uses a divide-and-conquer strategy[23]. The approach instead focuses on a data model known as the FP-tree that saves metadata on items and interactions. The transaction database is examined once to generate the FP-tree[21], and the group of candidate itemset F is then calculated and organized in support values.

Numerous measurements were presented to identify the significance and instructiveness of an association rule.

The sections that follow give two measures.

Support:

The support for a set of transactions Tr by an itemset is determined as follows:

$$\text{Support}(X) = |\{tr \in Tr; X \subseteq tr\}| / |Tr| \quad (1)$$

Confidence:

The proportion of the transaction's maximum set of frequent items and X values.

$$\text{Conf}(X \Rightarrow Y) = \text{Support}(X \cup Y) / \text{Support}(X) \quad (2)$$

### G. ANN Model

An Artificial Neural Network is made up of numerous neuron nodes [24] that are divided into three levels: input, output, and hidden layers. In current technological research and development, ANN approaches are most commonly used to identify feature sets that enable the revelation of suitable predictions [25], considering both the maximum of commonly used formal metrics and the understandability of the model's behavior for knowledge extraction from data collection.

We trained on 80% of the feature data set and tested on 20%. The proposed approach is defined as a multilayer-perceptron with single hidden layers, as seen in Fig. 2. The Rectified Linear Unit function is used to activate the neurons in the hidden layer. The input layer contains far more neurons than there are sources in the data set. However, the output layer contains only one neuron with a ReLu activation function, which is suitable for classification problems because it distributes actual content in the range of 0 to 1.

$$\text{relu}(z) = \max(0, z) \quad (3)$$

The computation costs have been reduced using an optimization strategy. With 10 epochs and a batch size of 10, the Adam optimizer developed to train artificial neural networks was employed and has reached the highest accuracy. Researchers really intended to broaden the outcomes of the research and establish that our method is applicable to future programs that emerge.

## IV. RESULTS AND DISCUSSION

Our work will look at the key elements of the FIAR-ANN model in this section, starting with creating frequent items using association rules and then inputting the selected parameters into the ANN model. The implementation of the FIAR-ANN model is broken down into two sections in this article: feature extraction and the enhanced ANN model. Fig. 2 depicts the process of implementation.

### A. Experimental Framework

#### 1) Software

- Windows 10 is the most popular version of Microsoft's operating system (Intel Core-i3 processor, 64-bit operating system).
- The Google Collaborator is a toolbox for the Scikit-learn Python package[26], and it was used to run the samples on a computer system with seven different sorts of events coming from two separate sources, as indicated in Table II.

TABLE II. DATA SOURCE ATTRIBUTES ARE USED IN THE ANALYSIS

Attributes	Proclamation
enrollment_id	A registered participant's unique identifier.
source	Actions based on the server and browser.
event	We devised seven distinct activities as
	Pbm - Putting intellectual tasks to use
	Video - Participants are observant of the filmed content.
	Access - Getting access to a lot of the learning resources.
	Wiki - Browse the internet for information.
	Discussion - Using discussion boards to exchange intelligence
	Navigate - Exploring several aspects of the software.
Page_close – Depart from the webpage.	
Output	The success (value 0) or failure (value 1) of a participant in a course

2) *Baseline models*: Our work applied five classic machine learning models as baseline models, especially Logistic Regression (LR), Decision Tree (DT), Random Forest (RF), K-Nearest Neighbor (KNN), and Naive Bayes (NB), to offer a point of comparison for the outcomes of the FIAR-ANN model.

3) *Logistic regression*: The extended linear regression model is the basis of the supervised machine learning classification strategy used in logistic regression. It uses the regression coefficients of one or more components to calculate the likelihood of occurrence.

A strategy for estimating class-based predictor factors (x) is logistic regression [27]. It enables us to determine the possibility (p) of components of a specific class. A binary result is classified as a dropout or non-dropout in this work and it is represented as a 0 or 1.

The classic logistic regression model for evaluating the result of an occurrence, given a variable (x), is  $p = 1 / [1 + \exp(-y)]$ .

$$\text{In which } y = b_0 + b_1 * x \tag{4}$$

The exponential function is  $\exp()$ .

Given x, p is the probability of an event occurring.

The logistic function for the multiple parameters is as follows:  $b_0 + b_1 * x_1 + b_2 * x_2 + \dots + b_n * x_n = \log [p / (1-p)]$ .

The predictive beta coefficients are b0 and b1. Increases in x will be proportional to increases in p if b1 is positive. On the other hand, a negative b1 indicates that increasing x could result in a considerable decrease in p.

4) *Decision tree*: A decision tree leads to increased demand for developing and depicting forecasting tactics. It's

easy to learn and implement, and it's widely used for predictive analysis [28]. The basic goal is to divide a massive volume of information into smaller chunks. In predictive analytics, decision trees exhibit the prominent features in the datasets. The tree's root is at the top, with limbs descending. A node is a point on the limb wherever researchers divide the big bunch into shrinking units at every instance. A "leaf" is the term for the end node. In a decision tree, each limb represents a section, and each leaf node reflects the highlight attribute's result within a set range. The decision procedure begins at the root node, checks the related attribute of the item to be sorted, and chooses the outcome depending upon the level till it hits the leaf node.

5) *Random forest*: Bagging entails the use of many samples instead of a single sample. A trained model is a set of events that can be used to produce predictions. The decision trees' varied results make up the random forest algorithm. The final product will be chosen using a majority-voting procedure. Anomalies, as well as distortion, are less noticeable in Random Forest [29]. The Gini impurity is used for Random Forest class labels to minimize overfitting and bias errors, as well as prediction errors.

6) *KNN*: In the dropout prediction of this work, we utilize learner interaction within the dataset. In our KNN method, first choose a value for K. Using the Euclidean distance; calculate the distance between k neighbors [30]. Examine all of our neighbors to find which one is closest to our position. Our attribute is assigned to the class with the highest number. KNN looks for correlations between predictors and values within the dataset.

7) *Naive bayes*: According to the Naive Bayes classifier [31], the availability of one variable in a class appears to be unconcerned with the appearance of other variables in the same class [32]. It's simple to set up and especially handy for large amounts of data.

The Bayes theorem allows us to derive the posterior probability  $P(c|x)$  from  $P(c)$ ,  $P(x)$ , and  $P(x|c)$ .

Have a note of the following equation.

$P(c|x)$  denotes the posterior probability of a given class (c, target-dropout) given indicators (x, variables).

$P(c)$  is the class prior probability.

$P(x|c)$  denotes the probability of an indicator given a class.

$P(x)$  is the indicators prior probability.

8) *FIAR-ANN-Hyper parameters*: The information is screened once for the rapid miner tool, and the set of frequent items, F, is then calculated and arranged in the size of the items with support values using FP-growth, as shown in Table III.

After preprocessing, the dataset contains 72,142 tuples, and the model must be built by selecting features with a minimum support value of greater than 0.5 and a maximum itemset size of 3, as shown in Table IV.

In Table V demonstrates the ReLu activation functions, which are present in the hidden and output layers, including the Adam optimization method and a learning rate of 0.2 with a 10 epoch rate, which is applied to ANN approaches.

**B. Evaluation Metrics**

The performance measures are evaluated metrics[33]like accuracy, precision, recall, and F1 – score, Training & Test Score. In this analysis, the class label is used as a binary classification method.

**C. Comparison and Analysis with the baseline Model**

ML approaches are used in the majority of dropout forecasts. The values in Table VI demonstrate the prediction accuracy of the overall learner behavioral features [26], and in Table VII, the selected features by our technique are significantly better than those of the benchmark method, indicating that our feature extraction method is effective.

TABLE IV. SELECTED LEARNER ACTIVITY PARAMETERS

Features	Description
enrollment_id	The learners' unique enrollment number.
server:problem:problem	The number of issues that the server is encountering determines the behavior.
server:access:UNKNOWN	The behavior is defined by the number of requests received from the server.
server:navigate:UNKNOWN	The size of server-based navigations to other regions of the course is used to calculate the behavior.
server:discussion:UNKNOWN	The behavior is determined by the number of users who access the course forum from the server.
browser:access:UNKNOWN	The learner's behavior is defined by the amount of browser accesses obtained.
Output	Label of the dataset

TABLE V. APPLIED CONSTRAINTS

Constraints	Implications
Learning rate	0.2
Epochs	10
Activation function	ReLu
Optimizer	Adam

TABLE VI. USING BASELINE MODELS, CONTRAST THE OVERALL LEARNER BEHAVIORAL RESULTS

Fig. 3. The Results of Employing Several Classifiers to Predict Overall Learner Behavior.

Fig. 3 shows that the results of several basic supervised machine learning algorithms are used as input data for the whole learner's behavioral actions. In comparison to other models, the KNN model achieves the best accuracy rate of 79%.

To begin, we compared the models to a preset baseline model using the FIAR-ANN model. Table VII shows the findings for the various machine learning algorithms used in the research. The experimental findings with the best values are indicated as strong.

Compare the accuracy level with the selected features by using FIAR-ANN method, entire learner behavior and whole attributes in the dataset as 92%, 78% and 72%. Therefore the vital features produces the best result related to the others.

In terms of the four metric values, the FIAR-ANN model outperforms the other five models. Fig. 4 depicts the evaluation metrics for each model.

TABLE VII. RESULTS IN HYPER PARAMETERS COMPARED TO THE BASELINE MODEL

S.No	Metrics/ Learning Method	Accuracy	Precision	Recall	F1-score
1	LR	0.85	0.86	0.96	0.95

Fig. 4. The Extracted Feature Results are Compared to the Baseline Model's Results.

The findings show that certain machine learning models and the selecting input described in this work are better suited to predicting the dropout problem in MOOCs than others.

According to the findings.

1) In the large-data MOOC, the FIAR-ANN model developed in this research focuses on solving the dropout prediction problem and improving the baseline technique.

2) Using learner behavioral data from the KDD CUP 2015 dataset, the FIAR-ANN model, which has 92 percent accuracy, can be used to predict dropout rates for new programs.

## V. CONCLUSION

Researchers devised a number of methods to predict learner dropout in online programs. From primary behavioral data, we identify and retrieve a number of interpretive behavior aspects. The frequent candidate itemset is generated using an association rule mining-FP growth method. The itemset contains the most often observed learner behavior. Then select the parameters that are present in the three most common items. An artificial neural network approach is applied for the evaluation of the selected parameters. Our proposed method for assessing the efficacy of the KDD CUP 2015 dataset parameters and their values was applied to several machine learning approaches. Then compare the ANN and ML techniques' performance measures. The FIAR-ANN model incorporates the consequences of behavioral characteristics of dropouts, promptly enhancing the dropout prediction accuracy. In this work, we are limited to evaluate learner behavioral activities on the computer related courses, but enhance the work in future with other essential characteristics and also in other discipline courses. Put more emphasis on the attributes that are relevant to different types of platforms in the future.

# Sentiment Analysis of Online Movie Reviews using Machine Learning

Isaiah Steinke, Justin Wier, Lindsay Simon, Raed Seetan  
Department of Mathematics and Statistics  
Department of Computer Science  
Slippery Rock University  
Slippery Rock, PA, USA

**Abstract**—Many websites encourage their users to write reviews for a wide variety of products and services. In particular, movie reviews may influence the decisions of potential viewers. However, users face the arduous tasks of summarizing the information in multiple reviews and determining the useful and relevant reviews among a very large number of reviews. Therefore, we developed machine learning (ML) models to classify whether an online movie review has positive or negative sentiment. We utilized the Stanford Large Movie Review Dataset to build models using decision trees, random forests, and support vector machines (SVMs). Further, we compiled a new dataset comprising reviews from IMDb posted in 2019 and 2020 to assess whether sentiment changed owing to the coronavirus disease 2019 (COVID-19) pandemic. Our results show that the random forests and SVM models provide the best classification accuracies of 85.27% and 86.18%, respectively. Further, we find that movie reviews became more negative in 2020. However, statistical tests show that this change in sentiment cannot be discerned from our model predictions.

**Keywords**—Decision tree; machine learning (ML); natural language processing (NLP); random forests; sentiment analysis; support vector machine (SVM); reviews

## I. INTRODUCTION

As we move more of our lives online, it becomes possible to find people's thoughts and opinions on nearly anything, from the quality of their commute to their thoughts on the most picayune political issues. One common way that people express their views online is through user reviews. These extend from assessments of mundane household items on Amazon to more commonly reviewed media such as films, music, and video games. Given the growing prevalence of online reviews, researchers have devoted a significant amount of time to determining their sentiment [1]–[3]. The literature related to natural language processing (NLP) is extensive and outlines techniques used to process text and fit models that can determine—among other things—whether a review is positive or negative.

The importance of online reviews has increased in recent years because potential customers are increasingly using them to make purchasing or viewing decisions [1], [3]. However, the number of reviews for many products, movies, and TV shows is rather large, given the massive amount of data available online. As a consequence, summarizing information from multiple reviews and finding reviews that provide relevant and useful information for decision-making are tedious and

formidable tasks for users. Therefore, potential movie viewers could avoid information overload using an automated method that summarizes and classifies the opinions of online movie reviews.

Since the early 2000s, the field of sentiment analysis (or opinion mining) has grown to address many of the challenges associated with determining people's opinions, emotions, and attitudes [1]–[3]. This field has seen explosive growth in the past two decades mainly because of the increased use of social media, the aggregation of reviews on many websites, the prevalence of blogs, and the increased use and development of machine learning (ML) techniques for NLP. Further, the opinions of consumers have had great value in business, politics, marketing, and public relations [3], as determining the opinions of consumers can potentially result in large monetary savings.

In this study, we utilize sentiment analysis to determine a user's sentiment towards a movie using only that user's review (i.e., document-level analysis). Established in 1990, the Internet Movie Database (IMDb) [4] remains a reliable reference for film aficionados, and popular new releases receive thousands of user reviews. Hence, we use two datasets of IMDb reviews in our analyses. The first dataset is a benchmark dataset and is used to train classification models that determine review sentiment. These models are then applied to a second dataset to analyze user reviews submitted before and during the coronavirus disease 2019 (COVID-19) pandemic. Specifically, we use these results to investigate whether there is a change in review sentiment that may be attributed to the increased stress experienced from lockdowns and the threat of COVID-19 infection.

## II. RELATED WORK

Sentiment analysis is currently a very active area of research, especially given the prevalence of vast amounts of data on the Internet that can be mined for sentiment. Sun *et al.* [2] review a variety of NLP techniques for this purpose. They report that the most popular techniques are Naïve Bayes classifiers, support vector machines (SVMs), latent Dirichlet allocation (LDA), and a variety of neural networks. Further, they discuss the notable preprocessing techniques used for NLP, which include tokenization, word segmentation, part-of-speech (POS) tagging, and parsing. In addition, they review toolkits that are currently available, supervised and

unsupervised techniques, and opinion mining at various levels, e.g., document- and sentence-level opinion mining.

Many of the challenges associated with sentiment analysis have been outlined in the surveys in [1] and [3]. In particular, a review may contain both positive and negative sentiments, but the review itself may be either positive, negative, or neutral. Further, a review may contain many words associated with positive sentiment, but the review may be, for example, negative overall. An early study by Peng *et al.* [5] showed that the use of a human-derived list of keywords to determine sentiment at the document level performed worse than a list of keywords chosen with simple statistics. Moreover, some of the keywords chosen with simple statistics would likely not be chosen by a human to determine sentiment.

Hirschberg and Manning [6] review the latest advances in NLP, focusing on advanced topics such as machine translation, spoken dialogue systems, conversational agents, and machine reading. They also discuss the mining of data on social media, which is a rich area for sentiment analysis. Nadkarni *et al.* [7] present an introduction to NLP as it pertains to the medical field, particularly issues that are related to clinical text. They also provide a brief overview of the techniques preferred for medical NLP, which include SVMs, hidden Markov models (HMMs), and conditional random fields (CRFs), and discuss the importance of N-grams.

Hu and Liu [8] present a set of techniques to mine and summarize consumer reviews of products. They demonstrate that their techniques are able to provide useful feature-based summaries of products sold online. The summarization of movie reviews has also been studied using RapidMiner [9] and in mobile environments [10].

Many researchers have used NLP techniques to analyze the sentiment of movie reviews. Pouransari and Ghili [11] classified two datasets—one with binary class labels and the other with multiple classes—using random forests, SVMs, logistic regression, and recursive neural tensor networks (RNTNs). They propose a new type of RNTN called a low-rank RNTN, which is able to reduce computational costs compared to the standard RNTN while retaining a similar accuracy. Govindarajan [12] utilized naïve Bayes and genetic algorithm (GA) classifiers to classify movie reviews, achieving an accuracy of just over 91% with these two classifiers separately. Moreover, they were able to increase the accuracy to 93.80% using a hybrid naïve Bayes/GA classifier. Khan *et al.* [13] presented a method for the classification and summarization of movie reviews. To improve classification accuracy, their method employs unigrams, bigrams, and trigrams. They were able to achieve high accuracies (~90%) on three different datasets using a naïve Bayes classifier with their proposed method.

Sahu and Ahuja [14] utilize feature extraction and ranking to train classifiers based on decision trees, random forests,  $k$  nearest neighbors (KNN), naïve Bayes, and bagging. They achieved accuracies as high as 88.95% with random forests. Kumar *et al.* [15] use a hybrid feature extraction method to determine the sentiment of IMDb movie reviews. They employed SVM, naïve Bayes, KNN, and maximum entropy

classifiers, realizing an accuracy as high as 83.9% with the maximum entropy classifier.

Many of the techniques used in previous studies require high-performance computational resources, e.g., neural networks. Hence, given our available computational resources, we chose to build models using decision trees, random forests, and SVMs. These techniques were chosen because they are well-established powerful ML techniques with robust performance and prior use by other researchers in the NLP domain. Further, these techniques do not require high-performance computational resources and have achieved some of the best classification accuracies according to literature results.

### III. DATA

#### A. Stanford Large Movie Review Dataset

To build suitable models for the classification of movie reviews, we used the benchmark dataset, “Large Movie Review Dataset,” compiled by researchers at Stanford [16], [17] (we will refer to this dataset as the “Stanford dataset” hereafter). This dataset contains 50,000 reviews from IMDb, which are evenly split into training and test sets, each with 25,000 reviews. Each review is stored in a separate plain text file. In addition, each of the test and training sets are evenly balanced to contain 12,500 positive and negative reviews. Positive reviews are defined as reviews with IMDb ratings of 7 or higher, while negative reviews have ratings of 4 or lower. Neutral reviews were excluded from this dataset. Moreover, the number of reviews was limited to no more than 30 per movie since reviews for the same movie tend to have correlated ratings. Finally, the training and test sets comprise a disjoint set of movies, which avoids the potential for performance gains by “memorizing” movie-specific terms.

#### B. IMDb Dataset

To test for potential changes in sentiment amid the COVID-19 pandemic, we assembled our own dataset of 2,498 IMDb reviews for films released in 2019 and 2020. First, we determined the top 100 films released each year according to popularity by the number of ratings that a film received. We further narrowed this list by removing films released in January through March in 2020, as the effects of COVID-19 were not fully prevalent throughout the U.S. until mid-March. We also removed films that did not receive a U.S. release to mitigate the potential problem of foreign language reviews. After these steps, we selected the top 50 films according to the number of ratings for each year.

Second, we scraped the first page of reviews (25 reviews per page, except for two cases) and the rating assigned by the user; for a review with no rating provided by the user, the rating was input as NA. The final dataset includes 1,249 reviews from 2019 and 1,249 reviews from 2020 with data related to the film’s alphanumeric IMDb code, title, date, average rating, number of ratings, year, and the individual user review and rating.

Fig. 1. Flowchart of our Model Process.

#### IV. ANALYSIS METHODS

##### A. Preprocessing

Fig. 1 shows the overall flow of our model process. The raw textual reviews require preprocessing before they can be input into classification models. We utilized the *quanteda* (v. 2.1.2) package in R (v. 4.0.3) to carry out much of this preprocessing. After constructing corpora of reviews, each text review was tokenized, and punctuation, symbols, and numbers were removed. In addition, we removed common English-language stopwords such as “a,” “the,” “of,” and other frequently occurring words that offer little information related

to sentiment. We then converted all words to lower case and reduced them to word stems (e.g., “worst” and “worse” both reduce to the “worst” stem). The use of stemming reduces the total number of features, which is helpful for reducing the computational costs associated with model building.

After calculating the term frequencies for each word stem in each review in the corpora, we calculated the term frequency-inverse document frequency (TF-IDF) for each word stem. The TF-IDF weights the term frequency for a word stem by the inverse of its document frequency in a corpus. Thus, a word stem with a high term frequency that appears in many reviews will have a lower TF-IDF, as it will not be of much use in distinguishing sentiment since it appears in many reviews.

Initially, we built a simple decision tree model with the top 2,500 features having the highest TF-IDFs. The resulting decision tree was primarily built from nine features, all of which were ranked in the top 250 features according to TF-IDF. As more complex models require considerable computation times, we reduced the dataset to use the top 1,000 features with the highest TF-IDFs. Thus, our full training set contained 25,000 reviews with 1,000 features as the input to our models.

The IMDb dataset was preprocessed in the same way as the Stanford dataset so that it used the same 1,000 features/word stems. We also created two versions of the IMDb data. One, which we will refer to as the “unfiltered” version, includes all 2,498 observations/reviews. This means that reviews with ratings of 5 or 6 and those labeled NA were retained. The other, which we will refer to as the “filtered” version, was processed in a similar manner as the Stanford dataset. That is, reviews with ratings of 5, 6, or NA were removed. This reduced the number of reviews to 1,063 for the 2019 films and 1,048 for the 2020 films.

In addition to the 1,000 features, we also explored the use of an additional feature: the length of (or total number of words in) a review. However, after comparing histograms of this feature for the negative and positive reviews in both the training and test sets of the Stanford dataset, we found that the central values and distributions were quite similar. Hence, we did not incorporate this feature since it did not appear that the lengths of reviews would be an effective discriminator of negative and positive reviews.

##### B. Exploratory Analysis of the IMDb Dataset

In sentiment analysis, visualization of the data is often beneficial for understanding the results. After preprocessing all of the textual data in the IMDb dataset, a list of the top 1,000 features according to TF-IDF was reclassified for visualization. By cross-referencing the term frequencies within positive, negative, and neutral reviews, each of the top 1,000 words was assigned a corresponding class. We then used the R package *wordcloud* (v. 2.6) to visualize the 200 most dominant features, as shown in Fig. 2. At a glance, we see that common word stems such as “charact” and “feel” fall into the neutral category and have little use in determining the sentiment of a review. Word stems such as “bad,” “noth,” and “dont” dominate the

negative class, and “good,” “great,” and “watch” stand out for the positive class.

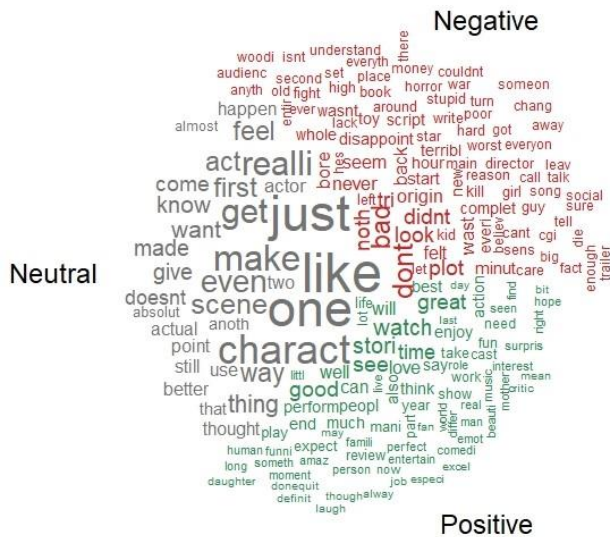

Fig. 2. Word Cloud of the 200 most Prevalent Terms in the IMDb Dataset Categorized as Negative, Neutral, and Positive.

Fig. 3(a) and 3(b) show histograms of the ratings of the reviews in the IMDb dataset for movies released in 2019 and 2020, respectively. Note that movies with no rating (i.e., “NA”) are not accounted for in these histograms. This is a rather small number of ratings: 29 and 28 for 2019 and 2020, respectively. For both years, the numbers of reviews at the extreme ends of the scale, i.e., ratings of 1 and 10, tend to be the highest. Moreover, there is a notable decrease in the number of reviews with a rating of 10 from 2019 to 2020 (with a nearly corresponding increase in movies with a rating of 1).

C. Modeling

All modeling and analyses were carried out in R (v. 4.0.3) on a computer equipped with an AMD Ryzen 7 3800X processor (operating at 3.9/4.5 GHz base/boost clocks) and 32 GB of RAM. We built models using decision trees, random forests, and SVMs, which were respectively implemented using the rpart (v. 4.1-15), ranger (v. 0.12.1), and e1071 (v. 1.7-6) packages in R. In particular, the ranger package allows trees to be built in parallel, which provides a considerable reduction in runtime when building the models.

Since the size of the training set is sufficiently large (25,000 observations), the full training set was split at a ratio of 80:20 into training and validation sets. Given the runtimes for building the random forests and SVM models and our time constraints, we decided against the use of cross-validation (CV) and instead used a single validation set. Models were built using the reduced training set containing 20,000 observations. The validation set containing 5,000 observations was used to tune the hyperparameters of the random forests and SVM models. For the decision tree model, no parameters needed to be tuned.

For the Stanford dataset, we have a binary classification problem, i.e., a review to be classified as either positive or negative. After building a model on the reduced training set,

we tested its performance on the validation set by comparing the class predicted by the model to the actual class. These results are typically summarized with a confusion matrix, from which the numbers of true positives *TP*, true negatives *TN*, false positives *FP*, and false negatives *FN* are obtained. Using these quantities, we assessed the performance of our models using the accuracy *Acc*, precision *Pre*, recall *Rec*, and *F*<sub>1</sub>-score (hereafter denoted by *F*<sub>1</sub>), which are expressed as

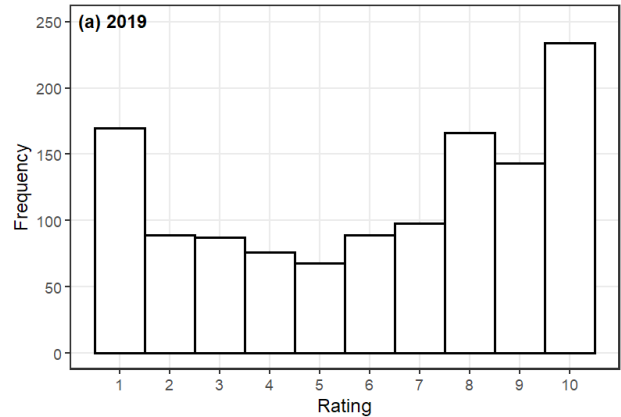

Fig. 3. Histograms of the Ratings of Reviews in the IMDb Dataset for Movies Released in (a) 2019 and (b) 2020.

$$Acc = \frac{TP+TN}{TP+TN+FP+FN} \tag{1}$$

$$Pre = \frac{TP}{TP+FP} \tag{2}$$

$$Rec = \frac{TP}{TP+FN} \tag{3}$$

$$F_1 = \frac{2 \times Pre \times Rec}{Pre + Rec} \tag{4}$$

For the random forests model, we tuned the number of trees, *n*<sub>trees</sub>, and the number of predictors sampled at each split, *n*<sub>preds</sub>, using the training and validation sets with a grid search. The number of trees was varied from 100 to 1000, and the number of predictors was varied from 5 to 200. The hyperparameter values that provided the best overall values of *Acc*, *Pre*, *Rec*, and *F*<sub>1</sub> on the validation set were *n*<sub>trees</sub> = 1,000 and *n*<sub>preds</sub> = 5. These values were then used for the random forests model in subsequent analyses. We additionally tuned the minimum number of observations in a node but found that

this parameter did not substantially increase *Acc*; thus, we used the default value.

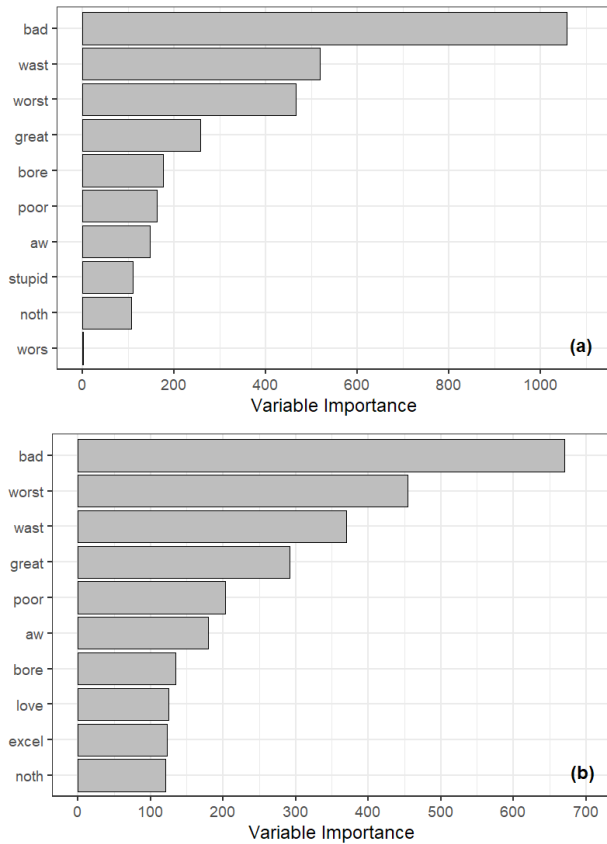

Fig. 4. Plots of the Top 10 most Important Variables for the (a) Decision Tree and (b) Random Forests Models.

For the SVM models, we tuned the hyperparameters for two different kernels: linear and radial. For the linear kernel, we only tuned one parameter, the cost  $C$ , which controls the bias–variance tradeoff [18], over the range of 0.01–1000. For the radial kernel, the hyperparameter  $\gamma$  was also tuned in addition to  $C$ . For this kernel,  $C$  was varied in the range of 1–100, and  $\gamma$  ranged from 0.5 to 5. We found that the radial kernel with  $C = 10$  and  $\gamma = 1$  resulted in the best overall values for *Acc*, *Pre*, *Rec*, and  $F_1$  on the validation set. Again, these values were then used for the SVM model in subsequent analyses. Finally, we also attempted to build SVM models with a polynomial kernel. For the few sets of hyperparameters we tried with this kernel, we obtained poor classification performance on the validation set. For all cases, the models always predicted that a review would be negative, resulting in a low *Acc* value of 0.5. Hence, we did not further tune models with this kernel.

## V. RESULTS

### A. Performance of the Models on the Test Set of the Stanford Dataset

Table I summarizes the performance metrics in (1)–(4) for the decision tree, random forests, and SVM models for the test set of the Stanford dataset. The random forests and SVM models use the best parameters discussed in Section IVC. We

see that the decision tree achieves  $Acc = 73.78\%$ . However, we can greatly increase *Acc* to 85.27% and 86.18% with the random forests and SVM models, respectively. Moreover, the random forests and SVM models provide large increases in *Pre*, *Rec*, and  $F_1$  relative to the decision tree model. Overall, the SVM model has the best overall performance, even though *Pre* is slightly higher for random forests.

TABLE I. PERFORMANCE METRICS FOR THE MODELS ON THE TEST SET OF THE STANFORD DATASET

Model	<i>Acc</i>	<i>Pre</i>	<i>Rec</i>	$F_1$
Decision Tree	73.78%	71.40%	79.34%	75.16%
Random Forests	85.27%	84.93%	85.77%	85.34%
SVM	86.18%	84.62%	88.45%	86.49%

TABLE II. PERCENTAGES OF NEGATIVE AND POSITIVE REVIEWS PREDICTED BY THE MODELS FOR THE UNFILTERED IMDB DATASET

Year	Model	% Negative	% Positive
2019 ( $n = 1249$ )	Decision Tree	35.15%	64.85%
	Random Forests	43.31%	56.69%
	SVM	44.84%	55.16%
2020 ( $n = 1249$ )	Decision Tree	35.23%	64.77%
	Random Forests	46.28%	53.72%
	SVM	48.52%	51.48%

### B. Variable Importance for the Tree-Based Models

For the decision tree model, we noted the variables used in the construction of the tree and their importance. In addition, we looked at the variable importance of the features in the random forests model using the best parameters in Section IVC. Fig. 4(a) and 4(b) show plots of the 10 most important variables for the decision tree and random forests models, respectively.

Both of the decision tree and random forests models found “bad” to be the feature of highest importance. The same eight words appear in the top 10 features of both methods with varying degrees of importance. Further, the majority of these word stems fall into the negative category in the word cloud analysis (e.g., “bad,” “bore,” and “wast”) with some positive word stems (e.g., “great” and “excel”). Notably, these terms make intuitive sense for distinguishing negative and positive movie reviews.

### C. IMDB Dataset

We used our trained models to classify the reviews in the IMDB dataset. Table II summarizes the percentages of movie reviews classified as negative and positive for the unfiltered IMDB dataset. The decision tree model classifies fewer reviews as negative compared to the random forests and SVM models. This is most likely related to the large difference in the performance metrics in Table I, as *Acc* is much worse for the decision tree.

Table III summarizes the percentages of movie reviews classified as negative and positive for the filtered IMDB dataset. Since this dataset has been filtered to only contain negative and positive reviews, as discussed in Section IVA, we have also tabulated the actual percentages of negative and positive reviews using the rating on IMDB for comparison. Here again, we see that the decision tree model classifies fewer reviews as negative compared to the other models. However,

we see that it is the furthest away from the actual percentages than the random forests and SVM models. Surprisingly, the percentages for the random forests model are closer to the actual percentages than those for the SVM model, despite the slightly lower performance metrics for the random forests model. This may be partially attributed to the slightly higher value of *Pre* for the random forests model relative to that of the SVM model. This suggests that it might be better to tune the models to control *FP*.

TABLE III. PERCENTAGES OF NEGATIVE AND POSITIVE REVIEWS PREDICTED BY THE MODELS FOR THE FILTERED IMDB DATASET

Year	Model	% Negative	% Positive
2019 ( <i>n</i> = 1063)	Decision Tree	33.68%	66.32%
	Random Forests	40.73%	59.27%
	SVM	42.80%	57.20%
	Actual	39.70%	60.30%
2020 ( <i>n</i> = 1048)	Decision Tree	33.87%	66.13%
	Random Forests	44.08%	55.92%
	SVM	46.18%	53.82%
	Actual	44.37%	55.63%

The results in Tables II and III show that the percentage of negative reviews increases from 2019 to 2020 for all models and for the actual data. This is also observed in the histograms in Fig. 3. To ascertain whether these results were real, we conducted a chi-squared test of homogeneity [19]. For the unfiltered IMDB data, we found that both of the random forests ( $p = 0.1475$ ) and SVM ( $p = 0.0711$ ) models did not show a statistically significant difference in the distribution of percentages at a level of significance,  $\alpha$ , of 0.05. For the filtered IMDB data, the conclusion was the same for random forests ( $p = 0.1302$ ) and SVM ( $p = 0.1289$ ). However, if we carry out this test with the actual data ( $p = 0.0332$ ), we find that there is a statistically significant difference. Thus, even though there is statistical evidence that there is a change in sentiment from 2019 to 2020 in the actual data, our models do not appear to be sufficiently performant to indicate this difference. This could be an important consideration if we wish to use our models to ascertain changes in sentiment over time, especially if we have unsupervised data, i.e., reviews with no ratings.

We also carried out additional statistical tests of the difference between two population proportions [20] to confirm these results. Here, we only chose to test the SVM model, which has the highest overall performance. Again, there is no statistical evidence (at  $\alpha = 0.05$ ) that there is a difference between population proportions for the unfiltered ( $p = 0.0651$ ) and filtered ( $p = 0.1180$ ) IMDB sets. However, the actual data do indicate that there is statistical evidence of a difference in proportions ( $p = 0.0298$ ), as before.

## VI. DISCUSSION AND CONCLUSION

We have developed models using decision tree, random forests, and SVM ML techniques to classify the sentiment of movie reviews. Our models were trained and built on the Stanford dataset, which is a benchmark dataset in the literature. In addition, we constructed a new dataset consisting of movie reviews from IMDB posted in 2019 and 2020. Using the Stanford dataset, we find that the SVM model provides the best overall performance, with  $Acc = 86.18\%$ ,  $Pre = 84.62\%$ ,

$Rec = 88.45\%$ , and  $F_1 = 86.49\%$ . The random forests model also provides good performance that is slightly worse than the SVM model. The variables that are important for the tree-based models are quite similar, and they tend to utilize words that would be useful in distinguishing negative and positive reviews.

For our IMDB dataset, we find that the random forests and SVM models tend to classify more reviews as negative compared to the decision tree model. Moreover, the random forests model more closely replicates the actual percentages of negative and positive reviews in our filtered IMDB set. However, the models are not able to provide statistical evidence of a change in sentiment from 2019 to 2020. The actual percentages of negative and positive reviews indicate that there is a change in sentiment; that is, issues related to the COVID-19 pandemic may have resulted in an increase in negative reviews. Further time-series analyses may be needed to tell if the increase in negative reviews can be solely attributed to the COVID-19 pandemic. Our analysis does not consider whether this increase was a result of increased negative attitudes elicited by pandemic stressors; studios' decisions to postpone high-profile releases such as *Black Widow*, *Dune*, *F9*, and *No Time to Die*; and other factors that we did not consider.

There is considerable scope for improvement in the performance of our models. During preprocessing, we reduced the number of features to the top 1,000 features according to the TF-IDF. This was done solely to keep the computational times of our models to a reasonable level within our time constraints. It is possible that we may realize additional improvements by increasing the number of features. Further, we did not utilize any feature-reduction techniques, e.g., singular value decomposition (SVD), which may also be employed to increase performance. Although the term frequencies were calculated, we did not build models using them, as longer reviews that repeat a unique term could bias the term frequencies. However, it is possible that models built with the term frequencies could provide better results, especially if we remove terms that appear in both negative and positive reviews at high frequencies. Our time constraints also reduced the number of hyperparameter combinations that we could test and prevented us from employing CV. Additional hyperparameter tuning and CV could increase the performance of our models, although we expect that this is likely to be limited to a few percentage points.

Our models were simple bag-of-words (BoW) models that only used unigrams. As shown by Khan *et al.* [13], we may improve classification performance by including more complex two- and three-word phrases (i.e., bigrams and trigrams, respectively). By using bigrams, a phrase such as "no good," which has a negative connotation, would be used as a bigram instead of the unigrams "no" and "good," which have negative and positive connotations, respectively.

Finally, we were only able to test a small number of ML techniques. According to the literature review in Section II, other techniques can be used to achieve quite high classification accuracies of more than 90%, e.g., naïve Bayes classifiers, GA classifiers, and many types of neural networks.

Hence, additional techniques could be employed in future work to increase classification performance.

# Detection and Extraction of Faces and Text Lower Third Techniques for an Audiovisual Archive System using Machine Learning

Khalid El Fayq<sup>1</sup>, Said Tkatek<sup>2</sup>, Lahcen Idouglid<sup>3</sup>, Jaafar Abouchabaka<sup>4</sup>  
LaRIT, Faculty of Sciences, Ibn Tofail University, Kenitra, Morocco

**Abstract**—As part of the audiovisual archive digitization project, which has become a complex field that requires human and material resources, and its automation and optimization have so far represented a center of interest for researchers and media manufacturers, in particular those linked to the integration of artificial intelligence tools in the industry, an elaborate work for the development of an optical character and face recognition model, to digitize the tasks of audiovisual archivist from the manuscript method in automation, from a TV news video. In this article, an approach to develop an example of lower third in Arabic language and facial detection and recognition for news presenter that provide accurate classification results as well as the presentation of different methods and algorithms for Arabic characters. Many studies have been presented in this area, however a satisfactory classification accuracy is yet to be achieved. The comparative state-of-the-art results adopt the latest approaches to study face recognition or OCR, but this model supports both at the same time. It will present the context of realization, the method proposed to extract the texts in the video, using machine learning, about the specificity of the Arabic language, and finally the reasons that govern the decisions taken in the steps of realization. The best results from this approach in real project at the media station was 90.60%. The dataset collected via presenters images and the character dataset via the Pytesseract library.

**Keywords**—Image processing; OpenCV; Tesseract; video OCR; face detection

## I. INTRODUCTION

In recent years, significant and rapid developments in the field of artificial intelligence (AI), the demand for smart applications has increased and found significant interest and use in many fields. As expected, audiovisual production is no exception to this, but radical transformations have taken place in the production process, facial recognition, text, and sound, and also video editing thanks to a set of tools that rely on AI technologies, as a support to the human element, most notably in tasks that require time and repetitive effort. This success in the use of AI is due to two main reasons:

- 1) Big Data Availability, such as photos and videos, in media stations and on the Internet.
- 2) Advances in digital computing manufacturing.

This article is the result of work carried out within Moroccan Television, for the purpose of researching a processing model that will allow the analysis of audiovisual

streams of television news, by analyzing the news presenter faces and the writing in each news coverage.

Videos have become a great source of information; the text of the video contains a substantial amount of information in a non-editable form. If this text is converted into an editable form, it becomes easier and more efficient to store and redistribute [1].

It has been observed that media channels in general have a growing need for automatic facial and handwriting detection systems to integrate into their systems.

One only has to think of the need for the development of active systems to extract the data in the television news videos in order to help the archiving service to fill in the current file, which is currently manually filled in on a daily basis in a register (Fig. 1).

The user must first provide the video as the input from which he wants to extract text. The system will then process the video and generate the editable text output. The latter must ensure the reliability of the information to an acceptable percentage. The solution must extract information from people who appear on the screen, using two methods: facial and text recognition in the video.

It should be noted that there are now commercial automatic tools for processing texts, photos, and videos [2][3], with a complex background, alignment and color variants, etc.

This work will be limited to automating the task of gender recognition from faces only and optical character recognition from the Lower Third present in the video. Also proposed in this work is a video processing chain which includes parts of detection, and tracking of faces and text at the same time.

Effective and efficient text extraction has been a difficult topic in recent years, and the Arabic language is one of the most popular languages in the world. Hundreds of millions of people in many countries around the world speak Arabic as their native language. However, due to the complexity of the Arabic language due to its cursive nature, the recognition of printed and handwritten Arabic text remained untouched for a very long time and did not receive the same attention, compared to the Latin script [4].

The remaining of this paper is structured as follows:

related works developed for text and face recognition from scenes/videos, diagnosis and analysis of the implementation

project and its difficulties, in the face detection and Arabic writing step are discussed in Section II, the presentation of Lower third and face extraction technique and the algorithm to follow for the deployment of this system, discusses the process of preparing the data set are mentioned in Section III and Section IV, the conclusion and some future work discussions are mentioned in Section V.

## II. RELATED WORK

Although a large number of printed Arabic character recognition approaches have been proposed in recent years, there is still a need to improve the recognition rate in Arabic OCR systems. This section presents some of these approaches.

Text recognition methods can be categorized into three broad categories, where some approaches recognize text using text segmentation and offering profiling learning with their own features. Methods in the second category recognize text without text segmentation, using a framework based on multiple hypotheses. The methods of the third category improve the text to increase the recognition rate by using binarization of scene images.

Each of these three categories has its own limitations. Approaches in the first category only work well for data from specific scripts, as they need training from their own samples and a classifier to recognize text based on that training. Methods in the second category require multiple hypotheses to set thresholds, but it is unclear how to derive different hypotheses to set specific thresholds. However, the methods of the third category do not need any classifier or hypotheses to define certain thresholds and they also improve the recognition rate through binarization. However, the approaches due to the third category do not provide satisfactory recognition performance for low resolution scene/video images [5], however, these methods perform well on horizontal scene text.

### A. BACKGROUND: Text Recognition

Many systems have been developed to detect text in videos. Each system is based on a specific method and has its associated shortcomings. Some of the commonly used methods to detect text are:

#### 1) Method based on the Sliding Window:

This approach uses a sliding window to search for specific text. It first takes a small rectangular block of a given image.

The rectangular patch has a specific size. Drag this rectangular block over the entire area covered by the image to check if there is any text in this image block. Different sliding window classifiers are used to determine if there is text in the patch. The window is initially placed in the upper left corner of the image, and slides to different positions of the image starting from the first row, then slides through the other rows of the image. This method is slow because the image must be processed at several scales.

#### 2) Method based on Connected Components:

In the connected component-based approach, it first extracts regions of pixels that have a similar color, edge strength, or texture and evaluate each of them to be text or not using techniques of machine learning.

The connected component method works well for caption text with single background images, but it doesn't work well for images with a grouped background.

Text recognition in video images is more difficult than that of natural scene images, difficulties video text analysis are due to complex background images, color variations, font size, camera movement, etc.

Aasim Zafar; Arshad Iqbal [6] compared K-Nearest Neighbor (KNN) and Support Vector Machine (SVM) classifiers in the recognition of printed Arabic characters.

First, feature extraction techniques such as oriented gradient histogram (HOG) and local binary pattern (LBP) have been applied for feature extraction based on the structure of Arabic handwritten texts. SVM has been found to perform better than KNN. Amara et al. [7] presented Arabic OCR using Support Vector Machines (SVM). Although SVM has proven its effectiveness in different fields among other classification tools, SVM has not been effectively applied to recognize Arabic characters.

Saidane and Garcia [8] proposed a convolutional network-based binarization method for the color text area of video images and its performance depends on the amount of training samples used.

Ahmed H and Mahmoud [9] proposed a small-sized printed Arabic text recognition approach based on the estimation of the Hidden Markov Model (HMM). Although applying a hidden Markov model has some advantages (such as no pre-segmentation), the poor image quality of small printed Arabic text makes it difficult to find accurate model boundaries.

Sarfraz and al. [10] proposed an offline Arabic character recognition system. The proposed system has four steps. In the first step, the text preprocessing step removes the isolated pixel and corrects the drift. A pixel is considered isolated if it has no neighboring pixels. Drift is corrected by rotating the image according to the angle with the greatest number of occurrences between all angles of all line segments between any pair of black pixels in the image. In the second step, line and word segmentation is performed using horizontal and vertical projection. Words are segmented into individual characters by comparing the vertical projection profile with a fixed threshold. The feature space is constructed using the moment invariance technique [11].

Zagoris and al. [12] proposed an approach to differentiate handwritten text from machine-printed text. The text image is segmented into blocks. Each block is represented as a vector of words, which contains local features identified using scale-invariant feature transformation. Based on support vector machines, the proposed approach decides whether the text block is handwritten, machine-printed or noise by comparing its word vector with the codebook.

### B. Background: Reconnaissance Facial

Facial recognition started about twenty years ago, and play an important role in various fields, the OpenCV library [13] is free, used in the field of research, because it provides a large number of important tools (more of 500 functions) in the field of computer vision.

The processing and description of audiovisual content presents several opportunities for description through automation and machine learning. Some methods are entirely based on image and sound content, such as facial recognition and audio indexing; other methods rely on text, either inherent in the digital file or extracted from audio or video.

It will discuss the state of the art of facial recognition then face detection methods have been classified by Yang [14], in four approaches:

- Approach based on recognition.
- Approach based on invariant characteristics.
- Approach based on template matching.
- Approach based on appearance

Image classification can be implemented using various supervised techniques such as Naive Bayes [15], K-Nearest Neighbor (KNN) [16], Support vector machines (SVM) [17] [18] [19], Decision trees [20], Random forests [21], Convolutional Neural Network (CNN) [22] [23] and Recurrent Neural Networks (RNN) [24]. These techniques process and classify images into different classes.

In Eidinger, Roe, & Tal [25], they proposed a method based on two tasks based on face representation with local binary patterns (LBP) and linear SVM with dropout. Dropout-SVM is based on the assimilation of a linear SVM to a single layer of a neural network.

Hassner, [26] used the same classification technique as Eidinger, Roe [25], on the front view, projecting 2D points of interest from the front to the 3D face as a reference. They showed that reconstruction of the face in the forward position can improve the performance of facial recognition tasks, in particular gender recognition.

Recently, AZZOPARDI, [27] also proposed a method based on artificial face extraction representation (cosfire-filters), similar to LBP. These representations are also inputs for the linear SVM.

Levi & Tal, [28] implementation of a convolutional neural network (CNN) with tree convolutional layers and three fully connected layers for the task of estimating age and sex; he was specially trained by Audience. To make predictions, they made

several crops of different sizes around the face. The final forecast is the average forecast value of all these crops.

Moreover, Afifi & Abdelhamed, [29] also applied a method based on local facial features, dividing it into several parts (mouth, eyes, nose). They also include insightful strokes around the face while blurring it. Then use these images to train multiple CNNs.

Other papers have also presented a CNN as Ranjan, M. Patel, & Chellappa, [30] proposed two Hyperface models, a CNN network based on the AlexNet architecture and a residual network based on the ResNet 101 architecture. Models are multitasking and can be trained to perform face detection, POI coordinate prediction, pose estimation, and gender recognition simultaneously.

Wolfshaar, F. Karaaba, & A Wiering [31], use a CNN (ImageNet's BVLC) designed to recognize objects belonging to 20,000 categories. In a separate experiment, two datasets (ColorFeret and Adience) of the face were further trained. Then extract the visual features from the penultimate convolutional layer and use them to train the linear SVM.

Ozbulak, Aytar, & Hazim, [32], showed that transfer learning domain-specific models (such as VGG Face) can perform better than recycled CNN with limited data. They achieved this by comparing GilNet (a shallow benchmark CNN trained on the Adience dataset) with two enhanced deep CNNs (one for the VGGFace face and the other more general Alexnet). Then these two enhanced CNNs are used as descriptor extractors, and these descriptors will become the training data of SVM.

### C. Problem Statement

For the moment, Laâyoune TV does not have a computerized archiving system, neither a desktop application nor a web application, and only uses handwritten recording.

On a daily basis, the archivist proceeds to view each video clip, and writes the visual information of each video, which drew my attention to the design of a model that uses two methods of machine learning, in particular the vision by computer, in order to help the television set up an automated system which does the same work of an archivist to extract the data from the video as it is written in the register, with the aim of minimizing the lead time of the archiving task which consumes about one hour of work daily which will free the archivist to use this time for other more important tasks.

Also depending on the global health situation due to the Corona 19 epidemic [33], the Moroccan national radio and television company complies with government laws that encourage remote work.

The main purpose of a text extraction system is to accept video files, detect the text, extract it, and produce an ASCII file including the text in a format that can be used by other applications.

Text detection is performed in each frame of the video. The rectangles representing the location of the text are followed during their period of appearance to associate the corresponding rectangles in the different frames.

This information is necessary to improve the content of the image, which can be achieved by integrating several rectangles containing the same text. This phase must produce sub-images of a quality in accordance with the prerequisites of an OCR process. Therefore, face recognition of news anchors is used to separate each story from the other.

This system makes it possible to extract several information of the news anchor (Fig. 2), the cities (Fig. 3), the people who speak in the microphone (Fig. 4), and the journalists who work in the reports (Fig. 5), in order to provide a complete document.

Fig. 2. Example of a TV News Presenter.

Fig. 3. Example of a City Name in a Report.

Fig. 4. Person Speaks with a Microphone.

Fig. 5. Example of a Team that Produced a Report.

The detection and recognition system must be able to observe a scene. The acquisition conditions of each sequence of images obtained are checked. Usually, capturing the news anchor's face images will be done in front view and in best Full HD (1980x1080) image quality. "Table I" summarizes the video resolution specifications.

TABLE I. VIDEO TECHNICAL SPECIFICATIONS

Type	Video
Codec	MPEG-2 Video (mp2v)
Resolution	1920X1080
Frame rate	25
Planar decoded format	4:2:2 YUV

This system tries to extract and process much information to extract each text frame and recognize faces at the same time (Fig. 6).

Fig. 6. Processing Model Diagram.

There are two types of text in a video:

- Natural text.
- Overlay text.

1) Natural text is the text that appears in the video when it is recorded. These texts are part of the scene where the video is recorded. Example: nameplate number, text on a man's t-shirt, license plate number (Fig. 7).

Fig. 7. The Name Appears in a Drinking Water Cistern.

2) Overlaid text is the text that was not part of the video when it was recorded, but is overlaid to give additional information about that particular scene. Example: text appearing in the Lower third of TV shows (Fig. 8).

Fig. 8. Example of Lower Third.

Natural text is not of much use because it contains less important information, but overlay text contains information that is of great importance. Therefore, the main objective of the

proposed system is to detect the superimposed text appearing in the video.

News Lower third is static or scrolling depending on the choice of news channel. Both variants have their own challenges. Static Lower third have a fixed space on the video frame to accommodate all text. News channels decrease font size to accommodate more text in some cases. Some channels also perform horizontal compression of text within the frame.

In the context of news videos, the space allocated to the Lower third is fixed and generally designed to accommodate most ligatures, but some are complex.

#### D. Material and Method

Lower third Extraction, has been refined an implementation of the efficient and accurate scene text detector (Tesseract) using the Python programming language [34], on a video to be able to return the bounding boxes of all text in a frame image (Fig. 9).

Fig. 9. Extraction using a Text Detector (Tesseract).

Python has very strong community support with many useful packages and libraries. It is also one of the most popular programming languages for data science, machine learning, artificial intelligence, and scientific computing in general.

The Tesseract engine supports multilingual text recognition [35] [36]. However, recognizing cursive scripts using Tesseract is a difficult task, the Tesseract engine is analyzed and modified for recognition of Arabic writing style. The original Tesseract system has accuracies of 65.59% and 65.84% for 14 and 16 font sizes respectively, while the modified system, with reduced search space, yields accuracies of 97.87% respectively, and 97.71%, this algorithm uses the characteristic of the densities of special symbols in each line of text, which is calculated using the built-in character classifier in Tesseract [37].

### III. TEXT RECOGNITION AND EXTRACTION

#### A. Segmentation

This step is applied to each Frame or image, using the OCR algorithm, the text box is detected. The detected text regions are then refined to increase the efficiency of text extraction. The effectiveness of text detection depends on the font color, text size, background color, and video resolution.

#### B. Classification

Classification is a form of data analysis that extracts patterns describing classes of data, these patterns are called classifiers, and they predict class labels. In this step, the system

must make a decision based on the used algorithm. This analysis can help us better understand the data set.

#### C. Competition Dataset

In this section, he discusses in detail the process of preparing the dataset and the rigorous measures that were taken to ensure maximum diversity throughout in the dataset, through the collection of newsreel video recordings from the source of the National Radio and Television Company (SNRT), in High Definition (HD). At the face recognition level, there is a Database (Dataset) of 7 TV news anchors (Fig. 10), where the system will process these 7 faces to detect them in the video.

The storage of the extracted information for each video is ensured in a separate file bearing the title of the video in the form of a text file, with a small volume.

The videos are stored in a storage server, each video bears the name of the log “newsfeed” + the date (Fig. 11).

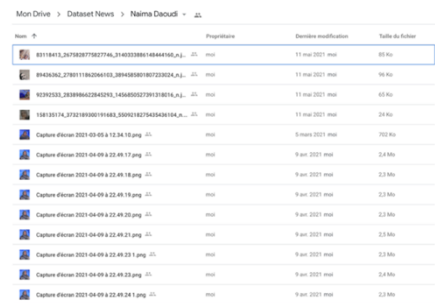

Fig. 10. Training Dataset for Face Detection.

Fig. 11. News Video Clips Stored in Hard Drive.

The advantages of this system:

- Facilitates the task of the archivist and makes the data search and classification simpler.
- Generates a complete newscast information file for extraction. The disadvantage of this system
- Must have a robust computer capable of mass computing and processing information.
- Very slow extraction due to processing each frame for text and face recognition at the same time.

### IV. RESULTS AND DISCUSSION

The extraction of the Lower third was however more complex. It is useful to know the fixed position and speed of the Lower third output for each part. Using this information,

the algorithm extracts the two parts of the recognition to prepare each frame received from the video file in MXF format for the news anchor face localization stage (Fig. 12).

Start of the video with the main presenter (start of the report 0) -----> report 0 -----> senior reporter  
 start report 1 -----> report 1 -----> senior reporter

After entering the correct addresses (Fig. 13), you will have access to the reception platform which consists of:

- The "Choose a file" button to load the selected video into a disk.
- The "Download video" button to start the extraction.

In this Application, two techniques have been implemented; face detection and text detection.

Before launching data extraction, it is first necessary in the first time to use this system, to train the news presenters in order to generate a PICKLE type file.

In this case, 900 photos from these seven news presenters are used.

Once the news presenters to be recognized does not correspond to any person in the file (PICKLE), a message will be displayed to indicate that this person is unknown, this message will also appear in the final result file and also a copy of the images in the "image" folder. If the news anchor you want to recognize exists in database, the application will display his first and last name.

The objective of this final report is to filter useful information for the archiving service in order to recognize the news anchor, the people, the number of reports and the employees who produced the television news.

Given the amount of potential software in the audiovisual field that can be based on this type of application, this software must meet the requirements of speed and robustness of results.

Fig. 12. Facial Recognition and OCR Home Interface.

Fig. 13. Facial Recognition and OCR Home Interface.

Finally, a custom web application is created (Fig. 14). The user interface (frontend) is implemented using HTML, CSS and JavaScript. The (backend) of this test application was built using Python with Flask [38], a library for building APIs, combined with the packages and scripts needed to implement OCR and facial recognition. The use of this web application is allowed to get an idea of the video treatments that can be processed successfully.

## V. CONCLUSION

In this paper, a prototype audio-visual archiving system based on face and text detection in Arabic language is designed and implemented. Experimentation shows that the overall recognition accuracy is greater than 88%.

On the other hand, the majority of research works related to video presents a variety of approaches concerning different domains and processes video in general, but does not consider integrating both face and text recognition into a single model. This is therefore the first objective to be attained through this paper.

This approach ensures that human resources help achieve the desired objective by automating the required filing system fixed by managers. This study shows that this problem is very

complex. For this, it was used the algorithm of SVM as well as CNN and library Pytesseract at the same time to solve this problem by the good choice of the parameters and the tolerance coefficient. The optimal solution obtained makes it possible to validate the proposed approach but has a problem of program execution time given the complexity of video processing and computer processors. In future work, he will study similarity semantics for image video text classification. Additionally, it will try to build a bigger model for different languages.

## ACKNOWLEDGMENT

The authors would like to acknowledge the support of the General Administration of the National Society of Moroccan Radio and Television (<http://www.snrt.ma/>), as well as the Faculty of Sciences of Ibn Tofail University (<https://fs.uit.ac.ma/>).

**Abstract**—Data recovery is one of the forensic techniques used to recover data that has been lost or deleted. Data recovery is carried out if there is a condition where the data that has been owned is deleted or damaged. If the data has been lost or deleted or even tampered with, then a forensic expert has several ways to restore data that has been lost or damaged. One of them is to use a complete data recovery method using forensic tools, namely, TSK Recover, FTK Imager, Foremost Recover, and Testdisk Recover. Unfortunately, tools such as FTK imager and TSK recover have a weakness, namely that some damaged or corrupted data files cannot be restored in their entirety; they can only be recovered but not be opened. This study uses a tool comparison method approach using foremost recover and Testdisk recover. It's just that this method cannot be used using the graphic user interface (GUI) but using the CLI (Command Line) in the LINUX operating system. And the files that have been recovered will be fully recovered.

**Keywords**—*Recovery; tools; FTK imager; foremost; Testdisk*

## I. INTRODUCTION

Data loss is a condition where the data that has been owned becomes corrupted or deleted [1]. According to several researchers, there are many companies or individuals who accidentally delete their personal data. It is very important for digital forensic analysts to have the right tools to recover data [2]. All devices store a lot of important data and information that is always used for personal and corporate purposes. Forensic tools are used by thousands of digital forensic professionals. The functionality of forensic tools varies greatly [3].

Currently, there are many simple data recovery tools; several features have been provided consistently for more effective forensic extraction to get the whole data [4], including image storage, file data hashing, data visualization, and data carving on damaged images. However, most of these tools are paid for [5]. Due to the limited inspection features, the extracted data cannot be ported directly to the circuit to extract additional evidence. In this study, I present several tools that will help forensic analysts perform open source-based data recovery on Linux [6].

Data recovery is the process of recovering a problematic or lost system so that it can be recovered as usual [7]. Data recovery is also a forensic technique that is often used to search for digital artifacts that have been lost or deleted from devices such as cellphones, computers, and laptops [8]. Data

backup, which is a preventive measure that is intentionally done to protect data by copying or copying data to other storage media [9].

This study aims to determine the forensic tools that are useful today and in the future. To overcome the occurrence of data loss, a digital forensics expert is needed [10]. Data recovery is one of the techniques that must be mastered by digital forensic experts [11]. If there is data damage or data loss, then it is the job of a forensics officer to recover data that has been lost or damaged [12]. Several cases of data corruption or data loss are one of the challenges that digital forensics experts must face. There are several data recovery tools used by digital forensic experts, such as Autopsy, FTK imager, TSK recover, Foremost, and Testdisk [13].

In the case of previous research, many forensic experts use this tool as a tool to find evidence [14]. This tool is very helpful for recovering data that has been lost or damaged, but this tool has a certain weakness, when restoring data or data recovery, namely data that has been damaged can only be recovered but cannot be opened in its entirety, therefore the solution what is needed is a complete recovery, data that has been retrieved / damaged can be recovered and reopened the same as before. To overcome this problem, a forensic expert uses recovery tools in a storage [15].

Recovery of the data to be recovered is in the allocated space and unallocated space [16]. This space stores all files that are still available and can be read logically, and stores all files that are no longer available, even if they have been deleted from storage and cannot be read logically [17].

From some of the references found, it can be concluded that previous research related to the themes discussed included many case studies that used forensic tools and used several methods to recover lost data [18]. The data is stored in various storage devices such as flash drives, HDDs, SSDs, and RAM. The storage is on mobile devices, computers, and even servers. Data recovery methods also vary depending on the storage to be processed. One of them is using autopsy tools or other forensic tools [19]. This tool is very helpful for forensic experts to find lost data files, such as JPG, MP4, PDF, PNG, Doc, Zip, Rar files, and so on. It's just that this tool has certain weaknesses when it comes to data retrieval or data recovery. Data that has been damaged can only be recovered but cannot be opened in its entirety. Therefore, the solution needed is full

recovery. Data that has been lost or damaged can be recovered and reopened the same as before [20].

Efforts to provide data recovery solutions for handling digital evidence on a storage device such as a smartphone have been discussed by Wilson & Chi (2017) using digital forensic tools to make it easier to acquire data. The most important thing about recovering data is the recovery method because there are many ways to acquire and recover data [12].

However, there are several researchers who provide reviews of data recovery with different techniques and different devices, as discussed by Povar & Bhadran (2011). The carving technique is what is meant. This technique helps in finding hidden or deleted files from digital media or with the data acquisition technique that has been discussed by Jo et al. (2016) regarding data acquisition using forensic tools, namely Autopsy. This technique is very helpful for a forensic expert to collect data or evidence [21].

Several films and photographs in the form of corrupted or damaged JPG, MP4 and PNG files will be used as part of the data to help solve this issue. Additionally, it will be processed afterwards using a number of forensic programs, including Testdisk Recover, Foremost, and the Sleuth Kit Autopsy. These tools will receive this data and begin the recovery procedure [22]. The final step allows for a comparison of numerous efficient tools that can be used to carry out a complete recovery. Using digital forensic tools to aid data capture, Wilson & Chi outline efforts to provide data recovery solutions for digital evidence on a storage device like a smartphone. Since there are numerous ways to obtain and recover data, the recovery method is the most crucial factor [23]. Using a live forensics procedure with the Foremost recovery program or Testdisk recover is the suggested solution for flawless data recovery. Data can be acquired with this tool from storage devices as HDD, SSD, FD, CD/DVD, zip, and rar [12].

This study compares the forensic tool settings that will be utilized to recover deleted or damaged data in the form of data file formats that will be used as evidence in cybercrime case resolution [24]. In this investigation, data recovery is carried out on Linux utilizing the live forensic method. The findings of this study should aid in our understanding of digital forensics, particularly with regard to data recovery [18].

A forensic technique applied while the system is operating is called live forensics. This is because when the system is switched off, the data that needs to be recovered can be lost. This live forensic technique is typically applied to memory scenarios where data can be written to or erased from—this type of memory is also known as volatile memory or non-volatile memory [25].

## II. RESEARCH METHOD

The procedures needed to conduct a study are known as the research technique. These procedures are taken so that a scientific process can be used to tackle the difficulties that develop by providing logical and systematic solutions, as shown in Fig. 1.

Fig. 1. Research Methodology.

### A. A Study of the Literature

In order to support the overall objective of this research, the purpose of this literature review is to gather information materials on research topics that can be sourced from articles, papers, journals, papers in the form of theories, research reports, or previous findings. We also visit several websites on the internet that is related to these theories about digital forensics, evidence, and recovery.

### B. Tools for System Preparation

This is a step in creating the hardware and software specifications needed for research projects like planning and putting into practice a comparative examination of data recovery utilizing a flash drive. Such as setting up the system and installing software. The physical machine has Microsoft Windows 11 Home installed as its operating system. The employment of physical computer hardware and software as research tools and materials is necessary for the successful operation of the experimental implementation. The following tools and materials are employed in this process:

- MSI Modern 14 laptop with specifications:
  - a. Processor : Intel Core™ I7-10510U CPU  
1.80Ghz
  - b. Memory : 512 GB / 8 GB RAM
  - c. OS : Windows 11 home insider 64-bit
- Flashdisk 8 GB
- TSK recover tool
- Foremost recover tool
- Testdisk Recover tool
- Oracle VM virtual box (CSI Linux)

### C. Proposed Methodology

#### 1) Foremost Recover Forensic Method

In order to replicate the functionality of the DOS carving software for usage on the Linux platform, the most recent recovery technique was developed in March 2001. Special agents Kris Kendall and Jesse Kornblum from the Office of Special Investigations of the US Air Force originally wrote

Formost. The program was altered in 2005 as part of a master's thesis by Nick Mikus, a researcher at the Naval Graduate School's Center for Information Security Studies and Research. Among these changes were improved accuracy and foremost extraction rates.

This method is intended to read and copy data straight from the disk into the computer's memory without taking into account the underlying file system type. The method of file carving is used by Formost Recover to look for header file types that coincide with those in the formost configuration file. There are no alternatives for a graphical user interface, hence the command line interface is primarily used. The JPG, GIF, PNG, BMP, AVI, EXE, MPG, WAV, RIFF, WMV, MOV, PDF, PLE, DOC, ZIP, RAR, HTM, and CPP file formats can all be recovered using the first approach. Additional file types can be specified in the configuration file formost.conf, which is typically located in /usr/local/etc. It can be used to recover data from hard disks that use the ex3, NTFS, or FAT file systems as well as directly from picture files. In example, it can be used to retrieve data from a smartphone via a computer as shown in Fig. 2.

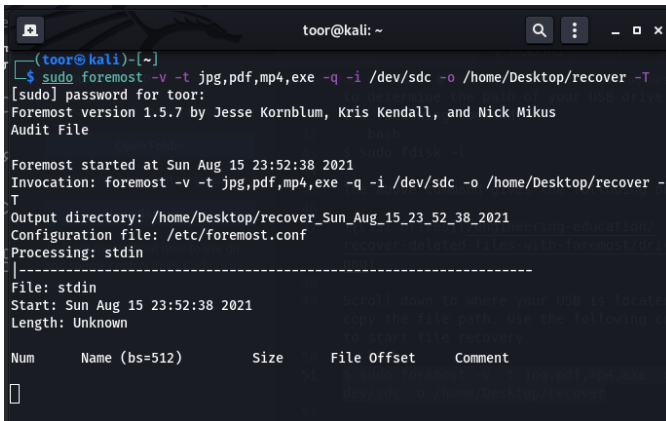

Fig. 2. Example Image Foremost Recover Method.

### 2) Testdisk Recover Forensic Method

A free and open-source utility called Testdisk is used to recover data from missing or deleted partitions. There is no user interface version of this utility; it is CLI driven. A digital forensics specialist can utilize this to restore partitions that are unable to boot due to things like virus attacks and, of course, purposeful or unintentional destruction of the partition table. This testdisk can also do a number of additional tasks, including:

- Recover FAT32 boot sector from backup
- Recover boot sector FAT12/FAT16/FAT32
- Recover NTFS boot sector
- Restore NTFS boot sector from backup
- Fix MFT using MFT mirror
- Find backup superblocks ext2/ext3/ext4
- Undelete file from FAT, exFAT, NTFS, and ext2 file system

- Copy file from FAT, exFAT, NTFS and partitions deleted ext2/ext3/ext4

A forensic expert who is looking into a case involving data loss or corruption will find this Testdisk to be of great assistance. Fig. 3 depicts a sample of the Testdisk recover technique.

Fig. 3. Example Image Testdisk Recover Method.

### D. Recovery Method Workflow

Workflow recovery methods are phases or steps that digital examiners must go through when performing digital tasks, beginning with preparation, extraction, and analysis. As shown in Fig. 4.

Fig. 4. Workflow Method Recovery.

- Preparation

By providing storage space for data that will be recovered and extracted, we set the stage.

- Extraction

This carries out file extraction by locating and restoring deleted files. The properties of the file structure, deleted data, file name, file size, and location will all be made known through file extraction.

- Analysis

It is in the process of analyzing the outcomes of file-checking. In order to assess or evaluate the success of data file extraction and can suggest the technologies that are best for file recovery in this investigation.

E. Data Recovery Comparative Analysis

Using forensic tools like TSK recover, Formost, and Testdisk recovery, the data recovery stage of comparative analysis was extracted. Damaged data files like JPG, PNG, and MP4 on flash drives, HDDs, SSDs, and other storage will be examined using a data file recovery approach utilizing a number of tools, which will then discover variations that impact data recovery on these tools so that they may be opened again. in full. Tables I and II show many tables that depict the outcomes of the recovery based on the findings of the forensic investigation.

TABLE I. FLASHDISK DATA RECOVERY RESULTS

Storage	Flasdisk	
Tools	TSK recover, FTK imager, Foremost, Testdisk	
Jenis File	JPG, PNG, MP4	
Recovery status	Succeed	Not successful
	√	

TABLE II. HDD/SSD DATA RECOVERY RESULTS

Storage	HHD / SSD	
Tools	TSK recover, FTK imager, Foremost, Testdisk	
Jenis File	JPG, PNG, MP4	
Recovery status	Succeed	Not successful
	√	

III. RESULTS AND DISCUSSIONS

A. Preparation

By providing storage space for the data that will be recovered and extracted, the preparation stage is prepared. In this study, we used flash storage that contained unopenable rar files containing JPG, PNG, and MP4 files. The tests and findings obtained have as their goal getting a full recovery file so you can compare the forensic tools utilized. Some of these files are hashed, as indicated in Tables III and IV, to demonstrate their validity in comparison to the findings of forensic analysis and recovery.

TABLE III. MD5 HASH

No	Data file	Initial MD5 Hash
1	.JPG	459d4d4d38993bb270d9f8d7d5029a5c
2	.PNG	120695b94e5d3bf867862eb42715a4a4
3	.MP4	677f7dca67cdf3741d3f924a668fc2b2

TABLE IV. SHA1 HASH

No	Data file	Initial SHA1 Hash
1	.JPG	1b036089c09444fe5ae1fb0f4279de1f99200fa8
2	.PNG	ccc7286c0ba4a4fb1a61a1793dfa4fc8b60ef60d
3	.MP4	13d1fcd6ef10140dc80726640564aabee08a6161

B. Extraction

File extraction will also expose the characteristics of the file structure, deleted data, file name, file stamps, file size, and location during the extraction stage, which is to extract files by locating and recovering deleted files. The tools that aid in the extraction process run on Linux and use Guymager using the tools TestDisk and Foremost for data recovery.

Another independent acquisition tool that may be used to clone disks and make forensic pictures is Guymager. Guymager, created by Guy Voncken, is entirely open source, only works on Linux-based hosts, and shares many of the same capabilities as DCLDD. Guymager, the forensic imager included in this package, is made to operate quickly, support a variety of image file types, and be extremely user-friendly. It leverages parallel compression in its high-speed multi-threaded engine to maximize performance on multi-processor and hyper-threading engines. It is shown in Fig. 5.

Fig. 5. The Process of Mounting File in Guymager.

1) Recovery Process

The recovery step involves a data recovery procedure using a number of programs for comparison, including TestDisk Recovery, TSK Recovery, FTK Imager, and Foremost. After that, the recovery process will use the extracted files. One of the Linux CLI-based tools for data recovery is the TSK recover utility. There are some JPG files that cannot be accessed, as illustrated in Fig. 6; however the recovery procedure utilizing the TSK recover tool was successfully recovered.

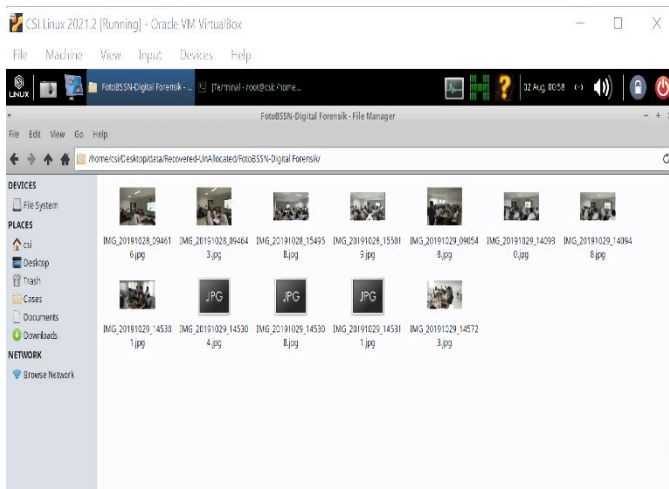

Fig. 6. File Recovery Process on TSK Recover.

A tool that is frequently used for imaging files is the FTK Imager. The FTK Imager has a number of features, including:

- Functions & Features
- Full Disk Forensic Image
- File Decryption & Password Crack
- Parsing Registry Files
- Collect, Process, and Analyze Data Sets Containing Apple's File System
- Locate, Manage and Filter Mobile Data
- Visualization Technology

This utility is frequently used to restore erased data. However, it is clear that allocated and unallocated files differ throughout the recovery step. As seen in Fig. 7, it is a file that can be recovered but cannot be opened.

Fig. 7. File Recovery Process on FTK Imager.

The Foremost Recovery Tool is a program created to read and copy certain areas of the disk straight into the computer's memory while ignoring the underlying file system type. For

the majority of recovers, it employs a technique called file carving to search for header file types that coincide with those contained in the primary configuration file. The best recovery tool for JPG files has been used to successfully recover all of the files. It is shown in Fig. 8.

Fig. 8. File Recovery Process on Foremost Recover.

Data can be recovered from lost or deleted partitions using the free and open-source Testdisk recover utility. A digital forensics specialist can restore partitions that are unable to boot due to reasons including malware attacks and purposeful or unintentional loss of the partition table using this CLI-based application, which does not have a user interface version. Fig.9 illustrates how the recovery procedure using the Testdisk recover program was successful in restoring lost and damaged files.

Fig. 9. File Recovery Process on Testdisk Recover.

### C. Analysis

The analysis step is where the outcomes of the files that have been checked are examined. A comparison of the data recovery tools, when situations like missing or damaged files arise, you must use the resources at your disposal to find a solution. You must experiment with all of the forensic tools, not just one. It makes sense that certain tools are unable to recover files perfectly while others are successful in doing so, as in this study is shown by Tables V and VI.

TABLE V. RESULTS OF STATUS RECOVERY ALLOCATED FILES

No	Tools	Status File Recovery		
		JPG	PNG	MP4
		Allocated		
1	TSK Recover	100%	100%	100%
2	FTK Imager	100%	100%	100%
3	Foremost Recover	100%	100%	100%
4	TestDisk	100%	100%	100%

A sort of file storage known as allocated space is still accessible, and the files contained therein can still be read logically. All files in the designated space can be fully recovered after conducting research with the aforementioned instruments.

TABLE VI. RESULTS OF UNALLOCATED FILES RECOVERY STATUS

No	Tools	Status File Recovery		
		JPG	PNG	MP4
		UnAllocated		
1	TSK Recover	50%	50%	100%
2	FTK Imager	50%	50%	100%
3	Foremost Recover	100%	100%	100%
4	TestDisk	100%	100%	100%

Files that are no longer accessible or have been erased and cannot be read logically are stored in unallocated space. Not all files have been totally and flawlessly retrieved after utilizing the following utility to do research on data files in unallocated space

#### IV. CONCLUSION

Based on the results of research on the comparison of data recovery using open source-based tools on Linux, the results of the comparison of these tools with previous research are very different. Due to the limited features available in open source forensic tools like the TSK recover tool and FTK Imager; it makes investigators hard to get valid evidence. It can be concluded that among these tools there are those that can recover data files that have been damaged and can be reopened in their entirety and some are not. One of the open source based tools that can be used is foremost recover and Testdisk recover. This tool is a solution to the problem of

recovery. Of the tools that have been tested, only 50% have been fully recovered. Namely, TSK recover and FTK imager. While the foremost tool, Testdisk, can recover 100% completely. However, tools that can't recover completely don't mean they're not good. These tools are still recommended and can be used to assist investigators in the investigation process. Investigators can have several options for forensic tools to carry out the investigative process. This study aims to determine the forensic tools that are useful today and in the future.

# Advanced Persistent Threat Attack Detection using Clustering Algorithms

Ahmed Alsanad<sup>1</sup>, Sara Altuwaijri<sup>2</sup>

Department of Information Systems  
College of Computer and Information Sciences  
King Saud University, Riyadh 11543, Saudi Arabia

**Abstract**—Advanced Persistent Threat (APT) attack has become one of the most complex attacks. It targets sensitive information. Many cybersecurity systems have been developed to detect the APT attack from network data traffic and request. However, they still need to be improved to identify this attack effectively due to its complexity and slow move. It gets access to the organizations either from an active directory or by gaining remote access, or even by targeting the Domain Name Server (DNS). Nowadays, many machine learning (ML) techniques have been implemented to detect APT attack by using the tools in the market. However, still, there are some limitations in terms of accuracy, efficiency, and effectiveness, especially the lack of labeled data to train ML methods. This paper proposes a framework to detect APT attacks using the most applicable clustering algorithms, such as the APRIORI, K-means, and Hunt's algorithm. To evaluate and compare the performance of the proposed framework, several experiments are conducted on a public dataset. The experimental results showed that the Support Vector Machine with Radial Basis Function (SVM-RBF) achieves the highest accuracy rate, reaching about 99.2%. This accurate result confirms the effectiveness of the developed framework for detecting attacks from network data traffic.

**Keywords**—APT Attack detection; DNS; network; cybersecurity; clustering algorithms

## I. INTRODUCTION

People and organizations worldwide use technology for most of their daily activities. This change is called digital transformation, which requires organizations to profoundly transform their business model, infrastructure, processes, and culture. So, the usage of the Internet is increased [1]. Although technologies and the Internet make life easier, they have been used for harmful purposes. Cybersecurity crimes impact society [2] since these crimes occur through modern communication devices using internet connections. The actors who cause a cybercrime are called attackers, and they are different kinds and have multiple goals; one of those kinds is APT Attacks. APT stands for Advanced Persistent Threat [3], and it is one of the top cybersecurity concerns in enterprise networks [4]. APT means: Advanced, which means the attacker is stealing, targeting, and data-focused attacks [5]. Persistent means an attacker identifies the target to breach, hide, and exploit them [6]. Word Threat in APT means the extraction of critical data [5]. APT are complex, and they are well-planned security attacks [7]. So, its consequences will impact the organizations by stealing intellectual property, compromising and stealing sensitive information, stealing

classified data, critical organizational infrastructures, and accessing diplomatic communication channels. Also, the ability to detect APT activity at the network level is heavily dependent on leveraging threat intelligence [8]. Attackers use multiple techniques to hide and infect the targets; the method is not limited to phishing, zero-day attack, waterhole attacks [3], and denial of service (DoS) attacks [9]. APT attack functions are developed to avoid detection as long as possible [10]. So, many techniques have been used to detect change controlling, sandboxing, and network traffic analysis [11].

Increasing the frequency of security breaches and cyberattacks on the Internet of Things (IoT) requires dependable security solutions [12]. In addition to firewalls, the Network Intrusion Detection System (NIDS) is the second network infrastructure security system that detects malicious activity and prevents attacks [13-15]. Moreover, security administrators typically choose password protection systems, encryption techniques, and access controls to protect the network. These measures, however, are insufficient to protect the system [16]. As a result, the administrators prefer to utilize Intrusion Detection Systems (IDSs) to monitor network traffic and detect malicious attacks [17-21]. For example, in [22], the authors proposed an over-sampling Principal Component Analysis (PCA) to address the anomaly detection problem.

Today, alert correlation is done using Security Information and Event Management (SIEM) systems such as Splunk, LogRhythm, and IBM QRadar [23]. They collect multiple log events and alert various sources. But the APT Attack has evolved to bypass security mechanisms that are difficult for technologies to find [24]. This paper studies how to detect APT attacks according to the framework. Currently, there is a significant potential for cyber-attack these days. A cyber-attack is intentionally exploiting computer systems, infrastructures, and networks. Cyber-attack has been done throw the attackers; the attackers are multiple kinds and category. These attackers are different from each other in terms of the goals and methods they use. Common types of cybersecurity attacks are malware attacks, Denial-of-service attacks, password attacks, and APT attacks. APT is a complex and multi-stage attack. Since its complex, they need many stages to meet their target by collecting information as much as possible and carefully [25]. Afterward, they will use their technique to reach what they need, such as phishing. Attackers then collect confidential data using multiple malware after they breach the network. Also, they use various techniques to send the data taken to another server.

Based on the NIST framework, cybersecurity programs have five primary functions. These functions are, identify, protect, detect, respond and recover. Some attackers will be known in the preserve or prevent phase, and others in the detection phase. In this paper, we focus on detecting APT attacks. That detecting APT attacks is challenging because it defeats and supersedes the premier defense devices by injecting their techniques as part of large normal traffic [25]. They are also closely linked to each other and are hidden, so it is usually too late to detect them. The attacker needs more time to efficiently distribute the attacker's activities and behaviors, with a challenging possibility to be detected. So, for APT attack detection, we use multiple techniques and tools to detect it using an attack signature, monitoring the network, and collecting network information.

Several techniques are implemented to detect the APT attack by using the tools in the market. These techniques are either using artificial intelligence (AI) or machine learning (ML) methods. However, still, there are limitations in terms of accuracy, efficiency, and effectiveness, especially the lack of labeled data to train ML methods. Significantly, the APT attacks are brutal to be detected. They usually target sensitive and critical data. An organization infected and exploited by APT attacks will harm and lose many essential assets or data. APT attacks are very complex due to their lifecycle and evolution complexity.

This paper's scope is to develop a framework and apply it as a tool to identify and detect APT attacks. Using machine learning for analyzing the attacker's behavior, the framework is implemented to help the cybersecurity specialist, especially those working in the Security operation center (SOC), to know and detect if their organization is breached and hacked by APT attackers. This framework will minimize the harm and impact that the APT attack will do. Also, it will be more accessible to cybersecurity vendors to build their detection tools. Through the proposed framework, the research contributions to the field can be summarized as follows.

- A framework to detect APT attacks is proposed to tackle the lack of labeled data using unsupervised clustering algorithms such as the APRIORI algorithm, Hunt's algorithm, and the K-means algorithm.
- The proposed framework is implemented on the CSE-CIC-IDS2018 dataset for achieving the performance of supervised learning of the ML models.
- A comparative study of the five ML classifiers is performed to detect the APT attacks.
- The framework's performance results are evaluated using several evaluation measures on the dataset.

The rest of the paper is structured as follows: Section II gives a background for the study. Section III presents the literature review of the previous work on detecting APT attacks. Section IV explains the proposed framework to identify and detect an APT attack. Section V introduces the experiments with findings and discussions. Finally, Section VI summarizes the conclusions and future research work.

## II. BACKGROUND

An APT attack's lifecycle is more complex than other kinds of attacks. A successful APT attack can be divided into multiple stages [26]. In the first stage, the attacker will define the target by determining who he will target and why he wants to target him. Next, he will select the team members and identify the required skills. Then the attacker will find the existing tools or develop new ones he/she needs. After that, the attacker will discover who has access to what he needs and what HW/SW will use. Then, the attacker will test if he/she can detect or not by deploying a miniature version of the tool, piloting a connectivity and alarm trail, check and spotting any weaknesses. Later on, he/she will launch full fledged attack on the victim's platform.

Fig. 1. APT Lifecycle.

The first entrance will be shown in the network where the target is. After that, he will establish a secure connection from victim's platform to his Command-and-Control Center. He will obtain credentials by creating a hidden Trojan on the victim platform. Then, he will start navigating through the rest of the platform to create more Trojans. After that, and once he gets what he was looking for, he will cover the tracks to remain undetected and make sure to clean up after himself. Fig. 1 shows and summarizes the stages of the APT attacker's lifecycle.

## III. LITERATURE REVIEW

This section discusses the previous work related to detecting APT attacks. An intrusion detection system (IDS) is an inevitable line of defense against cyber threats [27]. The challenge here is that IDS lacks typical evaluation methodologies to detect this attack. This section will do a literature review for detecting APT attacks and what the target is.

To detect APT attacks, two main approaches are commonly used, which are:

- Detection based on signature: It is a well-known technique based on the attack's signature [28] and low efficiency.
- Detection based on behavior: it is an enhanced technique that focuses on the attacker's signature and behavior [28], and its result is high efficiency and high processing costs.

The literature review of APT attack detection will be divided based on what the attacker targets the system, network, or domains.

#### A. APT Attack Targeting Active Directory

As Active Directory (AD) is a system that manages the organization's accounts for windows systems. This fact makes it a target for APT attacks since it is expected that domain admin privileges have been accessed by APT attacks.

To detect this attack, various research talks about it how to use machine learning and focus on the attacker's signatures and characteristics [29], and they are:

- Detection using authentication files: Using machine learning (Unsupervised) to analyze authentication files or monitor abnormal user behavior.
- Process-based detection: utilizing backlist in conjunction with signature-based detection in the log files [29], then false negatives will arise case the attackers manipulate file names of the tools because the file name is the main element on the signature algorithm.
- Detection through network traffic monitoring: an example of the methods is Golden Ticket [29] by traffic monitoring. But this feature is not implemented for windows systems.

The proposed approach was for outlier detection using Domain Controllers logs with machine learning related to processes. The advantages of this kind of method are their ability to detect AD attacks with high accuracy by abusing the command and tools that attackers are using. Also, because it uses only Domain Controller logs, it is very cost-effective. The target is detecting attacks that require control of admin privileges of the Domain Administrator.

The algorithms used are machine learning utilizing existing data without any programming effort. With this unsupervised learning, there is no need to provide correct answers [29]. So, no need to analyze the attacker's behavior.

After evaluating the methods, machine learning was the most appropriate algorithm for their way. The other one was preprocessing for machine learning which describes the necessary preprocessing for machine learning. Any logs that show a particular feature, such as logs with blank values, need to be eliminated because they can be identified with no value. When the attackers disguise their identity as an official Domain Administrator account, and the hijacked Domain Administrator account uses tools or commands, the attacker also uses false

detection. This means that Administrators use commands which are rarely used [29]. The APT Attack against AD is brutal to be detected since that attackers usually take advantage of processes and legitimate accounts [29].

#### B. APT Attack and Intrusion Detection Event

The prediction model for intrusion detection is based on events that show the probability of threat intrusion detection events through the prediction task [30]. After the analysis, it detects the attacks before or after a particular attack exists in a correlation [30]. By extracting the events of intrusions, a specific scenario is configured. When it takes place after detecting it, the next attack in the plan can be predicted by investigating at which stage of the attack scenario the intrusion detection events occur. That will result in enabling the prediction of the last threat [30].

The intrusion detection event based on the prediction model collects and pretreats intrusion detection events [30], extracts sessions and threads, creates scenarios of the attackers through correlation analysis, predicts intrusions, & expresses the analyzed results [30].

The prediction based on intrusion detection events leads to a search of an event on a scenario of the attacker when an intrusion detection event is detected [30]. When a single event occurs, other events can take place afterward. The issues that face intrusion detection events can be given as follows:

- Time required in prediction and verification of intrusion detection events: the daily average count of intrusion detection events was tremendous and incomparable with the duration of the collected data. So, it is necessary to extract successful attack events by time unit, attack type, and organization, distinguishing them from all intrusion detection events [30].
- Validity of prediction due to narrow gap in intrusion detection events: the time difference in the collected intrusion detection events verified their correlation was primarily within several seconds. Intrusion detection events in government organizations are managed by the enterprise system to monitor the database every five minutes [30]. So, the response to the events is primarily impossible, and the use of anticipated events is less.
- Intrusion detection data and intrusion detection rule: these rules are frequently added, modified, and deleted [30]. Even though those rules are changed, the sequential rules must be learned, and the rules must be applied to an independent prediction model based on intrusion detection events [30]. To do this task, a full-time employee needs to monitor and track it and be dedicated to this.
- Stability of intrusion detection system: the rule-based system used for monitoring cannot provide stability to detect the continuously changing types of attacks [30].

Based on the intrusion detection event model, prediction and verification of the events problems are not only of the time required, but the issues of cybersecurity threat prediction, such as problems in intrusion detection rules, intrusion detection

data [30], and the stability of IDS systems. In addition, the main problem is that it requires automated monitoring detection to predict different APT attacks.

### C. APT Attacks Targeting Network Infrastructure

Network infrastructure APT attacks are many. The first, called Moonlight Maze, targeted government networks [5]. The other one is called operation Aurora targeting cloud computers [5]. To detect those, the author wrote that many challenges would be faced; these challenges are [5]:

- Unsupervised anomaly-based detection approaches to discover all anomalies.
- Supervised alert correlation-based approaches decide whether some attacks are related or are a portion of a more advanced APT attack.

Evaluation and training of those approaches would require entire labeled traces of networks with widespread abnormal and intrusions behaviors [5] and need to be labeled specially for APT-correlated alerts. Also, there are several constraints in detecting an APT attack that targets network, such as:

- No one unique path in which all APT attack activities can be detected.
- Over time the APT attacks tend and adapt to use new tools and vulnerabilities.

The approaches of the IDS, including APT detection methods, consider the feature construction and selection stages as the first-time consuming step. The features can be built using machine learning and data mining methods or manually, such as association mining, sequence analysis, and frequent episode mining [5]. Some of their features categories are:

- Basic features: the essential attributes and features are collected from the connection of TCP/IP.
- Traffic features: the attributes and features that can be computed or extracted from concerning a window interval.
- Content features: the attributes and features that can be extracted from the data payload for suspicious behaviors.

The result of targeting network infrastructure should be focused on automated methods for APT attack detection. It can cover two types of use cases according to the essential infrastructure. In the first use case, the large enterprise networks are considered to have known attacks, such as GhostNet [5], Moonlight Maze, and attacks on cloud computing-based systems like Aurora Operation. Usually, the detection is based on the attack model. For the second use case, the goal network is typically used to extract sensitive information [5]. One of the achievements of this paper is the investigation and description of the existing methodologies and the detailed overview of APT detection approaches related to their infrastructure.

### D. APT Attack to Get Remote Access

The APT attack will get remote access to the target by embedding malware, installing them on the target's device,

connecting to the control server, and maintaining the control channel [31]. To maintain control of the contact, the heartbeat mechanism is also used [31]. They use HTTP, email protocol, and FTP [31] to get remote access. These protocols are standard protocols of application transport for communication to communicate between the inject sides and controls as hidden as possible to avoid security equipment inspection and audit [31]. Remote access is a perfect way for the anomaly to hide in the regular traffic since there are no variances between the communication of remote control and regular network application communication [32].

### E. APT Attacks based on Domain Name Server

One of the techniques to detect APT attacks is analyzing the domain name server (DNS). This is because DNS request constitutes only a tiny fraction of the overall traffic of the network, making it appropriate for analysis and investigation the large-scale networks [33]. Also, DNS traffic contains many significant features to recognize domain names that might be associated with malicious events. These features can be more enriched with related information [25].

The DNS feature extraction can be used to achieve an effective detection of APT attacks. There are three kinds of these features host, time, and domain. The APT Unsupervised Learning Detection (AULD) framework is proposed to detect APT attacks [25] using the DNS features. It can detect suspicious DNS domains with APT attacks based on unsupervised machine learning. The first step is to preprocess the collected DNS request; ten features have been extracted based on host, time, and domain. AULD framework can analyze many DNS log files and obtain the list of APT attacks. Also, it can extract the host, time, and domain features from the DNS log data regarding the behaviors of attackers during an APT attack detection [25].

The results have shown that the framework could detect APT activities effectively [25]. The list of suspicious domains can be detected by cybersecurity experts to define the entire APT attack detection process [25]. Also, the AULD framework can enable cybersecurity experts to analyze suspicious domains and block APT events as soon as possible [25].

### F. APT Attacks based on Accessing Unknown Domains

This section describes an architecture for detecting and monitoring APT attacks depending on access to unknown domains [28]. The architecture module of the APT attack detection and monitoring solution is shown in Fig. 3, and its methods are described as follows:

- Accuracy: APT attacks are prepared through email spam, social phishing, and email phishing [28] to reach their targets. The APT attack detection by unknown domains has a high accuracy result if one unknown domain has been detected. Others will send an alarm to users [28]. Accordingly, admins will take the appropriate action.
- Detection Time: APT attack detection can be handled in a real-time manner [28]. It is a very critical factor for preventing APT attacks at the early stages.

The algorithms for detecting an APT attack that targets these kinds are proposed as follows:

- Algorithms for detecting unknown domains: these algorithms will identify the malicious domains that are possibly suspicious domains of APT attacks [28].
- Algorithms for monitoring access to unknown domains: these algorithms will monitor suspicious activities. The unknown domains will be detected using this algorithm that will be checked by using the generation rule algorithms and simply monitoring techniques [28].

The system model used to monitor and detect the APT attacks of unknown domains is shown in Fig. 2. The model has a number of components, given as follows:

- Datacenter: the data center stores data, including weblogs, network traffic, and normalized data [28]. It gives information for monitoring and tracking network attacks. This extracted information is related to the activities and behaviors of the attackers.
- APT attacks monitoring and detection component: these components monitor and detect APT attacks using DNS logs [28]. The data center provides input for this component. This component includes the following:
  - Database: it is used to provide and store data, which is associated with the signatures of the attackers.
  - Processing component: This component implements the algorithms, methods, and techniques which are used for processing to detect APT attacks [28]. The output of this component is a set of APT attacks and suspicious domains.

- Alarm component: It is responsible for issuing warnings and alarms at different levels with evidence that the APT attacks penetrate the systems being monitored [28].

The architecture module of the APT attack detection and monitoring solution consists of the following components:

- Database: this includes:
  - Signatures of APT attacks database: it stores the signatures of all APT attacks.
  - Detecting result database: it saves the domains that are analyzed and collected by the unknown in the database [28].
  - Monitoring result database: the domains used for analysis DNS logs of unknown domains are stored in the database.

Fig. 2. Detection of APT Attacks from Unknown Domains.

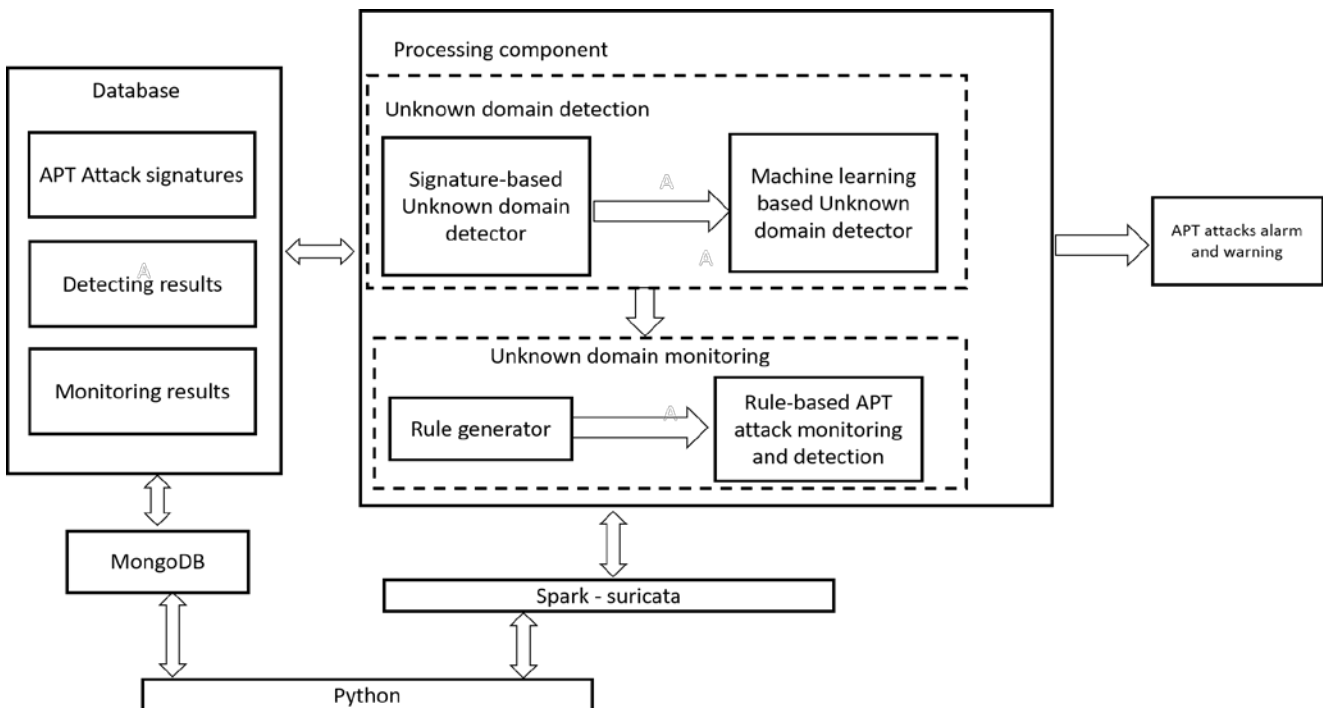

Fig. 3. Architecture Module of the APT Attack Detection and Monitoring Solution [28].

- Unknown domain detection: it consist of a set of algorithms to detect and monitor unknown domains, and it includes:
  - Signature-based unknown domain detector: they collect and extract the signatures from the described APT attacks DNS logs. They are used as evidence for APT attack detection. It compares the domains signatures in the DNS logs with the collected actual APT attack signatures. If the signatures are matched, then these domains are malicious; otherwise, they are benign [28].
  - Machine learning-based unknown domain detector: this is done to identify unknown APT attack domains. A set of suspicious domains is provided as input, and a set of unknown malicious/benign domains is returned [28]. In this study, a clustering technique was employed.

As a result, the APT attack has multiple stages and steps of its implementation. If one stage fails, the whole APT will fail [28]. The method presented is for APT attacks that uses monitoring access to the unknown domains in a real-time manner in high efficiency and effectiveness.

The persistent nature of this kind of attack reveals the necessity of having precise analysis to measure the damages in the absence of proper diagnosis and treatment. This raises several concerns:

- 1) Continues activities from adversaries to breach victims' platforms and to seek the weakest link. This requires continuous monitoring activities and applying the rights update to the media.
- 2) It is not easy to detect the breaches once the advisories gain access to the victims' platform. This requires specialized tools and skilled human resources.
- 3) Recovery will take time to clean up all the resources because of the methods used during the breach.
- 4) Cost again this type of attack is high since it requires advanced detection and protection tools and continuous monitoring.
- 5) Skilled resource availability will be playing a significant role, and it has to be appropriately addressed.

#### IV. PROPOSED FRAMEWORK TO IDENTIFY AND DETECT AN APT ATTACK

APT attacks are complex and hard to be detected. This paper introduces a framework for identifying and detecting APT attacks. The framework is an automated unsupervised machine learning [25], and the output is a set of suspicious DNS domains by analyzing the DNS features. This framework can report the suspicious domains to the security engineer and help the defenders detect faster APT attacks [25]. The framework is divided into four stages: the data collection stage, data preprocessing stage, feature extraction stage, and clustering stage. Fig. 4 shows the flowchart of the proposed framework.

Fig. 4. Flowchart Diagram of the Proposed Framework.

The first part of this framework is data collection, which will collect DNS data log records for a certain period. When finding a precise time sequence for an IP of the internal host, the accessing date, the accessing domain, and other fields among the APT attacker's reports and giving some malicious domains, this will star detect the APT attack.

The second part is data processing; in this part, we will do the following [25]:

- By extracting a valid field and changing the format of the data in the data raw.
- Folding domain into the next level of domain.
- Deleting the whitelist of sites.
- Deleting famous websites within the internal network to get the experimental data.

A feature extraction will then be done by knowing the number of devices that get access to the domains, the domain's popularity, access time, automatic connection, domain age, and similarity of a domain. This is all based on the three types of features, which are time, host, and domain. The last part is the clustering process, and this is done according to the proper algorithm upon testing them such as K-mean clustering algorithm, or Hierarchical clustering, or Density-based clustering algorithms. The framework contains the following steps:

- Data preparation: This is the stage of data preprocessing in which unnecessary features and duplicate instances are removed in preparation for identification. Convert categorical attributes to numerical values through data digitization. Normalization for modifying the scale, type, and probability distribution of variables in a dataset is an example of a data transformation.
- Feature selection and reduction: using the PCA technique to pick the most relevant features subset approaches the detection phase as input.

Detection: On the CSE-CIC-IDS2018 dataset, we improved classification accuracy by utilizing KNN, decision tree, and two kernels (linear, RBF) with SVM machine learning classifiers, as well as a random forest classifier.

### A. Model Evaluation

After the model is trained using the training data samples, it can pass into the test step. Inspecting how the model works in practical circumstances is the aim of testing. This stage allows us to evaluate the model's precision. In this study, the model attempts to identify the APT attack using the knowledge gained during the training step. The evaluation process is vital because it enables us to determine whether the model accomplishes the objective of classifying the network traffic. The previous procedures must be repeated until the requisite accuracy is attained if the model does not function as anticipated during the testing phase. As previously indicated, it should not use the same data that was used during the training phase. It needs to utilize a different data splitter from the data set for analysis.

The accuracy of the outcome is one of the classification measures taken into consideration for evaluating the trained models. When producing classification outputs, there are four possible outcomes: true positives, true negatives, false positives, and false negatives. These four outcomes are represented on a confusion matrix. The matrix can be created based on the results after classifying the test inputs, and each output can be classified as one of the potential outcomes. The model's accuracy is measured by the proportion of correct classification from the test data. The number of correctly classified instances divided by the total number of instances gives the result of accuracy. Additionally, classification models are assessed using additional metrics such as precision and recall.

### B. Adopted Algorithms in the Framework

This section proposes an intrusion detection system based on machine learning algorithms. A Principal Component Analysis (PCA) algorithm is used for feature reduction. This method improves the performance detection task [22]. Traditionally, PCA reduces the feature dimension by linearly transforming original  $n$ -dimensional features into  $n$  orthogonal axis, as shown in Fig. 5. By projecting an observation onto each of these axes, a new set of  $n$  uncorrelated variables is created. The new feature vector is composed of a subset of these variables with a high eigenvalue. However, each derived feature requires  $n \times n$  multiplications and the use of all original features to compute. The computation time for feature extraction will rise as a result of this. In this study, a PCA removes some unnecessary features from the feature set. The information extracted from the coefficients of the Principal Components (PC) is used for feature ranking and reduction.

The covariance matrix ( $C$ ), of the  $n$ -dimensional features vector taken from positive training samples, is created first. The Principal Components are then determined using  $C$ 's eigenvalues and eigenvectors (PCs). There are a total of  $n$  potential PCs. Each of the PCs has  $n$  coefficients, each of which is associated with a correlated feature from the original feature pool. The characteristic associated with the PC's largest coefficient is placed in the highest rank by starting with the first PC. The same technique is used on succeeding PCs to generate a list of features in descending order. A varying number of low-ranked features are deleted depending on the ranking to generate a subset of reduced features.

Fig. 5. PCA Feature Reduction by Linearly Transforming Original  $n$ -dimensional Features into  $n$  Orthogonal axis.

- Experiments have been conducted to determine the smallest number of characteristics that can accurately represent the entire feature set. After that, we achieved a comparative study of the five proposed classifiers, which are:
- Decision Tree (DT).
- Random Forest (RF).
- K-Nearest Neighbor (KNN).
- Support Vector Machine with Linear Function (SVM-Linear).
- Support Vector Machine with Radial Basis Function (SVM-RBF).

## V. EXPERIMENTS AND DISCUSSIONS

### A. CSE-CIC-IDS2018 Dataset

In this section, we describe the CSE-CIC-IDS2018 dataset [1] used to evaluate the proposed framework. It includes detail on intrusions as well as protocol specifics. The Canadian Institute for Cybersecurity released its most recent dataset in 2018-2019. This dataset contains seven different forms of assaults: Botnet, infiltration, DoS, Heartbleed, DDoS, Brute force, and Web attacks. The compromised firms had 30 servers and 420 PCs, while the attacking infrastructure had 50 terminals.

The CICFlowMeter-V3 dataset [26] is collected traffic of AWS network and machine log files with more than 70 extracted features. The best way to test and evaluate the system

framework is represented by the network's applications and the lowest level entities; it also refers to the move from static data to dynamic data, which is real-time traffic on the Amazon platform (AWS). Furthermore, the dataset was improved by taking into account the standards that were designed to produce CIC-IDS2017. In addition to the basic criteria, it has the following advantages:

- There are very few duplicate data records.
- Uncertain data is almost non-existent.
- The dataset is in CSV format so that it can be used immediately without further processing.

### B. Evaluation Metrics

Some evaluation metrics such as confusion matrix, accuracy, detection rate, precision, recall, and F1-score are used to evaluate the effectiveness of the framework's ML algorithms.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

$$Recall (True Positive Rate (TPR)) = \frac{TP}{TP+FN} \quad (3)$$

$$F1-Score = 2 * \frac{Precision*Recall}{Precision+Recall} \quad (4)$$

- Confusion matrix: In intrusion detection, a confusion matrix is a useful tool for predicting the type of network attack. It contains where TP refers to true positive instances (TP), true negative instances (TN), false positive instances (FP), and false negative instances (FN).
- Accuracy: The percentage of positive data cases detected correctly.
- Precision: The number of attacks correctly returned.
- Recall or True Positive Rate (TPR): The number of attacks the system returns.
- F1-score: In our approach, the rate of precision and recall:

### C. Experimental Results

The CSE-CIC-IDS2018 dataset [1] is first preprocessed by eliminating eleven non-essential features such as the timestamp, average number of bulk rates, and number of times the PSH flag was set in packets. The parameters are set by default in all of the implemented algorithms in this report, with the exception of KNN, which uses the n nearest neighbor's property ( $n = 3$ ). The number of classes in the suggested algorithm was determined to be one (zero for non-attack types and one for attack types). The most recent dataset available was used for training and testing the CSE-CIC-IDS2018 dataset. In the trials, training and test data were divided into 80 percent and 20 percent to assess the performance results related to training and testing.

Although PCA aims to maximize the distance between data points, it has no concept of classes. The default libraries in

Python programming language like the Scikit-Learn library, are used. In the experiments, most of the hyper-parameters for machine learning algorithms were set to default. Table I shows the hyper-parameter values for ML algorithms classifiers.

The accuracy definition is crucial since accuracy is an essential criterion for evaluating the efficiency of prediction systems. Accuracy is frequently used to refer to a system's perfect accuracy. However, accuracy can also relate to a class individual accuracy. For researchers working with unbalanced datasets, the definition of accuracy is the average of the accuracies of all classes, which is crucial. In this report, we used K-Nearest Neighbor (KNN) [34], Random Forest (RF) [3], linear support vector machine (SVM-linear) [31], Decision Tree (DT) [30], and Radial basis function (RBF) support vector machine (SVM-RBF) [11] classifiers to classify and detect benchmark CSE-CIC-IDS2018 intrusion detection dataset.

An intrusion detection system should ideally have a 100 percent attack % true-positive rate (TPR) and a 0% false-positive rate (FPR). However, it is difficult to achieve in practice. Table II and Fig. 6 depict the results of these metrics.

The SVM-RBF classification algorithm, as shown in Table II, is the most successful, with a 99.2% accuracy rate. With a 99.1% accuracy rate, the RF classifier algorithm is the second most efficient. Finally, the DT classifier, which had the lowest accuracy rate of 94.2% was applied to the proposed dataset.

With a precision rate of 99.9%, the random forest classifier classification algorithm, as indicated in Table II, is the most successful. The SVM-RBF algorithm is the second most efficient, with a 99.3 % precision rate. Finally, when applied to the proposed dataset, the DT classifier had the lowest precision rate of 79.9%.

TABLE I. MACHINE LEARNING CLASSIFIERS HYPER-PARAMETER VALUES

Algorithm	Hyper-parameter
Decision Tree (DT)	criterion='gini', splitter='best', min_samples_split=2
Random Forest (RF)	n_estimators=1000, criterion='gini', min_samples_split=2, min_samples_leaf=1
K-Nearest Neighbor (KNN)	n_neighbors=3, weights='uniform', leaf_size=30, metric='minkowski'
Support Vector Machine (SVM-linear)	Regularization parameter (C) =1, kernel='linear'
Support Vector Machine (SVM-RBF)	Regularization parameter (C) =1, kernel='rbf'

TABLE II. COMPARISON OF THE RESULTS USING FIVE MACHINE LEARNING CLASSIFIERS

ML algorithm	Accuracy	Precision	F1-score	TPR
DT	0.942	0.799	0.865	0.941
RF	0.991	0.999	0.976	1.000
KNN	0.970	0.888	0.926	0.970
SVM-Linear	0.960	0.853	0.905	0.959
SVM-RBF	0.992	0.993	0.979	0.998

Fig. 6. Performance Analysis of Proposed Framework.

The KNN classifier classification algorithm, as seen in Table II, has the highest recall rate of 96.8%. The second most efficient approach is the SVM-RBF, which has a 96.6% Recall rate. Finally, the DT classifier had the lowest recall rate of 94.3%.

With a 97.9% F1-score rate, the SVM-RBF classification technique, as indicated in Table II, is the most successful. The RF classification algorithm is the second most efficient, with an F1-score rate of 97.6%. Finally, when applied to the provided dataset, the DT classifier had the lowest F1-score rate of 86.5%.

The RF classification algorithm, as shown in Table II, it is the most successful, with a true-positive rate (TPR) of 100%. With a TPR rate of 99.8%, the SVM-RBF algorithm is the second most efficient. Finally, the DT classifier had the lowest TPR rate of 94.1% when applied to the proposed dataset.

## VI. CONCLUSIONS AND FUTURE WORK

The APT attack is not easy or soft kind of attacker. So, detecting it in the early stages will reduce the organization's impact after exploiting it. Also, detecting it using the security exiting tools throw the proposed framework will let it done in a systematic approach. Because of the widespread usage of the Internet in recent years, computational devices can now connect to the universal network from anywhere. However, the anonymous nature of the Internet leads to numerous security flaws in the network, resulting in intrusions. Modern attackers are more intelligent, and they may create new malware and

malicious code with the assistance of automated development tools, depending on the limited capability of IDS. This paper uses data transformation and normalization with a reduction procedure using PCA. The benchmark CSE-CIC-IDS2018 dataset is consisted of five different machine learning classifiers for malware IDS detection (DT, RF, KNN, SVM-Linear, and SVM-RBF). The experimental finding showed that the proposed models had a satisfactory performance, specifically when using Random Forest and support vector machine with Radial basis function classifiers, which have a 100% true-positive rate. Several machine learning methods are being transferred to deep learning models due to the convenience of big data technologies. This paper is a preliminary experiment to see how machine learning algorithms can simply and effectively detect attacks from network data traffic. As a result, in the future, deep learning algorithms are recommended to be applied for big DNS data requests.

## ACKNOWLEDGMENT

“The author is thankful to the Deanship of Scientific Research, College of Computer and Information Sciences (CCIS) at King Saud University for funding this research.”

Department of Computer Science & Application, Odisha University of Technology & Research, Bhubaneswar, India<sup>2</sup>

**Abstract**—Lifetime of the network and the quality of operation are the two important issues in a wireless sensor network system meant for object detection and tracking application. At the same time, there should be a tradeoff between network cost and the quality of operation as high cost of the network limits its real-time usability. Heterogeneous wireless sensor networks promises the prolonged network lifetime as well as enhances network reliability as they contain a mixture of nodes with different characteristics. Further prolongation of network lifetime can be achieved by managing the available node energy in a proper way, i.e, by minimizing number of communication, minimizing node density, minimizing overhead information generated during operation etc. Proper node deployment scheme not only helps to enhance the lifetime of the network but also helps in reducing deployment cost while maintaining the quality of operation in terms of object detection accuracy. This paper focuses on the energy efficient node deployment in heterogeneous wireless sensor network system with the features of maximum network coverage, optimum node density and optimum network cost. This paper proposes a novel energy efficient node deployment algorithm that determines the number of static and mobile nodes required for deployment and then relocates the mobile nodes to cover up the coverage hole using 8-neighbourhood and Particle Swarm Optimization (PSO) algorithm. The performance of the proposed algorithm is compared with corresponding model of Harmony Search Algorithm (HSA) and PSO based node deployment and it is seen that the proposed model outperforms better in comparison to them.

**Keywords**—Heterogeneous wireless sensor network; energy efficiency; node deployment; object detection network; particle swarm optimization; harmony search algorithm

## I. INTRODUCTION

Wireless Sensor Network (WSN) is a network of tiny connected sensors deployed in different fields like surveillance system, disaster management, wildlife monitoring, and health care system for surrounding environment information collection and processing and to initiate action according to the result of processing. According to the type of node, there are two types of sensor network:-homogeneous network and heterogeneous network. In homogeneous network, all nodes are with same characteristics whereas in case of heterogeneous network they can be of different characteristics. Heterogeneous wireless sensor networks better in comparison to homogeneous network as they support high

lifetime and high coverage.

The main constraint of WSN is limited energy. WSN meant for object detection and tracking must have sufficient lifetime to complete the desired operation and must have full coverage of the monitoring area. Otherwise, the quality of operation cannot be relied. At the same time, while designing the network for this kind operation the cost factor cannot be ignored. Having powerful nodes in a network to have large network lifetime is not sufficient to have actually the long network life .Also, the power should not be wasted in unnecessary communications and should be properly utilized. One of the way to minimize the unnecessary power usage is to have a proper node deployment scheme for the designated application. There are two important factors relating to any node deployment scheme:-node density and node location. Node density is defined as the minimum number of nodes required to cover a given area. Determining optimum node density is a NP complete problem. Low node density creates coverage hole which creates problem in achieving accuracy in result and may initiate wrong action in response to the result. Similarly, high node density increases number of routes to base station (BS) and number of communication which leads to wastage of energy. High node density also increases the system cost. Therefore, determination of optimum node density is very much important to maintain the quality of the network.

There are two types of node deployment: random deployment and deterministic deployment [1, 2]. In random deployment, sensor nodes are randomly placed in the target area and hence there is the chance of creation of coverage hole in the network. This type of deployment is well suited for large WSN and particularly in the area which is inaccessible easily to the human being. In deterministic deployment, sensor nodes are deployed in pre-calculated position and hence suitable for small size WSN. From the point of network cost factor, deterministic deployment is costly if the size of the network is kept constant for both types of deployments.

There are two types of sensing models: binary disk sensing model and probabilistic sensing model [1, 2].

There are three different types of coverage of target area:-blanket or full coverage, barrier coverage and point coverage [1, 2]. In full coverage, entire monitoring area is covered by sensors. In barrier coverage, barrier of the sensor nodes are monitored whereas in point coverage method, the point of

interest is covered by sensor nodes. Blanket coverage is most suited for object detection and tracking operation. The factors that affect the coverage are characteristic of sensor nodes and coverage algorithm adopted for the application.

This paper considers the problem of node deployment in terms of node density, maximization of coverage area, network lifetime and network cost. Node density has the direct impact on lifetime of the network, network coverage and cost of the network. For a target tracking WSN, the quality of the tracking depends on both network coverage and network lifetime. The cost of the network is directly proportional to the node density. Network coverage depends on node density and location of nodes in the monitoring area.

The rest of the paper is organized as: Section II gives a description of the related works, Section III describes the terminologies defined, problem statement, Section IV gives a description of proposed model and Section V gives the description of performance evaluation of the proposed model.

## II. RELATED WORK

Balancing the deployment quality and deployment cost is a challenging task in random deployment in wireless sensor networks. Connectivity in the network depends on the node density and network coverage. Though a lot of research works are done in past to address this issue, still no work is robust. While some papers focuses on maximization of network coverage, some focuses on cost of the deployment. But the WSN designed for object detection and tracking operation must have a balanced feature of maximum network coverage, cost of deployment and energy efficiency. This section gives a description of earlier attempts made by researchers to solve this issue.

B. A. Fuhaidi et al. [3] have proposed a node deployment model based on harmony search algorithm (HSA) and probabilistic sensing model (PSM) in which attempt is made to maximizing network coverage with minimum cost. The cost of the deployment is controlled by controlling the number of mobile nodes to be deployed in the area of interest (AOI). The area of interest is divided into a number of equal sized cells and the centre of the cell is considered as target point. Thus, AOI contain a set of target point. Static nodes are deployed using random deployment scheme initially. PSM is used to calculate the network coverage using target point set. If two or more sensors cover the same target point, then, it is said that sensors are overlapped. The probability of coverage overlapping is determined on the basis of coverage threshold. Next, mobile nodes are added according to the requirement. HSA is used to optimize the mobile node location so that overlapped region can be minimized. The authors claim that the proposed model contains less number of nodes and has maximum network coverage in comparison to homogeneous deployment and HEWSN model. No doubt, heterogeneous wireless sensor networks are better in comparison to homogeneous wireless sensor network and are more useful for the application like object detection and tracking. This feature cannot be ignored in the name of cost because quality of operation also matters. So, there is a need of balancing between different types of nodes used in the network so that quality will not be compromised. The authors have not

considered this matter. C. Zygowski and A. Jaekel [4] have proposed an algorithm based on mixed integer linear programming for effective path planning for mobile nodes to fill the coverage hole and to maximize area coverage. The algorithm focuses on minimum distance travel for mobile nodes and in minimum time. The deployment cost is not taken into consideration here. I. Alablani and M. Alenazi [5] proposed a node deployment strategy named Evaluated Delaunay Triangulation-based Deployment for Smart Cities (EDTD-SC) that focuses on sensor distribution and sink placement in smart cities. The algorithm utilizes Delaunay triangulation and k-means clustering to optimize the node location to improve coverage while maintaining connectivity and robustness with obstacles existence in the area of interest. The deployment scheme outperforms random and regular deployment in terms of network coverage. The work is suitable for small sized network and do not explore the feature of heterogeneity in node deployment. P. Prabhakaran et al.[6] have proposed an adaptive virtual force algorithm for node deployment in hybrid wireless sensor network meant for object tracking. Initially, static nodes are deployed and coverage hole is determined. Then, for hole patching mobile nodes are used. The optimum location of the mobile nodes is calculated using adaptive virtual force algorithm. The scheme does not focus on the cost of the network. J. Mao et al.[7] have proposed a partitionable polyhedral node deployment scheme for warehouse monitoring systems. This scheme proposes a node deployment collaborative perception model based on 0-1 perception model and exponential model. The 3D space is divided into a number of voronoi cells and at the center of each cell, one sensor is deployed. The work focuses on maximization of coverage area and uses deterministic deployment. F. Alassery [8] has proposed a node deployment design based on virtual multiple-input multiple-output technology to increase the performance of cluster based wireless sensor network. The height of the antenna of nodes is taken into consideration as an additional parameter for node deployment. This is helpful in increasing transmission range of nodes and minimizing relay nodes. X. Song et al. [9] have proposed a secure node deployment scheme based on evidence theory approach and caters for 3D underwater wireless sensor networks. This scheme implements sonar probability perception and an enhanced data fusion model to improve network coverage. It requires fewer nodes for large coverage area without compromising the quality of detection ability. Also it focuses on lifetime of the network. The cost of deployment is not considered here. S.M. Koreim and M.A. Bayoumi [10] have proposed a coverage hole detection algorithm for detecting coverage hole in wireless sensor network resulted due to damage of sensor nodes in area of interest due to flood or fire spreading. The algorithm partitions the area of interest into equal sized cells and each cell is cut into different triangles and then identifies the triangles that are not covered by any sensor. The triangles are formed with the help of three neighbouring sensor nodes. Energy efficiency here is achieved by minimizing the number of participating sensor nodes for hole detection. S. S. Kashi [11] proposed an algorithm named Heterogeneous Distributed Precise Coverage Rate (HDPCR) that detects holes and calculates coverage area of heterogeneous wireless sensor network using localized

mechanism. Boundary detection mechanism is used to determine the boundary of the hole area. A. Katti and D. K. Lobiyal [12] have proposed deterministic 3D node deployment strategy for wireless sensor network that includes prism deployment, pyramid deployment, cube deployment, hexagonal prism deployment for finding coverage prediction. It also determines the minimum number of sensor nodes required for specific coverage prediction. They have also proposed a scheduling algorithm for enhancing network lifetime. The work is suitable for small sized network. K. Wei [13] proposed a novel node deployment algorithm based on multi-objective evolutionary algorithm that optimizes average energy consumption, average sensitivity area and network reliability. In order to achieve the objectives, they have improved MOEA/D method by incorporating uniform design to generate aggregation coefficient vector and quadratic approximation for local search. The algorithm is designed for homogeneous network and no attempt is made to balance the energy efficiency and quality of operation.

N. Rai and R. D. Daruwala [14] have proposed an empirical formulation for estimation of randomly deployed nodes for attaining desired coverage for any size network. The formula includes the parameters that affect the optimum number of nodes. The formula is based on regression analysis using least square polynomial curve fitting technique. Sensor device characteristics are taken into consideration to devise the formula. Mainly, the authors have focussed on node density for desired coverage. S. Indumathi and D. Venkatesan [15] have proposed a dynamic node deployment model using genetic algorithm with gap cluster technique that uses different types of sensors. Gap cluster technique is used to determine the coverage hole resulted after initial deployment of nodes. In order to improve the network coverage and to minimize the number of gap clusters, additional nodes are deployed in gap region. The authors have not focused on the issue of energy efficiency and cost of the deployment. J. W. Lee and W. Kim [16] have proposed randomly deployed node deployment scheme that uses swarm intelligence for improving network lifetime and network coverage for heterogeneous wireless sensor network. This paper uses binary valued swarm intelligence algorithm such as Particle Swarm Optimization, Ant Colony Optimization, and Artificial Bee Colony Optimization. The work considers two types of nodes such as ordinary nodes and powerful nodes and focuses on minimization of network cost by minimizing number of nodes without compromising guaranteed coverage. The work is silent about how to handle the coverage hole problem in the network. M. R. Serik and M. Kaddour [17] have proposed a node deployment scheme for camera based wireless sensor network which focuses on optimization of deployment cost by minimizing the number of camera nodes required to cover a set of target objects with a pre-defined level of quality, position of camera nodes and orientation of camera nodes. Binary particle swarm optimization algorithm is used to minimize the number of camera nodes. The work is silent about energy efficiency of the network. Y. Yoon and Y. H. Kim [18] have proposed a node deployment algorithm based on the genetic algorithm for maximization of network coverage. A mixture of different types of static sensors is used for the deployment. The work focuses on the determination of

number of sensor of each type while maximizing network coverage. Network coverage is determined using Monte-Carlo method. When the sample size is very large or very small this way of network coverage calculation gives incorrect result. Z. Kang et al. [19] have proposed a decentralized, coordinate free, node based coverage hole detection algorithm which uses boundary critical points to determine hole and uses concept of perpendicular bisector for hole patching. The algorithm is suitable for grid type network and randomly deployed network. The objective of the algorithm is to achieve full coverage. S. Babaie and S. S. Pirahesh [20] have proposed a method that detects holes and their sizes in area of interest using voronoi diagram. Then holes are filled with mobile sensors. The issue of deployment cost and energy efficiency are not addressed. J. Wang et al. [21], proposed a PSO based energy efficient coverage control technique for homogeneous wireless sensor network in which the network in which the node locations are adjusted with respect to the coverage rate and energy consumption of each grid.

### III. ASSUMPTIONS, DEFINITION AND PROBLEM STATEMENT

#### A. Modelling Assumptions

- The area of interest is a two-dimensional plane area over which sensor nodes are randomly deployed.
- Sensor network is a heterogeneous sensor network.
- Sink knows the location of all nodes.
- Sensing region of a sensor is a circle.
- Cost of deployment is only based on number of nodes used for the deployment.
- Energy consumption is minimized by minimizing number of communication with the sink at the time of deployment.
- As network lifetime depends on energy consumption, by minimizing energy consumption lifetime can be increased.
- There is no obstacle in the network and the environment is noise free.
- Target object can be detected if it is in the sensing range.

#### B. Definitions

Let  $ST = \{1, 2, \dots, n\}$  are the static nodes and  $MB = \{1, 2, \dots, m\}$  are the mobile nodes are to be deployed on the area of interest. Out of  $m$  mobile nodes, some nodes are powerful mobile nodes and some nodes are ordinary mobile nodes. Area is divided into  $m1 \times n1$  grids and each cell size is  $d \times d$  where  $d$  is the diameter of sensing disk of static sensor (see Fig. 1). Let  $S = \{s_1, s_2, \dots, s_k\}$  is the set of  $k$  subsets, where  $k$  is the number of cells present in the area of interest (AOI). Each subset  $k_i$  consists of end points and center point of a cell:  $s_i = \{(x_{i1}, y_{i1}), (x_{i2}, y_{i2}), (x_{i3}, y_{i3}), (x_{i4}, y_{i4}), (c_{ix}, c_{iy})\}$ , where,  $(x_{ij}, y_{ij})$ ,  $j=1 \dots 4$  are the end points of the cell and  $(c_{ix}, c_{iy})$  is the center point of cell. A cell is individually analyzed to determine the hole.

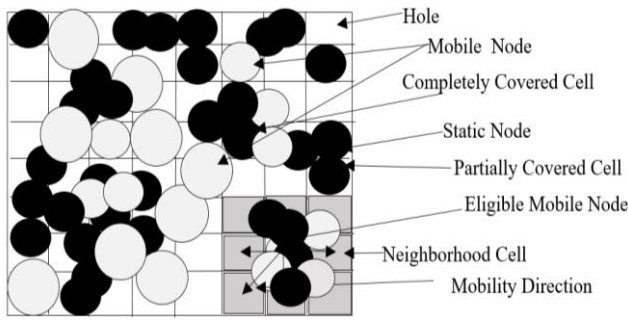

Fig. 1. Graphical Representation of Definition of Different Terminologies.

- Completely Covered Cell:-A cell  $i$  is said to be completely covered if all the points belonging to subset  $s_i$  is covered by sensors.
- Partially Covered Cell: - A cell  $i$  is said to be partially covered if at least one points belonging to subset  $s_i$  is not covered by any sensors and there is no intersection between the cell  $i$  and any of the sensor's sensing range.
- Uncovered Cell: - A cell  $i$  is said to be uncovered if none of the points belonging to subset  $s_i$  is covered by any sensors and there is no intersection between cell and sensing disk which is assumed as circle here.
- Hole:-It is the uncovered portion of cells.
- Hole Segment:-It is the area covered by adjacent holes.
- Eligible Mobile Nodes:-The mobile nodes whose sensing region is completely or partially overlapped with the sensing region of static nodes are said to be eligible mobile nodes.
- Neighborhood Cell:-Each cell is surrounded by eight equal sized neighborhood cell. A neighborhood cell of a cell may be uncovered, covered, partially covered by sensors.
- Optimum Location of Mobile Node:-It is the location that maximizes network coverage with minimum power usage if a mobile node is relocated to this location.
- Mobility Direction for Mobile Nodes:-An eligible mobile node can travel in any direction to cover the hole.
- Coverage Ratio:-It is the ratio between total covered cell and total number of cells present and its value lies in the range of  $[0, 1]$ .
- Detection Accuracy: - It is the ratio between the area under sensing coverage and the size of the AOI.

### C. Problem Statement

In a WSN designed for object detection and tracking, the full coverage of area of interest is required for continuous tracking of object. But when the nodes are deployed randomly across the region, coverage holes are created which leads to frequent failing of detecting the target even if the target is present. The matter worsens when the hole is present at the boundary of the area of interest and the size of the hole is

large. One of the solutions to it is to deploy additional nodes. Though, deployment of additional nodes helps to achieve full coverage but this limits network lifetime and increases network cost. Thus, there is a need of economic deployment plan that balances network coverage and network lifetime.

## IV. PROPOSED MODEL

### A. Optimum Number of Node Determination

This step deals with calculation of optimum number of nodes required to achieve desired coverage. Nodes deployed in the area of interest are a mixture of static and mobile nodes.  $M$  number of powerful mobile nodes and  $N$  number of ordinary nodes are used. One-third of  $N$  ordinary nodes are mobile nodes and remaining two-third nodes are static nodes. Ordinary nodes are with same sensing range, transmission range and battery power. Powerful mobile nodes are with high sensing range, transmission range and battery power in comparison to static nodes. The optimum number of powerful mobile nodes and ordinary nodes are determined using Particle Swarm Optimization (PSO) Based Technique [21, 22]. The PSO is a meta-heuristic optimization algorithm which is based on the behavior of the birds. The steps of the algorithm are given in Fig. 2.

```

1. Initialize Population and define search parameters
2. Initialize the velocity and position of the swarm. Also initialize best
   value of individual swarm ( $Pbest_i$ ) and global best ( $Gbest$ )
3. Find the fitness of the swarm using objective function
4. Update  $Pbest_i$  and  $Gbest$ 
5. Update the position and velocity of the swarm
The equation for updation of position and velocity are:

$$v_i(t+1) = w*v_i(t) + c_1*r_1*[Pbest_i(t) - x_i(t)] + c_2*r_2[Gbest(t) - x_i(t)]$$

$$x_i(t+1) = x_i(t) + v_i(t+1)$$

where,  $v$  is the particle velocity,  $x$  is the particle position,  $r_1$  &  $r_2$  are random numbers in the range of 0 and 1,  $c_1$  &  $c_2$  are learning factors.  $w$  is the inertia weight.
6. Repeat steps 3 to 5 until termination criteria is reached.
    
```

Fig. 2. Pseudo-Code of PSO Algorithm.

The objective function for node optimization is:

$$\text{Minimize } f(N, M) = N + M \quad \text{subject to}$$

$$C_{coverage}(N, M) \geq C_{guaranteed\_coverage}$$

$$\text{and } N > 0 \text{ and } M > 0 \quad (1)$$

Where,  $C_{coverage}(N, M)$  is the total area covered by  $N$  and  $M$  number of sensors.  $C_{guaranteed\_coverage}$  is the desired coverage area.

$$C_{guaranteed\_coverage} = \sum_{i=1}^N S_R + \sum_{i=1}^M S_{R1} \quad (2)$$

Where,  $S_R$  and  $S_{R1}$  are sensing range of ordinary sensor and powerful sensor respectively.

$$C_{coverage} = (1 - e^{-\pi\lambda})(1 - e^{-\pi\lambda}) \quad (3)$$

$$\text{Where, } \lambda = (N \times S_R^2) / \|A\| \quad (4)$$

Where  $\|A\|$  is the area of the monitoring area.

$$\lambda' = (M \times S_{R_1}^2) / |A| \quad (5)$$

$\lambda$  and  $\lambda'$  represents the probability of a point being covered by normal node and heterogeneous node respectfully.

$(1 - e^{-\pi\lambda})$  is the mean of the probability of covering a point by  $N$  normal nodes in the given area and  $(1 - e^{-\pi\lambda'})$  is the mean of the probability of covering a point by  $M$  heterogeneous nodes in the given area.

$$F(N, M) = \begin{cases} f(N, M), & \text{if } g(N, M) \geq 0, N > 0, M > 0 \\ f_{max} + |g(N, M)|, & \text{otherwise} \end{cases} \quad (6)$$

Where  $f_{max}$  is the worst fitness value of particles.  $g(N, M)$  is a normalized constraint which is calculated as follows

$$g(N, M) = \left( \frac{c_{coverage(N, M)}}{c_{guaranteedcoverage}} \right) - 1 \quad (7)$$

### B. Hole Determination

This step deals with the identification of hole in cells and calculating the size of the hole. The process of hole determination in a cell is treated here as the case of intersection of circle and rectangle. Each circle is a sensing disk and each rectangle is a cell in the area of interest. Let  $A, B, C, D$  are the end points of the rectangle.  $E$  and  $R$  are center and radius of the circle, respectively. A circle intersects a rectangle if the distance between the point of the rectangle closest to the center of radius is less than the radius of the circle. If  $(p_x, p_y)$  is an end point of the rectangle and  $(q_x, q_y)$  is the center of the circle and then, the Euclidean distance between them is:

$$distance = \sqrt{(p_x - q_x)^2 + (p_y - q_y)^2} \quad (8)$$

The hole area in the cell is determined using the formula of circle, sector, triangle and intersection of lines. If no end points are inside the circle and there is no intersection between circle and rectangle, then there is no overlapping between circle and rectangle and the rectangle is completely a hole. If all the end points are inside the circle, then circle has completely overlapped the rectangle. Different cases of intersection between and circle are:

- 1) All the end points of the rectangle are inside the circle.
- 2) Circle completely inside the rectangle.
- 3) Circle intersecting one side of rectangle.
- 4) Circle intersecting two adjacent sides of rectangle (including and excluding corner).
- 5) Circle intersecting two opposite side of the rectangle.
- 6) Circle intersecting three sides of the rectangle.
- 7) Circle intersecting four sides of the rectangle.

Following is an example of calculation of hole in a rectangle when circle intersects one side of rectangle. See Fig. 3(a). Let  $L$  and length and  $B$  is breadth of rectangle,  $\theta$  is the angle of sector and  $R$  radius of the circle, and radius of both circles are same then,

$$\text{Hole in ABCD rectangle} = (L \times B) - \text{Area of shaded region} \quad (9)$$

For Fig. 2(a),

$$\text{Area of shaded region} = 0.5 \times R^2 (\theta - \sin \theta) \quad (10)$$

Where,  $\theta$  is the angle between two sides of the sector.

Fig. 3. (a)-(b): Intersection of Circle and Rectangle.

For the case of Fig. 3(b), individual case of overlapping is determined and then circle-circle intersection area is determined to calculate the hole region in the rectangle. The area of overlapped portion is the difference between area of rectangle and (sum of the shaded portion of circle-overlapped area of circle). The area of overlapping  $AO$  between two circles for circles having two different radius  $r$  and  $R$  is calculated as follows:

$$AO = r^2 \times \text{atan2}(t, d^2 + r^2 - R^2) + R^2 \times \text{atan}(t, d^2 - r^2 + R^2) - \left(\frac{t}{2}\right) \quad (11)$$

Where,  $d$  is the distance between center of two circles and

$$t = \sqrt{(d + r + R)(d + r - R)(d - r + R)(-d + r + R)} \quad (12)$$

If  $t$  does not contain any imaginary part, there is no intersection between circles.

There may be single hole region or multiple hole region in a rectangle. The area of hole in a rectangle is determined as:

$$Hole_{Area_i} = \sum_{j=1}^k A_j \quad (13)$$

Where  $k$  is the no of hole regions present in the  $i_{th}$  rectangle. A hole segment consists of adjacent hole regions (see Fig. 4).

$$Hole_{AOI} = \sum_{j=1}^{m1 \times n1} A_j \quad (14)$$

Where  $Hole_{AOI}$  is the total hole area in area of interest and  $m1 \times n1$  are the number of cells in area of interest.

Fig. 4. Hole Segment (Black Marked Region).

### C. Hole Filling

Ordinary mobile node movement is restricted to the hole region of neighborhood cell whereas powerful mobile nodes can travel optimum distance to cover the hole area. By doing so, energy consumption can be minimized at the time of node redeployment and network coverage can be maximized. First, the list of eligible nodes for relocation is prepared. In the first phase, eligible ordinary mobile node movement is done and

they are moved to the optimum location of the neighborhood. The node must move at most  $d1$  distance towards neighboring hole region to maximize coverage. See the Fig. 5(a),  $A$  and  $B$  are the center of two circles respectively.  $C$  and  $D$  are the intersection point of two circles.  $AG$  and  $BF$  are the radius of first and second circle respectively. The value of  $d1$  is calculated as follows:-

$$d1 = FG + rand \quad (15)$$

Where  $FG = FE + EG$  and  $rand$  is a random number in the range of  $[0, 1]$ .  $FE$  and  $EG$  can be calculated using the equation for calculating the area of the circular segment in a sector of a circle. New location in the neighborhood is shown in Fig. 5(b). Hole area in each concerned cell is updated after relocation of ordinary mobile nodes.

Fig. 5. (a) Width of Overlapping Sensing Area between Two Nodes (b) Optimum Location for Relocation of Ordinary Mobile Node.

In second phase, the optimum location of the eligible powerful nodes is decided for relocation in order to increase the network coverage. PSO algorithm is used to determine the optimum location of these mobile nodes. The objective function here used is

$$f(x_{new}, y_{new}) = ((x_{old} + U_{u1}), (y_{old} + U_{u2})) \quad (16)$$

$$\text{Subject to } ((\sum_{i=1}^N \pi r^2 + \sum_{j=1}^M \pi R^2) - A_{ov}) > TC$$

$$0 > U_{u1} \leq X \text{ and } 0 > U_{u2} \leq Y$$

Where  $(x_{new}, y_{new})$  is the new location of eligible powerful mobile node,  $(x_{old}, y_{old})$  is the current location of it.  $U_{u1}$  and  $U_{u2}$  are the amount of change required in x-direction and y-direction, respectively.  $TC$  is the area coverage currently and  $A_{ov}$  is the overlapping area.  $X$  and  $Y$  define AOI size.

$$U_{u1} = \min(dif f_{x1}, dif f_{x2}, dif f_{x3}, \dots, dif f_{xk}) \quad (17)$$

$$U_{u2} = \min(dif f_{y1}, dif f_{y2}, dif f_{y3}, \dots, dif f_{yk}) \quad (18)$$

Where  $dif f_{xi}$  is the distance between x-coordinate of node and the x-coordinate of centroid of hole  $I$ ,  $dif f_{yi}$  is the distance between y-coordinate of node and the y-coordinate of centroid of hole  $i$ .

The flowchart of the proposed model is given Fig. 6 and its corresponding algorithm is described below:

1. Initialize the AOI size
2. Determine number of static nodes, ordinary mobile nodes and powerful mobile nodes required for desired coverage in AOI.
3. Initialize sensing radius of all sensors

4. Deploy all nodes randomly
5. Divide AOI into grids and define coordinate of each cell.
6. For  $i=1$  to number of cells //Hole Detection and its size //calculation  
 $NS=0$ ;  
 $Cell_i = \text{End points of cell } i$   
 For  $k=1$  to  $\text{size}(Cell_i)$   
 For  $j=1$  to number of sensors  
 Calculate  $d(j)$  for all end points of  $i$ th cell  
 If  $d(j) < \text{sensing range}$   
 Update  $NS$  by 1.  
 End  
 End  
 End  
 For  $j=1$  to number of sensors  
 Find the intersection between  $i$ th cell and  $j$ th sensor  
 End  
 If  $NS=0$  and there is no intersection between sensor and cell  
 $Cell\_status(i) = \text{'Hole'}$   
 Store the Hole area size  
 Else if  $NS=4$   
 $Cell\_status(i) = \text{'Completely Covered'}$   
 Else if  $NS < 4$  and there is overlapping between sensor and cell  
 $Cell\_status(i) = \text{'Partially Covered'}$   
 End  
 If  $Cell\_status(i) = \text{'Partially Covered'}$   
 Identify hole regions and calculate their size  
 Find the sum of all hole regions  
 End  
 End  
 7. Calculate the total Hole size in AOI  
 8. For  $j=1$  to number of mobile nodes //Hole Filling  
 Determine the eligible mobile nodes for relocation  
 End  
 9. For  $i=1$  to number of eligible ordinary mobile nodes  
 Determine the new location for nodes in neighborhood  
 End  
 10. For  $i=1$  to number of eligible powerful mobile nodes  
 Determine the new location for nodes in AOI  
 End  
 11. Calculate Hole size in AOI

Fig. 6. Flow Chart of Proposed Model.

#### D. Energy Model

For static node, energy consumption is negligible at the time of deployment and hence, the consumption value is neglected. In case of mobile nodes, it is based on the distance travelled by the node and the communication done with sink. If each packet size sent to the sink is  $k$ -bit and each node sends one packet to sink and receives one packet from the sink, then the power consumption for sending and receiving packet from sink, the following set of equation can be used to calculate the energy consumption by the mobile node.

$$E_{TX}(k, d) = \begin{cases} k * E_{elec} + k * E_{amp} * d^2, & \text{if } d < d_0 \\ k * E_{elec} + K * E_{fs} * d^4, & \text{if } d \geq d_0 \end{cases} \quad (19)$$

Where  $E_{TX}$  the energy required for packet transmission,  $d$  is the distance between source and destination and  $d_0$  is the threshold distance.  $E_{elec}$  is the base energy which required to run the transmitter or receiver.  $E_{fs}$  and  $E_{amp}$  are the unit energy required for transmitter and amplifier.

$$\text{Where, } d_0 = \sqrt{\frac{E_{fs}}{E_{amp}}} \quad (20)$$

The energy required for receiving  $k$ -bit message is:

$$E_{RX}(k) = k * E_{elec} \quad (21)$$

Let  $E_{RELOC}$  is the energy required to relocate a node from one location to other location situated at distance  $d$ .  $E_{RELOC}$  depends on the distance between old location and new location of the same node. Then the total energy consumed by the node for movement from one location to other is:

$$E_c = E_{TX}(k, d) + E_{RX}(k) + E_{RELOC} \quad (22)$$

## V. PERFORMANCE EVALUATION

### A. Simulation Environment and Parameter Setup

The proposed model is simulated using MatLab R2020b. The AOI size is 500m×500 m. The network is a heterogeneous wireless sensor network and nodes are deployed randomly. All static and ordinary mobile nodes are with same sensing radius and same battery power. The only difference is the mobility. The sensing radius and battery power for this category homogeneous node are 20m and 5J respectively. To reduce the power consumption in case of ordinary mobile nodes during node deployment, their mobility is restricted to short distance. Powerful mobile nodes are with sensing radius of 30 m and battery power of 10J. The communication range in case of all nodes are the twice of their sensing radius. The location of the sink is [500,500]. The total number of nodes required for full coverage of AOI is calculated using PSO algorithm i.e. the number of same characteristic nodes  $N$  and powerful nodes  $M$  are optimized. One-third of  $N$  nodes have the mobility. The coverage degree  $k=1$ . Total 60 static nodes, 30 ordinary mobile nodes and 46 powerful mobile nodes are used for deployment. For the movement of ordinary mobile nodes, a 3×3 mask is used and 8-neighborhood cells of the cell containing overlapped mobile node is determined. The ordinary mobile node is moved to the hole present in the neighborhood. For the powerful nodes, PSO algorithm is used to determine the optimum location. Algorithm runs for 200 iterations. As one of the factor that affects the network cost is the number of nodes used for deployment, we assume that the cost can be minimized if the number of hardware to be used is minimized. Also, when the number of nodes is minimized, number of communication between sink and nodes are minimized. Hence, Energy is saved. Following are the values of PSO parameter:  $c1=c2=2$ ,  $0.4 \leq w \leq 0.9$ ,  $v=0.1 \times \text{InitialPosition}$ , number of swarm=100. The values of parameters for harmony search algorithm are:  $\text{hms}=5$ ,  $\text{hmcr}=0.95$ ,  $\text{par}=0.25$ ,  $\text{bw}=0.2$ ,  $\text{numRows}=30$ .

### B. Simulation Result

Fig. 7(a) shows the random deployment of nodes in AOI resulting multiple coverage hole and Fig. 7(b) scenario after hole filling. The quality of operation in a network mainly depends on network coverage and lifetime of the network. There is a direct relationship between lifetime of the network and network coverage. Also, when an object is in the hole region is not detected by any sensor. Object's movement is simulated and the moving path is a simple straight line. At every 't' time interval, a sensor searches for presence of an object in its sensing coverage area.. So, the detection accuracy depends on the maximum area coverage. Hence, we define the

object detection accuracy in terms of sensing area coverage. Fig. 7(b) shows the status of AOI after moving mobile nodes to the hole region. Fig. 8(a) and 8(b) conveys that the network coverage increases when the overlapping area between sensors are decreased. Fig. 8(c) shows the energy consumption during movement of mobile node. Table I shows the performance of the proposed algorithm for varying area size with constant sensing range of nodes.

In Table II, area size(AS) is  $500 \times 500 \text{ m}^2$ .  $SR_1$  is the sensing range of static sensor and ordinary mobile sensor. NS is the number of static node, NOM is the number of ordinary mobile node and NOP is the number of powerful mobile nodes. CBD is the coverage before deployment and CAD is the coverage after deployment.  $SR_2$  is the sensing range of powerful mobile sensor. Coverage ratio(CR) is the ratio of number of cell fully covered by total number of cells. From the Tables I and II, it is clear that coverage ratio depends on the on the location of sensor nodes in AOI. Fig. 9(a) and 9(b) shows the performance comparison between the proposed model and other existing model. The number of nodes shown in the Fig. 9 is for different area sizes mentioned in Table I. From Fig. 9(a) and 9(b), it is clear that coverage ratio and energy efficiency of proposed model is better in comparison to HSA and PSO algorithm. Both HSA and PSO based node deployment technique are silent about the effect of node density on energy efficiency and cost of the deployment.

Using static nodes only for deployment makes the system cheaper but creates a lot of coverage hole in AOI which greatly affects the quality of operation, particularly when the network is used for object tracking application. Coverage holes resulted the missing of object and hence increases the rate of reporting the false negative message about object's presence. It is obvious that when coverage hole minimizes, object detection rate increases under the assumption that the environment is noise free and the signal attenuation is in the tolerable limit. The detection accuracy is directly proportional to the coverage area. Proposed model achieves 97% accuracy in the case of no obstacle in the monitoring area and the surface area is a 2d-plane.

Fig. 7. (a) Node Deployment before Node Location Optimization (b) Node Deployment after Node Location Optimization.

Fig. 8. (a) Sensing Area Coverage Optimization (b) Overlapping Area Optimization (c) Energy Consumed for Node Movement of Proposed Model.

TABLE I. PERFORMANCE OF PROPOSED MODEL FOR DIFFERENT AREA SIZE FOR CONSTANT SENSING RANGE

AS (in $\text{m}^2$ )	NS	NOM	NOP	CBD (in %)	CAD (in %)	CR
$500 \times 500$	60	30	40	76.6760	96.9956	0.9100

Fig. 9. Performance Comparison of Proposed Model with Other Model (a) Coverage Ratio (b) Average Energy Consumption.

Using mobile nodes only for deployment achieves high quality of operation by achieving full coverage but makes the system costlier. So, the proposed model tries to balance between cost of the system with quality of operation by considering both type of nodes for deployment. To calculate the deployment cost, we have considered the hardware cost only. Let for deploying a static node, deployment cost is 1 unit of money, for ordinary mobile node it is 1.5 unit of money and 2 unit of money for powerful mobile node, then, the deployment cost for an area of size  $500 \times 500 \text{ m}^2$  is 185 unit of money.

## VI. CONCLUSION

Network coverage and connectivity is the one of the factor on which the object detection accuracy in WSN depends. Coverage hole problem is a common problem in a randomly deployed network. Presence of object in hole region cannot be detected and necessary action cannot be initiated. The full coverage of AOI is desired which can only be achieved by deploying additional mobile nodes in hole region. It is exactly difficult to calculate that how many mobile nodes will be deployed. A large number of mobile nodes increases the deployment cost and shortens network lifetime whereas the small number of mobile nodes will not be able to fill the hole. In our work, we have tried to balance the number of mobile nodes with network cost and energy. We assume that when the number of nodes is minimized, number of communication can be minimized which in turn will increase energy efficiency. Proposed model uses a mixture of static nodes and two types of mobile nodes. Number of static nodes and mobile nodes for deployment are optimized using PSO algorithm. After initial deployment, the overlapped ordinary mobile nodes are shifted

to the hole region present in the neighborhood. For determination of destination for them, a  $3 \times 3$  mask is used and 8-neighborhood cells are determined. Nearest destination is the new location of the ordinary mobile node. For powerful mobile nodes, the new location is determined using PSO algorithm. The performance of the proposed model is evaluated and its coverage ratio is 0.91 and coverage percentage is 96.9956. Its performance is compared with other existing algorithms and the proposed model is found better in comparison to other. The detection accuracy for the proposed model is 97%. In future, we will try to focus on other artificial intelligence techniques that can further improve the detection accuracy by improving the coverage ratio. In this work, we have considered the disk model of sensing for coverage calculation. We will also focus in other model of sensing for the same.

**Abstract**—Cloud computing has been in existence as an adaptable technology that gets integrated with IoT, Big-Data, and WSN to provide reliable, scalable and mesh-free services. However, because of its openness in nature, the privacy of the cloud is an important parameter for today's research. The most important privacy factor in cloud is access control and user trust. Many articles related to access control and trust management were presented, but most of them include highly complex algorithms that result in network overhead. This proposed security framework is for a better and more effective system wherein multiple distributed centers are created with trust-based computing for authentication and validation of requests from users and their resources. The idea of trust here is for efficient decision-making and establishing reliable relationships among users and resources using least computations. Each user has different permissions for each file present in the cloud server. The simulated results shows improvement in the rate of successful transactions, time cost and network overhead.

**Keywords**—Fine-grained; distributed; access control; trust

## I. INTRODUCTION

The security issues like privacy, trust, authentication and authorization need more attention with the rapid advancement in day-to-day technologies. Among them, access control and trust management are critical and complex issues that require more focus. But in the cloud environment, the access control approaches are semi-trusted because of the users snooping nature [1-2] that offer the resource or its attributes a complete access based on the rights of the user. Most of the access management methods [3-7] use encryption and decryption algorithms for protection of legit users. To reduce the computation overheads, many researchers [8-12] used the trust parameter in the process of decision-making for validation and authentication of user and their resources.

The research issues subjected to existing techniques involve the following:

- 1) The methods related to fine-grained involve lot of mathematical computations.
- 2) Trust-based involves subjective assignment of weights to the attributes considered for calculation of trust value which leads to time cost, and
- 3) Centralized-based leads to network overhead.

Hence, the designed model is named as distributed fine-grained access control using trust management (DFGACT). In this work, multiple distribution centers are created for

accessing the data by authorized users on basis of their trust values associated with them. Rest of the paper is organized as follows: Section II is literature survey, Section III is proposed approach and Section IV is results and analysis about the proposed approach followed by a conclusion in Section V.

## II. RELATED WORK

One of the mostly used cryptographic access control method is designed by Sahai [13] for volatile cloud situations. Many literature papers used CP-ABE and KP-ABE schemes to secure data processing in the cloud and WSN [14-18]. In these methods, the complexity of encryption growth is linear with the count of each attribute and conveys heavy computation overheads. CP-ABE schemes are the most used for fine-grained security in cloud computing. The attribute statistics [19] are completely hidden inside the access policy by way of the use of the randomizable fuzzy approach for decryption purposes. Somchart et al. [20] used the CP-ABE method for mobile cloud environments by way of introducing new proxy encryption to reduce the cost of decryption and encryption for mobile users. But the outsourcing encryption isn't always specified. CP-ABE calls for data proprietors to generate multiple ciphertexts which result in sizable overheads in computation. To triumph over this, an LSSS based CP-ABE has been proposed [21] that can decrypt the records that are relatable with this matched part.

Anil Kumar et al. [22] tried to triumph over the troubles associated with RBAC, where users can access entire object without any further authentication once access is granted by manipulating swift storage. Qian et al. [23] proposed a Merkle tree based on time and attribute that stores private keys of the user for decryption purposes to efficient access of the resources. A lightweight statistical computation [24] is carried out by the cloud server for granting unique access privileges to individual users. However, with the increasing variety of attributes the overhead increases.

The large statistics are stored specifically in the cloud for controlling the access of a massive amount of data with closed permissions of individual users [25]. However, this scheme hides total attributes of a user for getting an entry pass to the access rights. The conventional cloud storage structures goes through a hassle of returning the incorrect seek consequences or not going back to the total seek results, this can be solved by using the applied decentralized system model with the cipher textual content-based key-word seek characteristic according to the smart reduced in size Ethereum blockchain [26].

Qi Li et al. [27] constructed a scheme named SEMAAC for mHealth applications that have IoT enabled to achieve the functions of de-centralization. Here, each CSP computes the decryption costs by interacting with Associated Authority. But, the verification time of each PDC increases linearly with the number of associated authorities. For a specific biological system of healthcare industry in cloud computing [28] the user's closed permissions are mixed with fog computing to provide high-level security.

Roy et al. [29] constructed a concept in the direction of transportable cloud computing for the healthcare industry. This portable cloud display helps in analyzing the statistics with recognition of the patients' records and in removing proposals in medicinal services programs. A dynamic authorized system was proposed for cloud computing [30] where the authorized users are identified based on trust value. The access privileges of these users are created on their behaviour with the system. However, this work adds an overhead due to its various assignments and removal of permissions for malicious users.

### III. PROPOSED WORK

There are three important issues while accessing data from the server. Firstly, users having access to servers may additionally try and access data that isn't always intended for them. To keep away from such problems, every user needs to have a particular privilege to access the server. Secondly, Trust is an important parameter for improving the relationship between the user and their resources. Thirdly, a maximum of the theories mentioned for improving safety features are liable to a single point of failure. However, the decentralized version has higher throughput and lower fees together with overcoming the failure of single-factor issues within the system as compared to the traditional cloud storage device.

The main idea behind this research is to eliminate the complex computations that are involved in the existing state of art methods. The novelty behind this access-control method lies in the combination of 1) Decentralized approach to avoid single-point failures 2) Fine-grained approach for unique privileges for users and 3) Trust for an effective authorization process. Although many methods related to the above discussed issues are existing but none of the techniques is a combination of these three tactics. The reason to combine these three tactics is for better time cost, success rate and reduction of network overhead.

This phase of work defines a simplification of the proposed scheme DFGACT. Requirements in this approach are:

- 1) Multiple VMS of cloud that acts as a distribution center for the scheme.
- 2) Each DC has a cloud service provider that takes care of the incoming requests from the user and owner of the file/resource.
- 3) The distribution center stores the consumer/User information, trust matrices and permission table of the resource.
- 4) Each file has a permission table, the owners of the file/resource decide on the permissions that a user/consumer

should have and accordingly receives the PID of the file/resource that authorize them to access records.

Here, the user/consumer request is processed through these modules as shown in Fig. 1 to undergo the authorization and authentication system. The consumer request is of the form (UID, PID, RID, Trust value). The representation for the same is given in the table 1. To gain access control, the method used an idea similar to [31]. The access policy is a fine-grained in nature; this combines three methodologies RBAC, ARL and ABAC. For fine-grained precision, a set of access rules is assigned to each user that defines the access rights of that resource/file. In the proposed case, each file has a set of permissions in the form of attributes. The values associated with the attribute decide the right to access the resource/file. Every file/resource and a unique permission ID has been assigned to the user based on the initial demand/request. No two users can have the same permission ID for that resource.

However, the uniqueness of the work is addition of distribution centers that distributes trust matrices among neighboring CSPs for identification of valid users to avoid malicious requests for a better network overhead. Besides, trust computing is taken into consideration as a measurable factor in the scheme that considers users trust credentials and computing power of resources for better success rate. Table I describes the notations used in the paper.

TABLE I. NOTATIONS

Sl.no.	Notation	Meaning
1	AC	Authorization Centre
2	DC	Distribution Centre
3	DO	Data Owner
4	CNM	Data Consumer
5	ALC	Access level code or permission IDs
6	CSP	Cloud service provider
8	$C_a$	Type of user
9	$C_t$	Authentication degree
10	$T T_{VAL}$	Total Trust value
11	$T_{THRS}$	Trust threshold
12	$M$	Unique code in the permission table
13	$N$	Set of permissions associated with FILE
14	$Z$	File name
15	$RQ$	Degree of request potentiality
16	$r$	Priority of current request and is decided by CSP of DC
17	$RQ_f$	Number of times the user requested for the resource
18	$RQ_s$	Degree of valid request.
19	$R_{id}$	Request ID
20	$(U_{id})$	USER ID
21	$P_{id}$	Permission ID
22	$(F_{id})$	FILE ID

Fig. 1. System Architecture of DFGACT.

The scheme starts with an authentication procedure which involves the verification of user identity by its necessary associated credentials, such as User-Id, password, and RSA token. For the valid user, the activity is been recorded by the system in a log file for future reference. The request gets dropped for an invalid user and the information about the same is sent to remaining distribution centers. Followed by an authorization procedure, where the DC extracts the permission ID of the resource from the user request and assign the data to client according to the permissions associated with the  $F_{id}$  ( $P_{id}$ ).

#### A. System Architecture

The proposed architecture distributed fine-grained access control with trust computing named DFGACT includes a trust management module and an access control module in conjunction with four entities as shown in Fig. 1. The entities are Authorization center (AC), Distribution Center (DC), Data Owner (DO), and Data Consumer (CNM). In the proposed scheme, the consumer can get the right of entry to the resource through the ALC code of the report/ resource. Each of the entities with its functionalities is mentioned as underneath:

**USER/Owner:** This entity can store or access the information; the one tries to read /write the resource and this must be a valid user before accessing the resource.

**CSP:** This entity provides services to the authorized users. This resides inside the distribution centre.

**Distribution Centre (DC):** Each distribution center generates ID'S to user and owner of the resources. This entity stores the permission table of each resource, access policy, information about the owner and consumer. Every distribution

center has a CSP provider to validate the authorized users for accessing the resources.

**Authorization Centre (AC):** Authorization center creates various distribution centers. A unique ID is associated for each distribution center. This entity acts as a database for storing information about the distribution center.

Fig. 2. Flowchart of the Proposed Architecture DFGACT.

The working principle of DFGACT is as under and the flowchart for the same is shown in Fig. 2:

- 1) Request from USER or Consumer to get entry into the Cloud data or Services through web interface of a specific distribution centre.

2) The distribution centre authenticates every individual via analysing the important related credentials such as  $C_a$  to identify the user is a trusted or untrusted. If the  $C_a$  are determined legitimate, then the request for access undergo trust evaluation process, or else the request of the consumer is denied for any additional processing.

3) If authentication check fails the CSP in that particular DC's drops the request and transfer the trust information among CSP of different DC's. The trust values of the user are computed by taking the inputs from user trust credentials and trust matrices as shown in Fig. 2. There are three distinct instances for inspection of trust value:

a) *Instance 1: Reliable user and Non-reliable user:* Here, CSP of each DC authenticates the request based on its frequency and user trust. If  $TT_{VAL} < T_{THRS D}$  then CSP of that particular DC drops the request and informs other DC's about the incoming threat.

b) *Instance 2: New/Unidentified user:* In case of any new or unidentified user, the CSP checks the trust value of the requesting user from its neighboring CSP. The fetched value is added to its own trust matrices.

c) *Instance 3: Malicious Attack:* CSP keeps track of the requests received at that distribution centre. If any suspicious activity is found then user's trust value is decreased otherwise value of trust increases.

4) For valid requests, CSP of that DC finally allow the subject to use the resource.

### B. Evaluation Startegy

The evaluation strategy of this model is setup in three phases: 1) Network phase, 2) Access control strategy and 3) Trust Evaluation strategy.

In the approach, each Distribution Centre has a table that contain trust matrix of each user associated with that DC. For every attempt by the user with the cloud resource, the DC share the trust matrices of that user to its neighboring DCs. The user requests are verified and are either granted or denied to access the service.

1) *Network model:* The network consists of several Distribution Centers(DC), cloud service providers (CSP), Owners (OWN), and Users(U).

$$DC = \sum_{i=1}^{dc} DC_i \quad \forall (1 \leq i \leq dc) \quad (1)$$

$$CSP = \sum_{i=1}^{csp} CSP_i \quad \forall (1 \leq i \leq csp) \quad (2)$$

$$OWN = \sum_{i=1}^{own} OWN_i \quad \forall (1 \leq i \leq own) \quad (3)$$

$$U = \sum_{i=1}^n u_i \quad \forall (1 \leq i \leq n) \quad (4)$$

Every pair of DCs can communicate securely and has a set of disjoint users U which means no two users can belong to same DC,  $i, j \in DC$  and therefore is written as  $U_i \cap U_j = \emptyset$ . The OWN of the resource decides the attribute values of the file, that carries a set of rights to perform a specific task on the resource.

2) *Access control strategy:* Each file stored has a set of attributes and are named as permissions in this work. The permission values to the file are decided by the owner of the file. The permission ID (PID) uniquely determines the permissions associated with that. Every Distribution Centre in the network assigns the PID to the user according to the service plan.

This approach uses the access policy similar to [31]. Here, the file/resource permissions are arranged in tabular structure with unique permission ID (PID), and its adjacent columns are represented in Boolean format. The permissions for each file are arranged as shown in the Table II.

TABLE II. PERMISSION TABLE OF THE RESOURCE

PID	Read	Write	Edit	Move	Share	Download	Delete
1	1	0	0	0	1	1	1
2	1	1	1	0	0	1	0
3	1	0	0	0	1	1	0
4	1	0	0	1	1	1	0
5	1	0	0	0	0	0	0

Each user is assigned with a unique code to access the resource. Each file will set access limits to requesting user according to permissions from set, and is represented in the equation below:

$$M \rightarrow N \quad (5)$$

Where:

"M" is a unique code in the permission table,

"N" is a set of permissions associated with Z.

For e.g., if any user has assigned with PID-4 of that file then no other user can have PID-4 for that resource/file.

3) *Trust assessment model:* The authorization process of this scheme is depended on trust-based evaluation for an efficient decision making. The users trust value is calculated and is compared with the threshold trust  $T_{THRS D}$ . After each transaction these trust values gets updated in the database. The value of the trust is related to the CSP of that particular DC in a particular session. For the evaluation of trust, the following parameters has been considered: 1) User interactions with the system  $C_a$ , 2) Type of user C, 3) The number of times the user requested for the resource  $RQ_f$ , 4) Degree of valid request  $RQ_s$  and 5) Estimated computing power of the resource  $E_{CP}$ .

The Trust matrix is of form  $\langle T_{VAL}, E_{CP} \rangle$  where:

The trust value  $T_{VAL}$  of each user for a particular session is calculated from the equations below:

$$RQ = r \times \frac{RQ_s}{RQ_f} \quad (6)$$

$$RC_{VAL} = C_t \times C_a \times RQ \quad (7)$$

Where:

$C_t$  value increases with valid requests and declines at invalid ones.

$C_a$  value greater than 0.5 is a trusted user and less than 0.5 is invalid or malicious user and equals 0.5 is for new user.

RQ value for degree of request potentiality.

$RC_{VAL}$  handles the type of user and potentiality of the request.

The ongoing limit of a cloud asset influences the exhibition of the cloud supplier and exchange execution. In this manner, the ongoing asset limit boundaries like CPU, RAM, and Network ought to be thought about while assessing trust an incentive for a cloud asset to empower a framework to gauge on the off chance that the asset can execute the expected work or not. Hence, the CPU time of resource is considered as Estimated Computing Power ( $E_{CP}$ ).

$$E_{CP} = \frac{CPU_{JOB}}{CPU_{RESOURCE}} \quad (8)$$

In this work, the trust value  $T_{VAL}$  is calculated from two attributes, the first attribute handles the frequency of the request and type of user. The second attribute handles the computing power of the resource.

$$T_{VAL} = RC_{VAL} + E_{CP} \quad (9)$$

At the end of each transaction from the DC to USER, the trust value  $T_{VAL}$  gets updated and broadcasted to the other DC's. The other DC's keeps a record of these values so that there should not be any discrepancies while handling the requests.

Algorithm: Proposed DFGACT

1. **Input:** Parameter associated with calculation of trust value
2. **Output:** Updated Trust Value
3. While(true)
4. User send request ( $T_{VAL}$ ,  $E_{CP}$ ) to DC
5. if ( $C_t \leq 1$  &&  $C_a > 0.5$ ) then
6. if ( $T_{VAL} \leq T_{THRS}$ ) then
7. Continue with the service;
8. Calculate RQ using eq.6
9. Calculate  $RC_{VAL}$  using eq.7
10. else
11.  $RQ = RQ - 1$  ;
12.  $C_t = C_t - 1$ ;
13. end if;
14. Calculate  $T_{VAL}$  from eq .9 and update the database with this new value
15. end if;
16. Broadcast ( $T_{VAL}$ ,  $E_{CP}$ ) to other DC's
17. DC extracts access level permission for the user.
18. if ( $R_{id}(U_{id}) \rightarrow true$  &&  $F_{id}$ ) then
19.  $R_{id}(U_{id}) \leftarrow P_{id}(F_{id})$
20. end if ;

21.  $RQ_s \leftarrow RQ_s + 1$
22.  $RQ_f \leftarrow RQ_f + 1$
23. end while;

#### IV. RESULTS AND ANALYSIS

This paper used a CloudSim3.0 [32] and experiment environment is eclipse editor. The programming language used is java to simulate the proposed method. It is assumed, each VM of the cloud as a Distribution Centre (DC). Likewise, 8 DC's are created for the evaluation of proposed scheme. The scheme evaluates the user's behaviour according to trust management module. At the beginning, trust value of registered users is defined as "0.5". Depending on the successful attempts, the trust value of user keeps changing, but the value should not exceed trust threshold. In this approach trust threshold is assigned as 1. The results of DFGACT and literature [30] are compared thorough simulation. The results are proved that DFGACT has better efficiency than literature [30].

Fig. 3 represents time cost of both the schemes in comparison with no. of users. From the result it can be seen that with the increasing number of users the time cost increases for Mehrjaj [30]. On the other hand, the DFGACT less delay is because this scheme has simple way of accessing request in fine-grained manner, whereas in Mehrjaj [30] the conversion of roles into tasks into permissions results in delay at higher cost that increases with the increasing no. of users.

Fig. 4 shows the network traffic rises with the no. of requests for both schemes. However, DFGACT has less overhead in comparison with the other approach. The DFGACT has less overhead as compared to Mehrjaj [30] because of DFGACT distributed nature. Mehrjaj [30] has higher overhead because of its centralized approach and at the same time various assignments of roles-tasks-permissions. Hence from the results, it is evident that DFGACT could nearly improve the security by minimizing the resources for computation.

Fig. 5 represents the rate of successful transaction with respect to time, here the DFGACT scheme has higher success rate than that of Mehrjaj [30]. The dynamic nature of user leads to increase or decrease of RST. Rather than the time factor, the person's conduct is considered for changes at the side of the variant of behavior functions.

Fig. 3. Time Cost of the Schemes.

Fig. 4. Network Overhead vs. No. of Requests.

Fig. 5. Rate of Successful Transactions vs Time.

## V. CONCLUSION

In order to reduce the computational overhead due to complex equations in encryption and decryption schemes, the distributed fine-grained access control using trust assessment has been proposed. To enable cost saving, such as time cost, network overhead and rate of successful transactions the DFGACT scheme assists in creation of multiple distribution centers for providing services to the authorized users on the basis of their trust values. To achieve fine-grained access a set of access rights list is generated for each file/resource and stored in distribution centers. The evaluations had shown that this approach has 25% more better rate of successful transactions with less time and overhead than the existing ones. In future, the application of Swarm intelligence technique for the DFGACT scheme will be implemented for handling of attacks and better throughput.

#### AUTHORS' PROFILE

Ms. Aparna Manikonda worked in various prestigious institutions across India. Currently, she is pursuing Doctorate degree in computer science. She is having 15 years of teaching experience along with research and published various numerous publications. She has 8 International journal publications. She has presented papers in 15 International conferences and attended 12 Seminars/Workshops/FDP/QIP. She has organized 2 conferences, 4 workshops. She has published 2 patents and 4 books titled 'Internet and web Technology', 'Internet and Web Technology 2.0', 'Cloud computing for Beginners', 'Object Modelling using UML A software Perspective'. Her research areas include Cloud Computing, Ad-hoc and Sensor networks, IoT and Image Processing.

Dr. N. Nalini is a Professor in the Department of Computer Science and Engineering at Nitte Meenakshi Institute of Technology, Bangalore. She received her MS from BITS, Pilani in 1999 and PhD from Visvesvaraya Technological University in 2007. She has more than 24 years of teaching and 17 years of research experience. She has numerous international journal and conference publications to her credit, She has served as Technical Committee member and reviewer in various International conferences and has delivered technical talks at various Institutions. She Published book on "INTERNET OF THINGS: Advanced Wireless Technologies for Smart Ecosystems" having ISBN-13: 979-8679630055. Recognized as FSIESRP (Educational- Professional Membership Grade: Fellowship) & Editorial Board Member Registration as Hon. Consulting Editor. Program Committee Member in BIOMA International Conference since 2010. Organizing Committee Member in the Congress of the "International Conference on Electronics & Electrical Engineering" Seoul, South Korea. She has guided EIGHT candidates to complete their Ph.D successfully and currently guiding five more candidates. She has guided more than fifty PG students to complete their thesis. Her areas of research include Cryptography and Network Security, Cloud Computing, Artificial Intelligence and Machine Learning, Wireless and Distributed Sensor Networks, Optimization Heuristic Techniques.

# BERT-Based Hybrid RNN Model for Multi-class Text Classification to Study the Effect of Pre-trained Word Embeddings

Shreyashree S, Pramod Sunagar, S Rajarajeswari, Anita Kanavalli

**Abstract**—Due to the Covid-19 pandemic which started in the year 2020, many nations had imposed lockdown to curb the spread of this virus. People have been sharing their experiences and perspectives on social media on the lockdown situation. This has given rise to increased number of tweets or posts on social media. Multi-class text classification, a method of classifying a text into one of the pre-defined categories, is one of the effective ways to analyze such data that is implemented in this paper. A Covid-19 dataset is used in this work consisting of fifteen pre-defined categories. This paper presents a multi-layered hybrid model, LSTM followed by GRU, to integrate the benefits of both the techniques. The advantages of word embeddings techniques like GloVe and BERT have been implemented and found that, for three epochs, the transfer learning based pre-trained BERT-hybrid model performs one percent better than GloVe-hybrid model but the state-of-the-art, fine-tuned BERT-base model outperforms the BERT-hybrid model by three percent, in terms of validation loss. It is expected that, over a larger number of epochs, the hybrid model might outperform the fine-tuned model.

**Keywords**—Multi-class text classification; transfer learning; pre-training; word embeddings; GloVe; bidirectional encoder representations from transformers; long short-term memory; gated recurrent units; hybrid model; RNN

## I. INTRODUCTION

On March 11<sup>th</sup>, 2020, the World Health Organization (WHO) proclaimed Covid-19 a global pandemic, making human lives increasingly digital. This massive amount of digital data aids data scientists in discovering new patterns and gaining a new perspective on any area of interest. With the rise of Artificial Intelligence (AI) in data science, machines might have the ability to perform all human tasks much better than humans. Natural Language Processing (NLP), a sub-domain of AI, is an interesting research field, in which, Text Classification (TC) is a simple and yet a challenging problem that is well-recognized in the domain. It is a process of categorizing samples of text into few pre-defined categories/classes, which are of two types, viz, binary classification and multi-class text classification (MTC). Applications of TC range from sentiment analysis to topic labelling. Using TC, we can easily categorize emails, social media posts like Tweets etc. to maintain and understand the text better for making any data-driven business decisions.

The approaches to perform TC are rule-based (uses hand-crafted rules), deep-learning techniques (uses neural networks) and hybrid methods. Out of these techniques, the most significant one is the deep learning method because they are powerful and provide good results [1-2]. And this paper concentrates on classifying a Covid-19 twitter dataset of into 15 pre-defined categories. There are two parts for TC, the first part being the feature engineering, where one of its methods called word embedding is used and the second part being the classification. The main objective of this paper is to perform a comparative study on the performance of hybrid classifiers with their respective pre-trained word embedding techniques. This project performs a comparative analysis between 1) hybrid Recurrent Neural Network (RNN) model with the help of either Global Vectors for Word Representation (GloVe) and Bidirectional Encoder Representations from Transformers (BERT) pre-trained word embeddings and 2) BERT-base model. The main reason for choosing hybrid architecture over others is that it helps in boosting the performance of the overall model. With regards to embeddings methods, BERT was mainly chosen because of the following reasons.

- 1) It provides contextual embeddings.
- 2) It considers the order of words before providing the embeddings.
- 3) While other pre-trained embedding models have pre-generated embeddings, BERT has to be trained to generate dynamic embeddings (as it considers context).
- 4) It generates embeddings for Out-Of-Vocabulary words.

In order to study them, a Covid-19 twitter dataset has been used, that contains approximately two lakhs of tweets and their respective labels. There are 15 different categories of tweets in this dataset.

## II. LITERATURE SURVEY

Shah et al. [3] have developed a text classification system for BBC news by using three traditional machine learning algorithms separately, namely Logistic Regression, K- Nearest Neighbor and Random Forest Algorithms, and compared these models to choose the best one. The classification is divided into four parts, viz text pre-processing, text representation, implementation of classifier and finally the classification of news. Text pre-processing involved removing of stop words and stemming, text representation involved the use of TF-IDF

algorithm to convert the text into suitable format. The comparison between the classifiers has been done in terms of five metrics: Precision, Accuracy, F1-score, Confusion matrix and support. According to the experiment, logistic regression performed the best with 97% accuracy. Kumar et al. [4] have provided the method of text mining using popular machine learning classification algorithms and has also provided a SWOT analysis of these algorithms to summarize the work done so far in the usage of ML classification algorithms on the task of sentiment analysis, one of the major tasks of text classification. Authors have also observed that most of the classification algorithms use bag-of-words for representing text. As sentiment analysis is a significant part of text classification, it can be performed either using machine learning approach or a lexicon-based approach. Harjule et al. [5] have explored both the methods by using SentiWordNet and Word Sense Disambiguation in the former approach and Multinomial Naïve Bayes (MNB), Logistic Regression, SVM and RNN in the latter approach. Along with the above-mentioned classifiers, an ensemble classifier consisting of MNB, SVM and LR is also implemented. Later, these classifiers are being compared. The text pre-processing is done using NLTK that involves casing, removal of stop words, punctuations, URLs and hashtags, POS tagging and tokenization. The datasets used are “Sentiment140” and “Crowdfunder’s Data for Everyone library”. The observations indicate that the RNN model (LSTM) provides better results. Xia Sun et al. [6] have proposed a different approach to SA, where in the context of the text were captured using Bi-GRU and many DL models were used to classify. Among them, CNN+LSTM model outperformed all. The main focus of their work is the discovery of Drop Loss, which focuses on hard examples i.e., texts that are easier to get misclassified. This way, the classification accuracy was improved upon four sentiment datasets viz. MOOC, IMDB-2, IMDB-10 and SST-5. The CNN+LSTM architecture was also used by Giannopoulou et al. [7] to categorize e-books into pre-defined book categories using their table of contents as the text samples. Software As-A Service (SaaS) is one of the popular software delivery models. Customers should be clarified on which SaaS provider is best suited for them, in order to use cloud services. There are many service quality pillars [8] that are to be considered before choosing a right provider. Hence, Raza et al. have performed multi-class text classification on these customer reviews, with service quality pillars as categories. The classification algorithms used are machine learning algorithms and an ensemble of all the ML algorithms. The representation of text is done using TF-IDF technique after text cleaning. The results show that Logistic Regression performs better than all the models, including the ensemble model. There is also the field of citation intent classification that can be benefitted by different word embedding techniques.

Roman et al. [9] have used word embedding techniques like GloVe, InferSent and BERT to classify the citation context with citation intent, on 10 million records of Citation Context Dataset. It has been observed that the method using BERT provides a highest of 89% precision of all. Before BERT or transformer models were discovered, Bi-LSTM architectures were leading in many of the downstream tasks of

NLP. Hence, Huang et al. [10] have experimented by combining Bi-LSTM with transformers. Considering the fact that adding more hidden layers to BERT will not improve its performance, the authors have added a Bi-LSTM layer to each of the transformer entity, called TRANS-BLSTM, and have observed that their model provides an F1-score of 94.01% on SQUAD 1.1 development dataset. Hao Wu et al. [11] have proposed a weighted multi-class text classification model where the text is converted to its numerical terms using Word2Vec technique; weights are applied to those vectors using TF-IDF algorithm, and the word vectors are multiplied with these weights to provide the final representation of text. Context is captured using a BiLSTM layer, followed by an Attention layer and a softmax layer to classify. This model has observed to have 91.26% accuracy. Kumar et al. [12] have also used Bi-LSTM layers in their proposed model, SAB-LSTM, where they have applied model and network optimizer with a dropout layer around the Bi-LSTM layer to provide best accuracy when trained on COVID-19 dataset, in comparison with LSTM and Bi-LSTM models individually. Another hybrid model CNN+RNN with attention mechanism was proposed by Guo et al. [13] to perform MTC.

The text classification method also finds its application in the field of medicine prescription, where, it can be detected whether the prescribed medicine has been misused or not. Al-Garadi et al. [14] have experimented in this domain on a Twitter dataset using BERT and its variants but with fusion. The fusion models involved combining the probabilities of each text sample from BERT and its variants using either a logistic regression classifier or a Naïve Bayes classifier. These fusion models were observed to provide higher accuracy than the individual transformer models. Shaik et al. [15] have developed a text classification model that classifies the course learning outcomes (CLOs) and assessment texts into a pre-defined class of Bloom’s taxonomy, contributing to the education domain. This model uses Skip-gram word embedding technique and LSTM classifier to perform MTC, which provides an accuracy of 87% on CLOs and 74% on assessment texts. The Skip-gram technique is also used by Aslam et al. [16] to perform MTC on Google Play app reviews using CNN as its classifier with a precision of 95.49%. The CNN is also combined with Bi-LSTM using attention layer having Word2Vec as word embedding technique, proposed by Zhenget al. [17]. Similarly, CNN is combined with GRU layers as an ensemble model to perform MTC on news sources by John et al. [18], to help women select the state they want to travel or relocate to, based on the recent criminal activities. As a better alternative to CNN, CapsNets are used along with Bi-GRU layers as a hybrid model, using Word2Vec technique to perform Text classification by Gangwar et al. [19]. The detection of fake news also is a significant sub-task of MTC, where in IulianIlie et al. [20] have proposed a comparative study of 10 DNN models using GloVe, Word2Vec and FastText word embedding techniques, in which RCNN performed the best. The fastText method is used as a feature extraction method and also as a classification method to classify emails into multiple classes [21]. Aydoğan et al. [22] have performed a comparative study between CNN, LSTM, RNN and GRU networks on Turkish datasets, using word2Vec word embeddings. The results indicate that both

LSTM and GRU perform the best. Sunagar et al. [23] have conducted a comparative study between various deep learning models for the task of MTC on Covid-19 dataset, amongst which, RNN with Bidirectional LSTM performed better. The comparison between ML algorithms was also considered for the task of news topic classification [24] to study the different ML models. Many researchers have also carried out the works like detecting the disease, predicting the end of pandemic [25] and creating a decision support system [26] for Covid-19. Many authors have carried out the research on the features extraction from text and tried to establish how this will help in attaining the better accuracy [27-29].

In the existing system, classification of the text focuses on Sentiment Analysis, Movie Review etc. Due to Covid-19 pandemic, lot of tweets are being generated on various topics like, safety measures, social distancing, advisories, etc. by Government agencies, WHO, Scientists, NGOs and individuals. Classifying these tweets into different categories like Social Distancing, Vaccination, Advisories etc. is one of the motivations for the taking up this project. The recent works do contribute to the accuracy of the models discovered, may it be hybrid, traditional or an ensemble model. But this paper mainly focuses on the fact that, more the number of neural network layers, more the accuracy, with regards to the hybrid RNN model, that is inspired by the work of Sunagar et al. [30]. To boost the accuracy of the model, the BERT embeddings are being considered along with the hybrid RNN model, as they are contextual in nature and support Out-Of-Vocabulary words. And this model is being compared with the fundamental BERT-base model, by considering the importance of pre-trained word embeddings.

### III. PROPOSED MODEL

Text classification is a challenging yet interesting problem of NLP. It is a method of classifying sample texts into few pre-defined categories. The categories can be two or more in number. If the number of categories is two in number, it is called binary classification. The applications of binary classification are Sentiment Analysis, Spam filtering, Credit Card fraud detection etc. If the number of categories is more than two, then it is called multi-class text classification. The applications of MTC are Product categorization, News categorization, Citation intent classification, E-book classification etc. This project focuses on performing MTC on a COVID dataset consisting of tweets collected from Twitter and Kaggle with 15 unique categories.

#### A. Architecture of Proposed and Related Models

1) *The process of building an MTC model involves two parts:* Extraction of Embeddings: In order to perform MTC on the above dataset, the model that is built to do that only understands numerical data and not the raw text. Hence, it is necessary to convert the text samples into numerical vectors. This conversion of raw text data into numerical values is called a word embedding technique [31]. There are two types of word embedding techniques: Frequency-based and Prediction-based.

One of the earliest prediction-based embedding techniques is Word2Vec [32], which is a contextual word embedding method that provides an association between words having similar meaning. There are two models of Word2Vec method to use, in order to create word embeddings. 1) CBOW (Continuous Bag-Of-Words) model – which takes context words as input and tries to predict the target word as output. 2) Skip-gram model – predicts context words given the target word. The disadvantages of Word2Vec model are that it cannot handle out-of-vocabulary words, it relies on local information, requires large corpus to get an optimal solution and word sense is not captured separately. In order to consider the co-occurrence of words in the document, GloVe was invented [33]. This embedding technique was developed by Stanford University that is used to generate embeddings using an unsupervised approach. The training of GloVe model involves the use of global word-word co-occurrence matrix that is points out the number of times each word co-occurs with another.

Fig.1 shows an example of a co-occurrence matrix, where each row consists of unique words in the document and each column denotes the context. Here, the context length is one. E.g., It says that the word “digital” co-occurs with the word “computer” 1670 times for the selected corpus. This large matrix is factorized to provide a lower-dimensional matrix, where, each row of the lower-dimensional matrix acts as word vectors for the respective word. The model has been pre-trained to provide various dimensional word vectors. This project concentrates on using word vectors of dimension 50, where the model is trained on 6 billion tokens taken from both Wikipedia 2014 and Gigaword 5. Hence, the pre-trained word vectors will be inside a text file of name “GloVe.6B.50d.txt”. Unlike Word2Vec model, this method uses global information to construct the embeddings. The main disadvantages of using GloVe model are that it requires large memory to store the co-occurrence matrix, it cannot handle out-of-vocabulary words and word Sense is not supported. These and many other pre-trained models have one disadvantage in common, which is the unidirectional that restricts the power of those models. This led to the discovery of a specific type of transformer networks [34], BERT [35-37]. It is a pre-trained model that considers the left and right context of a word in all layers, while generating embeddings.

In order to pre-train BERT, WordPiece embeddings are used with 30,000 vocabulary size. There are two special tokens inserted into each sentence of BERT’s input, they are [CLS] and [SEP] tokens. [CLS] token represents the beginning of every sequence, which is also a classification token, for the task of NSP. Every sequence in input is separated by [SEP] token. The BERT has a powerful input representation, shown in Fig. 2, which is a combination of three embeddings: Token embeddings: Embeddings that represent each token in the document, Segment embeddings: Embeddings that are used to identify to which segment/sentence does the token belong to and Position embeddings: Embeddings representing the position of each token. There are two pre-training tasks of BERT, shown in Fig. 3, Masked Language Modeling (MLM) and Next Sequence Prediction (NSP).

Fig. 3. Pre-training Architecture of BERT.

This paper intends to implement two word embedding methods, 1) GloVe 2) BERT-base architecture, that contains 12 transformer encoder layers, 12 self-attention heads, 768 as hidden size and 110M parameters. GloVe and BERT models are used widely due to the use of transfer learning. It is a method that saves training time of deep learning models for the data scientists. In traditional learning, the model used to be built from scratch [38] [39]. If there is a task of classification of reviews into positive and negative, and a task of classifying spam email, both these tasks were implemented separately by building two independent models from scratch. This might consume a lot of training time in general. But in case of transfer learning, the model built for classifying reviews is used as an initial checkpoint for the task of classifying spam emails. The latter task is implemented by just fine-tuning or adjusting the weights of the former model. The model that is trained for the former task is called the pre-trained model [40-41]. The latter model is called the fine-tuned model. Hence, transfer learning is a method of using the knowledge, gathered while training a model for a task, to train a similar task. Another main advantage of using transfer learning approach is that for the fine-tuning approach, the second similar task need not have a large dataset. This project uses two pre-trained models for generating word embeddings.

2) *Classifier*: At the early days of neural networks, feed forward networks (FFN) were very popular to perform many tasks. They were known for their accuracy and speed. But they had their own disadvantages:

- a) Unable to process sequential data.
- b) Current input can't be considered.
- c) Cannot remember previous inputs.

RNN (Recurrent Neural Networks) were discovered to overcome the above-mentioned problems. They belong to a class of neural networks which takes previous layer outputs and feeds them as input to the current layer, passing information from the past. This is implemented with the concept of “memory” that keeps information about previous calculations till time step  $t$ . The main reason why RNN is used in NLP is because text is a sequential data. But RNNs suffer from vanishing gradient problem, in which, the gradients are so small that the updates of parameters are insignificant. This problem occurs while processing long sequences. Hence, there are two variants of RNN that have been discovered: LSTM (Long-Short Term Memory) and GRU (Gated Recurrent Units). In RNN, in order to add new information, the whole memory context is modified and there is no consideration for important information. To overcome this, LSTM is used [42]. LSTM has the ability to forget or restore information of choice. And it is implemented by three Gating mechanisms. 1) Forget Gate: This gate is used to forget all the insignificant information from the memory context. 2) Input Gate: This gate is used to add or update new information into the memory context. 3) Output Gate: This gate is responsible for selecting important information and passing it out to the downstream network. GRU, on the other hand, is another variant of RNN similar to LSTM, except that it has two Gating mechanisms [43]: 1) Reset Gate: This gate is responsible for deciding how much of previous information should be forgotten. 2) Update Gate: This gate is responsible for deciding how much of previous information should be passed along the network. This paper uses both LSTM and GRU layers to classify tweets. Fig. 4 shows the architecture of the proposed hybrid RNN model.

Fig. 4. Architecture Diagram of Hybrid Model.

The input word sequence is provided to the input layer, where tokenization (Word/Sub-word, depending on the embedding technique) takes place and the tokenized data is given to the second layer (Embedding Layer). This layer can use either GloVe or BERT pre-trained word embedding techniques to generate meaningful word embeddings. These embeddings are given to the third layer, which is a combination of LSTM, Dropout and GRU layers. This is the hybrid classifier. The fourth layer is the softmax output layer which gives out the probability for all the classes, with highest probability for the predicted class.

### B. Working of Models

Fig. 5 depicts the generic workflow. The dataset used in this project contains tweets collected from Twitter till April 2020. The total number of tweets collected are 260000. There are three attributes in the dataset: Tweets, labels and label ids.

All the tweets are labelled as one of the 15 labels. These tweets, before feeding into the models, have to be cleaned and pre-processed such that it is easier for the models to learn quickly.

---

### Algorithm for proposed model

---

**Input:** The COVID dataset

**Output:** A model trained on the COVID dataset and one of the 15 pre-defined classes for each tweet in the test dataset

---

1. Import the dataset.
  2. Pre-processed\_tweets, labels = Data\_PreProcessing(dataset).
  3. Split the Pre-processed\_tweets and labels into training and testing set with a ratio of 80:20.
  4. Either perform BERT\_Tokenization() or GloVe\_Tokenization() depending on the choice of embedding technique.
  5. Create an embedding matrix for every word in the vocabulary
  6. Build hybrid model as shown in step 7 to step 13.
  7. Add an EmbeddingLayer() with weights as the embedding matrix
  8. 3 LSTM() Layer
  9. Dropout layer
  10. 1 LSTM() layer& 1 GRU Layer
  11. Dropout layer
  12. 1 GRU() Layer
  13. Dense() layer with Softmax activation function.
  14. Train the model on the training set.
  15. Evaluate the model on the test set.
- 

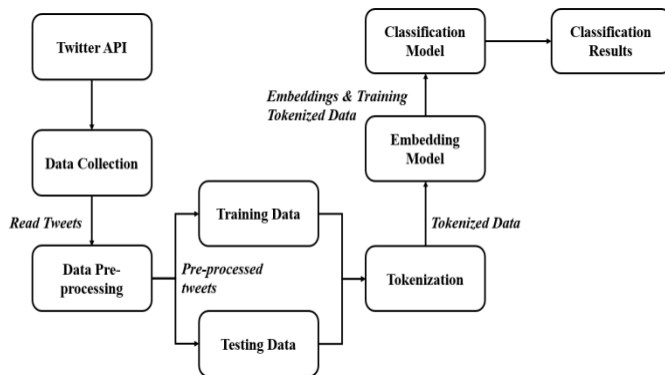

Fig. 5. Generic Workflow.

After the pre-processing, the dataset is split into training and testing set with 80:20 ratio, where each sample from each set is tokenized (GloVe or BERT Tokenization) and is given to the embedding model (GloVe or BERT) to generate the embeddings which is given to the classification model (Hybrid or BERT-base) to produce the results (one of the 15 classes of the dataset). There are two ways to use BERT model. 1) Fine-tuning approach [44] – Using the BERT model as a whole to generate embeddings from 12 encoders and 1 classifier. 2) Embeddings extraction approach – Using BERT model to just extract the embeddings and use a different classifier altogether. This project suggests the use of Hybrid RNN model for this approach as a classifier. The reason being,

LSTM is more accurate and complex compared to GRU because of the number of gating mechanisms and in terms of speed, GRU is better than LSTM. Hence, to combine the advantages of both the models this hybrid model has been proposed. For the second approach, the embeddings can be extracted in various ways. We can extract the embeddings from 1) the last layer 2) the last few layers and sum them 3) the last few layers and get an average. This paper uses the second approach. Following is the algorithm for the approach towards the hybrid model.

## IV. RESULTS AND ANALYSIS

### A. Dataset

This paper uses a COVID-19 dataset that is prepared with tweets from twitter and Kaggle in the period 2020-21. The structure of this dataset contains tweets, labels in words and label ids. In terms of MTC, the dataset contains 15 unique classes to categorize the tweets that are: Entertainment, Essential Workers, Facts, General, Government Action, Medical Test & Analysis/Supply, Tribute, Pandemic, Panic Shopping, Political, Self-Care, Social Distance, Stay-At-Home, Taco Tuesday and Telecommuting Life.

### B. Experimental Settings

The setup requires Google Colab Pro subscription that is linked to Google Drive, where the dataset is contained. The BERT repository is cloned in the Colab platform, and is used to access files that help in extracting embeddings from BERT's encoder layers. The python files extracted for this purpose are modified for the current use case accordingly. Also, the configuration files of uncased-BERT model, "uncased\_L-12\_H-768\_A-12", is downloaded to the drive, that contains vocabulary file, configuration file and checkpoint of pre-trained BERT-base model. These files are given as parameters to the BERT repository files to extract embeddings. Following is the list of all main parameters considered for configuring all 3 models:

For both the Hybrid models:

- Number of LSTM layers: 3
- Number of GRU layers: 2
- Number of dropout layers: 2
- Output function: SoftMax
- Learning rate: 0.001
- Batch size: 256
- Optimizer: Adam
- Dropout rate: 0.5

For BERT-Hybrid model:

- Maximum sequence length: Maximum sentence length
- Embedding dimension: 768
- Vocabulary size: 30522
- No. of encoder layers for embeddings extraction: 4

For GloVe-Hybrid model:

- Maximum sequence length: 500
- Embedding dimension: 256

Vocabulary size: 1 lakh approx.

### C. Performance Measures

Table I describe the validation loss, validation accuracy, precision, recall and F1-score of BERT-hybrid, GloVe-hybrid and BERT-base models. From the tables, we can say that, for three epochs, BERT-base model performs better than the hybrid models with an accuracy of 96.59%. It is estimation that for larger number of epochs, hybrid model might work better than the base model. If we compare between the two hybrid models, the model that uses BERT embeddings shows a slight improvement in performance, indicating that the use of embeddings plays a major role in deciding the performance of any model.

TABLE I. LOSS, ACCURACY, PRECISION, F1-SCORE AND RECALL OF MODELS

MODEL	LOSS	ACCURACY	PRECISION	RECALL	F1-SCORE
GLOVE-HYBRID	0.156	0.953	95.74	95	95.34
BERT-HYBRID	0.1475	0.9568	95.75	95.55	95.63
BERT-BASE	0.1185	0.9659	96.93	96.85	96.88

Fig. 6 depicts the training and prediction time of implemented models. As the BERT-base model is more complex in architecture, it takes more time to train and predict. BERT-hybrid model takes least amount of time to train, with a smaller number of parameters and small vocabulary size. Also, the time-consuming task of generating embeddings is a one-time process for the BERT-hybrid model, and hence the small training time. The GloVe hybrid model takes more time to train than BERT-hybrid model due to its larger vocabulary size and parameters. With respect to the prediction time, BERT-hybrid takes less time to predict than the other models, approximately five minutes, which leads to a fact that there is a trade-off between time and accuracy when we use BERT-hybrid model. Fig. 7 and Fig. 8 below show the comparison between models on validation accuracy and validation loss in a graphical format respectively.

Fig. 6. Training and Prediction Time of Models.

Fig. 7. Validation Accuracy of Models.

Fig. 8. Validation Loss of Models.

### V. CONCLUSION AND FUTURE WORK

The research presents a novel hybrid RNN model that experiments between GloVe and BERT embeddings. In terms of accuracy, performance, and speed, this hybrid model utilizes the capabilities of both the LSTM and GRU layers to fill in the gaps. It also uses many layers of LSTM and GRU to apply the concept that deeper the model, greater the accuracy. For three epochs, it is shown that the state-of-the-art BERT-base transformer model outperforms both hybrid RNN models, with an accuracy of 96.59 %. It is expected that the hybrid RNN models will perform better over a larger number of epochs. Furthermore, the BERT-hybrid model outperforms the GloVe-hybrid model, demonstrating that contextual representation improves performance. In the future, different BERT model versions might be utilized to produce embeddings and feed them to the hybrid model for better performance.

**Abstract**—Stock liquidity forecasting is critical for investors, issuers, and financial market regulators. The object of this study is to propose a method capable of accurately predicting the liquidity of stocks. The few studies on stock liquidity forecasting have focused on single models such as Seasonal Auto-Regressive Integrated Moving Average with exogenous factors, the nonlinear autoregressive network with exogenous input, and Deep Learning. A new trend in forecasting which attempts to combine several approaches is emerging at the moment. Inspired by this new trend, we propose a hybrid approach of Wavelet Transform, Convolutional Neural Networks, and Gated Recurrent Units to predict stock liquidity. Our model is tested on daily data of companies listed on the Casablanca Stock Exchange from 2000 to 2021. Its forecasting performances are evaluated based on the Mean Absolute Error, the Root Mean Square Error, the Mean Absolute Percentage Error, Theil's U statistic, and the correlation coefficient. Finally, the outperformance of the proposed model is confirmed by comparison with other reference forecasting models. This study contributes to the enrichment of the field of prediction of financial risks and can constitute a framework of analysis allowing to help the stakeholders of the financial markets to forecast the liquidity of the actions.

**Keywords**—Stock liquidity; wavelet transform; convolutional neural networks; GRU cell; Casablanca stock exchange

## I. INTRODUCTION

"A stock is considered liquid if large transactions can be made rapidly without significantly impacting the stock price and without incurring substantial losses, and if any price variation caused by a random shock is quickly adjusted" [1]. Before the financial crisis of 2007-2008, stock liquidity risk was largely underestimated by investors, financial market regulators, and researchers. Yet, it has negative financial and economic consequences. In fact, It increases equity market risk [2], [3], [4], and reduces bank liquidity [5], [6]. Stock liquidity affects financial stability [7], [8]. It also impacts the financial structure and cost of capital [9], [10], the dividend distribution policy [11], and the risk of corporate failures [12], [13].

Forecasting stock liquidity is crucial for investors, issuers, and financial market regulators. It allows investors to forecast the illiquidity premium to be charged to compensate for lower returns [14]. Stock liquidity prediction helps issuers to choose the right time to go public, increase their capital or carry out financial packages such as takeover bids, sales, or the outs. Financial market regulators are also concerned with liquidity predictions as it allows them to act a priori to safeguard financial stability.

Only a few studies have attempted to address forecasting stock liquidity. We are aware of only two research articles in this area. In a comparative study, [15], concludes that the Nonlinear Autoregressive Network with exogenous inputs (NARX) has better predictive performance than the Seasonal Auto-Regressive Integrated Moving Average with exogenous factors (SARIMAX). These authors found that SARIMAX method is inaccurate because stock liquidity is irregular, noisy, and nonlinear time series. However, this study has some shortcomings.

It is based on only 108 observations, a number that we consider to be low for the learning processes of an algorithm capable of making effective predictions. The training of this type of algorithm on the basis of the large dataset can generate the problems of vanishing and exploding of the gradient. Since the number of hidden layers is low, NARX neural networks cannot capture hidden functional relationships in the historical stock liquidity dataset. As a result, their predictive performance is very limited.

The author in [16] compared linear regression model, multilayer perceptron, and Long Short Term Memory (LSTM). Based on daily data of companies listed on the Ho Chi Min and Hanoi Stock Exchanges in Vietnam from January 2011 to December 2019, the authors conclude that the LSTM model has the lowest Mean Square Error (MSE). This result seems logical to us because LSTM neural networks have more advantages than the linear regression model and the multilayer perceptron. Compared to linear regression, the LSTM model capture the characteristics of even nonlinear data. The multilayer perceptron assumes that inputs and outputs are independent of each other. On the other hand, the LSTM model takes into account the temporal dependencies while avoiding the problem of vanishing gradient. However, despite the advantages of the LSTM model, the results of this study are less convincing. First, the predictive performance is only evaluated on the basis of a single criterion (MSE). Second, despite their power, LSTM neural networks alone cannot capture all abrupt and dynamic changes in financial time series [17]. Stock liquidity is noisy, volatile, and non-linear. It requires pre-processing before forecasting.

The Wavelet Transform (WT) is an effective tool for denoising the most complex time series. By decomposing a signal into different scales, the WT can capture the hidden features of the time series. Therefore, to further improve the efficiency and accuracy of forecasting, researchers have started

to develop hybrid models that combine WT and deep learning algorithms. These hybrid models are used to predict time series, such as wind [18], solar energy [19], water quality [20], nickel futures price [21], gold returns [22], and stock prices [23]. Exploring this approach, we propose a hybrid model that combines a Wavelet Transform (WT), a Convolutional Neural Network (CNN), and a Recurrent Neural Network (RNN) with a Gated Recurrent Unit (GRU) layer. The purpose of this study is to find out if stock liquidity denoising by WT can improve the predictive performance of deep learning algorithms. The proposed WT-CNN-GRU model is tested on daily data of companies listed on the Casablanca Stock Exchange from 2000 to 2021. Our database contains 5478 trading days.

This study brings three novelties. First, the originality of our approach is the denoising of stock liquidity data by the WT before proceeding to the forecasting by deep learning algorithms. Second, unlike previous studies that used unique signal decomposition methods to denoise the data, we use adaptive approaches consistent with the characteristics of different measures of stock liquidity. Third, the proposed model showed better performance in accurately predicting the strong disruptions in stock liquidity caused by the COVID-19 pandemic.

While the predictive performance of the previously presented models is measured by a single criterion, the proposed model in this study is evaluated by a multitude of parameters such as Mean Absolute Error, the Root Mean Square Error, the Mean Absolute Percentage Error, Theil's U statistic and the correlation coefficient. By showing superiority over previous studies, the proposed model is considered a step forward in improving the prediction of stock liquidity.

The rest of the paper proceeds as follows. The next section describes the adopted methodology. Section 3 presents the empirical process, results, and comparative analysis of stock liquidity forecasting. Section 4 presents the conclusions and offers some suggestions and perspectives.

## II. PROPOSED METHODOLOGY

To forecast stock liquidity, the proposed methodology is a hybrid approach between a WT, CNN, and GRU. Fig. 1 shows the general procedure of our model.

Fig. 1. Flowchart of the WT-CNN-GRU Model.

The normalized and denoised stock liquidity measures are inputs to the mixed CNN-GRU model. The detailed steps for processing the pre-processed data in the CNN-GRU model are shown in Fig. 2.

This section discusses the main steps of the hybrid WT-CNN-GRU model: (1) data preprocessing (2) a hybrid CNN-

Fig. 2. Flow Chart of the CNN-GRU Model.

GRU neural network and (3) forecasting performance evaluation.

### A. Data Pre-Processing

1) *Data Normalization*: The normalized data is calculated using the Z-Score method. Z-scores measure the distance between a data point and the means in terms of standard deviation. The standardized data set has a mean of 0 and a standard deviation of 1, and retains the shape properties of the original data set (same skewness and kurtosis). The standardized data are obtained by (1).

$$x^* = \frac{(x - \bar{x})}{\sigma} \quad (1)$$

$\bar{x}$  is the mean of the original data and  $\sigma$  is the standard deviation of the original data. Normalization supports machine learning algorithms in measuring the distance between the standard deviation and the mean of processed data samples. Conversely, The original data can be derived as follows:

$$x = \sigma x^* + \bar{x} \quad (2)$$

2) *Wavelet Transform*: Financial series are noisy, volatile, nonlinear, and non-stationary. As a consequence, they require pre-processing. The Discrete Wavelet Transform (DWT) is a mathematical tool that decomposes the input signal into several physically significant components, invisible in the raw data. These components can be frequencies, trends, edges, or breaks. This facilitates the analysis of each component in isolation and the reconstruction of the original signal into the desired components to be extracted. This facilitates the denoising of the input signal. The purpose of this step in our model is to eliminate the noise that can characterize stock liquidity.

There are several signal decomposition techniques such as Maximum Overlap Discrete Wavelet Transform (MODWT), Empirical Mode Decomposition (EMD), Empirical Wavelet Transform (EWT), Tunable Q-factor Wavelet Transform (TQWT), and Variational Mode Decomposition (VMD). The choice between these techniques depends on the characteristics of the input signal [1]. MODWT is adapted for signals containing oscillations with trends or transitions. TQWT and VMD are most suitable for signals containing high or low-frequency oscillations. EWT is intended for extracting low-frequency oscillations. EMD is used when the input signal contains trends.

However, before proceeding with the decomposition of input signals, it is necessary to analyze them in time frequency to choose the most appropriate decomposition method. The Continuous Wavelet Transform (CWT) is more efficient for performing time-frequency analysis of a signal than the DWT because the scales are discretized more finely in CWT. In this study, we prefer Morse Wavelets because it has the advantage of varying amplitude and frequency over time [24].

### B. A Hybrid CNN-GRU Model

1) *Convolutional Neural Network*: A Convolutional Neural Network (CNN) is a network architecture for deep learning that learns directly from the data, eliminating the need for manual feature extraction. Fig. 3 shows a simple CNN architecture.

Fig. 3. Basic Architecture of the Convolutional Neural Network.

In addition to the input and output layers, three different layers are normally present in CNNs, such as the convolution layer, the pooling layer, and the fully connected layer. The convolution layer is a set of filters whose purpose is to extract local features from the input layer. This ensures that the network focuses on low-level features in the first hidden layer, then it assembles them into higher-level features in the next hidden layer, etc. Convolution layers are used in our study to extract chaotic, irregular, and fluctuating features from liquidity measurements. Pooling layers are used to retain only the most relevant features of the liquidity measures and to deepen them. Pooling can be of two types, maximum pooling, and average pooling. In this study, we retain maximum pooling because pooling by the mean is an outlier. The fully connected layer is similar to a Feedforward Neural Network whose goal is to extract the global feature of the inputs. Each neuron in these layers is connected to all hidden neurons in the previous layer.

2) *Recurrent Neural Network: The Closed Recurrent Unit Layer*: In contrast to deep Multilayer Perceptron (MLP), Recurrent Neural Networks (RNN) have interdependent input and output layers. RNNs are suitable for modeling sequential data and their associated temporal dynamics with greater accuracy. However, simple RNNs are generally characterized by the vanishing gradient problem, where, depending on the activation function, information "vanish with time," and the term nonlinearity is often inadequate for longer-term memory. To overcome this problem, Long Short-Term Memory networks (LSTMs) have been developed. LSTMs help to preserve errors that can be back-propagated across time and layers. By maintaining these errors, LSTMs allow RNNs to continue learning more efficiently across many time steps.

Compared to LSTM networks, GRUs [25], have only two gates; a reset gate and an update gate. The update gate behaves

similarly to the forget gate in LSTM by deciding which information to keep and which new information to add, while the reset gate is another mechanism to determine the amount of past temporal information to delete. We retain GRUs in our model because they are less easy to construct than LSTMs, due to fewer tensor operations.

As mentioned earlier, this study proposes a hybrid model of CNN and GRU, with corresponding parameters summarized in Table I.

TABLE I. PARAMETER OF THE CNN-GRU MODEL

Hybrid model	Parameter	Values	
Network CNN	Input layer	1	
	Dimension convolution layer	1 D	
	Number of convolution layers	2	
	Number of Pooling layers	2	
	Number of filters	1	
	Width of filters	1	
	Pooling method	Max Pooling	
	GRU network	Number of GRU layers	1
		Number of masked units	300
		Activation function to update the masked state	Tanh
Activation function to be applied to gates		Sigmoid	
Dropout layer Options	dropout rate	0.4	
Options Learning Network CNN-GRU	Epochs	300	
	optimizer	Adam	
	Initial learning rate	0.005	
	Loss function	Mean Square Error	

3) *Evaluation of the Forecasting Performance*: To evaluate the prediction performance of the proposed model, five statistical evaluation indicators are used to compare the performance of the associated models, including MAE (Mean Absolute Error), MAPE (Mean Absolute Percentage Error), RMSE (Root Mean Square Error), Theil's U statistic and the correlation coefficient ( $R^2$ ) which can be calculated as follows:

$$MAE(X, \vec{X}) = \frac{\sum_{t=1}^T \|X_t - \vec{X}_t\|}{T} \quad (3)$$

$$MAPE(X, \vec{X}) = \left( \sum_{t=1}^T \frac{\|X_t - \vec{X}_t\|}{X_t} \right) / T \quad (4)$$

$$RMSE(X, \vec{X}) = \sqrt{\frac{\sum_{t=1}^T (X_t - \vec{X}_t)^2}{T}} \quad (5)$$

$$U(X, \vec{X}) = \left( \sqrt{\frac{\sum_{t=1}^T (X_t - \vec{X}_t)^2}{T}} \right) / \left( \sqrt{\frac{\sum_{t=1}^T (\vec{X}_t)^2}{T}} + \sqrt{\frac{\sum_{t=1}^T (X_t)^2}{T}} \right) \quad (6)$$

$$R^2(X.\vec{X}) = 1 - \left( \frac{\sum_{t=1}^T (X_t - \vec{X}_t)^2}{\sum_{t=1}^T (X_t - \bar{X})^2} \right) \quad (7)$$

Where  $T$  is the number of observations,  $X$  is the actual value,  $\vec{X}$  is the forecasted value.

### III. EMPIRICAL RESULTS AND DISCUSSION

#### A. Sample, Liquidity Measures, and Data Analysis

1) *Sample and Liquidity Measures:* To test our model, we collect the best bid and ask price, closing price, and daily trading volume of 75 companies listed on the C.S.E from 04/01/2000 to 12/31/2021. These data come from the CDG Capital Bourse database. Stock liquidity is evaluated using three indicators to account for its multidimensional nature, including the displayed range (Qs), the Amihud illiquidity measure (Amh) and the zero return (Zr). The formulas for calculating these indicators are as follows:

$$Qs_{i,t} = \frac{(P_{i,t}^A - P_{i,t}^B)}{P_{i,t}^M} \quad (8)$$

$$Amh_{i,t} = \left( \sum_{t=1}^D \frac{\|r_{i,t}\|}{Vol_{i,t}} \right) / D_{i,t} \quad (9)$$

$$Zr_{i,t} = \begin{cases} 1, & r_{i,t} = 0 \\ 0, & r_{i,t} \neq 0 \end{cases} \quad (10)$$

With  $P_{i,t}^A$ ,  $P_{i,t}^B$ ,  $P_{i,t}^M$ ,  $r_{i,t}$  and  $Vol_{i,t}$  are the best ask price, best bid price, closing price, daily return, and daily volume of stock  $i$ , respectively. The displayed range  $Qs_{i,t}$  measures the depth of the market. The larger the spread between the best ask price and the best bid price, relative to the market price, the lower the liquidity of the stock [5]. Amihud's illiquidity ratio ( $Amh_{i,t}$ ) describes the change in daily price for a given trading volume; a low trading volume generating a higher return is synonymous with illiquidity. The zero return ( $Zr_{i,t}$ ) measures the number of days when the return is zero. It takes the value 1 if the return is zero and 0 otherwise. A high number of days of zero return is synonymous with low liquidity.

Each indicator is calculated daily per company; the aggregate daily indicator is an average of all companies. In sum, we have 5268 observations for Qs, 5469 observations for Amh and 5475 for Zr.

2) *Descriptive Statistics:* Fig. 4 shows that the measures of stock liquidity are chaotic, erratic, asymmetric, and non-linear to time. These characteristics are evidenced by the descriptive statistics presented in Table II. The liquidity measures are volatile as indicated by the coefficients of variation that are close to 0.5, and exceed 1 for the Amihud illiquidity ratio (Amh). Respectively, the Skewness and Kurtosis coefficients, indicate that the displayed range (Qs) and Amihud illiquidity ratio (Amh) are left skewed and pointed, while the zero return (Zr) is right skewed and flattened.

Fig. 4. Evolution of the Liquidity of Shares in the Casablanca Stock Exchange.

TABLE II. DESCRIPTIVE STATISTICS

	Qs	Amh	Zr
Number of observations	5268	5475	5475
Average	0,012	6,06E-06	0,362
Median	0,012	2,33E-06	0,397
Std	0,007	1,16E-05	0,167
Coefficient of variation	0,607	1,914	0,461
Kurtosis	6,512	34,004	1,874
Skewness	1,116	4,805	-0,196

#### B. Data Pre-Processing

The raw liquidity measures are first normalized by the Z-Score method; then denoised by the WT. However, since the choice of the decomposition method for the liquidity measures depends on the characteristics of the data, we first perform a time-frequency analysis of the liquidity measures. From Fig. 5, we can observe that Qs, Amh, and Zr experience low and medium frequency oscillations.

Fig. 5. Magnitudes Scalograms of Liquidity Measures.

Based on the time-frequency analysis while following the approach of [26], we present in III the methods used to decompose the stock liquidity measures.

TABLE III. MULTIREOLUTION ANALYSIS TECHNIQUES

Input signal	Signal characteristics					Decomposition technique
	Low frequency	Average frequency	Increase in frequency	Breaking	Trend	
Qs	Yes	Yes	No	No	No	VMD
Amh	Yes	Yes	No	No	No	VMD
Zr	Yes	Yes	No	Yes	No	MODWT

Since Qs and Amh experience low and medium frequency oscillations and peaks but no trend or break, the most appropriate method to decompose them is VMD. The latter decomposes the original signal into K intrinsic mode function (IMF) components. Fig. 6(a) shows the decomposition of Qs into five MFIs. The first IMFs (IMF1 to IMF3) locate low frequency oscillations, IMF4 locates mid-frequency oscillations and IMF 5 locates peaks. The Qs signal has experienced a few spikes between the year 2000 and 2021; the first ones are related to the effect of the 2007-2008 financial crisis while the last ones are due to COVID-19. Qs is noisy with midrange frequencies and spikes. Therefore, to reconstruct the noisy Qs signal, we neutralize IMF4 and IMF5. Fig. 6(a) highlights the original signal and the reconstructed signal.

Fig. 6. Decomposition and Denoising of Qs.

Fig. 7(a) clarifies the decomposition of the Amh signal into five MFIs. This decomposition clearly shows that under the effect of COVID-19, the Amh signal experienced mid-frequency oscillations (MFI4) and spikes (MFI5) during 2020 and 2021. This has caused Amh to become very noisy. Thus, in order to denoise it, we reconstruct the signal while neglecting IMF1, IMF2, and IMF3. This reconstruction is shown in Fig. 7(b).

Fig. 7. Decomposition and Denoising of Amh.

Zr is decomposed by the MODWT method, as it experiences low and medium frequency oscillations and a jump in 2011. The MODWT method decomposes the original signal into wavelet coefficients and scaling coefficient. The wavelet coefficients identify high-frequency oscillations, while the scaling coefficients capture trends and jumps in a time series. Fig. 8(a) shows the MODWT algorithm’s decomposition of the Zr signal into five levels using the orthogonal Daubechies wavelet, with a level 1. We can observe from Fig. 8(a) that the Zr signal is noisy by medium frequency oscillations. Fig. 8(b) shows the reconstruction of the Zr signal after removing the noise.

1) Experimentation of the WT-CNN-GRU Model:

a) Presentation of the Empirical Results: In subsection III-B1, Qs and Amh were decomposed by the VMD method while Zr was decomposed by the MODWT method.

Fig. 8. Decomposition and Denoising of Zr.

After the decomposition and denoising operations, we have 5469 MFIs for Amh, 5268 MFIs for Qs and 5475 approximation coefficients for Zr. The selected MFIs and approximation coefficients constitute inputs for the CNN-GRU model. The data for these inputs are further splitted into 80% training data and 20% test data. Table IV details this split.

TABLE IV. TRAINING AND TEST DATA

Liquidity measurement	Training data		Test data	
	Number of observations	Period	Number of observations	Period
Qs	4215	November 01, 2000 to October 03, 2017	1053	October 04, 2017 to December 31, 2021
Amh	4370	January 04, 2000 to July 19, 2017	1099	July 20, 2017 to December 31, 2021
Zr	4380	January 04, 2000 to July 31, 2017	1095	August 01, 2017 to December 31, 2021

The CNN-GRU model is trained according to the parameters described in Table I. A comparative study between the forecasted and actual values of the three denoised liquidity measures is shown in Fig. 9 to Fig. 11. We can observe that the forecasted values are almost equal to the actual values and that our model is able to make accurate forecasting even under sudden shocks, such as the case of COVID-19 in 2020 and 2021. From Fig. 9 to Fig. 11, we can also notice that the number of outliers in the test errors of the proposed model is very small.

Table V lists the metrics for evaluating the predictive performance of test data. From Table V, we can notice that the proposed model gives very low MAE, MAPE, and RMSE, Theil’s U statistics less than 1, and ( $R^2$ ) close to 1. Our model demonstrates excellent forecasting performance compared to models proposed in previous studies.

The author in [5] proposed a NARX neural network to predict the liquidity of stocks listed on the Casablanca Stock Exchange. Their model is evaluated based on MSE which indicates a value of 0.0083 for Qs and 0.0023 for Zr. The author in [6] estimates that the LSTM model is more efficient than the linear regression method and the multilayer perceptron. The results of this study indicate that the LSTM model exhibits better MSEs. The MSE of the Amihud ratio indicates a value of 0.0169 and 0.0252 on the Ho Chi Min and Hanoi Stock Exchange respectively.

Statistically, our model far exceeds the performance of models postulated by previous studies. Moreover, these models are only tested on a small number of observations. The authors in [5] and [6] only tested their model on the basis of 12 and 110 observations respectively, whereas our model is tested on 1053 observations for Qs, 1099 for Amh, and 1095 for Zr. As a result, the MSEs of earlier models are less reliable. The commonality of previous studies is the use of MSE as an endpoint. However, the latter is more sensitive to outliers. On the contrary, our model is evaluated on the basis of multiple indicators.

Fig. 9. Comparison between Actual Qs and Qs Predicted by the WT-CNN-GRU Model.

Fig. 10. Comparison between Actual Amh and Amh Predicted by the WT-CNN-GRU Model.

*b) Comparison with Similar and Alternative Models:*

To prove the effectiveness of the proposed model, we compare its performance to similar models, such as WT-CNN-LSTM and WT-CNN-BILSTM. In addition, since the focus of our study is whether the introduction of WT improves the predictive ability of deep neuron networks, the proposed

Fig. 11. Comparison between Actual Zr and Zr Predicted by the WT-CNN-GRU Model.

TABLE V. INDICATORS FOR EVALUATING THE PREDICTIVE PERFORMANCE OF THE CNN-GRU MODEL

Liquidity measurement	MAE	MAPE	RMSE	Theil's U	R <sup>2</sup>
Qs	3.1e-05	0.062	0.004	0.072	0.7379
Amh	0.0002	0.096	0.001	0.037	0.6325
Zr	-0.0025	0.022	0.074	0.079	0.7880

model is compared to alternative models such as CNN-GRU, CNN-LSTM and CNN-BILSTM. While the inputs of the similar models (WT-CNN-LSTM and WT-CNN-BILSTM) are denoised data, those of the alternative models (CNN-LSTM, CNN, BILSTM, and CNN-GRU,) are normalized raw data.

As showcased in Table VI, if we compare the proposed WT-CNN-GRU model with the CNN-GRU model, we can notice that the denoising of the data by WT improved the forecasting results of stock liquidity. At the level of Qs, the WT was able to reduce MAPE and Theil's U by 33% and 57% respectively, and increase R<sup>2</sup> by 48%. In addition, denoising the Amh data contributed to the improvement of MAE, MAPE, RMSE, Theil's U and R<sup>2</sup> by 154%, 84%, 21%, 94% and 40% respectively. Finally, the denoising of Zr data by WT strongly improved MAE, MAPE, RMSE, Theil's U and R<sup>2</sup> by 14%, 72%, 24%, 9% and 97% respectively. These improved results are obtained not only from the denoising of the data, but also from the appropriate choice of the decomposition methods.

In Table VI, we can also notice that the proposed model WT-CNN-GRU also outperforms similar models, such as WT-CNN-LSTM and WT-CNN-BILSTM. The GRU closed cell is therefore the most effective hybrid model when it is compared to the LSTM and BILSTM cells. GRU contains several hidden layers, which can efficiently identify the fluctuation characteristics of liquidity measures. GRU also optimizes the network structure and reduces information redundancy.

TABLE VI. EVALUATION CRITERIA VALUES FOR DIFFERENT FORECASTING MODELS

	Models	MAE	MAPE	RMSE	Theil's U	R <sup>2</sup>
Qs	WT-CNN-LSTM	6.71e-05	0.09	0.008	0.1619	0.7174
	WT-CNN-BILSTM	0.0001	0.117	0.004	0.1834	0.4953

	CNN-GRU	0.0022	0.0793	0.0976	0.0865	0.3992

#### IV. CONCLUSION

Forecasting equity liquidity is crucial for investors, issuers, and financial market regulators. As a financial series, stock liquidity is non-stationary, non-linear, chaotic, and noisy. Therefore, it is very difficult to accurately forecast inventory liquidity. The purpose of this study is to propose a model capable of effectively predicting inventory liquidity. Inspired by the hybrid research stream in financial time series forecasting, we proposed a WT-CNN-GRU model.

By testing it on all stocks listed on the B.V.C, our model showed excellent forecasting performance compared to models from previous studies and other similar or alternative models, such as WT-CNN-LSTM, WT-CNN -BILSTM, CNN-GRU, CNN-LSTM, and CNN-BILSTM. These improved performances are jointly explained by the neural networks WT, CNN, and the closed cell GRU. Choosing the right method for data decomposition and denoising was key to improving the results. The CNN was used to capture features that the WT did not capture, and they worked together to denoise the data. The GRU cell captured the time dependencies of stock liquidity, which has an advantage over the LSTM or BILSTM cell due to its ability to quickly catch time dependencies while avoiding information redundancy.

This study has three contributions. First, it is considered to be one of the few studies that have addressed the issues of forecasting inventory liquidity. Second, unlike previous studies that used a single data denoising method, we opted for methods consistent with our data. Third, the proposed model can predict stock liquidity even in the face of adverse shocks, such as the COVID-19 pandemic.

This study contributes to the enrichment of the forecast field of the financial series. It can be a useful analytical framework capable of helping investors, issuers, and financial market regulators predict stock liquidity. The model proposed in this study is also extended to predict other financial risks.

However, to verify its robustness, we suggest that future researchers test it in other emerging and developed markets. We also believe that our results can be improved by integrating into the proposed model global and specific exogenous variables for companies listed on stock exchanges.

**Abstract**—Drones have been quickly developing for civilian applications in recent years. Because of the nonlinearity of the mathematical drone model, and the importance of precise navigation to avoid possible dangers, it is necessary to establish an algorithm to localize the drone simultaneously and maneuver it to the desired destination. This paper presents a visual-based multi-stage error tolerance navigation algorithm of an autonomous drone by a tag-based fiducial marker detection in finding its target. Dynamic and kinematic models of the drone were developed by Newton-Euler. The position and orientation of the drone, related to the tag, are determined by AprilTag, which is used as feedback in a closed-loop control system with an Adjustable Proportional-Integral-Derivative (APID) controller. Parameters of the controller are tuned based on steady-State error, which is defined as the distance of the drone from the desired point. The sequence of path trajectory, that drone follows to reach the desired point, is defined as a navigation algorithm. A model of the drone was simulated in a virtual outdoor to mimic hovering in complex obstacles environment. The results present satisfactory performance of the navigation system programmed by the APID controller in comparison with the conventional Proportional-Integral-Derivative (PID) controller. It can be ascertained that the proposed navigation system based on a tag marker in the closed-loop control system is applicable to maneuvering the drone autonomously and useful for various industrial tasks in indoor/outdoor environments.

**Keywords**—Proportional-Integral-Derivative (PID) controller; AprilTag detection system; autonomous navigation; fiducial marker detection

## I. INTRODUCTION

The drone has the advantage of reaching high locations and extreme environments that are difficult to be accessed by humans and other ground vehicles [1], [2], [3]. Since its deployment to industrial applications, drones have attracted a lot of attention in various industries [4], [5], [6]. For instance, Huang et al. [7] presented for scene detection by high-resolution imagery adopted through autonomous drone navigation using landmark detection and recognition

The drone can be navigated autonomously or by a human pilot. There are several works about developing the navigation algorithm for the drone [8], [9], [10], [11]. Hodge et al. [12] presented a generic navigation algorithm that utilizes onboard sensors' data of the drone to navigate the drone to the target. Miranda et al. [13] developed a navigation system for autonomous drones that generates a path between a start and a final point and controls the drone to follow this path.

Tang et al. [14] studied an algorithm based on a multi-sensor system including multiple cameras and a 2-D laser scanner using the AprilTag target for drone application. Malyuta et al. [15] presented an autonomous drone for precision agriculture applications by employing the drone, flying through the farmland, for long-term monitoring missions without any human supervision by using AprilTag for localization. Lee et al. [16] established drone navigation by mapping the definitions of vehicular autonomy levels to specific drone tasks in order to create a clear definition of autonomy when applied to drones.

From literature [12], [13], [14], [15], [16], there are various types of strategies to increase the performance of navigation of the drone. Developing a simpler navigation strategy with more efficient performance has attracted much attention from researchers. The contributions of this paper are given as follows:

- The kinematics and dynamics of the drone are determined.
- The visual-based navigation and Adjustable Proportional-Integral-Derivative (APID), in which the actual position of the drone is captured by Fiducial Marker Detection, are investigated.

This paper is organized as follows: dynamic models of a drone are expressed in Section II. Section III addresses the development of APID and visual-based navigation. Section IV represents the performance and result of the proposed APID and navigation strategy in real-time navigation of a drone model in the virtual environment interacting with Robot Operating System (ROS). The conclusion is mentioned in Section V.

## II. DYNAMICS OF DRONE

The mathematical model of the drone is presented as follows [17]:

$$\dot{\eta} = \eta\nu \quad (1)$$

where the vector  $\eta$  represents position and orientation in the earth or inertial frame shown in Fig. 1 as follows:

Fig. 1. Drone Model Coordinate Systems.

$$\eta = |x \ y \ z \ \phi \ \theta \ \psi|^T \quad (2)$$

And the equation of motion for the drone can be represents as,

$$M_{RB}\dot{\nu} + C_{RB}(\nu)\nu = \tau \quad (3)$$

where  $M_{RB}$  is the rigid-body inertia matrix,  $C_{RB}(\nu)$  represents the centripetal and Coriolis terms and  $\tau$  is the generalized forces and torques, all of which are expressed in the body-fixed frame.

And vector  $\nu$  represents the linear velocities and angular velocities of the drone in the body-fixed frame as follows:

$$\nu = \begin{vmatrix} V^B \\ \omega^B \end{vmatrix} = |u \ v \ w \ p \ q \ r|^T \quad (4)$$

where  $V^B$  is the linear velocities in the body ( $B$ ) frame and  $\omega^B$  is the angular velocities in the body frame respectively. In 3 dimension rigid body dynamics, the two reference frames are linked by the linear and angular velocities as,

$$\nu = R(\eta)V^B \quad (5)$$

$$\omega = T(\eta)\omega^B \quad (6)$$

In general,  $j(\eta)$  is the transformation matrix of the orientation and position of the body frame with respect to the inertial frame of the drone can be shown as [18],

$$j(\eta) = \begin{vmatrix} R(\eta) & 0_{3 \times 3} \\ 0_{3 \times 3} & T(\eta) \end{vmatrix} \quad (7)$$

The transformation matrix that indicates the relation between angular velocities in the body frame and angular velocities in the inertial frame is represented as follows,

$$T(\eta) = \begin{vmatrix} 1 & s_\phi t_\theta & c_\phi t_\theta \\ 0 & c_\phi & -s_\phi \\ 0 & s_\phi/c_\theta & c_\phi/c_\theta \end{vmatrix} \quad (8)$$

The transformation matrix  $j(\eta)$  with the rotation matrix  $R(\eta)$  which describes the relationship between the linear velocities in the body-fixed frame and the linear velocities in the inertial frame is shown as,

$$R(\eta) = R_B^E(\psi)R_B^E(\theta)R_B^E(\phi) \quad (9)$$

$$R(\eta) = \begin{vmatrix} c_\psi c_\theta & -s_\psi c_\theta + c_\psi s_\theta s_\phi & s_\psi s_\theta + c_\psi c_\theta s_\phi \\ s_\psi c_\theta & c_\psi c_\theta + s_\psi s_\theta s_\phi & -c_\psi s_\theta + s_\psi c_\theta s_\phi \\ -s_\theta & c_\theta s_\phi & c_\theta c_\phi \end{vmatrix} \quad (10)$$

Since the vector of linear and angular velocities  $\dot{\eta}$  in earth frame can be expressed as,

$$\dot{\eta} = \begin{vmatrix} \dot{x} \\ \dot{y} \\ \dot{z} \\ \dot{\phi} \\ \dot{\theta} \\ \dot{\psi} \end{vmatrix} \quad (11)$$

The kinematics relation between the linear and angular velocities of the body-fixed frame related to the inertial frame is described by

$$\dot{\eta} = \begin{vmatrix} u(s_\psi c_\theta) + v(s_\psi s_\theta s_\phi + c_\psi c_\theta) + w(c_\psi s_\theta c_\phi + s_\psi s_\phi) \\ u(c_\psi c_\theta) + v(c_\psi s_\theta s_\phi - s_\psi c_\theta) + w(s_\psi s_\theta c_\phi - c_\psi s_\phi) \\ u(-s_\theta) + v(c_\theta s_\phi) + w(c_\theta c_\phi) \\ p + q(s_\psi t_\theta) + r(c_\psi t_\theta) \\ q(c_\psi) - r(s_\psi) \\ q\left(\frac{s_\psi}{c_\theta}\right) + r\left(\frac{c_\psi}{c_\theta}\right) \end{vmatrix} \quad (12)$$

By assuming that the center of mass is fixed at the center of the origin of the body frame and the body has rotational symmetry around the center of mass, the resulting rigid-body inertia matrix  $M_{RB}$  is presented as,

$$M_{RB} = \begin{vmatrix} mI_{3 \times 3} & 0_{3 \times 3} \\ 0_{3 \times 3} & I \end{vmatrix} = \begin{vmatrix} m & 0 & 0 & 0 & 0 & 0 \\ 0 & m & 0 & 0 & 0 & 0 \\ 0 & 0 & m & 0 & 0 & 0 \\ 0 & 0 & 0 & I_{xx} & 0 & 0 \\ 0 & 0 & 0 & 0 & I_{yy} & 0 \\ 0 & 0 & 0 & 0 & 0 & I_{zz} \end{vmatrix} \quad (13)$$

where  $m$  is the total mass of the drone and  $I_{xx}$ ,  $I_{yy}$  and  $I_{zz}$  are the moments of inertia [19]. By using Newton-Euler equation, the drone rigid body are affected by external forces  $F^B$  and torques  $\tau^B$  as,

$$\begin{vmatrix} mI_{3 \times 3} & 0_{3 \times 3} \\ 0_{3 \times 3} & I \end{vmatrix} \begin{vmatrix} \dot{V}^B \\ \dot{\omega}^B \end{vmatrix} + \begin{vmatrix} \omega^B \times mV^B \\ \omega^B \times I\omega^B \end{vmatrix} = \begin{vmatrix} F^B \\ \tau^B \end{vmatrix} \quad (14)$$

Expanding the equation above, we obtain,

$$\begin{pmatrix} m & 0 & 0 & 0 & 0 & 0 \\ 0 & m & 0 & 0 & 0 & 0 \\ 0 & 0 & m & 0 & 0 & 0 \\ 0 & 0 & 0 & I_{xx} & 0 & 0 \\ 0 & 0 & 0 & 0 & I_{yy} & 0 \\ 0 & 0 & 0 & 0 & 0 & I_{zz} \end{pmatrix} \begin{pmatrix} \dot{u} \\ \dot{v} \\ \dot{w} \\ \dot{p} \\ \dot{q} \\ \dot{r} \end{pmatrix} + \begin{pmatrix} -rmv + qmw \\ rmu - pmw \\ -qmu + pmv \\ -rI_{yy}q + qI_{zz}r \\ -rI_{xx}p + pI_{zz}r \\ qI_{xx}p - pI_{yy}q \end{pmatrix} = \begin{pmatrix} F_x^B \\ F_y^B \\ F_z^B \\ \tau_x^B \\ \tau_y^B \\ \tau_z^B \end{pmatrix} \quad (15)$$

The external forces and torques for each component of x, y and z axis can be determined as,

$$F_x^B = m(\dot{u} - rv + qw) \quad (16)$$

$$F_y^B = m(\dot{v} + ru - pw) \quad (17)$$

$$F_z^B = m(\dot{w} - qu + pv) \quad (18)$$

$$\tau_x^B = I_{xx}\dot{p} - rq(I_{yy} - I_{zz}) \quad (19)$$

$$\tau_y^B = I_{yy}\dot{q} + rp(I_{xx} - I_{zz}) \quad (20)$$

$$\tau_z^B = I_{zz}\dot{r} - qp(I_{xx} - I_{yy}) \quad (21)$$

The centripetal and Coriolis terms are represented by the matrix

$$C_{RB}(\nu)\nu = \begin{pmatrix} 0 & 0 & 0 & 0 & mw & -mv \\ 0 & 0 & 0 & -mw & 0 & mu \\ 0 & 0 & 0 & mv & -mu & 0 \\ 0 & 0 & 0 & 0 & I_{zz}r & -I_{yy}q \\ 0 & 0 & 0 & -I_{zz} & 0 & I_{xx}p \\ 0 & 0 & 0 & I_{yy}q & -I_{xx}p & 0 \end{pmatrix} \begin{pmatrix} u \\ v \\ w \\ p \\ q \\ r \end{pmatrix} \quad (22)$$

The generalized forces  $\tau$  can be divided into three components,

$$\tau = \tau_{gravitational} + \tau_{damping} + \tau_{actuators} = G(\eta) + D(\nu) + \tau_c(u) \quad (23)$$

where  $G(\eta)$  is the gravitational component,  $D(\nu)$  is the damping component,  $\tau_c(u)$  is the forces generated by the actuators and  $u$  is the input vector to the drone's motors.

The gravitational component points downwards along the z-axis with respect to the earth frame which in the body frame corresponds to:

$$G(\eta) = \begin{pmatrix} R_E^B & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 \\ 0 \\ -mg \\ 0 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} -mgs_\theta \\ mgc_\theta \sin\phi \\ mgc_\theta c_\phi \\ 0 \\ 0 \\ 0 \end{pmatrix} \quad (24)$$

where  $R_E^B$  denotes the inverse of  $R(\eta)$  as rotation matrix of the body-fixed frame relative to inertial frame.

$$R_E^B = \begin{pmatrix} c_\psi c_\theta & s_\psi c_\theta & -s_\theta \\ c_\psi s_\theta s_\phi - s_\psi c_\phi & s_\psi s_\theta s_\phi + c_\psi c_\theta & c_\theta s_\phi \\ c_\psi s_\theta c_\phi + s_\psi s_\phi & s_\psi s_\theta c_\phi - c_\psi c_\phi & c_\theta c_\phi \end{pmatrix} \quad (25)$$

The damping component is the linear matrix

$$D(\nu) = D_0\nu = \begin{pmatrix} D_{0,u}u \\ D_{0,v}v \\ D_{0,w}w \\ D_{0,p}p \\ D_{0,q}q \\ D_{0,r}r \end{pmatrix} \quad (26)$$

The forces and torques generated by the actuators are assumed to be linear in the input,

$$\tau_c(u) = u = \begin{pmatrix} 0 \\ 0 \\ u_{trottle} \\ u_{roll} \\ u_{pitch} \\ u_{yaw} \end{pmatrix} \quad (27)$$

$u_{trottle}$  is the control input of the trust force as the force affecting the velocity  $w$  in the z-direction. The force of trust gives a lifting power that makes the drone flies and depends on the sum of the speed of the four propellers. Since the rotors are fixed their total thrust will always pull upwards along the z-axis of the body frame.

$$u_{trottle} = k_f \sum_{i=1}^4 \Omega_i^2 = k_f(\Omega_1^2 + \Omega_2^2 + \Omega_3^2 + \Omega_4^2) \quad (28)$$

where  $i$  is the number of motors (propeller),  $\Omega_i$  is the speed of motor  $i$  and,  $k_f$  is thrust constant. Next, by increasing or decreasing the speed of the four rotors independently, it will create torques around the x-y-z axes and thus create roll-,pitch- and yaw-rotations. By always decreasing the speed of one rotor as much as increasing the speed of another the total thrust is retained. Therefore, the control input of roll  $u_{roll}$  and  $u_{pitch}$  are related to the torque and can be obtained by multiplying the force by the distance and the rotors will affect the total rotation about a certain axis differently depending on the distance from the center of gravity(CoG) of the drone.

$$u_{roll} = k_f l(-\Omega_2^2 + \Omega_4^2) \quad (29)$$

$$u_{pitch} = k_f l(\Omega_1^2 - \Omega_3^2) \quad (30)$$

$$u_{yaw} = k_M(\Omega_1^2 - \Omega_2^2 + \Omega_3^2 - \Omega_4^2) \quad (31)$$

where  $k_f$  is the coefficient of the force affecting the velocity  $w$  in the  $z$ -direction related to the thrust constant of the drone. Meanwhile,  $l$  is the distance between the axis of rotation of each rotor to the origin of the body reference frame which should coincide with the CoG of the drone and  $k_M$  is the moment constants, respectively.

### III. DEVELOPMENT OF APID FOR VISUAL BASED NAVIGATION

In order to maneuver the drone autonomously, based on the position and orientation of the tag marker to the drone body frame, a closed-loop control system with APID is occupied, in which its parameters are tuned by an Adjustment Mechanism (AM) [20], [21]. PID has been regarded as one of the most popular controllers in the industry because of its ease of implementation, and efficient performance [22], [23], [24]. Fig. 2 shows the control system of AprilTag navigation.

Fig. 2. Block Diagram of the Control System.

The output of AM,  $\Theta = [K_p \ K_i \ K_d]$ , is a matrix of APID parameters. The steady-State error is determined as the difference between the actual and desired position of the drone, given as follows:

$$E_r = X_d - X_a \quad (32)$$

where  $E_r = [e_{r_x} \ e_{r_y} \ e_{r_z} \ e_{r_\phi}]^T$

is the error matrix;  $X_d = [x_d \ y_d \ z_d \ \phi_d]^T$

is desired matrix;  $X_a = [x_a \ y_a \ z_a \ \phi_a]^T$

is the actual path matrix. The output of the APID is the velocity of the body frame, which is influenced by the proportion, integral, and derivative of the steady-State error. The mathematical model of the controller is expressed as follows:

$$C(t) = K_p E_r + K_i \int E_r dt + K_d \frac{dE_r}{dt} \quad (33)$$

$G(t)$  is the equation of motion for the body frame of the drone regarding the earth frame as a rigid body. The actual data is captured by the camera, which is attached to the body of the drone. Because the coordinate of the AprilTag marker  $\{t_i\}$  and the drone's body frame  $\{B\}$  does not match, a rotation

matrix is needed to align the axes of the tag marker with the axes of drone movement [25], as follows:

$$R_t^B = -R_t^B(\theta)R_t^B(\phi) \quad (34)$$

where  $R_t^B(\theta) \in R^3$  and  $R_t^B(\phi) \in R^3$  are pitch and roll rotation matrix of tag frame  $\{t\}$  to drone body frame  $\{B\}$ . Fig. 3 represents schematic of drone navigation based on tag marker.

Fig. 3. Schematic of Drone Navigation based on Tag Marker.

The parameters of APID controller are tuned in such a way to prevent overshoot to avoid drone collision and achieve it slowly. Therefore AM is introduced for tuning of APID controller, in which three rules for distances and angle have been determined. Three sets of APID parameters have been established as follows:

$$\Theta_{s1} = [0.05 \ 0.01 \ 0.009] \quad (35)$$

$$\Theta_{s2} = [0.1 \ 0.05 \ 0.01] \quad (36)$$

$$\Theta_{s3} = [0.2 \ 0.1 \ 0.02] \quad (37)$$

Table I represents the rules for AM to tune APID controllers and sets of APID parameters and related error range.

TABLE I. RULES OF AM FOR APID PARAMETERS AND ERROR RANGES

Error range	Category	PID parameters
$0(m) \leq e_{r_{x,y,z}} < 0.2(m)$	N	$\Theta_{s1}$
$0.2(m) \leq e_{r_{x,y,z}} < 1(m)$	AN	$\Theta_{s2}$
$1(m) \leq e_{r_{x,y,z}} < D_{max}(m)$	F	$\Theta_{s3}$
$ e_{r_\phi}  \leq 20^\circ$	SA	$\Theta_{s1}$
$ e_{r_\phi}  \geq 20^\circ \ \& \  e_{r_\phi}  \leq 45^\circ$	MA	$\Theta_{s2}$
$ e_{r_\phi}  \geq 20^\circ \ \& \  e_{r_\phi}  \geq 45^\circ \ \& \  e_{r_\phi}  \leq A_{max}^\circ$	WA	$\Theta_{s3}$

$D_{max}(m)$  and  $A_{max}^\circ$  are the maximum distance and angle that can be recognized by AprilTag system. Fig. 4 represents a flowchart of rules for AM to adjust the APID parameters.

The scenario of the navigation algorithm is divided into four stages. Firstly the control system is applied to uplift

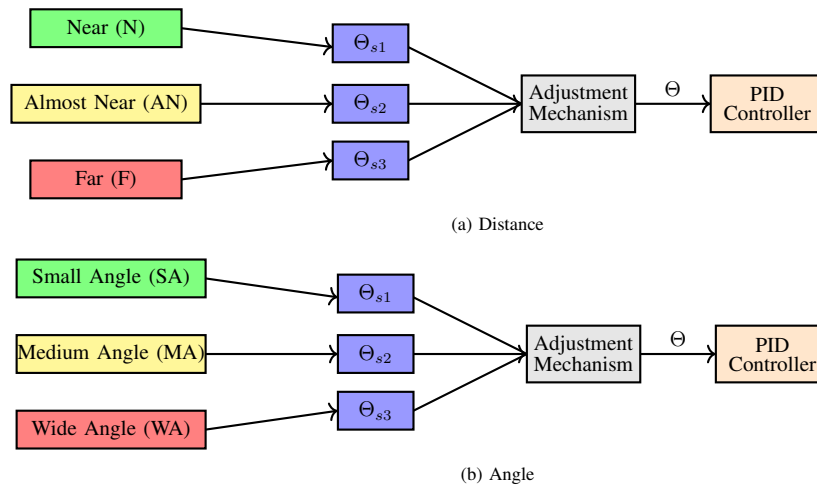

Fig. 4. Flowchart of Rules for Adjustment Mechanism.

the drone upward, z-axis. After the drone reached a certain desired height, it rotated at a yaw angle until desired tolerance error range is obtained. Then it moved to its side direction of the y-axis. The last stage is the forward direction, the x-axis. Whenever the drone carries out the defined tolerance in all the stages, the drone will be in the desired position. Algorithm 1 exhibits the pseudo-code, which is the scenario of the navigation system.  $\mu$  is the error tolerance.

**Algorithm 1** Pseudo Code of Navigation Algorithm

- 1: Start
- 2: Take off
- 3: Navigate drone in z-axis
- 4: if  $e_z < \mu_z$  :
- 5:   Navigate drone in yaw-axis
- 6: if  $e_z < \mu_z$  &  $e_{yaw} < \mu_{yaw}$  :
- 7:   Navigate drone in y-direction
- 8: if  $e_z < \mu_z$  &  $e_{yaw} < \mu_{yaw}$  &  $e_y < \mu_y$  :
- 9:   Navigate drone in x-axis
- 10: if  $e_z < \mu_z$  &  $e_y < \mu_y$  &  $e_{yaw} < \mu_{yaw}$  &  $e_x < \mu_x$  :
- 11:   Land
- 12: End

In the scenario of the navigation system, the trajectory is presented to lead the drone to reach its target point. Therefore, a desired path trajectory to the target can be predicted to avoid potential crashes. In addition, the velocity of the drone is determined as the angular velocity of the propellers that are dependent on body frame velocity,  $V^B$ .

**IV. RESULTS AND DISCUSSION**

In order to validate the navigation system, a model of the drone was created in a virtual environment called Gazebo integrated with Robot Operating System (ROS) [26], [27], [28].

To validate the performance of the tag-based navigation algorithm, a multi-target navigation strategy is utilized to move

the drone from the home point to the destination point. The multi-target navigation strategy is divided into three states. Each stage is marked by a tag with a different ID and the drone hovers in front of them before moving to the next stage. When the drone hovers in front of the first tag marker with the same procedure of hovering navigation, it rotates toward the next marker tag to face the next tag marker. This trend is followed for the next stages with different tag marker ID until the drone reach and land at the destination point. Therefore, the drone follows the defined trajectory to reach the target point without demanding the saved map in indoor/outdoor environment. Algorithm 2 represents the pseudo code of multi-target navigation.

**Algorithm 2** Pseudo Code of Multi-Target Navigation Algorithm

- 1: Start
- 2: Take off
- 3: Go forward to tag marker #1
- 4: Hover in front of tag marker #1
- 5: If  $e_x \leq \zeta_x$  and  $e_y \leq \zeta_y$  and  $e_z \leq \zeta_z$  and  $e_\phi \leq \zeta_\phi$  :
- 6:   Rotate  $90^\circ$
- 7: If  $e_\phi \leq \zeta_\phi$  :
- 8:   Go forward to tag marker #2
- 9: If  $e_x \leq \zeta_x$  and  $e_y \leq \zeta_y$  and  $e_z \leq \zeta_z$  and  $e_\phi \leq \zeta_\phi$  :
- 10:   Rotate  $-90^\circ$
- 11: If  $e_\phi \leq \zeta_\phi$  :
- 12:   Go forward to tag marker #3
- 13: If  $e_x \leq \zeta_x$  and  $e_y \leq \zeta_y$  and  $e_z \leq \zeta_z$  and  $e_\phi \leq \zeta_\phi$  :
- 14:   Land
- 15: End

Fig. 5 represents the comparison of the proposed navigation systems powered by APID and convention PID controller with constant parameters.

The results show that the navigation system enriched with APID converged faster to the target point significantly. Because it uses multiple sets of parameters for controlling based on the error range. When the error is in the F range, the drone moves

Fig. 5. Comparison of APID and PID Performance.

faster to the target than it is in N and AN ranges.

Fig. 6 shows the trajectory of the drone in  $x$  and  $y$  direction from the home point to the target point. The drone took off in the home point moved forward to tag #1, hovered in front of it, then rotated to the second tag. Similarly, the drone moved to the destination point.

Fig. 6. Multi-Target Navigation.

The trajectory error and APID parameters changes are represented in Fig. 7 and 8, respectively.

In Fig. 8, it is represented that if the error is in the range of each set, the adjustment mechanism sets the set of parameters for the APID controller. For instance, in Fig.

8a between starting and 2.6s the APID parameters are the first parameters set,  $\Theta_{s3}$ , because the error is more than 1m. Subsequently, when the error is between 0.2m and 1m, from 2.6s to 3.16s,  $\Theta_{s2}$  is set. Finally, after 3.16s until the drone reached the target, the APID parameters follow  $\Theta_{s1}$ . In Fig. 8b, the switching time for APID parameter sets are 0.36 s and 1.57s. Furthermore, in Fig. 8c, at 4.46s the APID parameters turned from  $\Theta_{s3}$  to  $\Theta_{s2}$ , and it turned to  $\Theta_{s1}$  at 4.94s, when the error reduced from more than 1m to less than 1m and then decreased to less than 0.2m, respectively. In Fig. 8d, the turning times for APID parameters are 0.8s and 2.7s based on the ranges of the error shown in Fig. 7d. By considering the turning times, it can be obvious that turning times are in ascending order. The first turning times are 0.39s, 0.8s, 2.64 s, and 4.46s, for  $y$ , yaw,  $x$ , and  $z$  direction, respectively. Similarly, the second turning times are 1.57s, 2.7s, 3.16s, and 4.46s, for the  $y$ , yaw,  $x$ , and  $z$  direction, respectively. This mimics the scenario of the navigation system as shown in Algorithm 1.

## V. CONCLUSION

The paper presented a visual navigation system for an autonomous drone that hovers and navigates by using tag marker position and orientation autonomously. The kinematic and dynamic models of a drone have been determined by Newton- Euler. Moreover, AprilTag marker tag was introduced to obtain the position and orientation of the drone.

The results showed the navigation system using APID controller performed four times faster than the navigation system powered by the conventional PID controller. In addition, it demonstrated higher accuracy and reliable performance of the algorithms to accomplish various designed trajectories.

Besides its reliability and accuracy, one of the APID's advantages is less computational time rather than complex and memory consumable controllers. In addition, the tag navigation system and APID utilized an onboard camera available and usable for the light drones that cannot carry heavy sensors

Fig. 7. Trajectory Error based on the Camera Frame.

Fig. 8. Changes of the APID Controller's Parameters.

such as laser sensor for navigation and localization. Although it can be ascertained that the proposed method is efficient, there are some limitations. For instance, in an outdoor environment, the shininess of the tag marker can affect the view of the camera and navigation system. Moreover, the tag marker should be in the camera view for the drone to follow the desired trajectory. In future work, fuzzy and adaptive control systems can be investigated for visual-based navigation. In addition, this proposed algorithm can be validated for drone

navigation based on a laser sensor.

#### ACKNOWLEDGMENT

The authors would like to thank Universiti Kebangsaan Malaysia (UKM) and the Ministry of Higher Education Malaysia for the financial support received under research grant KK-2020-014 and TAP-K014062.

Facultad de Ingeniería, Universidad Privada del Norte, Lima, Perú<sup>4</sup>

**Abstract**—Currently, the logistics process is an important part for any company because it helps to manage the assets and products that enter and leave it. Some companies carry out this process physically, saving the information on sheets of paper or Excel files, which takes longer to do and is not at the forefront of how companies do it, which is by using mobile applications to improve this process. Likewise, it has been decided to implement a mobile application with the aim of improving the logistics process in the Callao No. 15 fire company. For the elaboration of the application, the RUP methodology was used to do it in a more optimal way, in the end, a survey of experts in Google Forms was conducted, addressed to 10 experts to know the evaluation of the mobile application. In the end, a favorable result was obtained from the opinion of the experts on the mobile application; 70% of the respondents indicate that the usability of the mobile application has a “Very high” level; it can be seen that 80% of respondents indicate that the presentation of the mobile the application has a “Very high” level; it can be seen that 90% of the respondents indicate that the functionality of the mobile application has a “Very high” level; besides, it can be seen that 80% of the respondents indicate that the security of the mobile application has a “Very high” level.

**Keywords**—Fire company; logistics process; mobile application; RUP methodology; expert survey

## I. INTRODUCTION

From previous years to the present, in the fire company No. 15 of Callao they do not adequately apply the processes to be able to have an order in the logistics process. We found the inventories carried out by the firefighters themselves, since they have not defined how to carry out an entry and exit process in an inventory in the general services area. At the time of carrying out the inventory, the person in charge uses paper and a pen, in which he indicates the assets that belong to the company, and then passes it digitally to a program to be able to save, said program is called Microsoft Office Excel Spreadsheet. Although it is true that papers are used, this happens many times that these papers are lost, in the course of being digitized to the computer, causing loss of time, since everything has to be done again, which generates discomfort and dissatisfaction for part of the heads of the company and the areas, since they all work with the window to be able to be guided by where each element, object or object is located, since the company's warehouse is small, so they are also stored in other environments. In the program used in the company, when more than 500 articles are entered, the program is slow, since the computer is not prepared for this storage capacity. It

is also observed that everything is disordered in the program, showing a disorder by areas.

According to the authors Rasheed et al. [1], indicate that the World Health Organization (WHO) has decided to optimize its supply chains so that losses are lower in the medicines it has. In addition, the solution that was applied for this case was the development of a logistics software to control the medicines in its warehouse. Although the WHO in 2005 had already used software for this case, they decided to use more updated software. On the other hand, this new software has facilitated the logistics of medicines due to how friendly the system is, being faster, more efficient and safer.

On the other hand, the authors Bernal et al. [2], tells us The recommended solutions meet current and emerging needs in an agile B2B or B2C e-commerce environment. Rather, suppliers and customers offer and demand mobility, storage and customs services for the products it offers. In this case, your goal is to ensure that your logistics processes have added value from the beginning to the end of the business processes in the trade. On the other hand, this will also generate more profit for the companies that use them.

According to Pekarckikoba [3], when today's software and digital tools are used, the result is more efficient, taking less time to execute and giving a more optimal result. Furthermore, these tools have standards, are transparent and reduce unnecessary work. Rather, the modeling that was implemented and the e-kanban test when it was commercialized increased the efficiency of logistics in its processes. On the other hand, this model can be used as a digital solution for business processes.

Besides, the authors Fedorko et al. [4], suggest that the use of for the logistics of the company optimizes the storage of the products it offers in the warehouses. The objective is to reduce the time needed to collect the orders that the company's customers have made. Although the logistics processes have been optimized to cover various needs of the production processes in the warehouse. On the other hand, with the optimization of logistics, a time saving of 48 minutes and 36 seconds has been achieved.

The author Zhao [5], the goal is to find key points that affect customer satisfaction and warehouse utilization to achieve time reduction and minimize system congestion. In addition, a method called Box-Behnken was used to optimize and increase the speed of classification, distribution, storage through software. However, this method has parameters such as the speed of classification, distribution and storage capacity to

optimize the logistics of companies. Rather, when this method was used, a better response was obtained in the company's logistics system in terms of distribution and storage, achieving it in less time.

This project is carried out for the Callao No. 15 fire company, which will be implemented in the general services area, who is in charge of the logistics process, in this case inventories. This project is being carried out in order to optimize time and so that physical paper cannot be used, in which case it could be lost in the process of typing it into a computer. It will be done through a system, with the URP methodology which helps us to carry out the designs, programming, training, etc. This project is important, since with this you can improve the fire company, in the case of making everything more didactic and easy on the subject of inventories and thus make a digital transformation. The problem that is being solved is the losses and delays caused by doing everything on physical paper. The positive repercussions for this project is that they can be motivated to continue with the digital transformation in the different areas of the fire company. The negative repercussions of this project is that there will be people who will not want to adapt to new technologies and stay with the old as they are used to.

The people who are going to benefit from this project are the chief of general services, the deputies, and the first chiefs of the fire company, as well as all the firefighters, since they could also use it throughout their firefighter career.

The objective of this project is to facilitate logistics process for the fire company Callao No. 15, ordering the products that are used, the products that arrive, with the detail data of each product and secure the data through a mobile application design.

The article has the following structure: In Section II the literature review, in Section III establishes the Rup methodology, in Section IV the results, in Section V the discussions and finally Section VI with the conclusions and work future

## II. LITERATURE REVIEW

In this section of the article, emphasis was placed on the analysis of the research carried out on the subject of logistics software, where it will be seen what methods have been used and what their results were.

The authors Angolia and Pagliari [6], in this case a simulation is described in the dynamic environment for logistics decision-making with software. In addition, strategies for sales and operations were used to improve logistics and the supply chain in the company's inventory. On the contrary, this software helps to comply with the weight regulations that the products must have for the carriers. On the other hand, logistics software generates a great advantage for the recruitment of employees by the company.

The authors Byun et al. [7], take into account that the use of mobile applications in the logistics field called logistics in life. In addition, this sector has been used for mobile applications, which outperform traditional logistics companies. Likewise, the goal of this research is to measure whether these apps comply with the rules of use to satisfy users through measurement and evaluation. Specifically, evaluations of the

use of apps in Korea and other countries were carried out through the analysis of Big Data.

According to the author Nuanmeesri [8], this work has developed a mobile supply chain application for a window with a goal of marketing, distribution of products and logistics in agriculture and consumption according to the economic guide of Thailand 4.0. In addition, this work on the delivery supply chain of agricultural products focuses on trade, delivery and logistics using algorithms to find delivery routes for the products. Also this app fits the distribution of products, supply chain in an economy that is based on values. As a result, the mobile application has resulted in its effective use for the distribution of agricultural products in the supply chain in trade, distribution and logistics regarding Thailand 4.0.

The estimation of data on the reuse of waste by means of special statistical software and using the principles of logistics. Furthermore, such research goes beyond the research called "Environmental Assessment of Waste Recycling Based on Logistics Principles and Computer Simulation Design", which creates a succession of data that must be examined and evaluated separately. Likewise, these data that symbolize 15 classes of waste for 5 years, enter the analysis. As a result, the classes of waste that form a large part of the final manufacture of waste were located through descriptive statistics [9].

According to authors Ahmad and Bamnote [10], it informs us that software cost estimation (SCE) is an emerging concern for software companies during the software development period, because it asks for elements of effort and cost to create the software. In addition, these elements are created using Artificial Intelligence models, which can be less accurate and less reliable by increasing the risk factor of software projects. Said investigation. Also, this research proposed an algorithm whose function is to develop a model to optimize the price of the software. Since this research used a set of data collected from a software engineering database to run an effective performance study.

According to the authors Naseer et al. [11], tells us that Software engineering is a professional field in terms of education and practice. Software projects are key elements of software engineering courses. The goal of this project is to forecast the teams that are expected to achieve an evaluation that is not above average in the production of software products. The proposed method that stands out among the others in the forecast of teams that have a low performance in a phase of premature appreciation. The proposed method supported by J48 stands out from others by conceiving 89% correct forecasts.

The authors Garnov et al. [12], the reason for this research is to evaluate the effects of the digitalization method of cargo and logistics provision in the agriculture of the country of Russia. In addition, a technique has been used that handles information from Rosstat, GooglePlay provision and Yandex.Radar provision as information source. Likewise, this work reveals that one of the important trends in the field of freight transport is the use of technologies, such as transport and warehouse management systems, to automate the trading methods of carriers with mobile applications for shipments. and product orders. In conclusion, this digital system will connect all market users and increase the transparency and

traceability of freight transport.

The authors Rajabizadeh and Rezghi [13], the automated search for snake portraits will be able to help avoid venomous snakes and also offer an excellent method for patients. Also, in this work, k-nearest neighbors, support vector machine and logistic regression techniques are used in combination with principal component analysis and linear discriminant analysis as the feature extractor. Furthermore, this research shows MobileNetV2 as an effective deep neural network algorithm for snake portrait categorization that you can use even on mobile devices. Ultimately, this discovery shortens the path to creating mobile applications for the search for snake portraits.

Social networks today play a very important role in disaster response by locating needs in a short period of time and, therefore, optimizing situational awareness. In addition, this research aims to increase interest in a reserved search book to qualify this feature. Also, an overview chart is shown to check if it is feasible to act on the data created by the users before their review of the logistics planning of disaster replication. In conclusion, this research is adjustable to a diversity of logistics organization difficulties, this research shows its handling by means of a mobile delivery application of disaster replication basic goods [14].

The authors Barbosa et al. [15], the applied sciences of portraiture have increased to a significant horizon in recent years, used in different branches of research, such as those focused on the search for plants. Also, in this research, HerbApp, a mobile application that is used to separate herbal plants from non-herbal ones, is shown in order to spread the knowledge among people about the importance of plants. Likewise, other plant traits and traits are used to do pattern finding and data analysis. In conclusion, the experiences show that guidance facilitates efficient results.

In conclusion, to improve the logistics process of the Callao N°15 fire company, it is necessary to stop using Microsoft Excel as a database and start using a mobile application for this process, thus storing the data of the products that are used and the products that are used. The gap found is that there is still a lack of the use of emerging technologies that allow optimizing its processes.

### III. METHODOLOGY

In this section, the methodology that was used to develop and implement the mobile application for the Callao N°15 fire company, which is the object-oriented methodology called Rational Unified Process (RUP).

#### A. Processes of the RUP Methodology

According to the author Tia [16], RUP, as shown in Fig. 1, is a methodology for making software used by software companies. Likewise, there are different types of RUP software projects, which are small scale, large scale and re-engineering, which have needs and uses for each role. In addition, in this methodology there are different roles that one person cannot do because they work at the same time. In conclusion, the objective of the RUP methodology is to be able to develop high-quality software that meets the expectations of users and customers.

Fig. 1. Methodology RUP (Rational Unified Process).

In Fig. 2, it indicates that they have six processes (business modeling, requirements, analysis and design, implementation, test, deployment). It is a software engineering process that provides an orderly approach to the assignment of tasks and commitments in a software development company.

Fig. 2. Processes of the RUP Methodology.

#### B. Prototype Tools:

1) *Bizagi Modeler*: It is a Platform that consists of three components. Each of them facilitates a key step in the transformation and automation of your business processes. According to the author Germanía [17], Bizagi is a software for the representation of processes through sketches, structures, trade rules, actors. Likewise, the moments of the work process between their tasks are published, the time it takes for each task and the process are shown. Furthermore, the phases of Bizagi software development are modeling, building and process execution. In conclusion, the Bizagi software is very important when carrying out a process improvement [18], because it details what the process is like and what parts can improve to optimize the process.

2) *Star UML*: It is a software modeling tool based on the Unified Modeling Language (UML) and MDA (Model Driven Architecture) standards. The authors Naing et al. [19], Star UML is software for developing a fast, flexible, extensive,

full-featured and freely available Unified Modeling Language platform. It also uses UML for software design, uniting the notorious approaches to detailing organization and behavior. In addition, it is excellent in characterization for the user’s environment and has greater extensibility in its functions. In conclusion, Star UML is used to create detailed process diagrams in the UML language.

3) *Figma*: According to the author Arifin et al. [20], Figma is a prototyping interface layout program that runs on a web page via a browser. Likewise, said page layout program, but it is actually considerably more than that. In addition, this program can make software prototypes for computers, cell phones and tablets. In conclusion, the author’s final opinion about Figma is surely the best program for developing layout projects collaboratively as a team.

C. Development Tools:

1) *C#*: It is a component-oriented object-oriented programming language. According to the author Jankowski et al. [21], C# is an object-oriented, type-safe programming language. Likewise, it allows developers to establish several types of consistent and secure apps that run in the environment. In addition, it has its foundations in the C language group and will subsequently involve a group for C, C++, Java, and JavaScript developers. In conclusion, C# is a language that can be used for both desktop and mobile applications.

2) *Microsoft Visual Studio*: The Visual Studio IDE is a creative launch pad that you can use to edit, debug, and build code, and then publish an app. According to the author Hrabovskiy [22], Microsoft Visual Studio is an IDE (Integrated Development Environment) developed by the Microsoft company for software development. Likewise, it is available for OS (Operating Systems) such as Windows, Linux and macOS, not counting free and paid versions. In addition, it has compatibility with programming languages such as C++, C#, Visual Basic .NET, F#, Java, Python, Ruby, and PHP. In conclusion, Microsoft Visual Studio is an integrated development environment for making desktop, web, and mobile software.

3) *Microsoft SQL Server*: In this section was development of the six processes of the RUP methodology to know what steps the mobile application has followed to improve the inventory logistics of the Callao No. 15 fire company.

D. Development Methodology

In this section was development of the six processes of the RUP methodology to know what steps the mobile application has followed to improve the inventory logistics of the Callao No. 15 fire company.

In the Canvas model, it will be described how the mobile application is constituted in all aspects to know what objective it wants to achieve with its implementation.

1) *Requirements*: As shown in Table I and Table II, an interview was conducted with the client to find out the requirements that the mobile logistics application will have so that it works as the fire company wants. In the functional requirements table it will be shown what functions the logistics mobile application will have.

In the non-functional requirements table it will be shown how the logistics mobile application will work.

TABLE I. FUNCTIONAL REQUIREMENT

Non-functional requirement	Requirement Description	System Use Case	System Use Case Description
RF001	Register product	CUS001	Manage check-ins and check-outs
RF002	Search product	CUS001	Manage check-ins and check-outs
RF003	Modify product	CUS001	Manage check-ins and check-outs
RF004	Delete product	CUS001	Manage check-ins and check-outs
RF005	Consult product	CUS002	Operability of tools, accessories
RF006	Observe product status	CUS002	Operability of tools, accessories
RF007	Modify product status	CUS023	Operability of tools, accessories
RF008	Browse product	CUS003	Manage Location
RF009	Observe product location	CUS003	Manage Location

TABLE II. NON-FUNCTIONAL REQUIREMENT

Non-functional requirement	Requirement Description	Classification	Priority
RNF01	The response time for patient search of 8 seconds	Response Time and performance	High
RNF02	Access will be for authorized users only	Security	High
RNF03	User-friendly design and interface	Usability	High
RNF04	Navigability between fields and interface components (tab key, enter)	Usability	High
RNF05	A specific system function will be accessed based on your role	Security	High
RNF06	The application can support changes in its functions	Maintainability	High

2) *Analysis and Design*: As shown in Fig. 3 to Fig. 11, see how the logistics process of inventories works through the graphics made in Bizagi and StarUML, you will also see the design of the mobile application through a prototype.

Fig. 3. Business Process Diagram.

In Fig. 3 is observed business process diagram will describe

in detail the logistics process of the business product company, which will describe how the process is carried out and who is involved in it.

In Fig. 4 shows the use case diagram of the system, it show

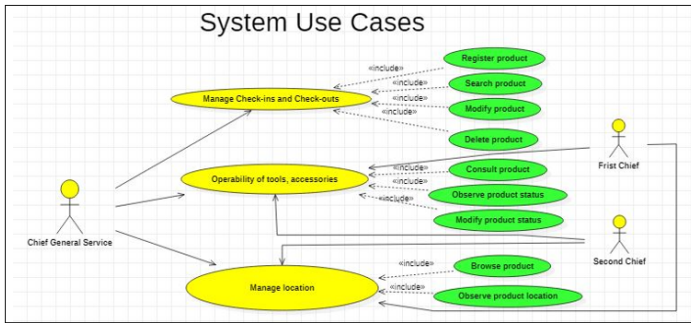

Fig. 4. System Use Case Diagram.

what functions the mobile application must have according to what the fire company requires and needs for its logistics process.

In Fig. 5 shows the input and output activity diagram, that

Manage Check-ins and Check-outs

Fig. 5. Input-Output Activity Diagram.

the mobile application performs for the input or output of the products involved in this process.

In the operability activity diagram you will see the steps that the mobile application performs to see the outputs operability of the products involved in this process.

In the location activity diagram see the steps that the mobile application performs to see the location of the products involved in this process.

In the input sequence diagram, see how the user interacts with the mobile application when they input a product to the fire company.

In the output sequence diagram, see how the user interacts

with the mobile application when it outputs a fire company product.

In the sequence of operation diagram, look like the user interacts with the mobile application when needed to view the location of a fire company product.

In the operability sequence diagram it will be seen how the user interacts with the mobile application when he needs to see the location of a fire company product. In Fig. 6 shows

Fig. 6. Class Diagram.

the class diagram, it describes how the mobile application database is composed with its respective attributes and operations that each table contains.

(a) Star (b) Login

Fig. 7. Prototype Start and Login.

3) *Implementation:* The final design of the mobile application interfaces made in the Visual Studio IDE will be observed.

4) *Tests:* It will be observed how the inventory logistics mobile application works.

(a) New user (b) Menu

Fig. 8. Prototype New User and Menu.

(a) Outputs (b) Operability

Fig. 10. Prototype Outputs and Operability.

(a) Inputs - outputs (b) Inputs

Fig. 9. Prototype Inputs - Outputs and Inputs.

Fig. 11. Prototype Location.

5) *Deployment*: It was observed how the logistics mobile application will be executed on the mobile devices of the employees of the fire company.

#### IV. RESULTS

This section show the results of the case study, such as the RUP methodology, which was used in this work.

##### A. About Expert Judgment

As indicated in Table III, for this part a survey of experts was carried out in order to know how the experts feel with the implementation of the mobile application in the fire company,

dividing them into four criteria. which are usability, presentation, functionality and security. It was made with the likert scale from 1 to 5, where 1 is very low to 5 is very high.

The expert opinion table will show the survey that was done to each expert and what each one answered regarding the logistics mobile application.

1) *Usability Criteria*: Interpretation: From Table IV. It can be seen that 70% of the respondents indicate that the usability of the mobile application has a "Very high" level. In other words, there is 70% of those surveyed who reaffirm a very positive position and 30% consider it "High".

2) *Presentation Criteria*: Interpretation: From Table V. It can be seen that 80% of the respondents indicate that the presentation of the mobile application has a "Very high" level. In other words, there is 80% of those surveyed who reaffirm

TABLE III. EXPERT JUDGMENT

Criterion	Question	Half	Standart desviation	Scale
Usability	1. You feel that you are satisfied with the ease of use of the mobile application.	4.30	0.83	High
	2. You feel that you are comfortable with the use of the mobile application.	4.20	0.79	High
	3. You feel that the use of the mobile application is simple.	4.50	0.71	High
	4. You feel that using the mobile application you will complete your tasks in less time.	4.10	0.74	High
	5. You feel that using the mobile application you will complete your tasks more optimally.	4.50	0.71	High
Presentation	6. The mobile application interface is user friendly.	4.50	0.71	High
	7. The mobile app interface is well organized.	4.30	0.82	High
	8. The mobile application interface represents the image of the company.	4.30	0.82	High
	9. The colors of the mobile application interface have contrast with each other.	4.50	0.71	High
	10. The images of the interface help to understand what the functions of the mobile application are.	3.70	0.68	High
Functionality	11. The functions of the mobile application meet the needs of the user.	4.50	0.71	High
	12. Each functionality of the mobile application is properly located.	4.60	0.70	High
	13. The functions of the mobile application are understandable for the user.	4.00	0.94	High
	14. Mobile app features improve the way you get things done.	4.80	0.42	High
	15. The functions of the mobile application is adequate for this area.	4.50	0.53	High
Security	16. The mobile application is more secure allowing entry to only registered users.	4.50	0.53	High
	17. The mobile application protects the integrity of the information.	4.40	0.52	High
	18. The mobile application gives reliability to the information.	4.20	0.63	High
	19. The mobile application is safe for users.	4.60	0.52	High
	20. Mobile app security optimally protects data.	3.80	0.79	High

TABLE IV. USABILITY

		Usability (Bundled)			
		Frequency	Percentage	Valid percentage	Accumulated percentage
Valid	High	3	30,0	30,0	30,0
	Very high	7	70,0	70,0	100,0
	Total	10	100,0	100,0	

a very positive position and 20% consider it "High".

3) *Functionality Criteria:* Interpretation: From Table VI. It can be seen that 90% of the respondents indicate that the functionality of the mobile application has a "Very high" level. In other words, there is 90% of those surveyed who reaffirm a very positive position and 10% consider it "High".

4) *Security Criteria:* Interpretation: From Table VII. It can be seen that 80% of the respondents indicate that the security of the mobile application has a "Very high" level. In other words, there is 80% of those surveyed who reaffirm a very positive position and 20% consider it "High".

### B. About the Case Study

The mobile application has in its design 9 interfaces for its elaboration, operation and implementation for the fire company to improve its logistics process, which are:

- Star: It is the presentation of the software with the logo of those who carry it out [Fig. 7(a)].
- Login: It is the interface that will allow the registered user to enter a username and password registered in the application [see Fig. 7 (b)].
- New user: It is the interface that allows new users to register to have access to the mobile application [Fig. 8(a)].
- Menu: It is the interface that allows the user to see and access the functions of the mobile application [Fig. 8(b)].

- Inputs - outputs: It is the interface where it shows the functions that can be accessed and they are to input products and output them [see Fig. 9(a)].
- Inputs: It is the interface that allows the user to register a product through their data, which are names, description, stock, color, code and location see [Fig. 9(b)].
- Outputs: It is the interface that allows the user to exit the products that are no longer needed by means of their name and the reasons for which they are exiting [see Fig. 10(a)].
- Operability: It is the interface that allows the user to know and modify the operability of the product through its name [see Fig. 10(b)].
- Location: It is the interface that allows the user to know where it is located by means of its name (see Fig. 11).

### C. About the Methodology

- Benefits: The benefits of the RUP methodology are:
  - Encourages reuse of software code.
  - Reduce the difficulty of maintenance by making it easy to improve the changes that can be made and add more features to the software.
  - It makes it easy to reuse some functions of the software for other projects.
  - Maintenance is easier to perform using this methodology.
  - It can be applied to different software to make them of quality.

TABLE V. PRESENTATION

<b>Total</b>	22	24	16

- Comparison: As indicated in Table VIII, in this part you will make a comparison between the RUP, SCRUM and XP methodologies, this comparison will be made through 5 criteria that the methodologies have. The rating will be from 1 to 5, with 1 being very poor, 2 being poor, 3 being fair, 4 being good and 5 being excellent.

## V. DISCUSSIONS

The mobile application made in comparison to the prototypes the author Nuanmeesri [8], which is a mobile application for the logistics of agriculture and its consumption, whose function is used in the distribution of agricultural products to find routes for supply from the farms to its destination where it is marketed, instead the mobile application for the fire company apart from knowing the location of the products that enter and leave the fire company, you can know the state in which they are find the product and that can avoid mishaps when using it. Also, in the aspect of the function of the mobile application of the authors Garnov et al. [12], has the objective of managing the process of transport and warehouse logistics by automating this process through the use of technology for the processes of shipments and orders of products offered by Russian agriculture, a similar case to the one that has the fire department application that is being implemented for the logistics process for the fire company that also has the

same functions, but the information that is handled in the fire company is from its own database, otherwise it is the of the aforementioned authors who used information from other databases that are not their property but from other agencies or applications such as Rosstat, Google Play and Yandex.Radar, generating satisfaction in both cases for the users to whom it is addressed. Also take into account the security that you must have in the logistics part [23].

## VI. CONCLUSIONS AND FUTURE WORK

The conclusions of this article are that by using the mobile application it helped to improve the logistics process of the fire company, reducing the time in which said process is carried out and helping to organize the products that are inside the warehouse the company. Likewise, the RUP methodology is suitable for developing and implementing mobile applications, software and other technologies, related to logistics or sales of many companies that want to optimize and automate their processes to compete in the current market, these types of technologies being mandatory have the companies to grow more in the area in which it works. The expert judgment carried out for this mobile application has given an affirmative response to the implementation of the mobile application for logistics processes because its rating was always high or very high regarding the criteria in which the mobile application was rated. In conclusion, in the future, the RUP methodology should be used to create software related to logistics and sales, using mobile applications, software or other technologies to optimize company processes digitally, leaving behind the sheets and Excel files that they generate. an unnecessary waste of money and time for the company, preventing it from competing in the current market.

**Abstract**—In this paper, we propose an approach to early detect students at high risk of drop-out in MOOC (Massive Open Online Course); we design personalised interventions to mitigate that risk. We apply Machine Learning (ML) algorithms and data mining techniques to a dataset extracted from XuetangX MOOC learning platforms and sourced from the KDD cup 2015. Since this dataset contains only raw student log activity records, we perform a hybrid feature selection and dimensionality reduction techniques to extract relevant features, and reduce models complexity and computation time. Besides, we built two models based on: Genetic Algorithms (GA) and Deep Learning (DL) with supervised learning methods. The obtained results, according to the accuracy and the AUC (Area Under Curve)-ROC (Receiver Operator Characteristic) metrics, prove the pertinence of the extracted features and encourage the use of the hybrid features selection. They also proved that GA and DL are outperforming the baseline algorithms used in related works. To assess the generalisation of the approach used in this work, The same process is performed to a second benchmark dataset extracted from the university MOOC. Then, a single web application hosted on the university server, produces an individual weekly drop-out probability, using time series data. It also proposes an approach to personalise and prioritise interventions for at-risk students according to the drop-out patterns.

**Keywords**—MOOC; drop-out; dimensionality reduction; features selection; personalised intervention

## I. INTRODUCTION

Following the emergence of new digital technologies aiming to modernize the traditional education system. Massive Open Online Courses (MOOCs) have gained popularity in recent years [1]. In 2020, 16,300 courses were offered by 950 universities, and the number of enrollment has reached more than 180 million learners worldwide [2]. MOOCs have become an ideal source of self development that bridges the gap between industry requirements and skills acquired in the university [3]. Despite these benefits that bring a substantial improvement to the student learning experience. MOOCs are facing many problems today. Among the most cited are the high drop-out and the low completion rate. The average completion rate for a MOOC is 12.6% [4]. We can also cite the weak interactions and the absence of tutor support to the significant number of enrolled participants. This excessive attrition rate in MOOCs, has prompted researchers to consider the use of learning analytic for early prediction of learners at risk of drop-out [5].

Learning analytic consists of analysing the log trace and the data collected while students interact with the MOOC courses

[6]. Then, using supervised machine learning, mathematical models can automatically detect student at-risk of drop-out based on their previous behaviour and interactions during the course. The use of learning analytic has shown an encouraging potential and reduced visibly the attrition rates in MOOCs [7], [8]. However, it is limited, given the enormous number of enrolment either by 1) the late detection of students at-risk, by 2) the absence of prioritization which will considerably reduce the number of students that the instructor must address each time. Finally 3) the prediction models provide no clues for the monitor to propose a personalized intervention for each droppers pattern. Thus, a system that is capable of detecting at-risk students and providing a customised intervention is therefore needed.

The aim of this paper is to build an intelligent system using DL and GA in the field of learning analytic, and able to overcome these three limitations. This paper will describe the process followed to address the problem related to early prediction student drop-out, prioritizing student needing intervention according to a weekly temporal model prediction based on student drop-out probability. In the light of the obtained results, a timely personalized intervention can be designed and delivered to retain students at-risk. The obtained system gives the possibility to meet the challenges of identifying on a large scale students at high risk of dropping- out, while also satisfying the requirement to be able to support early intervention.

This paper is organised as follows: the next section present a brief overview of related work. The Section 4 is devoted to describe the different components of the used dataset and the extracted features. Section 5, is dedicated to presenting the methods used to predict student drop-out. Section 6, is dedicated to discussing the obtained results. Finally, we conclude the paper and give some perspectives on future work.

## II. RELATED WORK

Many researchers have recently focused on MOOCs student drop-out. Time consideration is very significant when tackling this problem. Early detection plays a masterful role in reducing the attrition rate. In fact, several studies have proved that 75% of drop-outs occur in the first weeks [9]. Similarly, Gitinabard et al. [10] analyse students logs and forum data of an annual MOOC lessons. They apply Logistic Regression and Support Vector Machine (SVM) to predict drop-out in the first weeks of each course. The students were flagged as drop-out with the precision of 70% after the third

week. Berens et al. [11] developed an early predicting system using demographic data and a boosting algorithm combining several ML algorithms: Linear Regression, Neural Network, Decision Tree, AdaBoost. The system provides an accuracy of 58.2% for the first semester and 81.5% for the fourth semester. Authors in [12] used deep learning and achieved an accuracy of 0.92% in the first week. In [13] ALJ et al. used several baseline machine algorithms and obtain an AUC ROC score of 90%. The performance of machine learning algorithms highly depends on the used dataset used. ML algorithms are unable to provide effective parameter setting method. Therefore, feature selection of parameters is another research content of this paper. A hybrid features selection method is proposed. Besides, Genetic Algorithms (GA) are used for parameters tuning.

GA are generally used for optimization problems and tuning classifiers in multiple fields such as emotion recognition [14] and medicine [15], and feature selection [16]. Despite GA are not quite used in the field of student drop-out, they are producing significant results.

This study contributes to the current state-of-the-art of the field in two main directions. First, by developing a comprehensive approach for studying and detecting early drop-out in a data perspective. Second, by designing a prioritized and personalized intervention for student at-risk of drop-out.

### III. DATA

#### A. Data Description

This study use a dataset provided from KDD cup [17], an annual Data Mining and Knowledge Discovery competition organised by ACM Special Interest Group. In KDD cup 2015, the dataset used in the competition contains users trace log extracted from XuetangX which is one of the biggest Chinese MOOC learning platforms. The aim was to predict users drop-out using different data mining techniques and machine learning algorithms.

The detailed description of the five parts of dataset is as follows:

- 1) The first part of the dataset contains information about the start and the end date of each course according to the Table I.

TABLE I. COURSE INFORMATIONS

Fields	Type	Description
Course-ID	Nominal	Course Identifier
Course-S	Date	Course Starting Date
Course-E	Date	Course Ending Date

- 2) Information about the modules of each course, sub-modules and also the category of modules and their start date according to the Table II.

TABLE II. MODULE INFORMATIONS

Fields	Type	Description
Course-ID	Nominal	Course Identifier
Module-ID	Nominal	Module Identifier
Module-cat	Nominal	Module Category
Module-child	Nominal	Sub-Module
Module-S	Date	Module Starting Date

- 3) Informations about enrolments: an enrolment is a (Student, Course) entry according to the Table III.

TABLE III. ENROLMENT INFORMATION

Fields	Type	Description
Enrolment-ID	Nominal	Enrolment Identifier
Student-ID	Nominal	Student Identifier
Course-ID	Nominal	Course Identifier

- 4) The fourth part of the dataset contains a log trace of every enrolment, log timestamps, and the source and the type of the event according to the Table IV.

TABLE IV. LOG INFORMATION

Fields	Type	Description
Enrolment-ID	Nominal	Enrolment Identifier
Student-ID	Nominal	Student Identifier
Course-ID	Nominal	Course Identifier
Event-Time	Timestamps	Time when the event occurs
Source	Nominal	Source of Event (Server / Browser)
Event	Nominal	e1 Problem
		e2 Access
		e3 Video
		e4 Wiki
		e5 Discussion
		e6 Navigate
		e7 Page Close

- 5) The last part of the dataset contains information about the real value of enrolment result according to the Table V

TABLE V. ENROLMENT RESULT

Fields	Type	Description
Enrolment-ID	Nominal	Enrolment Identifier
Result	Boolean	0 Success
		1 Drop-out

The dataset captures a trace log of 79186 students and 120543 enrolment, because every student can enrol in multiple courses. If a user leaves no records for course C in the log during the next 10 days, it is defined as drop-out from the course.

We notice that for all courses the drop-out represented by 1 in the table of enrolment results exceeds 65%. The majority class is drop-out with (95581) 79% compared to success (24961) 21% of enrolments. In this case, a class imbalance problem is faced. In order to balance the dataset, we will oversample the minority class in order to increase its cardinality to be equal to the majority class.

Oversampling: this technique duplicates copies of some points from the minority class to increase its cardinality to be equal to the majority class. New samples can be generated by random repetition or using more sophisticated methods such as SMOTE or ADASYN.

Synthetic Minority Oversampling Technique (SMOTE) [18] uses the KNN algorithm to generate new synthetic data points that combine features of the data point and its K closest neighbours. However, it still has some weaknesses regarding the oversampling logic used. On the one hand, it does not consider generating new samples from neighbours which may come from the other class. The synthetic observations can overlap with other observations of the majority class. On the other hand, generating multiple synthetic observations risks introducing additional noise in the dataset, this could potentially bias the model.

ADASYN [19] for Adaptive Synthetic, a version of SMOTE that has been improved. Instead of generating the same number of synthetic observations for each observation of the minority class, ADASYN adapts the oversampling to the distribution density of the observations of the minority class. Concretely, it produces more synthetic samples in regions of feature space where the density of minority observations is low and fewer samples in regions with higher density.

The selection of the technique to use remains strictly linked to the data set used. For our example, SMOTE gives better results. Finally, we end up with two datasets Unbalanced Dataset (UB) and Balanced Dataset (BD).

### B. Feature Engineering

The information available on the KDD cup 2015 dataset lacks personal information (e.g. age, sex, nationality) and information regarding the course (e.g. prerequisites, difficulty level). The logging trace remains the most potent source of information. Our feature extraction method is based on counting the log of every enrolment; an enrolment is a (student, course) entry. The extracted features can be divided into two parts:

**Enrolment History Features :** It contains features about the history of interaction with the MOOC, such as the number of successful courses, the number of failed courses, the cumulative number of days spent on the MOOC during old registrations, and the cumulative number of logs of each event present on the catalogue in Table IV.

**Current Enrolment Features:** It contains features about the number of days spent on the MOOC during the current enrolment and the count of logs of each event.

We also extract the count of minutes spent for every enrolment; after examining the log trace, we notice that all sessions start with the **Navigate** event and sometimes with the **Access**. We calculate the difference of time expressed in minutes between one of the two events and the end of the session expressed with the **Page\_close**. The accumulation of minutes is recorded for each enrolment in the variable m according to the following algorithm:

### ALGORITHM 1

Algorithm of Connected Minutes

```
Data : Raw log data
Result: Connected minutes per enrolment
@ConnectedMin = 0; @BeginDay = "00:00:00"
@EndDay = "23:59:59"; @TBegin = ""; @TEnd = "";
while not at the end of enrolment log rows do
  read current
  if @Event='Navigate' or (@Event = 'Access' and
  @TimeBegin = "") then
    @TimeBegin= Time-Event;
  end if
  if @Event='Page close' then
    @TimeEnd= Time-Event;
  end if
  @Diff=DateDiff(MIN,@TBegin,@TEnd);
  if @Ddiff > 0 then
    @x=DateDiff(MIN,@hdebut,@EndDay);
    @y=DateDiff(MIN,@BeginDay,@hfin);
    @Ddiff= @x+@y;
  end if
  @ConnectedMin= ConnectedMin+@Ddiff;
end while
```

Finally we end up with features presented in the Table VI.

TABLE VI. EXTRACTED FEATURES

N	Features
1	Enrolment Identifier
2	Count of student previous enrolments
3	Count of student previous succeeded enrolments
4	Count of student previous drop-out enrolments
5	Count of log for the current enrolment
6	Count of log for all previous enrolments
7	Count of days between first and last log
8	Count of days between first and last log for all previous enrolments
9	Count of log for the event : Problem
10	Count of log for the event : Problem for all previous enrolments
11	Count of log for the event : Video
12	Count of log for the event : Video for all previous enrolments
13	Count of log for the event : Navigate
14	Count of log for the event : Navigate for all previous enrolments
15	Count of log for the event : Page-close
16	Count of log for the event : Page-close for all previous enrolments
17	Count of log for the event : Access
18	Count of log for the event : Access for all previous enrolments
19	Count of log for the event : Discussion
20	Count of log for the event : Discussion for all previous enrolments
21	Count of log for the event : Wiki
22	Count of log for the event : Wiki for all previous enrolments
23	Count of logs in the first 10 days of course
24	Count of logs in the second 10 days of course
25	Count of logs in the last 10 days of course
26	Count of active minutes
27	Count of active days
	Enrolment result : Success 0 /Drop-out 1

### C. Feature Selection

When solving a classification problem, processing extracted data vectors is an important step. Indeed, the performance of the classifier highly depends on the correct choice of the content of these vectors. However, the problem becomes difficult to re-solve and very expensive in terms of training time and resources owing to the large dimension of these vectors. Consequently, it is useful, and sometimes necessary to reduce the dimensionality of these vectors to be compatible with resolution methods, even if this reduction may lead to a slight loss of information. Reducing the number of explanatory variables has a double advantage. On one hand the model will be easily interpretable due to the few number of variables. On the other hand, the prediction error will be reduced by removing the non-informative variables.

Feature selection is a process allowing to select a subset of features considered as the most relevant from a starting set using various criteria and different methods. The process is working as follows:

- 1) From the initial set of variables, the selection process determines a subset of variables that he considers to be the most relevant.
- 2) The subset is then evaluated with the classifier to assess the performance and relevance of the selection.
- 3) Depending on the result of the evaluation, a criterion for stopping the process determines whether the subset of variables can be used in the learning process, otherwise another subset of variables is generated and tested. The stopping criteria can be a predefined number of features to keep or a fixed number of iterations or even a criterion related to the evaluation function.

Methods used for selection can be classified into three main categories: Filter, Wrapper and Embedded.

1) *Filter*: The filter approach was the first method for selecting features [20]. It is considered a pre-processing step before the learning phase; the evaluation of features is usually done independently of the classifier. We define an importance score for each feature that reflects its quality as a predictor. We also define a score of similarity between two characteristics. The objective is to select the variables with the highest importance score and the lowest similarity scores to reduce redundancy. The main advantage of filtering methods is their computational efficiency and robustness against overfitting. Unfortunately, these methods do not consider interactions between characteristics and tend to select characteristics involving redundant rather than complementary information. The filter method used in this work is the Chi-squared test.

2) *Wrappers*: The main drawback of filter approaches is ignoring the influence of the selected variables on the learning algorithm's performance. To solve this problem, Kohavi and John introduced the concept of a Wrapper for selecting features [21]. Wrappers use the accuracy of the learning algorithm as an evaluation function to estimate the relevance of the variable. The Wrapper methods are generally considered to be better than those of filtering. They can select proper small subsets of features. However, features selected by this method are only

suitable to the classification algorithm and are not necessarily valid if we change the classifier. Also, the complexity of the learning algorithm makes the Wrapper methods very expensive in terms of computation time. It has been demonstrated by [21] that Wrapper methods produce better performance than some filtering methods. This paper will use Recursive Feature Elimination with both Random Forest (RFE-RF) and Gradient Boosting (RFE-GB).

**Recursive Feature Elimination (RFE)** is a selection algorithm based on backward elimination, in which recursive elimination aim to select a subset of optimum features. The learning is performed first with all the  $p$  variables, the least discriminant variable is removed, then the learning is performed on the  $p-1$  remaining variables. This process is iterated until the number of desired variables is obtained.

3) *Embedded*: Embedded methods incorporate the selection of variables into the learning process. Embedded methods can use all the dataset as a training set which is an advantage that can improve the result. In addition, Guyon and Elisseeff [22] specify that Embedded approaches surpass Wrapper approaches concerning the computation times and the robustness against overfitting. In this study, we are using both regularization: Ridge and lasso as Embedded methods.

**Regularisation** in ML adds a penalty term to the different coefficients of the model. The main purpose of Regularization is to avoid overfitting by improving the generalisation of the model. It improves the performance of models on new data. the main types of regularisation are Ridge and lasso:

Lasso regression (L1): Adds the squared magnitude of coefficients as a penalty term to the loss function.

$$L + \lambda \sum_{i=0}^n x_i^2$$

Ridge regression (L2): Adds the absolute value of magnitude of coefficients as a penalty term to the loss function.

$$L + \lambda \sum_{i=0}^n |x_i|$$

It is therefore used for variable selection. While L1 set the coefficient of unnecessary variables to 0, L2 is approaching them to zero.

In this study, we will implement a hybrid approach that combines all the methods seen previously. Each method will participate to elect if the variable will be selected or not. The scores obtained for each method will be then aggregated and normalised so that they are between 0 for the lowest rank and 1 for the highest. Variables with a high average will be selected according to score obtained in the Table VII.

TABLE VII. FEATURES RANKING

N	Lasso	REF-RF	REF-GB	Ridge	Chi-2	R-Lasso	Mean
1	0.0	1.0	0.7	0.0	0.0	0.48	0.36

According to the results found on the Table VII. The dimensionality of the dataset will be reduced to the eight following features:

- Count of student previous succeeded enrolments
- Count of log for the current enrolment
- Count of days between first and last log
- Count of log for the event : Access
- Count of logs in the second 10 days of course
- Count of logs in the last 10 days of course
- Count of active minutes
- Count of active days

In the next section, in order to prove the relevance of our selection, results obtained with this set of features will be compared with the results obtained using the initial set of variables.

#### IV. METHODOLOGY

The variable enrolment result has two alternative outcomes 1 for drop-out and 0 for success. Thus, the problem can be modelled as a binary classification. Besides, since the data used for training and testing is already labelled, the models are built with supervised learning. Fig. 1 present the methodology used in this paper.

Supervised learning begins with the training process. During training, the algorithm optimises the mapping function through a pair consisting of an input vector and the desired output value. The goal is to create a model that correctly classifies new unseen data. The predicted outputs are then

Fig. 1. Methodology.

compared to the accurate observation on the validation set to compute the model’s performance and generalisation ability. In this study, we will implement both GA and DL to create our models.

#### A. Deep Learning

DL is based on the models of NN with many hidden layers, called DNN. While a traditional NN can only handle a single hidden layer as show in the Fig. 2. DL data processing is carried through multiple layers to compute the output. Each layer is made of many artificial neurons imitating the biological neurons in a very simplified way. Each connection in the network is characterised by a coefficient or a synaptic weight that mainly describes the behaviour of the network.

Fig. 2. Deep Learning.

During the learning process, weights are calculated in order to determine whether to amplify or dampen the output. The weights are adapted to minimise the difference between the network output and the expected output.

Fig. 3. Artificial Neuron.

As Fig. 3 shows, the neurons receive the information produced by other nodes through the input connections. Each

neuron J performs a weighted sum of the n input values. Weights assigned to the neuron’s inputs are stored in a matrix W. The value  $w_{ij}$  represents the weight of the input connection  $X_i$  of neuron j. Then to this sum a bias  $b_j$  is added. This total represents the biased post-synaptic potentials formulated as follows:

$$P_j = \sum_{i=1}^N w_{i,j} X_i + b_j$$

Finally, an activation function f transforms this biased potential to obtain the activation value of the neuron. This value is then transmitted to other neurons. Among the commonly used activation functions we can find Rectified linear unit (ReLU), Sigmoid and Hyperbolic tangent.

$$X_j = f(P_j)$$

### B. Genetic Algorithms

GA are stochastic optimization methods belonging to the family of evolutionary algorithms. They are commonly used for resolving complex optimization and search problems. GAs are inspired by the Darwinian mechanisms of the natural evolution of biological populations and rely on derived techniques such as selection, mutation and crossing. GA use the principle of survival of individuals considered to be the strongest or best suited to the environment by combining the strengths of each individual to create the next generation considered to be a better solution to the problem. This process is repeated several times until finding individuals have genetic information that corresponds to the best solution to the problem. In general, the process of a GA as presented in Fig. 4 is based on the following phases:

Fig. 4. Architecture of a Genetic Algorithm.

(1) **Initialization:** This GA mechanism must produce a non-homogeneous population of individuals who will serve as a parent for future generations. The choice of the initial population is important because it can make the convergence to the global optimum more or less rapid. The initial population must be distributed over the entire research area.

(2) **Evaluation:** Evaluate each capacity to the target variable with high accuracy. The LR algorithm was used to build prediction models. Individuals selected by the GA search were used as an input for LR, and the results from LR are used again with different variable sets in order to enhance the prediction score.

(3) **Genetic Operators:** Operators guarantee the possibility of diversifying populations over the generations and exploring the solution space. We apply the following operations during a GA cycle: Selection, Crossing and Mutation.

(a) **Selection:** The selection consists of choosing the individuals serving to create the next generation, the individuals who will survive. The selection of individuals is carried out most often on the basis of the evaluation function. Several selection operators are used such as the roulette wheel selection [23], Rank in the population [24] or tournament selection [25].

(b) **Crossover:** Crossing is responsible for constructing an individual solution for the problem from the mixture of many other solutions. In crossing, the chromosomes exchange sequences of genes between them. This process is applied to each pair of chromosomes selected with a certain probability of P. The pairs of chromosomes are copied without modification into the next generation with the probability 1 - P. The higher P, the more new individuals appear in the population.

We present the best-known ones among the most used crossover methods: the one-point crossover and the multi-point crossover.

**One-Point Crossover :** It is about randomly choosing a crossing point for each pair of chromosomes and performing a swap of the sets of sequences of this point between the two parents, giving birth to two new offspring as shown in Fig. 5.

Fig. 5. Single-Point Crossover.

**Multi-Point Crossover :** In this case, several crossing points are selected and the swap is done on the different parts of the sequences surrounded by these points between the genes of the parents as shown in Fig. 6.

Fig. 6. Multipoint Crossover.

(c) **Mutation :** Mutation is defined as the unexpected change in the value of a gene in a chromosome. Fig. 7 illustrates

an example of a mutation applied to the fourth position of a binary chromosome. The mutation plays the role of noise which prevents the evolution from stopping. It allows the extension of space exploration and guarantees that the global optimum can be reached. This operator, therefore, avoids a convergence towards the local optimum.

Fig. 7. Exemple of Mmutation.

The following section will be dedicated to presenting the results and scores obtained by applying the methods presented in this section on the data obtained in the fourth section .

### V. RESULTS

After performing a hybrid feature selection method in Section 4, we end up with two datasets: a first dataset containing all extracted features (All) and a second one containing only the seven selected features (selected). To assess the relevance of this selection, we will compare the Accuracy and AUC-ROC scores for the two datasets using DL and GA models.

TABLE VIII. MODELS SCORES

Model	Features	Accuracy	AUC ROC
GA	All	0.926	0.898
	Selected	0.933	0.894
DL	All	0.943	0.876
	Selected	0.938	0.887

According to the results obtained in Table VIII, we notice that the scores remained almost the same even after eliminating several features. It is explained by the fact that some eliminated features had no role in predicting the target variable. In other cases, they may introduce noise. The score has been improved for the GA model after eliminating the unnecessary variables.

We also notice that the two algorithms used in this work outperform the basic algorithms used in previous work. It is explained by GA evolutionary and self-correcting character and DL methods.

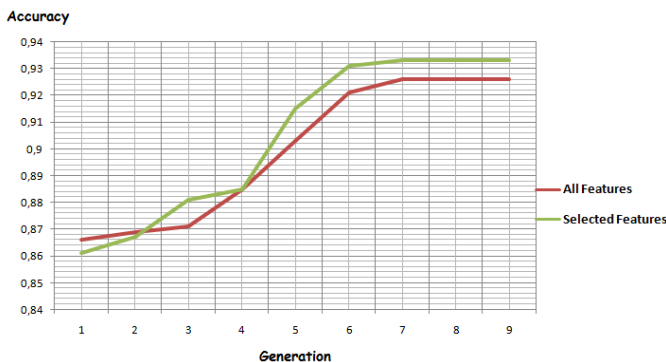

Fig. 8. Accuracy Evolution over Generations.

Fig. 8 provides information about how quickly the GA converges to the optimal solution. After only seven generations, the algorithm found an optimal solution for the problem. This rapid evolution of accuracy over generations depends highly on the value of mutation rate. In practice; it consists of a high mutation rate at the start of the algorithm to allow better solutions for space exploration. Then a decrease in this rate allows the convergence of the algorithm.

Fig. 9. Loss Evolution over Epochs

Learning curve graphs presented in Fig. 9 are commonly used for the NN model. It plots the variation of loss or accuracy over epochs. The data is divided into two parts training and validation sets. Learning curve graphs are firstly used to examine the model convergence; we expect that the loss decreases and the accuracy increase as the number of epochs increases. We also expect that the model will converge after training for several epochs. Secondly, It is used to diagnose if the model has over-fitted or under-fitted the learning set.

Fig. 9 show that we obtain an accuracy of 90% after 40 epochs for the dataset using all features. The same accuracy is obtained after only 10 epochs for the dataset using selected features, which is explained by the fact that a model containing fewer features will be less complex and require fewer epochs to converge. Fig. 9 show that for both datasets, we can safely stop the training process at 50 epochs without fearing over-fitting or under-fitting.

After proving the relevance of models and the set of features used in this article, and since the temporal aspect is present in our dataset, the next step in this work is to use ARIMA to predict independent variables for future weeks for every enrolment. After obtaining these values, we use them as an observation for the models to predict the value of the target variable Y. With the function predict.proba() in python sickit-learn library, we can find the weekly drop-out percentage.

Fig. 10. Log Count Error Prediction

We can judge the accuracy of the ARIMA model predictions through the normalized RMSE (Root Mean Squared Error) value. Fig. 10 shows an example of the error between the actual value of the number of logs per day and the predicted value. The normalized RMSE value is suitable for all variables and indicates the accuracy of the ARIMA model and stationary time series of the variables.

At our university, we extracted student logs from the university MOOC to build a dataset similar to the KDD cup dataset. This dataset has undergone the same process mentioned in this article, starting with feature extraction and feature engineering and ending with models' predictions score. Table IX presents the different model scores for the university dataset.

TABLE IX. MODELS SCORES UNIVERSITY DATA

Model	Features	Accuracy	AUC ROC
GA	All	0.931	0.876
	Selected	0.921	0.887
DL	All	0.888	0.875
	Selected	0.898	0.886

An intelligent system was hosted in the university server based on a single web page using Python and Streamlit framework. The system inputs the enrolment entry (student, course), fetches the corresponding logs and aggregates them by week. In addition, the ARIMA method is used to predict new observations for the following weeks using the previous ones. The system offers the possibility to choose the model used to predict the drop-out rate each week, as shown in Fig. 11 and Fig. 12.

Fig. 11. Web Page Interface.

Fig. 12. Results Web Page.

In order to determine student drop-out profiles and patterns, We performed a correlation analysis between extracted features and the student's final performance (completion or drop-out). We found that when the pattern is: Access — Video — Assignments — Discussion is respected, The accuracy of retention is increased visibly. It means that the expected behaviour of the student is to access the course link represented by the event (Access), watch the course content through videos, and then visit the Assignments page. Finally, discuss the ambiguous and misunderstood points on the discussions page. Similarly, the student behaviour on assignments pages, the count of the viewing Video events, Discussion, and wiki page measured weekly, provided an indicator of student engagement and persistence and were an excellent early predictor of the drop-out rate and performance.

When we used K-mean clustering, we found three main clusters for droppers: According to our analysis of weeks 1 and 2, data indicates three dominant clusters.

- **cluster 1** student with little time spent watching videos. This cluster corresponds to students who didn't complete the course videos. This grouping was a strong indicator of drop-out 95% of these students did not complete the course.
- **cluster 2** concerns students who complete watching videos but have a few visits and time spent on the assignments page. In other words, these students have completed most of the course but didn't take quizzes and exercises. This

grouping was also a strong indicator of drop-out: 80% dropped out in the fourth week.

The reasons which explain the behaviour of the students of clusters 1 and 2 can be linked to several causes extracted from related works:

- **causes linked to student:**

- The lack of students motivation and engagement: is considered one of the most influential factors preventing students from completing a MOOC. For instance, [26] surveyed 134 students who had not completed the MOOC courses and found that the majority of students had the intention to complete their study but they were unable to do so due to low motivation and poor feedback.
- The students lack the abilities/skills and prerequisites to follow the course. According to previous studies [27], [28], [29], demonstrating the effect of students' academic skills and abilities and their prior experience on the drop-out rate in MOOCs.

- **causes linked to the course:**

- It can also be linked to the course length and difficulty. According to [30], [31], [32] the complexity or the difficulty of the course content was found in many studies to be associated with students drop-out rates

- **causes linked to instructors:**

- The lack of instructor supervision: The poor feedback provided by the instructors due to the massive number of enrolled students per course has been reported to be an significant predictor of students drop-out in MOOC courses [33] and [34].

- **cluster 3** concerns students who have spent an average time on the videos and assignments page but have few visits to the discussion page. It can be interpreted that those students are not social enough to communicate with others students or ask questions about ambiguous points in courses or exercises.

Isolation and lack of interactivity in MOOCs directly affect students drop-out. A survey [29] about MOOCs drop-out showed from the droppers' comments that they mentioned feeling isolated and unmotivated to continue due to low interaction and communication with students and instructors. They complained that the instructor did not praise or motivate them after the quizzes. They also stated that instructors did not engage learners in discussion or facilitate brainstorming.

After detecting patterns of the student at high risk of drop-out, the following section outlines examples of interventions:

- **Interventions for cluster 1 and 2:** For students lacking the necessary prerequisites to take the course, it is wise to detect them through a survey or quizzes at the beginning of each course. Then send them courses and exercises containing the prerequisites they lack to follow the course. According to the literature, there is a myriad of interventions aiming to increase students motivation and engagement by creating interest in the course topics [35]. Some interventions dealt with demotivation through an email mechanism [36]. Other interventions try to get absent students back into the course and collect their reasons for

leaving [37].

The lack of instructor supervision and the poor instructor feedback is due to the considerable enrolment number per course in MOOCs. The solution here is to focus on students flagged at high risk of drop-out on a particular week according to the drop-out rate given by the system.

Regarding the course content, the course must appear helpful for the students in real life. It should contain a lot of application and practical exercises. The skills learned in the course must apply to real-world problems, particular career goals, or later life roles.

- **Interventions for cluster 3:** Multiple research has found that social connectedness to school is linked to higher rates of student academic success [38], teachers and peers can serve as sources for facilitating this social connection. The intervention proposed for this cluster is a weekly peer-support group meeting that focuses on enhancing students' academic and interpersonal skills combined with daily interactions. It will improve outcomes for students flagged as a potential drop-out. We could form a peer-support group of three to four participants, and the 5th is the student flagged as a drop-out. This methodology is more suitable for blended learning; it has been tested in the university, and the results obtained improved classroom behaviour, increased academic engagement, and positive peer and teacher interactions.

The cost of a students drop-out is very high in terms of wasted time, effort and money. When a student decides to leaves, connection with that student is lost, and generally nothing is done to determine the reasons behind. Institutions can implement this system or similar, to anticipate and reduce the number of drop-out.

Several other drop-out patterns might be detected, and such predefined intervention strategies can be learned from expert teachers or from historical data [12]. The current study is just a first step toward an ultimate automated personalized intervention system.

From an algorithmic perspective, the experiment in this study showed that deep learning is outperforming other baseline algorithms either in prediction accuracy or in generating more accurate drop-out probabilities. Moreover, deep learning showed more robustness against over-fitting.

## VI. CONCLUSION

The excessive drop-out rate in MOOCs encourage to use data mining techniques and ML algorithms in order to predict students at risk of drop-out. In the light of the obtained results we can conclude that for classification problems based on raw activity records, features extraction and data preparation is a necessary step before building models. The hybrid features selection algorithm adopted in this work is effective. One of our main contributions was obtaining competitive prediction results with a minimum number of variables.

According to the result obtained we can also conclude that our proposed models using GA and DL are producing very competitive results in this problem. Models used in this study are outperforming the obtained result using the baseline algorithms in previous works. This study was very useful, and optimises the drop-out prediction in the university MOOC,

because it is not only focusing on early detecting students at risk of drop-out, but it also personalise intervention and seeks for the reasons behind, in order to increase retention rate in the MOOC. As a perspective, the methodology used in this article must be tested on other benchmark datasets in order to assess its relevance.

#### ACKNOWLEDGMENT

We would like to gratefully acknowledge the organizers of KDD Cup 2015 as well as XuetangX for making the datasets available.

**Abstract**—Coronary Artery Disease (CAD) is one of the most common cardiac diseases worldwide and causes disability and economic burden. It is the world's leading and most serious cause of mortality, with approximately 80% of deaths reported in low- and middle-income countries. The preferred and most precise diagnostic tool for CAD is angiography, but it is invasive, expensive, and technically demanding. However, the research community is increasingly interested in the computer-aided diagnosis of CAD via the utilization of machine learning (ML) methods. The purpose of this work is to present an e-diagnosis tool based on ML algorithms that can be used in a smart healthcare monitoring system. We applied the most accurate machine learning methods that have shown superior results in the literature to different medical datasets such as RandomForest, XGBoost, MultilayerPerceptron, J48, AdaBoost, NaiveBayes, LogitBoost, KNN. Every single classifier can be efficient on a different dataset. Thus, an ensemble model using majority voting was designed to take advantage of the well-performed single classifiers, Ensemble learning aims to combine the forecasts of multiple individual classifiers to achieve higher performance than individual classifiers in terms of precision, specificity, sensitivity, and accuracy; furthermore, we have benchmarked our proposed model with the most efficient and well-known ensemble models, such as Bagging, Stacking methods based on the cross-validation technique, The experimental results confirm that the ensemble majority voting approach based on the top three classifiers: MultilayerPerceptron, RandomForest, and AdaBoost, achieves the highest accuracy of 88,12% and outperforms all other classifiers. This study demonstrates that the majority voting ensemble approach proposed above is the most accurate machine learning classification approach for the prediction and detection of coronary artery disease.

**Keywords**—Machine learning; smart healthcare; coronary artery disease

## I. INTRODUCTION

No cure exists for Coronary Artery Disease (CAD), as a combination of environmental and inherited factors is thought to be associated with several risk factors, including a family history of heart disease, age, overweight, inactivity, poor diet, and tobacco usage. The diagnosis of coronary artery disease is very challenging for the General Physician (GP). When a

patient experiences chest pain, he consults the GP. The chest pain is the main reason for consultation in approximately 4% of cases and in only 15% of cases [1], Coronary Artery Disease (CAD) ultimately will be diagnosed as the reason for the symptoms, The difficulty for the GP is to identify CAD on the basis of symptoms, age, and gender. Distinguishing a life-threatening disease from a non-life-threatening disease is crucial for the effective prevention and management of the disease, but it can be difficult, especially in cases of atypical blood pressure or non-specific chest complaints [1], [2]. Currently, approximately 105,000 people 53% of whom are women are being recommended to a cardiologist, each year in the Netherlands. In fact, only 5% of males and 1% of females have coronary disease needing invasive therapy. Therefore, a clinical need exists in the population suffering from chest pain for optimizing the diagnosis and orientation to the cardiologist [3]. Thus, the development of an accurate diagnostic tool based on ML algorithms would assist GPs in identifying the likelihood of coronary artery disease and in guiding the management of patients. In addition, early diagnosis of chronic diseases saves the expense of medical care and reduces the likelihood of more complex health problems, especially considering the lack of doctors in underserved areas and developing countries. In this case, the association of Wireless Body Area Networks (WBANs) and machine learning methods should be used to assist practitioners in the early diagnosis and identification of CAD by offering predictive models for better and faster decision support. Nevertheless, it is worth noting that machine learning tends to be looked upon with suspicion by some due to what can be termed a “black box” [4]: being unable to reveal its inner decision-making mechanism. However, this inability to explain its inner decision-making tends to lead to skepticism among consumers and slow adoption by end-users in the domain of health care. It is crucial to build trust, especially in healthcare, where errors can be fatal, to be able to convey both the underlying reasoning and the process required to obtain a machine learning prediction. This paper aims to develop a CAD detection, classification, and prediction tool that can be integrated into a smart healthcare system. Through the use of ensemble machine learning approaches combining the best

classifiers Multilayer Perceptron, Adaboost and RandomForest, such a system would be capable of predicting whether a person is likely to have CAD on the basis of various relevant indicators, supplying physicians with an advance diagnostic assessment. The classification models were evaluated using various metrics, namely, F-measure, accuracy, recall, precision, sensitivity, and the ROC curve (receiver operating characteristic curve) to select the most efficient classifier. Several relevant features that can potentially be utilized to predict coronary artery disease have been taken from the best classifier scheme. The Z-Alizadeh Sani dataset [5] is used for the purposes of this work. The Z-Alizadeh Sani dataset comprises 303 records of patients, with 55 features. All the features can be regarded as CAD indicators, as stated in the literature [5]. Features are categorized into four categories: demographics, symptoms, laboratory, and ECG features. Accordingly, every patient may be classified in two different possible classes: CAD or normal. The patient is classified as having CAD if his or her narrowing diameter is greater than 50% and if not, he is normal.

#### A. An Overview of the Smart Healthcare Monitoring System

A Smart Healthcare Monitoring system based on Wireless Body Area Networks (WBANs) is organized into a three-layer telemedicine system as shown in Fig. 1. This system consists of a network of wireless sensors that continuously track the health parameters of patients [6], [7]. Furthermore, this healthcare monitoring system is interconnected to the high-level biomedical server via an internet-based network system.

1) *Tier 1*: is also called the WBAN level, in which, each patient under healthcare monitoring is connected to several small Body Sensor Networks (BSNs), These inhomogeneous sensors are placed either in the body or in wearable devices As shown in Fig. 1, the BSN detects different physiological body parameters. These include electroencephalogram (EEG), pulse rate, electromyography (EMG), blood pressure, electrocardiogram (ECG), and so forth [6], [8], [7]. To communicate within the WBAN level, those BSNs are using radio waves to communicate with themselves and with the coordinator, A sink node is operating as a hub for all the BSNs .

2) *Tier 2* : The second level is implemented in a PC/laptop, mobile phone, or PDA. The data collected from the BSNs in various formats, including graphics, digital, audio and so forth [6], [8], are transferred to a healthcare server. It employs several technologies, such as 4G/5G or WiFi, to communicate with a remotely located medical server.

3) *Tier 3*: It consists of a large network of various devices, services, healthcare practitioners, and healthcare services providers that are interconnected. This layer delivers many services to potentially thousands of clients through the use of healthcare systems as a centralized point of contact. These medical servers store the health data of patients and deliver various additional services to these patients and other related stakeholders [6], [7]. The tasks of the health server involve authentication of patients, acceptance, and submission of their medical data, and formatting and analysis of the data to identify the severity of health problems. If the analyzed data shows that the patient's potential medical condition is of a life-threatening type, the health server alerts emergency caregivers. Patients and their doctors can access the analyzed data at their

location via the Internet. Patient data is reviewed by doctors to assess whether it is in accordance with the desired healthy ranges (e.g. pulse pressure, heart rate, etc.) and whether the given or prescribed medical treatment is working. The rest of the article is organized in the following sections: Section 2 provides a review of the state-of-the-art literature on coronary heart disease and heart disease research, while Section 3 presents the proposed methodology, Section 4 reports the results of the experiments and the discussion, The limitations of this article and future work are described in Section 5, and Section 6 provides a conclusion to the article.

## II. RELATED WORKS

Up to now, various research studies have been carried out on the early diagnosis of coronary artery disease and heart disease. They have utilized various machine learning prediction approaches and achieved remarkable performance. This section provides an extensive literature review of research studies in the field of heart disease diagnosis supported by machine learning techniques: In [9] Yadav et al. presented a novel method for ensemble machine learning utilizing Pearson correlation and chi-square feature selection-based algorithms for the correlation strength of heart disease attributes and the Random Forest ensemble method for the diagnosis of heart disease. The authors performed experiments with their proposed system on the CHDD dataset, and they were able to achieve the best performance considering many evaluation metrics Correctly Classified Instances, Mean absolute error, Incorrectly Classified Instances, Kappa statistic, Root relative squared error, Relative absolute error, and root mean squared error, the Random Forest ensemble method outperforms various machine learning techniques RF, AdaBoostM1, Gradient Boosting. In [10] Li et al. proposed a high-performance and intelligent approach for detecting cardiac diseases, and the model is based on a feature selection method (FCMIM) with a support vector machine classifier (SVM). They conducted experiments with their proposed method on the CHDD dataset and were able to achieve the best performance considering many evaluation parameters: accuracy, MCC specificity, processing time, and sensitivity against various machine learning techniques SVM, LR, ANN, kNN, NB, and DT. In [11] Javeed et al. introduced a new heart failure prediction diagnostic method using a random search algorithm (RSA), which is applied for feature selection, and a random forest model to perform classification and prediction. They carried out experiments with their proposed system on the CHDD dataset and were able to achieve the best accuracy, sensitivity, specificity, and MCC. The proposed method outperforms various machine learning techniques, including the random tree model, the Adaboost model, SVM with a linear kernel function, the additional tree ensemble model, and the support vector machine (RBF kernel). In [12] Saxena et al. presented an innovative automated system that combines Generalized Discriminant Analysis (GDA) as an effective feature reduction algorithm together with a Radial Basis Function (RBF) kernel and Online Sequential Extreme Learning Machine (OSELM) based on a Sigmoid activation function, Hardlim, RBF and Sine as a binary classifier for the detection of congestive heart failure (CHF) and coronary artery disease (CAD). They performed experiments with their proposed system on the NSR-CAD, NSR-CHF, and CAD-CHF datasets and were able to obtain the best results in terms of

Fig. 1. General Architecture of a Smart Healthcare Monitoring System.

accuracy, sensitivity, specificity, mean  $\pm$  SD and p-value. The proposed method outperforms the different machine learning techniques GDA-Kernel Function (Gaussian, Polynomial, and RBF) and OS-ELM (RBF activation, Sigmoid, Hardlim, and Sine). In [13] Dwivedi et al. proposed an approach for accurately diagnosing heart disease using the logistic regression method. They conducted experiments with their proposed technique on the StatLog heart disease dataset and were able to achieve the best performance considering many evaluation parameters: classification accuracy, precision, F1-measure, false positive rate (FPR), sensitivity, specificity, negative predictive value (NPV), misclassification rate (MRR), compared to five different data mining techniques: ANN, SVM, kNN, CT, and NB. In [14] Gupta et al. presented an intelligent decision-support model that can help medical experts in predicting heart disease through an advanced ensemble classifier. They conducted experiments with their proposed system on the CHDD dataset and were able to achieve the best performance considering many evaluation parameters: classification accuracy, specificity, F-measure, recall accuracy, MAE, ROC, and RMSE against various machine learning techniques: MLP, NB, J48, RF, SVM, AB, boosted tree, and binary discriminant. In [15] Verma et al. presented a new hybrid method for the diagnosis of CHD, including the identification of risk factors using correlation-based feature subset selection (CFS) with particle optimization search (PSO) and K-means clustering approaches. They conducted experiments with their proposed system on the CHDD dataset and they were able to obtain the best model performance against five different machine learning techniques: MLP, MLG, FURI, and DT (C4.5). In [16] Miao et al. proposed an improved ensemble machine learning scheme using an adaptive boosting algorithm for accurately diagnosing Coronary Artery Disease (CAD). They have performed experiments with their proposed method on

CHDD, HHDD, LBMC, and SUH datasets and they were able to achieve the best performance considering many evaluation parameters: accuracy, ROC, classification error, precision, sensitivity (or recall), F-score, K-S measure, specificity, and AUC, and to outperform other machine learning techniques. In [17] Long et al. proposed a heart disease diagnostic system using rough set-based feature reduction and type 2 fuzzy logic systems (IT2FLS) for early stage heart disease detection, in which the authors implemented the BPSORS-AR Binary Particle Swarm Optimization and the rough set-based feature selection technique. They conducted experiments with their proposed model on the heart disease dataset and the SPECTF dataset, and they were able to achieve the best performance compared to the different data mining techniques, NB, SVM, and ANN. In [18] Nilashi et al. proposed a new methodology for heart disease diagnosis using machine learning algorithms. Such a model was built with unsupervised and supervised machine learning methods. using the implementation of Fuzzy Logic and the Support Vector Machine (SVM)-based ensemble model, and Principal Component Analysis (PCA) was employed with two processes for imputation. Both imputation methods were essentially used for missing value imputation. In addition, they have implemented the Augmented FSVM and Augmented PCA for augmented learning of the data. This was done to reduce the computational time. This was associated with the prediction of the disease. According to the results, it was deduced that the ensemble model showed high accuracy in classifying heart disease and also decreased the computational time required for disease diagnosis. From this brief state of the art, it can be deduced that there is a great interest in the scientific community for the prediction and detection of heart diseases, but in reality, machine learning tools are not yet widely applied in diagnostic systems for heart diseases, especially in developing countries, where the mortality rate

from heart disease is very high. This is because many proposed schemes are too complex to be implemented in a smart healthcare monitoring system for heart disease; hence, there is still space for improvement. In this work, a new approach based on a majority voting ensemble model that combines the prediction of three classifiers (Adaboost, Multilayer Perceptron, Random Forest) is proposed. Unlike other approaches, this approach is simple to implement and gives excellent results in the detection and prediction of coronary artery disease.

### III. PROPOSED METHODOLOGY

In Section 3, we provide a description of the proposed methodology and also explain that the proposed approach is a process defined by the following steps, as shown in Fig. 3.

#### A. Dataset Pre-Processing

1) *Dataset Description:* A variety of experiments were performed utilizing the Z-Alizadeh Sani dataset. Originally, this dataset was provided by the Shaheed Rajaei Cardiovascular Medical and Research Center. It was constructed from the records of 303 random visitors, The reason for choosing this dataset is that it includes clinical and non-clinical features that can be gathered remotely via WBANS, such as ECG features (EF-TTE, RWMA, Q-wave, and T-inversion), in contrast to other datasets and which have a significant impact on the prediction of coronary artery disease. The predictor variables are Age, Diabetes Milletus(DM), Hypertension(HTN), Blood Pressure(BP), Typical Chest Pain, Atypical, Nonanginal, T-inversion, Fasting Blood Sugar(FBS), Erythrocyte Sed rate(ESR), Potassium(K), Ejection Fraction(EF-TTE), Regional Abnormality(Region RWMA), as shown in Table I The dataset consists of 303 instances, divided into 216 CAD instances and 87 healthy instances The target variable identifies whether a person has CAD, represented by 1, or not, represented by 0 The description of the parameters of each attribute in the dataset, including the mean, the median, the maximum and minimum, and the value of the standard deviation, is presented in Table II.

2) *Data Cleaning :* Data cleaning is the following phase of the machine learning process. It is regarded as a key step in the workflow process of our approach because it either builds the model or breaks it. Different aspects of data cleaning need to be considered:

- Noise, Duplicates, Invalid or missing data
- Normalization
- Filter unwanted outliers
- Deal with imbalanced datasets.

a) *Dealing with Outliers :* It is essential to identify faulty measurements (outliers) that are divergent from other measurements and to detect sensor faults in emergency situations in order to minimize false alarms. Anomalous measurements should be excluded in order to minimize unnecessary false alarms and interventions by health professionals. As shown in Fig. 7 and Fig. 6, there are abnormal measurements (outliers) in the Fasting Blood Sugar (FBS), Erythrocyte Sed Rate (ESR), and Potassium (K), or extreme values in the Fasting Blood Sugar (FBS). Therefore, to extract the outliers and

extreme values, we have proceeded to apply the interquartile range filter. The Fig. 2 shows the number of outliers and extreme values found in the dataset. In order to solve the problem of outlier values and extreme values, and since there are not many instances in the dataset (only 303), we proceeded to standardize the features.

Fig. 2. Outliers and Extremes Values Percentages in the Data.

b) *Dealing with Imbalanced Dataset :* The unbalanced class instances in the health dataset are a critical issue. In fact, the dataset that was employed in our classification experiment was unbalanced since the instances of the first class exceeded the instances of the second class by a significant ratio, which means that the instances are not adequately distributed among the different classes. Therefore, the results of the classification from unbalanced class data produce a biased outcome in favor of the dominant class as shown in Fig. 4. In order to balance the unbalanced dataset, there exist two main techniques, namely, oversampling and undersampling. In the Z-Alizadeh Sani dataset used for this work, positive instances exceeded negative ones, which were solved using the SMOTE method as shown in Fig. 5, Out of the variety of oversampling techniques that exist, SMOTE has demonstrated tremendous potential [19] and is thus widely used by scientists in the medical research community. SMOTE is a technique of oversampling proposed to prevent the issue of class imbalance in the dataset. It improves the classifier's performance and joins the lesser class points to the line segments with the unreal points positioned on these lines. With SMOTE, newly created instances are generated by synthetically resampling the minor class data points, as has been performed in the conventional oversampling method [20], [21] This varies from the conventional approach by the fact that it is carried out in the space of features rather than data space, by regard to the instance of the smaller class at its nearest vector [20], [21] The newly created synthetic data parameters may be generated by applying two distinct approaches, One approach employs the ratio of oversampling, whereas another approach employs the k-nearest neighbors.

Fig. 3. The Proposed Approach.

This means that SMOTE generates the synthetic data points for the minority class [19] in order to shift the bias of the classifier’s learning from the dominant class to the minor class.

Fig. 4. Distribution of Classes before Applying the Smote Technique.

Fig. 5. Distribution of Classes after Applying the Smote Technique.

3) *Features Selection*: In this paper, we employ the Gain Ratio method [22] to identify the most pertinent and useful features. The gain ratio method allows us to check the closeness of features by different methods. The gain ratio provides one of these techniques. It identifies the pertinence of every feature and selects the attributes that have the maximum gain ratio with regard to the likelihood of each feature value. The chosen test must acquire a large gain of information, which

should be inclusive of or larger than the average of the gains of the assessed tests, with the aim of penalizing the spread of the nodes, and must be large when the data is uniformly distributed as well as small if the data belongs to a single branch. Each attribute’s Gain Ratio is computed according to the formula:

$$GainRatio(Attr) = \frac{IG(Attr)}{H(attr)} \quad (1)$$

where

$$H(attr) = \sum -P(val_i) \log_2 P(val_i) \quad (2)$$

and  $P(val_i)$  is defined as the probability of having the value  $val_i$  as a factor of  $t$  global values for a given attribute  $i$

The dataset used contained 55 features; we applied the gain ratio algorithm with various thresholds regarding the number of most relevant attributes that should be utilized in these experiments, and in fact, by using the 12 features, we found the greatest accuracies.

### B. Exploratory Data Analysis

The following section presents a statistical overview of the CAD dataset, described in the Table II. Pair plots provide a simple mechanism to examine how two attributes correlate with each other. Every variable from the dataset is presented in a correlation matrix, which can be immediately visualized. It also provides an effective way to determine the appropriate classification method that should be conducted, Fig. 10 also illustrates the feature distribution in the Coronary Artery Disease dataset, providing a useful representation of the distribution of attributes in the dataset. Fig. 10 represents the plot of all attributes in the dataset (12 attributes). One can observe that three of the attributes, specifically age, K, and BP, are normally distributed. In addition, the dominating value of Tinversion, DM, Atypical, Nonanginal, and RegionRWMA is 0, whereas for the attributes HTN and TypicalChestPain, the

most frequently occurring values are 1 and the least occurring value is 3. Furthermore, Fig. 10 depicts that there were six categorical and six numerical attributes.

1) *Analysis of the Correlation Heatmap*: The Correlation Heatmap is presented in Fig. 8, it is defined as a graphical plot of a cross-correlation matrix that reveals the interrelationship of various attributes. Within the -1 to 1 range, the coefficient of correlation can be given any value. If there is a direct linear relationship between two variables, this relationship is statistically termed a correlation. One can also describe this as a correlation measurement involving two variables. The aim in this case is to identify a correlation between multiple variables and to arrange the results. In this context, a matricial structure of data has been used to store the information. The Fig. 8 shows the correlation feature by feature. In the Fig. 8 we can see various elements of information. First of all, the three features that present the strongest dependency between class and feature are Typical ChestPain, Atypical, Age, RegionRWMA, HTN, Nonanginal and EF-TTE with corresponding correlations of -0.54, 0.42, -0.36, -0.32, -0.29, 0.29, 0.27, and 0.23, respectively. The next fact points out the correlation between two features in HTN-BP, DM-FBS, Atypical-Typical Chest Pain, and RegionRWMA-EF-TTE with corresponding correlations of 0.57, 0.68, -0.72, -0.45, respectively, whereas FBS, K, ESR, BP, and DM have the weakest correlation with the class.

2) *Analysis of The Scatter Plot Matrix*: The scatter plot matrix shown in Fig. 9 is useful for finding pairwise relationships of features. From this, we can deduce the relationships between the features in advance: The more scattered the points, the weaker the relationship, and the more clustered they are, the stronger the relationship. Referring to the scatter plot matrix as shown in Fig. 9 we deduce that there is a relationship between the selected features, such as between DM and FBS, between BP and HTN, and Age.

### C. Methods

In this paper 10, high-level classifiers that showed superior performance in detecting cardiac diseases were selected based on the literature and two ensembles of voting classifiers that we designed by combining a set of three high-level classifiers, the novelty is that this combination, to our knowledge, has never been done before in the literature. The Ensemble voting classifiers are based on the majority voting method for predicting coronary artery disease, the parameters of the Random forest Multilayer Perceptron and Adaboost classifiers have been optimized using the Grid search and CVParameterSelection hyperparameter techniques and eventually, 10 folds cross-validation technique have been utilized to validate the models. The description of the three classifiers that compose our model is presented below:

1) *Adaboost Classifier*: Using the ADAboost classifier is a well-known boosting method. This classifier aids in the consolidation of several weak classifiers into a single effective classifier. Initially, a classifier is fitted on the initial dataset, and then repeated duplicates from the classifier are fitted to the similar dataset, with the weights of erroneously categorized instances modified such that later classifiers concentrate more on challenging situations.

2) *Random Forest (RF)*: Researchers are paying more and more attention to Random Forest, it is an advanced machine learning scheme that demonstrates the overall ensemble learning abilities and ease of use. Both regression and the creation of random subsets require the RD approach. Classification is the principal application of the concept of “bagging” which boosts accuracy rates by mixing learning models, numerous decision trees, of which each is employed in the RF method, make up an ensemble classifier. Since every decision tree is built separately, subsequent trees are intended to be independent of preceding trees [23], each tree in the forest is created to depend on a random vector’s values selected separately using a bootstrapped data set sample, and all the forest trees use the same distribution. In the RF-produced model, random sampling with substitutions is implemented [24]. A random subgroup of the entire set of predictors is used to create the best classifier for each node [25]. The fact that RF uses more computing resources—such as storage spaces—than other algorithms is one of the key shortcomings [26] it addresses, but because of its outstanding prediction accuracy, overfitting avoidance, and scalability it is favored by many researchers.

3) *Multi-Layer Perceptron*: Instead of learning by observation, supervised learning procedures use “learning by example”. To build a learning model, a trained data set has been produced. The learning model is used to test the current input, and predictions, are made. The MLP approach allows for the training of a back propagation-based multilayer feed-forward neural network, which calculates the associated network weights based on the intended outcomes and training patterns. MLP belongs to the class of supervised neural networks that iteratively learn a set of weights for categorical variable prediction [27]. An MLP network’s components are represented by the layers in Fig. 11 input and output layers and several hidden layers [28]. The three parameters of the MLP network may be altered depending on the kind and amount of data. The best prediction should be found by optimizing the parameter’s momentum, learning rate and the number of hidden layers. The learning rate is a measure of how quickly the network is being trained. In other words, when learning rates rise, networks train more quickly but at the risk of creating networks that are unstable. By balancing the network [29], the momentum avoids potential issues that might arise from choosing a fast learning rate that renders instability on the network [30]. Various objective functions and characteristics of input are represented by including the hidden layers.

## IV. EXPERIMENT AND RESULTS

### A. Method of Validation of the Models

This research paper utilized the cross-validation technique with ten folds and four performance evaluation measures. More detail is provided in the subsections below:

1) *Cross-Validation (CV)*: In the present study, a 10-fold cross-validation method [31] is employed to validate the classification model. Aiming to minimize the bias related to selecting random sets from the training data samples while making a comparison of the predictive accuracies of at least two different methods, a k-fold crossvalidation technique was used. In the k-fold cross-validation technique the training dataset S is partitioned randomly into k mutual subsets folds

Fig. 6. The Box Plot of the Features.

Fig. 7. The Violin Plot of the Features.

Fig. 8. Correlation Heatmap.

$Sa_1, Sa_2, \dots, Sa_k$  of roughly the same sizes The estimator will be trained  $k$  folds and then tested every time  $\eta 1, 2, 3, \dots, k$  it is trained on  $Sa_t$  and then tested again on  $Sa_t$  The accuracy of the cross validation technique is calculated as the number of classifications that are correct subdivided by the total number of records in the dataset, Thus formally we can state that  $Sa_i$  is the test dataset containing the instance  $m_i=(r_i, p_i)$  and therefore the accuracy of the cross validation is

$$accuracy_{cv} = \frac{1}{n} \sum_{(r_i, m_i) \in S} \sigma(I(Sa\xi_{(i)}, r_{je}), p_i) \quad (3)$$

2) **Confusion Matrix:** The Confusion Matrix typically assesses the outcome of the classification model for a given

request. This summarizes the count values of the correct and incorrect hypotheses by effective class. Table III illustrates the confusion matrix. For the purpose of this study, the negative class is the 0 class and the positive class is the 1 class. With True Positive (TP) showing the positives that are correctly classified and True Negative (TN) showing the negatives that are correctly classified, False Positive (FP) shows misclassified instances that are positive, and False Negative (FN) represents misclassified negative instances, respectively.

3) **Accuracy:** The accuracy of the model is the proportion of correctly classified prediction points divided by the number of total predictions evaluated, as follows:

$$Accuracy = \frac{(TP + TN)}{(TP + FN + FP + TN)} \quad (4)$$

Fig. 9. The ScatterPlot Matrix of the Features.

Fig. 10. Histogram of each Feature.

TABLE I. RANGE VALUE OF SELECTED FEATURES FROM THE Z-ALIZADEH SANI DATASET

Feature Type	Attribute	Values
Demographic	Age	30–86
	Diabetes Milletus(DM)	Y,N
	Hypertension(HTN)	Y,N
Symptom and examination	Blood Pressure(BP)	90–190
	Typical Chest Pain	Y,N
	Atypical	Y,N
	Nonanginal	Y,N
ECG	T inversion	0,1
Laboratory tests	Fasting Blood Sugar(FBS)	62–100 mg/dl
	Erythrocyte Sed rate(ESR)	1–90 mm/h
	Potassium(K)	3.0–6.6 mEq/lit
	Ejection Fraction(EF-TTE)	15–60%
	Regional Abnormality(Region RWMA)	0,1,2,3,4

4) *Sensitivity*: This is calculated by dividing the ratio of the number of coronary patients diagnosed as true positives by the total number of patients with coronary artery disease. It, or the true positive rate, is also called recall. It is assessed as following:

$$Recall = \frac{(TP)}{(TP + FN)} \quad (5)$$

5) *Specificity*: The specificity, or “True Negative” TN rate, is the percentage of reported diseases that are correctly

diagnosed. It is assessed as follows:

$$Specificity = \frac{(TN)}{(TN + FP)} \quad (6)$$

#### B. Results of the Machine Learning Algorithms

We implemented a variety of models and used the cross-validation technique with 10 folds, in order to select the best performing models, the more accurate models are employed in the voting ensemble, and the resulting accuracies of the models are shown in the Table IV and as it is represented

TABLE II. STATISTICAL SUMMARY OF SELECTED FEATURES FROM Z-ALIZADEH SANI DATASET

Feature	Count	Mean	Std	Min	25%	50%	75%	Max
Age	303.0	58.897690	10.392278	30.0	51.0	58.0	66.0	86.0
DM	303.0	0.297030	0.457706	0.0	0.0	0.0	1.0	1.0
HTN	303.0	0.590759	0.492507	0.0	0.0	1.0	1.0	1.0
BP	303.0	129.554455	18.938105	90.0	120.0	130.0	140.0	190.0
Typical Chest Pain	303.0	0.541254	0.499120	0.0	0.0	1.0	1.0	1.0
Atypical	303.0	0.306931	0.461983	0.0	0.0	0.0	1.0	1.0
Nonanginal	303.0	0.052805	0.224015	0.0	0.0	0.0	0.0	1.0
FBS	303.0	119.184818	52.079653	62.0	88.5	98.0	130.0	400.0

TABLE III. CONFUSION MATRIX

	CAD	NORMAL
Actual CAD	TP	FP
Actual Normal	FN	TN

graphically in Fig. 13, the best-performing machine learning classifiers are the RandomForest, Multilayer Perceptron, Stacking, Bagging and Adaboost. In addition, different ensembles were constructed and tested by combining these classifiers, as shown in Fig. 13 and detailed in Table IV, We evaluated the classifiers in terms of accuracy, sensitivity, specificity, F-measure, and Matthew’s correlation coefficient (MCC) to measure performance. As shown in Table IV, the ensemble voting classifier has the greatest classification accuracy of 88.12% compared to the other classifiers. Taking into account the other factors, the voting classifier has the greatest F-measure and MCC with values of 88.12 and 73.4, respectively, as illustrated in Fig. 14. The ensemble voting classifier has the best precision of 89.4% and the best recall of 88.1%, while the Multilayer Perceptron has the second-best precision of 87.79%. Once again, the voting classifiers have the best ROC and the precision values of 93.21% and 89.41% respectively, as shown in Fig. 14. The diagnostic ability of the classifier is shown in Fig. 12 by the calculated and presented ROC curves. The better the diagnostic ability of the model, the closer the ROC curve area value is to one.

### V. LIMITATIONS AND FUTURE WORK

The Z-Alizadeh Sani dataset contains the records of 303 patients from a nearby population of the Department of Cardiovascular Imaging, Rajaei Cardiovascular Medical Research Center, University of Iran, Tehran, Iran. Some limitations of the Z-Alizadeh Sani dataset are that patients under 30 years of age are not presented, as well as people from developing or low-income countries who are at high risk of developing CAD. This is to allow generalization of the proposed approach to a larger population with Coronary Artery Disease, To overcome this limitation, we suggest extending this research beyond the Z-Alizadeh Sani dataset to other CAD datasets and then investigating its generalizability to state-of-the-art machine learning models, The aim will be to design a one-time diagnostic system for Coronary Artery Disease, regardless of age or origin.

### VI. CONCLUSION

The aim of this paper is to design a more accurate classification model that predicts coronary artery disease by taking advantage of clinical and non-clinical features such as symptoms, examination, ECG, and laboratory tests. This will support remote monitoring and diagnosis of patients using vital signs and gathering features. In order to enhance the classification results with respect to accuracy, sensitivity, specificity, and Matthews correlation coefficient, however, the accuracy is improved by incorporating the gain ratio feature selection method. In addition, the benchmark dataset is experimented with to check whether there is a meaningful enhancement in prediction using the feature selection methods among the twelve classifier models. The proposed ensemble voting classifier outperforms the State-of-the-Art Machine Learning Models in terms of precision, accuracy, recall, and F-measure. The results of the proposed ensemble voting classifier are even more encouraging, as it achieved a prediction accuracy of 88.12% compared to the other classifiers. Therefore, an e-diagnosis tool based on an Ensemble Voting classifier (RF + Adaboost + MLP) would be beneficial to remote patients through cost-effective diagnosis and monitoring. Furthermore, the research can be extended by using other datasets to predict other diseases.

# Estimation of Varying Reaction Times with RNN and Application to Human-like Autonomous Car-following Modeling

Lijing Ma, Shiru Qu, Junxi Zhang, Xiangzhou Zhang  
School of Automation, Northwestern Polytechnical University, Xi'an, China

**Abstract**—The interaction between human-driven vehicles and autonomous vehicles has become a vital issue in micro-transportation science. Compared to autonomous vehicles, human-driven vehicles have varying reaction times that could compromise traffic efficiency and stability. But human drivers can anticipate future traffic conditions subconsciously, which guarantees qualified performance. This paper proposes an estimation method of varying reaction times and a human-like autonomous car-following model. The varying reaction times are estimated based on recurrent neural networks (RNNs) after the cross-correlation analysis of human-driven vehicles' trajectory profiles. A human-like autonomous car-following model is established based on Intelligent Driver Model (IDM), considering both varying reaction times and temporal anticipation, and the short form is IDM\_RTТА. The analytical string stability of IDM\_RTТА is deduced and illustrated. The trajectory simulation result shows that increasing accuracy of trajectory prediction is obtained with the proposed model, which will benefit the interaction between human-driven vehicles and autonomous vehicles.

**Keywords**—Car-following model; intelligent driver model; human-driven vehicle; autonomous vehicle; varying reaction time; string stability

## I. INTRODUCTION

Autonomous driving technology has developed rapidly, and with the gradually pervading use of autonomous vehicles, road traffic will experience the coexistence of human-driven and autonomous vehicles. In this situation, the interaction between human-driven vehicles and autonomous vehicles has become a vital issue in micro-transportation science. Due to the nature of human characteristics, the car-following behavior of human-driven vehicles differs from autonomous driving implemented in most microscopic models, which is a controversial topic in traffic flow analysis and simulation [1].

Reaction time is a widely recognized human driver factor, which has been incorporated into car-following modeling. Although these contributions of human-driven vehicles' reaction time have great achievement in the investigation of human characteristics and autonomous driving, the reaction time considered in car-following modeling is usually assumed as one or several constants without elaborately estimated. Furthermore, to the best of the authors' knowledge, few studies consider the inter-driver heterogeneity as well as the intra-driver heterogeneity (i.e., one driver's reaction times change from event to event [2]) of reaction times, in this case, the varying feature of reaction times is not deeply investigated and incorporated into car-following models.

To bridge these gaps, in this paper, we suggest a data-driven method to estimate the varying reaction time based on real human driving data. The estimation method includes first analyzing human-driven vehicles' trajectory profiles with cross-correlation and then learning and predicting reaction times with recurrent neural networks (RNN), which can reflect the inter-driver and intra-driver heterogeneities of reaction time. Moreover, the estimated varying reaction times are applied to car-following modeling by extending the intelligent driver model (IDM). The proposed model shows qualified analytical string stability and simulation accuracy.

The rest of this paper is organized as follows. Section II deploys the literature review of reaction time estimation and the corresponding car-following models. The estimation method for varying reaction times and the modified IDM is proposed in Section III. The estimation results are applied to the proposed car-following model, and the stability analysis and trajectory simulation are conducted, which is presented in Section IV. Section V gives the conclusion.

## II. LITERATURE REVIEW

As car-following behavior is essential to microscopic traffic research, recent studies attempt to incorporate human characteristics into car-following models for the in-depth investigation of human-driven vehicles. Compared to autonomous vehicles, human-driven vehicles, on the one hand, have reaction times that could compromise traffic efficiency and stability. On the other hand, unlike machines, human drivers can anticipate future traffic conditions subconsciously, which guarantees qualified performance. Reaction time is composed of mental processing time, body movement time, and vehicle response time [3]. Multiple studies used real trajectory data for analysis to estimate the reaction time, and there was agreement that reaction time can be estimated by the gap between stimulus and response [4], [5], [6], [7], [8]. A hybrid model is proposed by [9], which estimates the desirable acceleration of the driver by car-following model then estimates the reaction time by an artificial neural network. Reference [10] calibrated the reaction time as a constant using the field data of the intersections.

As a widely recognized human driver factor, reaction time has been incorporated into car-following modeling. The popularly used safety distance car-following model, Gipps model, involved a constant reaction time [11]. Gazis-Herman-Rothery (GHR) model [12] incorporated reaction time and was extended by [13] considering the inter-driver heterogeneity of reaction time. Optimal velocity (OV) model that takes reaction

time into account was presented in [14], and was modified by [15] with small reaction times and long reaction times considered separately for realistic performance. Reference [16] incorporated reaction time into car-following model and analyzed the impact of reaction time on traffic flow linear stability. Meanwhile, as the importance of human drivers' anticipation demonstrated by [17], the temporal anticipation was used as compensation to balance the negative effect of reaction time for stability [17], [18], [19], [20], [21].

### III. METHODOLOGY

#### A. Human-Driven Vehicles' Reaction Time

Reaction time refers to the fact that humans have an inevitable time delay in decision-making and actions, such as driving a car. Most studies presented there is a time lag from vehicle speed profile to acceleration profile and inclined to use this time lag to define the reaction time. However, some have recognized that other information in the trajectory profile is also crucial to reaction time estimation, such as gap distance [6].

Time headway is an important indicator for evaluating driving safety, closely related to traffic flow composition and driving behavior. Time headway represents the time difference between two vehicles passing through the same place. It can be calculated by dividing the headway of two vehicles (i.e., from the leading vehicle's front bumper to the subject vehicle's front bumper) by the speed of the subject vehicle, presented in (1). As time headway includes the information of gap distance as well as velocity, it can be regarded as the stimulus and acceleration as the response. Therefore, we define reaction time ( $T$ ) as the time lag between time headway and acceleration, as shown in Fig. 1.

$$thw_t = \frac{h_t}{v_t} \quad (1)$$

where  $thw_t$  and  $h_t$  are the time headway and headway between the subject vehicle and the leading vehicle at time  $t$ .  $v_t$  is the speed of the subject vehicle at time  $t$ .

Fig. 1. The Profile of Time Headway and Acceleration.

#### B. Estimation of Varying Reaction Times based on RNN

Since it is difficult to obtain the time lags by measuring them manually, we apply the cross-correlation analysis as presented in (2)-(4) to estimate them [12]. As capturing the time-varying feature of reaction times, a sliding window is set to follow the time lags over time. To reasonably set the minima, maxima, and the length of the sliding window for estimation, we investigated the recent studies and summarized them in [22]. We assume the reaction time is distributed from 0.4 s to 3.0 s, i.e.  $\alpha = 4$  and  $\beta = 30$ , and set the length of the sliding window as 10 s, which could capture the time-varying feature of reaction time, as illustrated in Fig. 1.

$$R_\tau = E[thw_t a_{t+\tau}] \quad (2)$$

$$\rho_\tau = \frac{R_\tau - \mu_{thw}\mu_a}{\gamma_{\Delta v}\gamma_a} \quad (3)$$

$$\tau^* = \{\tau | \max(\rho_\tau), \alpha \leq \tau \leq \beta\} \quad (4)$$

where  $R_\tau$  represents the cross-correlation function.  $E[\cdot]$  denotes the expectation function.  $thw_t$  and  $a_{t+\tau}$  are the time headway and acceleration sequences.  $\mu_{thw}$  and  $\mu_a$  denote the mean values of the time headway and acceleration sequences respectively.  $\gamma_{thw}$  and  $\gamma_a$  are the standard deviations of the sequences.  $\alpha$  and  $\beta$  are the minima and maxima of the reaction time, as analyzed and assumed above.

With the cross-correlation method, we are able to collect a dataset that contains the trajectory and the corresponding reaction time. We further apply a recurrent neural network (RNN), which is good at processing sequence learning problems, to learn the varying reaction times from the dataset. Fig. 2 shows the architecture of a typical RNN that takes on an input sequence to generate an output, and the inputs are in order. The RNN learns the hidden sequence order and the corresponding output value, as presented in (5)-(6). The input  $X_t$  is the trajectory data, including gap distance ( $\Delta x_t$ ), relative speed ( $\Delta v_t$ ), speed ( $v_t$ ), acceleration ( $a_t$ ), and time headway ( $thw_t$ ). The output  $O_t$  is the reaction time ( $T$ ). Thus, the varying reaction times can be estimated from a given trajectory.

$$S_t = \tanh(U \cdot X_t + W \cdot S_{t-1}) \quad (5)$$

$$O_t = f(V \cdot S_t) \quad (6)$$

where  $U$  is the weight matrix from the input layer to the hidden layer.  $W$  is the weight matrix considering historical input data.  $V$  is the weight matrix from the hidden layer to the output layer.

#### C. Car-Following Model with Varying Reaction Times

The Intelligent Driver Model (IDM) was first proposed by [23] to simulate bottleneck congestion, as formulated in Eqs.(7)-(8). It is a distinguished mathematical car-following

model that provides collision-free behavior as well as self-organizing properties, which can be used in adaptive cruise control (ACC) [24].

$$\dot{v}_t = \tilde{a} \left[ 1 - \left( \frac{v_t}{\tilde{v}} \right)^4 - \left( \frac{S(v_t, \Delta v_t)}{\Delta x_t} \right)^2 \right] \quad (7)$$

$$S(v_t, \Delta v_t) = s_0 + t_0 v_t - \frac{v_t \Delta v_t}{2\sqrt{\tilde{a}\tilde{b}}} \quad (8)$$

where  $S(v_t, \Delta v_t)$  denotes the desired space headway function that is obtained from the vehicle's speed ( $v_t$ ) and relative speed ( $\Delta v_t$ ).  $\Delta x_t$  is the gap distance between the subject vehicle and the leading vehicle at time  $t$ , which differs from  $h_t$  and can be calculated by  $h_t - l$ , in which  $l$  is the length of the leading vehicle. The desired speed ( $\tilde{v}$ ), the maximum acceleration ( $\tilde{a}$ ), the maximum deceleration ( $\tilde{b}$ ), the desired time headway ( $t_0$ ), and the minimum space headway ( $s_0$ ) are the model parameters need to be calibrated.

We extend IDM based on varying reaction times and temporal anticipation to establish a human-like autonomous

$$\dot{v}_t = \tilde{a} \left[ 1 - \left( \frac{v_{t-T} + a_{t-T}T}{\tilde{v}} \right)^4 - \left( \frac{s_0 + t_0(v_{t-T} + a_{t-T}T) - \frac{(v_{t-T} + a_{t-T}T)(\Delta v_{t-T} - a_{t-T}T)}{2\sqrt{\tilde{a}\tilde{b}}}}{\Delta x_{t-T} + \Delta v_{t-T}T} \right)^2 \right] \quad (13)$$

Fig. 2. RNN Architecture.

#### IV. EXPERIMENTS

##### A. Data Preparation

Analysis and simulation for human-driven vehicle interaction with autonomous vehicles require in-depth insights into human-driven vehicle behavior based on real-world human-driven vehicle trajectory data. The NGSIM dataset [25] is human-driven vehicle trajectory data collected from the real world, extracted from high-definition video by the Next Generation Simulation (NGSIM) computer program. The Interstate 80 (I-80) freeway dataset was collected on April 13, 2005, on eastbound I-80 in the San Francisco Bay Area in Emeryville, California, which was conducted under the NGSIM program. This study area has one high-occupancy lane (lane 1) and five regular lanes (from lane 2 to lane 6), including an on-ramp, and the length of this area is 503 m, as shown in Fig. 3. The author in [26] reconstructed this dataset to meet the consistency of vehicle kinematics and the reasonability of

car-following model, designated as IDM\_RT TA. Reference [17] suggested applying the constant-acceleration heuristics method to calculate future velocity. According to this concept, we formulated temporal anticipation in (9)-(11), which predict the future  $t$  timestep based on the trajectory at  $t - T$  timestep. Therefore, for the estimation result of varying reaction time ( $T$ ), the extended IDM function is established in (12), which can be further expanded as in (13).

$$\Delta x'_t = \Delta x_{t-T} + \Delta v_{t-T}T \quad (9)$$

$$\Delta v'_t = \Delta v_{t-T} - \dot{v}_{t-T}T \quad (10)$$

$$v'_t = v_{t-T} + \dot{v}_{t-T}T \quad (11)$$

$$\dot{v}_t = f(\Delta x', \Delta v', v')_t = f(\Delta x, \Delta v, v, \dot{v})_{t-T} \quad (12)$$

microscopic traffic dynamics. We extract car-following events from this reconstructed dataset to analyze the behavior of the human-driven vehicle and establish human-like autonomous driving. We obtain 1338 car-following events involving 636842 trajectory data points, and the trajectory resolution is 10Hz, i.e., the time interval between two adjacent time steps is 0.1 s. To ensure the testing process is independent, we select the car-following events in Lane 2 involving 330 vehicle pairs as testing data. Thus, 1008 vehicle pairs' car-following events in the rest of the lanes (from Lane 3 to Lane 6) are used as training data.

Fig. 3. Schematic of Eastbound/Northbound I-80.

##### B. Varying Reaction Times and Model Calibration

The time lags are obtained from the training dataset with the cross-correlation method and used as output data in the RNN training process. In this process, the RNN model can learn to output the reaction times from trajectory profiles, and its internal parameters update with the training samples for better output accuracy. The configuration of RNN is validated and summarized as follows:

TABLE I. CALIBRATED PARAMETERS OF IDM AND IDM\_RTТА

$T$	$\tilde{a}$	$\tilde{b}$	$\tilde{v}$	$t_0$	$s_0$
/	1.05	1.76	27.14	1.25	2.09
0.4	1.89	2.60	25.29	2.75	4.05
0.5	2.58	1.72	29.14	2.53	5.66
0.6	2.36	2.71	29.53	2.19	2.90

- Number of hidden layers: 1
- Number of neurons: 10
- The cost function: mean squared error
- The optimization algorithm: Adam [27]
- Batch size: 32
- Epochs: 20

The well-trained RNN model is applied to testing data. The estimated reaction times are obtained, and their percentages are illustrated in Fig. 4. The result indicates that this method could estimate the varying reaction times from trajectory profiles. The great majority of reaction times distribute from 0.4 s to 1.1 s. Then, this method will be integrated into the extended IDM model (IDM\_RTТА) for online estimation to imitate human-driven vehicle behavior as human-like as possible.

Fig. 4. Distribution of Dynamic Reaction Times.

We calibrate the proposed IDM\_RTТА for different reaction times ( $T = 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0, 1.1$ ) with the Genetic Algorithm (GA) [28], which is a stochastic global search optimization algorithm. The calibrated results are presented in Table I. The parameters of IDM are also calibrated, as shown in the first line of this table, for further model comparison.

### C. Stability Analysis

The stability of car-following models is a hot topic in the studies of traffic flow theory [29]. A car-following model can be simply represented by a control equation as in (12), and its equilibrium situation is presented in (14).

Fig. 5. String Stability for Varying Reaction Times.

$$f(\Delta x_{t-T}^*, 0, v_{t-T}^*, 0) = 0 \quad (14)$$

where acceleration and relative speed are zero in equilibrium situation, i.e.,  $\dot{v}_t = a_{t-T} = 0$  and  $\Delta v_{t-T} = 0$ , and there is an equilibrium solution for gap distance and speed, i.e.,  $\Delta x_{t-T} = \Delta x_{t-T}^*$  and  $v_{t-T} = v_{t-T}^*$ .

Empirical observations suggest that the unstable speed-spacing relationship can manifest in traffic flow as only one vehicle deviates from equilibrium (e.g., a slight change in speed) because the perturbations propagate to upstream traffic [23]. If a car-following model has string stability, for an infinite platoon of vehicles in equilibrium, the disturbance will decay as it propagates upstream [23], [30]. Although there are plenty of studies on the stability of the car-following models [1], as the IDM\_RTТА model is built with varying reaction times, the impact of this new variable on the string stability of traffic flow needs to be explored.

The research in [30] supposed a small deviation from the equilibrium state and deduced the control equations. The unstable condition are given in (15):

$$\frac{1}{2}f_v^2 - f_{\Delta v}f_v - f_{\Delta x} < 0 \quad (15)$$

where  $f_{\Delta x}, f_{\Delta v}, f_v$  are the partial differential of the coupled differential equation for gap distance, relative speed, and speed, which can be calculated by (16).

$$\begin{cases} f_{\Delta x} = \frac{\partial f(\Delta x, \Delta v, v, a)}{\partial \Delta x} \Big|_{(\Delta x_{t-T}^*, 0, v_{t-T}^*, 0)} \\ f_{\Delta v} = \frac{\partial f(\Delta x, \Delta v, v, a)}{\partial \Delta v} \Big|_{(\Delta x_{t-T}^*, 0, v_{t-T}^*, 0)} \\ f_v = \frac{\partial f(\Delta x, \Delta v, v, a)}{\partial v} \Big|_{(\Delta x_{t-T}^*, 0, v_{t-T}^*, 0)} \end{cases} \quad (16)$$

This string stability analysis method is applied to IDM\_RTTA, and the following partial differential results are derived in (17). Combining (15) and (17), the string stability of IDM\_RTTA can be evaluated, and for the varying reaction times and corresponding parameters presented in Table I, the stability value against equilibrium speed is plotted in Fig. 5. This clearly visualizes that the calibrated IDM\_RTTA with varying reaction times stays stable at most circumstances. The model is unstable for equilibrium speeds below 10 m/s when reaction time is 1.1 s, as shown in Fig. 5h.

$$\begin{aligned} f_{\Delta x} &= 2\tilde{a} \frac{(s_0 + t_0 v_{t-T}^*)^2}{\Delta x_{t-T}^{*3}} \\ f_{\Delta v} &= \sqrt{\frac{\tilde{a}}{\tilde{b}}} \frac{v_{t-T}^*(s_0 + t_0 v_{t-T}^*)}{\Delta x_{t-T}^{*2}} - 2\tilde{a} \frac{T(s_0 + t_0 v_{t-T}^*)^2}{\Delta x_{t-T}^{*3}} \\ f_v &= -2\tilde{a} \left[ \frac{2}{\tilde{v}} \left( \frac{v_{t-T}^*}{\tilde{v}} \right)^3 + \frac{t_0(s_0 + t_0 v_{t-T}^*)}{\Delta x_{t-T}^{*2}} \right] \end{aligned} \quad (17)$$

#### D. Trajectory Simulation

Trajectory simulation enables measuring the driving models' operation accuracy by comparing them to human-driven trajectories. The comparison is usually evaluated by a measure of performance (MoP), as shown in (18). The simulated trajectory (speed-time and space-time profiles) can be calculated by a discrete-time car-following process based on the acceleration obtained from IDM\_RTTA, as formulated in (19). Moreover, the mean square error (MSE) of the simulated and observed trajectories is calculated.

$$\text{MSE} = \frac{1}{M} \sum_{t=1}^M [x_t - \hat{x}_t]^2 \quad (18)$$

$$\begin{cases} \hat{v}_t = \hat{v}_{t-1} + \hat{a}_t \Delta t \\ \hat{x}_t = \hat{x}_{t-1} + \hat{v}_{t-1} \Delta t + \frac{1}{2} \hat{a}_t \Delta t^2 \end{cases} \quad (19)$$

Where  $x_t$  denotes the observed location.  $\hat{a}$  denotes the predicted acceleration.  $\hat{v}$  and  $\hat{x}$  denote the estimated speed and location.

TABLE II. MEASURE OF PERFORMANCE (MSE)

Model	Mean	SD
IDM	34.37	75.66
IDM_RTTA	29.75	57.95

Trajectories are simulated on the testing data (330 car-following events) with IDM and IDM\_RTTA. The statistical metrics of MSE are compared (see Table II), and the trajectory profiles of one randomly selected car-following event are shown in Fig. 6. IDM is a mathematical car-following model with excellent performance, and simulations show that it can provide reliable results for trajectory reproduction. Their MSE values distribute with different mean values (34.37 for IDM and 29.75 for IDM\_RTTA). Moreover, the standard deviation (SD) suggests that the IDM\_RTTA model has a smaller range of MSE values and a denser distribution pattern. These results indicate that the extended human-like car-following model not only produces higher accuracy in reproducing trajectories but also shows a more stable driving quality.

#### V. CONCLUSION

In conclusion, we focus on estimating varying reaction times and the human-like autonomous car-following modeling. We investigate the existing reaction time estimation methods and identify the importance and possibility of incorporating human-driven vehicles' time-varying reaction times and temporal anticipation properties into autonomous car-following modeling. The extended IDM (IDM\_RTTA) shows qualified string stability and demonstrates higher simulation accuracy for longitudinal control. Although the high-fidelity NGSIM data used in this paper is suitable for discovering human driver behavior, the proposed estimation method for varying reaction times still needs to be validated and tested on more real-world datasets, which is the direction of future work.

#### ACKNOWLEDGMENT

The authors would like to thank the editors and reviewers for their time and valuable insights.

**Abstract**—Diabetes is an ever worsening problem in modern society, placing a heavy burden on healthcare systems. Due to the association between obesity and diabetes, food journaling mobile applications are an effective approach for managing and improving the outcome of diabetics. Due to the efficacy of nutritional tracking and management in managing diabetes, we implemented a deep learning-based Convolutional Neural Network food classification model to aid with food logging. The model is trained on a subset of the Food-101 and Malaysian Food 11 datasets, including web-scraped images, with a focus on food items found locally in Malaysia. In our experiments, we explore how fine-tuning of the image dataset improves the performance of the model.

**Keywords**—Convolutional neural network; deep learning; diabetes; food journal; mobile application; nutritional tracking; Malaysia

## I. INTRODUCTION

Diabetes is becoming an increasingly prevalent disease in modern society. It was estimated that in 2017 at least 6% of world population were affected by type 2 diabetes (T2DM) [1]. Urbanization has caused a shift in dietary patterns among the populace towards food with a higher associated risk of diabetes [2]. Diet affects an individual's diabetes outcome in various ways, both directly and indirectly. The sugar content of a meal directly influences an individual's blood glucose levels, whereas an indirect factor such as the consumption of high-fat foods causes obesity, which then contributes to the onset of diabetes [3]. It is well-established that there is a strong link between obesity and diabetes, where excess weight plays a part in up to 90% of the cases of T2DM [4]. Consequently, diet management plays a crucial role in managing the disease outcome among the diabetics and in disease prevention among the non-diabetics.

In Malaysia, the incidence rate of diabetes in adults has increased from 15.2% in 2011 [5] to 17.5% in 2015 [6]. A long-

standing health problem for the country, diabetes in Malaysia lays an increasingly heavy burden on the country's healthcare system, costing it approximately RM2.04 billion in 2011 alone [7]. Due to the association between diet and diabetes [8], food journaling applications can improve T2DM disease outcomes by helping users to plan and monitor their diet. The use of food journaling software and other related nutritional tracking applications is an emerging approach that may improve an individual TD2M management outcome [9], [10], [11]. For instance, *Diabetes Notepad* was developed to assist diabetics in managing the disease via self-care through diet monitoring, leading to an improved clinical outcome of diabetes in Korea [12]. In Malaysia, despite a consensus that having mobile food journaling app with image-snapping feature would be highly desirable to help with T2DM management, more than half of the people surveyed were unaware of such dietary logging applications [13].

In this paper, we present a new food journaling application tailored to the Malaysian demography. The challenges in developing the application are non-trivial. Because the onset T2DM is strongly linked to environmental, sociodemographic and cultural factors [14], an effective food journaling application should be contextualised to its target population and capable of recognising nutritional components of local diets (e.g. *Diabetes Notepad* is targeted at South Korean demography). Many food databases still contain inconsistent or missing nutritional content of certain food makes it difficult to estimate one's nutritional intake [9]. For instance, they may not sufficiently document non-standard food types such as restaurant food, ethnic food, food prepared by friends and party food. It is therefore important to develop a solution which focuses on a specific demography such as Malaysia.

Our contributions are two-fold. First, we propose a new mobile food journalling application that uses a convolutional neural network (CNN) architecture to enhance the classifica-

tion of food images taken with mobile phones. The amount of calorie intake from the classified food is automatically calculated for the users to help with personal diet planning and monitoring, which is crucial in managing such chronic diseases as T2DM. Second, we propose a way to enhance the performance of the classification model via transfer learning, a strategy that appears to work well on non-conventional images of local Malaysian food.

The remaining of this paper is organized as follows. Section II reviews some related work, with a specific appreciation of food journalling app development in Malaysian context. Section III describes the proposed system architecture, software components, and the method for training CNN classifier. In Section IV, we explain our experiments and report the results. Section V summarises and discusses the experimental results. The limitations of the system are described in Section VI. Section VII concludes this paper.

## II. RELATED WORK

### A. Food Recognition and Classification

Food recognition and classification algorithms form the internal machinery of food journalling apps, executed as part of the food entry workflow that reduce the burden of food entry by users. Convolutional Neural Networks (CNNs) are a popular method for food classification due to their increased efficacy over traditional machine learning-based approaches [15]. The success of CNNs can be attributed to transfer learning, where a model that is pre-trained on a large-scale image dataset such as ImageNet is retrained on a different dataset [16], [17].

There are several existing works in the literature that apply transfer learning to train CNN-based food classification models [15], [18], [19], [20], [21]. Meyers et al. [19] developed *Im2Calories*, a food diary application that uses an ensemble of CNN classifiers for food detection, classification, segmentation, and volume estimation. Their system is able to detect food from 23 different restaurants as well as perform general food detection. Pan et al. [20] proposed *DeepFood* which leverages CNN-based transfer learning algorithms for deep feature extraction. The author's goal is to classify fresh food ingredient images indexed in the Mealcome image dataset [22]. In the most recent example, Sahoo et al. [21] developed *FoodAI*, a CNN model trained to classify various dishes with a focus on food found locally in Singapore. The model is able to predict a wide variety of Singaporean and South-East Asian dishes, recognizing 756 distinct food classes.

### B. Food Journalling Apps Development in Malaysia

There is limited documentation of food journalling apps that specifically target T2DM management for Malaysian population. A recent survey of mobile diabetes management apps showed that existing apps focused only on reporting and setting reminders for meal time, without automatic food recognition ability [23]. Where automatic food image recognition is available, it is not in the context of T2DM management. For instance, [24] used artificial neural network to recognise five different types of Malaysian traditional dessert: *curry puff*, *'kuih ketayap'*, *'kuih kosui'*, *red tortoise cake*, and *'putu piring'*. Calories were subsequently computed from the detected food images but no implication of T2DM management was

documented. The algorithm reported 80% food recognition accuracy. [13] proposed a food journalling app that uses deep neural network model trained with InceptionV3 and MobileNetV2 on Food-101 dataset. Although the app was designed to assist T2DM management, it does not provide the capability to automatically compute calorie amount based on classified images.

## III. METHOD

In this section, we describe the internal workings of our proposed food journalling app. Fig. 1 overviews the essential workflow of the app. The user snaps a picture of food item, which is sent to a web server running the food image classification algorithm. The classification result is subsequently returned and displayed to the user, who then confirms the food type and provides further information about the amount of food that was consumed. The app relays these information back to the server, which computes and returns the estimated consumed calories. Fig. 2 shows the technology components used for the development of the app.

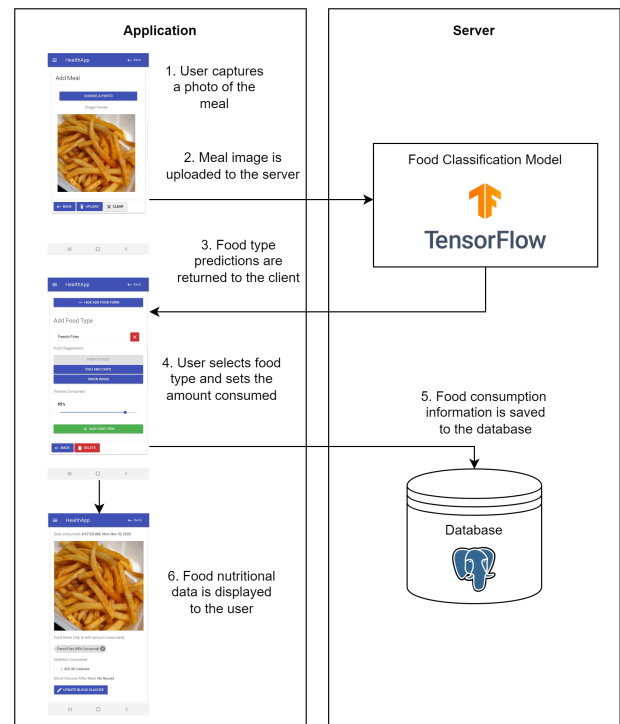

Fig. 1. Workflow of the Proposed Food Journalling App.

### A. Food Dataset

The food image classifier forms the backbone of the app. To construct an initial dataset for training the model, we combined images from the Food-101 [25] and Malaysian Food 11<sup>1</sup> datasets. Several food categories regularly consumed by Malaysians have previously been identified by [26]. These include cereal products, beverages, fruits and vegetables, confectioneries, meat products, fish products, milk products,

<sup>1</sup><https://www.kaggle.com/karkengchan/malaysia-food-11>

Fig. 2. Technology Components Used by the Proposed App.

condiments, eggs, legumes, and spreads. We use these categories to select food classes from the two datasets for training the model. An additional local noodle dish from Sarawak, *kolo mee*, is included in the dataset. The *kolo mee* food images were scraped from the web.

In cases where both the Food-101 and Malaysian Food 11 datasets have overlapping food classes (*fish and chips*, *fried rice* and *hamburger*), the images from the Malaysian food dataset are used for training the model and the Food-101 images are discarded. This is to reduce the class imbalance in the dataset while also ensuring that the training images are as visually similar as possible to the way the local dishes are prepared. The *apple pie* and *kolo mee* classes were manually processed for reasons explained later. One image was removed from the *Nasi Lemak* class due to corruption. The remaining food classes were used without any further preprocessing. The final dataset consists of 31335 images across 32 classes. Details of the food dataset for training the model are shown in Table I.

**B. Model Training**

We implemented the CNN using the *Keras* deep learning framework with *TensorFlow 2.2* backend and trained it on the dataset. To shorten the training duration and improve the model’s performance, transfer learning is used for training the model. Transfer learning allows for the features learnt in

TABLE I. FOOD CLASSES SELECTED FOR TRAINING THE MODEL

Food Class	Images	Food Categories
Apple Pie	883	Confectionaries
Caesar Salad	1000	Fruits & Vegetables
Chocolate Cake	1000	Confectionaries

Waffles	1000	Confectionaries

one domain to be transferred into another domain, such that the resulting performance on the new domain is improved, as opposed to training a new model from scratch [27], [28].

Fig. 3. CNN and Transfer Learning Architecture

Fig. 3 illustrates our CNN and transfer learning training architecture. The base model used for transfer learning is VGG16 [29], initialized with weights pre-trained on the ImageNet dataset [17]. The weights of the convolutional layers were frozen so that they do not update, while the fully connected layer of the model was replaced with three fully-connected layers with widths of 1024, 1024, 1024, and 512, respectively, and the output layer was also updated to 32 classes.

The images in the dataset are split into three: 60% for training, 20% for validation and 20% for testing. In order to prevent the model from overfitting, the images in the training set were augmented. Image augmentation allows the model to generalize better by applying a random transformation on the images according to certain parameters as they are being

fed into the model during training [30]. The parameters used for augmentation of the test images that produced the best performing model are the following: image rotation between  $-90$  and  $90$  degrees, random horizontal flipping of the images, varied brightness ranging between  $75\%$  to  $100\%$ , and image size rescaling between  $80\%$  to  $100\%$ .

The model was trained on a local machine equipped with an Nvidia GTX 1060 6GB GPU. Training was performed in three steps with different learning rates and a fixed batch size of 50. The initial learning rate was set to  $1 \times 10^{-4}$  and the model was trained until the accuracy stopped increasing. When the accuracy stopped increasing, the learning rate was updated and the training step was resumed. The learning rate for the second and third training steps were  $1 \times 10^{-5}$  and  $1 \times 10^{-6}$  respectively. A complete model takes an average of 6 hours to train. The best performing model achieved a top-1 accuracy of  $76.77\%$  and a top-5 accuracy of  $94.37\%$ .

#### IV. EXPERIMENT AND RESULTS

##### A. Initial Results

During the initial training of the model, the original apple pie images from the Food-101 dataset (1000 images) were used without any manual preprocessing. However, during testing of the model, it was found to have performed poorly in predicting apple pie images, with an accuracy of  $53.5\%$ .

Upon inspection of the apple pie images, we hypothesized that the model's below average performance was due to a portion the images in apple pie class that poorly represented the features of the food class. In order to confirm this hypothesis, we retrained the model after manually preprocessing the images to remove images that were suspected to be causing the model's poor performance. Three categories of images were identified and removed from the apple pie image class: non-food images, incorrectly labelled images, and images that poorly represent the food class, which includes images where the apple pie is mostly blocked from view or are mixed with different food classes. Fig. 4 shows a sample of the removed images. A total of 117 images were removed from the dataset and the model was retrained. The images in the other 31 classes of the dataset remain unchanged.

Fig. 4. The Images Removed During Preprocessing of the Apple Pie Class Includes Severely Occluded Images (a, b), Non-Food Images (c, d), and Other Food Images (e, f).

TABLE II. IMAGES MISCLASSIFIED BY THE MODEL WHEN TRAINED WITH THE UNPROCESSED AND PREPROCESSED DATASETS. THE FOOD CLASSES WITH FEWER MISCLASSIFICATIONS ARE HIGHLIGHTED.

Class	Unprocessed	Preprocessed
All Food Classes	93	72
Caesar Salad	1	1
Chocolate Cake	4	3
Donuts	5	3
Dumplings	3	2
Fish and Chips	2	2
French Fries	0	0
Fried Noodles	0	0
Fried Rice	1	3
Garlic Bread	6	3
Hamburger	1	1
Hot Dog	5	6
Ice Cream	7	4
Kaya Toast	8	4
Kolo Mee	1	0

Lasagna	2	5
Mixed Rice	0	2
Nasi Lemak	3	0
Onion Rings	2	3
Pancakes	12	4
Peking Duck	6	3
Pizza	3	1
Popiah	0	5
Ramen	0	0
Roti Canai	3	7
Satay	2	0
Spaghetti Bolognese	0	0
Spaghetti Carbonara	1	0
Steak	0	0
Tiramisu	10	8
Waffles	5	2

After retraining using the preprocessed apple pie class, the model's performance on apple pie images noticeably improved from  $53.5\%$  to  $59.32\%$ . Table II shows the incorrect classifications of the two models, where *Unprocessed* denotes the model trained on the original 1000 *apple pie* images and *Preprocessed* denotes the model trained on the preprocessed apple pie images. There is an overall reduction in misclassifications observed in the retrained model. In the table, the model which made fewer misclassifications on a specific food class is highlighted. Several of the classes with the largest improvements observed are those which share visual similarities (*pancakes* and *kaya toast*), and *ice cream*, which is commonly served as a topping or alongside an *apple pie*.

Additionally, the retrained model was found to have misclassified fewer non-*apple pie* images as an *apple pie* despite the images in the other food classes remaining unchanged. The total number of images from the other food images which were incorrectly classified as *apple pie* was reduced from 93 to 72. These results suggest that the model's accuracy can be further improved by manually processing the images in the remaining food classes to ensure that each image in the dataset significantly represents the features of their respective classes.

##### B. Effects from Incorporating Additional Local Food Classes

Seven additional food classes were included to the dataset in order to increase the model's coverage of local food classes, namely: *Ais Kacang*, *Ayam Pansuh*, *Beef Noodle Soup*, *Boiled Eggs*, *Fried Eggs*, *Kampua Noodles*, and *Layer Cake*. The new images were obtained by scraping the web and manually processing the images to remove unrelated images. We trained two models on the new dataset, one with the same parameters

TABLE III. PREDICTION ACCURACY FOR THE MODELS TRAINED ON THE UPDATED DATASET WITH AND WITHOUT FOCAL LOSS (FL). THE COLUMNS WITH HIGHER ACCURACY ARE HIGHLIGHTED

Food Class	Images	Accuracy (No FL)	Accuracy (FL)
Ais Kacang	435	80.46%	72.41%
Ayam Pansuh	120	58.33%	66.67%
Beef Noodle Soup	520	73.08%	76.92%
Boiled Eggs	623	87.20%	85.60%
Fried Eggs	398	81.25%	77.50%
Kampua Noodles	292	63.79%	63.79%
Layer Cake	669	91.04%	86.57%
Model Accuracy	34412	75.51%	74.17%

as the original model, and another using focal loss optimizer [31]. The focal loss optimizer is introduced in an attempt to account for the high class imbalance in the new food classes. Focal loss puts greater focus on the classes that the model has difficulty classifying during the training process. The images contained in each class and the results of the two models are shown in Table III.

Upon evaluation of the two new models, the model trained using the same parameters as described in Section III-B achieved an accuracy of 75.51% whereas the model using the focal loss optimizer achieved an accuracy of 74.17%. The lower accuracy of the two new models can be attributed to the class imbalance of the newer classes due to a lack of available images on the web. The results of both models are shown in Table III. The model with focal loss is observed to perform better in classifying *Ayam Pansuh*, which has the greatest class imbalance of all the food classes. Although focal loss is observed to allow for higher performance on the highly imbalanced class, the model performs poorer in classifying the other food classes in the dataset.

### C. Sample Use Case

In this section, we describe the meal recording process on the web application. In order for users to use the application, they must first register an account and log in.

Fig. 5(a) and 5(b) shows the account creation and log in interfaces. After the user has logged in to the application, they can begin tracking their meals and view their meal history via the *Smart Diet Watcher* module. The module is accessible from the application’s main menu as shown in Fig. 5(c).

The first step in the meal logging process is uploading an image of the meal. Fig. 5(d) shows the meal creation interface for uploading a meal image. The user can choose between taking a photo of the meal or choosing an image from the device. The meal image that the user has selected is previewed before upload.

After uploading the meal image, the user can add food items to the meal. Fig. 6(a) shows the interface for adding food items to the meal. The food item suggestions are provided by the model’s predictions based on the food image. Users can add multiple food items to the meal in cases where the food image contains multiple dishes. Once food items are added to the meal, users can edit or delete them as shown in Fig. 6(b). The user can optionally record their blood glucose levels after the meal.

Once the user has completed logging their meal, they can view a summary of the recorded meal as shown in Fig. 6(c).

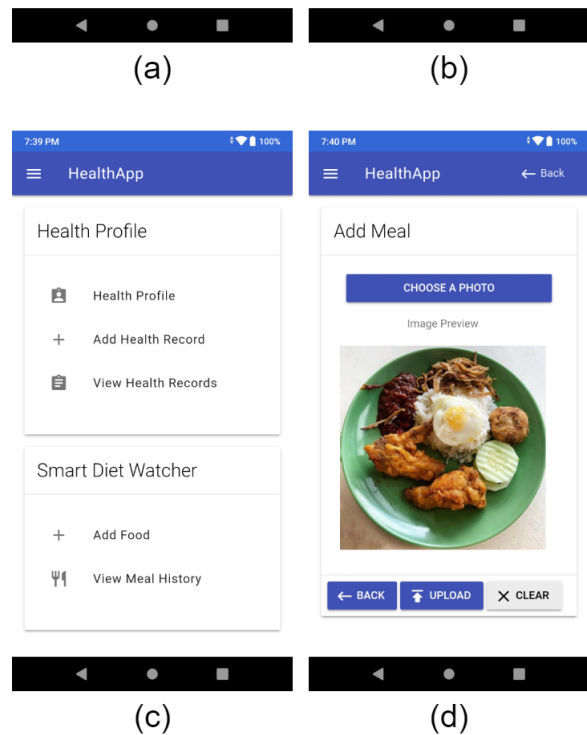

Fig. 5. (a) Shows the Account Creation, (b) Shows the Login Interface, (c) Shows the Main Menu Interface, and (d) Shows the Meal Creation Interface.

The meal summary shows the food items contained in the meal image, the meal’s nutritional value and the user’s blood glucose level after the meal. The nutritional values shown in the meal summary is calculated based on the percentage of each consumed food item that was set by the user. The baseline nutritional values that are used for the nutrition calculations are based on the amount of a single full portion serving. Lastly, the user can view their past meal records from the meal history menu as shown in Fig. 6(d).

## V. DISCUSSION

To summarise, we trained a CNN model to predict food items found locally in Sarawak, Malaysia. Two publicly avail-

Fig. 6. (a) Shows the Interface for Adding Food Items, (b) Shows the Interface for Updating Food Items and the Post-Meal Blood Glucose Record, (c) Shows a Summary of the Meal, and (d) Shows the Meal History Menu.

able food datasets, Food-101 and Malaysian Food 11 datasets, were used for the initial model training. This was followed by incorporating local food items that were scraped from the web.

Upon training the initial model, we found that the *apple pie* food class was poorly performing. Thus, we investigated the effect of further preprocessing the images to improve the model's performance. We removed poor quality and unrelated images from the dataset, retrained the model and reported the effects of the preprocessing step in detail, shown in Table II. There was an improvement in accuracy despite the smaller number of training images, which is likely due to the images in the preprocessed dataset better representing the apple pie

class.

Next, we incorporated images of local Sarawakian food items scraped from the web into the dataset and retrained the model. Due to concerns of class imbalances for the web scraped images, focal loss was introduced. We explored the effect of focal loss on the model's performance, as shown in Table III. Interestingly, we found that the model without focal loss performed better overall, achieving a higher accuracy on most of the web scraped food classes despite the class imbalance. One notable case however is the *Ayam Pansuh* class which is severely imbalanced. The results obtained indicates that while focal loss is generally expected to improve performance when there is a class imbalance, it may be beneficial to train another model that does not implement focal loss as well in case the use of focal loss unexpectedly results in a poorer performing model.

## VI. LIMITATIONS

Currently, the number of food classes that the model can predict is limited. We plan to expand the total number of food classes that the model can predict by collecting local food images and using them to retrain the model. Our final goal is for the model to recognize most local food consumed in Malaysia.

The model's performance has been shown to improve through manual preprocessing of the apple pie class, indicating that there is a possible performance gain if all the images were manually processed. In particular, *FoodAI* [21] managed to achieve a top-1 accuracy of 83.2% where the authors put significant effort into manual inspection of the food images by domain experts while constructing the dataset. However, in our case, time and resource constraints limit the manual preprocessing of the dataset. This limitation can be addressed in future work by looking into methods of automating the dataset preprocessing via CNN-based feature extraction and clustering [32] to group visually similar images for batch labeling.

## VII. CONCLUSION

In this paper we implement a food classification model with a CNN-based architecture. Transfer learning was applied to boost the model's performance and reduce training time. We explored the effect of manually preprocessing of the dataset on the model's performance. Results indicate that the model's performance can be improved further by carefully curating the images that are used for training the model. In future work, we plan to expand the food classes that the model can predict to classify more local Malaysian dishes.

## ACKNOWLEDGMENT

The authors extend appreciation to collaborators in the Clinical Research Centre, Sarawak General Hospital for validating our works and testing our applications. The project is funded under Prototype Research Grant Scheme from the Malaysia Ministry of Higher Education, Ref: PRGS/1/2019/ICT02/SWIN/01/1.

# Rethinking Classification of Oriented Object Detection in Aerial Images

Phuc Nguyen\*, Thang Truong\*, Nguyen D. Vo, Khang Nguyen\*\*  
University of Information Technology, Ho Chi Minh City, Vietnam  
Vietnam National University, Ho Chi Minh City, Vietnam

**Abstract**—With the help of the rapid development of technology, especially the prevalence of UAVs (unmanned aerial vehicles), object detection in aerial images gains much more attention in computer vision and deep learning. However, traditional methods use horizontal bounding boxes for object representation leading to inconsistency between objects and features. Therefore, many detectors are being built to tackle this problem, and normally they use the conventional approaches of training and testing to achieve the results. Our pipeline proposed to strengthen not only the classification but also localization via independent training processes using convex-hull transformation in data pre-processing phase. We experimented with the well-designed S2ANet, R3Det, ReDet, RoI Transformer and Oriented R-CNN on the well-established oriented object detection dataset DOTA. Then we adopt the best detectors with the well-known classification network EfficientNet to our proposed pipeline and achieve promising results on the oriented object detection DOTA dataset. Moreover, our pipeline can flexibly be adapted to various oriented object detection baselines improving the results in classification via independent extensive training cycles.

**Keywords**—Aerial images; classification; convex-hull transformation; data processing; oriented object detection

## I. INTRODUCTION

Object Detection in Aerial Images (ODAI) has always been important in our real life with tremendous real-world applications such as surveillance, disaster prediction, emergency rescue, and even urban management [1] [2] [3]. Nowadays, it is becoming more feasible thanks to the increasing growth of studies in deep learning and the fast-paced development of information and communication technology. However, objects collected from aerial images appear in a variety of representations. They are often distributed in arbitrary orientations leading to confusion for many latest deep learning models, which opens a new study aspect in computer vision. To tackle this problem, a lot of experiments conducted show that using oriented bounding box representation (OBB) instead of horizontal bounding box (HBB) representation will alleviate the mismatch features and increase object detection accuracy [4] [5] [6] [7].

ODAI is extremely crucial to this world so it requires high accuracy and fewest mismatched objects in the prediction task as possible [8]. Although detecting objects in aerial images is vital, there is a lack of data about it. Many well-designed methods follow the traditional pipeline without refining class

labels for output predictions, which could lead the model to behave biased toward less significant objects. Our proposed pipeline ensures that classes are treated equally, and models learn as much as data features from not only inside but also outside of the dataset through an independent classification training process.

In this study, we propose and provide a deep analysis of an effective training and testing pipeline to surge the performance of oriented object detectors in aerial images. Our pipeline applies the convex-hull transformation on ground-truth oriented bounding boxes to extract proper instances for the training and testing processes. Furthermore, we can use extra data for the independent training process to ensure the model classify proper label instances. We conduct extensive experiments on multiple baselines and apply the pipeline on them, yielding promising results.

We summarize our contributions in this paper as:

- Proposing a novel training and testing pipeline to improve classification performance flexibly adapt to many latest models.
- Providing a wise way to prepare data for classification training and an effective ensemble method in testing models.
- Using convex-hull transformation technique to transform oriented bounding boxes to horizontal ones for the further training process.
- Give a deep analysis of why we are choosing this pipeline and what are common problems of nowadays object detection methods in aerial images.
- Carrying out extensive experiments with the latest oriented object detection methods and providing an in-depth evaluation of the best deep learning models to strengthen our proposal.

The rest of the paper is: Section II is Related works; Section III is Methodology; Section IV is Our approach; Section V is Experiment and finally the last one, Section VI is Conclusion and Future Work.

## II. RELATED WORKS

### A. Oriented Object Detection

For the past decade, there have been various well-established object detector methods designed for tackling the horizontal object detection task, many of which have made remarkable progress such as Fast R-CNN [9], Faster R-CNN [10],

\*\*Corresponding author

\*Equal Contributor

Dynamic R-CNN [11], Deformable DETR [12], SSD [13], YOLOF [14], YOLOX [15], etc. However, these general object detection methods cannot tightly locate the object leading to the inconsistency between the classification and localization processes. Therefore, the extended branch of study using an oriented bounding box to represent the object's ground truths receives extensive attention to meet the need for applying deep learning to real-world applications (Fig. 1).

Current oriented object detection methods heavily depend on the original horizontal object detection task. They adopt the mechanism from extracting deep features and generating proposals to refining the final bounding boxes results. For example, Ding et al. introduced RoI Transformer [16] to tackle the problem of misaligned between regions of feature and objects, they applied the spatial transformation to Regions of Interest and configured the model to learn these geometric parameters using oriented bounding boxes labels. Jiang et al. introduced Rotational Region CNN [17] for detecting arbitrary-oriented texts in natural scene images. The model adopted the Faster R-CNN baseline using the region proposal network (RPN) to generate HBBs of texts and those HBBs will integrate many pooled RoI features to produce the final regressed OBBs. Han et al. introduced Single-shot Alignment Network (S2ANet) [18], addressing the issues of inconsistency between classification and localization. S2ANet consists of two main components: Feature Alignment Module (FAM) and Oriented Detection Module (ODM). The FAM specifically uses the Alignment Convolution to generate well-qualified anchors on which the active rotating filters of the ODM apply to encode the orientation information. Eventually, the network produces orientation-sensitive and orientation-invariant features to mitigate the inconsistency between classification scores and localization accuracy.

Fig. 1. Oriented Bounding Box (OBB)  $[(x, y), w, h, \theta]$ , where  $(x, y)$  is the Center and  $w, h, \theta$  are the Width, Height and Angle of an OBB.

## B. Classification

Classifying objects in aerial images using their CNN extracted features has always been a challenging problem since aerial images usually contain a tremendous number of various-shape instances. In 2020, Dosovitskiy et al. proposed a method Vision Transformer [19] following the baseline of the original architecture Transformer with the fewest modification possible. ViT splits images into many patches and connects these patches (NLP-vibes) using a sequence of linear embeddings. As the result, these patches are treated as tokens like in NLP and receive object queries for output labels. Tan and Le introduced EfficientNet [20] achieving better accuracy and efficiency than previous ConvNets by leveraging a multi-objective neural

architecture search that optimizes both accuracy and FLOP. EfficientNet-B7 achieves state-of-the-art 84.3% top-1 accuracy on ImageNet while keeping inference time faster than prior ConvNets methods. Xie et al. introduced a multi-branch architecture called ResNext [21]. The deep network inherited by ResNets [22] consists of repeating building blocks aggregating a set of transformations with the same topology. By conducting extensive experiments, the authors came up with the conclusion that increasing cardinality is a more effective way of gaining accuracy than going deeper or wider, especially when depth and width start to give diminishing returns for existing models. The ResNext outperforms ResNet-101/152 [22], ResNet-200 [23], Inception-v3 [24] and Inception-ResNet-101/152 [25] on the ImageNet [26].

## III. METHODOLOGY

The fundamental step to tackle Object Detection in Aerial Images is to collect a sufficient amount of data for training models, however in real life, especially in aerial images, objects are often distributed randomly, leading to hardship in data preparation steps. Therefore, humans unintentionally create many imbalanced datasets (Fig. 2) and passively bias the deep learning models.

Object detection in aerial images appears challenging when detectors have to deal with the variety in object scales and orientations, making them extremely difficult to identify. The most common way to approach these problems is image augmentation [27] (more image-more feature-high performance). In addition, the Elhagry and Saeed proposed many methods in [28] to solve this problem, such as modifying generated anchor sizes for region proposals and investigating multiple backbones and loss functions and achieved an improvement of 4.7 mAP over the baseline.

Consider image augmentation as a feasible solution for these problems. Some basic data augmentation methods are applied frequently, such as random crop, random rotate, random flip, zoom, etc. These augmentation techniques only apply to the whole image (Fig. 3), so what about class imbalance? It seems extreme to improve classification performance via improving the classification branch inside the models due to common batch sampling methods.

What if we train the classification independently from the object detection network and ensemble the results together? Although this approach might look heavy, ensure that not only you can modify each class independently (augmentation, removing noises) but also add extra necessary data for extended training cycles (Fig. 4).

## IV. OUR APPROACH

### A. Pipeline

Our pipeline consists of two main parts: training and testing. In the training phase, Fig. 5, we train independently two networks (classification network and oriented object detection network). For the classification training data, we crop out oriented bounding boxes using convex-hull transformation and then carefully interpolate them to horizontal images. The data then proceeded to the classification network with a re-weighting mechanism. For the oriented object detection network, we train it with the original dataset to ensure regressed

Fig. 2. Data Distribution Leads to the Problem of Class Imbalance in our Dataset. Our Target is to Implement the Model so that it Behaves Unbiased Toward Every Class.

Fig. 3. Data Augmentation is a Common Method to Enrich the Amount of Data used for Training Object Detection Models. It only Enriches the Amount of Data, While we need the Instances Enrichment in Each Class.

Fig. 4. Data Augmentation for Every Instance for each Class Ensures Richness in Features for the Classification Training Procedure.

bounding boxes are accurate. In the testing phase, Fig. 6, predicted oriented bounding boxes then be cropped out and interpolated to horizontal boxes. They will be re-labeled by the classification network (keeping high confidence score) and ensemble with the results of the oriented object detection network. Finally, those with low confidence scores will be removed as long with the NMS process from the prediction set.

Fig. 5. Training Phase: Training Data Passed through an Oriented Object Detector's Network Contributes to Training Classification and Localization as in Other Well-Known Pipelines. However, the Required Data Preparation for Training the Classification Network is an Indispensable Step. Oriented Ground-Truths First are Interpolated to Cropped Oriented Bounding Boxes via Convex-Hull Transformation, then they're Transformed to Horizontal Images Fed to a Classification Network Together with not only the Re-Weighting Mechanism but also Image Augmentation Methods.

Fig. 6. Testing Phase: Different from the Training Phase, the Testing Image is Fed into Only the Oriented Object Detection Network. Then these Regressed Oriented Bounding Boxes Produced from the Network are Fed into the Classification Network after being Interpolated to Output the Predicted Label. Finally, we Ensemble the Outputs from Both Networks to Get the Appropriate Results in the Final Prediction set via Score Fine-Tuning and Non-Maximum Suppression.

### B. EfficientNet

EfficientNet [20] adopting the idea of the CNN network can be scaled in three dimensions: depth, width, and resolution. The depth of the neural network corresponds to the number of layers in the network. The width refers to the number of neurons in each layer or the number of channels in each Conv layer (the number of channels of the output). Resolution is simply the height and width of the input image. The following Equation 1 describes the compound scaling method where  $d$  is

Fig. 7. EfficientNet-B0 [31] Structure.

Fig. 8. Difference between Residual Block and Inverted Residual Block [30].

the depth,  $w$  is the width and  $r$  is the resolution. Moreover,  $\phi$  is a user-defined coefficient determining the available resources for model scaling and  $\alpha, \beta, \gamma$  specify how to assign these extra resources to network width, depth, and resolution.

$$\begin{aligned} d &= \alpha^\phi \\ w &= \beta^\phi \\ r &= \gamma^\phi \end{aligned} \tag{1}$$

Following the constraints:

$$\begin{aligned} \alpha \cdot \beta^2 \cdot \gamma^2 &\approx 2 \\ \alpha \geq 1, \beta \geq 1, \gamma \geq 1 \end{aligned}$$

The compound scaling method can generalize to existing CNN architectures such as MobileNet [29] and ResNet [22]. However, choosing the base network is important to get the best results because it only increases the predictive power of the neural network by reconstructing the parameters and structure of the base network. The author also uses Neural Architecture Search to build an efficient network architecture - EfficientNet B0. It achieves 77.3% accuracy on the ImageNet with 5.3M parameters and 0.39B FLOPS (ResNet-50 achieves 76% accuracy with 26M parameters and 4.1B FLOPS).

The main building block of EfficientNet-B0 is the MBConv block. The MBConv block, Fig. 8 is similar to the inverted residual block used in MobileNetv2 [30]. In this block, there is a shortcut connection between the beginning and the end of the block. The input is scaled with a 1x1 Conv layer to increase the number of channels or the depth of the feature map. Then they use Depthwise convolution 3x3 and Pointwise convolution (Conv layer 1x1) to reduce the number of channels of the output. A shortcut connection connects narrow layers (a small number of channels) while wider layers are in the middle of the shortcut connection (Fig. 7). This structure helps to reduce the number of parameters and the number of operations.

### C. R3Det

ReDet [4] proposed to take a huge step from horizontal object detection to oriented object detection by solving feature misalignment during the feature extraction process. The model uses the Feature Refinement Module together with feature interpolation to extract position information related to the

refined bounding box and reconstructs feature maps to achieve feature alignment. R3Det adopts Refined Rotation RetinaNet as the backbone with multiple stages of refinement like Cascade while speeding up the model by reducing the number of refined bounding boxes in the first stage.

### D. S2ANet

S2ANet [18] proposed to solve the inconsistency between classification and localization performance. It adopts the Feature Pyramid Network to extract high-level features. Anchor generator, namely Feature Alignment Module, generates high-quality anchors which then pass through Oriented Detection Module for classification and regression.

### E. RoI Transformer

RoI Transformer [16] tackles the problem of using horizontal bounding boxes (mismatch features). The model consists of the lightweight Rotated RoI learner with a 5 dimensions fully connected layer representing the offset of the rotated RoI corresponding to the HRoI. Rotated RoI warping generates fixed-size geometry robust features for classification and regression via feature maps and rotated RoIs.

### F. ReDet

ReDet [32], namely the Rotation-equivariant Detector adopts ResNet [22] and Feature Pyramid Network so as to extract rotation-equivariant features. RiRoI Align proposed along with the model transforms rotated RoIs generated by an RPN and RoI Transformer [16]. The final feature extraction step regresses final oriented bounding boxes and classifies corresponding labels.

### G. Oriented R-CNN

The well-designed two-stage detector Oriented R-CNN produces high-level features for oriented object detection. The main structure inherits from the two-stage object detector baseline while introducing a new representation of region proposals. The oriented RPN encodes features received from each level feature of the FPN [33] and decodes them into RoIs under the Midpoint Offset representation. Due to the Midpoint offset representation, the oriented proposal generated by oriented RPN is usually a parallelogram, so the model will slightly adjust the shorter diagonal to the same length as another diagonal obtaining oriented bounding boxes. Finally, each RoIs is divided into  $m \times m$  grids to produce a fixed-size feature map  $F'$ . The idea that produces feature map  $F'$  adopts the idea of the rotation transformation the same as [5] and these fixed-size feature maps  $F'$  are then fed into fully-connected layers regressing the offset and assigning categories for each oriented bounding box.

### H. Non Maximum Suppression

In the process of improving this result, after relabeling the result by EfficientNet, we use non-maximum suppression (NMS) to sift out the overlapping bounding box instances as follows (Fig. 9):

**Input:** a list of oriented bounding box  $A$ , corresponding confidence score  $S$  and overlap threshold  $N$ .

Fig. 9. Objectives of Non-Maximum Suppression. (a) Before NMS. (b) After NMS.

**Output:** a list of sifted bounding box B.

**Algorithm:**

Step 1: Select the bounding box with the highest confidence score, remove it from A and add it to the final list B.

Step 2: Now compare this bounding box with all the bounding boxes in A (calculate the IoU). If the IoU is greater than the threshold N, remove that bounding box from A.

Step 3: This process is repeated until there is no more bounding box left in A.

We calculate IoU between two oriented bounding boxes as IoU between two rectangles (each is the smallest horizontal rectangle that includes the corresponding oriented bounding box) as Fig. 10.

Fig. 10. Intersection over Union.

### I. Results Post-Processing

After having regressed the oriented bounding box, we transform it to the horizontal one and feed it through the classification network to get the appropriate label. Also we ensemble the classification results with the oriented object detection network to make cleaner results. Finally, NMS will be activated to sift and get the right fitter bounding boxes. This approach will ensure that there will be no more overlapping bounding boxes for one object caused by class imbalance and inconsistency between regression and classification (common problems in aerial images dataset).

## V. EXPERIMENT

### A. Experiment

**DOTA Oriented Dataset:** In this study, we conducted experiments on the DOTA dataset [34], which is a large-scale dataset widely used for the oriented object detection problem in aerial images. The DOTA was introduced in 2018, containing 2,806 images, and the proportion of the training set, validation set, and testing set were 1/2, 1/6, and 1/3, respectively. The dataset contains 188,282 instances which are accurately labeled of 15 common object categories includes: plane (PL), baseball-diamond (BD), bridge (BR), ground-track-field (GTF), small-vehicle (SV), large-vehicle (LV), ship (SH), tennis court (TC), basketball court (BC), storage tank (ST), soccer-ball-field (SBF), roundabout (RA), harbor (HA), swimming pool (SP), and helicopter (HC).

**Data Preparation for Classification Training:** To train the EfficientNet model, we need an input dataset that is an object image set (bounding box of objects) on each DOTA class. This process is illustrated in Fig. 11.

Step 1: Determine the object bounding box to be extracted [Fig. 11(a), red quadrangle].

Step 2: The object bounding box shape we need to take out is a rectangle but DOTA's labeled bounding box is arbitrary quadrilateral, so we take the smallest oriented bounding box that covers DOTA's labeled bounding box (convex-hull transformation) [Fig. 11(b), green bounding box].

Step 3: Rotate the image so that the bounding box to be taken becomes a horizontal bounding box. To reduce the calculation cost, we define the smallest area of the image that includes the box to be extracted, then proceed to rotate this area [Fig. 11(c), 11(d)]

Step 4: Extract the object bounding box [Fig. 11(e)].

Fig. 11. Data Preparation Steps using Convex-Hull Transformation.

Apply the above steps to all instances on DOTA's train and validation set, then we get the train and validation set to train EfficientNet, the detail as shown in Fig. 12. DOTA is the imbalance dataset - a normal problem in real-life aerial images data where vehicles and ships outweigh most of them.

**Experimental Configuration:** We implement Oriented R-CNN, S2ANet [18], ReDet [32], R3Det [4], RoI Transformer

Fig. 12. Illustration of the Number of Ground-Truths in Training and Validation set of DOTA Dataset.

[16] on MMRotate [35] and EfficientNet-b3 on MMClassification [36] framework with repeat factor sampling methods [37] solving class imbalance problem using 2x GPU RTX 2080Ti

**Evaluation Metric:** To evaluate the performance of the models, and our pipeline on the DOTA dataset, we use the mAP score (mean Average Precision). Mean Average Precision is a popular evaluation metric used for object detection. It is the average of AP in every class in a dataset.

### B. Analysis

In this study, we test five models, R3Det, RoI Transformer, ReDet, S2Anet, and the Oriented R-CNN along with post-processing methods on the DOTA dataset and achieve the results presented in Table I.

For the initial results, all models perform very well in directional object detection (mAP ranges from 70% to 77%). In which the highest resulting model is ReDet (mAP = 76.68%) and the lowest is R3Det (mAP = 69.8%). Across DOTA's 15 layers, the accuracy of each model on each class varies widely (accuracy ranges from 50% to 90%), of which the highest are tennis-court (about 91%) and plane (about 89%); Especially the lowest is the helicopter class, resulting in a sizable difference between models (the highest is on ReDet 66.71%, the lowest is on R3Det 37.44%). Besides, R3Det also achieved very low results on the bridge class (45.41%) compared to other models in this class.

However, in the results of the above models, there is the same limitation which is the discovery of many other bounding boxes of the different classes located on the same instance (Fig. 13).

The two most accessible post-processing solutions:

- The first is the result of sifting out boxes, the scores of which are less than a certain threshold. The results are pretty good [Fig. 14(b)], but there are still some overlapping bounding boxes because these wrong bounding boxes have a score greater than the sifting threshold [Fig. 15(a)]. And this besides removing bounding boxes also removes quite a lot of true bounding boxes [Fig. 15(b)];

- The second is that as a result of using multi-class non-maximum suppression, similar to the first solution, the result of removing bounding boxes is also quite good [Fig. 14(c)]. However, this also has a limitation, which is the removal of bounding boxes in case 2 objects overlap. Both solutions caused the model's mAP results to decrease (about 2%).

After applying our initial solution: relabel all bounding boxes using EfficientNet, then apply non-maximum suppression to sift out overlapping bounding boxes. The result is that there is only one bounding box per object, which is more effective than all 2 conventional solutions above [Fig. 14(d)]. However, the accuracy of the results is significantly reduced (down almost 10-40% from the original). Among them, the most affected classes are soccer-ball-field (about 20-40%), bridge (about 14-60%), and helicopter (about 17-30%), ground-track-field (about 12-50%). The subjective reason for the decrease in results on layers is due to the misidentification between classes of EfficientNet, between classes with similar characteristics that make the model easily confused (between small-vehicle and large-vehicle, ship; between roundabout, plane and helicopter) (Fig. 16). The objective reason is that the imbalance of big data between classes (Fig. 12, small-vehicle and ship over 20k bounding boxes, while the remaining classes such as soccer-ball-field, ground-track-field are only about over 300 bounding boxes) makes the quality of layering between classes uneven; And the lack of information about the surroundings, because EfficientNet is only trained on the image, are bounding boxes (the similarity between ship and small-vehicle when cut into bounding boxes, Fig. 17).

So, to improve the accuracy of our pipeline, we combine the results between the original model and the results of EfficientNet, in detail: we will not be too confident in EfficientNet, which means that there will be no relabeling if the results returned by EfficientNet belong to soccer-ball-field, helicopter, bridge, and ship (which are classes that the EfficientNet model classifies inefficiently and affects the other classes analyzed above); it only be relabeled if the original model gives an uncertain result, which means that there will be a threshold if the model gives results below this threshold, then relabel will be applied.

The final score result of our pipeline is close to the original result (on three models with highest original results, RoI Transformer, ReDet, Oriented R-CNN), higher than the usual two solutions, and also very high efficiency in sifting wrong bounding boxes (Fig. 18). The other two models (S2Anet, R3Det) have a lot of wrong boxes, having a relabel doesn't work well either.

Besides efficiency, our pipeline is still wrong in several instances [Fig. 19(a)], which is still limited in cases where wrong bounding boxes or bounding boxes are part of the instance of the true bounding box (e.g. on container truck objects surrounded by large-vehicle boxes, but another bounding box covers the front of the car as a small-vehicle, Fig. 19(b))

In summary, our pipeline has solved the problem of multiple different boxes on the same object while keeping accuracy. The solution still does not resolve the case where wrong bounding boxes or different classes bounding boxes are part of the object of the true bounding box.

## VI. CONCLUSION

Generally, our pipeline adopts very well to many lots of SOTA baselines, yielding promising results and solving problems of inconsistency between classification and localization. According to our experimental results, our pipeline yields promising results on the oriented DOTA dataset by extracting oriented bounding boxes and feeding to independent training cycles. In the future, we are researching more training and testing pipelines, seeking more baselines for oriented object detection. Our work introduces a fine pipeline for tackling mismatched features in classification, if exploited well enough, it will significantly boost detection performance.

## ACKNOWLEDGMENT

This research is funded by Vietnam National University Ho Chi Minh City (VNU-HCM) under grant number DS2021-26-01. We also would like to show our gratitude to the UIT-Together research group for sharing their pearls of wisdom with us during this research.

# TextBrew: Automated Model Selection and Hyperparameter Optimization for Text Classification

Rushil Desai<sup>1</sup>, Aditya Shah<sup>2</sup>, Shourya Kothari<sup>3</sup>, Aishwarya Surve<sup>4</sup> and Dr. Narendra Shekokar<sup>5</sup>  
Department of Computer Engineering, Dwarkadas J. College of Engineering  
Mumbai, India

**Abstract**—In building a machine learning solution, algorithm selection and hyperparameter tuning is the most time-consuming task. Automated Machine Learning is a solution to fully automate the process of finding the best model for a given task without actually having to try various models. This paper introduces a new AutoML system, TextBrew, explicitly built for the NLP task of text classification. Our system provides an automated method for selecting transformer models, tuning hyperparameters, and combining the best models into one by ensembling. Keeping in mind that new state-of-the-art models are being constantly introduced, TextBrew has been designed to be highly flexible and thus can support additional models easily. In our work, we experiment with multiple transformer models, each with numerous different hyperparameter settings, and select the most robust models. These models are then trained on multiple datasets to obtain accuracy scores, which are then used to build the meta-dataset to train the meta-model. Since text classification datasets are not as abundant, our system generates synthetic data to augment the meta-dataset using CopulaGAN, a deep generative model. The meta-model is an ensemble of five models, which predicts the best candidate model with an accuracy of 78.75%. The final model returned to the user is an ensemble of all the best models that can be trained under the given time constraint. Experiments on various datasets and comparisons with existing systems demonstrate the effectiveness of our system.

**Keywords**—Automated machine learning; AutoML; NLP; transformer models; hyperparameter optimization; CopulaGAN; generative model; meta-learning

## I. INTRODUCTION

As more and more people recognize the actual value of data and try to get the most out of it, the demand for machine learning tools is increasing. But the complexity of the tasks involved in machine learning can be overwhelming for non-ML experts, and this is where automated machine learning comes into the picture. Non-ML experts can use AutoML for building ML projects. ML experts can also use it to perform repetitive tasks to save time and accelerate machine learning research by automating the development of models. Using AutoML, one can train high-performing models without worrying about hyperparameters, model architecture, or cross-validation strategies [1]. It aims to automate the model selection process, as shown in [2], [3], and its applications are increasing by the day, hand-in-hand with the growth of applications of machine learning.

Machines must use complex data processing and state-of-the-art machine learning algorithms to work with natural language. It is also essential to decide the particular machine learning method based on the dataset and the task. Selecting the correct method may become difficult as more

accurate methods are constantly being developed. Even after considering all these factors for choosing the algorithms and methods, getting the best result is not assured. AutoML for text classification (TextBrew) can address all these challenges.

Finding the best model and the best set of hyperparameters is tedious. This task requires a lot of time and resources since training a model on a dataset may take hours or even days, subject to the size of the dataset and the model being used, and then changing hyperparameters and training the dataset all over again becomes an even more tedious and patience-testing task. We aim to tackle this issue and give the user the best model for an NLP classification task.

This paper presents a system that returns the trained model predicted to be the best for it within a particular time limit when given a dataset as an input. Our system is such that it is effortless to add new state-of-the-art transformer models to the pre-existing pool of models for the system to consider those models. In this paper, we have performed all experiments on BERT [4], ALBERT [5], and XLNet [6] for text classification using multiple hyperparameter combinations for each. A major part of building our AutoML system is creating the meta-dataset, which is made by training and testing several deep learning models on multiple text classification datasets. This process has been made efficient using generative models to synthesize data instead of running models on many datasets. The results demonstrate the effectiveness of our system.

### A. Contribution and Organization of the Paper

To sum up, we aim to reduce the time spent by a data scientist on selecting a particular model and its hyperparameter values. As seen in the next section, a significant drawback of many AutoML systems is the inability to support additional, more complex models. TextBrew has been developed keeping this problem in mind. The contributions of our paper are as follows:

- 1) We show the effectiveness of using deep generative models to synthesize the training data instead of spending hours running models on a large number of datasets.
- 2) TextBrew is a flexible system that can accommodate the new models with the least number of changes possible as it is not built around any specific set of models. All that is needed for the inclusion of a new model is for it to be added to the model pipeline which is run while generating the meta-dataset.

This paper is structured as follows. In the next section, we review the related literature. Section III discusses the

methodology we have adopted. The results are described in Section IV, followed by the discussion in Section V. Sections VI and VII outline the conclusion and a plan for future steps, respectively.

## II. REVIEW OF LITERATURE

AutoML is a relatively new research topic and has made significant progress in recent years. Many surveys [7] summarize the works of other researchers on this topic. Most of these works focus on individual modules such as neural architecture search (NAS) or hyperparameter optimization (HPO) in classifying tabular data using classical algorithms. There is significantly less work done on AutoML for text classification, which is quite different from classifying tabular data because textual data is unstructured and requires more computationally intensive algorithms.

There are works published that compare the performance of various existing AutoML tools on text classification tasks. Blohm et al. [8] attempt to answer the question of whether AutoML can be effectively applied to text classification or not. They compare the performance of four AutoML tools on thirteen text classification datasets and document how they perform as opposed to human-engineered models. Their experiments show that AutoML systems perform better than humans on 4 out of 13 tasks, and this number will continue increasing as more sophisticated AutoML tools for NLP tasks are developed.

Some individual works have tackled the problem of AutoML for text classification. Madrid et al. [9] propose a method that automatically builds text classification pipelines based on the metadata obtained by running experiments using standard algorithms on 81 datasets. While it is effective, metadata obtained from 81 datasets could be insufficient for a machine learning model to learn and give optimal results.

Wong et al. [10] incorporate transfer learning to reduce the computational cost of Neural AutoML. Their system learns the hyperparameter choices common to multiple tasks and uses this to accelerate the network design for a new task. The results show a reduction in convergence time for text classification. The drawback of this system is that meta-overfitting has not been dealt with, which is an issue.

Gomez et al. [11] have used a hyper-heuristic approach by employing a genetic algorithm to evolve a population of meta-rules to decide the best model for the particular text classification dataset. This work considers only simple models: K-Nearest Neighbor, Logistic Regression, Support Vector Machine, and Multinomial Naive Bayes. While this approach is interesting, it is not ideal because an AutoML system for the task of text classification needs to be able to handle the high computational cost and complexity of state-of-the-art transformer models.

A similar issue is present in the system proposed by Feurer et al. [12]. They use Bayesian optimization to capture the relationship between the hyperparameter values and the model performance. This system includes 15 classifiers, 14 feature preprocessing methods, and 4 data preprocessing method in its search space. Including deep learning methods would have made their system more competitive with other AutoML systems for text classification.

Additionally, there exist some open-source AutoML systems that work with text data. Jin et al. [13] propose the AutoML system AutoKeras, which efficiently performs neural architecture search using Bayesian optimization, enabling it to select the most profitable operation each time. Shi, Mueller, et al. [14] in their paper use transformer networks and stack ensemble them with classical tabular models to handle data that contain text, numeric, and categorical features. A drawback of this system is that it works with a limited search space compared to other AutoML tools.

We propose TextBrew, a simpler system for AutoML for text classification, which offers an automated way for selecting the best transformer models and then training these models on the dataset with hyperparameter tuning within the time constraints provided by the user. The issue of creating a large meta-dataset, which takes a tremendous amount of time and effort, is solved by using GANs [15] to synthesize additional data.

## III. METHODOLOGY

### A. Overview

The system offers an automated way for selecting the best transformer models and then training these models on the dataset with the proper hyperparameter settings. It is designed in such a manner that it can handle both binary as well as multiclass prediction datasets without explicitly stating so. As shown in Fig. 1, this system for automated text classification can be segregated into two parts:

- 1) Building and Training the Meta-model.
- 2) Using TextBrew for Model Prediction.

Meta-model refers to the model produced on training the meta-learning algorithm. In the first part, “Building and Training the Meta-model”, top-performing transformer models with many different combinations of hyperparameters are considered. After conducting experiments, the best-performing candidate models are shortlisted. “Candidate model” is used in this paper to refer to a model with a particular combination of hyperparameter values. Next, the multinomial Naive Bayes model is trained along with the selected candidate models on a collection of text classification datasets. Due to the small size of the meta-dataset (the dataset on which the meta-model is trained) generated at this stage, CopulaGAN [16] (a deep generative model) is used to synthesize additional data, helping our meta-model train better. From the meta-dataset, we use the accuracy of the Naive Bayes and ALBERT\_2 models along with the dataset size as the predictor variables to predict the performance of other models. A soft voting ensemble consisting of five models was used for building the meta-model, and this meta-model was trained on the generated dataset to achieve better accuracy.

In the second part, “Using TextBrew for Model Prediction”, the meta-model is used for model prediction. The best model predicted by the meta-model is trained on the dataset provided by the user under the given time constraint. After training the best candidate model predicted by the meta-model, the next best predicted model is trained if time remains. This is continued until the specified time is exceeded. Finally, an ensemble of all these models is returned to the user.

Fig. 1. Architecture Diagram of the TextBrew System.

### B. Building and Training the Meta-Model

Here, we describe how the meta-dataset is created and how the meta-model is trained.

For the real-world usage of this system, the system needs to be able to take into consideration a lot of different models. Transformer models are state-of-the-art machine learning models for NLP text classification tasks. There are a lot of different choices available, with GPT [17], BERT [4], RoBERTa [18], ELECTRA [19], ALBERT [5] and BART [20] being just a few of them. In fact, several different pre-trained models are based on each of these language models. For instance, BanglaBert [21] is a BERT-based Natural Language Understanding model pre-trained in Bangla. In addition, new models are being built at a blazing pace, and state-of-the-art models are being replaced frequently. This begs for a flexible system to accommodate the new models with the least number of changes possible.

1) *Candidate Model Selection:* Since transformer models are computationally costly, we perform all experiments needed to design this system using three models. The system is independent of the model choices and count. One can add more models in the same way described in this paper.

Gasparretto et al. [22], in their work, tested many algorithms on multiple text classification datasets, and it can be seen that these XLNet and BERT-base are among the top performing models in terms of accuracy.

In addition to these two models, we select ALBERT (A Light BERT) as one of our models as it has an architecture similar to that of BERT but has a fraction of the total number of parameters [5]. This makes it fast and less computationally expensive and so can help save time. Above are the reasons for selecting XLNet, BERT-base, and ALBERT for our experiments. These models are among the best for text classification.

Since all three transformer models have multiple hyperparameters that need to be tuned to an appropriate value, there are effectively many candidate models from which to choose. So, the next step is selecting the hyperparameter values for each model. We experimented with different combinations of hyperparameter values and picked the ones that gave us the best results when trained on multiple datasets.

The selected possible values of the hyperparameters for the models are shown in Table I. A short description of the

TABLE I. HYPERPARAMETERS AND SELECTED VALUES

Hyperparameters	Selected values
num_warmup_steps	[0, 1]
init_lr	[2e-5, 1e-5]
adam $\beta_1$	[0.8, 0.9]
adam $\beta_2$	[0.9, 0.999]
powers	[1, 1.5]
epochs	[3, 5]

hyperparameters is given below:

- 1) Num\_warmup\_steps: It is a parameter used to lower the learning rate to reduce the impact of deviating the model from learning on sudden new data set exposure.
- 2) Init\_lr: It is the initial learning rate before training and after warm-up steps.
- 3) Adam  $\beta_1$ , Adam  $\beta_2$ : The hyper-parameters  $\beta_1$  and  $\beta_2$  of Adam are initial decay rates used when estimating the moments of the gradient, which are multiplied by themselves at the end of each training step.
- 4) Powers: The power to use for polynomial decay.
- 5) Epochs: The number of passes or iterations of the training dataset by the machine learning model.

We choose the best set of hyperparameters by using an algorithm similar to grid-search. We run the transformer models with each possible combination of the hyperparameter values and compute the set of hyperparameters for which the model returns the best accuracy as output. In this case, each model effectively has  $2^6$  candidate models, counting all combinations of the six hyperparameters mentioned above.

Next, we selected three datasets to reduce bias in training the models. The three datasets are Sarcasm Detection [23], E-Mail classification NLP [24] and Financial phrase-bank [25]. Before training the candidate models on these datasets, the datasets were passed through a standard preprocessing pipeline. First, the text is converted to lowercase, and then we remove the URLs, non-ASCII characters, punctuations, and stopwords from the text. As this paper focuses mainly on model selection and hyperparameter optimization and not on the preprocessing of the data, the same preprocessing pipeline is used to clean all the datasets which are passed through the system.

All the candidate models for the three models, XLNet, BERT-base, and ALBERT, were then trained on the preprocessed datasets. Our system records how each hyperparameter combination performs on each dataset. Taking every possible combination of the hyperparameter values, we get 64 possible outcomes for each model. Hence, on trying these 64 outcomes for each of the three models for each of the three datasets, we effectively train 576 candidate models. The system records the accuracy attained by that particular model and the time required to train the model. From this dataset, we select the top six models (two from each of the three transformer models) as the shortlisted candidate models. We did this by averaging the accuracy of each unique hyperparameter combination model across the three datasets and taking the top two best-performing candidate models. This handles the situation where a model performs exceptionally well on one dataset and poorly on another. The top 6 models and the corresponding hyperparameter values are mentioned in Table II.

TABLE II. TOP SIX MODELS AND THEIR CORRESPONDING HYPERPARAMETERS

Model Name	Hyperparameters				
	epochs	warmup_steps	learning_rate	adam $\beta_1$	adam $\beta_2$
BERT_1	5	0	2e-5	0.9	0.999
BERT_2	5	0	1e-5	0.9	0.9
ALBERT_1	5	1	2e-5	0.8	0.9
ALBERT_2	3	0	1e-5	0.9	0.9
XLNet_1	3	1	1e-5	0.8	0.9
XLNet_2	3	1	2e-5	0.8	0.999

2) *Meta-Dataset Preparation:* After selecting the top six models, we create the meta-dataset for training the meta-model. We curated a list of 44 datasets consisting of both binary and multiclass text classification datasets. A longer list of datasets would have been beneficial, but for the task of English language text classification, the datasets publicly available are limited in number. On the other hand, a longer list of datasets means a lot more time to build the meta-dataset as more model training would have to be done. We solve this problem by synthesizing data using GANs, as described later in the paper. For each dataset, our system automatically trains all the selected candidate models and one additional multinomial Naive Bayes model. The accuracy and the training time taken for all these models are recorded.

The pipeline for training the multinomial Naive Bayes model consists of a count vectorizer that transforms the text into a vector based on the frequency of each word. A count matrix is created in which a column of the matrix represents each unique word in the dataset, and each row of the dataset is a row in the matrix, and the cells contain the count of the word in that text. Then, we transform the count matrix into a normalized TF-IDF representation. We use TF-IDF instead of the raw frequencies to reduce the impact of the frequently occurring words that are less informative than other words that occur in a small fraction of the dataset. We then train the multinomial Naive Bayes classifier on this. The reason for considering Naive Bayes for our model prediction is stated in the next section.

Table III shows a few records from our final meta-dataset.

3) *Feature Extraction:* The prerequisite step for training a classifier is feature extraction. Text embedding is the most

popular feature extraction method for text-oriented tasks [29]. Calculating embeddings for entire datasets is not feasible because of the computational expense that comes with it. Since the performance of any model depends on the dataset it has been trained on, the performance metrics of a model can be treated as a feature that is representative of the dataset. This approach is the basis for feature extraction in this paper.

Above is the reason for including multinomial Naive Bayes in the list of models. The accuracy of the Naive Bayes model is part of the feature space. The reason for choosing Naive Bayes is that it is extremely fast to train on the datasets compared to other models, making it efficient for use as a feature extraction tool. We also use the number of records in the dataset to predict the accuracy values of various models. Further, since ALBERT is A Light BERT model, it is faster to train than other transformer models we have chosen. Studying Table IV, we see that ALBERT\_2 consistently takes the least time to train. This makes it possible for us to take ALBERT\_2 accuracy scores as the third predictor variable to expand the feature space and, in turn, increase the accuracy of our meta-model. After running experiments to validate our hypothesis, we see that using the performance of the ALBERT\_2 model along with Naive Bayes performance and the dataset size improves the accuracy of the meta-model for predicting the best model. Adding the ALBERT\_2 accuracy score to the feature space boosts the accuracy by 26%, from 0.625 to 0.788, as shown in Fig. 2.

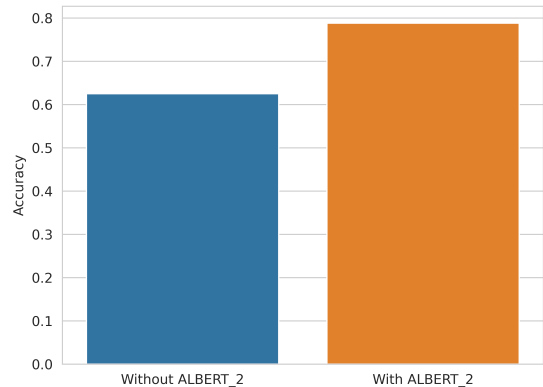

Fig. 2. Improvement in Overall Accuracy after Adding ALBERT\_2 Accuracy Score to the Feature Space.

4) *Using Generative Models to Synthesize Data:* Creating an extensive dataset requires a lot of time, and even if time constraints were not to be considered, publicly available text classification datasets are limited in number. Furthermore, overfitting is a problem faced by a model when the model predicts exceedingly well on the training dataset but cannot provide similar results on the testing dataset. It is known that small datasets are prone to overfitting. As a result, we need to tackle the overfitting problem caused by the small size of the dataset.

In this paper, we use GANs [15] to synthesize data and increase the dataset size to obtain a better result from the meta-classifier. Generative adversarial networks are an unsupervised learning approach to generative modeling using deep learning methods such as convolutional neural networks (CNN). Generative modeling involves automatic learning of patterns and the

TABLE III. CANDIDATE MODELS AND THEIR ACCURACIES ON DIFFERENT DATASETS

regularities of the data in a way that can be used to synthesize new examples that plausibly could have been drawn from the original dataset.

We employ the CopulaGAN model [16] to generate 150 data points for each group of datasets having a particular candidate model as the best model. This ensures that the resulting dataset is not unbalanced. The CopulaGAN model is a variation of the CTGAN model [30] which takes advantage of the CDF-based transformation that the GaussianCopulas apply to make the underlying CTGAN model task of learning the data easier. We make use of different metrics to compare the synthesized data and the original data. Seeing the results in Table V, we can be assured of the quality of the synthetic data.

TABLE V. METRICS FOR SYNTHETIC DATA EVALUATION

Kolmogorov-Smirnov Test	Multiclass Decision Tree Classifier
0.69	0.59

The Kolmogorov-Smirnov test [31] is based on the maximum difference between an empirical and a hypothetical cumulative distribution. The test concerns the agreement between the generated data and the original data. The Multiclass Decision Tree Classifier test lets the generated data pass through a decision tree generated on the original dataset. The resulting accuracy of this test indicates the percentage of data points that fall perfectly in accordance with the original data.

5) *Meta-Model Details:* We use a soft voting ensemble as our meta-model. This means that we predict the class with the largest summed probability from all the models that are part of the ensemble. Our ensemble consists of five models, each of which can perform a multiclass classification.

- 1) Multinomial Logistic Regression [32]
- 2) XGBClassifier [33]
- 3) C-Support Vector Classification following the One-vs-Rest scheme [34]
- 4) Random Forest Classifier [35]
- 5) AdaBoost Classifier [36]

We then use the generated data to train the meta-model. To see how the synthesized data improves the meta-model

performance, we train it on the original data, record the accuracy, and then do the same on the synthetic data. As expected, we get a low accuracy of 0.475 on training the meta-model on a small dataset. This accuracy score is boosted to 0.7875 after using synthetic data, which consists of a lot more data.

### C. Using TextBrew for Model Prediction

In this section, we describe how the user would use our proposed system and how the system makes use of the meta-model we trained in the previous section. The user passes a text classification dataset and an optional parameter: *allowed\_training\_time* as input to the system. The parameter *allowed\_training\_time* denotes the upper limit for the time the user expects the trained model to be returned as an output. This parameter helps users set a time limit for training the model if they have a time constraint. The default value of this parameter is set as 15 minutes in our experiments.

First, the dataset is passed through the same preprocessing pipeline we created for the datasets used for training, which is mentioned in the above sections. The preprocessing pipeline helps to clean the data and eliminate inconsistencies. The next step is to train Naive Bayes and ALBERT\_2 models on the preprocessed dataset. We considered Naive Bayes because it is swift to train, as shown in Table IV. ALBERT\_2 was considered because it was the fastest to train out of the six transformer models and could be used as a feature to predict the best model. The output of these two models, plus the size of the dataset, forms the feature space. These features are input to the meta-model, which predicts the best-performing model. The dataset given as input to the system is then trained on this predicted model, and the time taken for training is monitored. After training is completed, if the system has not exceeded the *allowed\_training\_time*, then it trains the next best model predicted on the same dataset. This continues until it exceeds the allowed time. Finally, an ensemble of all these trained models is created using a soft voting ensemble algorithm. The prediction probabilities for all the class labels are summed up, and the class label with the most considerable sum is selected as the predicted class. This ensemble is returned as the output.

#### IV. RESULTS

As mentioned in the previous section, we developed a meta-model that correctly predicted the best model with an accuracy of 78.75% on using CopulaGAN to synthesize data, compared to 47.5% on using the original data. This is a strong score given that the meta-dataset is generated using only 44 datasets because of the limited availability of open-source datasets for text classification. Additionally, 95% of the time, the first model predicted is among the top three models in terms of accuracy. These numbers indicate that it is highly likely that the best model will be part of the ensemble returned by the system as it consists of the first few models predicted to perform well by the meta-model.

We also present the results of the experiments that were performed using different datasets and different existing AutoML solutions for text classification. FakeNews, Covid Tweets Sentiment Analysis, and Cyberbullying Classification are the datasets used. We compare our system with AutoKeras [13] and AutoGluon [14]. In order to create an unbiased environment for all tests, we use Intel® Xeon® 2.00GHz CPU, Tesla P100 16GB GPU, and 13 GB of free memory for our usage.

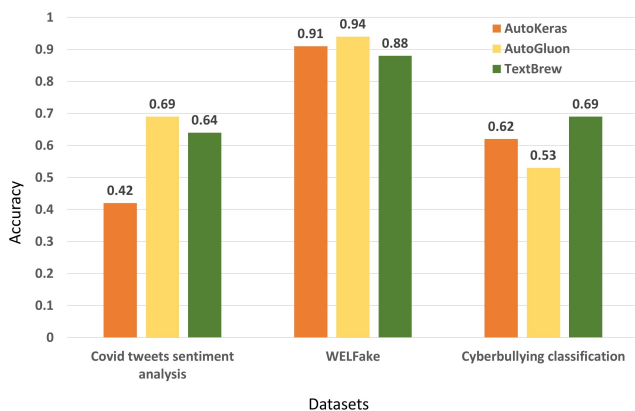

Fig. 3. Comparison of AutoML Systems, Including TextBrew (green), AutoKeras (orange) and AutoGluon (yellow).

We can see from Fig. 3 that our system gives the best accuracy on one dataset and a reasonable accuracy on the rest compared to AutoKeras and AutoGluon. Given that this is a prototype of our system and has only six candidate models originating from three different transformer models, i.e., BERT-base, XLNet, and ALBERT, the performance, as seen in Fig. 3, is extremely promising. Increasing the number of models described in the methodology section would lead to much better performance.

#### V. DISCUSSION

Today, very few AutoML systems for the NLP task of text classification exist that incorporate state-of-the-art deep learning models. AutoGluon is one of the best-performing AutoML models for text classification, as seen in Fig. 3, and TextBrew follows closely behind. In fact, TextBrew beats AutoGluon on one out of the three datasets with an accuracy that is 16% higher. With access to more computing power, we can incorporate more state-of-the-art deep learning models and a more comprehensive range of hyperparameter options, which

will enable TextBrew to be competitive and could challenge the best AutoML tools present today.

Moreover, TextBrew returns an ensemble of models that would give the best results on the given dataset. The best possible model out of the six selected models is found to be in the top three with an accuracy of 95%, of which 78.75% constitutes the situation where the first model predicted is actually the best. These numbers convey that the probability of the best candidate model being included in the ensemble generated by the system is very high.

The workings of our system back up the suggestion that automated machine learning does not have to be complicated to give good results. This is because this system does not employ any complicated methods or algorithms like genetic algorithms as seen in [11], deep reinforcement learning as seen in [10] and Bayesian optimization as visited in [12], [13]. The approach here is to build a meta-dataset and train classical ML models, which are used to predict the suitable transformer model. Nevertheless, TextBrew performs competitively considering the dataset's size and the approach's simplicity.

#### VI. CONCLUSION

This paper proposes TextBrew: an automated machine learning system for text classification. As discussed in the previous section, TextBrew suggests that AutoML systems do not have to be highly complex to perform well. The meta-model predicts the best possible model and suitable hyperparameters while considering the user's time constraint. Our meta-model predicts one of the top three models 95% of the time, with the best candidate model being predicted with an accuracy of 78.75%. This means that it is highly likely that the ensemble created by the system will include the best models.

The final model returned to the user is an ensemble of all the top candidate models that can be trained under the given time constraint. As seen in the results section, considering the low number of models in our system, TextBrew is promising, and it backs the idea that automated machine learning is not as complex as one would think.

#### VII. FUTURE WORK

For our future work, we aim to manually build and compile a greater number of text classification datasets to train our meta-model better. Additionally, we aim to access a more powerful computing system to include a much larger number of models and hyperparameter choices in our system.

# On-Device Major Indian Language Identification Classifiers to Run on Low Resource Devices

Yashwanth Y S

R.V College of Engineering  
Computer Science and Engineering Department  
Bengaluru, Karnataka, India

**Abstract**—Language Identification acts a first and necessary step in building intelligent Natural Language Processing (NLP) systems that handle code mixed data. There is a lot of work around this problem, but there is still scope for improvement, especially for local Indian languages. Also, earlier works mostly concentrates on just accuracy of the model and neglects the information like, whether they can be used on low resource devices like mobiles and wearable devices like smart watches with considerable latency. Here, this paper discusses about both binary classification and multiclass classification using character grams as the features. Considering total nine languages in this classification which includes, eight code mixed Indian languages with English (Hindi, Bengali, Kannada, Tamil, Telugu, Gujarati, Marathi, Malayalam) and standard English. Binary classifier discussed in this paper will classify Hinglish (Hindi when written using English script is commonly known as Hinglish) from seven other code-mixed Indian Languages with English and standard English. Multiclass classifier will classify the previously mentioned languages. Binary classifier gave an accuracy of 96% on the test data and the size of the model was 1.4 MB and achieved an accuracy of 87% with multiclass classifier on same test set with model size of 3.6 MB.

**Keywords**—Character grams; code-mixed; deep learning; Indian languages; language identification; NLP; social media text

## I. INTRODUCTION

In recent years, there has been a boom in the social media usage, especially in India, because of deep penetration of internet connectivity among people. There are close to half a billion active social media users with a growth of 4.2% every year [1]. Due to this rapid increase, people of various demographics and ages have started to use social media and in turn code mixed language has become more popular than ever on social media. Usually, a local regional language is mixed with English. Be it for hate speech detection on social media or to generate auto reply suggestions to incoming text message or any other NLP system that involves code mixed data, requires language tagging as first step and will determine the accuracy of the system as whole to a great extent. There are many difficulties with language tagging. Even though large amount of code-mixed language data is available to us as raw data (tweets, posts, blogs, etc.) on social media, we don't have a readily available tagged data set suitable for supervised learning [2]. Also, there are many dialects of same language, and so there are different spellings and pronunciations of the same word in code mixed context. Another important difficulty is, if the data set is not diverse, then the supervised language tagging model will suffer from over fitting [3]. This

paper aims in building code mixed Indian languages classifiers that can run on low resource devices with little latency, so that they can be used in real time applications like auto reply systems.

The reason for choosing the previously mentioned nine languages for classification is, 82% of Indian population speak one of the nine languages as their first language [4]. Since Hindi is spoken by 58% of Indian population [4], this article also considers a binary classifier that distinguishes Hinglish from other languages along with the multi class classifier. Collected close to 120k sentences for all the nine languages to create a separate train set and test set for training and testing model respectively.

In this article presents Stacked Bi-LSTM network that uses trigrams as features to classify Hinglish from other languages and Ensemble CNN - Bi-LSTM with attention network with both trigrams and quad grams as features for multiclass classification [5][6][7].

## II. RELATED WORK

In recent years, lot of research on language identification is done, which essentially is the first step in NLP systems, although less work is done where it involves detection of multiple Indian languages. Inumella Chaitanya et al. describe how common word embeddings like Continuous Bag of Words (CBOW) and Skip Grams models can be used to generate embeddings that can be feed to common machine learning models like support vector machine, Logistic Regression and K-Nearest neighbors among other algorithms [8]. Anupam Jamatia et al. in their paper describe about two models i.e., Bi-LSTM classifier and Conditional Random Fields (CRF) classifier and suggest that Bi-LSTM classifier performs better. Ramachandra Joshi and Raviraj Joshi describe about various input representations like character, sub-word and word embeddings, for language identification task in their paper. They also pass these representations as input to CNN and LSTM based models. They indicate that sub-word representation combined with LSTM model gives the best results [9].

Sourya Dipta Das et al. train multiple LSTM models and create an ensemble model using stacking and threshold technique which helping in increasing the accuracy of the model instead of using a single model [10]. Neelakshi Sarma et al. have developed a framework for language identification which is capable of recognizing words that are borrowed from other languages and used in multiple languages and predict

the language. This framework also considers the context of the sentence [11].

Monojit Choudhury et al. used both word embeddings and character embeddings, then concatenated both of them to predict the language [12]. Harsh Jhamtani et al describes a method which combines word embeddings, character n-grams and POS tagging to predict the language [13]. Shruti Rijhwani et al presents a unsupervised model for language detection that does not require any annotated data to train the model. It is also capable of detecting large number of languages [14].

### III. PROPOSED SOLUTION

This section discusses about the dataset creation, pre-processing steps, embeddings generation and finally about the classifiers i.e., binary and multiclass classifiers. In summary, first a data set is created by collecting data from various sources. Vocabulary or Embeddings are generated from the data set, which will be used to encode the input before giving it the model. All the steps are explained in detail, in following sections and summary of the steps in very high level is shown in Fig. 1.

Fig. 1. Summary of Steps of Proposed Solution.

#### A. Dataset

There was no readily available dataset for the previously mentioned nine languages. Had to create one by collecting data from multiple sources like reddit, Facebook posts, twitter tweets, WhatsApp chats and blogs. English language sentences are easy to collect but it is difficult to find and collect other Indian local languages code mixed with English. Data for Indian languages code mixed with English, was collected by scrapping from dedicated subreddit topics and twitter tweets. Also, used Google translate API, where we provide a English sentence as input to translate function of the API and set the destination language to any one of the Indian languages [15]. The translate function returns an object that has a pronunciation attribute. This pronunciation is a close approximation of Indian language sentences written in English script. In addition to this, after collecting the data, some irregularities to the spellings were introduced in the data set, so that the model does not suffer from overfitting problem. In total, the dataset consists of little above 100k sentences and the test set consists of about 13k sentences. The test data consists mostly of real world data and the approximation data generated from google translate API is not included. The distribution of train set and test set is shown in Table I and Table II, respectively.

#### B. Pre-Processing

These common preprocessing steps are applied to all the sentences in dataset and also to the input sentence given to

TABLE I. TRAIN SET

Languages	Number of Sentences
Hinglish	26804
Bengali	11570
Kannada	11148
Tamil	11115
English	11069
Gujarati	11032
Telugu	9231
Marthi	8166
Malayalam	6836
Total	106971

the trained model to predict. Removed the components of the sentences that don't help us in identifying the language. Digits, punctuation marks, extra whitespaces, HTML tags and emojis are removed.

Apart from these common preprocessing steps, irregularities to spellings of Indian languages is introduced into only train set. This is because, Indian language words when written in English script can have different spellings. For instance, the word "why" in Telugu language is spelled as "enduku" or "yenduku", when written in English script. Similarly, "where" in Kannada language is spelled as "ellige" or "yellige". So, introduced these extra letter in some cases into train set so that the model generalizes well and does not suffer from overfitting problem. The summary of preprocessing steps are shown in Fig. 2.

Fig. 2. Summary of Pre-Processing Steps.

TABLE II. TEST SET

Languages	Number of Sentences
Hinglish	2496
Bengali	689
Kannada	1338
Tamil	1554
English	3226
Gujarati	262
Telugu	1599
Marthi	1942
Malayalam	442
Total	13548

### C. Vocabulary/Embeddings Generation

Generated trigrams and quadgrams using all the sentences from the dataset and stored these character grams in form of a dictionary, where the character gram string is the key and a unique integer starting from 1 as the value for the key. So, each character gram is unique identified by an integer. Zero (0) is used to indicate out of vocabulary (OOV) character grams. Only top 20k (in terms of number times it appears in dataset) trigrams and quadgrams are selected. We are limiting the size of the embeddings to limit the size of the model, keeping in mind that we need models that can run on-device with as little resource utilization as possible. Separate dictionaries are created for trigrams and quadgrams. Trigrams are used as embeddings in binary classifier and both trigrams and quadgrams are used in case of multiclass classifier. These dictionaries are stored as csv files.

The process of encoding the input that must be given to the model, using the vocabulary dictionaries generated is described next. For instance, lets consider the following trigram vocabulary dictionary and input sentence in English as shown in Fig. 3. The input sentence is then split into trigrams and each of these trigrams are searched in the vocabulary dictionary. If there is a match, then value associated with the trigram in the dictionary is used for encoding. If the trigram match is not found, then it is a case of out of vocabulary (OOV) and 0 is used to encode such trigrams. Same is done when quadgrams are used as features.

### D. Binary Classifier

After following the preprocessing steps, the sentences in the train set are encoded using the earlier generated embeddings. Each sentence encoded is padded to have a size of 50. The first layer of the model is Embedding layer with vocab size of 20k, as previously mentioned and with both the input and output dimensions to be 50. The activation function for this layer was relu. The embedding layer is followed by a dropout layer (rate = 0.5). This followed by stacked Bi-LSTM layers with output dimensionality of 32 and 16. Stacking the Bi-LSTM layers, helped in boosting the accuracy of the model. This is followed by a dense layer with output dimensionality of 8 followed by drop out layer (rate = 0.5). Last is the output layer with sigmoid as the activation function. The summary of the model is shown in Fig. 4. The entire model was compiled with adam as optimization function and binary cross-entropy

Consider the following example vocabulary and input

```
trigram_vocabulary = [ 'hai':10 , 'kya':20 , 'hel':5 , 'the': 16 ,  
                      'ell':7 , 'llo':10 , 'ere':14 , 'her':8 ]
```

```
input = [ 'hello there' ]
```

Input Sentence is split into trigrams

```
input_trigrams = [ 'hel', 'ell', 'llo', 'lo ', 'o t'  
                  , ' th', 'the', 'her', 'ere' ]
```

See whether vocabulary has the trigram and encode with corresponding value, otherwise 0

```
input_encoding = [ 5 , 7 , 10 , 0 , 0 , 0 , 16 , 8 , 14 ]
```

Fig. 3. Steps to Encode Input.

as loss. The number of epochs was set to 3 and batch size was set to 64.

The trained model is then saved as a TensorFlow Lite (tflite) model in order to compress the size and decrease the latency of the model [16], without losing much on accuracy and tflite models are easier to use on low resource devices like mobiles or even embedded devices. The tflite model size came to be 1.4 MB. The coming sections discuss about the accuracy and performance of the model in detail.

### E. Multiclass Classifier

The preprocessing and encoding steps are same as for binary classifier, except both trigrams and quadgrams are used. Siamese neural networks are used, whose output is concatenated and given to a dense network to form an ensemble model [17][18]. Built two models, with trigrams as features for one and quadgrams as features for the other, then concatenated the outputs and feed it to a deep network as shown in Fig. 5. After the embedding layer we use Conv1D layers with varying kernel sizes (here 3, 4 and 5) with relu as activation function and followed spatial dropout (rate = 0.2) and max pooling cells. Using filters of various sizes, dropout and max pooling cells helped reduce overfitting and variance largely. This is followed by Bi-LSTM stack with attention with 32 and 16 sizes orderly. The output from two identical networks using different features was combined by a concatenate layer followed by two dense layers of 16 and 9 orderly as shown. The entire model was compiled with adam as optimization function and categorical cross-entropy as loss. The number of epochs was set to 3 and batch size was set to 64. Even the multiclass classifier is stored as a tflite model and the size comes to 3.6 MB. The accuracy and performance of the model is discussed in the coming sections.

TABLE III. MODELS PERFORMANCE SUMMARY

Models	Accuracy	F1-score	Model Size	Latency	Peak RAM Usage
Binary Classifier	96%	0.96	1.4MB	8-10ms	4.7MB
Multiclass Classifier	87%	0.88	3.6MB	30-35ms	8.3MB

Fig. 4. Binary Classifier Model Summary.

#### IV. EXPERIMENTAL RESULTS

The parameters on which the models was judged are accuracy, f1-score, size, latency and the peak RAM usage by the model. The test set described earlier is used to measure the performance of the model. A c++ program was written to perform the earlier discussed preprocessing steps on the input which is to be given to trained model and to load the saved tflite model and predict the output. The reason for writing c++ code to estimate the performance of the models rather than python was, c++ code runs faster than python [19].

The latency of the model was estimated by recording the time (say t1) when the input is given for preprocessing and again recording the time (say t2) when model predicts the output. The latency is calculated as difference of t2 and t1. So, this latency also includes the time taken for preprocessing steps as well. The now() function of high\_resolution\_clock class as part of chrono c++ header was used to record time t1 and t2 [20]. The range of latency of both the models is recorded in Table III.

TABLE IV. BINARY CLASSIFIER PERFORMANCE FOR EACH CLASS

Languages	Precision	Recall	F1-score
Hinglish	0.95	0.96	0.95
Other Languages	0.98	0.97	0.97

TABLE V. MULTICLASS CLASSIFIER PERFORMANCE FOR EACH CLASS

Languages	Precision	Recall	F1-score
Hinglish	0.92	0.96	0.94
Bengali	0.84	0.98	0.90
Kannada	0.83	0.86	0.85
Tamil	0.87	0.82	0.84
English	0.90	0.90	0.90
Gujarati	0.75	0.62	0.69
Telugu	0.86	0.88	0.87
Marthi	0.98	0.98	0.98
Malayalam	0.67	0.48	0.59

The peak RAM usage was estimated using massif tool, which is heap profiler [21]. Massif comes as part of valgrind, which is collection of tools for memory profiling. The peak usage for both the models is recorded in Table III.

The same vocabulary dictionaries saved as csv files earlier are used to encode the test input sentences given to the trained models to predict the output. The predicted labels given by the trained model is stored and compared with the actual labels, then the classification report is generated based on it. The classification report for both binary classifier and multiclass classifier generated using classification\_report part of scikit-learn package [22] and is reported in Table IV and Table V, respectively.

#### V. ANALYSIS

The binary classifier performs well on most kinds of data. The only drawback observed was, when the input sentence is very short and mostly filled with English, then it misclassifies Hinglish as English. For instance, “Relatives aya” (which means “Relatives came” in English) is classified as English sentence instead Hinglish. This is because the sentence is very short and has only a three letter Hindi word as part of it and the model finds it difficult to predict the correct label. Similarly, “Ek spoon” (which means one spoon) is also misclassified as English.

The multiclass classifier does well on most languages, except Malayalam and Gujarati. The F1-scores for Malayalam and Gujarati classes are 0.59 and 0.69 respectively, which is way less compared to other classes as seen from Table V. These classes also pull down the overall accuracy of the multiclass classifier. The main reason for this is because Malayalam language is very closely related to Tamil Language. Out of 442 Malayalam sentences in the test set, 190 of are missclassified

Fig. 5. Multiclass Classifier Model Summary.

as Tamil. These two languages are spoken by people of adjacent states of South India, and the root words of both languages are very similar. For instance, “come home” in Malayalam is “Vittir varu” and in Tamil is “Vittirku va”. The encoded sequences of these two sentences using trigrams or quadgrams will be very close. This is the reason the model confuses for Malayalam sentences and classifies them as Tamil sentences. The same reason goes for Gujarati language class, where Gujarati language is very closely related to Hindi and encoded sequences are also close and the model misclassifies. Out of 262 Gujarati sentences in the test set, 70 are misclassified as

Hinglish.

## VI. CONCLUSION AND FUTURE WORK

The binary classifier performs really on diverse data and generalizes well, expect for really small sentences. The multiclass classifier performs well on seven out of nine languages. With model sizes of 1.4 MB and 3.6 MB for binary classifier and multiclass classifier, these models can be used on any low resource devices like smart watches, mobiles or any embedded system where memory and RAM consumption are a constraint.

The future work would be to collect more real world data to train, in place of approximate data generated using Google translate API. Also, the vocabulary size was restricted to limit the resource usage on the device. So, if the models are run on powerful devices, then the vocabulary dictionaries can be further extended further and models can be retrained with the extended vocabulary and check if there is any effect on accuracy of the models. Also, the embedding layer size and the number of hidden layers of the neural network can be increased to increase the accuracy the model.

**Abstract**—During emergency operations in Disaster Management System (DMS) for natural and man-made disasters, any breakdown in the existing information and communication technology will affect the aspect of effectiveness and efficiency on an emergency response task. For Vehicular Ad-hoc Sensor Network (VASNET), the limitation in terms of infrastructure that consists of RSU (Roadside Sensor Unit) may partially or fully destroy the post-disaster scenario. As such, performance degradation of VASNET affects the network infrastructure on high packet loss, delay, and produce a huge amount of energy consumption in DMS. Thus, modification of VASNET and integrate with Internet of Thing (IoT) technology is a must to improve and solving the current problem on VASNET technology. Therefore, the main objective of this study was to investigate the performance of the proposed modified VASNET framework integrated with IoT at DMS in terms of energy consumption and packet loss. A suggested node in the proposed framework was introduced to implement low data rate and high data rate in evaluating the proposed framework using LTE and LTE-A transmission protocol. It was found that LTE-A contributes more energy by 25.33 (mJ/Byte) compared to LTE on 20 (mJ/Byte) on a high data rate. On the other hand, in terms of low data rate, LTE-A influences the most on the proposed framework by recording 19.82(mJ/Byte), LTE only 19.33 (mJ/Byte). For packet loss, LTE shows a high packet loss rate by contributing 11.39% compared to LTE-A, which is 8.0% in terms of low data rate, and 14.80% compared to LTE-A, only 11.97% for high data rate. Consequently, LTE-A on high data rate contributes more energy consumption and LTE in packet loss on same data rate.

**Keywords**—Energy consumption; packet loss; LTE-A; VASNET; IoT

## I. INTRODUCTION

With the rapid growth of smart devices in Internet of Thing (IoT) technology is estimated that in 2025, the total quantity of smart devices could rise to 1.56 billion globally [1]. As such, research interest on wireless networking communication has focused on reducing energy consumption by applying various methods. Moreover, energy dissipation could pollute our environment caused by electronic devices becoming unhealthy and significant impact on our daily lives.

In connection with this, various natural disasters like landslides, volcanoes and earthquakes may rise from year to year affecting millions of innocent human life [2]. To cope with this problem, research work was done on existing Disaster Management System (DMS) to integrate different types of wireless network technologies to be more efficient. Therefore, the integration of VASNET and IoT in DMS is introduced in

this research. The interface plays the leading role in linking both VASNET and IoT in the DMS [2]. The modification of Vehicular Ad-hoc Sensor Network (VASNET) is hugely challenging in terms of protocol that used to be compatible with current IoT technologies. The modified sensor node from VASNET should be equipped with sensing, processing and transmitting the data [3] concerning Base Station (BS) in Bi-directional mode. Furthermore, the data dissemination must cover a large geographical region [4]. The sensor nodes on disaster areas can capture data in the cluster environment from the tracked region, manipulate data and broadcast to main nodes with more collection points called Gateway, actively using the interface for further data analysis or tracking location [5].

One of the critical resources in sensor nodes that affect the performance and reliability of DMS is the energy supplied [4]. The primary role of power was providing the necessary energy to achieve the mission of sensor nodes typically [6]. A proper energy reduction potentially prolonged the DMS system in terms of stability and lifetime [3]. This enables the Emergency Response Team to save more human life as much as possible [2].

Consequently, energy-saving becomes essential when sensor nodes are powered by their restricted battery. Sensors spread over a large area or in a harsh or hostile area such as volcanoes or even deep-sea when battery power is depleted. It could be difficult or uncomfortable to exchange or recharge the battery [7].

The leading cause of sensor node's energy waste is the radio system [4]. For that reason, several concepts and strategies has been emphasized on power saving in reducing the data sending like scheduling, aggregation, routing and clustering [8]. Generally, when selecting different types of wireless network technologies linking with DMS, a few considerations we need to take into account on the particular application like power consumption and maximum distance range [9].

Overall, this research work greatly benefits the community in terms of minimizing human life as much as possible that contributes to DMS, which is listed below.

- Multichannel
- Network Establishing and Channel Formation
- Interface

Therefore, the principles and structure of this research work are to identify the method proposed in DMS with

modifying VASNET on IoT technologies that determine by using energy consumption and packet loss. This paper was structured as follows: the main challenges on VASNET and IoT are discussed in Section II, related works in Section III, proposed framework in Section IV, performance evaluation and method in Section V, result and discussion in Section VI and conclusion in Section VII.

## II. CHALLENGES ON VASNET AND IOT

There are challenges that cannot be avoided in any wireless network. The primary challenges and limitations in which it could affect the performance in the wireless network are discussed below [3], [10].

- 1) Security
  - Varies method has their strengths and weaknesses and none of them provide the best solution on it. For instance, vehicle-to-vehicle (V2V) focuses on several attributes including authenticity, authority, integrity with confidentiality. Different V2V applications such as e-health systems and smart metering may have various privacy requirements which need to be taken into account during the initial stage of system design [11].
- 2) Mobility
  - High mobility of VASNET for vehicles to move randomly compared to other wireless network infrastructures. Which may contribute a redundant data collected to nearby RSS (Road Side Station) or BS (Base Station).
- 3) Power limitation
  - In VASNET, power constraint is one of the most important challenges in which it shadowed all other aspects like routing, fusion, and the massive battery carried by the device. For instance, car batteries.
- 4) Devices challenges
  - In the same network, it may be equipped with various types of protocol capabilities on different sensors or devices. For instance, a vehicle system is a critical challenge especially in a tracking system as the node is movable [6].
- 5) Big Data
  - A huge amount of data may produce conflicting meanings(vagueness), which requires checking for quality and value. Multiple deployments on similar sensors increase data accuracy. However, it could experience extra noise data [12].
- 6) Other Challenges
  - Several challenges also impact the design of wireless network sensors. For instance, a group of sensor nodes moves into a particular portable robot or various automobiles. It would result in any sensor network topology constantly being altered in which request of changes is repetitive. Some needs for MAC

(Media Access Control) for density modification, routing on neighbour lists modification with data gathering.

## III. RELATED WORKS

The main objective of this review is to thoroughly examine the published works of literature that extend the sensor network regardless of the existing DMS system with VASNET modification in various applications and IoT. It shows a relationship in any sensor work in multiple methods related to this research field. There is limited research involving different types of wireless technologies to be executed in any state-of-art system, which will become very demanding in the future research area.

Below is the discussion of previous works done in any technique, algorithm and method related to the energy consumption in the IoT network field and wireless network.

Energy Harvesting system is introduced in the works of the author [3], in which a clustering algorithm was applied on sensor nodes to form a cluster with Cluster Head (CH). This CH was equipped with an external energy source to supply power to prolong the CH in terms of network efficiency. CH transmit and receive a signal link with BS to enable network communication between the sensor nodes in a particular area. However, this method was restricted when the node movement was dynamic and randomly caused frequent re-clustering and affected the energy supply to be depleted to a certain level.

Another well-known clustering base protocol is Low-Energy Adaptive Clustering Hierarchy (LEACH) in author work [13], has been discussed. In this LEACH, the sensor nodes were organised into the cluster, with each cluster are randomly selected. The weak point of this LEACH is that CH was experienced less residual energy on selected CH, which would result in inactive mode quickly. As such, the whole cluster would fall into a non-functional mode and reduce the effectiveness of this LEACH clustering protocol.

To reduce energy consumption on wireless networking for IoT, the author [4] proposed a data reduction method that works on Gateway of network level. It operates on a group of data received by identifying and removing the redundant data set that undergoes a classification process. The author suggested a clustering candidate set to verify a similarity among the members. The data sets after clustering candidate sets were able to transmit through Gateway with minimum energy consumption. To some extent, this research work may have risks when the same valuable data sets have been removed and time-consuming while facing many sensor nodes.

The compression algorithm applied from one data form of sensor node was installed in a wireless sensor network in an underground tunnel in terms of spatial-temporal data has been explored by the author [14]. The proposed algorithm effectively operates on temporal and spatial characteristics for the sensor's data. The data recovery method was nearly approximate to an initial data node. This algorithm served a high complexity for data compression and, therefore, was difficult to be considered on the limited resources node practice in IoT networks.

The idea of the Prefix-Frequency Filtering (PFF) technique was proposed by the author [15]. This technique is divided

into two phases; the sensor phase to utilize the local data processing and the aggregate stage for PFF with Jaccard Similarity mechanism that can consolidate data similar from nearby sensor nodes. However, this technique was not competitive in reducing redundant data before broadcasting to the BS.

Implementation of decentralized hierarchical clustering is proposed to avoid the redundant control message transmitted from sensor nodes to BS done by the author in [10]. The formation of sensor nodes clusters with a criterion of intra-cluster among sensor nodes and CH being selected according to the shortest distance between sensor nodes and BS. CH was revalidated each time on sensor nodes remaining energy. Thus, it identified energy depletion and overloading on any particular sensor nodes. But when operating in multiple criteria, this algorithm works in performance-less that includes heavy computational complexity in the data transferring process.

The author introduced an Adaptive Lossless Data Compression (ALDC) algorithm in [16] for wireless sensor networks. It incorporates several coding to achieve lossless compression alternatively. This method permits the adjustment of compression dynamically to the changeable source. It comprises blocks, and each block implements the optimal compression method. However, this method increases the time complexity and is not suitable to apply on the gateway.

#### IV. PROPOSED FRAMEWORK

In order to justify the reason to conduct this research work. The current VASNET and IoT framework underwent a study to identify the problem and limitations. RSU (Road Side Unit) linking with a gateway for VASNET networking is a disadvantage during disaster or catastrophe occur. RSU may partially or fully destroy during the impact of the disaster, especially by tsunamis and landslides. Communication breakdown in the affected area can cause survivors trapped inside the vehicle to face difficulty to be rescued by ERT members. High node density of vehicles in one area and shorten communication range can be a reason or problem for the existing VASNET framework. Packet congestion or high traffic on VASNET degrade the performance of data transmission and retrieve data that might be experienced by ERT members. On the other hand for the IoT framework. It will be costly to equip a device which able to sustain an extreme situation in high temperature and high-pressure environment, regardless of communication range or protocol. High maintenance of IoT networking is one of the main reasons, why IoT is not suitable to be implemented on existing DMS. It involves a large area, for instance, the metropolitan city which causes a million of financial support that not all the country can handle like the third-world country. As a result of this, modification of VASNET is a must to overcome the short-distance communication coverage and reduce network congestion by using IoT technology. IoT can suit this VASNET to implement point-to-point network connection to cost down current IoT infrastructure. As such, this research aims to combine and modify both VASNET and IoT to become more stable and reliable to apply to DMS systems. Consequently, the interface is introduced in this research study, which is a medium to link different protocols on VASNET and IoT through varying artificial intelligent devices like smartphones and smart switches through the algorithm proposed.

Fig. 1. Proposed Hybrid Framework.

The most complex and challenging part is integrating two different network topologies into a DMS system that enhances performance in terms of stability and reliability. The interface becomes the key that enables VASNET and IoT to communicate simultaneously. Thus, execution of both wireless networking potentially generates an unwanted energy dissipation which causes degradation of hybrid network performance. To solve this problem, the transmission medium and modulation module becomes crucial as the purpose is to reduce energy consumption as minimum as possible. Therefore, the proposed framework depicted in Fig. 1 illustrated this hybrid model implemented on the DMS system.

It can be observed from the diagram in Fig. 1, existing VASNET has to be modified by introducing an interface with Channel Assignment and Network Establishing algorithms. Those algorithms have been implemented by applying Markov Chains and LTE with LTE-A to configure a nearby node in a post-disaster scenario. Markov Chains potentially locate the latest state of survivor that depends on the existing state especially in heavy floods and volcano disasters, making the movement of humans trapped in random mode in any emergency. Therefore, Markov Chains implementation can connect and link all nodes (Survivor) in a certain disaster area. Furthermore, LTE and LTE-A are suggested as a communication protocols with less latency and coverage area up to 5km. With this, it enables the Emergency Respond Team (ERT) to connect with survivors without any barriers in terms of communication. This algorithm plays an important role to integrate with IoT structure and the idea of channel interface and structure architecture on interface able to link both VASNET and IoT together. The objective of this interface is designed for a multichannel or multimode approach. It permits the system to detect and identify as many victim locations (node) in the short and medium range.

This interface connects the VASNET and IoT architecture on particular Long Term Evolution (LTE) for Downlink and Uplink medium to optimize the communication flow. The LTE architecture in IoT can handle multi-node that result in shortened latencies in terms of signal control [17]. Moreover, IoT network architecture is upgraded to add in suggested Database in Cloud environment to the IoT architecture due with Platform as a Service (PaaS) and Infrastructure as a Service (IaaS) level. The advantage of IoT in the Multi-node approach is that it works on OFDMA in Downlink and SC-FDMA on Uplink, which is the main critical point on Downlink. It could contribute more energy when ERT (Emergency Response Team) communicates with various victims to locate the victim more accurately. OFDMA has the characteristics

of separating the data into several narrowband subcarriers to improve the bandwidth [17] during emergency periods.

The hybrid architecture would be connected to existing DMS to enhance the DMS performance in which the DMS system should equip with the coordination framework. This coordination framework is explored to suit the hybrid framework that can receive valuable data or information in a real-time situation during an emergency. Strategy Action Plan and Macro Task Scheduling is the idea to optimum the DMS system performance link with this hybrid framework, and capable to strategy the rescue plan effectively to rescue innocent people during disaster or catastrophe occurs.

### V. PERFORMANCE EVALUATION METHOD

To examine the performance of a hybrid framework in terms of stability and reliability. The energy consumption on BS in this hybrid framework will be determined as this is the most essential and significant part. As a result, the parameter of energy consumption and packet loss at BS will undergo testing, and all the evaluation methods or steps are elaborated on below.

Fig. 2. The Energy Consumption Model.

Fig. 2 depicts the power consumption model node consisting of power level (s), transmit  $T_x$  and receiver  $R_x$ , Base Band (BB), Bandwidth (BW) and radio frequency  $T_x$  and  $R_x$ . Where P is classified as total power consumption in idle and connected mode,  $R_{xRF}$  and  $T_{xRF}$  in RF part on  $R_x$  and  $T_x$  chains are consumption on each other.  $R_{xBB}$  and  $T_{xBB}$  are consumed on BB parts, and 2CW is increased while two codewords (CW) are in the downlink. For parameters on  $P_{Rx}$ ,  $P_{Tx}$  and  $P_{Rx+Tx}$  are on idle, receive, transmit, and use 2CW. The  $R_x$  and  $T_x$  power level is considered S and  $R_x$ , and  $T_x$  is the R data rate individually.

Each respective node was set to 50mW with low power consumption to obey LTE-A characteristics. Each packet converted was divided into power settings concerning the base station to gather each node's energy consumption.

$$\sum_{i=1}^n P_T = m_{idle(i \rightarrow n)} P_{idle(i \rightarrow n)} + \overline{m_{idle(i \rightarrow n)}} \{ P_{con} + m_{Tx} \cdot m_{Rx} \cdot P_{Tx+Rx} + m_{Rx} [P_{Rx} + P_{RxRF}(SR_x) + P_{RxBB}(R_{Rx}) + m_{2cw} \cdot P_{2cw}] \cdot m_{Tx} [P_{Tx} + P_{TxRF} + P_{TxBB} R_{Tx}] \} w \quad (1)$$

$$\sum_{i=1}^n P_T = \frac{\sum_{i=1}^n \text{Joule}}{\text{Seconds}} \quad (2)$$

$$\sum_{i=1}^n \text{Joule} = \sum_{i=1}^n P_T \times \text{Second}(s) \quad (3)$$

$$\begin{aligned} \sum_{i=1}^n \text{EnergyConsumption(Average)} &= \frac{\sum_{i=1}^n \text{Joule}}{\text{Byte}} \\ &= \frac{\sum_{i=1}^n (P_t \times \text{Second}(s))}{\text{Byte}} \quad (4) \end{aligned}$$

We apply LTE on the same hybrid framework to compare the LTE-A energy consumption.

### VI. RESULT AND DISCUSSION

We consider downlink as principles measurement for energy consumption as it is the most significant to contribute energy consumed on network access that can evaluate energy efficiency [18]. Furthermore, low and high data rates have also been used to determine the proposed framework in parameter CQI (Channel Quality Indication), which is CQI=2 (low) and CQI =7 (high). Below is the tabular form and graphical form of this experiment result obtained.

TABLE I. ENERGY CONSUMPTION FOR LOW DATA RATE ON 500M FOR 15s

Node	LTE	LTE-A
20	25.00	10.00
40	64.00	60.00
60	75.00	71.43
80	80.00	77.78
100	83.33	79.82

TABLE II. ENERGY CONSUMPTION FOR HIGH DATA RATE ON 500M FOR 15s

Node	LTE	LTE-A
20	50.00	33.33
40	75.00	66.67
60	85.00	80.00
80	90.00	87.00
100	95.00	92.00

Table I and II show the result for low data rate (CQI=2) and high data rate (CQI=7) on 500m and 15s.

Fig. 3 shows energy consumption for low data rate (CQI=2) and high data rate (CQI=7) for LTE and LTE-A with 500m range.

Fig. 3. Energy Consumption Result for 500m on 15s for High Data Rate (CQI=7) and Low Data Rate (CQI=2).

As presented in Fig. 3, the most effective increasing rate was at node 40 group that was showing high data rate for LTE contributes 25 (mJ/Byte), LTE-A 33.34 (mJ/Byte). LTE contributes 39 (mJ/Byte) for low data rates and LTE-A 50 (mJ/Byte). On node 40 onward, all LTE and LTE-A gradually increase, reaching LTE as 20 (mJ/Byte) for a high data rate, LTE-A 25.33 (mJ/Byte), respectively. LTE was 19.33 (mJ/Byte) and LTE-A for 19.82 (mJ/Byte) on low data rate. This is because network formation and channel establishment executed at an initial stage establish a connection among central stations with all the nodes nearby. Besides that, the high mobility of nodes could contribute to the amount of energy consumption as packet loss happens concurrently. Retransmission of packet needs more energy, and it keeps increasing with the condition of the number of nodes in increasing trend and various pattern change also increase simultaneously. Consequently, the channel quality reflected the amount of energy dissipation and consumed more on high data rate compared to the low data rate.

TABLE III. PACKET LOSS FOR LOW DATA RATE ON 300M

Node	LTE	LTE-A
20	8.87E-03	8.74E-03
40	9.58E-03	9.50E-03
60	9.88E-03	9.80E-03
80	9.89E-03	9.85E-03
100	9.96E-03	9.90E-03

TABLE IV. PACKET LOSS FOR HIGH DATA RATE ON 300M

Node	LTE	LTE-A
20	8.87E-03	8.87E-03
40	9.42E-03	9.42E-03
60	9.90E-03	9.73E-03
80	1.00E-02	9.83E-03
100	1.02E-02	9.94E-03

Table III and IV show the experiment results for packet loss for LTE and LTE-A for high data rate (CQI=7) and low data rate (CQI=2).

Fig. 4 and 5 show the tremendous packet loss increase fell into node 40 group for low data rate on LTE 11.39% and

Fig. 4. LTE-A and LTE Packet Loss for 300m (CQI=2).

Fig. 5. LTE-A and LTE Packet Loss for 300m (CQI=7).

LTE-A 8.0%. On the other hand, the high data rate presented 14.80% for LTE and 11.97% for LTE-A. Generally, LTE-A improved compared to LTE by about 19.12% for the 300m range.

The packet loss rate gradually increased for both LTE and LTE-A due to the random movement for the 300m range. High-speed mobility can cause the packet transmitted to lose its path because the transition node or relay is out of the network coverage as the central station has to reschedule and retransmit to any particular destination node. Therefore, the existing network has to reform with the neighbour's node to create a new channel and coverage. Instead, a high data rate (CQI=7) experienced a massive amount of energy needed to broadcast the packet in the node-by-node primary. It will produce a lot of energy consumption directly to the network coverage.

## VII. CONCLUSION

In this research work, the modification of VASNET integrated with IoT on DMS was successfully evaluated using low and high data rates. It was able to investigate the effect of stability and reliability by parameters applied to the proposed framework by using energy consumption with packet loss rate.

The result presented a high data rate showing significant influence with more energy on LTE-A as 25.33 (mJ/Byte) compared to LTE 20 (mJ/Byte). At low data rate, LTE-A also gives ultimate contribution by 19.82 (mJ/Byte) higher than LTE with 19.33 (mJ/Byte). The works of packet loss

determined that LTE contributed 11.39% higher than LTE-A on 8.0% for low data rate, and high data rate, LTE is also higher than LTE-A with 14.80% and 11.97%, respectively. Overall, it can be concluded that a high with low data rate on energy consumption parameter, LTE-A significantly impacts proposed framework performance. However, LTE on high and low data rate was higher in terms of packet loss parameter.

Therefore, for further work, 5G is suggested to evaluate the proposed framework in energy consumption measurement and packet loss.

#### ACKNOWLEDGMENT

**Abstract**—Social media platforms generate a huge amount of data every day. However, liberty of speech through these networks could easily help in spreading hatred. Hate speech is a severe concern endangering the cohesion and structure of civil societies. With the increase in hate and sarcasm among the people who contact others over the internet in this era, there is a dire need for utilizing artificial intelligence (AI) technology innovation that would face this problem. The rampant spread of hate can dangerously break society and severely damage marginalized people or groups. Thus, the identification of hate speech is essential and becoming more challenging, where the recognition of hate speech on time is crucial in stopping its dissemination. The capacity of the Arabic morphology and the scarcity of resources for the Arabic language makes the task of distinguishing hate speech even more demanding. For fast identification of Arabic hate speech in social network comments, this work presents a comprehensive framework with eight machine learning (ML) and deep learning (DL) algorithms, namely Gradient Boosting (GB), K-Nearest Neighbor (K-NN), Logistic Regression (LR), Naive Bayes (NB), Passive Aggressive Classifier (PAC), Support Vector Machine (SVM), Ara-BERT, and BERT-AJGT are implemented. Two representation techniques have been used in the proposed framework in order to extract features: a bag of words followed by BERT-based context text representations. Based on the result and discussion part, context text representation techniques with Ara-BERT and BERT-AJGT outperform all other ML models and related work with accuracy equal to 79% for both models.

**Keywords**—Machine learning; Arabic language; hatred detection; social network; classification algorithm

## I. INTRODUCTION

Low-resource languages, e.g., Arabic, Hindi, and Urdu, do not have a considerable amount of data for training and building conversational Artificial Intelligence (AI) systems. The Arabic language is the authorized language for 22 Arabic countries with roughly more than 422 million aboriginal speakers [1]. Additionally, it is a religious language spoken by more than 1.5 billion Muslims. There are three main types of it: *i*) Classical Arabic which is the language of the Holy Quran, *ii*) Modern Standard Arabic (MSA) which is used by academia, and *iii*) Dialectal Arabic which differs between regions since it is used for daily life networking [2]. Thus, the Arabic language, with a large number of speakers worldwide, is challenging task when we work with AI systems. Moreover, the Arabic language is identified as the 4<sup>th</sup> in the usage on

the internet [3]. However, the sophistication of the Arabic language makes the automatic identification of Arabic hate speech a complex task. Dialectal Arabic doesn't have formal grammar or spelling regulations. Moreover, spelled words can have different importance based on various dialects, which augments the vagueness of the language [4].

Sociable applications, e.g., Facebook, YouTube, and Twitter, are generating an extensive quantity of data which is considered a valuable goldmine for researchers. Social media-generated data helps in recognizing unlawful behavior, restricting potential hurt, and maintaining residents safe [2]. Some users utilize the wild adoption of online social networks to spread radical and biased statements that diffuse hate speech. *Sentiment analysis* (SA), i.e., opinion mining, analyses individuals' thoughts, attitudes, emotions, and opinions towards an entity, e.g., person, object, or service. The SA is implemented at various levels of granularity [5]: *i*) *document-level*: each text fragment is considered as a component with an opinion towards a single object. It aims to categorize a review as positive, negative, or neutral, *ii*) *sentence-level*: aims to extract opinions for a smaller text which is more challenging than SA for a document, and *iii*) *aspect-level*: determines the major features of a belief while focusing on aspect extracting and feeling categorization of aspects. The approaches of semantic analysis could be supervised, unsupervised, or hybrid. For *unsupervised* methods, numerous sentiment phrases are required to reveal the semantic orientation of texts. Thus, lexicon-based approaches are used. However, supervised techniques rely mostly on utilizing data mining tools to build a learning algorithm on a collection of tagged information. A prime application of SA is hate speech detection through online social network [6].

Hate speech is any class of inappropriate language, e.g., insults, slurs, threats, encouraging violence, and impolite language, that targets individuals or groups based on typical attributes such as nationality, religion, ideology, disability, social class, or gender. Hate speech includes racism, misogyny, religious discrimination, and abusive speech. *Racism* implies hate speech that attacks people based on their skin color, race, origin, class, or nationality [7]. *Misogyny* is the hate speech that targets females, i.e., women or girls [8]. Religious bias is hatred vocabulary towards somebody based on their beliefs, faiths, practices, or even the deficiency of religious faiths.

The *abusive speech* represents disrespectful, rude, or criticizing speech to hurt or deliver harmful sentiments.

Hate speech (HS) detection is a branch of offensive language detection. There is an increasing studies for abusive/HS detection for English language. However, it is still very limited for Arabic dialects due to the scarcity of the publicly obtainable resources required for abusive/HS detection in Arabic social media texts. The authors of [9] declared that the harmful online content on social media can be grouped into various categories including: Vicious, Vulgar, Offensive, Violent, Adult content, Terrorism and Spiritual hate speech.

This work targets *religious hate speech* (RHS) that could be insulting, abusive, or hateful. RHS aims to instigate hate, intolerance, or roughness toward people because of their religious faiths. The recent immense usage of social networks mandates applying different *text processing* on such cyberspace. The remarkable amount of generated data requires applying new monitoring tasks such as cyberbullying recognition [10], hate speech detection [6], irony identification [11], and discovery of offensive language [12]. Accordingly, battling hate speech mandates generating and elucidating a considerable amount of data for automatic hatred speech identification by building artificial intelligence-based models, i.e., ML and DL [13].

Lately, detecting abusive and hateful speech has gained increasing attraction from investigators in NLP and computational social sciences societies. Thus, detecting abusive speech and hate speech is essential for online safety. lately, various studies indicated that the existence of hate speech may be related to hate crimes [8]. Therefore, this work aims to enhance the detection of offensive language and hate speech on Arabic text. Detecting religious hate speech in any language, including Arabic, has different challenges, including : 1) the gigantic volume of the data generated over social networks makes it difficult to locate typical patterns and trends in the data, 2) noise may exist in the data, e.g., inaccurate grammar, misspelled phrases, Internet slang, abbreviations, lengthening of words, and multi-lingual scripts, 3) the comments being written in poorly text, and including paralinguistic signs, e.g., emoticons, and hashtags. Moreover, hate detection is a context-dependent task, and it is still missing a consense of what is forming hate speech due to the different cultures, customs and traditions, and 4) since the social networks prevent posting illegal content, users post information that looks authentic and simple but quietly causes a hate speech. Thus, building a tool for the automatic detection of hate speech would be complex [6].

Social platforms, e.g., Twitter and Facebook began battling online hate speech by explaining procedures that limit the use of violent and dehumanizing languages [14]. Moreover, various Arabic countries, where their users of social media sites are adding Arabic content, modified their laws to combat cybercrimes including hate speech. For example, Jordan added a new cybercrime laws [15] that defines hate speech as any action, writing, or speech planned to cause and raise ethical conflict or call for violence and provocation to fighting between the diverse segments of the nation. Regarding the Arabic language, there is a clear shortage in the conducted research for hate speech on online social networks. Thus, artificial intelligence, data mining, and machine learning techniques could be utilized to efficiently perform more research and

experiments on hate speech detection which constitutes a fertile resource for investigation. This work aims to design a prototype for the automatic identification of abusive and hate speech using various ML and DL techniques with a standard data set.

The remaining sections are organized as follows. Section II presents preliminaries necessary to understand the context of the work. Section III highlights some of the important related work. The various aspects of the proposed methodology are explained in Section IV. Section V introduces the experimental setup and analysis. The obtained results and their explanation are discussed in Section VI. Finally, Section VII concludes the paper with future directions.

## II. PRELIMINARIES

### A. Natural Language Processing (NLP)

Natural Language Processing is a major component of Artificial Intelligence (AI). It enables robots to analyse and comprehend human language, enabling them to carry out repetitive activities without human intervention. Machines can analyse and comprehend human language through a process known as NLP. NLP-based approaches process a considerable amount of data to obtain useful knowledge. For that different data mining and machine learning approaches are used. Thus, text pre-processing should be applied in order to prepare text for further processing such as representation features engineering that are required to extract features and pass it to ML approaches. For example, pre-processing could include text tokenization, and stop-word removal.

### B. Machine Learning (ML) Algorithms

ML is used in various applications, e.g., healthcare [16], hardware design [17], quality control [18], and NLP, where this work targets NLP application. Information is an organised collection of discrete pieces of data, and it conceals the whole spectrum of representational patterns. The machine's primary objective is to extract patterns that reflect a certain event. If the machine is able to recognise these patterns, then machine learning has taken place. It demonstrate that by adding fresh data or information, where the computer can make accurate predictions. The authors of [19] have mentioned that the advancements in machine learning especially deep learning enable us to design algorithms that use real-world information to make decisions that seem subjective. As shown in Section IV-B, there are different methods to prepare text for further processing. *Text tokenization*, which is also called text segmentation or lexical analysis, groups the text into tokens/words separated by space. Stop-words such as articles (e.g., a, an, the), conjunctions (e.g., and, but, if), and prepositions (e.g., in, at, on) [20], do not represent a specific meaning. Thus, they should be eliminated. Features in ML are essentially numerical attributes. However, the data may not contain numerical attributes, such as in sentiment analysis. Thus, various types of features (e.g., word, character, so on) are converted into numerical features where such operation is called representation and choosing from them which make ML working properly is called *feature engineering* (*feature selection and feature extraction*).

### C. Hate Speech

Recently, the broad usability of smartphones and the high availability of internet access increased the number of users on social media. Moreover, the rapid growth of social media has made it practically unattainable to manually monitor and inspect the massive amount of messages published online every day. Also, social media witnessed a substantial increase in hate and abusive speech, which is a severe problem worldwide that threatens the solidarity of civil communities. Therefore, automatic detection for hate speech, utilizing various classification techniques, is required to filter such harmful content. Twitter is one of the most importing social media platform which is ubiquitous, informal, and unstructured at the same time. Tweets usually have abbreviations, acronyms, spelling errors, and non-ideal punctuation so designing a model to handle this will be an interesting topic for future work.

### D. Transfer Learning (TL)

ML still has some constraints for specific real-world domains. For example, the requirement of having a tremendous amount of training data which have a distribution similar to the testing data could be difficult to satisfy [21]. Thus, semi-supervised learning could be utilized due to the shortage of labeled data. However, for a small amount of unlabeled data, the build model would be defective. Therefore, transfer learning is a promising procedure for such systems. Transfer learning (TL) is a branch of machine learning (ML) which aims to improve the performance of target learners on specific fields by transferring the knowledge possessed in separate but connected source domains [21]. Thus, constructing target learners will have a reduced dependency on a large number of target-domain data. In ML models, knowledge is not retained or accumulated, where learning is performed without considering past learned knowledge in other tasks. However, in transfer learning, the learning process can be faster, more accurate, and require less training data. TL can be classified into: 1) homogeneous where the disciplines are of the identical feature space, 2) heterogeneous where the disciplines have diverse feature spaces.

### E. Data Oversampling and Undersampling (Re-Sampling)

With the tremendous increase in the size of the generated data in various applications, there is a lack of equality in the labeled data. However, various ML techniques assume equal distribution for the target classes which is not always a realistic assumption. Such class imbalance problems will have a good accuracy while other evaluation metrics including precision, recall, F1-score, and ROC (Receiver Operating Characteristics) score, will not have enough scores. As shown in Fig. 1, Re-sampling including under-sampling or oversampling could be used to resolve the problem of an imbalanced data set. Under-sampling reduces the amount of the majority target samples. On the other hand, oversampling raises the quantity of minority class instances by yielding new instances or reproducing some instances [22].

## III. RELATED WORK

Various researches have been conducted to detect hate speech as a wide notion with different types in the English language. Many proposed works performed hate speech

Fig. 1. Undersampling vs Oversampling [22].

detection as a binary classification problem and considered a broad concept such as detecting bullying and derogatory language. In [23], the authors presented an original technique to detect hatred speech in English tweets. For that, they utilized three models, i.e., logistic regression (LR), XGBoost classifier (XGB), and support vector machine (SVM). The obtained performance showed competitive results compared to standard stacking, base classifiers, and majority voting techniques. The authors of [24] determined and discussed challenges encountered by online automatic techniques for hate speech detection in text. The limited availability of the data, sensitivity in language, and the exact definition of what forms of hate speech are well-known challenges. They proposed a SVM technique with high performance while the decisions are easier to interpret than neural methods. However, the used datasets did not include Arabic text.

In [25], the authors used different machine learning algorithms for the automatic identification of hate speech in tweets written in the Indonesian language. Their results showed that the Multinomial Naive Bayes algorithm has the most promising results with a value of 71.2% and 93.2% for accuracy and recall, respectively. The authors of [2] researched the capability of deep learning based on Convolutional Neural Networks (CNN), CNN-long short-term memory networks (CNN-LSTM), and bidirectional LSTM (BiLSTM-CNN) to automatically detect hateful content posted on social media. For that, they used the ArHS dataset with 9833 tweets, which is believed to be the largest Arabic dataset with hate speech content.

The authors of [14] aimed to identify Cyber hate speech within the Arabic content of Twitter where they used various NLP and ML techniques. In [26], the authors used Twitter to construct an Arabic text detection hate speech model. They use this knowledge to analyze a dataset of 11 thousand tweets. They apply the Term Frequency — Inverse Document Frequency (TF-IDF) words representation to the SVM model. Finally, they presented four deep learning models that can notice and classify Arabic hate speech on Twitter into several types.

In [27], the authors were the first who addressed the problem of recognizing speech encouraging religious hatred in the Arabic Twitter. Thus, they were able to detect messages that use provocative sectarian speech to promote hatred and violence against people based on their religious beliefs. They found that a simple Recurrent Neural Network (RNN) architecture with Gated Recurrent Units (GRU) can adequately detect religious hate speech. The used data set is available online at [28]. The authors of [29] presented the foremost publicly-available Levantine Hate Speech and Abusive (L-

HSAB) Twitter dataset. It is intended to be a benchmark dataset for automatic detection of online Levantine harmful contents. The dataset, which is available at [30], includes 5,846 tweets that could be of Normal class, Abusive, or Hate speech.

Considerable work has been investigated for hatred speech detection in the English language. However, rare work has targeted the detection of hate speech in the Arabic language. The majority of the Arabic research targeted web pages and search engines, while a few targeted comments on social networks. In this work, we target the Arabia language and use the data set of [28]. Thus, our constructed models would be mainly compared with [27].

#### IV. PROPOSED METHODOLOGY

The proposed architecture for Arabic hate speech detection is showing in Fig. 2. It includes the subsequent major steps: collection of labelled text document/tweet, text preprocessing, text representation and feature extraction, building of classification models (learning), and Relearning (testing) and classification process.

Fig. 2. The Proposed Architecture for Hate Speech Detection Model.

##### A. Data set: Collection of Labelled Text Document/Tweet

In this work we used the data set which was collected by [27] and it is available online at [28]. The data set contains 6164 Arabic tweets and concentrates on the four most typical sacred religions in the Middle East, which are Islam (93.0%), Christianity (3.7%), Judaism (1.6%), and Atheism (0.6%). Originally, the training data set contains 5,569 examples, while the testing data set contains 567 document. The data works for binary classification with two hateful and non hateful classes represented by 1 and 0 respectively. Since data re-sampling is utilized to settle the issue of an imbalanced data set, we performed re-sampling technique. According, the model built with data oversampling is called *Classifier-Over* while the model built with data under sampling is called *Classifier-Under*, where *Classifier* could be any of the six models we used.

##### B. Data Pre-Processing

Text pre-processing includes various techniques that prepare text for further processing. Pre-processing aims to remove the unwanted words from the text, e.g., punctuation, slang, and

stop words. Usually, we have to deal with various preprocessing techniques and a combination of them, including:

1) *Tokenization*: Tokenization is the activity of splitting text into terms, phrases, symbols or additional important elements, called tokens [31]. The obtained elements can be single items (1-gram) or a series of n words (n-gram). Items can be phonemes, syllables, letters, words or even sentences.

2) *Stopwords Removal*: Our work targets Arabic text. Thus, for pre-processing stage, we first remove the non-Arabic text. Every non-Arabic character is replaced with a whitespace character. Moreover, we remove *stopwords*, which appear frequently in the text and are not important for text classification, e.g., مع، أو، في، على، عن، لكن. A list of the most frequently used Arabic stop words is available at [20]. Approximately, 20%–30% of the total words in a record are stopwords, that is, terms that can be removed as they are redundant without any semantic value [32]. The traditional approach for extracting stopwords includes a pre-filled list, containing all words that are semantically irrelevant to a specific language. This technique is a static. On the other hand, the stopwords are recognized online and not specified previously for the dynamic technique. The features are specified based on their importance. Similar to the removal of stopwords, this work eliminates the punctuation and digits from the Arabic text.

3) *Stemming and Lemmatization*: In the Arabic language, various words could be generated from the basic/root word. For example, the words لاعبة، يلعب، ملعب، لاعب، لاعبة are derived from the word لعب. Thus, the stemming operation is applied to reduce the words into their stems. Stemming algorithms can be categorized into three classes: truncation, statistical and mixed techniques. This work conducts Light Stemming for Arabic words to reduce words to their stems. Light stemming withdraws common affixes from words without declining them to their stems. The main idea is that numerous word variants do not have identical meanings although they are developed from the same root. Light stemming aims to improve feature drop while keeping the words' meanings. It removes some specified prefixes and suffixes from the word instead of removing the original root. Lemmatization is a pre-processing approach similar to stemming; the purpose is to decrease the morphological forms of a word to its lemma.

There are many approaches proposed for stemming Arabic words, e.g., light stemming, morphological analysis, statistical-based stemming, and N-grams. Some approaches are language-independent while other approaches are language-dependent. Statistical approaches are language-dependent. Thus, can be tailored for Arabic. Light stemming does not reduce the word into a three-letter stem. However, it just expels the prefixes and suffixes and can achieve good information retrieval without morphological studies.

##### C. Text Representation/ Feature Engineering

The feature selection procedure allows selecting some of the initial feature set, removing the attributes with little predictive capability. For example, wrapper methods in WEKA, execute an investigation over the potential subsets of the initial feature set, assessing the implementation of a classifier over

each one. However, wrapper methods are unusable for large problems. Thus, they are discarded in text classification. On the other hand, filter methods are independent of the classifier with a less computational expense. Filters applied before using the feature selection metric incorporates the removal of infrequent words and overly common words. There are various techniques to convert string data into numerical data such as Bag of words (BoW), Term Frequency — Inverse Document Frequency (TFIDF), Word2Vec, and Bidirectional Encoder Representations from Transformers (BERT). In the following section, some of these techniques will be explained [33][13].

1) *Bag of Words (BoW)*: BoW is a textual representation method suitable for classification models, where the text is viewed as a set of words without considering its syntax or semantics. BoW reveals whether a word is present in the document or not, where the order of the words in the document is insignificant [34]. While constructing the BoW the list of stop words is excluded since they appear frequently with little of useful information. The performance of various ML methods we built utilizing BoW was poor due to the loss of semantic and syntactic information between words. Thus, we used other representation techniques that can handle semantics and syntactic in order to increase performance.

2) *Term Frequency — Inverse Document Frequency (TF-IDF)*: Term Frequency (TF) is a well-known textual representation model which is similar to the BoW technique. However, TF relies on the recurrence of the term in a provided text, while BoW depends on its presence. TF is the frequency of any *term* in a given *document*, which is expressed as given in Equation 1. However, words that are *common* in every document, such as *articles*, *conjunctions*, and *prepositions* rank low because they don't express much to the document. Therefore, we use Inverse Document Frequency (IDF) to reduce the significance of phrases that occur very often in the document collection and improve the importance of phrases that occur infrequently. IDF is constant per corpus and accounts for the ratio of documents that include that specific *term*. It is expressed as given in Equation 2. TF-IDF is a statistical standard to assess how much a phrase is related to a manuscript in a set of documents, i.e., corpus. TF-IDF is computed by multiplying TF by IDF. TF-IDF is regarded as a simple procedure for text classification. Thus, the TF-IDF is developed during model training and then utilized for the test set.

$$TF = \frac{\text{Number of times a term appear in the document}}{\text{Total number of terms in the document}} \quad (1)$$

$$IDF = \text{Log}_{10} \frac{\text{Total number of Documents}}{\text{Number of documents that includes the term}} \quad (2)$$

3) *Word2vec*: Word2vec is a word-embedding technique. It is useful in constructing guidance engines and making sense of sequential data [35]. Word2vec is a prediction-based approach built based on a persistent bag-of-words (CBOW) and a skip-gram (SG). These measures utilize small neural networks (NN) to realize the mapping of words to a point in a vector space. To train the word2vec, the number of the embedding dimensions

is set between 50 and 500 while the length of the context window is set between 5 and 10 [36].

4) *Bidirectional Encoder Representations from Transformers (BERT)*: BERT is a contextualized word representation model founded on a multilayer bi-directional transformer-encoder, where the transformer neural network uses parallel attention layers rather than sequential recurrence [37]. The authors of [37] introduced **BERT** (Bidirectional Encoder Representations from Transformers), where the proposed framework includes two phases: (1) pre-training: the model is prepared on unlabeled data over various pre-training tasks, and (2) fine-tuning: the model is initialized with the pre-trained parameters. Then, all of the parameters are fine-tuned using labeled data from the downstream tasks. Thus, deep bidirectional architectures of BERT allow the same pre-trained model to successfully embark on a broad set of natural language processing tasks. In this work, we used TF-IDF and Bidirectional Encoder Representations from Transformers for the Arabic language called (AraBERT).

#### D. Building of Classification Models (Learning)

We utilized the six ML-based models described next which are Gradient Boosting (GB), K-Nearest Neighbor (K-NN), Logistic Regression (LR), Naive Bayes (NB), Passive Aggressive Classifier (PAC), Support Vector Machine (SVM). Thus, we built the classifiers for these models. The default data partitioning was 80/20 where 80% of the data are used for building the classification model and the remaining 20% are used for model testing. For additional investigation, we built the same models/classifiers for 70/30 data partitioning as well as 90/10. Thus, we have a total of 18 configurations. Moreover, we used transfer learning and build a model based on Ara-BERT and another model called AJGT-BERT. The evaluation of the 20 models/classifiers we built based on different classification metrics is explained in Section VI.

1) *Gradient Boosting*: Boosting algorithm is an ensemble learning algorithm utilizing learning theory [38]. Thus, an group of weak classifiers with low classification accuracy are used to build a strong classifier with higher accuracy. The training procedure of expanding algorithm is incremental, i.e., develops a new classifier in each iteration. Thus, the classifier ranks all instances to evaluate the importance of each instance. Then, the importance of the earlier samples with misclassification are improved. Finally, a stable and better performance classification model is obtained. The gradient boosting (GB) algorithm [38] is an amended algorithm based on the classic boosting algorithm, where it shows better learning ability. Like boosting, GB builds the model with an iterative design, but the model is extended with an optimized loss function. Gradient Boosting is a method drawing awareness for its prediction quickness and accuracy, particularly with extensive and complicated data. Building a GB model start by creating a single leaf rather than a tree or a stump. This leaf symbolizes an starting prediction for the class of all instances. Like AdaBoost, Gradient Boosting build a fixed sized tree based on previous tree's errors where each tree can be larger than a stump. GB scales all the trees by the same amount.

2) *K-Nearest Neighbor (K-NN)*: The k-nearest neighbors (KNN) algorithm is a straightforward, easy-to-implement supervised ML algorithm that is applicable for both classification

and regression [33]. K-NN supposes the likeness between the recent and the known cases. Then, place the recent case into the class that is most identical to the available classes. K-NN algorithm keeps all the available data and categorizes a new instance based on the similarity. K-NN algorithm does not make any hypothesis on underlying data. Thus, it is a non-parametric algorithm [23]. KNN is a lazy learner algorithm because it holds the dataset and it achieves an activity on the dataset at classification, i.e., does not memorize from the training set immediately. However, as the number of independent variables increases the algorithm gets incredibly slower.

3) *Logistic Regression (LR)*: It is comparable to linear regression. However, it expects if a value is True or False rather than predicting a continuous value. Linear regression fits a curve to the data while LR fits an “S” shaped logistic function [23]. Logistic regression can perform on both continuous and discrete data. Thus, its ability to predict the probability and classify new samples makes it a popular ML method, where it is referred to as a probabilistic classifier since it predicts the probability of an output. Usually, logistic regression is used for classification. In linear regression, we fit the line between the data using “least squares”. However, the concept of “residual” does not apply to LR where the concept of “maximum likelihood” is rather used.

4) *Naive Bayes (NB)*: Naive Bayes classifier relies on Bayes Theorem, which works on conditional probability. The conditional probability is the likelihood that something will happen, given that something else has already occurred [39] [40]. The formula for calculating the conditional probability is given in Equation 3, where  $H$  is the hypothesis and  $E$  is the evidence.

$$P(H|E) = \frac{P(E|H) \times P(H)}{P(E)} \quad (3)$$

For a set of labeled training data, NB evaluates different model parameters, e.g., the likelihood of each class label to appear. Then, predict the class for any given test data based on its probability to be assigned for different classes. The maximum probability determines the predicted class [23].

5) *Passive Aggressive Classifier (PAC)*: This is an online ML algorithm, where it responds as passive for correct classifications and as aggressive for any miscalculation. In PAC we train a system incrementally by providing it samples sequentially, i.e., individually or in small groups called mini batches [33] [41]. The primary principle of this algorithm is that it notices data, learns from the data, and discards it without the need of storing the data. However, in batch learning the entire training dataset is used at once. Thus, PAC is suitable for systems that acquire data in a steady stream such as news and social media [42]. When the prediction is correct, we keep the model without any changes since the data in the example was not enough to change the model. Thus, it is called Passive. However, for incorrect prediction we introduce some changes to the model that could correct it. Thus, it is called Aggressive. PAC algorithm proved its effectiveness for online learning to solve various real-world problems [43].

6) *Support Vector Machine (SVM)*: SVM is a supervised classifier. For a set of labeled training data, SVM realizes

a hyperplane that distinctly classifies the data points while maximizing the margin between the data instances and the hyperplane itself [13] [44]. Then, the class of test data is determined based on the realized hyperplane [42].

7) *AraBERT*: Based on BERT [37], the authors of [45] presented **AraBERT** (transformer-based Model for Arabic Language Understanding), where they pre-trained BERT, especially for the Arabic language aiming to achieve the same success as BERT. The authors of [45] used the original configuration of BERT which has 12 encoder blocks, 768 hidden dimensions, 12 attention heads, 512 maximum sequence length, and a total of 110M parameters. Then, to better fit the Arabic language, they introduced additional preprocessing before model’s pre-training. To avoid information loss, they maintained words with Latin characters so they can cite named entities and scientific phrases in their original language. Thus, after eliminating duplicate sentences, the final size of the pre-training data sets was 70 million sentences.

8) *AJGT-BERT*: The authors of [46] introduced an Arabic tweets corpus documented in Jordanian dialect and Modern Standard Arabic (MSA) annotated for sentiment analyses. The generated AJGT corpus consists of 1,800 tweets with 900 classified as positives and the remaining 900 are negatives. The Arabic Jordanian General Tweets (AJGT) data sets is publicly available online at [46].

## V. EXPERIMENTAL ANALYSIS

A  $2 \times 2$  matrix, which is called a confusion matrix, is created to visually illustrate the performance of a binary supervised learning problem. Table I shows the confusion matrix for Arabic hate speech detection. It includes four classes, which are true positive, true negative, false positive, and false negative. In this work, **True Positive** (TP) indicates that the comment is actually hate speech and correctly classified as hate speech. **True Negative** (TN) indicates that the comment is non-hate speech and correctly classified as non-hate speech. **False Positive** (FP) means that the comment is actually non-hate speech but incorrectly classified as hate speech, and **False Negative** (FN) describes the comment that is actually hate speech but incorrectly classified as non-hate speech. For any classification model, we aim to maximize the value of TP and TN and minimize the value of FP and FN.

TABLE I. CONFUSION MATRIX OF ARABIC HATE SPEECH DETECTION

	Actual Hate Speech	Actual Non-Hate Speech
Predicted Hate Speech	True Positive(TP)	False Positive(FP)
Predicted Non-Hate Speech	False Negative (FN)	True Negative(TN)

### A. Implementation Environment

To accomplish all investigations in this work, we utilized a PC with the following details: Intel R © Core(TM) i7-6850 K processor with 8 GB RAM and 3.360 GHz frequency. Regarding the software, we have used Python 3.8.0 programming with Anaconda [Jupyter notebook] for ML and Colab for transfer learning models. We used various libraries such as NumPy, Pandas, Sci-kit-learn TensorFlow, and Keras.

## B. Evaluation Metrics

As given in Equation 4, **accuracy** denotes the number of rightly classified data samples over the total number of data samples. However, for an unbalanced dataset, where positive and negative classes have a different number of instances, the accuracy is not suitable to evaluate the model. **Precision** (positive predictive value) as defined in Equation 5, should be 1 for a perfect classifier while the value of FP is zero. **Recall** which is known as sensitivity or true positive rate is defined as given in Equation 6. For a perfect classifier, recall should be 1 while the value of FN is zero. For an ideal classifier, both precision and recall are 1. **F1-score** is a metric that depends on both precision and recall and is defined as given in Equation 7. F1-score becomes 1 only when precision and recall are both 1. So, F1-score is the harmonic mean of precision and recall and it is a better measure than accuracy [41] [44].

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (4)$$

$$Precision = \frac{TP}{TP + FP} \quad (5)$$

$$Recall/Sensitivity = \frac{TP}{TP + FN} \quad (6)$$

$$F1\ Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (7)$$

## VI. DISCUSSION AND RESULTS

In this section, we will explain the result of various machine learning models which we have used in this study. We have designed different models to detect and classify religious Arabic hate speech based on various methods, e.g., data partitioning, re-sampling and transfer learning. For that, we have divided our data (train/test) for three scenarios. The data is partitioned into (70/30), (80/20), and (90/10). For each partitioning, we use the original data sets in addition to the oversampling and under-sampling techniques. The best-obtained classification performance in partitioning scenarios was for (80/20), where a detailed explanation is given in Section VI-A. Then, Section VI-B explains the classification performance for 70/30 data partitioning while Section VI-C is dedicated to 90/10 data partitioning. The proposed models were evaluated on a testing data set related to religious hate speech in Arabic text [28]. In order to enhance the performance of the classifiers that we build for six ML algorithms, we have extended this implementation to include transfer learning methods. The transfer learning models called Ara-BERT and AJGT-BERT. The comparison of the performances of all models have been done in terms of accuracy, recall, precision, and F1 score using Arabic hate speech data set.

## A. Hate Speech Detection for (80/20) Data Partitioning

Fig. 3 shows the various obtained classification metrics based on various models, i.e., GB, K-NN, LR, NB, PAC, SVM, Ara-BERT, and BERT-AJGT. Clearly, the Ara-BERT model achieves the best classification metrics followed by AJGT-BERT while the KNN classifier has the lowest metrics. A detailed explanation for each metric is given next.

The obtained **precision** for the original data without re-sampling based on 8 classifiers is shown in Fig. 3. Both PAC and SVC has a precision of 75%. Moreover, the transfer-based classifiers, i.e., **Ara-BERT** and AJGT-BERT, have the highest precision with 79% and 78%, respectively. KNN classifier has the lowest precision of 69%. The obtained **Recall** based on 8 classifiers without re-sampling are very similar to the obtained precision. The transfer-based classifiers, i.e., **Ara-BERT** and AJGT-BERT, have the highest Recall with 79% and 78%, respectively, while KNN classifier has the lowest precision of 69%. Moreover, both PAC and SVC have a Recall of 75%. As given in Equation 7, **F1-Score** depends on both precision and recall. Regarding the obtained F1-Score for the various classifiers, the transfer-based classifiers, i.e., **Ara-BERT** and AJGT-BERT, have the highest F1-Score with 79% and 78%, respectively, while KNN classifier has the lowest F1-Score of 69%. When evaluating the **accuracy** we notice that it is very close to F1-Score of the various classifiers. Transfer-based classifiers are the highest while KNN classifier has the lowest accuracy, i.e., the accuracy of **Ara-BERT** model is 79%. Next, we are going to explain the classification metrics with data over-sampling and under-sampling.

## Hate Speech Detection for (80/20) Data Partitioning with Oversampling

With oversampling, we apply oversampling technique by increase the minority of samples to be same to majority like 2196 to 3650. Then, we used 80% of the data to construct the classification model and the rest 20% for testing the model/classifier. The obtained Precision, Recall, F1-Score and Accuracy of the various classifiers are shown in Fig. 3 where the name of a specific classifier is indicated as *Classifier-Over*. The various metrics for the Gradient Boosting and K-Nearest Neighbor (K-NN) classifiers with data oversampling remains the same as the original data set. However, with over-sampling the LR and NB classifiers have a 1% to 2% improvement of Precision and F-Score. Data oversampling reduces the various metrics of PAC by 2%. However, SVM based classifier is unaffected by data oversampling. Transfer-based classifiers are unaffected by oversampling. Thus, **Ara-BERT** has a value of 79% for Precision, Recall, F1-Score and Accuracy.

## Hate Speech Detection for (80/20) Data Partitioning with Under-Sampling

With under-sampling, we decreased the number of normal data from 3650 to 2196 to be equal to the hate speech. Then, we employed 80% of the data to construct the model and the remaining 20% for testing the model/classifier. The obtained Precision, Recall, F1-Score and Accuracy of the various classifiers are shown in Fig. 3 where the name of a specific classifier is indicated as *Classifier-Under-sampling*. With under-sampling, the various metrics of GB classifier are

Fig. 3. Various Classification Metrics for 80/20 Data Partition with Different Models.

Fig. 4. Various Classification Metrics for 70/30 Data Partition with Different Models.

reduced by 1% while they are increased by 1% for the KNN classifier. Similarly, the Precision and F1-Score of the LR classifier are enhanced by 1% while its recall and accuracy are unchanged. All metrics of the NB classifier are increased by 1% for under-sampling while they remain the same for the PAC classifier. The precision of SVC is increased by 1% to reach 76% while its recall, F1-Score and Accuracy are reduced by 1% to become 74% for all of them. Transfer-based classifiers are unaffected by under-sampling. Thus, **Ara-BERT** has a value of **79%** for Precision, Recall, F1-Score and Accuracy while the AJGT-BERT classifier has a value of 78% for the same metrics.

Based on the shown result for 80/20 data partitioning, the Ara-BERT models archives the best evaluation metrics with 79% for the precision, recall, F1-Score and accuracy. Data re-sampling introduced a 1% to 2% improvement where such insignificant gain is due to the original distribution of the training data.

### B. Hate Speech Detection for (70/30) Data Partitioning

Fig. 4 shows the various classification metrics for the different models with 70/30 data partitioning. AJGT-BERT classifier has the best metrics of 78% (for precision, recall, F1-Score and accuracy) while Ara-BERT classifier has a value of 75%. There are various classifiers that achieves 73% for all classification metrics including, LR-Over, NB-Over, NB-Under, and SVC-Over. We notice that sometimes data re-sampling introduces a minor improvement of 1% to 2% in few classifiers.

### C. Hate Speech Detection for (90/10) Data Partitioning

Fig. 5 shows the various classification metrics for the different models with 90/10 data partitioning. AJGT-BERT and SVC have the highest performance with 78% (for precision, recall, F1-Score and accuracy) followed by SVC with oversampling (SVC-Over) with 77% performance. Ara-BERT, SVC-Over,

Fig. 5. Various Classification Metrics for 90/10 Data Partition with Different Models.

TABLE II. COMPARISON OF CLASSIFICATION RESULTS OVER [28] DATASET

	Precision	Recall	F1-Score	Accuracy
Related work [27]	76	78	77	79
Ara-BERT with 70/30	75	75	75	75
AJGT-BERT with 70/30	<b>78</b>	<b>78</b>	<b>78</b>	<b>78</b>
Ara-BERT with 80/20	<b>79</b>	<b>79</b>	<b>79</b>	<b>79</b>
AJGT-BERT with 80/20	<b>78</b>	<b>78</b>	<b>78</b>	<b>78</b>
Ara-BERT with 90/10	75	75	75	75
AJGT-BERT with 90/10	<b>78</b>	<b>78</b>	<b>78</b>	<b>78</b>
SVC with 90/10	<b>78</b>	<b>78</b>	<b>78</b>	<b>78</b>

and NB-Over classifiers have 75% performance while NB-Under and LR-Under are 74%.

Table II shows a comparison of classification results over [28] where we used their dataset. The table compares various models we build with the related work [27]. Clearly, we were able to build models similar to or better than the related work. In most cases, transfer learning based models have the highest precision, recall, F1-Score, and accuracy, while other ML models have a very similar metrics

## VII. CONCLUSION

Hate speech is one of the major problems at this time, especially with the increasing number of users on social media. At the same time, an increasing number of crimes became a serious concern that threatens the cohesiveness and structure of civilian societies. Therefore, this work presents an efficient framework to detect Arabic hate speech based on the content of social networks. We utilize various ML and DL models to perform an efficient classification of users' comments. Based on the content of this work, the classes are hate speech or normal. The proposed framework has six ML algorithms and two DL, which are Gradient Boosting, K-Nearest Neighbor, Logistic Regression, Naive Bayes, Passive Aggressive Classifier, Support Vector Machine, Ara-BERT, and BERT-AJGT. For wider investigation, we utilized various scenarios of data partitioning, re-sampling techniques, and transfer learning. We were able to successfully have various classification models

with better results in terms of precision, recall, F1-Score, and accuracy compared to the most relevant related work. For future work, we aim to create huge and benchmark data sets. Moreover, working with the mixed language problem, multi-model and data augmentation can be interesting topics for future work on this topic, especially for the Arabic language. In future work, the classification can be expanded to cover many classes such as racism, misogyny, religious discrimination and so on.

**Abstract**—The multiple regression model is very popular among researchers in both field of social and science because it is easy to interpret and have a well-established theoretical framework. However, the multioutput multiple regression model is actually widely applied in the engineering field because in the industrial world there are many systems with multiple outputs. The ridge regression model and the Multi-Layer Perceptron (MLP) neural network model are representations of the predictive linear regression model and predictive non-linear regression model that are widely applied in the world of practice. This study aims to build multi-output models of a ridge regression model and an MLP neural network whose hyperparameters are determined by a grid search algorithm through the cross-validation method. The hyperparameter that produces the smallest RMSE value in the validation data is chosen as the hyperparameter to train both models on the training data. The hyperparameter in question is a combination of learning algorithms and alpha values (ridge regression), a combination of the number of hidden nodes and gamma values (MLP neural network). In the ridge regression model for alpha in the range between 0.1 and 0.7, the smallest RMSE is obtained for all learning algorithms used. While the MLP neural network model specifically obtained a combination of the number of nodes = 18 and gamma = 0.1 which produces the smallest RMSE. The ridge regression model with selected hyperparameters has better performance (in the RMSE and R2 value) than the MLP neural network model with selected hyperparameters, both on training and testing data.

**Keywords**—Filter approach; hyperparameter tuning; multi-response; neural network; ridge regression

## I. INTRODUCTION

The health of the mother during pregnancy and the condition of the baby at birth greatly affect the health and intelligence of the younger generation which is the continuation of the sustainability of a nation. Several factors, including the condition of pregnant women, food intake of pregnant women, and health conditions of the family environment affect the condition of the baby at birth, such as

stunting events [1]. The model for predicting the occurrence of a class category (stunting or not stunting) is called a classification model. Comparison of the performance of binary classification models, among others, was carried out by Widodo and Handoyo [2] comparing logistic regression and support vector machine, Handoyo et al [3] comparing logistic regression and Linear Discriminant, while Nugroho et al [4] comparing logistic regression and decision tree on the multiclass label response.

If the response variable has a numerical scale such as the length of the baby at birth [5], the predictive model is called a regression model. Santosa et al [6] used a partial least square approach to explain the effect of factors on maternal and child conditions on stunting where this factor is a latent variable. On the other hand, Sajjad et al [7] used multi-output modeling of response variables. Heating and cooling loads with predictor variables were factors related to the layout of a building. Multi-output response variables derived from the condition of the baby at birth (latent variables) consisting of several numerical indicators are very possible and also a challenge when building a model based on a multi-output system.

Regression modeling using machine learning methods has been applied in various fields, including industrial product design by Turetsky et al [8], wind speed prediction by Barhmi et al [9], prediction of imported soybean prices in Indonesia by Handoyo and Chen [10], and also prediction of beef and chicken prices by Handoyo et al [11]. In general, a model that is free from overfitting problems will have satisfactory performance. The ridge regression model is a multiple regression model which is given a penalty of l2 norm [12]. The regularization technique on the neural network is done by adding a penalty l2 norm to the loss function as an attempt to overcome the overfitting problem [13]. However, tuning hyperparameters on ridge regression and neural networks with regularization is generally done by trial and error. In order for these models to have an optimal combination of hyperparameters (producing the best performance), Tso et al

[14], and also Belete and Huchaiah [15] used the k-folds cross-validation method for hyperparameter tuning.

This study aims to build a multioutput model of ridge regression and MLP neural network on the survey dataset with the predictor and response variables derived from the latent variables. The selection of predictor variables that are free from multicollinearity elements is carried out using the filter approach method. In the ridge regression model, the learning algorithm and alpha values are tuned, while the MLP neural network model is carried out to tune the nodes number in the hidden layer and the gamma value using the grid search method. Evaluation of model performance with RMSE and R2 is carried out on both training and testing data.

## II. RELATED WORKS

Broadly speaking, there are 2 types of modeling in machine learning, namely supervised learning (predictive modeling) and unsupervised learning (descriptive modeling). An unsupervised learning model is characterized by the dataset used in the model building that does not contain a response variable [16]. The response variable measurement unit scale has a critical role, namely if the response variable on a numerical scale will lead to regression modeling, whereas if the response variable is on a categorical scale it will lead to a classification model. Modeling the dengue fever status of a village [17] and modeling the baby's weight status at birth [18] are examples of classification modeling. Regression modeling generally aims to determine the magnitude of the influence of the predictor variable on the numerical response variable and also predicts an unknown value of the response variable based on the values of the predictor variables of a certain instance [19-21]. The research above only involves a single response variable and there has also been no effort to produce a model that is free from overfitting problems.

Often researchers do not pay attention to the unit of measure for each variable contained in the dataset where the action will lead to the incorrect model construction. A commensurate nature of all variables involved in modeling must be maintained so that the arithmetic operations on all formulas used can be guaranteed validity [22]. In addition, correlations between predictor variables should be avoided in order to produce a model that has a low bias value. The selection of predictor variables that are independent of each other can be done before the process of building a model, namely the filter approach method [23]. The filter approach method will greatly reduce the computational cost of complex models involving many parameters [24]. The advantage of the filter approach method is that it reduces the number of predictor variables and still maintains the predictor variables in their original form.

Decision-making in the real world must take into account many factors related to the system being studied. A multi-output model can be a classification or a regression model which if it is given an input, can predict unknown multi-output simultaneously [25]. Assessment of product quality in the food, beverage, and fragrance industries uses a lot of semantic odor perception descriptors. Li et al [26] designed an odor perception descriptor selection mechanism based on a multi-output machine learning model including multiple regression

and neural network to find the main odor perception descriptors. Shams et al [27] compared the performance of Multiple Linear Regression and MLP neural networks to predict SO2 concentration in the air of Tehran. The predictor variables used include meteorological parameters, urban traffic data, urban green open space information, and selected time parameters, while the response variable is the daily concentration of SO2. The MLP model has a better performance than the regression model. Siavash et al [28] predict turbine performance using multiple linear regression and a neural network considering as many as 4 channel opening angles as response variables. The performance of the neural network model is more satisfactory than the multiple regression model. The performance comparison between the regression model and the MLP in the above study did not involve tuning the hyperparameters of both models.

The ridge regression model is widely used in practice because of its ease of interpretation, use, and strong theoretical guarantees. In many cases, the model hyperparameter is tuned by using cross-validation, but when the spectrum of the covariate matrix is almost flat and the observations in the observed model are not too high then cross-validation will be detrimental [29]. Meanwhile, van de Wiel et al [30] proposed fast hyperparameter tuning, and Meanti et al [31] proposed Efficient Hyperparameter tuning in the kernel of ridge regression based on cross-validation of data. Tuning hyperparameters on a neural network model using cross-validation data, among others, was carried out by Blume et al [32], and also by Linder et al [33]. Although there is controversy over the advantages and disadvantages of applying the cross-validation method to set up model hyperparameters, this method is systematic and fair.

## III. PROPOSED METHOD

A model is called a simple model if the model only involves a few predictor variables and the relationship between predictor variables is linear. The most sought-after models are those that are simple and have high performance. Variable selection is needed to avoid multicollinearity between predictor variables and also to reduce the number of predictor variables.

### A. Variable Selection and Data Formatting

In the dataset, each variable is related to its respective units of measure, giving rise to very diverse units of measure. The difference in the unit of measure for each of these variables must be handled in order to meet the rules in arithmetic operations. All variables before being analyzed must have an equivalent unit of measure (commensurate measure). The min-max transformation given to eq.(1) is a simple way to satisfy the commensurate measures of each variable [34].

$$N_i = \frac{P_i - P_{min}}{P_{max} - P_{min}} \quad (1)$$

Where  $N_i$  is the normalized value of the i-th instance,  $P_i$  is the observed value of the i-th instance, and  $P_{min}, P_{max}$  are respectively the minimum and maximum value of the predictor variable P. The eq. (1) will be used to transform all values of the predictor variable P into the range of [0,1] and without a unit of measures.

Variable selection with the filter approach is computationally inexpensive because the selection process does not involve the prospective model to be built. The selection of variables is only based on the level of dependence between two variables. The measuring scale of two variables evaluated for dependence lead to a kind of statistical test, namely the dependence between two categorical variables is evaluated by a chi-square test through a contingency table, and the dependence between numerical and categorical variables is evaluated by a one-way ANOVA test, and the dependence between 2 numerical variables is evaluated by correlation test [35]. The Pearson correlation formula given i.e. Eq. (2) measures a degree of dependence between two numerical variables.

$$r = \frac{\sum(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum(x_i - \bar{x})^2 \sum(y_i - \bar{y})^2}} \quad (2)$$

Where r represents a level of dependency between 2 numerical variables namely the x and y variables. The coefficient correlation r has a value in the range between -1 and 1. The value of r = 0 means that there is perfectly no dependency between 2 variables, while the value of r = abs(1) i.e. absolute 1 means that there is a perfect dependence between two variables. To make a simple task in evaluating dependency between two numerical variables, the value of threshold = 0.7 is set. If the value of r is less than absolute 0.7 then the two variables are declared to have no dependency, for the opposite condition means that the two variables have a dependency and as a result one of these variables must be dropped from the dataset [36].

Modeling in machine learning always provides the out-sample data, which is a subset of data obtained by splitting the dataset that separates from the data to build the model. Out-sample data is used to test the model's performance or often referred to as the testing data.

Fig. 1 presents the splitting of the dataset into training and testing parts, also into sub-training, and validation data [37]. In Fig. 1, Initially, the dataset was randomly divided into the training subset (80%) and the testing subset (20%). Furthermore, the training subset is divided randomly into k-fold which are used to form the sub-training and validation data. In this process, k pairs of sub-training and validation data were obtained. For example, if the fold 1 is as the validation data, the other k-1 folds are as the sub-training data, if the fold 2 is as the validation data, the other k-1 folds are as the sub-training data and so on. Model candidates are trained on all sub-training data with each candidate hyperparameter and the model's performance is evaluated on the corresponding validation data. The grid search method is a way to find the model's hyperparameters that give the best average performance on the validation data.

Training					Testing
fold_1	fold_2	fold_3	...	fold_k	
val_1	sub training				
...	...	...	...	...	
sub training					val_k

Fig. 1. The Formatting of the Training Data into k-fold Cross Validation.

### B. Multioutput Multiple Regression and Ridg Regression

In multiple linear regression, if there is more than 1 response variable, it will lead to multi-response modeling which in machine learning is better known as multi-output regression modeling. A simple multi-output regression modeling diagram is given in Fig. 2 as the following.

Fig. 2. The Multioutput Multiple Regression Diagram.

In Fig. 2, it is illustrated that there are three predictor variables, namely X1, X2, and X3 as inputs for a system that performs summation operation. This system produces two outputs, namely, Y1 and Y2. In addition, the input system also has a bias of 1. The diagram when expressed in the form of a mathematical formula is as follows:

$$Y_1 = b_1 + w_{11}X_1 + w_{12}X_2 + w_{13}X_3 \quad (3)$$

$$Y_2 = b_2 + w_{21}X_1 + w_{22}X_2 + w_{23}X_3 \quad (4)$$

$$Y = w^T X \quad (5)$$

Basically, regression model training is a process to obtain weight and bias values that minimize the loss function, which usually takes MSE (Mean Square Error) as the loss function in machine learning modeling given in the following formula:

$$MSE = \frac{1}{2n} \sum_{i=1}^n (Y_i - \hat{Y}_i)^2 \quad (6)$$

The MSE value was optimized using ordinary least squares and can be obtained as an analytical (close form) solution. However, this analytical formula will be problematic if there is strong multi-collinearity between the predictor variables [38-39]. The MSE of a multi-output system is similar to the MSE in Eq. (5) where each Yi and the associated prediction have at least 2 values.

If there are large predictor variables in the multiple regression model, a penalty will be given to the MSE loss function so that the new model is called ridge regression having the loss function formula as the following.

$$MSE_{ridge} = \frac{1}{2n} \sum_{i=1}^n (Y_i - \hat{Y}_i)^2 + \alpha \|w\|_2^2 \quad (7)$$

Eq. (6) is a loss function that must be minimized and is a non-linear function in the w parameter and also contains the alpha hyperparameter [40-41]. In this research, various learning algorithms and alpha hyperparameter values were

tested. The combination of the learning algorithm and the alpha value that produces the minimum loss function of the ridge regression is selected as the model's hyperparameters.

C. Multi-layer Perceptron Neural Network

A neural network is known as a reliable non-linear model for modeling a complex system. The main difference with a multiple regression model is that the weights on the neural network cannot be interpreted as in the multiple regression model, but the magnitude of the weights only indicates the strength or weakness of the relationship between two adjacent nodes. In addition, in the neural network model, each node uses a certain formula called the activation function which is generally a non-linear function [42]. The diagram of an MLP neural network model is illustrated in Fig. 3 as follows:

Fig. 3. The Multioutput MLP Neural Network Diagram.

The MLP neural network is characterized by the presence of a hidden layer located between the input layer and the output layer. When this hidden layer is dropped, it will be formed a diagram that is very similar to Fig. 2 except for the existing activation function in the output layer. The neural network model without a hidden layer (very similar to the multiple regression model) is known as the perceptron model. The most popular activation function is known as ReLu which stands for Rectified Linear Units. The ReLu formula is presented in Eq. 7 as follows:

$$ReLU(z) = \begin{cases} z & \text{for } z > 0 \\ 0 & \text{for } z \leq 0 \end{cases} \quad (7)$$

Where  $z$  is a linear combination between the input and the associated weight. For example, the output of the first node on the hidden layer uses the combination linear of  $z = b_1 + w_{11}X_1 + w_{12}X_2 + w_{13}X_3$ , and the first output of the MLP is obtained by using Eq. (8) as the following:

$$Y_1 = ReLu(output\_A1) \quad (8)$$

Where  $output\_A1 = b_h + w_{11} * A_1 + w_{12} * A_2 + w_{13} * A_3$  and  $A_1, A_2, \text{ and } A_3$  are respectively  $ReLU(z1)$ ,  $ReLU(z2)$ , and  $ReLU(z3)$ . In the neural network term, the process calculates the value of the neural network output such as in Eq. (8) is called the forward step.

The loss function of the MLP neural network is the same as the loss function of the multiple regression in Eq. (5) and

Eq. (6) (with and without penalty term). Because the MLP neural network model involves a non-linear activation function such as Relu, the optimal weights for the neural network model cannot be obtained using an analytical solution (close-form solution). The backpropagation algorithm which consists of a forward step and a backward step is used to train this model in obtaining the optimal weights. The forward step aims to calculate the predicted value (network output), while the backward step is the process of updating the weights by applying the gradient descent method and the chain rule to obtain a gradient descent at nodes that are further back [43].

IV. DESCRIBING DATA AND RESEARCH STAGES

This research uses datasets collected by the Center for Child Development Studies at the Midwifery Academy of Wira Husada Nusantara Malang in 2022. In the dataset, there are 696 sample points which are explained by 20 predictor variables and 3 response variables. The predictor variables were derived from several factors including the condition of pregnant women (variables X1 to X11), food intake of pregnant women (variables X12 to X16), and the health condition of the family environment (variables X17 to X20) which the factors were supposed to affect the condition of the baby at the time of birth (variables Y1 to Y3). The predictor variables consist of 12 Likert scales and 8 ratio scales, while the three response variables are all ratio scales. Table I presents the variables in the dataset along with their minimum and maximum values.

TABLE I. THE VARIABLES AND RANGE VALUES

Symbol	Variable	Min.	Max.
X1	Weight at first check	37	80
X2 (Likert)	Frequency of checks during pregnancy	2	4
X3	Weight gain during pregnancy	1	14
X4	Height at first check	139	170
X5	Circumference of the upper arm	18	36
X6	Body Mass Index	16.4	33.3
X7	Normal blood pressure	80	190
X8	Hemoglobin level	5.8	15.4
X9 (Likert)	The protein level in urine	1	4
X10 (Likert)	The number of complaints during pregnancy	1	5
X11	Gestational age when the baby is born	23	42
X12 (Likert)	Consumption of iron element intake	1	4
X13 (Likert)	Consumption of vegetable protein	1	4
X14 (Likert)	Consumption of animal protein	1	4
X15 (Likert)	Consumption of protein from milk intake	1	4
X16 (Likert)	Consumption of vitamin intake	1	3
X17 (Likert)	Family Income per month	1	5
X18 (Likert)	Quantity and quality of drinking water	1	5
X19 (Likert)	Condition of sanitary facilities	1	5
X20 (Likert)	Cleanliness of the house and environment	1	5
Y1	Baby weight at birth	1	4
Y2	Baby body length at birth	30	55
Y3	Baby health score visually	2	10

Differences in the unit of measurement for variables in this dataset must be addressed before modeling is carried out. All variables involved in building the model must have the same unit of measurement (commensurate measures). Therefore, it is necessary to preprocess all ratio-scaled variables using the minimax transformation. By using the formula in equation (1), the value of the transformation results in the range of 0 to 1, so that finally all variables in the dataset have the same unit of measurement.

Furthermore, broadly speaking, the stages of the process to produce the best model in this study are as follows:

- 1) Selecting variables using the filter approach method.
- 2) Splitting the dataset into training and testing subsets.
- 3) Dividing the training subset into k folds and formatting k fold cross validation data.
- 4) Tuning the hyperparameter model using the grid search method.
- 5) Multioutput regression modeling using training subset.
- 6) Ridge regression multi-output modeling with the best hyperparameters using the training subset.
- 7) MLP neural network multioutput modeling with the best hyperparameter using the training subset.
- 8) Evaluating the model performance in both training and testing subsets.

## V. RESULT AND DISCUSSION

The quality of the input data used to build a model significantly determines the model's performance. In this

section, we will discuss variable selection using the filter approach. The multioutput regression model with the least square of the parameter estimation was built based on the training data, the multioutput ridge regression model with the best hyperparameters obtained through cross-validation was built using training data, and the MLP neural networks model with the best hyperparameters obtained through the hyperparameter tuning process was built using the training data. Furthermore, the performance of the models is evaluated on both the training and testing data.

### A. Evaluate Independency among Predictor Variables

In developing a regression model, one of the conditions that must be met is that there is causality between the response and predictor variables. Causality has a meaning that the response variable is influenced by predictor variables. In multiple regression, the predictor variables must also meet the condition that they must be independent of one another. The measuring scale of each variable will determine the appropriate evaluation method to check the independence between the two variables. The independence between the two numerical variables can be evaluated by their correlation value [35]. Table II presents the Spearman correlation value between two predictor variables presented in the form of a matrix. The matrix main diagonal has a value of 1, which indicates the correlation value in the same variable. Because of the limited space, Table II only presents half part of its column elements. The correlation value of two different variables is expressed in the cells outside the main diagonal.

TABLE II. THE SPEARMAN'S CORRELATION BETWEEN 2 PREDICTOR VARIABLES

Variable	X2	X9	X10	X12	X13	X14	X15	X16	X17	X18
X2	1	0.2	-0.13	-0.23	-0.13	-0.26	-0.01	0.03	-0.26	-0.23
X9	0.2	1	0.23	-0.77	-0.68	-0.69	-0.5	-0.63	-0.66	-0.66
X10	-0.13	0.23	1	-0.22	-0.18	-0.19	-0.24	-0.19	-0.22	-0.21
X12	-0.23	-0.77	-0.22	1	0.79	0.75	0.63	0.74	0.8	0.79
X13	-0.13	-0.68	-0.18	0.79	1	0.68	0.58	0.64	0.65	0.66
X14	-0.26	-0.69	-0.19	0.75	0.68	1	0.47	0.55	0.68	0.65
X15	-0.01	-0.5	-0.24	0.63	0.58	0.47	1	0.43	0.56	0.58
X16	0.03	-0.63	-0.19	0.74	0.64	0.55	0.43	1	0.56	0.53
X17	-0.26	-0.66	-0.22	0.8	0.65	0.68	0.56	0.56	1	0.83
X18	-0.23	-0.66	-0.21	0.79	0.66	0.65	0.58	0.53	0.83	1
X19	-0.3	-0.68	-0.21	0.8	0.68	0.72	0.61	0.5	0.81	0.83
X20	-0.26	-0.66	-0.23	0.79	0.68	0.71	0.6	0.5	0.8	0.82
X1	-0.23	-0.34	-0.1	0.43	0.33	0.4	0.26	0.26	0.41	0.41
X3	-0.2	-0.62	-0.23	0.72	0.64	0.68	0.52	0.46	0.75	0.77
X4	0.11	0.23	0.04	-0.28	-0.2	-0.19	-0.19	-0.19	-0.23	-0.22
X5	-0.2	-0.4	-0.15	0.53	0.39	0.47	0.33	0.36	0.49	0.49
X6	-0.25	-0.4	-0.11	0.5	0.38	0.43	0.31	0.32	0.47	0.46
X7	0.12	0.9	0.22	-0.67	-0.6	-0.58	-0.43	-0.58	-0.53	-0.56
X8	-0.2	-0.55	-0.15	0.62	0.51	0.57	0.38	0.45	0.59	0.56
X11	-0.26	-0.49	-0.18	0.56	0.44	0.53	0.42	0.39	0.57	0.57

In this study, two numerical variables are considered independent if the Spearman correlation value is less than 0.7. An evaluation of the correlation values in Table II can be done either by row or column as the basis for selection. Look at the correlation value in column 1 (the variable X2 as the basis), it appears that all correlation values are less than 0.7. It can be interpreted that the variable X2 is independent of all other variables, so X2 is selected as a predictor that has no impact on other variables. Next, the correlation value in column 2 (the variable X9 as the basis) is found 2 correlation values that are greater than 0.7, they are the correlation value between variables X9 and X12, as well as the correlation value between variables X9 and X7. This shows that the three variables, namely X9, X12, and X7 are not independent of each other. The three variables can be represented by one of them as the selected predictor variable. In this research, so that the variable selection process is more structured, the variable that acts as the basis for selection (the variable X9) is determined as the predictor variable. Meanwhile, the row and column associated with variables X12 and X7 are removed or dropped from the correlation matrix member (not considered again in the next predictor variable selection process). The selection process is continued by considering the next column (the variable X10) as the selection bases where there were not find correlation values in the X10's column which are greater than 0.7. The variable X10 is selected as the member of the predictor variables without dropping other rows and columns.

As a summary of the predictor variable selection process in the forwarding next columns given a result that the selection process on the basis of variables X9, X14, X17, and X1 caused as many as 8 variables to be excluded from the set of predictor variables, namely variables X12, X7, X19, X20, X18, X3, X5, and X6. Thus the dataset used to build and evaluate the model in this study consists of 12 predictor variables and 3 response variables. The selected variable rows (12 variables) are the variables that have a role as the basis of the selection, and furthermore they as the predictor variable selected as independent variables or input variables of the model to be built.

### B. Multioutput Regression Model

Initially, the resulting dataset obtained from the selection variables was divided into a training subset (80%) and a testing subset (20%). The training subset data is used to build the model, while the testing subset data is used to evaluate the model's performance. The splitting of the training subset data into five folds aims to form five pairs of sub-training and validation data. The five data pairs will be used for hyperparameter tuning. The emphasis of this research is actually getting a multi-output ridge regression model having a combination of hyperparameters (solver method and alpha value) which produces the smallest MSE value in the

validation data. However, the author also considers it necessary to obtain a multi-output multiple regression model with the ordinary least square estimate as the benchmark model. The multi-output multiple regression model was built based on the training subset data obtained coefficients which are presented in Table III.

On the response variable Y1 (Baby weight at birth), the predictor variable X11 (Gestational age when the baby is born) has a very significant effect (13.893). It is followed by variables X16 (Consumption of vitamin intake), X10 (The number of complaints during pregnancy), and X4 (Weight at first check) which have an effect on the response variable of Baby weight at birth respectively 2.478, 1.907, and 1.662. On the response variable Y2 (Baby body length at birth), the 4 predictor variables with a moderate effect are X9(The protein level in urine), X10 (The number of complaints during pregnancy), X16 (Consumption of vitamin intake), and X15 (Consumption of protein from milk intake) where they have an effect on the response variable of Baby body length at birth respectively 0.16, 0.16, 0.137, and -0.132 respectively. In addition, the 4 predictor variables with a large effect on the response variable Y3 (Baby health score visually) are X14 (Consumption of animal protein), X17 (Family Income per month), X9(The protein level in urine), and X13(Consumption of vegetable protein) with the effect magnitude of -0.993, 0.555, -0.553, and 0.536 respectively. It is clear that the influence of the predictor variables on the response variable of Baby weight at birth is very large, while their influence on the response variable of Baby health score visually is greater than their influence on the response variable of Baby body length at birth.

Before building the multi-output ridge regression model using the training subset data, in this study, hyperparameter tuning (solver method and alpha value) was carried out using 5 folds cross-validation data that had been formed based on the training subset data. For each pair of fold cross-validation data, the model's performance is calculated on the validation data. For example, for solver of 'svd' and alpha of 0.1, parameter estimation is carried out with the 1st sub-training fold data, and then the MSE value is calculated on the 1st fold validation data. The parameter estimation is carried out with the 2nd sub-training fold data and the MSE value is calculated on the 2nd fold validation data. The above computation process is carried out up to the 5th sub-training fold and the 5th fold validation data. So each pair of both solver and alpha was performed five times parameter estimation and five times calculation of MSE value using different sub-training and validation data. Fig. 4 presents the average MSE of each combination of solver and alpha in the validation data that it is presented in the form of a heap map.

TABLE III. THE COEFFICIENTS OF MULTIOUTPUT REGRESSION MODEL

Resp.	X1	X2	X4	X8	X9	X10	X11	X13	X14	X15	X16	X17
Y1	0.231	0.127	1.662	-0.017	0.955	1.907	13.893	0.067	0.893	-0.063	2.478	0.223
Y2	0.004	0.029	0.022	-0.028	0.16	0.16	-0.063	-0.202	-0.09	-0.132	0.137	-0.053
Y3	-0.046	-0.01	0.11	0.219	-0.553	0.004	0.094	0.536	-0.993	-0.025	0.264	0.555

The hyperparameter tuning with grid search method and k-folds cross-validation requires a lot of computation tasks in estimating model parameters on sub-training data and calculating the MSE model performance on validation data. The MSE value in Fig. 4 was obtained from the average of 5 MSE values from five validation data and from 5 models generated from five sub-training data. So in this case, parameter estimation and MSE calculations were carried out 150 times. The smallest MSE average value is 1.561 which occurs at alpha values of 0.1 and 0.3 in all solver methods except the 'sag' solver method which has an MSE value of 1.562. If the MSE value used only considers 2 decimal digits, then all combinations of solver and alpha result in the MSE = 1.56 in all solver methods with an alpha value of less than 0.8.

The multi-output ridge regression model is built by choosing one combination of hyperparameters (solver = 'sag' and alpha = 0.5) having the smallest MSE using the training subset data. The resulted coefficients of the model are presented in Table IV.

The predictor variable having the largest effect on the response variable Y1(Baby weight at birth) is the variable X11(Gestational age when the baby is born). It has a very significant effect of 13.677 which is followed by variables X16(Consumption of vitamin intake), X10(The number of complaints during pregnancy), and X4(Weight at first check). They have an effect on the response variable of Baby weight at birth respectively 2.441, 1.891, and 1.636. For the response variable Y2(Baby body length at birth), the four predictor variables have a moderate effect namely X10(The number of complaints during pregnancy), X9(The protein level in urine), X16(Consumption of vitamin intake), and X15(Consumption of protein from milk intake). They have an effect on the response variable of Baby body length at birth respectively 0.156, 0.155, 0.136, and -0.133. In addition, the four predictor variables with a large effect on the response variable Y3 (Baby health score visually) are X14(Consumption of animal protein), X17(Family Income per month), X9(The protein level in urine), and X13(Consumption of vegetable protein) with the effect magnitude of -0.985, 0.556, -0.554, and 0.544 respectively. It is clear that the influence of the predictor variables on the response variable of Baby weight at birth is very large, while their influence on the response variable of Baby health score visually is greater than their influence on the response variable of Baby body length at birth.

C. MLP Neural Network Model

Neural network modeling is a type of non-linear modeling that is complex because it involves setting two groups of hyperparameters, namely it related to network architecture and it related to network training processes. The hyperparameters in the network architecture include the number of inputs, the number of outputs, the number of hidden layers, the number of

modes in each hidden layer, the activation function employed, the minimized cost function, and others. The hyperparameters in network training include learning algorithms, learning rate values, number of iterations, tolerance values, number of mini-batches, gamma regularization values, and others.

Because the dataset in this study consists of 12 predictor variables and 3 response variables, this leads to neural networks having the architecture of the number of inputs = 12 and the number of outputs = 3. Several hyperparameters were determined by the researcher through a trial and error process, namely the activation function = ReLu, the loss function = MSE, learning algorithm = SGD (stochastic gradient descent with learning rate = 0.01, and momentum value = 0.9), number of iterations = 100, and number of mini-batches = 30. There are two hyperparameters that are considered very important, namely, the number of nodes in the hidden layer and gamma values in L2 norm regularization are determined using the grid search method using the cross-validation data. The variations in the number of hidden nodes that were tested were [12, 18, 30, 42, 60, 78], while the variations in gamma values were [0.001, 0.005, 0.01, 0.05, 0.1, 0.5].

The process of finding the combination of the number of hidden nodes and the gamma value that produces the minimum average MSE value in the validation data is similar to that carried out in the process of obtaining the combination of the solver method and alpha value in multioutput ridge regression modeling. In essence, for each combination of the number of hidden nodes and lambda values, network training is carried out on five sub-training data and the MSE value is calculated for the five corresponding validation data, and finally, the average of the five MSE values obtained is calculated. After the average MSE for all combinations of the number of hidden nodes and gamma value is obtained, then in order to facilitate the process of the grid search method, the average MSE value is presented in a heap map in Fig. 5.

Fig. 4. The Heap Map for Grid Search of the Multi-output Ridge Regression Hyperparameters.

TABLE IV. THE COEFFICIENTS OF MULTIOUTPUT RIDGE REGRESSION MODEL

Resp.	X1	X2	X4	X8	X9	X10	X11	X13	X14	X15	X16	X17
Y1	0.235	0.124	1.541	-0.015	1.002	1.827	12.882	0.093	0.865	-0.048	2.304	0.228
Y2	0.001	0.027	0.02	-0.027	0.138	0.142	-0.071	-0.19	-0.097	-0.135	0.136	-0.05
Y3	-0.046	-0.011	0.113	0.222	-0.554	-0.004	0.12	0.574	-0.951	-0.026	0.269	0.562

Fig. 5. The Heap Map for Grid Search of MLP Neural Network Hyperparameter.

As explained in the proposed method session, this research uses an MLP neural network architecture whose main feature is that there is only one hidden layer. Based on the average MSE value in the validation data on the heap map in Fig. 5, it is clear that the average MSE value is in the range between 2.415 and 12.596 which is expressed in the darkest (black) and lightest (white) colors. The Heap map also implies that changes in the two hyperparameters greatly affect the MSE average. The combination of the number of nodes and the gamma value that produces the minimum MSE is a combination of the number of nodes = 18 and the value of gamma = 0.1 which will be used to train the network on the training subset data, and then calculate its performance on both the training and testing subset data.

Neural network training with features that include the number of inputs = 12, the number of nodes in the hidden layer = 18, the number of outputs = 3, the number of iterations = 100, and the mini-batch size = 30, the learning algorithm = SGD (learning rate = 0.01 and the momentum value = 0.9) and the value of gamma regularization = 0.1 in the training subset data obtained by the network weight values. The distribution of the resulting network weights in the hidden layer is given in Fig. 6. While the distribution of the resulting network weights in the output layer is given in Fig. 7.

The total number of weights in the hidden layer is  $(12 \times 18) + (1 \times 18) = 234$  where the magnitude of these weights only states the fire strength between each network input and each node in the hidden layer. Based on Fig. 6, it appears that the weight value with the highest frequency (more than 60 pieces) on the average class value = 0.00. The negative weights are about 60 pieces, while the rest are positive weights. Thus, the positive weight dominates in the hidden layer. The effect of the gamma regularization value is to ensure that the weights with very small values become zero, resulting in the number of zeros occupying the mode value of the histogram in Fig. 6.

Fig. 6. The Hidden Layer Weights Distribution.

Fig. 7. The Output Layer Weights Distribution.

In the output layer of this neural network model, there are weights as many as  $(18 \times 3) + (1 \times 3) = 57$  pieces. The weights relate the 18 hidden nodes to the 3 output nodes and also relate one bias in the hidden layer to the 3 output nodes. The weights around zero occupy the mode value of the histogram in Fig. 7 which is due to the effect of the l2-norm regularization. The distribution of weights in the output layer is almost similar to the distribution of weights in the hidden layer where positive weights dominate.

#### D. Discussion

In this section, a discussion is given of the results obtained in the previous session, and also the performance of the model is calculated both on the training and testing subset data using the RMSE and R2 measures.

Based on Table V, in general, the coefficient of the ridge regression model has a slightly smaller effect on the response variables than the coefficient of multiple regressions. This is due to the effect of giving the l2-norm regularization value in the ridge regression model. The predictor variable X11 (Gestational age when the baby is born) has a very dominant effect (13.677) on the response variable Y1 (Baby weight at

birth), the predictor variable X9 (The protein level in urine), and X16 (Consumption of vitamin intake) have the greatest influence (0.156) on the response variable Y2 (Baby body length at birth), and the predictor variable X14 (Consumption of animal protein) has the greatest effect (-0.985) on the response variable Y3 (Baby health score visually). The predictor variables X10, X16, and X9 have a considerable influence on two response variables at once. The performance of both regression models and also the MLP neural network model are given in Table VI.

TABLE V. THE COMPARISON OF THE PREDICTOR VARIABLES AFFECTS ON EACH RESPONSE VARIABLE

Response	Predictor	Regr ess	Ridge regress
Y1(Baby weight at birth)	X11(Gestational age when the baby is born)	13.893	13.677
	X16(Consumption of vitamin intake)	2.478	2.441
	X10(The number of complaints during pregnancy)	1.907	1.891
	X4(Weight at first check)	1.662	1.636
Y2(Baby body length at birth)	X9(The protein level in urine)	0.16	0.155
	X10(The number of complaints during pregnancy)	0.16	0.156
	X16(Consumption of vitamin intake)	0.137	0.136
	X15(Consumption of protein from milk intake)	0.132	0.133
Y3(Baby health score visually)	X14(Consumption of animal protein)	-0.993	-0.985
	X17(Family Income per month)	0.555	0.556
	X9(The protein level in urine)	0.553	-0.554
	X13(Consumption of vegetable protein)	0.536	0.544

TABLE VI. THE PERFORMANCE MODEL ON BOTH TRAINING AND TESTING SUBSET DATA

Model	Training		Testing	
	MSE	R2	MSE	R2
Regression	1.5073	0.6469	1.4362	0.6085
Ridge Regression	1.5074	0.6468	1.4336	0.6098
Neural network	2.2714	0.5823	2.1063	0.5574

All of the developed models have similar performance's characteristics which are the RMSE value in the testing subset is smaller than the RMSE value in the training subset. while the R2 value in the training subset is greater than the R2 value in the testing subset. The multiple regression models consistently have better performance than the ridge regression and MLP neural network model in both the training and testing subsets, although the performance difference between the multiple regression and ridge regression models is very small. This result is in contradiction with the level of complexity in the model building where the MLP neural network model

involves as many as 291 weights and also hyperparameter tuning which requires expensive computations. The coefficients of the multiple regression model are obtained based on the close form solution by the ordinary least square method. In another hand, the coefficients of the ridge regression model are obtained using a numerical optimization method that involves several hyperparameters.

Fig. 8. The Learning Curve of the Logistic Regression Model.

A closed-form solution can be obtained because the predictor variables are independent of each other so the resulting quadratic matrix is not singular. This is one of the impacts of the selection of predictor variables. The outperformance of the multiple regression model also shows that the relationship between the predictor variables and the response variables is based on a linear system. If a linear system is modeled with a non-linear model (such as ridge regression or neural network) it will result in an unsatisfactory performance caused by over modeling. The curve loss function in Fig. 8 strengthens the above argument.

As previously mentioned, the MLP neural network model involves 291 weights that must be optimized using a training subset of 556 instances. The loss function curve in Fig. 8 shows that the value of the loss function has sloped at less than 20 iterations. This means that the model training process is very fast, which only requires updating the weights less than 20 times. This indicates that the system being modeled is a linear system so if it is modeled with a non-linear model, it causes a lot of useless resources or an inefficient modeling process which ultimately results in unsatisfactory model performance.

## VI. CONCLUSION

The equivalence of measure units in the dataset must receive careful attention because arithmetic operations on all mathematical formulas can only work if all operands (variables) involved in the formula must be commensurate. The min-max transformation is often applied to satisfy the commensurate nature of the variable. Multi-collinearity between predictor variables must be overcome so that the influence of predictor variables on response variables is unbiased. The Spearman correlation value can be used as a basis for variable selection with a filter approach if the predictor variables are all numerical scale (interval or ratio).

The complexity of a model does not always result in better performance. In this study, the multiple regression model has the best performance compared with the ridge regression and the MLP neural network model. Even the MLP neural network model has the highest RSME and the lowest R2 value compared to the other two models and its performance gap is moderately large. In this dataset, both the predictor and the response variables are manifest variables that construct the variables of predictor and response latent. So it is an interesting idea if in future research this dataset is modeled with another approach such as the structural equation modeling method using the partial least squares algorithm.

**Abstract**—The application of the Internet of Things (IoT) plays a crucial role in the fourth industrial revolution. The sophistication of technology due to the integration of heterogeneous smart devices open a new threat from various aspects. Access control is the first line of defence to ensure that IoT resources are secure by preventing illegitimate users from gaining access to these resources. However, access control mechanisms face the limitation of technology in large scale IoT deployments since they are based on a centralized architecture. Significant research concerning decentralized access control solutions for securing IoT resources using combined techniques, such as blockchain, have caught much research attention in recent years. Nevertheless, research for decentralized access control for application in smart farming domain remain as a gap. Thus, this study presented a structured literature review on 81 articles related to the field of access control in IoT and blockchain technology to understand the challenges of centralized access control in securing IoT resources. This study serves as a foundation for decentralized access control using blockchain technology and its application to ensure the IoT actuators and sensors security with the aim to be applied in smart farming. This paper was deliberated based on systematic literature review that was searched from four different database platforms between 2018 and 2021. This study mostly addresses the relevant techniques/approaches including blockchain technology, access control model, key management mechanism and the combination of all three methods. The possible impacts, gap, procedures and evaluation of the decentralized access control are highlighted along with major trends and challenges.

**Keywords**—Blockchain; access control; smart contract; internet of thing

## I. INTRODUCTION

Smart farming is the technology enabler that support food security [1] and it has brought changes that reduce costs and minimise environmental constraints, thereby boosting production productivity [2]. Smart farming is capable in enhancing the quality and quantity of production, predicting any possible crop diseases, while optimising agricultural resources and its process. Technological advancement plays a vital role in catalysing the transformation of the smart farming [3]. Data collection using IoT devices such as actuators, sensors, drones and robots are connected to the network for real time data transmission to assist operations. However, the new norm of devices connectivity opened security and privacy

risks for device-based services. Unauthorised access to the devices is among the risk. The situation can be controlled by secure mechanism for authentication in all devices or connected systems. Access control and authentication are considered to be the first lines of defence in restricting unauthorised users from gaining access to IoT resources that provide the data to the smart farming ecosystem. Authentication enables legitimate users to access resources in an authorised manner [4] supporting by access control as the main mechanism for authentication and authorisation, as well as the authority to control resources [5]. Authentication will guarantee that only authorised users are allowed to access a resource. In IoT, access control assigns different privileges to various users regarding the resources of a wide IoT network [6]. However, most existing IoT systems have adopted a conventional access control method which relies on a centralized approach. This may lead to a single point of failure or performance bottlenecks. For instance, an attacker can act as an administrator by stealing authority to illegally access resources, causing a lack of confidence and integrity in such systems. Centralized systems can also be utilised to allow device tracking or related activities, which may compromise privacy. As the number of connected devices increases, it is difficult to manage massive numbers of devices in collecting and handling data using the traditional centralized approach. As a result, IoT has created a challenge in adopting centralized management since it is unable to cope with a large-scale system due to heterogeneous IoT and scalability issues [7], leading to frequent bottlenecks. Researchers have found that applying the blockchain technology can be an alternative solution to this issue. However, the adaptation of decentralized access control in smart farming requires further study to estimate the optimum level of adaptation. Based on the problem statement deliberated above, this research presents a systematic literature review (SLR) on the decentralized access control method using blockchain due to the importance of decentralized access control to manage the heterogeneity and expansion of IoT resources and their application in various domains especially in the domain of smart farming.

The contribution of this review paper is to provide extensive review of research articles to determine the existing gaps, methods and techniques in applying decentralized access control to secure IoT resources. The aim of this study is to

Corresponding Author\*  
FRGS/1/2021/ICT07/UPNM/02/1

understand the current state of related work to address the following research questions:

RQ1: What are the gaps in current access control systems within the IoT ecosystem which can be enhanced by applying blockchain technology?

RQ2: What methods/techniques/approaches are suitable for enhancing access control within the IoT ecosystem by applying blockchain technology?

RQ3: How the evaluation was done to determine the effectiveness of methods/techniques/approaches in previous studies.

## II. RESEARCH METHODOLOGY

The research methodology adopted in this study is the structured literature review (SLR). The SLR was conducted using the following methodology as shown in Fig. 1. Four databases (ScienceDirect, IEEE, Springer and ACM) were employed. Search query was performed to obtain the relevant research articles including journals, book chapters, proceeding papers and books. This paper examines all applicable articles related to decentralized access control for IoT environment application. The method described in [8] was utilised to choose the most important articles related to this research objectives. Articles filtering was done using the six filters that are defined in Fig. 1. A total of 8567 articles were gathered using the following search strings: "Access Control", "Decentral\*", "IoT" or "Internet of Thing" and "Blockchain". Then, after second filter was employed, 5964 articles published between 2018 and 2021 was selected. Next, used source types as filters to reduce the number of articles, thereby producing 2562 results. Then selected papers written in English which yielded 2560 articles. The computer science field was chosen according to the abstract of the paper, resulting in 146 articles. After thoroughly reviewing each paper, a final selection of 81 articles was made upon extensive evaluation based on this study's research questions.

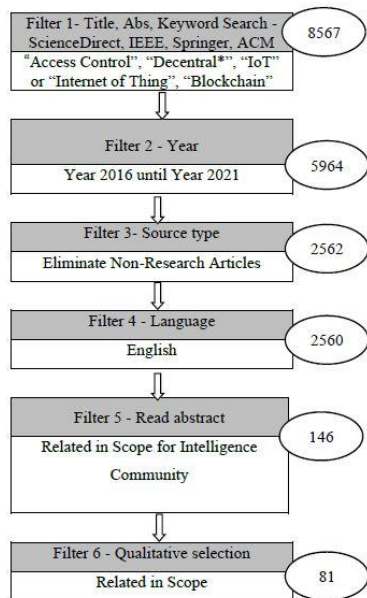

Fig. 1. Filters of the SLR Strategy.

## III. DISCUSSION

Blockchain technology adaptation has been proposed to overcome centralized access control issues. It is expected to be the first line of defence before information sharing of resources is being allowed [9]. Blockchain can also solve security and privacy issues using the decentralized feature by providing security and encryption, making it difficult for attackers since it can detect any illegal changes in its records [10]. To secure resources within an organisation, blockchain technology utilises a cryptography feature that has both a public key and private key that authenticate users who register themselves in the system. A user's personal information is applied to authenticate an individual's identity by employing unique identification, name or biometric data mapped on the user's public key and stored in the blockchain-based smart contracts. Thus, blockchain only provides access to authorised users when accessing resources by authenticating the public key [11].

### A. Gaps of Existing Access Control Systems in the IoT Ecosystem

Fig. 2 presents the research articles regarding access control in IoT by various sectors to determine the gaps to better understand access control issues in the IoT ecosystem. The findings was divided into the several sectors which include smart cities, smart vehicles, smart grid, smart homes, healthcare, banking, property, industry (manufacturing and construction) and general IoT [7], [11], [12], [13], [14], [15], [16], [17], [18], [19], [20], [21], [22], [23], [24], [25], [26], [27], [28], [29], [30], [31], [32], [33], [34], [35], [36], [37], [35], [38], [39], [40], [41], [42], [43]. To answer RQ1 formulated in this study, the analysis was done to understand current access control gaps focusing on the IoT ecosystem that is determined based on the SLR outcomes. The issues were categorised into four groups based on the gaps and problem statement of the literatures: 1) common insufficient IoT access control issues, 2) blockchain combination approaches utilised in the literature, 3) cyberattack issues and 4) lack of security and privacy issues. Based on the literature, several researchers have discussed the common problems in the IoT ecosystem which are: centralized architecture, single point of failure, scalability, heterogeneity, mobility and high energy consumption. The problems are added by the nature of IoT actuators and sensors that are resource-constraints with bandwidth limitations for communication and unable to execute high and memory-intensive computation operations. These problems are major challenges that hinder optimum access control [7]. Researchers in [44], [45, 46], [47] proposed the development of design and standards to secure communication protocols that are capable of interfacing existing systems, collecting data generated by IoT resources and exchanging data to solve trust issues among devices.

Currently, most existing solutions for IoT access control have been developed based on conventional access control architectures, mechanisms, models and policies that mainly rely on single server and third-party entities, leading to high possibility in serious information breach. Failure to ensure the effectiveness of access control may lead to access of information by restricted third party [48]. Thus, conventional access control are inadequate for addressing dynamic and

diverse access control requirements for future IoT ecosystems with new emerging capabilities and application [13] that lead to various security risk including exposure to cyberattack [14]. Common cyberattacks comprise of reuse attacks, DDOS attacks [49] and poisoning attacks. These attacks can cause various drawbacks by exploiting and hijacking the system to retrieve sensitive data. In [50], it was found that attackers can capture, steal or duplicate data to perform illegal activities. In [51], the discussion was done regarding single trusted entities that have become more challenging since these centralized security companies may be biased; permitting illegal or transitive requests while denying legal requests. Attackers can destroy, change or misuse sensitive data and sell it for monetary benefits, leading to data disclosure of user security [31] and lack of data integrity.

Various schemes and cryptographic algorithms were proposed to solve security related issues of IoT by researchers [52], [53], [54]. The proposed methods include a hybrid cryptographic algorithm technique capable of substituting conventional cryptographic algorithms. The same level of security can be simultaneously maintained, leading to additional cost and time for completing encryption and decryption processes [44, 47]. However, these techniques are not feasible since the IoT environment has resource constraints such as high computational power and energy consumption of IoT actuators and sensors. The cryptographic method that involve massive data encryption in IoT actuators and sensors that required higher energy consumption also is not possible to be implemented [55].

To eliminate the gap caused by conventional access control, researchers proposed that the combination of access control and blockchain technology in the IoT ecosystem to resolve issues related to the centralized mechanism. However, IoT network transactions that exceed the capabilities of IoT actuators and sensors, can cause further problems. The complexity of blockchain solutions using the consensus algorithm is beyond the capabilities of IoT actuators and sensors, resulting in constraints in computing and processing and limited bandwidth. Researchers also suggested the consideration of a lightweight key management solution with robust and low resource designs. Based on the deliberations in this section, this study presents a summary of the existing gaps mentioned in previous research in Table I.

Fig. 2. Access Control Application in IoT for Each Sector.

TABLE I. GAPS IN EXISTING ACCESS CONTROL SOLUTIONS

Current Gaps	Literature Articles
Conventional access control (in centralized architecture) causing single point of failure IoT characteristic related issues (heterogeneity, scalability, mobility, limited power resources, memory size, computational capacity)	[7], [11], [12], [13], [14], [15], [16], [17], [18], [19], [20], [21], [22], [44], [46], [48], [51], [53], [55], [23], [24], [25], [26], [27]
IoT actuators and sensors unable to store large transactions	[23],
Lack of trust and fairness in nodes	[48], [17], [20], [23], [28], [29], [30]
Information leak due to un-restricted access control	[14], [15]
IoT low performance for conventional access control	[31]
Privacy leak risk	[29]
Lack of strong encryption enforcement	[47], [32]
Lack of standardised communication protocol	[47]
Malicious attacks and cyberattacks (including identity spoofing, message eavesdropping, message tampering, content poisoning, physical and cloning attacks)	[11], [45], [46], [14], [49], [50], [20], [25], [33], [34]
Lack of authentication mechanism	[45], [52], [50], [19], [22], [27], [34], [36], [37], [35]
Resource constrained IoT actuators and sensors	[51]
Security weaknesses and vulnerabilities	[46], [49], [55], [33], [38], [39], [56]
Access control founded on blockchain technology related issues in IoT environment: higher cost, increased transaction delays and scalability	[53], [40], [41]
Complexity of consensus algorithm beyond the capabilities of IoT actuators and sensors	[53]
Lack of access control mechanism efficient for the IoT environment	[38]
Centralized client server structure and management schemes less efficient for IoT environment	[25], [32], [33], [42], [43] [42]
High costs in guarding security by combining multiple security technologies	[46]
Traditional fog/cloud computing issues	[57]
Low efficiency in centralized operating environment	[54]
Insufficient conventional storage	[55]
Lack of communication control in data flow	[13]

From the SLR, it can be concluded that to enhance the access control framework in IoT ecosystems, it is crucial to further investigate the following mechanism: access control, trust, elimination of third parties, authentication, privacy and security. The trade-off between the decentralised access control supporting technologies with computing and processing power are vital to be further researched to find the optimum solution.

### B. Techni[58]Ques and Approaches for Existing Decentralised Access Control in IoT

To employ decentralized access control in the IoT ecosystem, researchers have recently applied various techniques to solve the issues presented when addressing RQ1, which are: trust, communication, third party entities, privacy and security problems. Next, evaluated articles were discussed to address RQ2. Based on the literature review, all research papers have presented the use of either blockchain technology, access control models, key management or the combination of all three approaches to efficiently manage access control for IoT resources. The results revealed that only 10 papers used blockchain technology as a strategy for the decentralized access control, while another 10 applied the access control model by adopting the blockchain technology. A total of 12 papers had combined blockchain technology and key management, while three papers combined all three techniques (blockchain technology, access control model and key management techniques). Other techniques were also discussed in these papers, such as IOTA and tangle technology. IOTA is a protocol for securing data communication between IoT actuators and sensors with lightweight quantum resistant cryptocurrency devices. Tangle is an open-source distributed ledger similar to the blockchain technology [21]. Fig. 3 provides a summary of the reviewed papers in this study according to the type of decentralized access control approaches used.

Fig. 3. Type of Decentralized Access Control Approaches in IoT for Each Sector.

1) *Blockchain technology application in decentralized access control in IoT actuators and sensors:* From the literature review, 10 articles were found to have utilised blockchain technology as an approach for decentralized access control in IoT ecosystems. Blockchain is more suitable for decentralized access control due to its immutability and distributed ledgers. It can also handle access control without relying on third parties. Table II presents a summary of blockchain technology employed in decentralized access control including the objectives and techniques used. According to [59], blockchain can be categorised into two groups of access control: 1) global access control and 2) local access control. In global access control, blockchain operates as a distributed ledger and also employs smart contracts to

perform global access control tasks including authentication, authorisation, and key management according to the access control policy. Nguyen et al. proposed a framework for establishing a trustworthy access control mechanism on a mobile cloud platform utilising smart contracts [15]. This study applied blockchain to develop decentralized interplanetary file system (IPFS) on a mobile cloud platform by granting access permissions to each individual medical user to access resources in the environment. The authors further employed IPFS smart contracts to strengthen the security of decentralized cloud storage and data sharing control for better user access management. In the industry domain, Xiong et al. proposed a secure and fair coordinated recognition scheme for multiple IoT actuators and sensors using peer-to-peer edge device cooperation [29]. The study further suggested that using smart contracts can be beneficial in the interaction mechanism of trusted nodes by verifying the node. Among the verification mechanisms, the public key is used to authenticate the digital signature for each node in the environment.

In the second group of local access control, the blockchain is utilised as a distributed ledger that stores access control and verification rules, while the local storage maintains authentication and authorisation. Most researchers focus on the local access control which only stores in blockchain server and uses hash techniques to authenticate and authorise the user and device in the IoT ecosystem. The authors in [50,55] and [35] recommended a lightweight authentication by using lightweight cryptographic key to improve security in IoT actuators and sensors, such as the Merkle-Tree, Streebog Lightweight Hashing Algorithm and Hash-locks. Narayanan et al. proposed the Streebog Lightweight Hashing Algorithm hash generation for faster data encryption. The SALSA20 algorithm was also deemed suitable for the IoT environment in [55] since it can minimise the time consumption. The authors in [50] and [60] used the token mechanism as the access control strategy to authenticate each IoT resource and user. Generally, token consists of unique credentials such as addresses, IDs as well as public and private keys. The research claimed that this approach can reduce computational overhead, time costs for blockchain and enhance efficient access control in the IoT environment. The authors further proposed the combination of public and private blockchain for decentralized authorisation in IoT actuators and sensors. It was claimed that the combination approach can reduce the delay of transaction requests and the amount of data the client requires to send to cloud.

2) *Blockchain based access control:* From the SLR, nine articles were found to adopt an access control model implanted with blockchain technology to provide more fine-grained access control using smart contracts in the IoT ecosystem. Researchers mainly used the distributed attribute-based access control (ABAC) model, capability-based access control (CBAC) model, delegation model, XAML policies and access control list (ACL) model as the proposed approaches for decentralized access control strategy in determining access control of a particular IoT device service through blockchain

and smart contracts. Table III presents the common access control models that were adopted in previous research and their function.

TABLE II. BLOCKCHAIN TECHNOLOGY APPROACH IN DECENTRALIZED ACCESS CONTROL

Authors	Application Objectives	Techniques
[29]	To propose multiple IoT actuators and sensors cooperation driven by secure and fair coordinated recognition scheme using peer-to-peer edge devices	Blockchain, smart contract, YOLO algorithm
[14]	To propose a robust blockchain-based lightweight distributed architecture by leveraging high speed network infrastructure to disburse the computing platform	Blockchain, smart contract, hashing, symmetric encryption, digital signature
[4]	To propose a blockchain based high-efficiency access control framework by leveraging token technology	Blockchain, smart contract, access token, IPFS
[9]	To propose an architecture utilizing blockchain technology in IoT-based environments for healthcare	Blockchain, Hyperledger, chaincode, IPFS
[50]	To propose a blockchain-based authentication mechanism for IoT actuators and sensors	Blockchain, smart contract, Ethereum, token, digital signature algorithm (ECDSA)
[55]	To propose the application of blockchain in enabling secure data sharing among authorised users and devices in the cloud-IoT environment	Blockchain, Streebog lightweight hashing algorithm, SALSA20
[61]	To propose a secure data sharing and access control scheme for users to control the right and privacy of their digital footprint	blockchain, smart contract
[35]	To propose a secure and lightweight Blockchain based IoT authentication scheme	Blockchain, merkle-tree, sequence numbers (SN)
[43]	To propose a novel model for decentralized authorisation by considering limitation of constrained of IoT actuators and sensors	Two blockchain (public and private) Hyperledger, smart contract, Hashed Time-Lock Contracts (HTLCs)
[15]	To propose trustworthy access control mechanism with the application of smart contract on a mobile cloud platform	Blockchain, smart contract, IPFS

TABLE III. ACCESS CONTROL MODEL

Access control model	Functions
ABAC [34]	Attribute-based access control, or ABAC, uses real identities as a set of attributes representing access control policies in a fine-grained method.
RBAC [62]	Role-based Access Control, or RBAC, adopts "roles" as a method to assign permissions. Users are assigned associated role prior to the permission assignment.
ACL	Users of a specific resource will be directly assigned permission in Access control lists (ACLs).

Hossein et al. stored and retrieved data sharing of healthcare records with user-centric and fully distributed architecture of access control, removing trusted third parties in the system [51]. The authors employed different chains of access control policies to ensure that the access policies for the owners of the data are not tampered with, and access to patient data is restricted. The architecture proposes the utilisation of Cluster Head (CH) and Proof-of-Authority (PoA) consensus algorithm to increase the blockchain network throughput and improve system performance and scalability. This approach can reduce the time delay and decrease the number of nodes stored in a single transaction since only miners of each cluster will be kept. However, due to the decreasing number of miners, the risk of malicious activities can increase. In [19], a delegation model approach was employed by adopting blockchain technology for access control in the IoT ecosystem environment setting. The authors proposed an authorisation and delegation model for IoT-cloud based on blockchain technology by deploying smart contracts. The study outcomes indicate that the suggested approach has limitations. The delegation deletion module was not successful since gas requirements exceed the gas limit of the network and further research is required.

Although some limitations do exist, the uniqueness of blockchain technology has attracted technology providers and researchers. One unique feature is the smart contract which can self-execute certain programming conditions and eliminate the need for a trusted entity in the system [63]. Most studies implemented smart contracts to authenticate ownership or to function as a mechanism for controlling token access stored in blockchain. If IoT actuators and sensors are successfully authenticated and validated, devices can access the entire system based on pre-determined access level. Technically, when all authentications are automatically triggered by smart contracts, credibility and impartiality of authentication are theoretically guaranteed. For instance, [64] proposed a trust-based access control framework for decentralized IoT network by applying smart contract to enable decentralization. The authors deployed the ABAC mechanism to manage and limit resources accessed by any party under decided conditions based on the access policy that was set with pre-determined attributes. Access policy enforce smart contracts by assessing the incoming authorisation request to access resources based on context. The context was pre-set with the rulesets according to the specific Boolean attribute in the access policy. Successful authorisation will be followed by a process in generating an access token by smart

contracts. The token can be used to access the resources without repeating the authorisation process for the next access multiple times. This approach provides scalability and at the same time acting as a defender towards Sybil attacks and newcomer attacks that apply attribute registration mechanism way of attack. A similar approach was adopted in [17] by implementing smart contract that functioned as a smart policy to the access control policy. During the execution, a smart policy is created by the resource owner and stored on a blockchain after a proper transaction being transacted.

Meanwhile, in [65], blockchain and decentralized identifier (DID) techniques were used to manage identity and access control for IoT device authentication. This paper deliberated that, based on the proposed mechanism that the capability tokens play a vital component when a particular IoT device service is requesting to obtain the authorisation, the device owner must claim their ownership via the ownership management module to obtain authorisation using the capability token. This approach was determined as lightweight due to three smart contracts applied within the core components: DID registry, device ownership credential registry and device capability credential registry. However, related services need to be present to invoke the functions of these contracts. On the other hand, the work in [66] presented a mechanism where two entities were introduced to handle the delegation process which are labelled as delegator and the delegatee. The entity that executes the role in transferring the access right is called the delegator. The delegator plays a role as the entity that will perform the transfer of the access right, while delegate play a role as the receiving entity. The proposed approach commonly deploys delegation through smart contracts to eliminate the need for a central, trusted, third-party authority. Table IV presents a summary of access control models that adopt blockchain technology in decentralized access control, including the objectives and techniques used are discussed.

3) *Blockchain-based key management for decentralized access control*: From the SLR, 13 articles were found to use the distributed key management in the effort to strengthen IoT access control by applying blockchain to resolve privacy and security issues. Table V presents a summary of blockchain-based key management approaches including the objectives and techniques used for decentralized access control. The combination of distributed key management and blockchain technology is to provide secure authentication and trust communication between device/node in the network layer. The authors in [28] claimed that the use of public key infrastructure (PKI) has vulnerabilities, such as high computational complexity, and requires intermediate certificate authority (CA) to accomplish certificate verification key. Thus, the authors proposed key management in blockchain operated by security access managers (SAMs). SAM plays a crucial role as CA, which is responsible for storing and verifying entire blockchain transactions. Based on SLR, the researchers suggested the adoption of various types of cryptography algorithm techniques including digital signature, endow key trust, symmetric encryption algorithm,

session key, Elliptic Curve Cryptography (ECC), Aggregate signature scheme, Broadcast Encryption (BE) and Multi-Receiver Encryption (MRE) embedded with blockchain. These techniques aim to enhance the access control required for verifying the identity of resources by authenticating and authorising the IoT device and user before entering the system or communicating with other entities in the decentralized nature. For instance, Hammi et al. utilised a bubble of trust in the blockchain environment to provide secure communication to each trusted member device [46]. In this approach, two types of bubbles are present: the master bubble which acts as a certification authority, and the follower bubbles. To authenticate these bubbles, the authors used ECC to generate private/public key-pair since it is known as a lightweight key and is suitable for restricted devices. Smart contract is also applied to verify the uniqueness of the follower's identifier, checking the validity of the follower's ticket using the public key of the master bubble. If one condition is not satisfied, the object cannot be associated to the bubble. If successfully authenticated, the tickets are no longer needed to register new identification and make ACL for users in the system. Shi et al. proposed a blockchain-based access control scheme for privacy preserving in distributed IoT, which formalizes the distributed architecture in IoT and the traditional centralized access control model [25]. The authors utilised domain management server (DMS) to define information and permission of data on blockchain. They used the key-pair of DMS to sign and encrypt data permission on blockchain and employed the symmetric encryption algorithm to encrypt data. Although the data on blockchain is transparent to all nodes, it still reasonably protects the user's privacy.

4) *Blockchain-based access control model and key management*: Based on SLR, 3 articles were found to use distributed key management and access control model that adopted blockchain technology. Various access control models were proposed as access control strategies: RBAC, ABAC, Attribute-Based Signatures (ABS), Anonymous Attribute-Based Encryption (ABE) and Outsourced Attribute-Based Signature (OABS). Double authentication preventing signature (DAPS), Aggregate Signature Scheme, Endow Key Trust, Symmetric Encryption Algorithm and Digital Signature act as the key management for authenticating IoT actuators and sensors. Both techniques were applied together with blockchain technology for enhancing decentralized access control to secure IoT resources as well as improve security and privacy issues in the IoT ecosystem. This combination technique further increased scalability and feasibility of the proposed solution compared to existing solutions.

TABLE IV. BLOCKCHAIN-BASED ACCESS CONTROL APPROACH IN DECENTRALIZED ACCESS CONTROL

Authors	Objective	Detailed Techniques
[22]	To propose a blockchain technology combined with Zero knowledge Token-Based Access Control (BZBAC)	Blockchain, Ethereum, smart contracts, off-chain computation, on-chain, Zero knowledge Token-Based Access Control model
[64]	Trust-based access control framework was developed to support the implementation of decentralized IoT network with smart contracts as the main component	Blockchain, ABAC, smart contract, Trust and Reputation System (TRS)
[51]	To propose a novel access control architecture based on blockchain for storing and retrieving healthcare records	Blockchain, access control policy, cluster head (CH), proof-of-authority (POA) consensus algorithm
[31]	To propose a blockchain-based access control system by embedding ABAC and smart contract on the Hyperledger fabric platform	Blockchain, ABAC policy, smart contracts, Hyperledger fabric
[19]	To propose authentication and delegation mechanisms by using smart contracts and the Stack4Things framework. The mechanism is to support the migration to the decentralized environments	Blockchain, delegation mechanism, RBAC, smart contracts, universally unique identifier (UUID)
[39].	To propose “PrivySharing,” a framework developed based on blockchain aimed to provide secure and privacy-preserving data sharing	Blockchain, smart contracts, ACL rules
[38]	To propose a framework for access control embedded with blockchain technology to enhance privacy policy dedicated for Decentralized Online Social Networks (DOSN)s.	Blockchain, smart contract, ACL rules
[65]	To propose a decentralized capability for IoT access control by implementing blockchain technology with smart contract as the core component	Blockchain, smart contracts, capability based IoT access control, Decentralized Identifier (DiD)
[17]	To present an implementation reference of manipulating XACML policies in a case where Solidity language was used to write a smart contract and deployed on Ethereum platform	Blockchain, smart contracts, XAML policies

Lei et al. proposed a blockchain-based security architecture for improving security and privacy of named data networking (NDN)-based vehicular edge computing (VEC) network. The ABAC mechanism was adjusted into the decentralized architecture; therefore, access control decisions do not have to rely on a centralized policy decision point. The proposed ABAC applies a set of attributes to represent the

resource and the subject requesting the resource [34]. This work also suggested a blockchain-based solution that uses the endow key trust instead of the root key for verifying the authenticity of the key across the user trust domain. Other than that, the symmetric encryption algorithm is also applied to encrypt the content with a symmetric data key and used in access control by controlling the distribution of data key that can only be obtained by an authorised user. Kamboj et al. proposed the RBAC model using blockchain to assign a role in the organisation and management of interactions between users and resources [11]. The role checks and verifies credentials of roles by using smart contracts and digital signature algorithm for signing the transaction and for the generation of public and private keys. Table VI presents a summary of blockchain-based access control and key management approaches, including the objectives and techniques used for decentralized access control.

TABLE V. BLOCKCHAIN-BASED KEY MANAGEMENT APPROACH IN DECENTRALIZED ACCESS CONTROL

Author	Techniques
[40]	Access Control Header (ACH), Cryptographic, multi-layer BC, smart access control
[53]	Blockchain, identity-based signature, hash function, Verifier Control Centre (VCC), Certification Authority (CA)
[25]	Blockchain, symmetric encryption algorithm (SEA), Asymmetric Encryption Scheme (shared key), Management Server (DMS) (Storage)
[44]	blockchain, smart contracts, hybrid cryptosystem with lightweight cryptographic functions (Key Generation Centre (KGC), AES, ECDSA and One-Way Hash Function), angular distance (AD)
[7]	Blockchain, Elliptic Curve Digital Signature Algorithm (ECDSA), Algorithm (Public Key & Private Key), Smart Contract
[48]	blockchain, smart contracts, Elliptic Curve Cryptography (ECC)
[18]	Blockchain, Elliptic curve digital signature algorithm (ECDSA), one-way hash function, session key
[57]	Blockchain, Ethereum, smart contracts, Distributed, Self-Sovereign Identity, fog device authentication mechanism
[33]	Blockchain, cryptographic algorithm- public key, private key and secret key
[42]	Blockchain, Diffie–Hellman, public/private key pair, Session key, Trust Network Framework (TNC), ECDSA
[28]	Blockchain, smart contract, key management schemes, security access managers (SAMs)
[37]	Smart contracts, blockchain broadcast encryption (BE), certificateless multi-receivers encryption (CL-MRE) and Permission Data Hash Table (PDHT)
[46]	blockchain, smart contracts, Public Key Infrastructure (PKI), bubble trust (secure virtual zones), Elliptic Curve Digital Signature Algorithm (ECDSA), ticket

TABLE VI. BLOCKCHAIN-BASED ACCESS CONTROL MODEL AND KEY MANAGEMENT APPROACH IN DECENTRALIZED ACCESS CONTROL

Author	Objective	Detailed Techniques
[11]	Developing a role-based access control method using blockchain technology to manage user-role in the organisation	Blockchain, Ethereum smart contract, RBAC, public key infrastructures (PKIs), elliptic curve digital signature algorithm (ECDSA), digital signature, Keccak-256 cryptographic hash function
[34]	Developing novel security architecture using blockchain technology concept for application in NDN-based VEC networks to address security and privacy challenges	Blockchain, delegate consensus algorithm, access policy key management mechanism (endow key trust, symmetric encryption algorithm), ABAC
[49]	Privacy preserving IoT software update protocol by applying blockchain technology	Blockchain, smart contracts, double authentication preventing signature (DAPS), outsourced attribute-based signature (OABS)

5) *Blockchain with other approaches*: Based on SLR, seven articles were found to employ different approaches to the proposed decentralized access control in the IoT ecosystem. The approaches include Transitive Access Checking and Enforcement (TACE) mechanism which adopts blockchain, blockchain-based access control model, physical unclonable function (PUF), blockchain-based game theory and blockchain-based cross chain technology. Only two articles did not include blockchain adoption. Table VII presents a summary of blockchain combined with other approaches, including the objectives and techniques used for decentralized access control.

TABLE VII. BLOCKCHAIN COMBINED WITH OTHER TECHNIQUES IN DECENTRALIZED ACCESS CONTROL

Author	Detailed Techniques
[47]	Blockchain, smart contracts, Role-Based Access Control, hybrid PUF
[20]	Blockchain, evolutionary combination rule (ECR), smart contracts, game theory
[45]	Blockchain, PUF, smart contracts, Diffie-Hellman key, Chinese Remainder Theorem (CRT), Hash Function
[54]	Blockchain (main chain-consortium), byzantine fault tolerance (RIBFT) algorithm, smart contracts, cross chain technology
[21]	Tangle (store policies), ABAC policy, Decision Point (PDP)
[67]	Blockchain, TACE, Cross-Domain Access Control
[36]	MAM, Tangle, One-Time Signatures (OTS), Merkle Signature Schemes (MSS)

From this review, 39 articles were found to utilise blockchain technology for decentralized access control in IoT ecosystems. Only two articles used IOTA technology similar to blockchain technology. Most research used the ownership concept in the access control model. From SLR extraction, noticed that access control deploys smart contracts to create ownership of resources. The owner will register itself and its resources into smart contracts. After successful registration, smart contracts will generate the credential/token to authenticate the resource owner. The owner can access their resources any time using the credential/token. The deployment of smart contract occurs when two parties agree to the agreement made through coding and can then execute in an autonomous manner. Smart contract is built based on the role or attributes assigned by the authorizing admin who enrolled the smart contract. After deploying smart contract, the user/owner can use their credentials to access the entire network with permission. In a smart contract, several functions are present to operate based on the needs of a contract. Researchers used function add, update, delete and remove to operate in smart contracts. However, the negotiation process for the terms and conditions of smart contracts is unclear.

Access policy is also employed in smart contracts for access control in the IoT ecosystem by creating different levels of user authorisations to access resources. This access policy will be stored in the blockchain server to make it easier for users to invoke their access policy. Authentication and authorisation are also needed in access control for the IoT network. Several techniques that can be used to authenticate and authorise, such as BE, CL-MRE, PDHT, ECDSA and ECC. According SLR, the researchers used public key, private key and secret key to encrypt data for submitting or exchanging data to trusted entities in the IoT network. Several research also used key management to secure communication between device to device (D2D) and device to IoT network. As a result, it is guarded from malicious attacks such as eavesdropping, DDOS and hijacking. From all mentioned techniques, smart contract, authentication & authorisation and key management are the vital components in enhancing the decentralized access control in the IoT ecosystem. However, some techniques are not suitable due to the time delay of transactions and increased overhead. Thus, the trade-off between the techniques and transactions performance must be researched to find the optimum level. Table VIII presents the output of techniques used.

TABLE VIII. OUTPUT OF TECHNIQUES USED IN EXISTING SOLUTION

Author	Techniques	Output
[29]	Blockchain + smart contract	Better fairness and robustness Increased start-up delay
[11]	Ethereum blockchain + new RBAC + PKI + ECDSA	Less execution cost Less running time compared to the RBAC-SC
[47]	Blockchain + access control model + PUF	Cost-effective device in authentication Scalability Computational efficiency of IoT device
[61]	Blockchain + smart contract	Increased feasibility and effectiveness
[4]	Blockchain + smart contract + access token + IPFS	Secure and has low gas cost
[9]	Blockchain + Hyperledger + chaincode + IPFS.	Reduced mining costs and increased throughput
[50]	Blockchain + smart contract ECDSA	More effective in communication overhead compared to previous approach Less time for communication between IoT actuators and sensors with blockchain
[55]	Blockchain, Streebog Lightweight Hashing Algorithm, SALSA20	Better performance Suitable for a large-scale environment Lower time consumption due to spark environment High-level security
[18]	Blockchain + ECDSA + One-way hash function + session key	Low communication cost and access control phases than all existing schemes More computation time than some existing schemes
[20]	Blockchain + game theory	Compared to the environment without the protection shows effectiveness in latency overhead
[33]	Blockchain + public key, private key, secret key	Lower computation cost
[34]	Blockchain + delegate consensus algorithm + key management mechanism + ABAC	NDN: higher throughput in network architecture Time delay: increases total time to verify a transaction signature Increased overhead: encryption and decryption
[42]	Blockchain + public/private key pair + session key + TNC	Longer time to invoke smart contracts Provide stronger mechanism for verification of IoT actuators and sensors that adopt blockchain technology
[43]	Two blockchain (public and private) + Hyperledger + smart contract + HTLC	Decreased overall transaction delay
[15]	Blockchain, smart contract, IPFS	Flexibility in different platforms Availability of data in dynamic real time Decentralized IPFS to solve the single point of failure
[46]	Blockchain + PKI + bubble trust + ECDSA	Less energy and computation consumption
[36]	IOTA + MAM	Less time delay
[37]	Blockchain + BE + CL-MRE + PDHT	Smart contracts increased time cost

#### IV. EXISTING FRAMEWORKS FOR DECENTRALIZED ACCESS CONTROL USING BLOCKCHAIN

Developments in the field of decentralized access control in the IoT ecosystem have attracted various research efforts, resulting in several framework developments based on various objectives and goals. By taking into consideration that authentication and access control are important security aspects, especially with the increase in devices that generate content, various access control solutions have been proposed throughout the literature. In this SLR, found nine existing frameworks for decentralized access control in the IoT ecosystem. The findings are classified into three groups based on framework objectives. Table IX shows the objective regarding existing frameworks.

From the extraction of this SLR, four frameworks were found to develop an access control that focuses on communication control between various entities such as IoT device, gateway, cloud and users [4], [68], [69], [47]. To accomplish the objective of the proposed framework, researchers have adopted blockchain technology to design control communication between various entities by validating data flows before attempting to communicate with other entities. With the capability of blockchain in enhancing reliable communication between entities by utilising its distributed ledger with the hashing function and smart contracts, the authors in [69] designed intra-blockchain interactions within smart contracts. The authors also designed inter-blockchain communication from one node to other nodes and resources in the IoT network. The development of the framework was inspired by the microservice architecture that was build based on 3 proportions: right side, top right side and top left. The core part of this framework is the top right side which utilises 3 smart contracts for IoT systems. The 3 smart contracts have two functionalities: 1) contract level of communication between IoT actuators and sensors, and 2) contract to access data-sources and 3) interoperability of heterogeneous IoT smart contracts. In another approach, the authors in [4] developed access control in various entities and communication control frameworks for cloud-enabled IoT. This framework has three layers: the register model layer, blockchain-based token requesting mechanism layer and requesting data with token used to control the access of users in the system's layers. The authors also deployed pre-defined smart access policies to register resources by the upload mechanism using unique ID. After successful registration, the user must request a token for verifying authority and accessing resources.

In this SLR, two frameworks that focused on authentication and authorisation of user and device, as discussed in [24] and [28] was found. Ma et al. proposed a lightweight, scalable and adaptive key management scheme for the IoT system [28]. In this work, the authors deployed a key management mechanism performed in SAM. The mechanism that was proposed was utilised to record and verify transactions and administrating the key management information. The reason behind the proposed mechanisms is to enable a low-latency key management function for user equipment in the same deployment domain.

Several studies have discussed the constraints regarding devices installed in IoT applications, posing challenges in terms of reliability, cost delay and security. In this SLR, three frameworks that focused on security and privacy enhancements in IoT [70], [71], [72] were found. In the framework proposed in [71], the authors suggested a datagram transport-layer security (DTLS) protocol. The framework was designed with the aim to ensure secure communication that can be realized between three layers: the 1) data producer layer, 2) hybrid computing paradigm layer and 3) data consumer layer. To further strengthen the proposed framework, the authors also included three cryptography mechanisms in the form of algorithms to give higher protection towards system level privacy and security. The proposed combination of blockchain technology and DDSS framework was tested in the decentralized transparent healthcare management system. This framework can be utilised in the application of healthcare domain using a public ledger for each medical record and critical event to provide traceability as well. In addition, in this study, smart contracts usage was applied in automating event-based activities without medical professionals' interference. Meanwhile, in the framework discussed in [73], blockchain technology proposed to be applied in a data-sharing model for intelligent community by utilising the centralized model for access control. The model presented in three modules. In the first module, user authentication and identity management are addressed using enhancement multi-factor authentication model which relies on trusted third parties to manage user authentication. The authors chose not to use blockchain technology in their user authentication module so as to shorten the authentication process and preserve the system's security. However, this approach may lead to various problems in future due to the nature of centralized management. Thus, the gap must be addressed in future work to provide the improvement.

From the literature review analysis, from the observation that the proposed frameworks can be divided into three to five layers based on the physical layer, network layer and application layer concepts. These layers consist of several services and applications in different levels. The first layer is the physical layer, also known as the sensing layer. This layer consists of the IoT device and sensors responsible for collecting and processing data to send to the second layer. Before the IoT actuators and sensors being allowed to enter the network and raw data is transmitted, the access control mechanism will be the first line of defence that guarantee that only eligible actuators and devices will be allowed to access. After the devices clear the access control, then, lightweight key management approach is used to encrypt raw data. The second layer consists of gateway or network paths that are required to transmit IoT data. Any device or user that enters the network must be authorised. Some approaches use simple cryptographic, such as public key, to authorise. Other designs are based on PUF as the key generated for uniquely authenticating IoT actuators and sensors. The third layer is the blockchain layer which performs the transaction validation. This layer uses smart contracts as a core layer that only performs on legitimate devices for accessing resources in the system. Other researchers used a fourth layer as an application

layer which can be executed on cloud or local environments. This layer allows users to access resources by using the internet. To obtain authorisation, users require a valid token or credentials to gain network access.

TABLE IX. BLOCKCHAIN COMBINED WITH OTHER TECHNIQUES IN DECENTRALIZED ACCESS CONTROL

Author	Objectives of the Proposed Framework
[4]	To develop access control in various entities and communication control frameworks for cloud-enabled IoT in terms of data flow from one end to another in CE-IoT services/applications
[47]	To secure data communication and sharing in IoT networks using generated cryptographic keys by providing authenticated device using PUFs and blockchain technology
[71]	To improve the system's security capabilities in classic cloud-centric blockchain-based H-CPS
[70]	To secure and create tamper-resistant massive IoT transactions by improving scalability and the performance of massive IoT networks by utilising blockchain-based secure micro-services in Virtualised Network Functions
[68]	To generate reliable communication IoT eco-systems with reliable information integration between users by validating nodes based on inter-operable structures
[72]	To improve the transaction delay among IoT applications by using blockchain based in SDN architecture
[15]	To allow authorised entities (such as healthcare providers) to effectively retrieve EHRs on cloud, while preventing unauthorised access to EHRs resources
[24]	To enable secure and transparent collaborations for connected IoT actuators and sensors trust-based automation to recognise, authenticate and access control of devices in the perception layer
[28]	To achieve a lightweight, scalable, adaptive key management scheme and authorisation assignment mode by verifying the access query transaction based on logical topology in the IoT system
[69]	To enhance access control traditional development model with features that primarily support intra-blockchain interactions within smart contracts as well as enable inter-blockchain communication to other nodes and resources in the IoT network

## V. EVALUATION FOR DECENTRALIZED ACCESS CONTROL USING BLOCKCHAIN

How the evaluation was done to determine the effectiveness of methods/techniques/approaches in previous studies, is addressed in RQ3. Each reviewed study had been evaluated based on their proposed techniques, approaches and frameworks as the baseline for future investigations. This evaluation was accomplished during the experimental phase. Validation was conducted using pre-determined parameters and by comparing existing baseline models. These parameters and models have been used by numerous research works that reported satisfactory results and were then later examined and enhanced by others. To answer RQ3, this section lists the

datasets, parameters and tools (hardware/software) used to evaluate the performance of the proposed approach.

#### A. Dataset for Evaluation

For every proposal deliberated in the literature, experiments were done to validate the proposals. For the validation, most datasets used in access control experiments generated by nodes. Most nodes are used in the research to simulate the experiment scenario [7,15,31,44,51]. Data were generated by IoT actuators and sensors, such as raspberry pi system [7] sensors, collected from laptops and mobile phones to form a dataset. In [71] and [74], available datasets or open data are employed to conduct experiments. For instance, Guruprakash & Koppu used Kaggle which contains temperature readings from IoT actuators and sensors installed inside and outside anonymous buildings [74]. This dataset was analysed to validate the proposed system functionalities and capabilities [74].

#### B. Parameters for Performance Evaluation

Based on the literature, experiments have been accomplished to evaluate the different performances of the proposed approaches according to various parameters. The parameters frequently depend on the objective of the study and the goal of the experiments. The evaluation in blockchain technology can be categorised into two groups based on the evaluation goals, as follows:

1) *Parameter based on performance of blockchain technology*: The evaluation of blockchain performance metrics and parameters consist of transaction throughput, transaction latency, network latency, block size, computational cost, block validation, storage overhead, transaction delay and time delay [7], [9], [51], [15,25,54], [74], [75], [76]. Network latency is the total time taken for a transaction to be executed in the blockchain network. To evaluate these parameters, Table X displays the measuring units based on the parameters used: milliseconds (ms), second (s), minutes (m), joules (j), ethers, bytes, transaction (Tx), transaction per second (TPS), transaction per minutes (TPM). Based on the study of [15], the time taken is usually higher when the mechanism involved with user authentication is based on smart contracts that consume more time to process user requests, as compared to the non-authenticated scheme. The computation cost based on the time of deploying and invoking a smart contract increases [52]. The storage cost is normally based on the size of the stored data [74]. Transaction throughput is defined as the number of validated transactions per second. According to Zaabar et al., the throughput is separated into two sub-categories: the read throughput and the transaction throughput [9]. The read throughput is defined as the total number of reading operations performed across the blockchain network within the given timeslot, while the transaction throughput is the number of successful transactions performed in the blockchain network within the given timeslot.

2) *Parameter based on performance of access control in blockchain technology*: The evaluation of the performance access control in blockchain were proposed by allowing

authorised entities to effectively retrieve the database and prevent unauthorised access from resources. To verify and authenticate the authorised transactions and un-authenticate unauthorised transactions, several existing solutions consisting of many operations must be accomplished. The authors in [44] highlighted that to execute these operations, the system may consume more energy. For the evaluation of the authentication process, researchers utilised parameters such as energy consumption [44], time taken for encryption and time taken for decryption [52]. To evaluate energy consumption, researchers chose parameters such as cost, time (ms) and energy (j). Regarding the time taken for encryption and decryption, [55] defined the encryption time as the amount of time consumed to convert plaintext into ciphertext, which generally depends on data size and the key size used for encryption. The decryption time was defined as the amount of time taken by the algorithm to convert ciphertext into original data. Storage and communication costs are also parameters in access control. The measuring unit of both parameters is bytes [44].

TABLE X. PARAMETERS AND VARIABLES

Parameter	Variables (unit)
<b>Access Control</b>	
Energy consumption [44]	Cost, time (ms), energy (j)
Time taken for encryption and decryption [55]	Time(ms), data size (bytes)
Storage cost [44]	Cost, size of data key (bytes)
Communication cost [44]	Cost, size of data key (bytes)
<b>Blockchain</b>	
Transaction throughput [77]	Response time (m) and TPM (size of transaction)
Transaction latency	Time (ms) and invoking a transaction (Tx)
Network latency [78],[15]	Time (ms),
Block validation [74]	Processing time (s), number of blocks
Computational cost[79]	Time (s), cost, ethers
Storage overhead [44],[80]	Size of key (bytes), time(s)

3) *Tools for evaluation*: This section provides an overview of the technologies and tools adapted by the articles reviewed in this study. Researchers implemented their proposed solutions by setting up the experimental environment to serve as the underlying functions as well as to efficiently evaluate the proposed solutions or mechanisms and frameworks. The details of the setups are divided into two categories, as follows:

a) *Hardware*: From the extensive review of the selected literature, the commonly used hardware for conducting experiments included desktop pc, laptop, mobile phone, raspberry pi, memory and hard disk. The researchers mainly used large storage and equipment that are compatible with their experiments. The desktop pc and laptops were commonly

employed as the simulation platform and blockchain server to run the experiments. Memory ranging from 8 to 16 GB RAM [44] are necessary [81][34]. Raspberry pi can be used as lightweight IoT actuators and sensors, further acting as IoT nodes. The interaction between IoT nodes were developed using C++ language and the JsonRPC library for communication [7].

*b) Software:* Most studies, as in [59] and [75], chose a private blockchain (such as Ethereum) to develop their blockchain network and conduct experiments. Based on [50], Ethereum is the commonly used platform for building decentralized apps (dApps). It provides a secure way to perform transactions using the elliptic curves cryptography protocol. Ganache is also used to test the decentralized application without an actual set-up of the Ethereum network. Ganache is defined as a blockchain emulator, also known as a personal Ethereum client or node [7]. Several studies have deployed a blockchain network built on Hyperledger fabric to execute experiments, such as in [9,54]. Node.js is also used as an Ethereum network [81]. Many studies further developed an experiment in the virtual environment to build a blockchain network that can be deployed in Ethereum Virtual Machine (EVM), such as in [64]. Some researchers applied a simulator or emulator environment to conduct their experiments. A simulator, such as OMNeT++ [28], can create an environment similar to the original which can configure real devices. An emulator, such as Common Open Research Emulator (CORE) [72], can be used to duplicate all hardware and software features in real devices.

In terms of the programming language, most studies used the python language to create a prototype interface since it is considered to be a dynamic and scalable language across multiple platforms [50]. Web3.py library is frequently employed to enable users to interact with Ethereum clients and request functions written in smart contracts. Solidity programming language is also applied to write smart contracts [7], [10], [27], [62]. These smart contracts were implemented for testing, debugging and then deployment, either in Ethereum Virtual Machine (EVM) [11], Truffle [7], Testnet [62] or Remix IDE [56], before implementing them in the blockchain platform. Ropsten [11,55], Rinkeby and Kovan are Ethereum tools for testing and development purposes. Researchers have noted that benchmarking is important to measure the performance of the blockchain application [9]. The most commonly used benchmarking for the Hyperledger network is Hyperledger Caliper. The use of several appropriate protocols play a crucial role in an experiment. Common communication protocols used are IPV6 and 6LoWPAN [53].

## VI. CONCLUSIONS AND FUTURE WORKS

IoT actuators and sensors are capable to further improve the efficiency of smart farming. However, the security of the IoT actuators and sensors depending on the access control that act as the first line of defence via authentication and authorization. This paper presented the background of decentralized access control in this study. Based on extensive literature review, most commonly applied techniques to

authenticate and authorise users or devices in IoT networks are summarized as key management schemes including the asymmetric cryptographic algorithm, the symmetric cryptographic algorithm, session key, secret key, PKI (including hashing algorithms), Symmetric Encryption, Digital Signature, Elliptic Curve Cryptography (ECC) and Elliptic Curve Digital Signature Algorithm (ECDSA) based on blockchain technology. This approach is vital for securing access control and communication between D2D, user to device and device to network.

Meanwhile, the access control models - RBAC and ABAC, are frequently used to assign a user to a role in the system according to their attribute, credentials or authority to access resources. This approach can be commonly utilised as a strategy for designing various smart contracts for fine grained access control. In the smart contract operation, all information associated with a particular role or attribute will be stored on blockchain. This makes it more transparent and available for other users to access resources with the owner's permission. By deploying the access control strategy in blockchain in the form of smart contracts, the computation overhead of IoT actuators and sensors will be reduced, therefore, the framework can apply lightweight IoT actuators and sensors existed ecosystem.

Based on reviewed articles in this SLR study; tokens were incorporated into the strategy for subjects to obtain access rights by applying the token which can improve access efficiency. Other techniques are also used to make the system more scalable. Researchers commonly use off chain and on chain with other storages called IPFS. The assessment of all proposed techniques was accomplished by establishing the necessary steps to setup the evaluation. The literatures also reported that most research have developed an experimental environment on the Ethereum platform. Some experiments were executed in the virtual environment due to the requirements and needs for large storage and high CPU or laptop processors. The CPU or laptops are used as the main components in an experiment to simulate the blockchain server, or act as a gateway to collect data from IoT actuators and sensors. The core of the development system is smart contracts, which are developed using Solidity programming language. Regarding experiments, datasets were collected using IoT actuators and sensors according to pre-defined parameters for specific experiment designs. Evaluation was then performed to examine the proposed system based on established parameters. The parameters were also used as a baseline comparison with other relevant works and for validating the proposed system.

Among the gaps identified in the current access control data in the IoT ecosystem are: lack of mechanism and standardised protocol of access control and communication protocol, decentralized access control, authentication, privacy and security. From the finding that the mechanism in authorisation and authentication is not fully adapted in a decentralized manner. It remains in the same phase and requires a trusted entity in the validation process. Based on this study, most of the proposed solutions which influence decentralized access control in the IoT ecosystem include a lightweight distributed key management solution, a robust

design in smart contracts, efficient consensus approach and decentralized access control.

This study concludes that the decentralized access control is a relevant topic for researchers to explore and investigate. The combination of access control approaches that adopt blockchain technology can be a possible mechanism for enhancing decentralized access control in the IoT ecosystem. In addition, the access policy based on ABAC and RBAC model can be used to achieve flexibility and dynamic access control using smart contracts. Smart contracts can be used as an automation decision and authorization to eliminate centralized server into decentralized server. The use of multiple layers also plays a crucial role in reducing the scalability of IoT systems, speeding up the process of requesting transactions and reducing time delays. Thus, it is suitable for application in large scale IoT systems that manage big data processing.

Smart farming also relies on the IoT technology and smart systems to collect real-time data and provide observations in management operations on the farm, including pre- and post-harvest. For optimum access control decentralization in smart farming, Ethereum platform that include public and private blockchains can be utilised.

For future studies, in regard to the application of decentralized access control in smart farming, researchers should explore and investigate the enhancement of smart contracts design for access control since smart contracts play a vital role in blockchain. They were designed with the aim to perform event-based automation activities without human interference based on pre-defined contracts. Nevertheless, smart contracts can be the loophole for blockchain technology, which is another gap that must be addressed to further enhance decentralized access control in IoT, especially for the application in smart farming. Thus, the design and mechanism for applying the smart contracts concept in blockchain technology must be further examined to achieve an optimum design. This can be validated through simulations until the establishment of contracts is complete. This is crucial to further secure and strengthen a resource from unwanted threats, including smart contract-related scams and illegal activities.

#### ACKNOWLEDGMENT

The authors would like to acknowledge National Defence University of Malaysia (UPNM) and Ministry of Higher Education Malaysia (MOHE) for the approved fund which makes this research viable and effective. This research is supported by Fundamental Research Grant FRGS/1/2021/ICT07/UPNM/02/1.

# Research on Intelligent Control System of Air Conditioning based on Internet of Things Intelligent Control System of Air Conditioning

Binfang Zhang

Department of Art and Design  
Shijiazhuang University of Applied Technology  
Shijiazhuang, 050000, China

**Abstract**—The current air conditioning intelligent control system cannot achieve the ideal energy-saving effect. The indoor temperature and humidity control is not good enough either. Therefore, an intelligent air-conditioning control system based on Internet of Things technology is designed. The hardware part of the system includes system control motherboard, sensor module, execution control structure, wireless communication module and access layer. The software includes the design of communication layer, the design of monitoring management, and the design of intelligent indoor air-conditioning temperature remote control algorithm. The experimental results show that the control effect of the intelligent air conditioner is more accurate and energy-saving, the opening degree of the air conditioning valve is larger, and the comfort is improved. The indoor temperature and humidity of the proposed system are both more ideal.

**Keywords**—Internet of things technology; intelligent control of air conditioning; system design; double closed-loop load; virtual synchronizer of air conditioning

## I. INTRODUCTION

In recent years, science and technology have developed rapidly, and smart home control has become the most important part of the development of the decoration field. The research and development of smart home can greatly reduce the energy consumption of electrical equipment, reduce the cost of manual operation and management, and provide customers with more comfort and humane environment [1-2]. In the intelligent building, the central air-conditioning system consumes a lot of electricity, and it is the most important part in building the automation control system. In modern buildings, warm air conditioning is the basic supporting equipment, which can adjust the overall temperature and humidity of the building. Heating air conditioning system accounts for more than half of the total electricity consumption of the whole building, so it is necessary to find a suitable technology to reduce its energy consumption. Relevant scholars have found that intelligent control is the core of the entire intelligent system. In order to achieve low power consumption and low cost, and to ensure the safe and stable operation of the air conditioning system, reliable algorithms and selection of hardware and software are required to ensure the function of the system. [3-4].

However, at present, most of the air-conditioning intelligent control systems of engineering projects are idle and

resources are wasted. This is due to the design mistakes of relevant managers and the inability of air-conditioning intelligent systems to meet the needs of sustainable development and cost control. Researchers in this field have conducted relevant research on the above issues. For example, reference Yan Junwei et al. proposes an energy consumption prediction method based on machine learning divided operation modes. Firstly, the k-means algorithm is used to divide the system operation mode, and the main factors affecting the operation mode are selected by the random forest method. Then, the prediction model is established by BP neural network to predict the mode and energy consumption in turn [5]. Fu Huansen et al. designs a working algorithm of the air conditioning control system in different seasonal modes, analyzes the key points of PID control in Siemens s7-1200plc programming, and takes the combined air conditioning of an actual engineering project of a pharmaceutical group as an example to design the function of the touch screen configuration interface. The system ensures the priority control of humidity in the drug warehouse during the program design [6]. Li Xiaotong et al aiming at the characteristics of nonlinearity, large delay of central air conditioning system and the difficulty of establishing accurate model, proposes a temperature control method of central air conditioning system based on model free reinforcement learning. Aiming at the communication problem between Energy PI us and MATLAB, MLE + tool is used to realize the joint simulation of them. Comparing reinforcement learning algorithm with benchmark start stop strategy and model predictive control strategy, the method can minimize the energy consumption of air conditioning system on the premise of ensuring comfort [7].

According to the above-mentioned current domestic and foreign researches, the existing air-conditioning control effects cannot take into account low power consumption and intelligent effects, and most of the air-conditioning valves have a low opening degree, which makes it difficult to bring users a more comfortable and humanized experience. In order to solve the above problems, the research designs dual closed-loop loads and perfect communication layer, monitoring management and remote-control functions of intelligent air conditioners on the basis of the Internet of Things with intelligent improvement strategies.

## II. DESIGN OF AIR CONDITIONING INTELLIGENT CONTROL SYSTEM BASED ON INTERNET OF THINGS TECHNOLOGY

From the composition point of view, the air-conditioning remote control system is mainly composed of wireless controller, mobile phone software, remote management and data analysis system. With the help of the sensor, the communication module of wireless controller can get the air conditioning running status information in time. Through the wireless network, the user can set the temperature in advance. Far away, users can use mobile phones or computer software to operate the system. According to the basic operation condition, the management system can send the corresponding control command. After receiving the command, the controller can control the air-conditioning system in real time by sending infrared coded signal.

### A. Application Principle of Internet of Things in Air Conditioning Control

The rapid development of Internet of Things has provided an important basis for the application of smart house. In the application of the Internet of Things, we should take full advantage of wireless technology, such as radio frequency, Bluetooth, infrared sensing, ZigBee and WIFI. ZigBee technology's energy consumption is low, and the cost is less than other technologies. It can be widely promoted in the future development. Wireless sensor networks are mainly deployed in the monitoring area, which is a self-organizing multi-hop form. There are a large number of sensor nodes, using the characteristics of sensor cheap [8-9]. After the application program and physical setup are completed, the user is authorized by the Web or application program, and then the command to be executed can be sent out in a graphical way. After the central controller receives the command, it requires the simulative starter to perform the corresponding operation. When the user doesn't give the operation instruction, the central controller can use the network technology and wireless sensor to receive the change of the outside environment, and then judge the safety factor effectively. When there is a danger, the central controller will find the corresponding security warning, and the central control will activate the scheduled function to notify or alarm the user [10]. When the external environment is relatively safe, the central controller will activate the corresponding control information when it exceeds the set range.

### B. System Hardware Design

#### 1) System Control Motherboard

The main control board of the system adopts the Arduino Mega2560 SCM development board with USB interface, with 54 digital input/output (16 of which can be used as PWM output), 16 analog input, 4 UART interfaces, 1 16MHz crystal oscillator, 1 USB port, 1 power socket, 1 ICSP header and 1 reset button. The motherboard is easy to use, can meet the requirements of air-conditioning control system, and has a more stable performance.

#### 2) Sensor Module

The system sensor module includes temperature and humidity sensor, HC-SR501 human body sensor and photoresistor. Two temperature sensors are respectively installed in the air outlet and the side of the air conditioner. The difference of temperature data is used to judge the on-off state and the refrigeration and heating state. HC-SR501 human body sensor is an automatic control module based on infrared technology. It adopts imported LHI778 probe from Germany, with high sensitivity and strong reliability. HC-SR 50 can be used to judge whether the user is near the air conditioner or not.

#### 3) Enforcement Control Structure

In the remote-control system, the infrared ray sends the instruction information. After receiving the infrared code, the remote management carries on the next instruction operation according to the information characteristic. Because there are many air-conditioning manufacturers, there are some differences in infrared protocol. During the test, the infrared information of different remote controllers should be collected and analyzed. Analyzing the infrared signals of different brands of air-conditioning and storing them according to the requirements, so as to improve the expansibility of the system and make it can be used in different air-conditioning models.

#### 4) Wireless Communication Module

As shown in Fig. 1, the system adopts ESP8266 serial port WIFI chip, which is a complete and self-contained WIFI network solution specially developed for wireless connection requirements. Temperature and humidity sensor can timely obtain indoor temperature and humidity information, through collecting and uploading information, so as to monitor indoor temperature and humidity in real time and achieve reasonable control of temperature and humidity.

Fig. 1. System Framework

### 5) Access Layer

Wireless sensor network constitutes a perceptual control layer. It collects data information, uploads these data on the basis of network technology, and transfers them to the service management. Intelligent gateway plays the role of access layer, which can integrate multiple protocols, transfer the corresponding data by ZigBee protocol, and achieve the goal of Internet communication. The intelligent network also has the storage function. Through uploading the newest data, it helps the user to use the intelligent gateway to realize the information inquiry the function.

#### a) Control Architecture Design

As shown in Fig. 2, the basic control architecture of the intelligent control system for air conditioning. As a direct power supply device of air-conditioning virtual synchronizer,

storage battery can provide AC electronic supply with voltage between 220-380V. AC suction nozzle is a standard AC device, which can provide AC current with frequency between 360-800HZ for air-conditioning virtual synchronizer. The main control architecture consists of a virtual cabinet and a synchronous load cabinet. Virtual cabinets contain air conditioning temperature display, temperature control chassis, virtual operators, TUR equipment and a part of the blank reserved area. Under the condition of long-term load operation, there will be a large number of control instructions in the system, which are stored in the blank reserved area until the transmission channel is idle. Synchronous load chassis includes 429 bus module, load frequency conversion module, air conditioning power analog output module, load voltage acquisition module. Each module has different physical execution function.

Fig. 2. System Hardware Control Architecture.

#### b) Design of Governor for Virtual Synchronous Machine of Air Conditioner

The traditional DC/AC inverter topology is used to adjust the output power of storage battery by collecting the modal information of load electronic power supply. From the functional point of view, the virtual synchrotron governor is the key subordinate structure of the control architecture, which can integrate the fixed virtual load electronics in the original motor, and provide a certain excitation effect for these electronics with the support of the generator. When the

air-conditioned power analog output module sends out enough asynchronous sensing signals, the virtual power grid of the synchrotron changes from a closed state to an open state, absorbs all the load electronics, and temporarily stores them in the virtual control chip. In order to ensure the reasonable distribution of load electrons, two power-consuming components with the same resistance as the load voltage acquisition module must be installed around the generator, and the internal operating current of the governor must always be rated control current. The complete structure of the virtual synchronizer governor is shown in Fig. 3.

c) Load Double Closed Loop Design

The load double closed-loop design includes two parts: synchronous controller and virtual load unit. According to the regulation rules and control requirements of air-conditioning equipment, the synchronous controller can control the power load signal unilaterally, and the virtual load unit can obtain more AC load signals by transmitting the power consumption signal to the central processor of air-conditioning. In the case of higher requirements for system control instructions, the load double closed-loop system can choose parallel or series operation mode according to the power output of the system to ensure that the air-conditioning virtual synchronizer governor always has sufficient AC electrons [11-12]. In parallel mode, the load double closed-loop, air-conditioning virtual synchronous governor can be selectively connected to the control circuit at the same time, effectively avoiding the arbitrary notice of the battery system. In series mode, the load double closed-loop, air-conditioning virtual synchronizer governor can also be connected to the control circuit at the same time, but in this case, the automatic load electrons can easily reach the maximum value. Fig. 4 shows the detailed load double closed loop structure.

Fig. 3. Structure Diagram of Air Conditioner Virtual Synchronous Machine Governor.

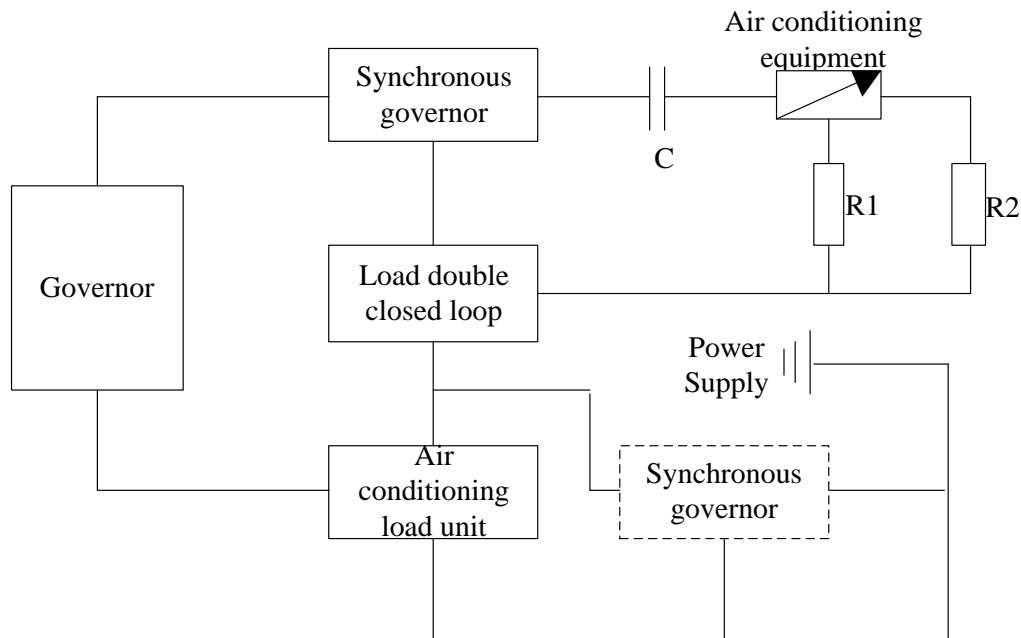

Fig. 4. Load Double Closed Loop Structure.

C. System Software Design

1) Communication Layer Design

The Modbus communication protocol in the communication layer adopts RTU transmission mode to realize data reading. RTU transmission mode message frame format: function code is 8, CRC check code is 16 bits, data area is  $n * 8$  bits, and slave bit address is 8. See Table I for common command codes and functions in the system of Modbus communication protocol.

TABLE I. COMMON COMMAND CODES AND FUNCTIONS IN THE SYSTEM OF MODBUS COMMUNICATION PROTOCOL

Command code	Effect
01	Read controller value
02	Forced input of single switching value
03	Read switch status
04	Force input controller value
05	For exception response
06	Communication diagnosis
07	On off state

### 2) Design of Monitoring Management

Through monitoring the management computer remote monitoring software with ModBus communication protocol and PLC communication, Real-time on-line monitoring of the operation of HVAC system is realized. The steps for remote online monitoring are shown in Fig. 5.

In order to convert the remote intelligent control mode of the system, the control signal is transmitted to the PCL control layer through the command code of ModBus communication protocol in remote online monitoring software. If the

automatic control mode is selected, the PCL selects the data in the controller, operates on the collected signal of HVAC according to the fuzzy self- adaptive PID controller. It judges the operation result, and automatically controls the stop or start of HVAC equipment. If you choose the manual control mode, in order to control the HVAC equipment, the input of single equipment switch is realized by ModBus communication protocol, the switch of relay in PLC is changed, and the manual remote control of HVAC equipment is stopped or started.

Fig. 5. Steps of Remote Online Monitoring.

### 3) Implementation of Remote-Control Algorithm for Intelligent Indoor Air Conditioning Temperature

The control structure of influencing factors of remote intelligent indoor air conditioning temperature control is shown in Fig. 6. The data actually measured by different sensors are sent to the PID controller after being adjusted, and the selection signal generated based on the parameters optimized by the PID controller, such as  $k_p$ ,  $k_i$  and  $k_d$ . They are used to keep the indoor air conditioner running and keep the room temperature, supply air temperature and supply air volume within the error control range [13-14].

The energy-saving principle of HVAC uses frequency

conversion technology to realize frequency conversion control of temperature, but frequency conversion control is unable to build accurate mathematical model. So, the fuzzy adaptive PID controller is added into the PLC control layer. In order to improve the control quality and make the PID controller have the intelligent performance of fuzzy control, the fuzzy adaptive PID controller is generated by combining the conventional PID control and fuzzy control. Fuzzy adaptive PID control principle, see Fig. 7.

The parameters of each variable, fuzzy control rule, fuzzy subset and the membership function of input and output variables are designed by fuzzy adaptive PID controller. Initial setup of fuzzy adaptive PID controller, see Fig. 8.

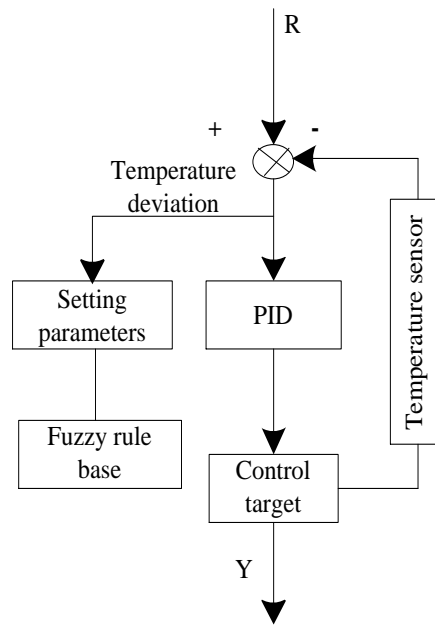

Fig. 6. Principle of Fuzzy Adaptive PID Control.

Fig. 7. Control Structure of Room Temperature, Air Supply Temperature and Air Supply Volume.

Fig. 8. Initial Setting of Fuzzy Adaptive PID Controller.

If  $K_d$  and  $K_p$  change in the predetermined range of  $[K_{d,\min}, K_{d,\max}]$  and  $[K_{p,\min}, K_{p,\max}]$ , normalized  $K_d$  and  $K_p$  convert them to the parameters between 0 and 1. The newly converted parameters are described by  $K_d'$  and  $K_p'$  respectively, and their conversion process is described by formulas (1) and (2) respectively:

$$K_d' = \frac{K_d - K_{d,\min}}{K_{d,\max} - K_{d,\min}} \quad (1)$$

$$K_p' = \frac{K_p - K_{p,\min}}{K_{p,\max} - K_{p,\min}} \quad (2)$$

Formula (3) represents the relationship between integral and differential time constants:

$$T_i = \beta T_d \quad (3)$$

Where  $T_d$  represents the differential time constant,  $\beta$  represents the parameter, and  $T_i$  represents the integral time constant.

The integral gain solution is described by formula (4):

$$K_i = \frac{K_p}{\beta T_d} = \frac{K_p^2}{\beta K_d} \quad (4)$$

The membership function of temperature deviation and temperature deviation change rate is a fuzzy subset language

variable, which is described by  $\{NL, NM, NS, ZO, PS, PM, PL\}$ , and each value width is consistent and distributed in a triangle.

In order to judge the reasoning rules of parameters  $K_d'$ ,  $K_p'$  and  $\beta$ , the decision is made according to the temperature deviation, the knowledge base summarized by experts (fuzzy rule base) and the change rate of temperature deviation. The rules are as follows:

if  $e(k)$  is  $A_i$ ,  $\Delta e(k)$  is  $B_i$ , then  $K_p'$  is  $C_i$ ,  $K_d'$  is  $D_i$ ,  $\beta = \beta_i$  ( $i = 1, 2, \dots, m$ ).

Among them,  $A_i$ ,  $B_i$ ,  $C_i$ ,  $D_i$  represent the language variable of  $e(k)$ ,  $\Delta e(k)$ ,  $K_p'$ ,  $K_d'$ ,  $\beta$ , a fuzzy relation has a rule, 7 fuzzy subsets have 49 fuzzy control rules [15]. Fuzzy control table is made up of 49 Fuzzy rules stored by computer. Fuzzy control table is made up of the relation between each input and output parameter according to expert's knowledge and experience, and then the Fuzzy control rules are made.

### III. EXPERIMENTAL DESIGN AND RESULT ANALYSIS

In order to verify the effectiveness of the intelligent control system based on Internet of Things, a simulation experiment is designed. The experimental comparison method is the composite air-conditioning control system and the central air-conditioning control system based on reinforcement learning proposed in reference [6] and [7] respectively. The PID parameters are set to  $k_{p0} = 0.18$ ,  $k_{i0} = 0.0012$  and

$k_{d0} = 0.5$ , and the input quantization factors of the PID controller are set to  $k_{up} = 0.005$ ,  $k_{ui} = 0.02$  and  $k_{ud} = 0.5$ . After setting the relevant values of each characteristic

parameter, the traditional PID algorithm and the PID control algorithm based on particle swarm optimization are analyzed, and the corresponding curve of the valve opening of each end of the PID controller is obtained as shown in Fig. 9.

Fig. 9. Valve Opening at Each End of Household Intelligent Air Conditioning Structure.

As shown in Fig. 9, the operation time of the air-conditioning structure is expressed in abscissa (unit: s); the change in the opening of the air-conditioning valve at each end of the air-conditioning structure is expressed in ordinate. The results show that the opening trend curve is stable and the dynamic regulation performance is more stable than that of the traditional control method, and the opening trend fluctuates greatly and the period is longer. When the air-conditioning structure works normally, the opening degree of the traditional air-conditioning valve is about 78%, and the opening degree of the air-conditioning valve obtained by this method can be controlled at 95%, so the friction loss formed by the air-conditioning valve in the actual work of the air-conditioning structure can be reduced to the greatest extent. It is proved that the intelligent air-conditioning structure of modern home remote control realized by this method is more accurate and energy-saving. The larger the opening degree of the air-conditioning valve is, the lower the operating noise of the corresponding air-conditioning structure is, and the comfort degree of the operating environment of the air-conditioning structure for users is improved.

Set the output variable is the indoor temperature, the input variable is the frequency of HVAC compressor. Transfer function model of setting room temperature and frequency of HVAC compressor, described by formula (5):

$$H(s) = \frac{G'}{Ts + 1} e^{-\phi s} \quad (5)$$

Where,  $s$  represents the complex variable,  $T$  represents the system time constant,  $G'$  represents the open-loop gain,

which is set to  $0.6^\circ\text{C} / \text{Hz}$ , and  $D$  represents the time constant of the delay link, which is set to 1000s.

In order to verify the effectiveness of the system in this paper, the system test is carried out with MATLAB. The comparison systems used in the experiment are the combined air conditioning control system proposed in reference [6] and the central air conditioning control system based on reinforcement learning proposed in reference [7]. The upper limit frequency of HVAC compressor is 240Hz, the indoor initial temperature is  $0^\circ\text{C}$ , the set temperature is  $24^\circ\text{C}$ , and the step input is applied to the three experimental systems. At the same time, the set temperature drops to  $20^\circ\text{C}$  at 5000ms and rises to  $24^\circ\text{C}$  at 9000s. After repeated tests, the indoor temperature response time curves of the three systems are recorded and described in Figure 10.

As can be seen from Fig. 10, the room temperature response speed and temperature control of this system are obviously higher than those of the other two systems. This system can quickly control the air conditioner and make the room temperature reach the set temperature. At 5000s, the room temperature drops to  $22^\circ\text{C}$ , and at 9000s, the room temperature rises to  $24^\circ\text{C}$  with a stable trend. Among them, the room temperature of document [7] system falls to  $22^\circ\text{C}$  only at 7000s, and the document [6] system is always in a fluctuating state, which does not meet the requirements of the set temperature, indicating that this system has a better temperature control effect.

In the cooling experiment, when the delay is 1000s, three kinds of system cooling-delay time curves are depicted in Fig. 11.

Fig. 10. Indoor Temperature Response Curve.

Fig. 11. Cooling Delay Time Curve.

It can be seen from Fig.11 that with the increase of the delay time, the cooling time curve of the system in this paper has little fluctuation and the cooling time is fast, while the cooling time curve of the other two systems has great fluctuation and the cooling time is slow, which shows that the cooling performance of the system in this paper is good.

In order to improve the energy-saving and emission reduction of HVAC, indoor relative humidity was set at 40% and CO<sub>2</sub> content was set at 70% in the experiment.

Fig. 12 shows that the effect of indoor relative humidity control of this system is superior to that of other two systems. The control effect of this system is less than 30%, the other two systems are not good, and the fluctuations of indoor

relative humidity are large.

Fig. 13 shows that the control effect of CO<sub>2</sub> volume fraction of this system is obviously better than that of the other two systems. The indoor CO<sub>2</sub> content of this system reaches 3000 ppm at 1000s, after which the control is relatively stable. Although the control time of the system [7] is short and unstable at 4000s, the control time of the system [6] is short and unstable. The system [6] has not met the requirements of the indoor CO<sub>2</sub> content. Therefore, the control of the indoor CO<sub>2</sub> content of this system meets the requirements of energy saving and emission reduction.

Under the condition of 0.77 air conditioning load parameter, the change of load spike frequency is recorded in

60s as the experimental time, respectively, after the application of the control system of the experimental group and the control group (the combined air conditioning control

system proposed in the reference document [6]). Experimental details are shown in Fig. 14.

Fig. 12. Indoor Relative Humidity Control Curve.

Fig. 13. Indoor Carbon Dioxide Content Control Curve.

Fig. 14. Frequency Comparison of Load Spikes.

Fig.14 shows that with the increase of experimental time, the frequency of load spike of experimental group presents a more stable trend, the frequency of load spike reaches 58% of the maximum value. The peak frequency of load in the control group also showed a more stable trend, but compared with the experimental group, this trend was significantly worse. The peak frequency of load in the control group reached 80%, much higher than the experimental group. There was no significant change in the peak frequency of load in the control group in the early and late experiment. In conclusion, under the condition of air conditioning load parameter of 0.77, the frequency of load spike can be greatly reduced by using the designed control system.

#### IV. CONCLUSION

In order to solve the current air conditioning, intelligent control system indoor temperature and humidity control effect is not enough ideal problem. Therefore, an intelligent air-conditioning control system based on Internet of Things technology is designed. The application principle of Internet of things in air conditioning control is analyzed. Based on this, the hardware and software of the system are designed. The hardware part of the system includes system control motherboard, sensor module, execution control structure, wireless communication module and access layer. The control architecture of the system and the governor of the virtual synchronizer are designed. In order to realize the energy-saving control of air conditioning, double closed-loop load is designed. The load double closed-loop design includes two parts: synchronous controller and virtual load unit. The software of the system includes the design of communication layer, the design of monitoring management, and the design of intelligent indoor air-conditioning temperature remote control algorithm. The experimental results show that when the air-conditioning structure is working normally, the opening of the traditional air-conditioning valve is about 78%, and the opening of the intelligent control system proposed by the study can be controlled at about 95%. In the research system,

the room temperature decreased from 5000s to 22° C, and the room temperature increased to 24° C in 9 000s. The trend was stable at this stage, but the room temperature of the system in [7] only dropped to 22°C at 7000s, and the system in [6] was always in a state of fluctuation. The control effect of this system is stable at 30%, while the indoor relative humidity of the other two systems fluctuates greatly. The indoor CO<sub>2</sub> content of the system reaches 3000ppm in 1000s, and then the control is in a stable state. The control of indoor CO<sub>2</sub> content can meet the policy requirements of energy conservation and emission reduction. Under the condition that the air-conditioning load parameter is 0.77, the load peak frequency can be greatly reduced by using the designed control system. In summary, the air-conditioning intelligent control system proposed in the study can effectively reduce energy consumption and carbon emissions, and provide users with a more intelligent and comfortable indoor environment. However, there are still shortcomings in the research. With the development of information technology, the application of low-power wide-area network technology in air-conditioning intelligent control systems can be further explored in the future.

**Abstract**—The past few years have observed substantial growth in death rates associated with brain tumors and it is second foremost source of cancer-related demises. However, it is possible to increase the chance of survival if tumors are identified during initial stage by employing various deep learning techniques. These techniques are helpful to the doctors during the diagnosis process. The MRI which refers to magnetic resonance imaging is a non-invasive procedure and low ionization radiation diagnostic tool to evaluate an abnormality that evolves in the form of shape, location or position, size and texture of tumour. This paper focuses on the systematic literature survey of numerous Deep-Learning methods with suitable approaches for tumour segmentation and classification (normal or abnormal) from MRI images. Furthermore, this paper also provides the new aspects of research and clinical solution for brain tumor patients. It incorporates Deep-Learning applications for accurate tumor detection and quantitative investigation of different tumor segmentation techniques.

**Keywords**—Medical image segmentation; convolutional neural networks (CNN); deep-CNN; feed forward neural networks; brain tumor segmentation (BraTS) and U-net

## I. INTRODUCTION

Brain tumors are neurological fatal disorders, a bunch of atypical cells that are found increasing in the human brain or by the surroundings of the brain that which affects the normal brain cells and further results in cancer [1]. They are classified into two variants malignant, which is cancer causing and benign which is non-cancerous. Benign tumours are less offensive, form gradually and are isolated from normal tissues regularly. Malignant tumors develop quickly, lack of defined boundaries, and are difficult to identify from normal tissues [1, 2]. These tumors cause more pain inside the brain and can migrate to the spinal cord. At the same time, malignant tumors are complex to eliminate entirely from the cells in the brain; moreover these tumours have tendency to transform to cancer which is deadly. The second prime reason for most cancer related deaths is the malignant kind of brain tumour [3].

As per statistics, there are approximately 12.7 million cancerous persons in the world each year, with 7.6 million people dying because of cancer [4]. The Hindu published an article in 2016 that reported that around 2,500 children of India suffered from malignant tumors every year and every year 20% of children were diagnosed with brain tumors if 4,000 to 5000

people were diagnosed [4, 5]. Conferring to the American Brain Tumor Association (ABTA), about 78,000 new brain tumour cases will be diagnosed by year end of 2018. According to a poll conducted by the “Times of India,” approximately three million individuals in India suffer from cancer, with one million being diagnosed with new kinds of cancer. As stated by the “WHO” (World Health Organization) one-third of brain tumours are cancerous [1-4]. As stated by the “UNI” (United News of India) brain tumours are the tenth most prevalent tumor in India. As per doctors’ point of view, 90% of brain tumor cases can cure and may save many lives when detecting the brain tumor at an early stage. Hence early detection of brain tumors can increase the chance of survival [2-4].

The manual analysis of MRI reports of human brain are utilized in finding the exact boundaries of the tumors by physicians which is an intricate and demanding task Not only because of little brightness and contrast of MRI reports but also similarities of intensities among brain organelles [6]. The physical evaluation tissues of brain membrane requires ample knowledge and time-overwhelming tasks to diagnose the patient. As per the “MOHFW” (Ministry of health and Family Welfare-Government of India), there is no specific reason for brain tumors, and the possible survival rate is less than 3%. All these issues motivated the author to investigate the different automated brain tumor segmentation techniques and suitable methods to reduce the mortality rate [4-6].

In this survey, the researchers have deliberated recent and popular state of the art Deep-Learning techniques not only to segregate the variants of tumours that affect brain but also to categorize the kinds of brain tumours including Machine Learning Techniques (MLT), Artificial Intelligence (AI), and Deep-learning techniques.

Among various modalities (CT, US, and PET), the MRI modality supports the identification of brain tumors by radiologists due to low ionization and noise. To soft brain tissues MRI is more appropriate and envisages the anatomy of the brain in three different planes such as axial, sagittal, axial, and coronal view [6, 7]. Fig. 1 shows the axial, sagittal, and coronal views of the brain captured using the MRI modality or imaging technique.

Fig. 1. Brain MRI Slices Captured from Different Directions (a) Sagittal, (b) Axial, and (c) Coronal.

MRI has various benefits over other imaging techniques, including i) high spatial resolution, ii) Functional brain measurement, iii) MRI test is acceptable for patients of any age, iv) No harmful effects on the body (no risks) due to no ionizing radiation effect, and iv) It can take images in any plan and capture finer details of soft tissues [8].

Today most of the research workout on machine learning algorithms intended to segregate the variants of tumors that affect brain automatically having capability, accuracy, reproducibility, scalability, and ease of a quantitative estimation of brain tumors [7, 9].

The methods are classified as Deep learning and Machine Learning methods. Traditional MLT use statistical learning approaches and better classify the features of low-level brain tumor. These learning methods concentrated on the estimation and localization of boundaries of the tumor [10]. The deep learning methods are requiring the smallest pre-processing steps and are more suitable for training large datasets as compared with traditional methods. Recently, in the medical field, convolutional neural networks (CNN) are more dominated than other techniques [11, 12].

As per the investigation, for automatic brain tumor detection, deep learning is a promising approach, and complex features are learned directly from input data. Deep learning approaches had been popular in the domain of computer vision due to their outstanding performance [13]. But it is required to train the samples without over-fitting and reduce the consuming time to the annotation of 3D ground truth MRI images [14].

In this survey, we have studied recent and popular Deep-Learning techniques to segment and categorize tumors from images of MRI including AI, ML methods, and DL methods.

This put forth, paper is structured accordingly: Section II is providing an overview of brain-tumor segmentation and classification; Section III and IV will provide the overview of various deep learning algorithms.

## II. TECHNIQUES FOR BRAIN-TUMOR SEGMENTATION

The process of partitioning the image (2D function) into disjoints objects and used to identify or locate the object boundaries. The ultimate goal of analysis is to detect the ROI (“region of interest”) such as location and its extension. In brain tumor segmentation techniques, the abnormal tissues are separated and identified from normal tissues [15].

Medical imaging technology plays a crucial role present in the medical field. So, the segmentation of the brain tumor region with the help of MRI scanning reports is difficult at the

primary level due to overlapping of tissues, boundary inefficiencies, dimensional differences i.e., size and shape, abnormalities, position, or location of the tumour. [16]

**Structural Segmentation:** These image segmentation techniques are depending upon the data of the structure of the desired part of the image that comes under structural segmentation techniques.

**Stochastic Segmentation:** This type of segmentation technique works on the discrete pixel value of the input image unlike structural segmentation techniques [17].

**Hybrid Segmentation Techniques:** The combination of both structural and stochastic segmentation techniques is referred to as hybrid segmentation techniques.

Depending on the human interaction, the techniques of segmentation are classified into i) manual, ii) semi-automatic and iii) automatic segmentation techniques.

### A. Manual Segmentation

In this, identifying the tumor part by the professional expert and they use a specialized tool for tumor assessment. The expert must have proper training, experience, and knowledge in the anatomy of the brain. The manual analysis of MRI reports of human brain for finding the exact boundaries of the tumors by physicians is a complicated, challenging task, and prone to error because of little or no ample brightness the reports obtained pose small amount of contrast MRI images and similarities of intensities among brain cell organelles [18]. The physical assessment of tissues in brain requires more prior knowledge and is time taking tasks to diagnose the patient. Fig. 2 depicted the edema (red-swelling), necrotic (yellow-dead), and active tumor (purple).

### B. Semi-Automatic Segmentation

This segmentation requires both human operators and computers. To initialize the segmentation process, human interaction must be required and results depend on the human operator. It consumes less time as compared with manual segmentation. Example of semi-automatic techniques is region-growing, tumor-cut method, and active contour models, etc. [18, 19].

Fig. 2. Anatomical Segmentation Manually by the Intersection.

### C. Automatic Segmentation

In this method, the human operator is not required. To solve the problem of the segmentation task, it combines both prior knowledge and artificial intelligence. There are two types of techniques as discriminating and generative methods [18,

19]. Supervised learning is one of the examples of the discriminating methods. In this, the relationship between the annotation and input image is learned through a large dataset. Unlike supervised learning, the unsupervised learning process uses the data without labels, and they are trained using the loss functions to obtain the patterns considering principal component analysis (PCA) and clustering methods [20]. Due to the complexity of (Because of high complexity (medical datasets), the machine learning techniques are not able to train the data. Recently, deep learning methods have earned a reputation due to their outstanding performance in particularly brain tumor segmentation and learning the parameters directly from data sets. The re-generative methods are utilizing the previous information involving the presence of different tumor forms [21].

### III. OVERVIEW OF DEEP LEARNING METHODS

The class of machine learning is deep learning; it can use multi-layers to learn multiple features directly from original data. In this section, the DL- concepts, techniques, and architectures for medical image analysis have been surveyed.

#### A. Neural Networks

Neural networks (NN) are the basis for deep learning methods and one type of learning algorithm. This NN has learned useful features from raw data and formed by connecting the neurons by directed links [22]. In the layers, the neurons are organized.

There are three layers (three different layers) such as i) input layer, ii) hidden layer, and iii) output layer. Typical FFNN by composing of three layers shown in Fig. 3.

In input layer each neuron is connected to another neuron in the upstream layer's output. Similarly, each neuron's output is coupled to all the neurons in the downstream layer's input. The weight is adjusted in each link during the learning process [22, 23]. The network's topology immediately forms an acyclic graph, and the network is known as a "FFNN" which refers to Feed Forward Neural Network" in which every neuron is linked or interconnected to the neurons in next layer. The deep neural network is made up of multiple layers, or hidden layers.

Fig. 3. Typical Structure of FFNN with Three Layers.

Recently, in a supervised manner, all the methods are trained to make easier the training procedure. There are more fashionable architectures utilized in the analysis of health care domain: convolution neural networks (CNNs) and recurrent neural networks (RNNs) [21, 24]. The CNNs are gaining

massive popularity to solve problems in medical field as compared to the RNNs. The overview of these methods is given in the following section.

#### B. Convolutional Neural Networks (CNNs)

The CNNs are used to work on convolutional operations and one type of neural network. There are two types of methods such as traditional and DL methods. The learning approaches in statistics are applied for the classification of low-level brain tumors, which is a regular task in conventional machine learning methods. The CNNs are the dominant area in the last years for segmentation of brain tumors and requires fewer pre-processing techniques and is suitable for training the large datasets than conventional techniques [25].

Fig. 4. Typical Structure of CNN.

Nowadays, to solve computer and medical image problems CNN is one among the dominant models, especially for segregation of diverse kinds of brain tumours. The CNN has many layers as shown in Fig. 4 that are transforming the input images into output (normal/abnormal) by using convolutional filters while learning the high-level features [26]. The CNN models have been learning the spatial features in the given data. The first convolutional layer can learn the low edges and second layer will learn high-level features. Next, the units of convolutional layers shrink the number of parameters to learn by distributing the weights. Thereby, increase the efficacy of the network [27]. Node graph for CNN is indicated in Fig.5 (a)

Fig. 5. Node Graph of 1D Representation of CNN Architecture used in Medical Imaging. (a) CNN, (b) Cascaded CNN, and (c) U-net.

The MLTs and CNNs majorly differ where the network shares the weights to perform the convolutional operation, no

need for separate detectors to learn, and weights do not depend on the original image size [28]. And also, due to the pooling layer in the CNNs the neighborhood pixel values are accumulated by using the “max or mean” functions [27, 28]. Regular neural networks (completely connected layers) are attached at the conclusion of CNN, but the weights are not shared. The distribution over classes is constructed by applying the SoftMax function and sending the activations into the final layer. Maximum likelihood [29] is used to train the network.

The layers of convolution are learning the local and complex features in the hierarchy from the original given data. To summarize the key features, the Pooling-Layer is included in the middle of consecutive convolutional layers to decrease the enormous parameters and then forwarded to downstream layers. The translation invariant was created to identify the learned patterns, irrespective of geometric transformations [30].

#### IV. DCNN: DEEP CONVOLUTION NEURAL NETWORK

There are different architectures proposed by researchers such as single pathway, dual pathway, cascaded, and U-net. All these architectures are briefed below:

##### A. Single Pathway

The architecture of a single pathway is looking like a feed-forward deep neural network (FFDNN) and it is a basic network for remaining architectures. In this single path, information is passed down from one of the input layers to the other layer of classification. The 3-D ‘single path CNN’ was proposed by Urban et al. [31]. This architecture consists of the completely connected convolutional layer as a classification layer and can classify multiple 3-D pixels into one. In [32] every image from the sensory system is supplied to the different 2-D CNN and features from the results of CNN are utilized to train a random forest classifier. The neighbourhood information is obtained from XX, YZ, and XZ planes near each center pixel. In convolutional layers, small kernels have been used by Pereira et al. [33], which can learn more features by obtaining the very deep and deep medic networks. The proposed architectures got a 1st and 2nd place in ‘BraTs-2013’ and ‘BraTs-2015’ challenges respectively.

##### B. Dual Pathway

Pixel-wise classification will be performed in many segmentation approaches, here extract the input patches from input MRI image, and then without considering the neighborhood information central pixels labels were predicted. Infiltrating the process can be risky and makes ambiguous boundaries. So, to achieve better results only local information is not sufficient. To avoid this problem, the authors [34] mix the neighborhood information by employing CNN with dual-path data streams. These dual paths were mixed to impact each pixel label prediction. Among two paths. The visual elements of the region near each center pixel are represented by one of the pathways. The second stream will relate to global information, and it will include the location of the discovered patch in the brain [35].

##### C. Cascaded Architecture

This architecture will make the multi-scale label prediction independently from others as compared with the dual-path way. The output of the CNN was chained with the other. There are several architectures, among them, input cascade is one of the most important architectures and used to chain the secondary CNN with contextual information. The typical multi-stream CNN is shown in Fig. 5 (b). The local pathway concatenation is a cascaded architecture in which the first CNN’s output is sequenced and added with second CNN’s first hidden layer output regardless of its input [36].

Another important cascaded architecture is the hierarchical segmentation [37], in which brain tumor segmentation of brain tumor region was accomplished by decreasing the “multi-class segmentation challenge” into a “multi-stage binary segmentation” problem. It uses the hierarchical architecture of tumor sub-regions to reduce false positives while simultaneously resolving the inherent imbalance problem. The entire tumor was segmented from the reports of MRI which has been given as inputs at the initial stage of the design, and then a boundary box was used in the second step. Next, separate the remaining sub-regions using either multi-class intra-tumor segmentation or successive binary segmentation. [38].

##### D. U-net

The U-net architecture [39] is constructed exclusively for biomedical image segmentation and looks like an encoder and decoder network. A U-shaped design consisting of an encoder at the contracting path and decoder at the expanding side which entirely builds up the U-net. In the contracting pathway, the ReLU layer and the max-pooling layer come after the two convolutional layers. The spatial data decreases as the path contracts, while the feature information increases. From contracting to skip connecting, the expanding path comprises a sequence of up-sampling processes paired with high-resolution features. The typical U-net showed in Fig. 5 (c).

#### V. CNN MODELS FOR BRATS

The current methods for segmenting and classifying kinds of tumours that affect human brain from MRI data is discussed in this section. The manual assessment tissue organelles of brain require an ample prior knowledge, are time taking tasks, and prone to error during the diagnosis process. Therefore, these issues motivated to development of automated tumor detection techniques by several researchers, and it becomes a significant area for research in medical image processing. This review article mostly concentrates on the segmentation and classification processes based on traditional AI, MLT, and DLM in the last five years.

The literature has highlighted several automated approaches in the domain of health care image analysis to diagnose the health issues such as tumours, lung cancer [19], skin cancer [20, 21], and more [22, 23]. Many strategies for pre-recognition and categorization of brain tumors are offered as a result of all of them.

Kumar Agrawal, Ullas, and Pankaj Kumar Mishra [40] studied various state-of-the-art algorithms for detecting and classifying tumors accurately. They revealed that deep learning

may be used in conjunction with several transfer learning approaches to construct a systematic and efficient approach for the early identification of tumours in brain in this proposed study.

Rehman, Amjad, and colleagues [41] suggested a novel DL-based technique for classifying microscopic brain tumours. The authors designed the 3D architecture of CNN, draw out the brain tumour and then send it to the pre-trained CNN model for parameter extraction. Next, to choose best features a correlation-based selection approach is employed. The chosen parameters are validated by employing the FFNN for the last classification. The authors utilized BraTS 2015, 2017, and 2018 for validation and achieved more than 92.67% of accuracy.

Sharif, Muhammad Imran, et al. [42] presented a new automated DL- method to classify the multi-class brain tumors. In the proposed method, the densenet201 pre-trained DL model was trained by deep transfer of imbalanced data learning. The average pool layer is used to retrieve the training model features. Two methods are used to pick the features. i) entropy-kurtosis-based high feature values (EKbHFV) and ii) metaheuristic-based modified genetic algorithm (MGA). The non-redundant serial-based approach is used to fuse the EKbHFV and MGA-based features. Finally, a multiclass SVM cubic classifier is used. They concluded that the presented method has achieved an accuracy of about 95.5%.

Khan, Amjad Rehman, et al. [43] presented new DL techniques to classify the tumours from MRI brain images. The author's method consists of pre-processing, segmentation using the K-means technique, and classification using the fine-tuned nineteen-layered visual geometric group (VGG19) model. To enhance the scale of the available data, the synthetic data augmentation idea is presented. The Put forth method outperformed earlier when compared with accuracy, the put forth model outperformed the previous state-of-the-art approach.

Khairandish, Mohammad Omid, and colleagues [44] created a hybrid model that uses CNN and SVM for classification and threshold-based segmentation for detection. To categorize benign and malignant tumors, the authors used a publicly available dataset. The suggested hybrid CNN-SVM technique achieves an overall accuracy of 98.4959 percent.

TAS, Muhammed Oguz, and Semih ERGİN [45] in this survey, the authors studied the segmentation of tumors from abnormal brain MRI images with DL and K-means approach. The proposed method was extracting the tumor area automatically with an accuracy and sensitivity of 84.45% and 95.04% respectively.

The authors [46] have been proposed the Google Net approach depending upon the CNN DL approach to classify the different types of tumors from MRI brain images and to overcome the difficulties in the classification of attributes such as variants in texture, size, and shape. The authors use MRI datasets to perform five-fold cross-validation and authenticated the put forth system's performance in terms of "area under the curve" (AUC), F-score, recall, precision, and specificity. The proposed system with transfer learning provides the

classification accuracy of 97.8% and 98% with the multiclass SVM method.

In [47], the stationary wavelet transform (SWT) approach and modern growing convolution neural network (GCNN) (alarmed CNN) was developed by the authors in this study to improve the efficiency of an automated brain tumor segmentation system. SVM and CNN have done better than the suggested work in all aspects.

For automatic segmentation, the authors [48] offered enhanced convolutional neural networks (ECNN) with loss function optimization via the BAT algorithm. They presented the optimization-based MRIs image segmentation. To overcome the overfitting problem, assigned the lesser weights to the network. The efficacy of the proposed system was authenticated by utilizing the different popular brain tumor datasets. The overall results indicate that the presented method shows better performance.

The segmentation in a DL approach [49] is done with CNN. The Convolution Neural Network has deep architecture; this approach employs three tiny kernels. For the pre-processing of pictures, intensity normalization and data augmentation were used. The method is evaluated using the famous dataset (BraTS 2013 and BraTS 2015).

The authors [50] presented a solution for the low accuracy of brain tumor segmentation using DL techniques. They studied MRI images in different angles and applied different networks for segmentation. Evaluated the effect of separate networks and compare them with a single network. The dice score 0.73 and 0.79 is achieved with single and multiple networks, respectively.

The DCNN-F-SVM was presented by Wu Wentao, et al. [51] for segregation of various types of brain tumour. The proposed segmentation model has three stages: first, DCNN is trained, then predicted labels are produced from the trained DCNN, and finally, the DCNN and an integrated SVM is a deep classifier which is connected in series. They used the BraTS and self-made datasets to run each model for brain tumors segmentation. The authors conclude the presented methodology has performed for brain tumor detection better than DCNN and SVM classifier.

Sun, Li, et al. [52] presented segmentation of brain tumor and glioma survival anticipation utilizing the based framework. For tumor segmentation, the researchers used multimodal MRI scans and three 3D CNN designs. For survival prediction, 4,524 radiomic characteristics are retrieved from segmented regions, and potent features are opted making use of both decision tree and cross-validation techniques. They trained a random forest model to predict the patient's survival rate. The authors were preferred BraTS 2018 and achieved 61.0% of classification accuracy for short, mid, and long survivors among 60+ participated teams.

Bhandari, Abhishta, Jarrad Koppen, and Marc Agzarian [53] investigated the potential use of CNNs by studying radiomics and analyzed quantifiable features tumours including texture, shape and ability to forecast clinical consequences such as survival and diagnosis. The authors also investigated the role of CNNs intended for brain tumors segmentation

through the education viewpoint and performed the literature review.

Sharif, Muhammad Irfan, et al. [54] presented a non-passive learning feature selection strategy for detecting and distinguishing brain cancers. The contrast enhancement is first fed into SbDL for the development of the saliency map, and then it is transformed to binary using thresholding algorithms. Deep feature extraction was done using the inception V3 pre-trained CNN model was utilized for extraction of deep features for the purpose of classification. Next, for better texture analysis, the features are sequenced and aligned with dominated rotated (DRLBP) and particle swarm optimization (PSO) is used to optimize the concatenated vector. The SbDL segmentation and classification strategy are applied on BARTS 2017 and BRATS 2018 to validate. The presented method outperforms for classifying and segregation of brain tumours) with accuracy of 93.7% and 92% respectively.

Khan, Muhammad A., et al. [55] developed an automated system based on marker-based watershed segmentation for extraction and classification of brain tumors using MRI images. The first contrast of the tumor was enhanced by using the gamma contrast stretching technique and then the segmentation process was performed using the marker-based watershed algorithm to detect the tumor exactly. Next, by using the chi-square max conditional priority feature method, the features are selected and then fused by the serial-based concatenation method before classification. The SVM was applied to classify the tumors using the datasets such as Harvard, BRATS-2013, privately collected. The overall results revealed that the presented system performs than existing systems with high accuracy.

## VI. DATASETS

On selected datasets of tumor MRI scans, all of the strategies described in this work were tried. The research groups interested in automatic tumor segmentation from abnormal brain images over the last five years. The researchers have used the different private and public datasets to evaluate the various algorithms. A number of datasets are accessible for training and testing purposes. The challenges of benchmark datasets provide the publicly available datasets such as DICOM [56], BRATS [57], BRATS 2013, 2013, 2015, 2016, 2017, 2018, and 2020), MICCAI [58], Brain Web [59], Harvard business school [60], Internet Brain Segmentation Repository (IBSR)[61],nyrosynth.org [62], ABIDE [63], National Bioscience Database Center (NBDC) [64], Med Pix, PGIMER dataset [65], SPL database [66] etc.

## VII. PERFORMANCE EVALUATION METRICS

The effectiveness of segmentation or classification methods can be measured in a number of ways. To demonstrate their results, the authors employ various performance measure parameters. The analysis of traditional methods is commonly evaluated by mean square error (MSE), peak signal to noise ratio (PSNR), entropy, and correlation. Among various image quality assessment parameters for analysis of the result, some of the overlapped based parameters are briefed below:

**Accuracy:** The ability to determine the precision or proximity of the tumor is referred to as accuracy. The following factors influence it:

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \quad (1)$$

True positive is denoted by TP, whereas true negative is denoted by TN. False-positive and false-negative are represented by the letters FP and FN, respectively [56].

**Precision:** It denotes the consistency of two or more values. The precision formula is as follows:

$$precision = \frac{TP}{TP + FP} \quad (2)$$

Where TP represents the true positive and FP represents the false positive. The fraction of true positives is referred to as precision. The valid positive results are evaluated by dividing valid positive outcomes aided by the segmentation algorithm. Similarly, the pixels are break down into the cluster and pixels that are of that cluster

Sensitivity or recall or true positive rate: It's the ability to find a tumor or any other affected location [50]. The mathematical equation is written as follows:

$$sensitivity = \frac{TP}{TP + FN} \quad (3)$$

The TP denotes true positive and FN denotes false negative. Sensitivity is the proportion of correctly segmented images to all segmented images. The greatest results for accuracy, precision, and sensitivity suggest that the brain tumor can be recognized precisely and without ambiguity.

**Confusion Matrix:** It is used to give required information about the actual and predicted results by a particular method. The confusion matrix revealed in Table I that was seen below:

TABLE I. THE REPRESENTATION OF THE CONFUSION MATRIX

Type	Predicted class 1	Predicted class 2
Actual class 1	T <sub>P</sub>	F <sub>N</sub>
Actual class 2	F <sub>P</sub>	T <sub>N</sub>

**SDE-Segmentation Distance Error:** It is used to assess the effectiveness of segmentation procedures and the equation is denoted as

$$SDE = \frac{\|\varphi F - \varphi D\|^2}{\|\varphi D\|^2} \quad (4)$$

Where  $\varphi F$  is the terminal contour and  $\varphi D$  is the aspired contour derived from the brain tumor ground truth image. The SDE returns the normalized contour between the intended and terminal contours. The SDE range from 0 to 1, here 1 indicates the inadequate segmentation [32].

**Jaccard Similarity Index (JSI):** The JSI is defined as the ratio of common voxels in the input image (X) to the union function, or the collection of voxels in the input image (X) and segmented output image (Y) [8, 17]. The JSI mathematical equation is given by:

$$JSI = J(X, Y) = \frac{|X \cap Y|}{|X \cup Y|} \quad (5)$$

It is a scale that runs from 0% to 100% in terms of similarity between the input image and the segmented image. The greater the similarity, the higher the percentage.

**SSIM -Structural Similarity Index Measure:** The SSIM is a perceptual parameter, which means that image quality may suffer as a result of data compression, lack of data transport, or other image processing procedures. This expression is provided by:

$$SSIM(x, y) = \frac{(2\mu_x\mu_y + c_1)(2\sigma_{xy} + c_2)}{(\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_2)} \quad (6)$$

Where  $\mu_x$  and  $\mu_y$  are the mean,  $\sigma_x$  and  $\sigma_y$  are the variance, and  $\sigma_{xy}$  is the covariance of x and y. The values  $c_1$  and  $c_2$  are constants. A larger SSIM value guarantees improved brightness, contrast, and structural material quality [55]. In addition to these characteristics, computation time and iteration count are utilized to calculate the performance of the suggested approaches.

### VIII. HARDWARE AND SOFTWARE TOOLS

Nowadays various open-source softwares are used by researchers to speed-up the deep learning systems. This section has covered a brief description of hardware and software used in research papers.

For deep learning purposes, there is the availability of computing libraries such as GPU and CPU. The GPUs have been performed parallel computation with a high execution rate as compared with the CPUs. The GPUs hardware in deep learning is 10-30 times faster than CPUs. These libraries of GPUs also provide various operations implementation in NN i.e., convolutions and user friendly. Due to the popularity of DL, there is more availability of open-source software packages.

Caffe [67] is first established for computer vision applications by graduate students (Jia et al., 2014) at Berkeley and supports C++ and Python interfaces. This deep learning framework is not only used in computer vision applications, but it can also use in other fields such as robotics, neuroscience, and astronomy. For deep learning, from training to architecture development, provides the complete tool kit with good examples. It allows the user to implement the building models and models of deep learning with various algorithms.

TensorFlow [68], developed by Google (Abadi et al., 2016) for large-scale machine learning applications and supports the

C++ and interfaces of Python. It is end-to-end distributed deep learning and supports the data flow graphs execution in mobile devices or heterogeneous devices. It is designed for fast experimentation with a deep learning model using a complete toolbox and simply the parallelism of the model.

Theano [69] was built in the Montreal lab called MILA (Bastien et al., 2012) and offers Python interfaces. It is used to execute and compile the mathematical expressions by syntax NumPy quickly using both GPUs and CPUs, especially for large-scale dataflow. The other high-level software packages constructed upon the Theano consider Pylearn2, Keras, and Lasagne.

Pytorch [70] is an important approach to construct the computational graph dynamically rather than static computational graph before running the model and open-source framework of deep learning. It is flexible, powerful, and easy of debugging (Collobert et al., 2011). The Pytorch is suitable for the production and execution of models on edge devices. It is used in Facebook AI research.

Pylearn2 [71] allows the user to construct or implement the machine learning models in an arbitrarily and free (open source) machine learning library. This library is flexible and easy to use. But unfortunately, due to the lack of active developers, it is fallen as compared with other frameworks.

Keras [72] is one of the rapidly developing application programming interfaces (API) for various applications of deep learning and supports multiple data-flow graphs like Theano. To run the experiments with models Keras consist of simple APIs which has provision to run in mobile devices and also in browsers. This platform was adopted for research areas and industrial applications due to its simplicity of usage (user-centric approach).

Lasagne [73] In Theano, the Lasagne is a trivial library for building and training NNs. To run the Lasagne, you will need Python 2.7 or 3.7, and instructions are running in MAC or Linux systems. It has the capability of powerful mathematical computations and constructed upon the Theano.

### IX. SUMMARY AND DISCUSSION

Deep Learning (DL) based approaches for segregation brain tumour have recently sparked a lot of interest. In brain tumour segmentation, deep learning systems are trained on big datasets to segment the tumour from MRI images by learning a hierarchy of complicated properties straight from data. As a result, CNN-based models are the most used in medical image analysis, with success in fields including natural language processing, audio identification, and brain tumour segmentation. For instance, in Fig. 6, CNN was used to segment brain tumors using a single node into CNN. Input, convolution with nonlinearity correction using ReLU, overfitting correction using pooling, feature map flattening into a column, and finally insertion into the neural network.

Fig. 6. Input the Image into a Single Node within a CNN.

In this work, recently published papers have been reviewed. It is clear that DL methods play a crucial role to address the

problems faced in automated brain tumor segmentation. Pre-trained CNNs are employed as feature extractors in recent studies, and these networks are installed and employed directly on the medical images for a specific purpose. In the previous two years, end-to-end trained CNNs have been favored for medical image analysis interpretation. Nowadays, deep learning approaches are integrated with traditional machine learning handcrafted methods. In recent works uses the U-net and ensemble methods to resolve the problem of segmentation of a brain tumor [74-78].

TABLE II. THE COMPARISON OF VARIOUS DEEP LEARNING TECHNIQUES BASED ON DATASETS AND ACCURACY

Author, Year	Method	Dataset	Accuracy (%)
K. Agrawal, 2021[40]	Transfer Learning method	BraTs 2018	97.17
Rehman, 2021[41]	3D-CNN Architecture	BraTs 2018	95.53
Sharif, 2021 [42]	Entropy–Kurtosis-based High Feature Values (EKbHFV) and modified genetic algorithm (MGA)	BraTs 2019	95.0
Khan, 2021 [43]	Deep learning approach- finetuned VGG19	BraTS 2015	94.06
Khairandish, 2021 [44]	hybrid CNN-SVM	BraTs 2019	98.49
TAS, 2020 [45]	Traditional Deep Learning Technique		84.45
Wu, 2020 [51]	DCNN-F-SVM	BraTs 2018	96.0
Sharif, 2020 [54]	Pixel Increase along with Limit (PlaL)	BraTs 2018	93.7
S. Deepak, 2019 [46]	deep CNN features via transfer learning	BraTS 2017	98
Mamta Mittal, 2019 [47]	Growing Deep Convolutional Network (GCNN)	BraTs 2018	97.7
Thaha, 2019 [48]	Enhanced Convolutional Neural Networks (ECNN)	BraTs 2015	92.0
Sun Li, 2019 [52]	3D CNN architectures (Cascaded Anisotropic CNN, German Cancer Research Center NET - DFKZ Net, 3D-U-Net)	BraTs 2018	91.0
Sobhaninia, 2018 [50]	LinkNet network	BraTs 2015	89.12

The ensemble approaches improve the robustness of every approach by combining the results of segmentation and providing better performance as compared to several models. The single U-net-based models support the argument. The overview of recent approaches used for brain tumor segmentation along with its accuracy is shown in Table II. For deep learning algorithms, we need an enormous quantity of training data to simplify properly invisible data and poses many challenges in the domain of medicine. It requires an experienced neuro-radiologist before applying to the supervised training.

So, it's an expansive, large memory resources, and time-consuming task. But recently the BraTS challenges provides training and testing to users and due to proper training, the over-fitting problem will be reduced. At the same time, the researchers have implemented data augmentation to avoid the problem of unavailability of large-scale datasets. The computational and memory requirements increased further due to 3D deep learning models.

As per the literature, the authors have used costly mathematical functions, well software libraries, multi-GPU environments and train the data in a distributed manner. To enhance the correctness durability of segmentation algorithms, authors must carefully initialize the hyper-parameters, employ proper pre-processed approaches and use Latest training methods

## X. CONCLUSION

We discussed methods for segmenting brain tumors, different architectures of deep learning methods for automatic

brain tumor segmentation, a literature review of recently published papers, tools for implementing the algorithms, dataset availability, and appropriate performance metrics to estimate the performance of each method in this paper. As compared with traditional techniques, the deep learning methods are still superior due their robustness and performance. The novel architectures of Deep-Learning have a great potential to avoid the inherent class imbalance problems in tumor segmentation by using proper pre-processing, initialization of weights, and sophisticated training methods. In many segmentation techniques, due to the lack of a large-scale training dataset, its performance will be degraded.

This paper contains an overview of contemporary strategies for segmenting and classifying brain tumors using MRI data. The goal of the presented survey is to demonstrate briefly about the most commonly used strategies for segmenting and classifying tumours. Various tumor segmentation techniques (manual, semi-automatic and automatic), deep learning methods (NN, CNNs, and DCNN), and different architectures are used in DCCN.

This paper consists of a review of the recently published research articles from science direct, IEEE explore, etc. The literature covered the ML techniques, DL methods, and hybrid methods for abnormality segmentation from MRI brain images. This paper also contains publicly available datasets or benchmarking challenges such as BraTS 2012-202, MICCAI, Harvard University, and Brain Web. As per the literature of various published papers, the authors have been primarily used datasets are BraTs-2013 followed by BraTs-2015.

**Abstract**—Classification of fish species in aquatic pictures is a growing field of research for researchers and image processing experts. Classification of fish species in aquatic images is critical for fish analytical purposes, such as ecological auditing balance, observing fish populations, and saving threatened animals. However, ocean water scattering and absorption of light result in dim and low contrast pictures, making fish classification laborious and challenging. This paper presents an efficient scheme of fish classification, which helps the biologist understand varieties of fish and their surroundings. This proposed system used an improved deep learning-based auto encoder decoder method for fish classification. Optimal feature selection is a major issue with deep learning models generally. To solve this problem efficiently, an enhanced grey wolf optimization technique (EGWO) has been introduced in this study. The accuracy of the classification system for aquatic fish species depends on the essential texture features. Accordingly, in this study, the proposed EGWO has selected the most optimal texture features from the features extracted by the auto encoder. Finally, to prove the efficacy of the proposed method, it is compared to existing deep learning models such as AlexNet, Res Net, VGG Net, and CNN. The proposed method is analysed by varying iterations, batches, and fully connected layers. The analysis of performance criteria such as accuracy, sensitivity, specificity, precision, and F1 score reveals that AED-EGWO gives superior performance.

**Keywords**—Fish species classification; deep learning; GW optimization; auto encoder decoder; feature selection

## I. INTRODUCTION

Object classification is an important area of research for underwater environments. To perform this, a high-resolution camera is used to scatter light and its absorption nature underwater [1]. Numerous researchers are interested in analyzing the health status of aquatic organisms, specifically the population and distribution of fish species [2]. Warming of the oceans will weaken aquatic life by increasing the pressure on fish species [3]. Accordingly, a cost-effective approach must be designed for underwater fish species analysis. In the past, fish species were classified by a laborious process involving the capture of fish or visual surveys conducted by deep-sea divers. Low contrast in the aquatic environment leads in very blurry pictures [4]. Due to the low quality of the images captured underwater, several minute features are lost. This will

certainly impact the performance of the underwater image analysis system.

With the advent of powerful graphical processing units (GPU) and massive amounts of data, deep learning algorithms have become popular in classification and pattern reorganization [5][6]. This study's primary objective is to develop the deep learning model in order to create a completely automated system for classifying fish species. However, the presence of noise in underwater images limits the deep learning models training capacity. Additionally, it makes deep learning models more computationally demanding. This study employs the popular deep learning architecture auto encoder-decoder to obtain texture features from underwater images. Feature selection and hyper parameter (learning rate selection, weight updating process, and others) tuning is the most challenging aspect of building deep learning models.

GWO is an evolutionary optimization technique based on grey wolves' hunting mechanism and leadership hierarchy. Comparing Genetic Algorithms (GA) and particle swarm optimization (PSP), numerous studies have demonstrated that the performance of the GWO optimization method is superior. Unfortunately, traditional GWO requires more iterations to determine the optimal value when the data size and image noise rise. So in this research, the existing GWO algorithm has been enhanced to discover the optimal features using the newly introduced EGWO algorithm with fewer iterations.

Finally, three types of experiments have been conducted to prove the efficiency of the proposed fish species classification system. First, the fish species classification efficiency has been evaluated with the most essential parameters, such as accuracy, recall, specificity, precision, and F1-Score. Secondly, the training and validation efficiency of the proposed AED-based deep learning model has been evaluated. Finally, the computational efficiency of the proposed method has been evaluated. Through these three types of experimental analysis, a comparative study is conducted between the proposed method and existing deep learning algorithms such as AlexNet, ResNet, VGGNet, and CNN. On the basis of these three types of experimental observations, it has been proven that the proposed methodology has excellent training efficiency, high accuracy, and low computing overhead. This study's significant contributions are summarized below.

- 1) First, the R, G, and B channels of the underwater images are normalized to enhance the object visibility.
- 2) Second, the fish morphology localization method has been implemented to eliminate objects that do not have an impact on classification.
- 3) Next, an auto encoder-decoder deep learning model is used to extract underwater images' texture and color features.
- 4) Finally, the EGWO approach is introduced to improve feature selection efficiency.

Highlights of the proposed methodology are as follows: In the second section of this study, the previously developed computer-based classification system for fish species is examined in greater detail. The proposed auto encoder-decoder and enhanced grey wolf optimization are discussed in detail in the third section. In the fourth section, the experimental analysis of the proposed fish species classification system has been comparatively analyzed with existing deep learning algorithms. Finally, the proposed method is concluded.

## II. LITERATURE REVIEW

Classification of underwater images is a challenging task. Manual classification methods demand considerable time and effort. In underwater classification, image size, color, texture, inter-class similarity, and intra-class dissimilarity pose the greatest obstacle. Recently, researchers have developed several machine learning and deep learning methods for classifying underwater fish species [7]. This section reviews the existing fish species classification methods.

The classification is mainly carried out on dead sections depending on shape and texture [8, 9]. The fish's length, width, and thickness are identified using laser light [10]. Classification of fish species is very difficult due to variation in luminosity, background, turbidity of water. Moreover, the similarity of shape and color of various fish species is very difficult to classify.

The fishes are categorized depending on the shape and texture patterns in unconstrained nature [11]. Classification of fish species depends on the biomass content [12]. Classification and identification of fish species depend on morphology, texture and geometry [13]. Fish species identification is done using live fish in the open sea [14].

Recognition of fish species can be done from low resolution images [15]. Combining sparse representation and PCA for classification will provide an accuracy of 82.8%. Gaussian mixture combined with support vector machine will provide a recognition rate of 78%. Few conventional methods are done at a constrained manner. Classification of fish species using shape and color of dead fish sections in organized background.

Grouping of fish species is done based on texture and physical features in unrestrained environments [16] [17]. These techniques will provide good results in fish species with the big difference in texture. The biometric approach [18] takes fish species from various distances and different illuminations. Weber's local descriptor provides classification by the Adaboost classifier.

Classification techniques depending on a mixture of various feature extracting approaches and clustering algorithms with input classifiers are less time-consuming and cheaper [19]. Regions with Convolutional Neural Networks (RCNN) provides good accuracy of 82% in fish species classification [20]. PCA method combined with binary hashing function along with SVM classifier is used for fish species recognition and provides an accuracy of 98% [21].

AlexNet model is pre-trained to perform fish species classification [22]. The CNN-based model and transfer learning use Res Net-152, and SVM classifier provides an accuracy of 95% [23]. Classification of fish species by combination of YOLO deep neural network with Gaussian mixture provides good accuracies in two data sets. VGGNet along with convolutional layers, provides fish species classification [24].

A convolutional neural network is built to rapidly classify the behaviorist of fishes. Few pressure settings are completed in the research center, the fishes' behavior positions are acknowledged, and the model database is recognized [25]. To order the fishes, convolutional neural systems are used. The Faster Regional Convolutional Neural Network strategy is used to eliminate the high spot of images [26]. A Deep CNN Fondest is used for fish recognition, and localization and grouping are done using visual data got from cameras [27].

A Mask R-CNN, together with GOTURN is used for real-time applications of fish recognition and classification [28]. A fish grouping using transfer learning and Matlab is used as the primary step of undertaking the issue. FishNet is an adjustment form of AlexNet to categorize different varieties of fishes [29]. An automatic fish classification based on sonar videos classify fishes based on shape and Movement [30].

The limitations of these surveyed publications are summarized below.

- Due to the poor contrast of underwater photographs, a number of existing methods are semi-automated.
- In many existing systems, the classification algorithm is trained on dead underwater images. Clearly, these techniques cannot be utilized to classify fish species in real-time.
- The accuracy of the fish species classification system depends on the color and texture features of the underwater images. However, no specific optimization approaches have been developed in existing methods for selecting the appropriate color and texture features from underwater images.

## III. PROPOSED METHODOLOGY

This section discusses the process flow and methodologies of the proposed fish species classification system. The entire process flow of the proposed methodology is illustrated in Fig. 1.

Fig. 1. Overall Process Flow of the Proposed System.

#### A. Dataset

In this study, the dataset is downloaded from GitHub ([https://github.com/primepake/Fishes\\_classification](https://github.com/primepake/Fishes_classification)) and internet sources. There are 1000 images of aquatic fish in this data set. Five type's fish species are included in the data set: aulonocara fire, discus, flame fish, king fish, and molly. Each fish species in the dataset is partitioned into a 4:1 ratio for training and validation purposes. Table I demonstrates the partitioning information for the dataset. Accordingly, 800 images are obtained for the training phase, and 200 are obtained for the testing phase. To boost training efficiency, fish images are artificially augmented using the following image processing techniques: image rotation (90, 180, and 360 degrees), horizontal and vertical flipping, and zooming.

#### B. Image Normalization

Table I demonstrates very clearly that underwater images contain a great deal of noise, particularly undesired dark regions and water backgrounds around the images. These undesirable dark regions impose an additional computational overhead on the classification algorithms. Hence it necessitates the implementation of pre-processing techniques. Generally, all images captured by underwater cameras are RGB images. These images have different color combinations. The majority of images captured from the bottom of the water are quite dark, and the visibility of the objects within them is extremely poor. At the same time, images captured from the surface of the water are extremely bright. When training the model with such images, the accuracy will undoubtedly suffer. Due to the un-normalized nature of underwater images, the red, blue, and green channels should be normalized. Therefore, in this research, the three colour channels of the underwater images are normalized to reduce classification loss. The following equation is used to carry out the underwater image normalization procedure.

$$r(\alpha, \beta) = \frac{R(\alpha, \beta)}{R(\alpha, \beta) + G(\alpha, \beta) + B(\alpha, \beta)} \quad (1)$$

$$g(\alpha, \beta) = \frac{G(\alpha, \beta)}{R(\alpha, \beta) + G(\alpha, \beta) + B(\alpha, \beta)} \quad (2)$$

$$b(\alpha, \beta) = \frac{B(\alpha, \beta)}{R(\alpha, \beta) + G(\alpha, \beta) + B(\alpha, \beta)} \quad (3)$$

Where  $\alpha$  and  $\beta$  indicates the dark and bright regions in the underwater images. ( $r, g$  and  $b$ ) specifies the red, green and blue colour channels of the underwater images. The range  $r(\alpha, \beta), g(\alpha, \beta), b(\alpha, \beta)$  is from 0 to 255, the value of  $r(\alpha, \beta), g(\alpha, \beta), b(\alpha, \beta)$  can vary from 0 to 1. Fig. 12(a) shows the underwater images before the image normalization. Fig. 12(b) shows the underwater images after image normalization.

#### C. Fish Morphology Localization

Fish morphology localization is a crucial element in fish classification. This will eliminate pixels that have no impact on fish classification. This study uses the Simple Linear Iterative Clustering (SLIC) approach to localize fish morphology from aquatic images. SLIC is the most used super pixels segmentation method, and its key benefits include it separates fish regions from aquatic images with little computational cost. SLIC method integrates image plan space and color dimensions to build consistent and realistic super pixels. In order to perform local clustering, the SLIC method performs clustering the pixel dimensions, which is the CIELAB color space ( $l^*a^*b^*$ ). Euclidean distances in  $l^*a^*b^*$  are measured by the following formulas, which calculate the pixel variation in the images.

$$D_{LAB} = \sqrt{((L_i - L_j)^2 + (A_i - A_j)^2 + (B_i - B_j)^2)}, \quad (4)$$

$$D_{xy} = \sqrt{((x_i - x_j)^2 + ((x_i - y_j)^2)}, \quad (5)$$

$$D = D_{LAB} + \frac{m}{s} D_{xy} \quad (6)$$

L=Lightness.

A=Red/Green Values.

B=Blue/Yellow Values.

The SLIC approach begins with cluster sample centers that are uniformly separated. The centers are then moved to initialization places based on the gradient position with the lowest value. Gradient values are calculated by the following formula (7).

$$g(x, y) = ||L(x + 1, y) - L(x - 1, y)||^2 + ||L(x, y + 1) - L(x, y - 1)||^2 \quad (7)$$

$L(x, y)$  is the pixel coordinates. According to the SLIC methodology, pixels in the neighbourhood of a large section will have the same labeling. The method then establishes relationships by relabeling disconnected portions with the labels of the closest neighboring cluster. Fig. 11(c) shows the proposed fish morphology localization procedure.

TABLE I. FISH DATASET DETAILS

Fish image	Total number of images	Training	Testing	Class Label
	200	140	60	King fish
	200	140	60	Discus
	200	140	60	Flame fish
	200	140	60	Molly
	200	140	60	Aulonocara fire

#### D. Auto Encoder Decoder

An auto encoder decoder is a deep learning method that uses unsupervised learning to conduct encoding and decoding [31][32]. Similar to an artificial neural network, it consists of input, hidden, and output layers [33]. Each layer has neurons, with the input and output layers having the same amount, but the hidden layer has fewer neurons than the input layer.

Fig. 2 depicts the architecture of auto encoder decoders. The pre-processed images from the fish dataset are supplied to the auto encoder for feature extraction. There are encoder and decoder sections here. Each encoder comprises a convolution with a filter bank, max pooling, and subsampling to generate the feature map. The encoder is composed of two convolution layers and an intermediate layer. Here, the convolution process of feature maps is not performed. Following batch normalisation, the convergence of local minima is enhanced. Additionally, the decoder comprises two layers of convolution. The convolutional auto encoder consists of output data Y that

generates from input data x that is comparable to the original input data. When the time reaches infinity, the optimal value of the cost function will be reached. F () and F\*(()) are the encode and decode functions. In this study, the nonlinear activation function Rectified Linear Unit (ReLU) is employed, which is represented by the following equation (8). If the function receives negative input, it returns 0, but for positive input, it returns the input value.

$$f(x) = \max(0, x) \quad (8)$$

By optimising the weight and bias term, it is possible to minimise the error. Using the back propagation method, the weight is modified.

$$F(X) = \sigma(wX + B) \quad (9)$$

$$X = \sigma(w(F(X)) + B) \quad (10)$$

The first layer of encoder has an input X. The next layer has input data  $X^L$ , weight  $W^L$  and bias term  $B^L$ . So the above equations are changed as

$$F(X^{L+1}) = \sigma(W^L X^L + B^L) \quad (11)$$

$$X^{L+n+1} = \sigma(W^{n-L}(F(X^{n+L})) + B^{n-L}) \quad (12)$$

This auto encoder is trained for 200 epochs. The weights are optimized in order to find the local minima. Hidden layer takes output of the preceding layer. Throughout the training phase  $\sigma$  value was 4. The mean squared error decreased till 14 for 100 epochs and the performance during the training phase is 0.00058. The error rate is reduced smoothly without over fitting. The trained parameters will be provided to the next layer. Each and every auto encoder is subjected to max polling layer and the result is subsampled by a factor of 2.

$$y_{i,j} = \text{maximum}(x_{i,j}) \quad (13)$$

Where  $x_{i,j}$  and  $y_{i,j}$  denotes the  $i$  region of  $j$  feature-map which is the feature map of input and  $i$  neuron of  $j$  feature-map which is the feature map of output respectively. The number feature-map remain the same both at input and output. In each and every decoder up sampling is done for its feature-map by applying the indices of maximum pooling from the corresponding feature-map of encoder. As a result sparse feature-map is produced. Convolution of decoder filter bank and feature map is done to regenerate the input.

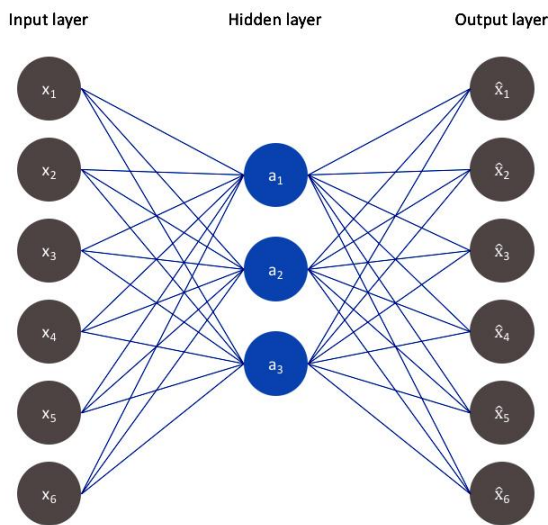

Fig. 2. Auto Encoder Decoder.

### E. Traditional GWO Method

This algorithm is based on the searching and hunting behaviour of grey wolves. According to GWO, the fitness value has three parameters one is alpha ( $\alpha$ ), the other is beta ( $\beta$ ), the third is the delta ( $\delta$ ). The hierarchical structure of grey wolves is illustrated in Fig. 3. The remaining solutions are called as omegas ( $\omega$ ). Three grey wolves will guide omegas in searching step. At time  $t=1$ , first iteration begins, at the time when a prey is found out. The omegas will encircle the prey with the help of alpha, beta and delta wolves. Three coefficients ( $a^{\rightarrow}, c^{\rightarrow}, d^{\rightarrow}$ ) will help in encircling process. They are.

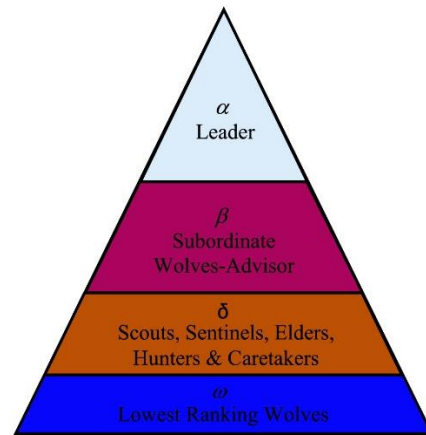

Fig. 3. Hierarchy of Grey Wolves.

$$d_{\alpha}^{\rightarrow} = |c_1^{\rightarrow} \cdot x_{\alpha}^{\rightarrow} - x_{(t)}^{\rightarrow}| \quad (14)$$

$$d_{\beta}^{\rightarrow} = |c_2^{\rightarrow} \cdot x_{\beta}^{\rightarrow} - x_{(t)}^{\rightarrow}| \quad (15)$$

$$d_{\delta}^{\rightarrow} = |c_3^{\rightarrow} \cdot x_{\delta}^{\rightarrow} - x_{(t)}^{\rightarrow}| \quad (16)$$

Where  $t$  is the current iteration.  $x_1^{\rightarrow}, x_2^{\rightarrow}, x_3^{\rightarrow}$  denote the position vector of alpha, beta and delta respectively.

$$x_1^{\rightarrow} = x_{\alpha}^{\rightarrow} - a_1^{\rightarrow} \cdot d_{\alpha}^{\rightarrow} \quad (17)$$

$$x_2^{\rightarrow} = x_{\beta}^{\rightarrow} - a_2^{\rightarrow} \cdot d_{\beta}^{\rightarrow} \quad (18)$$

$$x_3^{\rightarrow} = x_{\delta}^{\rightarrow} - a_3^{\rightarrow} \cdot d_{\delta}^{\rightarrow} \quad (19)$$

$$x_{(t)}^{\rightarrow} = \frac{x_1^{\rightarrow} + x_2^{\rightarrow} + x_3^{\rightarrow}}{3} \quad (20)$$

The parameters  $a^{\rightarrow}, c^{\rightarrow}$  are given by

$$a^{\rightarrow} = 2\alpha r_1^{\rightarrow} - \alpha \quad (21)$$

$$c^{\rightarrow} = 2r_2^{\rightarrow} \quad (22)$$

Where  $r_1^{\rightarrow}$  and  $r_2^{\rightarrow}$  are random numbers. The controlling parameter is  $\alpha$  which alters the value of  $a^{\rightarrow}$ . If the value of  $a^{\rightarrow}$  is greater than 1 the grey wolves will move farther away from the prey, which denotes that the omega will run away, representing global optimization. If the value of  $a^{\rightarrow}$  is lesser than 1, the omega will move towards the prey showing local optimization. The controlling parameter will decline from 2 to zero in a linear manner. This is given by

$$\alpha = 2\left(1 - \frac{it}{n}\right) \quad (23)$$

Where  $n$  is the maximum value of iteration number which is a cumulative iteration number.

Every grey wolf runs away or moves towards the prey with a suitable mean weight for an alpha, beta, and delta. On the start of the searching method, the weight of the alpha must be larger than the others i.e. beta and delta. The hierarchy in weight must be such that the weight of alpha is higher than that of beta and delta. Similarly, the weight of beta is greater than that of delta. The alpha wolf is given greater importance than others. The alpha wolf is considered to be nearer to the prey. The alpha wolf governs the searching. Beta and delta have a less important role. If beta or delta finds the best position, it is

transferred to the alpha wolf. In the searching process, the hypothesized prey is encircled, but in hunting, the real prey is encircled. The alpha is the nearest one to the prey than the beta. But the delta is farther away to beta. The omega wolf will alter and give their best positions to these dominants. Initially, the value of alpha is 1 and the value of beta and delta is zero. Finally, the dominants will encircle the prey, since they have the same weight. The weight of alpha has to be reduced, and the weight of beta and delta has to arise due to the cumulative iteration number. The position is updated as

$$x_{(t+1)}^{\rightarrow} = w_1 \bar{x}_1 + w_2 \bar{x}_2 + w_3 \bar{x}_3^{\rightarrow}$$

Where  $w_1 + w_2 + w_3 = 1$  such that  $w_1 \geq w_2 \geq w_3$  (24)

Algorithm 1 explain the process flow of traditional GWO. In the GWO algorithm, the initial population is generated by randomly. In this study, the population refers to the number of texture features. When initialising at random, there is a significant likelihood of irrelevant or redundant features. This raises the number of iterations of the GWO method, which increases the algorithm's running time and computational overhead. Therefore, the traditional GWO method must be enhanced in order to choose the desirable features from the fish data set with fewer iterations and in less time.

#### F. Feature Selection using Enhanced GWO Method

Feature selection is a very important part of artificial intelligence based prediction models [33][34]. Fig. 4 shows the

overall process flow of the proposed AED-EGWO. The proposed research AED extracts different types of colour and texture features from underwater images. When extracting features from underwater images using AED, redundant and irrelevant features are likely to be extracted. The formulas 25-33 determine the important texture features of this proposed method. The accuracy of classification algorithms is relies on effective feature selection techniques. The precision of deep learning models can be significantly enhanced by picking the most beneficial feature.

In addition, the computational burden of deep learning models is drastically lowered. The EGWO approach is used to eliminate irrelevant and redundant texture features from this classification system for fish species.

$$\text{Autocorrelation} = \sum_i \sum_j p(i, j) p(i, j) \quad (25)$$

$$\text{Contrast} = \sum_{n=0}^{N_e-1} n^2 \sum_{n=i}^{N_e} \sum_{n=j}^{N_e} \{p(i, j)\} \quad (26)$$

$$\text{Correlation} = \frac{\sum_i \sum_j p(i, j) p(i, j) - \mu_x \mu_y}{\sigma_x \sigma_y} \quad (27)$$

$$\text{Energy} = \sum_i \sum_j p(i, j) \quad (28)$$

$$\text{Dissimilarity} = \sum_i \sum_j |i - j| * p(i, j) \quad (29)$$

$$\text{Entropy} = \sum_i \sum_j p(i, j) \log(p(i, j)) \quad (30)$$

$$\text{Homogeneity} = \sum_i \sum_j \frac{1}{1+(i-j)^2} p(i, j) \quad (31)$$

$$\text{Variance} = \sum_i \sum_j (i - \mu)^2 p(i, j) \quad (32)$$

$$\text{Cluster shade} = \sum_i \sum_j (i + j - \mu_x - \mu_y)^2 p(i, j) \quad (33)$$

Here, an improved version of the GWO algorithm is proposed. Particularly in the population initialization phase, provide an intelligent initialization approach to achieve the optimal solution in early iterations. This intelligent initialization strategy accelerates the convergence of the algorithm. The key difference is that the population is now initialized using a correlation-based technique rather than at random method. The initial population is formed based on the correlation value, which decides whether a feature value is selected or not. The following equation represents the computation of the correlation for a feature f:

$$\text{Cor}_F = \frac{\sum(F_i - \bar{F})(C_i - \bar{C})}{\sqrt{\sum(F_i - \bar{F})^2 \sum(C_i - \bar{C})^2}} \quad (34)$$

Above equation, F indicates the texture features of underwater images. C represents the class values.  $\bar{F}$  and  $\bar{C}$  represents the mean values of features and classes, respectively.

EGWO Methodology for feature selection

AED Features extraction

Fig. 4. Overall Process Flow of the Proposed AED-EGWO.

A feature with higher correlation values is crucial for the classification. Therefore, employing the following formula, the suggested method assures that features with high correlation values are included in the initial population. Then, based on the correlation values, the new population is initialized as follows.

$$P(i) = \begin{cases} 1, & \text{if } rand < IG(i) \\ 0, & \text{if } rand \geq IG(i) \end{cases} \quad (35)$$

*rand* is a random number between 0 and 1, and  $P(i)$  is the binary representation of the *i*th feature in the initial population. According to formula (35), the features values with high correlation values are initialized for the initial population. This allows the traditional GWO method to get optimal features in a minimal number of iterations. Algorithm 2 explain the proposed EGWO based texture feature selection.

Input: AED extracts texture features from fish training data set

$(T_1, T_2, T_3 \dots T_n, T_c)$   $T_n$  is the number of texture features and  $T_c$  is the target class.

Output:  $O_{tf}$  (Optimal texture features)

Step 1: **Begin**

Step 2 : **for**  $i=1$  to  $n$  **do**

C=calculate the coefficient( $T_n, T_c$ ) using formula

**End**

Set the threshold level  $\tau=0.6$

Step 3: **if**  $\tau < 0.6$  // means there is no significant correlation between  $T_n$  and  $T_c$

Step 4: **for**  $I=1$  to  $m$  **do**

r=Calculate the significant between (C, $\tau$ )

**if** significant is high

**Then**

Add the features to  $\Rightarrow O_{tf}$

**End**

**End**

**Return**  $O_{tf}$

**End**

---

#### IV. RESULTS AND DISCUSSION

##### A. System setup and Configuration

The software tools used to develop this fish species categorization system are Matlab 2018 and deep learning libraries. Additionally, Windows 10 is used as an operating system. To run deep learning libraries and design the implementation model for this fish species classification system, a graphics processing unit with 4GB NVIDIA 1650, an Intel 10th Gen Core i5 processor, 256GB SSD, and 16GB RAM is utilized.

##### B. Classification Model Performances Evaluation

Existing deep learning approaches such as AlexNet, ResNet, VGGNet, and CNN are compared to the proposed methodology. The proposed method is evaluated with different configurations of the deep learning model, including fully connected layers, iterations, and batches, with and without optimization. The test image and the ground truth image must be compared. Five common performance measures that are typically used for classification are used to the analysis the performance of the proposed classification system: accuracy, sensitivity, specificity, precision, and F1 score. The mentioned accuracy measures are depending on the following variables.

**True positive fish species classification:** If the proposed method correctly recognises and classifies fish species from underwater images, this classification is known as a true positive fish species classification. The variable TP specifies the classification of true positive fish species.

**True negative fish species classification:** If the proposed method correctly identifies and classifies non-fish species from underwater images, this classification is known as true negative

fish species classification. The variable TN specifies classification of true negative fish species.

**False positive fish species classification:** If the proposed method mistakenly identifies and classifies non-fish species as fish species from underwater images, this is referred to as a false positive fish species classification. The variable FP specifies the classification of false fish species.

**False negative fish species classification:** False negative fish species classification happens when the proposed approach fails to recognise and classify non-fish species from underwater images. The variable FN specifies classification of false negative fish species.

The confusion matrices of the proposed and existing deep learning models are depicted in Fig. 5. According to Table I, 300 images are utilized to test the AED-EGWO approach. Accuracy, recall, specificity, precision, and F1-Score values are calculated based on the Confusion matrix, which are shown in Fig. 6 to 10.

In this study, the definition of accuracy is the correct classification of fish species from underwater images. To ensure the reliability of proposed model, it is essential to determine the proportion of true positives and true negatives among all of the instances that have been analyzed. Mathematically, accuracy is expressed as:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (36)$$

According to the classification of fish species, sensitivity involves accurately identifying fish species. Sensitivity can be determined by examining the proportion of true positives. Sensitivity has the following mathematical expression:

$$Sensitivity (Recall) = \frac{TP}{TP+FN} \quad (37)$$

According to the classification of fish species, specificity determines the reliability of non-fish classification results. To measure it, calculate the proportion of genuine negatives. Specificity has the following mathematical expression:

$$Specificity = \frac{TN}{TN+FP} \quad (38)$$

Precision is the ratio of the number of accurate fish classifications to the total number of positive fish predictions. Precision is calculated by the following formula.

$$Precision = \frac{TP}{TP+FP} \quad (39)$$

In an AI-based classification system, the F1-score is calculated using the overall precision and recall values. Formula for calculating the F1-score is as follows.

$$F1 - score = \frac{2(Recall \times Precision)}{Recall + Precision} \quad (40)$$

The confusion matrices of the proposed and existing deep learning models are depicted in Fig. 5. Accuracy, recall, specificity, precision, and F1-Score values are calculated based on the Confusion matrix, which are shown in Fig. 6 to 10.

Fig. 5. TP, TN, FP and FN Ratios of Proposed and Existing Methods.

Fig. 6. Accuracy Comparison Results.

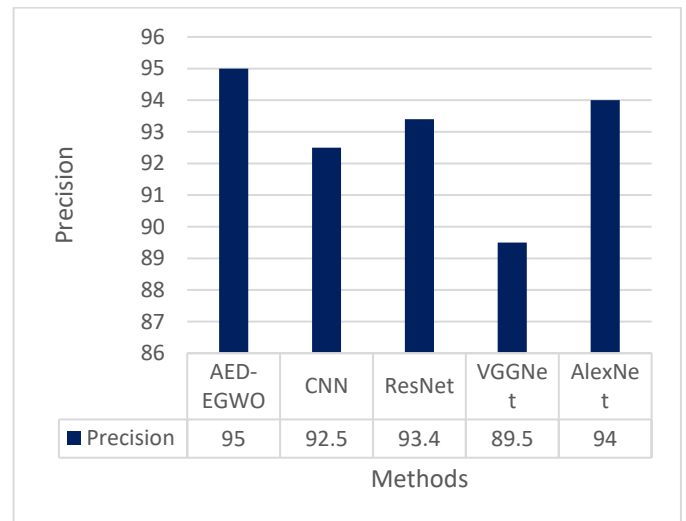

Fig. 9. Precision Comparison Results.

Fig. 7. Recall Comparison Results.

Fig. 10. F1-score Comparison Results.

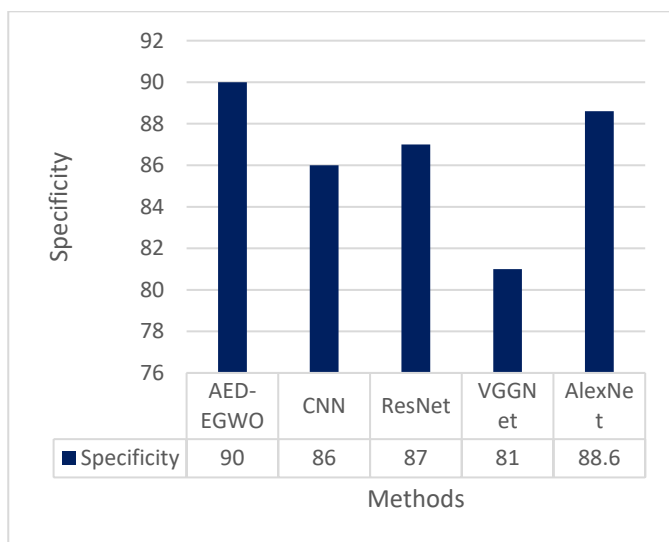

Fig. 8. Specificity Comparison Results.

The proposed methodology's performance is compared to traditional methods AlexNet, ResNet, VGGNet, and CNN. For a better analysis, the methods are experimentally implemented and their performance metrics are compared with the existing methods. The experimental results (accuracy, recall, specificity, precision and F1-Score) are presented in the Fig. 6 to 10. According to the experimental results, it is discovered that the proposed method is more accurate than the other state-of-the-art methods. Proposed fish classification system will have a greater number of true-positive fish pixel classifications; this will obviously improve the accuracy metrics. Following the proposed system, CNN and AlexNet have the highest accuracy (accuracy, recall, specificity, precision, and F1-Score). The ROC curve depicted in Fig. 10 has an AUC between 0.5 and 1.0, which indicates that it ranks a random positive sample higher than a random negative sample more than fifty percent of the time. Based on the results, it can be seen that the proposed methodology has fewer false positive fish pixels than other techniques. In addition, it is recognized that the number of true negative fish pixels is greater for the

proposed method than for the traditional deep learning techniques. In addition, the experimental results proves suggested technique reduces the number of false negative fish pixels.

Fig. 11. ROC Curve.

### C. Training efficiency analysis

This section examines the training efficiency of the proposed and existing approaches. For that, mean absolute error and mean squared error are two of the most important training efficiency evaluation metrics applied in this research. If the error values are minimal, therefore the training loss of the suggested technique is also limited.

1) *Mean absolute error*: Mean absolute error (MAE) is the average of the difference between actual and predicted values. It describes the variation between the predicted and the actual values. The following formula calculates MAE.

$$MAE = \frac{1}{n} \sum_{i=1}^n |y_i - \hat{y}_i| \quad (41)$$

$y$  represents the actual class value, while  $\hat{y}$  represents the outcome predicted by the proposed model.

2) *Mean squared error*: Mean squared error is the average of the squared differences between the actual and predicted values. The equation below is used to compute the MSE.

$$MSE = \frac{1}{N} \sum_{i=1}^N |y_i - \hat{y}_i|^2 \quad (42)$$

MAE and MSE provide positive integer values during training. If the value is near to zero, the deep learning model's training loss is very low; otherwise, the training loss is high. The MAE and MSE comparisons are summarized in Table II, it is observed that the proposed system has lower MAE and MSE. The proposed system is to less error-prone than existing traditional methods. As the error value is lower for the proposed approach, it is expected that the proposed system will be more effective than other conventional deep learning methods.

### D. Computational Efficiency Analysis

Table III summarized the computational efficiency of the AED-EGWO and existing methods. According to the experimental data, AED-EGWO takes 16 minutes to train the model, which is the shortest training time in the table, while RsetNet takes the longest of 23 minutes.

### E. Discussion

Classification of fish species is an essential component of marine research and oceanography. It contributes significantly to the migration, breeding, and monitoring of endangered fish species. In the meantime, the manual classification of fish species is a labour-intensive and time-consuming process. To automate the classification procedure, numerous computer-aided fish species classification systems have been developed. In existing methods, the deep learning or machine learning models are trained using images of dead fish taken out from under water. When training deep learning models using these photos instead of real-time underwater photographs, the FN and FP rates are increased. High FN and FP rates have a noticeable impact on the classification model's precision. To prevent this, the AED model in this study was trained using underwater photos of live fish. However, developing fish classification system using deep learning models with photos of underwater fish presents numerous challenges. Especially underwater, light penetration is very low, therefore pictures captured from this environment are extremely dim. Accordingly, the visibility of objects in underwater photographs are very poor. Therefore, underwater images have been normalized in this research to correct the problem. The normalized images through this research are shown in Fig. 12(b). Also, in the images taken from underwater, the color of water and other objects besides fish are occupied excessively, which increases the computational burden of the deep learning model. To correct it, in this research, the morphology of fish has been localized using the Simple Linear Iterative Clustering (SLIC) method. The results of fish morphology localization are shown in Fig. 12(b). Further, this study proposes the AED-EGWO framework for the classification of aquatic fish species. EGWO is being proposed for two significant responsibilities here.

TABLE II. TRAINING EFFICIENCY COMPARISON RESULTS

Methods	MAE	MSE
AED-EGWO	0.23	0.0529
CNN	0.42	0.1764
ResNet	0.77	0.5929
VGGNet	0.47	0.2209
AlexNet	0.31	0.0961

TABLE III. COMPUTATIONAL EFFICIENCY COMPARISON RESULTS

Methods	Training time	Classification time
AED-EGWO	16 minutes	1.37 Seconds
CNN	21 minutes	2.18 Seconds
ResNet	23 minutes	2.71 Seconds
VGGNet	19 minutes	1.92 Seconds
AlexNet	17 minutes	1.68 Seconds

Fig. 12. Experimental Results.

Initially, EGWO eliminates irrelevant and redundant texture information from the data set during AED model training. Next, EGWO method select the optimal texture features from the data set with the lowest possible iterations.

According to the proposed EGWO, feature initialization is based on correlation rather than randomness. Therefore, it only initializes features with a strong relationship to classification results. Thus, the optimization method can find optimal features with less iterations. This eliminates the unnecessary processing resources required for AED training. Further, it enhances the fish classification accuracy to some extent.

## V. CONCLUSION

In this study, the AED-EGWO methodology is developed for classifying fish species. This recommended classification method has two major components: optimal feature selection using EGWO and fish classification using AED. First, an improved grey wolf optimization approach is designed to identify the most important texture feature in the fish data set with the fewest possible iterations. Second, an auto encoder decoder network is developed to classify fish species based on

the identified features. Finally, experimental study has been conducted to evaluate the proposed method's reliability and classification effectiveness. The experimental results of the proposed AED-EGWO approach were compared to existing deep learning models. The comparison results demonstrate that the proposed strategy has greater classification precision and reduced training loss.

This fish classification system was evaluated using images of clear sea water. In the future, this research can be expanded to classify fish species in blurry fresh water images.

**Abstract**—Predicting noise pollution from building sites is important to take precautions to avoid pollution that harms the public. A high accuracy of the prediction model is required so that the predicted model can reach the true value. Forecasting models must be built on solid historical data to achieve high forecasting accuracy. However, data collected through various approaches are subject to ambiguity and uncertainty, resulting in less reliable predictive models. Therefore, the data must be handled accurately, to eliminate data uncertainty. Standard data processing processes are easy to use but do not provide a consistent method for dealing with this ambiguous data. Therefore, a method to deal with data containing uncertainty for forecasting purposes is presented in this paper. A new technique for providing uncertainty-based data preparation has been employed to develop an ARIMA-based model of environmental noise pollution. During the data preparation stage, the standard deviation approach was used. Prior to the development of the prediction model, it is crucial to manage the fuzzy data to minimize errors. The experimental findings show that the suggested data preparation strategy can increase the model's accuracy.

**Keywords**—Noise pollution; forecasting; ARIMA; uncertainty; standard deviation

## I. INTRODUCTION

One of the environmental challenges that has an impact on people's quality of life and well-being is noise pollution. Regular exposure to high levels of noise that might be damaging to people or other living beings is referred to as noise pollution [1] – [2]. Transportation noise, construction noise, manufacturing noise, and other extreme noise sources can all contribute to noise pollution [3] – [4]. Noise pollution has a long-term and short-term impact on human health, particularly hearing and mental health [5]. This causes awareness and action must be taken by the parties involved so that the effects of excessive noise do not cause emotional, mental, and physical health problems of people around the place involved.

Because diverse sounds occur on the construction site, the noise intensity might be extremely dangerous. Sound standard limits established by the Occupational Safety and Health Administration (OSHA) need ambient measurement. Noise levels at a construction site might vary based on the type of project and its stage of completion, whether indoors or outside

[6] – [7]. As the stage is completed, all activities on the building site change. This demonstrates that noise levels at a given stage are not consistent; they can be low or high [8] – [9]. Early stages of a construction site project, for example, include carpenters, cement workers, steelworkers, roofers, and bricklayers. Carpenters, ventilation installers, electricians, and plumbers begin their work in the following stages at the same time as drywallers, painters, and floor and ceiling installers. Depending on the task at hand, each of these stages employs a different set of tools. This will result in a wide range of noise, some of which is hazardous if it exceeds the standard noise limit [10].

Noise pollution has developed as a major environmental issue with substantial implications that are both stressful and harmful to one's health. Efforts must be made to reduce pollution. As with noise pollution, management must determine what steps should be taken to limit emissions. Forecasting is necessary for stakeholders to make better decisions and establish data-driven initiatives. It boosts management's confidence in making critical decisions. Because forecasting has become an important aspect of the planning process, particularly strategic planning, the establishment of a noise pollution forecasting model is critical [11]. To a large extent, the accuracy of management decisions is dependent on precise forecasting. Noise pollution projections are the foundation for efficient pollution management strategies as a preventive measure [12]. Much development of forecasting models has been done with noise pollution [13], [14], [15]. Noise prediction in construction sites [12], [16]. Statistical techniques, data analysis, and data mining are also used to model forecasts for noise pollution. Statistical techniques, data analysis, and data mining are also used to model forecasts for noise pollution. The findings of the study have supported this issue although improvements are needed to study other issues that arise.

Noise pollution data may involve uncertainty due to measurement error produces during pollution exposure assessment [17]. The measurement error is characterized by instrument imprecision and spatial variability [18]. Fault during measuring instruments in the technique used in the experiment give rise to uncertainty involvement in data collection [19]. Since most of the data comes from secondary sources, it could have problems with validity, bias, and representation. These problems could all lead to data inaccuracies and inefficient

forecasting models [20]. In short, the collected data or measured value contains uncertainty. When the data with uncertainty is analyzed to build a forecasting model, the uncertainty is carried through to the results, and thus reduces the model's accuracy. Handling uncertainty in data is one of the main challenges in forecasting. A widely used method to address the uncertainty lies in fuzzy theories [21]. Uncertainty involving noise pollution data has successfully used the fuzzy theory as a solution. Many studies have been produced with new solution model variants using fuzzy and hybrid concepts with other techniques [22] – [24].

Most studies in the literature focus on model development rather than data preparation. Good models, on the other hand, are often made from good data. Minimizing data collection and preparation errors can assist in the development of more accurate prediction models. Measuring the data collection accuracy is crucial to lower the chance of hidden errors in the created model. This paper proposes a systematic data preparation strategy for dealing with uncertainty during data preparation for forecasting, as measurement inaccuracy might have substantial implications for understanding noise pollution predictions. Time-series are used to store single-point data values and are best suited for classic time-series analysis techniques like autoregressive. The presence of underlying uncertainties, however, makes standard analysis ineffective in dealing with such data [25]. Considering this, addressing data uncertainties during data preparation is necessary as a stage in developing forecasting models. To solve the issues, this research introduces a new method of time series data preparation by modifying the spread of the symmetry triangular fuzzy number in the construction of autoregressive models.

In this paper, an experimental design for predicting ambient noise pollution by using ARIMA is established. In the data preparation stage, improvements were made due to the presence of fuzzy data. To obtain acceptable fuzzy values before building a prediction model, a systematic data preparation approach involving the translation of fuzzy data from a non-fuzzy number to a fuzzy number is required. The development of a triangular fuzzy number (TFN) that overcomes measurement uncertainties is offered as a systematic approach. To generate a triangular fuzzy number symmetry in the noise pollution data set, this strategy uses the standard deviation method to detect the triangle spread. Focus is placed on the preparation of fuzzy data and model forecasting, both of which are critical to explore to improve prediction value and accuracy.

The remainder of the paper is divided into the following subsections. Section 2 provides the theoretical foundations of this work, which include ARIMA and the triangular fuzzy number. Section 3 provides a description of the ARIMA-fuzzy solution approach. The proposed strategy is illustrated empirically in Section 4 using data on noise pollution. A few final observations are made in Section 5 to wrap things up.

## II. RELATED WORK

The ARIMA model has three parameters,  $p$ ,  $d$ ,  $q$  respectively corresponding to AR, I, MA. These three parameters affect the performance of ARIMA. In the

Autoregressive (AR) model, the current value of a variable is equated with the weighted sum of a set of part values and a completely random variation with the previous process and shock values. The  $p^{th}$  order autoregressive model AR( $p$ ), representing the variable  $y_t$  is generally written as follows:

$$y_t = c + \phi_1 y_{t-1} + \phi_2 y_{t-2} + \dots + \phi_p y_{t-p} + e_t \quad (1)$$

where  $c$  is constant,  $e_t$  is white noise (error), and  $y_{t-1}$ ,  $y_{t-2}$ , ...,  $y_{t-p}$  are past series. The process at some point in time is the result variable in AR (1), and  $t$  is only related to line periods that are one period apart.

$I$  is the number of times the differential sequence must be repeated until it reaches a stationary state. For the ARMA model to work, it must be stationary.

Meanwhile, a common strategy for modeling univariate time series is the moving average (MA) process. The output variable of the moving-average model is defined as being linearly dependent on the current and various historical values of a stochastic (imperfectly predictable) factor. The  $q^{th}$  order autoregressive model MA( $q$ ), representing the variable  $y_t$  is generally written as Equation (2).

$$x_t = \mu + \phi_1 w_1 + \phi_2 w_2 + \dots + \phi_p w_p + w_t \quad (2)$$

where  $\mu$  is the mean of the series and  $w_t$ ,  $w_{t-1}$ ,  $w_{t-2}$ , ...,  $w_{t-q}$  are white noise (error).

### A. Triangular Fuzzy Number (TFN)

The fuzzy number has been introduced to deal with imprecise numerical quantities in a practical way [26] and has commonly been used by researchers [27].

Definition 4: Let  $a$ ,  $b$ , and  $c$  be real numbers with ( $a < b < c$ ). Then the Triangular Fuzzy Number (TFN)  $A = (a, b, c)$  with membership function is as follows:

$$y = m(x) = \begin{cases} \frac{x-a}{b-a}, & x \in [a, b] \\ \frac{c-x}{c-b} & x \in [b, c] \\ 0 & x < a \text{ and } x > c \end{cases} \quad (3)$$

We define TFN as Equation (4),

$$\tilde{y} = [\alpha_l, c, \alpha_r] \quad (4)$$

where  $c$  is the center,  $\alpha_l$  is the left spread, and  $\alpha_r$  is the right spread of the TFN. Symmetry TFN  $\tilde{y}$  has the same spread where  $c - \alpha_l = \alpha_r - c$ , and is denoted as:

$$\tilde{y} = [c, \alpha] \quad (5)$$

$\alpha$  is the spread of triangular fuzzy numbers. If  $\alpha = 0$ ,  $\tilde{y}$  is a non-fuzzy number.

The information provided is utilized to create ARIMA forecasting models with data that has been processed using fuzzy methods. The data used to build the ARIMA prediction model must first be pre-processed with triangular fuzzy numbers since it contains fuzzy elements. From previous literary works, fuzzy theory has been successfully applied widely in various case areas to reduce uncertainty and inaccuracy. However, few studies have clarified the details of fuzzy data preparation, which addresses data uncertainty.

Typically, expert definitions are used to define fuzzy numbers to address ambiguity. The definition of an expert, on the other hand, may be difficult to obtain and inconsistent, making it a difficult effort. Thus, in this study, a standard approach has been introduced to address uncertainties during data processing. The next section will describe the ARIMA prediction experiment that uses triangular fuzzy numbers as the data preparation method.

### III. FUZZY ARIMA MODELING

The process of cleaning and converting raw data prior to processing and analysis is known as data preparation. Reformatting data, making data adjustments, and integrating data sets to enrich data are all part of this crucial stage before processing. For data specialists or business users, data preparation may be time-consuming, but it is critical to place data in context to turn it into insights and reduce bias caused by poor data quality.

Fig. 1. Design of Experiment for ARIMA based Fuzzy Data Preparation.

The steps for building ARIMA with standard deviation-based symmetry triangular fuzzy number,  $\Delta_s$  is explained as follows:

Step 1. Select times series datasets as input data. Table I shows the input data format.

TABLE I. INPUT DATA FORMAT

Data	1	2	...	$n$
Input	$y_1$	$y_2$	...	$y_n$

Step 2. Construct a fuzzy number of symmetrical triangles with spreads generated by the standard deviation method,  $\Delta_s$ .

1) *Generate spread, S*: In Equation (6), a fuzzy time-series data  $\tilde{y}_t^s$  at a time,  $t$  is written with symmetry triangular fuzzy number data.

$$\tilde{y}_t^s = [y_t - s, y_t, y_t + s] \quad (6)$$

where  $y_t$  is time-series data at a time,  $t(t = 1, 2, \dots, n)$  and  $\Delta_s$  is the triangular spread based on the standard deviation of the dataset. The concept of standard deviation, which measures the spread of data, strikes at the core of this strategy.

2) Forecast generated spread using statistical software.

3) Find center value for symmetry triangular fuzzy number,  $\bar{y}_t^s$ .

The center value for the symmetry triangular fuzzy number is computed as follows:

$$\bar{y}_t^s = 0.5(\tilde{y}_t^s + \bar{y}_t^s) \quad (7)$$

where  $\bar{y}_t^s$  represent a center point for the triangle.  $\tilde{y}_t^s$  and  $\bar{y}_t^s$  represent left predicted value and right predicted value, respectively. Table II shows the data format of the center point for symmetry triangular fuzzy number,  $\bar{y}_t^s$ .

TABLE II. DATA FORMAT FOR CENTER POINT,  $\bar{y}_t^s$

$y_t$	$y_1$	$y_2$	...	$y_n$
$\bar{y}_t^s$	$\bar{y}_1^s$	$\bar{y}_2^s$	...	$\bar{y}_n^s$

Step 3. Calculate the Mean Squared Error (MSE).

The results are analyzed after all of the datasets have been tested. MSE is used to evaluate the accuracy's performance. The MSE for each  $y_t^s$  is calculated using Equation (8).

$$MSE = \sum_{i=1}^n \frac{(y_t - \bar{y}_t^s)^2}{n} \quad (8)$$

where  $y_t$  is a time-series data and  $\bar{y}_t^s$  are a predicted times series data at a time,  $t(t = 1, 2, \dots, n)$  and  $n$  is a sample size.

Step 4. Calculate the Root Mean Square Error (RMSE)

The RMSE is also calculated to help with the analysis. The RMSE for each  $y_t^s$  is calculated using Eq. 9.

$$RMSE = \sqrt{MSE} = \sqrt{\sum_{i=1}^n \frac{(y_t - \bar{y}_t^s)^2}{n}} \quad (9)$$

where  $y_t$  is a time-series data and  $\bar{y}_t^s$  are a predicted times series data at a time,  $t(t = 1, 2, \dots, n)$  and  $n$  is a sample size.

Step 5. MSE and RMSE values are used to validate ARIMA with  $\Delta_s$  accuracy. The model with the least MSE and RMSE has a higher prediction accuracy.

Model building refers to the process of deciding what model to use for the context. Sometimes, existing well-supported theory or knowledge guides the choice of model, but sometimes the choice needs to be made empirically, which is based on real data. Ordinary Least Squares (OLS) is a linear regression technique utilized in this study to infer the association between a variable and an outcome, especially when other factors are present. The coefficient and constant of linear regression are calculated using OLS and used to construct a linear regression model. When employing interval data, the method for obtaining the center point is critical for the validation phase.

The ARIMA model is built with fuzzy number production from a single point value to resolve uncertainties, as indicated in the systematic methods described in this section. Because crisp reliability is insufficient to grasp data-inbuilt uncertainties, this phase is critical during the data preparation process [28] – [29].

IV. EXPERIMENTAL RESULT AND DISCUSSION

Noise data collected at the construction site were used to evaluate the performance of the methods proposed in this section. The ARIMA model of this data set is ARIMA (1,0,0). The data set used has 1000 data points and covers the period from March 1, 2020, to March 31, 2020. Data was collected using a web-based Environmental Site Monitoring (IoT) System [30]. The technology is designed to monitor ambient noise throughout the day and provide real-time sound updates. Favoriot platforms collect and store data on cloud servers.

Step 1. Select noise time-series datasets. Table III shows noise datasets.

TABLE III. NOISE DATASETS

Data	1	2	...	999	1000
Noise	74	58.8	...	81.5	80

Step 2. Build symmetry triangular fuzzy number based on Standard Deviation method,  $\Delta_s$ .

1) Generate spread,  $S$ : The standard deviation approach (see Section 3 step 2) is used to calculate the spread of symmetry triangular fuzzy numbers, which is based on Eq (6).  $(\tilde{y}_t^s, y, \tilde{y}_t^s)$  represents a symmetrical triangle fuzzy number with a standard deviation-based spread. Table IV depicts the range of possible numbers of fuzzy symmetrical triangles.

TABLE IV. SYMMETRY TRIANGULAR FUZZY NUMBER SPREAD

$n$	$y_1$	$y_2$	...	$y_{999}$	$y_{1000}$
$\tilde{y}_t^s$	66.6956	51.4956	...	74.1956	72.6956
$\tilde{y}_t^s$	81.3044	66.1044	...	88.8044	87.3044

2) Forecast generated spread using statistical software. The predicted result for the spread shown in Table V.

TABLE V. PREDICTED RESULT FOR THE SPREAD OF SYMMETRY TRIANGULAR FUZZY NUMBER

$n$	$y_1$	$y_2$	$y_3$	...	$y_{23}$
$\tilde{y}_t^s$	-	12.7987	12.9442	...	14.6047
$\tilde{y}_t^s$	-	14.1413	14.2848	...	15.9473

3) Find the center value of symmetry triangular fuzzy number,  $\tilde{y}_t^s$  using Eq. (7). To calculate the MSE, the predicted value is transformed from the symmetry triangular fuzzy number to a single point. Table VI shows the symmetrical triangle fuzzy number's center value.

TABLE VI. CENTER POINT VALUE FOR THE SPREAD OF SYMMETRY TRIANGULAR FUZZY NUMBER

$y_t$	$y_1$	$y_2$	$y_3$	...	$y_{999}$	$y_{1000}$
$\tilde{y}_t^s$	-	74.5032	64.6617	...	77.6864	77.3949

Step 3. The MSE for the noise data is calculated based on Eq. (8), and then presented in Table VII.

TABLE VII. MSE FOR NOISE DATA

Data	ARIMA	ARIMA $\Delta_s$
Training	33.8190	19.6161
Testing	33.8194	17.0045

Step 4. The RMSE for the noise data is calculated based on Eq. (8), and then presented in Table VIII.

TABLE VIII. RMSE FOR NOISE DATA

Data	ARIMA	ARIMA $\Delta_s$
Training	5.8154	4.4401
Testing	5.8154	4.1339

Step 5. Validate ARIMA with  $\Delta_s$  accuracy based on MSE and RSME.

The MSE and RMSE results are compared to verify the correctness of the prediction error. This proposed method is also compared to traditional autoregressive (AR), autoregressive with standard deviation based (AR $\Delta_s$ ), and conventional autoregressive moving average methods (ARIMA). Table IX summarizes the MSEs for the noise data.

The MSE and RMSE results are compared to ensure that the prediction error is correct. Traditional autoregressive (AR), autoregressive with standard deviation based (AR $\Delta_s$ ), and conventional autoregressive moving average methods are also compared to this proposed method (ARIMA). The MSEs for the noise pollution data are shown in Table IX.

TABLE IX. SUMMARY OF MSE

Data	AR(1)	AR(1) $\Delta_s$	ARIMA	ARIMA $\Delta_s$
Training	52.3412	33.8197	*33.8190	33.8194
Testing	173.2402	18.1800	19.6161	**17.0045

\* Smallest MSE for Training  
\*\* Smallest MSE for Testing

The results in Table IX show good enforcement when compared to the typical strategy. The proposed technique can achieve higher accuracy than traditional AR and conventional ARIMA. In the AR model, the proposed technique drove the MSE from 173.2402 to 18.10, and in the ARIMA model, it pushed the MSE from 19.6161 to 17.0045. To improve the outcome, the RMSE approach was also used. The RMSEs for the noise pollution data are summarized in Table X.

TABLE X. SUMMARY OF RMSE

Data	AR(1)	AR(1) $\Delta_s$	ARIMA	ARIMA $\Delta_s$
Training	7.2347	5.8155	*5.8154	*5.8154
Testing	13.1949	4.2744	4.4401	**4.1339

\* Smallest MSE for Training  
\*\* Smallest MSE for Testing

The outcomes in Table X surpass those in Table IX and are consistent with the standard model. The AR model's MSE may be increased from 13.1949 to 4.2744, and the ARIMA model's MSE can be increased from 4.4401 to 4.1339 using this strategy. The MSE and RMSE decrease as the results improve.

It has been demonstrated that symmetric triangular fuzzy numbers can be created using standard deviations. As shown in Tables IX and X, MSE and RMSE for ARIMA with standard deviation based are superior to other techniques. Eqs (9) and (10) show the prediction model.

$$AR(1) = ARIMA(1) = 26.59 + 0.70y_{t-1} \quad (9)$$

$$AR(1)_{\Delta_s} = ARIMA(1)_{\Delta_s} = (24.02, 29.17) + 0.65y_{t-1} \quad (10)$$

#### V. CONCLUSION

Data preparation is critical and is a necessary step before developing forecasting models. Hence, data processing is required, and it must be carried out using proper procedures to manage data errors. Furthermore, data preparation is critical for producing high-quality data. This is done by organising and reformatting the data set and ensuring the high quality of the data used in the study. A strong forecasting model can only be built with high-quality input data; hence this is an essential prerequisite. In addition, the provision of data may help relevant parties to make better business decisions. This is because fast, effective and high-quality business decisions are produced when high-quality data is handled, examined and processed more quickly and efficiently.

To address the uncertainties in the data, we describe a technique for creating symmetric triangular fuzzy integers with standard deviation. It offers a simple and easy-to-implement solution. This experiment compares the results of the suggested approach using a few different methods. The effectiveness of the suggested method has been described and evaluated against the current method. The experimental results demonstrate that this proposed strategy using symmetric triangular fuzzy numbers outperforms the others in terms of predicted accuracy. In short, symmetric triangular fuzzy numbers are one of the other approaches to improve time series forecasting outcomes, particularly in this experiment with noise pollution.

# Extractive Multi-document Text Summarization Leveraging Hybrid Semantic Similarity Measures

Rajesh Bandaru, Dr. Y. Radhika

Department of CSE, GST, GITAM (Deemed to be University)  
Visakhapatnam, India

**Abstract**—Because of the massive amount of textual information accessible today, automated extraction text summarization is one of the most extensively used ways to organize the information. The summarization mechanisms help to extract the important topics of data from a given set of documents. Extractive summarization is one method for providing a representative summary of a text by choosing the most pertinent sentences from the original text. Extractive multi-document text summarization systems' primary goal is to decrease the quantity of textual information in a document collection by concentrating on the most crucial subjects and removing irrelevant material. In the previous research, there are several methods such as term-weighting schemes and similarity metrics used for constructing an automated summary system. There are few studies that look at the performance of combining various Semantic similarity and word weighting techniques in automatic text summarization. We evaluated numerous semantic similarity metrics in extractive multi-document text summarization in this research. In the extractive multi-document text summarization discussed in this research, we looked at numerous semantic similarity metrics. ROUGE metrics have been used to evaluate the model performance in experiments using DUC datasets. Even more, the combination formed by different semantic similarity measures obtained the highest results in comparison with the other models.

**Keywords**—*Extractive text summarization; semantic similarity; sentence scoring; summary*

## I. INTRODUCTION

The amount of data and information available has exploded since the introduction of the World Wide Web. The volume of data has grown to the point where it is nearly difficult for any specific firm to analyze it all, or to summarize it. People are reluctant to engage in reading a lengthy piece of text and, as a result, typically skip crucial sections of it. This has boosted the need for text summarization automation [1].

In general, a person follows the three processes outlined below to create a summary: 1) interpreting the document's content, 2) selecting relevant chunks of meaningful information, 3) putting this content of data. Because of their difficulties, there is limited possibility of automating the first and third processes for any random text. As a result, the majority of techniques aim to automate the second phase [1].

Text summarizing is considered as single or multi-document summary terms of the number of documents studied and summarized at the same time. In single document summarizing, a summary is constructed from a single

document, but in multi-document summarization, a series of documents is examined for creating a summary. The task of summarizing many papers is more complex than the process of summarizing a single document. One of the most difficult issues in summarizing many publications is redundancy. Additional classification categories, such as single vs. multi-document categorization and mono-lingual vs. multi-lingual summarization, have been developed in the past based on many other factors [2].

Text summarization techniques often are divided into two categories: abstractive and extractive. The primary goal in extractive summarization included to retrieve the most essential sentences from a document(s) and combine them into a summary. This is in contrast to abstractive summarization, which involves reiterating the information in the text. The extractive summary contains sentences taken directly from the original content, whereas an abstract summary uses terms / expressions not present in the original source. Because of its greater practicality, extractive summarization has become a benchmark in text summarizing [3]. Abstractive text summarizing techniques try to generate summaries that summarize the crux of the text in the same way as people do after studying any text. This employs generative methodologies that can produce meaningful phrases while maintaining the semantics of the source text. This is regarded as a tough topic to tackle, and several novel ways have been presented.

Extractive summarization is divided into three stages: pre-processing, sentence scoring, and sentence selection. Several activities, like as tokenization, phrase and paragraph segmentation, are often carried out during the pre-processing phase. During the sentence scoring step, sentences are ranked based on certain criteria, and every sentence is assigned a score. Finally, the finest sentences are chosen and incorporated in summary during the sentence selection process. As previously stated, one of its most significant issues in multi-document summarizing is duplication, because identical phrases are more likely to be encountered in distinct documents, frequently [4].

Extractive text summarization is a simpler and more reliable method of creating summaries in which key lines from a text are chosen and provided to the user. Each sentence is scored, and the sentences with the highest scores are chosen for inclusion in the extract [5]. This is significantly easier than abstractive summaries, which need the production of phrases and words, as well as their organization into legible sentences, while yet giving an understandable substance of the subject. It

would need a significant amount of natural language processing, making it a significantly more complex task.

With the use of data-driven methods and semantic similarity approaches, extractive summaries will be produced in this study in order to meet the goal of text summarization. This involves analysing the large volume of information and creating a list of the sentences that could be the most helpful and contain the main idea of the text. Although most of the time, people strive to summarize texts in a way that conveys the same sense as the original text and do not see summaries as phrases taken literally from the source [6].

The remainder of the paper can be found in the sections that follow this one: Section 2 presents the results of a survey of the literature on text summarization using various approaches, which was carried out in order to create this paper. After providing a thorough explanation of the proposed algorithm in Section 3, Section 4 presents the results of the experiments conducted as part of the research. After a discussion of the findings and recommendations for future research are in Section 5.

## II. RELATED WORK

Since the 1950s, researchers have been studying automatic text summarization. It has since been extensively researched. Researchers working on document summarizing all around the globe are experimenting with a variety of approaches in order to produce ways that deliver the highest results. This work focuses on extractive multi-document summarization.

Various extraction-based strategies for generic multi-document summarization have been suggested so far. Statistical techniques deal with statistical aspects that aid in the extraction of relevant phrases and words from source material. Furthermore, traits and their weights play a significant influence in establishing sentence relevance. This section presents various models employed in the domain of multi-document summarization.

Jesus M. Sanchez-Gomez et al. [5] proposed a model with a set of multi objective functions. The objective functions defined in this work targets to coverage of content and reducing the redundancy. Using a combination of statistical and graph-based methods Mohammad Bidoki et al. [6] proposed a semantic framework for developing an extractive multi-document summarizer system. It is a dialect, unsupervised system. To learn the semantic representation of words from a set of supplied documents, the model uses the word2vec technique. It expands on each phrase using a one-of-a-kind method that employs the most informative and least repetitive words related to the statement's fundamental idea. Phrase expansion implicitly achieves word meaning disambiguation and adapts conceptual density to each sentence's main idea. The importance of sentences is then determined using the graph representation of the documents.

Begum Mutlu and colleagues [7] have created an English dataset including the proceedings of SIGIR 2018. Three readers used a manual labelling approach to classify the assertions in the opening parts as summary-worthy or summary-unworthy. It was shown that employing ensembled feature space considerably improved summarization

performance when both conventional classification and ROUGE-based analysis were used.

Hiren Kumar Thakkar et al [8] proposed a novel Domain Feature Miner (DOFM) mining algorithm. The summaries generated by DOFM are then subjected to automatic examination using ROUGE. This is a well-known programme for automated assessment of summaries. An error study revealed that 84 percent of the sentences from all DOFM generated summaries were selected by at least one of the three annotators. This highlights the DOFM's resiliency in terms of domain feature retrieval and extractive summarization, as well as its overall performance.

Ángel Hernández-Castañeda et al [9] uses Genetic Algorithm to identify the most effective grouping of words. This model organizes sentences in a text with the assistance of a clustering approach. Summaries generated not only contain matches of unique words, but also give context by matching terms in the text. One-of-a-kind technique for automated summarization is presented in this study. This method can be used to organize sentences in a text according to specific semantic and lexical qualities. It combines a vectorial space formed by a large number of feature generation algorithm(s) with a single summary strategy. It is not necessary to have a prior grasp of the underlying issue in order to generate vectors for this purpose. LDA, Doc2Vec, TF-IDF, and OHE do not need any prior knowledge of classes.

Kaichun Yao et al. [10] developed a extractive document summarizing approach based on Deep Q-Networks (DQN) to capture word salience and redundancy and train a strategy that maximises the Rouge score over gold summaries. The information given by the informative features not only provides informative features to describe the DQN's states but also generates a list of probable DQN actions from the document's words. Our model does not need extractive labels at the sentence level since it is trained directly on human-provided reference summaries. The Rouge measure is used to assess the model's performance on the CNN/Daily, DUC 2002, and DUC 2004 datasets. When applied to non-linguistic corpora, our technique outperforms or is on par with state-of-the-art models in terms of performance. The researchers believe this is the first time DQN has been used for extractive summarization in any scientific setting.

Luca Cagliero et al. [11] mention that annotating scientific articles with textual highlights, it is feasible to provide readers with potentially valuable result-oriented insights that may be used immediately. Unfortunately, the majority of the time, rather than automatically, the annotation process is performed by hand. A further problem is that the highlight information is completely lacking from the vast majority of earlier publications. The solution provided here overcomes the issues noted above by using supervised learning on previously annotated article data.

Jesus M. Sanchez-Gomez et al. [12] using three distinct term-weighting algorithms performed the task of multi-document text summarizing, and the authors found that they were all successful. Different unique similarity metrics that are employed in text-similarity have been taken into consideration by this work. The average and Pearson's coefficient of

variation are two of the computations that were employed in this investigation.

Mohammad Mojri et al. [13] proposed the MTSQIGA approach, which is a novel multi-document text summarization approach. It is designed to extract salient sentences from a source document collection in order to generate a summary of the information contained in the collection. It is proposed that a modified quantum measurement, as well as a self-adaptive quantum rotation gate, be used in conjunction with a summary generator that is dependent on the quality and length of the summary that is generated. A benchmark dataset from the DUC 2005 and 2007 was used to evaluate the proposed system in terms of ROUGE standard measures.

Akanksha Joshi et al. [14] proposed SummCoder, a method for extracting text summarization from single documents, makes this task much easier. The summary is generated using three metrics: content relevance, novelty, and position relevance. The following are the outcomes: An auto-encoder network is used to determine the relevance of sentence content by exploiting the similarity between embeddings in distributed semantic space, and the novelty metric is derived from this similarity. In this feature, which was created by hand, a dynamic weight calculation function based on the overall length of the document is used to give more weight to the document's first few sentences. It is also possible to create a document summary by ranking the sentences based on a combined final score derived from three different sentence selection metrics. A new summarization benchmark, the Tor Illegal Documents Summarization (TIDSumm) dataset, will benefit law enforcement agencies (LEAs). These summaries were created manually for 100 documents from onion websites in the Tor (The Onion Router) network and are included in the dataset. When compared to other methods, this text summarization approach achieves comparable or better performance for a wide range of ROUGE metrics for the DUC 2002, Blog Summarization, and TIDSumm datasets.

Manh et al. [30] used corpus based measures like LSA and LDA along with K-means to perform the task of summarization. The results of this work are comparatively good as corpus based measures explores different possibilities of evaluation. But the semantic similarity is not explored by Manh et al. [30]. The authors [31], [32] provided the applications of semantic similarity measures for the evaluating verb similarity and sentence with contradictory similarity. The works [31], [32] also discussed the importance of semantic similarity in the current research domains of natural language processing.

Table I provides the summary of the models compared in this article. Table I gives an insight into the models target and whether sentence scoring is performed in the model or not. This section presented various multi-document summarization models based on the different techniques. The models presented in this work are limited to analysing the similarity between the sentence and document title using term weighting schemes. The significance of knowledge based measures is not considered in the works highlighted in this section. We propose a novel knowledge based metric based on information content and path length in the next section.

The next section gives the proposed model and the significance of knowledge based measures in the sentence similarity evaluation.

### III. PROPOSED MODEL

This section presents the proposed work to perform the document summarization. This section also proposes a novel metric using the concepts of semantic similarity to estimate the values of sentence scoring. The first part of this section covers the knowledge-based measures and the second part covers the document summarization aspects.

The measures that produce synonyms and also deal with various word forms are knowledge-based measures. Similarity based on knowledge is determined by the information content or the length between the terms [22]. To determine similarity, knowledge-based methods make use of a well-constructed taxonomy (also known as a lexical database) to infer semantic similarity between concepts.

Information content (IC) is the probability regarding the availability of a concept in the corpus.

$$IC(C_k) = -\log(P(C_k)) \quad (1)$$

Where  $P(C_k)$ , is probability of the concept  $C_k$  in the corpus.

$$P(C) = \frac{f(C)}{N} \quad (2)$$

Where  $f(C)$  is the frequency of the concept in the corpus,  $N$  represents the number of words in the corpus.

Path (or path length) between two concepts gives the possible shortest path between the concepts.

The depth (D) is referred as the length of concepts and maximum depth (Dmax) of a concept the length from the concept to root in the taxonomy.

Least common subsumer (LCS) of two concepts in the taxonomy is another concept which is the root of the two concepts.

#### A. Semantic Similarity Measures

Various semantic similarity measures which are knowledge based are discussed in this subsection. The following are the standard knowledge based semantic measures.

Res Measure [21]: This measure estimates the similarity between the concepts  $C_i, C_j$  by considering the information content of the lowest common subsumer.

$$resnik(C_i, C_j) = IC(C_{LCS}(C_i, C_j)) \quad (3)$$

Jcn [22] Measure: This measure to calculate the similarity between the concepts  $C_i, C_j$  proposes the following equation,

$$jcn(C_i, C_j) = IC(C_i) + IC(C_j) - 2 * IC(C_{LCS}(C_i, C_j)) \quad (4)$$

Lin Measure [23]: This measure is defined as,

$$lin(C_i, C_j) = \frac{2 * IC(C_{LCS}(C_i, C_j))}{IC(C_i) + IC(C_j)} \quad (5)$$

Lch [24] Measure: This measure considers the maximum depth of the taxonomy and the length of concepts  $C_i, C_j$  in the taxonomy.

$$lch(C_i, C_j) = -\log\left(\frac{len(C_i, C_j)}{2 * D_{max}}\right) \quad (6)$$

Wup [25] (wup) Measure: This measure uses depth of lowest common subsumer of the two concepts  $C_i, C_j$  and individual depths of the concepts to estimate the similarity between concepts.

$$wup(C_i, C_j) = \frac{2 * D(C_{LCS})}{D(C_i) + D(C_j)} \quad (7)$$

Path Measure [26] (path): This measure calculates the inverse of semantic distance between the concepts  $C_i, C_j$  as the similarity between the concepts.

$$pathdistance(C_i, C_j) = length(C_i, C_j) \quad (8)$$

$$path(C_i, C_j) = \frac{1}{1 + pathdistance(C_i, C_j)} \quad (9)$$

Li measure [27] (li): This is a non-linear measure to estimate the similarity of the concepts. This measure uses depth and length between the concepts  $C_i, C_j$  to calculate the similarity.

$$li(C_i, C_j) = e^{-\alpha * l} * \frac{e^{\beta * D} - e^{-\beta * D}}{e^{\beta * D} + e^{-\beta * D}} \quad (10)$$

Where  $\alpha, \beta$  are parameters and  $\alpha = 0.2, \beta = 0.6$ .

#### B. Proposed Measure

The metrics indicate that they are all attempting to calculate how much information is shared between them in order to determine how closely two concepts are related. The problem of concepts with the same length and giving the same value even when there is less similarity between the concepts is also not addressed by measures based on the distance between concepts. The issue of equal route length can be solved by adding depth using techniques like wup and li. Greater granularity has the unintended consequence of making the concepts at the top of the hierarchy less detailed. This indicates that the path and depth problems are being addressed using the data. Compared to the route- and depth-based assessments, the information content measurements are more accurate. These measures will give the same similarity score for two concepts that have the same LCS, regardless of how differently their contents are expressed. For this problem, the information content serves as a guiding weight, and the measure may be represented as follows:

$$\text{Hybrid measure}(C_i, C_j) = \frac{1}{1 + path(C_i, C_j) * k^{IC(2 * C_{LCS}(C_i, C_j)) / (IC(C_i) + IC(C_j))}} \quad (11)$$

The suggested metric has various weights for the path length, which eliminates the issue of ideas having the same path length and hence having the same LCS difficulties. Conceptual similarity is estimated by taking into consideration the semantic distance between ideas and their respective information content as well as the information content of each concept measured separately (LCS).

The sentence scoring is calculated by deriving a sentence feature vector. The sentence feature vector is calculated by using the NLTK and proposed semantic similarity measure.

#### C. Proposed Extractive Multi-Document Summarization

In this section, we discuss our proposed system. Fig. 1 gives the architecture of the proposed model. The input to the model is a set of documents. The documents are taken from reliable datasets.

The first phase in the model is preprocessing of data. In the preprocessing, sentence segmentation is performed initially. Later the sentences are tokenized, and each sentence is represented as a set of tokens at this step. The parts-of-speech tagging relative to the words in the sentence is also preserved. The most irrelevant words from the sentence are removed and the remaining words are stemmed.

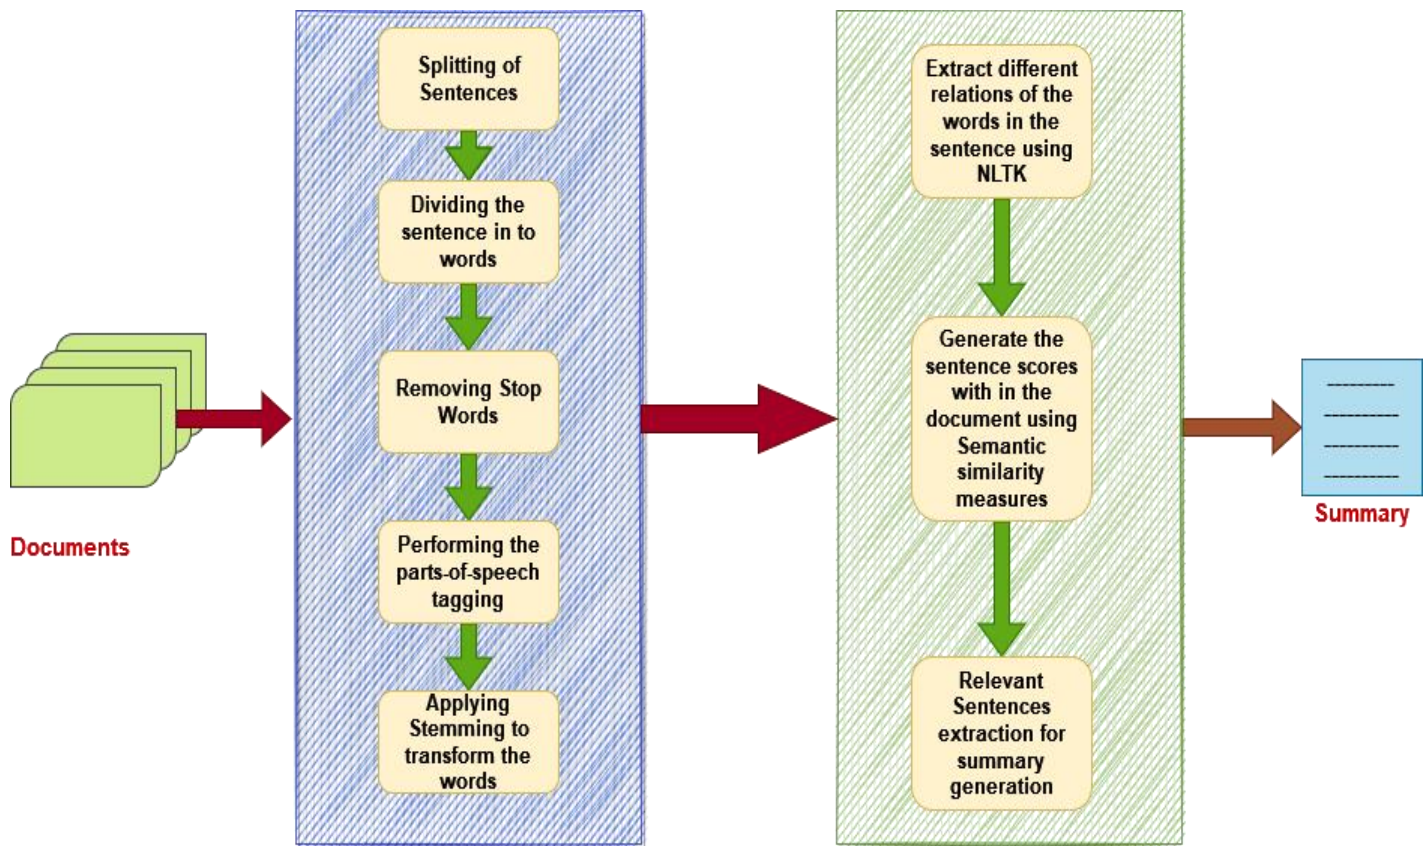

Fig. 1. Architecture of the Proposed Model.

The next stage in the proposed model is to extract multiple senses of each word preserved in the sentence. The relations are extracted from the NLTK package. The next step in the second stage is to generate the sentence scores. The sentence scores are used to generate the summary of the documents. Later the performance metrics are used in the evaluation.

Preprocessing is accomplished by the use of a pipeline that is often used for multi-document summarizing jobs, in which a cluster of documents is represented by a collection of phrases. In other words, we're discussing the presence of a cluster  $D$  containing  $m$  documents  $D = [d_1, d_2, \dots, d_m]$ .

The initial step was to decompose each document  $d_i$  in the cluster  $D$  into individual phrases, which we performed with the help of the free and open-source software package spaCy for Advanced Natural Language Processing. The next phase uses the Natural Language Toolkit (NLTK) and regular expressions to clean up these phrases by converting all words to lower case and deleting special characters, unnecessary whitespace, HTML elements, URLs, and email addresses from the source code.

#### D. Semantic Relationship between Words

We employ semantic similarity metrics and WordNet to capture the semantic links between words. We begin by assessing the word's resemblance to the document title. The highest degree of similarity that a word achieves is referred to as the word score. The TF-IDF, a term weighting approach, is used to weight these word scores.

We use multiplication to integrate TF-IDF and word scores in our current work. To create a sentence vector, we integrate all of the sentence's word weighed scores. The TF-IDF assists in mapping the phrase to a distributed semantic vector, with the exception that the most frequently occurring words have a smaller influence on the outcome. Finally, we acquire a vector representing all sentences in the corpus; this vector is referred to as the average sentence vector.

#### E. Extracting Different Features

The linguistic features of the sentence are also extracted as important features to calculate the sentence score. Representation of the calculations of the sentence vector using different features is mentioned in Fig. 2.

1) *Noun and verb phrase*: The noun or verb phrases in a sentence are essential and given more weight in a sentence. Each sentence's noun and verb phrase weight is computed as follows:

$$NV_{Phrases} = \frac{No. (Verbs, Nouns)}{Sentence Length}$$

2) *Sentence position*: In general, the sentences at the beginning and end are more informative.

3) *Sentence length*: Sentences with large length are more significant in the document.

Fig. 2. Proposed Algorithm.

Based on the features and sentence vectors the sentence scores are generated and the sentences with higher scores are considered as more relevant sentences and these sentences are combined together to generate the summary of sentences. The different steps involved in calculating the sentence scores are mentioned in the proposed algorithm. The different features used for scoring the sentence are discussed above.

This section covers the overall description of the proposed model and the results regarding these models are presented in the next section.

#### IV. RESULTS AND DISCUSSION

This section covers the experimentation of the proposed similarity measure on word pair similarity dataset and the proposed model to perform multi-document summarization of data. The first part of the results is with respect to the semantic similarity on different word pair datasets.

##### A. Metrics Used

**Pearson correlation:** This correlation is used to evaluate the performance of various semantic similarity measures.

**Spearman Correlation:** This is also another well-known correlation that is used to evaluate the performance of various semantic similarity measures.

**ROUGE Score:** Many researchers and practitioners use this metric to assess how well multi-document summarizing algorithms function.

##### B. Datasets

- RG dataset [28]: This dataset, which includes 65 noun pairs, is used to assess word similarity tasks.
- MC dataset [29]: This dataset, which includes 30 noun pairs, is used to assess word similarity tasks.
- DUC 2007 dataset: The dataset consists of 45 separate subjects that are each covered by 45 unique documents, all of which cover all 45 categories.

##### C. Tools used for Implementation

- NLTK
- Spacy
- ROUGE
- SCIKIT learn
- Anaconda

The results of several semantic similarity tests performed on the RG dataset and the MC dataset are shown in Tables II and III, respectively. The findings show that combining the length between the concepts with the information content leads in greater correlation values. The proposed hybrid measure is able to achieve better results when compared with all the existing models.

As a baseline for our current research, we utilise the primary task dataset from the Document Understanding Conference (DUC 2007). Automated text summarization assessment is carried out by NIST using the DUC 2007 dataset. The DUC 2007 dataset is made up of news stories from a variety of publications. The dataset contains 45 separate subjects and 45 individual texts, each of which discusses all 45 themes.

Fig. 3 is an example of how summarization works. The proposed model after sentence scoring extracts the relevant sentences according to the document in the shown example. The results of the summarization are with respect to a compression rate of 15%. It can be observed from the figure that the relevant sentences are extracted according to the given data.

TABLE II. RESULTS OF CORRELATION ON RG DATASET

<b>Proposed</b>	<b>0.80</b>	<b>0.86</b>

Because of the massive amount of textual information accessible today, automated extraction text summarization is one of the most extensively used ways to organise the information. The summarization mechanisms helps to extract the important topics of data from a given set of documents. One of the summarization techniques named extractive summarization selects the most relevant sentences from the text to provide a representative summary. The main purpose of extractive multi-document text summarization systems is to reduce the amount of textual information in a document collection by focusing on the most important topics and avoiding unnecessary portions. In the previous research, there are several methods such as term-weighting schemes and similarity metrics used for constructing an automated summary system. There are few studies that look at the performance of combining various Semantic similarity and word weighting techniques in automatic text summarization. We evaluated numerous semantic similarity metrics in extractive multi-document text summarization in this research. In this paper, we explored various semantic similarity measures in the extractive multi-document text summarization. Experiments have been performed with Document Understanding Conferences (DUC) datasets, and the model performance has been assessed with eight Recall-Oriented Understudy for Gisting Evaluation (ROUGE) metrics. Even more, the combination formed by different semantic similarity measures obtained the highest results in comparison with the other models.

The main purpose of text summarization systems is to reduce the amount of textual information in a document collection by focusing on the most important topics and avoiding unnecessary portions. One of the summarization techniques named extractive summarization selects the most relevant sentences from the text to provide a representative summary. There are few studies that look at the performance of combining various Semantic similarity and word weighting techniques in automatic text-editing systems.

Fig. 3. An Example of Extractive Summarization of the Proposed Model.

Because each subject has 45 subtopics, we may construct a summary for each of them in our suggested approach. For each of the comparative models and our recommended strategy, we've compiled summaries. Summaries of various sizes were created using different compression ratios of 5 percent, 15%, 25%, and 50% of the original material. The ROUGE-N score metric assesses the quality of the summaries that were created for the purposes of this section.

When it comes to automated summaries, ROUGE is often regarded the gold standard. Rouge contrasts the summaries produced by machines with the summaries created manually (reference summaries). ROUGE-1, ROUGE-2, and ROUGE-L summaries are evaluated at various levels of granularity, giving findings in terms of Precision (P), Recall (R), and F-score (F). For evaluation, ROUGE-1 is used and the results articulated in the following tables are for ROUGE-1. The results of the proposed model on DUC 2007 dataset are articulated in the Tables IV, V and VI.

TABLE IV. AVERAGE F-SCORE ROUGE SCORE VALUES AT COMPRESSION 5% , 15%, 25% RATES

Measure	ROUGE Score (5%)	ROUGE Score (15%)	ROUGE Score (25%)

When compared to the literature, our experimental data has shown that our suggested strategy outperforms the state-of-the-art methodologies, which we feel is important. According to the findings, Table IV further demonstrate that the average Recall values across a variety of variables improve as a consequence of increasing the length of the summary, as can be seen in the tables. Because our model's recall is lower in certain places than it is in others, it is possible that this is due to either a shorter summary or the removal of statistically important characteristics from the model's development process throughout its development. Following an increase in the compression rate from 5 percent to 25 percent, the macro-average F-score values decline somewhat as a consequence of a reduction in the overall accuracy score of the different metrics when the compression rate is raised, according to the study's findings.

However, when comparing the Macro-Averaged F-score values at 22 percent and 23 percent compression rates to the comparative models, as shown in Tables IV, V and VI, the difference is not statistically significant; the difference between the two models is not statistically significant. This demonstrates that the approach given is competitively efficient when compared to the current state of the art. In Table VI, it is shown that, when constructing an average length summary at a 25 percent compression rate, the suggested technique may result in a summary that is more informative than comparison models in certain cases.

This section presented the results of the proposed model and proposed hybrid semantic similarity on word pair similarity and DUC 2007 datasets. The presented results show the efficiency of the model.

## V. CONCLUSION

In light of the vast amount of textual information that is now available, automated extraction text summarization is one of the most widely used methods of organising the data available. Summary techniques make it possible to extract the most important information from a large number of texts in a short amount of time and with minimal effort. When summarizing a text, an extractive summarization method is used that selects the most relevant phrases from the text and presents them in a way that is accurate representation of the text in its entirety. Information extraction systems that extract

information from a large number of documents, such as text summarizing systems, have as their primary objective the reduction of textual information in a document collection. Achieving this is accomplished by concentrating on the most important themes and eliminating any unnecessary information. When it came to developing an automated summary system, the previous study discovered that a variety of strategies, including term-weighting schemes and similarity metrics, were used in the process of development. Currently, there is only a small body of research that examines how different Semantic Similarity and word weighting algorithms perform when used in conjunction with one another in the field of automated text summarization. This study looked at a number of different semantic similarity metrics in the context of extractive multi-document text summary, and we discovered that they were all fairly accurate in terms of similarity. This research looked into different semantic similarity metrics that could be used in extractive multi-document text summarization, and the results were published. Various ROUGE criteria were used to evaluate the model's performance in this study, which was carried out using DUC dataset. When the results of the various semantic similarity metrics were combined, the resulting model produced the most favourable results when compared to the other models in this study.

**Abstract**—Gender-based violence is a public health issue that needs high concern to eliminate discrimination and violence against women and girls. Several cases are through the offline organization and the respective online platform. However, many victims share their experiences and stories on social media platforms. Twitter is one of the methods for locating and identifying gender-based violence based on its type. This paper proposed a hybrid Long Short-Term Memory (LSTM) and Convolution Neural Network CNN with GloVe to perform multi-classification of gender violence. Intimate partner violence, harassment, rape, femicide, sex trafficking, forced marriage, forced abortion, and online violence against women are eight gender violence keyword for data extraction from Twitter text data. Next is data cleaning to remove unnecessary information. Normalization converts data into a structure the machine can recognize as model input. The evaluation considers cross-entropy loss parameters, learning rate, an optimizer, and epochs. LSTM+GloVe vector embedding outperforms all other methods. CNN-LSTM+Glove and LSTM-CNN+GloVe achieved 0.98 for test accuracy, 0.95 for precision, 0.94 for recall, and 0.95 for the f1-score. The findings can help the public and relevant agencies differentiate and categorize different types of gender violence through text. With this effort, the government can use as one of the mechanisms that indirectly can support monitoring of the current situation of gender violence.

**Keywords**—Gender-based violence; deep learning; convolution neural network; long short-term memory; convolution neural network - long short-term memory; long short-term memory - convolution neural network; global vector; multi-class text classification

## I. INTRODUCTION

GBV is a worldwide public health concern [1]. GBV refers to any violence toward any individual because of the individual's gender [2]. One-third of women have experienced sexual or physical violence [3]. GBV is a type of violence perpetrated against women and girls. It can physically, sexually, and mentally injure women and girls through violence, compulsion, or arbitrary denial of liberty. The Sustainable Development Goals sought to eliminate gender discrimination and violence against women and girls [4]. As a result, everyone should feel safe at home or in public, especially women who may be victims of violence.

For example, an actress, resorted to social media to expose her experiences with sexual harassment in Hollywood. The public's focus on this issue has increased awareness of GBV, particularly sexual harassment [5]. Meanwhile, a Malaysian woman resorted to Twitter to complain about harassment using an e-hailing service [6]. These stories raise public consciousness. However, online social media allows disaffected people to control specific people's lives and utilize the anonymity or social distancing afforded by the internet to harass others [7]. Sexting the other sex, for example, is one of the most divisive issues on social networking. The evidence leads to sexual harassment and mental health problems [8].

People who seek to harass women and advocate violence against women can do so anonymously through social media platforms [9]. This campaign primarily targets female public figures, including politicians, journalists, and public figures [10]. Consequently, measures must be taken to address the seemingly endless instances of gender-based violence. Additionally, domestic violence instances are underreported, with the police, the health care system, and non-governmental organizations saying that just 7 percent of victims sought assistance from these institutions [11]. The principal perpetrators face stigma and societal pressures [12]. The fifth Sustainable Development Goal (SDG) seeks to eliminate all types of prejudice and violence. As a direct consequence of this, these challenges require attention.

Social media to collect data for a study on gender violence. On the other hand, a study utilizing 0.7 million tweets and a deep learning system discovered that sexual assaults are more likely to be performed by someone who knows than by someone who does not know [13]. Researchers also used Twitter data to construct a detection tool for sexual harassment and cyberbullying using machine learning and frequency inversion document frequency (TF-IDF) [14]. In addition, one study analyzed patient anecdotes about their healthcare experiences using topic modeling with Latent Dirichlet Allocation (LDA) and sentiment analysis on Twitter data [15]. As a result, this research aims to conduct a text classification that can separate the meaning of GBV-related text content. This study improves the current method for managing violent content on social media, namely the detection of Gender-Based Violence.

The following are the significant contributions of the subsequent paper:

- This study data collection is from Twitter, the public data on social media related to gender violence issues during the Covid-19 pandemic from January 01, 2022, until April 01, 2022, worldwide.
- The proposed model of deep learning classifier Convolutional Neural Network-Long Short-Term Memory with GloVe (CNN-LSTM+GloVe) and LSTM-CNN+GloVe applies to sentiment analysis for gender violence.
- The comparative analysis of different deep learning and hybrid classifiers with the suggested model verifies its performance.

The section is organized in the following manner throughout the rest of the paper: Section II goes over the connected works. The materials and methods are in Section III. Section IV presents the results of the experiment. The discussion offered in Section V and Section VI constitutes the study's conclusion.

## II. RELATED WORKS

A text categorization method is a supervised machine learning in which unstructured text assign to specified categories. Text categorization aids in the organization, structuring, and classification of text documents such as Twitter data, news articles, and medical records. The process of text classification is appropriate for extracting new information from a textual source [16]. The study looks at how text classification identifies gender violence as one of the text's features. They seek occurrences of violence in social media data using text categorization in Arabic dialect. One of the objectives of this study will be to evaluate different text classification methods. This study uses supervised machine learning techniques such as support vector machine (SVM), K-nearest neighbors (KNN), and Bayesian boosting with complement naive Bayes to extract information from 700,000 tweets. The hashtag #Metoo appears in these messages. According to him, there is a scarcity of studies that use Arabic for data analysis. As a result, additional research is required.

Using text classification algorithms, investigating domestic violence in intimate relationships to grasp the clinical importance of the victim is better accomplished by using a technique known as a "word cloud," which sorts text based on Python scripts [17]. This study's primary source of information was the Rio Grande do Sul Legal Medical Department. Based on the findings of this study, they concluded that using a word cloud to assess a variety of topics presented by participants was feasible. Despite this, they emphasized the need for more

significant research into the applicability of these techniques [18]. According to their research findings, this work recognized GBV messages on social media using BERT and NLP. This study evaluates the material to determine whether it was aggressive or peaceful.

The researchers discovered that after incorporating a preprocessing step in the initial dataset, the area under the curve, accuracy, sensitivity, and specificity for a total of 16421 messages were, respectively, 0.9603, 0.8909, 0.8826, and 0.8989. Overall, their findings indicated that the categorization performance of their text dataset was satisfactory [18]. A study that used the Latent Dirichlet Allocation method on Twitter data produced roughly 56% coherence and 18 ambiguities [19]. The coherence and complexity scores look to be excellent, but there is an opportunity for development to attain even higher outcomes. Based on the findings, it can be inferred that many studies on gender violence and social media have been conducted. One connected study uses gender violence data from Twitter to classify the corpus using text classification based on previously labeled data.

Furthermore, Khatua et al. used Twitter data to build a multilayer perceptron (MLP), convolutional neural network (CNN), long short-term memory (LSTM), and bidirectional LSTM, all of which are similar to the approaches outlined in this study (Bi-LSTM) [13]. Their study examined the many types of sexual violence and the associated hazards. Between October 15, 2017, and October 26, 2017, they collected 0.7 million tweets using the hashtag #Metoo. CNN, LSTM, and bi-LSTM achieve precisions of 0.83, 0.82, and 0.81 during the text classification process, whereas MLP achieves a precision of 0.77. CNN has the highest accuracy of the four algorithms; moreover, all have an accuracy of less than 0.90, improving with ongoing research. CNN has the highest level of accuracy. According to the text categorization research, it is conceivable to undertake an additional study on deep learning algorithms such as CNN, LSTM, and the hybrid LSTM-CNN technique.

## III. MATERIALS AND METHODS

This section describes the study's structure, method, and procedure. A few steps of this work adapted Offer's approach [20]. This study methodology includes data collection, preprocessing, feature extraction, and modeling. Twitter text data is scraped using Twitter Intelligence Tool (Twint). After scraping, the dataset is preprocessed to remove text noise. The training set will be labeled by GBV dataset. The dataset is then used to generate training and testing sets. The model's training process uses the CNN, LSTM, and LSTM-CNN machine learning algorithms. If a text does or does not contain GBV can be predicted using the testing set, which is not labeled. The conceptual framework for the research is shown in Fig. 1.

Fig. 1. Research Framework.

A. Data Preparation

This section briefly explains the steps in data preparation, including data acquisition, data labeling, data merging, manual observation, filtering, and stopwords.

1) *Data acquisition*: In this phase, the research data scrape from the web. We use Twitter Intelligence Tools (Twint) to extract tweets based on a keyword. It is a Python web scraping program that allows users to scrape tweets without limitations, considering that it does not use Twitter. This research requires many documents or results relating to Twitter's unlimited API, which only delivers 3200 tweets each. An open-source tool with various features. The total data gathered for each category of gender violence are 300000. The keyword used to extract the data is in Table I. We determined eight categories of GBV, which are domestic violence, sexual harassment, rape, femicide, sex trafficking, forced marriage, forced abortion, and female genital mutilation [21][22].

2) *Data labeling*: Labeling annotates every tweet in the dataset with appropriate classes. All tweets in the dataset into eight GBV classifications to create multi-class data.

3) *Data merging*: Data merging involves combining the obtained datasets into a single dataset from eight datasets representing eight categories of GBV.

4) *Manual observation*: Recall (R) is a combination of all objects grouped into a specific class. The formula of recall is in Eq. 4.

TABLE I. TYPE OF GBV BASED ON KEYWORDS

Class	Keywords
Domestic Violence	Intimate partner violence, domestic violence, domestic abuse
Sexual Harassment	Sexual harassment, harassment, stalking
Rape	Rape, rape culture, corrective rape
Femicide	Femicide, femicide, honor killing, honour killing
Sex Trafficking	Sex trafficking
Forced Marriage	Forced marriage, child marriage
Forced Abortion	Forced abortion, forced sterilization, coerced sterilization, unwanted sterilization, forced miscarriage
Female Genital Mutilation	female genital mutilation, female circumcision, female genital cutting

Manual observation can refer to an individual's observation of certain things or works. Typos or grammatical errors and Unwanted data from the dataset may include text report articles and duplicated content. Meanwhile, features such as location, language, mentions, and URLs are unimportant to the research because they provide no meaningful information or value to the study.

5) *Filtering*: Several undesired things inside the phrases during the manual observation procedure can be deemed noise to the dataset. As a result, the filtering process will remove all of the extraneous noise within the corpus, such as emojis, URLs, mentions, and hashtags. It is necessary to lower the dataset dimensions and improve the learning process.

6) *Stopwords*: Stopwords are commonly used in a text mining project with little influence [23]. "The", "A", "Is," and "Are" are stop words. Stop words removed to lower the document's high dimensionality and computing time. Before filtering, each data set had 107 words; after, it had 52. Fewer words will lead to a faster calculation.

### B. Data Normalization

Before the dataset can be applied to the deep learning model, it must undergo a data normalization procedure. It is to verify that the dataset is in the same format or condition, particularly for text data, which will be the primary component of the training process. The four primary processes are the word indexing procedure, padding, word embedding, and one-hot encoding in this study's dataset.

1) *Word indexing*: As the machine does not understand words, it converts them to integers. This study uses Keras library functions fit on texts and sequence on texts.

2) *Padding*: This study used padding to standardize each dataset's text data length. Due to the dataset's varied text lengths, this procedure is essential so that it may be model input. First, we require the dataset's maximum length. Set all text properties to the same length.

3) *Word embedding*: This study uses GloVe embedding to perform a pre-trained word-vector model. The GloVe has educated 2 billion tweets and 1.2 million vocabularies. (R) is a combination of all objects grouped into a specific class. The formula of recall is in Equation 4.

4) *One-Hot encoding*: Each tweet's class attribute is hot encoded. It converts categorical data into 1 and 0 classes. 1 represents this category, 0 otherwise.

### C. Splitting Datasets

The training dataset comprises 80% of the total, whereas the testing dataset will comprise 20%. This project employs supervised learning. As a result, we require validation.

### D. Proposed Model

In this phase, constructing and implementing a deep learning model will be done. The deep learning model that will be used is the convolutional neural network (CNN), long-short term memory (LSTM), LSTM-CNN, and CNN-LSTM. Thus, in this section, the model's architecture will be discussed. Fig. 2 illustrates the model architecture for all four models.

1) *CNN*: CNN's deep learning model is popular. Fig. 2 shows that the model will accept input at the embedding layer.

The convolution layer extracts features and generates feature maps. The pooling layer shrinks feature maps. The first dense layer utilized the "relu" activation function, second layer used "softmax" Output is text type or topic prediction. In this design, the embedding layer translated input into embedding vectors before delivering them to LSTM. Each LSTM cell in the LSTM layer took each embedding vector, determined the relevant information, and formed a new encoding vector. Two dense layers would assist in increasing the class categorization based on input vector attributes. The first dense layer utilized the "relu" activation function. The second layer used the "softmax".

2) *LSTM*: In this design, the embedding layer transformed the input into a sequence of embedding vectors before sending them to the LSTM layer. Each LSTM cell in the LSTM layer took each embedding vector, selected the critical information that needed to be maintained, and then generated a new encoding vector based on the previously stored information. Two dense layers to improve class categorization based on the features gathered from the input vectors. The first dense layer utilized the activation function "relu," while the second layer used the activation function "softmax" to predict the output.

3) *Hybrid CNN-LSTM*: In this setup, initially, the embedding layer converted the input phrases into embedding vectors. Once the embedding vector is received, the convolution layer produces feature maps by extracting features. The pooling layer will help to reduce the feature maps. Next, the LSTM layer took the output of the convolutional layer and selected the critical information to be maintained. Then a new encoding vector based on the previous information will be stored. Lastly, two dense layers will help to improve the class categorization. (R) is a combination of all objects grouped into a specific class. The formula of recall is in Equation 4.

4) *Hybrid LSTM-CNN and CNN-LSTM*: In this configuration, the embedding layer first turned the input phrases into embedding vectors before the model could begin to run. After receiving each embedding vector, the LSTM layer learned the words in order, stored them, and created a new encoding vector. The convolution layer processes the output and creates a series of feature maps, which are subsequently combined by the pooling layer. Two dense layers increase class categorization based on input vector attributes. The first dense layer employed "relu" and the second layer considered a dataset to predict the output. As a result, the training dataset is divided by 9:1, with 90% remaining as training and 10% retraining and validation. Fig. 2 illustrates the overall model architecture of CNN, LSTM, CNN-LSTM, and LSTM-CNN models. (R) is a combination of all objects grouped into a specific class. The formula of recall is in Eq. 4.

Fig. 2. Model Architecture.

### E. Model Evaluation

Supervised learning involves training and testing to find the optimum model for training accuracy, loss, and computational time confidence. Total predictions divided by accurate predictions is model accuracy. Accuracy increases model performance. Equation (1) calculates accuracy. (R) is a combination of all objects grouped into a specific class. The formula of recall is in Equation (4).

$$accuracy = \frac{\text{Number of Correct Predictions}}{\text{Total Number of Predictions}} \quad (1)$$

Loss is the difference between the actual value of the issue and what the model forecasts. The less accurate the model, the more significant the loss. A categorical cross entropy function calculates loss. Thus, Eq. (2) shows loss evaluation.

$$Loss = -\sum_{i=1}^{\text{output size}} y_i \times \log \hat{y}_i \quad (2)$$

where output size is the number of scalar values in the model output,  $y_i$  is the goal value, and  $\hat{y}_i$  is the  $i$ -th scalar value in the model output. A testing technique predicts the trained model's correctness to determine its accuracy. After the modeling phase, CNN, LSTM, and hybrid LSTM-CNN performance will be evaluated. Precision, recall, and f1-score can evaluate text classification performance [24]. Precision (P) estimates the ratio of the true positives among the cluster. The formula of precision is in Eq. 3.

$$Precision = \frac{\text{True Positive}}{\text{True Positive} + \text{False Positive}} \quad (3)$$

Recall (R) is a combination of all objects grouped into a specific class. The formula of recall is in Eq. 4.

$$Recall = \frac{\text{True Positive}}{\text{True Positive} + \text{False Negative}} \quad (4)$$

F-measure (F) is a combination of precision and recall that measures the cluster that contains only objects of a particular class and is used to balance false negatives by weighting recall parameter  $\eta \geq 0$ . The formula of the F-measure is in Eq. 5.

$$F\text{-measure} = \frac{(2 \times \text{Precision} \times \text{Recall})}{(\text{Precision} + \text{Recall})} \quad (5)$$

To calculate these performance indicators, we need a confusion matrix of the model. True positive (TP) describes how well the model predicts the class. True negative (TN) means the model predicts it to be false. False positive means the model inaccurately predicts the true statement or class, while false negative means the opposite. The illustration is different in a multi-class classification with more than two labels. Thus, Fig. 3 depicts a confusion matrix with more than two classes [24].

		Predicted Class			
		C <sub>1</sub>	C <sub>2</sub>	...	C <sub>N</sub>
Actual Class	C <sub>1</sub>	C <sub>1,1</sub>	FP	...	C <sub>1,N</sub>
	C <sub>2</sub>	FN	TP	...	FN
	...	...	...	...	...
	C <sub>N</sub>	C <sub>N,1</sub>	FP	...	C <sub>N,N</sub>

Fig. 3. Multi-class Confusion Matrix.

#### IV. EXPERIMENTAL RESULTS

##### A. Datasets

The experiment used Twitter text as primary data based on the eight gender violence categories. The total tweets extracted are 103 197 English tweets from around the world. The dataset has undergone data preprocessing and cleaning, including manual observation, filtering, stop word removal, and normalization. After preprocessing and cleaning, there were 85,697 tweets. The class attributes in this dataset need to be balanced. This dataset is homogeneous as it only contains string values after preprocessing and cleaning.

##### B. Parameter Settings

This subsection explains CNN, LSTM, CNN-LSTM, and LSTM-CNN model parameters. Four models employ essentially constant parameters. The complete experiment's embedding dimension is 100 since the GloVe pre-trained embedding dimension is 100. The data set shows 61766 words. However, we account for one vacant space. The long sentences in the dataset are 42 words; hence in this experiment, the maxlen parameter is set at 42. CNN has 100 filters. LSTM's hidden layer is 100. Max Pooling is utilized as the pooling layer because it is frequent in deep learning models. This research will implement two dense layers: the first will employ 100-dimensional Relu activation, while the second will use 8-dimensional Softmax activation. Next, we use Adam as the model's optimizer with a learning rate of 0.0003. Set 20 epochs. Table II lists parameters.

TABLE II. PARAMETER SETTING

Parameter	Parameter Value
Embedding Dimension	100
Number of words (unique)	61767
Maxlen	42
Pooling	Max Pooling
Dense (1)	Activation = 'relu', dimension = 100
Dense (2)	Activation = 'softmax', dimension = 8
loss	categorical_crossentropy
Learning rate	0.0003 @ 3e-4
optimizer	Adam
Validation split	0.1
Epoch number	20
Word embedding	With GloVe and without embedding

##### C. Experimental Results

The study features two experiments using GloVe and without GloVe. The analysis will be based on experiments on

the four models, comparing their performance in training and testing.

1) *Training result without GloVe*: The accuracy and loss learning curves of the CNN, LSTM, LSTM-CNN, and LSTM-CNN are depicted in Fig. 4(a), (b), (2), (d), (e), (f), (g), and (h). LSTM, as shown in Fig. 4(c), has the smallest gap in accuracy and measurement compared to other models. The same result for loss value. The hybrid LSTM-CNN and CNN-LSTM, on the other hand, outperform a single CNN in terms of accuracy. LSTM has training and validation accuracy of around 0.3418 to 0.9995 and 0.6412 to 0.9781, respectively, while training and validation loss is 0.3031-0.049133. and 0.1823 to 0.0287.

Fig. 4. Learning Curves Graphs (a) Accuracy for CNN (b) Loss for CNN (c) Accuracy for LSTM (d) Loss for LSTM (e) Accuracy for LSTM-CNN (f) Loss for LSTM-CNN (g) Accuracy for CNN-LSTM (h) Loss for CNN-LSTM.

2) *Testing results without GloVe*: Table III displays the testing performance of the models using the confusion matrix accuracy and loss measure of the multi-classes Twitter text data. Overall, all models receive a comparable categorization score. This demonstrates that for most classes, the TP value is more notable than the FP and FN scores, except for the femicide class, whose TP and FP+FN scores are comparable. Overall, CNN and LSTM memory scores for domestic violence and rape are 0.99, whereas femicide scores are 0.80. The f1 score for domestic violence, rape, and sex trafficking is 0.99. TP is superior to FP and FN for both CNN-LSTM and LSTM-CNN. Overall, the model achieves an accuracy of 0.981 with a loss of 0.039 on the testing dataset. According to the model, sex trafficking, sexual harassment, and femicide had an

accuracy of 0.99 and 0.85, respectively. Domestic violence and rape have a recall rate of 0.99, while femicide is 0.77. The f1 score for domestic violence, rape, and sexual harassment was 0.99.

On the testing dataset, CNN's femicide class achieves a precision of 0.982% with a loss of 0.048. According to the model, forced abortion has a precision of 1.00, while femicide has a precision of 0.78. However, the femicide class has the fewest records in the test dataset of 235. This class yields comparable results for LSTM, CNN-LSTM, and LSTM-CNN models. Based on the test set, we can predict that the label with the most significant number of datasets will have the highest scores for performance metrics.

TABLE III. RESULT OF CNN, LSTM, CNN-LSTM, AND LSTM-CNN WITHOUT GLOVE

Label	CNN+GloVe						LSTM+GloVe						LSTM-CNN+GloVe						LSTM-CNN+GloVe					
	P	R	F1	S	Loss	Acc	P	R	F	S	Loss	Acc	P	R	F1	S	Loss	Acc	P	R	F1	S	Loss	Acc

Sexual Harassment	0.98	0.98	0.98	5041			0.98	0.98	0.98	5041			<b>0.99</b>	0.98	<b>0.99</b>	5041			0.99	0.97	0.98	5041		
Average	0.96	0.94	0.95	1678	0.94	0.94	0.94	1678	0.96	0.94	0.95	1678	0.93	0.94	0.94	1678								

3) *Training result with GloVe*: The training results for CNN+GloVe, LSTM+GloVe, LSTM-CNN+GloVe, and CNN-LSTM+GloVe models are in Fig. 5(a)-5(h). Fig. 5(a) depicts CNN's training accuracy over 20 epochs. The models' training accuracy ranges from 0.8923 to 1.0000, and validation from 0.9595 to 0.9756. It suggests a positive pattern in which both the training and validation sets produced strong results, but there is a significant generalization gap between the two sets. The training loss ranges from 0.0798 to 0.000046438. Fig. 5(b) shows that the validation loss began at 0.0333 and stopped at 0.0394.

Fig. 5(c) shows that the LSTM+GloVe training accuracy is 0.6558 to 0.9906, and its validation accuracy is 0.9146 to 0.9830. It suggests a positive pattern in which the training and validation sets produced good results with a small generalization gap. It is worth noting that the training loss begins at 0.1888 and finishes at 0.0064. The validation loss started at 0.0561 and terminated at 0.0127. According to the data and graph in Fig. 5(d), training and validation loss exhibit a decreasing pattern with a minimal generalization gap at the end of training. In terms of training and validation accuracy and loss pattern, the LSTM-CNN+GloVe and CNN-LSTM+GloVe appear to follow a similar trend. LSTM-CNN+GloVe, on the other hand, offers training accuracy that starts at 0.9141 and ends at 0.9994, while validation accuracy starts at 0.9607 and ends at 0.9815. It suggests a positive pattern in which both the training and validation sets produced good results, and there is a large generalization gap between the two sets. The training loss ranges from 0.0582 to 0.00069372. The validation loss started at 0.0267 and finished at 0.0265. Training loss shows a decreasing pattern based on the data and graph. However, validation loss shows an increasing tendency. CNN-LSTM+GloVe produced comparable results.

Table IV shows that the CNN+GloVe's accuracy is 0.976 with a loss of 0.040. Domestic abuse and sex trafficking have the highest precision (0.99), whereas femicide has the lowest (0.62). On recall, domestic violence has 0.99, and femicide is 0.63. The f1-score gives domestic violence 0.99. LSTM shows that the model achieves a 0.983 accuracy value with a 0.013 loss on the testing dataset. The model's average precision value is 0.95, with most labels achieving 0.99 and femicide showing 0.72. For recall, almost all labels score above 0.94, where 0.99 is the highest and 0.68 is the lowest, where seven out of eight label f1 scores average 0.95.

LSTM-CNN+GloVe and CNN-LSTM+GloVe have acceptable results since the TP value is more than FP and FN. FP and FN are higher than TP for just femicide. Table IV indicates that the model achieves a 0.981 accuracy value with a 0.039 loss. The model finds that the average precision value is 0.94, with forced abortion achieving the highest precision (1.00) and femicide the lowest (0.60). Most labels indicate a positive recall above the average of 0.95, where the highest score has been 0.99 and the lowest is 0.73. Seven of eight label ratings are above average for the f1-score (0.94). Meanwhile,

the lowest performance is the femicide since it is the one that has the least number of test datasets with only 235 records.

4) *Results based on computational time*: Table IV demonstrates the computational time that was recorded from the highest training accuracy and loss value. CNN+GloVe, LSTM+GloVe, LSTM-CNN+GloVe, and CNN-LSTM+GloVe recorded more than one hour compared to the models without GloVe. The minimum computational time consumed by CNN+GloVe of about 9 minutes and 10 s; meanwhile, the maximum is LSTM-CNN of about one h 59 min 27 s.

Fig. 5. Learning Curves Graphs (a) Accuracy for CNN+GloVe (b) Loss for CNN+GloVe +GloVe (c) Accuracy for LSTM (d) Loss for LSTM+GloVe (e) Accuracy for LSTM-CNN+GloVe (f) Loss for LSTM-CNN +GloVe (g) Accuracy for CNN-LSTM+GloVe (h) Loss for CNN-LSTM+GloVe.

## V. DISCUSSIONS

This study finds that the LSTM model using the GloVe word embedding pre-train model delivers the best results after extensive training and testing. To classify the model's output, the following parameters were used: a 100-layer LSTM hidden layer, a max pooling layer, a relu activation function used at the first dense layer and a softmax activation function on the second dense, a learning rate of 0.0003 with the Adam optimizer, and a total of 20 epochs. Metrics such as the gap between the two sets, the accuracy of both sets, and the precision, recall, and f1-score value reveal differences between the training and testing sets.

The gap between the two measures of accuracy, training, and validation, narrows to a reasonable level during model training. In comparison, other models' validation accuracy becomes linear after a few epochs, although training accuracy is substantially higher. Another model has been overfitted, but because the FP is the measure, the LSTM has very little overfitting. Furthermore, during the testing phase, the LSTM with the GloVe embedding word had the maximum consistency across all three performance parameters. It is supported by the capability offered by GloVe [25].

Furthermore, the data with the fewest labels has the lowest precision, recall, and f1 score. Throughout the experiment, the femicide-labeled data has the lowest precision, recall, and f1-score. Most labels usually result in the best accuracy, recall, and f1-score.

All models with and without GloVe test findings are elaborated. Deep learning models can effectively categorize tagged text without using a pre-trained GloVe. The accuracy of CNN is 0.982, followed by LSTM-CNN of about 0.981, and then LSTM is 0.980. Although the dataset was unbalanced, the model nevertheless achieved respectable levels of accuracy. The outcomes ranged from 0.94 to 0.96. According to the study's preliminary settings, all GloVe-based models perform admirably on the testing set. Tagging is not required to succeed in a deep learning system that does not use a pre-trained GloVe as a word embedding model. In terms of accuracy, LSTM+GloVe is superior to CNN+GloVe, CNN-LSTM+GloVe, and LSTM-CNN+GloVe at 0.983. The model's accuracy, recall, and f1-score are all within an acceptable range 0.92 to 0.95 despite using an unbalanced dataset.

Furthermore, when comparing standard word embedding to GloVe's pre-trained word embedding, deep learning models using GloVe show significant improvement, particularly in computing time. When GloVe word embedding is not utilized, the computational time for all three models combined exceeds an hour: 1 hour 27 minutes for the CNN model, 1 hour 40 minutes for the LSTM model, and 1 hour 59 minutes for the LSTM-CNN model. When employing GloVe word embeddings, the CNN model takes 9 minutes, the LSTM model 44 minutes, and the LSTM-CNN model 33 minutes to compute.

All models that classify femicide class have produced the lowest result in precision, recall, and f1-score. This could be because the femicide class has the lowest data among all the classes. Meanwhile, the largest class, such as domestic

violence, sexual harassment, and rape, tend to have the highest precision, recall, and f1-score. More research on multi-class text classification is required to obtain a better result [26].

## VI. CONCLUSIONS

This research compares machine learning models that utilize the GloVe and without GloVe embedding methods to see if there is an improvement in text multi-classification problem-solving. The proposed hybrid LSTM-CNN and CNN-LSTM with GloVe and without GloVe can classify the multi-class text. However, the experimental results prove that the effectiveness, capability, and efficiency of the LSTM-CNN and CNN-LSTM with GloVe significantly improved the multi-class performance in GV tweet data compared to those without GloVe. It is also better than a single CNN and LSTM in terms of accuracy. It can be said that the hybrid solution and embedded GloVe have demonstrated a reduction in computational time. Thus, it is expected that the hybrid LSTM-CNN and CNN-LSTM with GloVe can be used in other domains. In the future, evaluating the tweet text data from a different domain and considering larger multi-class datasets are recommended.

## ACKNOWLEDGMENT

The authors would like to acknowledge Institute for Big Data Analytics and Artificial Intelligence (IBDAAI), Universiti Teknologi MARA, for the financial support provided to this research project.

**Abstract**—For years, humans have pondered the possibility of combining human and machine intelligence. The purpose of this research is to recognize vehicles from media and while there are multiple models associated with this, models that can detect vehicles commonly used in developing countries like Bangladesh, India, etc. are scarce. Our focus was to assimilate the largest dataset of vehicles exclusive to South Asia in addition to the more common universal vehicles and apply it to track and recognize these vehicles, even in motion. To develop this, we increased the class variations and quantity of the data and used multiple variations of the YOLOv5 model. We trained different versions of the model with our dataset to properly measure the degree of accuracy between the models in detecting the more unique vehicles. If vehicle detection and tracking are adopted and implemented in live traffic camera feeds, the information can be used to create smart traffic systems that can regulate congestion and routing by identifying and separating fast and slow-moving vehicles on the road. The comparison between the three different YOLOv5 models led to an analysis that indicates that the large variant of the YOLOv5 architecture outperforms the rest.

**Keywords**—*You Only Look Once (YOLOv5); vehicle detection; neural network; deep learning; vehicle tracking*

## I. INTRODUCTION

Advancements in automobile manufacturing have given rise to more affordable cars which has resulted in over five million registered vehicles [1] coasting through the roads of Bangladesh. Road infrastructures in this country were not designed to hold the growing number of vehicles which presents grave environmental and health concerns. Given the circumstance, congestion is inevitable, and this significantly contributes to the rising air and noise pollution levels in the city. To circumvent this obstacle, restless drivers resort to maneuvering chaotically without any regard to traffic rules and are thus responsible for most of the road fatality cases in the country. One of the biggest obstacles is that traditional methods of prevention such as traffic lights and pedestrian crossings are not sufficient because they are generally ignored.

To address this issue, an intuitive system is needed to observe traffic patterns and direct different vehicles into proper lanes. Most vehicles in South Asia are very different than those in the western world as they differ drastically in shapes, sizes, and colors. This is a major challenge the algorithm will face [2]

as it needs to differentiate between these vehicles to identify them individually. The height and angle at which these vehicles are posed and captured also factor into this problem. Datasets that include traditionally used South Asian vehicles are scarce and do not contain the required amount of data which presents a separate challenge. Due to the erratic nature of traffic in South Asian countries, different CNN models that are usually tested in other environments have not been applied enough to see how they perform in the tumultuous streets of cities like Dhaka. A major challenge of our research is that we have had data scarcity, particularly for south Asian vehicles.

Machine learning has progressed enough to make use of traffic cameras [3] to track vehicles and their patterns. Additionally, using Neural Network-based Object Detection can produce valuable tracking and surveillance data that could be essential to coming up with a solution to the traffic problem. Further applications in the division of slow- and fast-moving vehicles and the identification of missing vehicles can also be pursued through Deep Learning. Smart traffic systems [4] can utilize these applications to reduce mishaps while also improving the flow of traffic. Autonomously driven cars [5] can also employ the previously mentioned applications to avoid different vehicles, clogged roads, and potential accidents while on the road.

However, one of the key difficulties in using machine learning algorithms is the requirement of a vast amount of data to train a model. In this research, we develop a sizable vehicle dataset from scratch and train a model to accurately recognize them. The intention was to set our work apart from conventional vehicle detection systems. Our research is distinctive in that we have curated a dataset consisting of 21 classes of vehicles commonly available worldwide and those that are only seen in South Asian regions. Unique vehicles like rickshaws, human haulers, three-wheelers, etc. all vary in build and proportion. The collected images are put through a lengthy process of cleaning, augmenting, and finally labeling through bounding box annotations. To address the data scarcity issue, we used different augmentation techniques to balance the dataset. This is done to ensure we have enough data for accurate testing and training. We chose a well-known object detection algorithm called YOLOv5 (You Only Look Once) [6] to use in our model for training and we compared the

\*Corresponding Author.

performance of different architectures of YOLOv5 models: Small, Medium, and Large. Previous versions [7] were an option but the new update presented a more efficient and time-saving alternative. YOLOv5's hyperparameters are tweaked to accurately detect objects in real-time through bounding box coordinates of objects from the carefully labeled data it has been trained with. This model will be able to recognize different native vehicles which can then be used in systems to reduce the traffic problem that plagues South Asian cities.

## II. LITERATURE REVIEW

The subject of object detection has attracted attention from various independent researchers over the years. Different detection systems were used over the years for identifying objects. LIDAR (Light Detection and Ranging) was used in the form of sensors attached to both vehicles and certain points of the road to detect oncoming vehicles [8]. Other non-intrusive methods like ASFF (Adaptive Spatial Feature Fusion) [9] and Radar Sensors [10] were also used. The interest in this field and its innovations date back to the 1970s [11].

Object detection [12] by the camera has become more prevalent in recent years and more accurate and cost-effective than other sensors. To accurately identify vehicles, real-time detection speed and high accuracy are required for a quick response to fast-moving vehicles and to get a reduced latency. While most algorithms repurpose classifiers by taking images at multiple scales and locations and applying the algorithm to perform detection [13], YOLO applies a neural network that dissects an image into different parts and can predict bounding box regions based on predicted probabilities [14]. YOLO detects objects using a single inference which makes it faster than its peers, SSD (Single Shot Detector) and Faster R-CNN (Region-based Convolutional Neural Network) [15].

Research by Liu & Zhang [16] aimed to improve the standard YOLOv3 model by training it to adapt to actual traffic conditions and applying a scale prediction layer to improve the detection accuracy of large vehicles. They use the k-means++ algorithm to improve the efficiency of the anchor box dimension clustering as shown in Fig. 1. The resulting F-YOLOv3 algorithm clocked in at 91.12% on the mAP (Mean Average Precision) accuracy scale beating out Faster R-CNN at 90.01% and base YOLOv3 at 78.68%. The recognition performance of large vehicles is poor when compared to small vehicles because of their contrasting characteristics.

Fig. 1. Anchor Box Dimension Clustering [16].

Redmon [17] suggested the integration of classification and localization into a single convolutional neural network which would improve the speed at the cost of precision. While it achieves a combined accuracy of 75.0%, the model has difficulty in detecting smaller grouped objects due to the spatial constraints imposed by YOLO and objects in different aspect ratios. Chandan suggested a different approach [18] where he opted to use OpenCV to detect objects in a python environment with the assistance of the Single Shot Detector algorithm. This algorithm used optical flow and background subtraction to achieve an optimal accuracy in detecting standard vehicle classes and this was a great basis for comparison with the earlier versions of YOLO. A detection system for localized mobile environments like roads and railways was made by Chen [19]. Using the same COCO dataset, they compared YOLOv3, and the Single Shot Detector mentioned above to find their efficiency and applicability in traffic. It was found that YOLOv3 had attained an 85% score over SSD's 79.5% in terms of mAP at high resolution. A more recent comparison of YOLOv4 with SSD and Faster R-CNN was conducted by Kim [20] for real-time vehicle detection. After evaluating the different models, it was observed that YOLOv4 performed at 98.1% precision while Faster R-CNN and SSD performed at 93.4% and 90.5% respectively.

Phillips suggested a system [21] for distance estimation between vehicles in traffic to avoid collision by mounting a monocular camera to a vehicle dashboard. It is fitted with systems for object tracking and detection and is modular enough to switch out systems for other uses. Errors in estimation increase as the distance increases. Wang has used edge Detection technology [22] to demonstrate the detection of objects such as vehicles by their outer edge lines. The edge detection technique must remove noises from an image background using a higher threshold before identification of the vehicle in question can begin. This changes how we can detect vehicles from a certain height and makes detection possible using image-capturing objects like Drones.

Sokalski [23] produced another alternative that combines edge detection with color identification to differentiate between artificial and natural objects. The only drawback is the process of extracting the nine features from various channels of each color in the image which are used to define the edges. An identification approach by thickness estimation and edge detection was put forward by Kanistras [24] where angle vectors of an elevated image would be determined in its edge guide. These vectors are constantly changing by determining the standard deviation of slope vectors therefore pre-defining edges to detect vehicles.

Different datasets and their use in creating a large diverse dataset in the training of algorithms are discussed by Xiao & Kang [25]. This paper has influenced how we approached diversifying and enriching our dataset to obtain satisfactory test results. The paper also provides tips for being efficient in collecting and labeling datasets properly. The importance of data augmentation is made clear by Zoph [26] in his discussions about how different augmentation strategies such as rotating, shearing, equalizing, changing colors, etc. can not only expand the dataset but also increase accuracy up to 6% but at the cost of data loss during training.

A YOLO-based traffic counting system developed by Lin [27] was employing three different pieces. The detector generates the bounding boxes of the vehicles, the buffer stores the vehicle coordinates, and the counter is responsible for counting the vehicles. Images/videos are put through the detector where it passes through filters and then the YOLO algorithm. Data access is built from the frame number input and output, previous and current array in buffer, and vehicle counting algorithm in counter. Checkpoints are also added for validation of detection whereas the overall accuracy is determined by using a video that has a different height and angular perspective. The counting accuracy seen during the day was around 95% but dropped to unfavorable rates at night due to factors such as headlight exposure, dim streetlights, etc. which was later improved upon by implementing night vision technology. An alternate YOLO method created by Tao [28] removes the last two layers of the connected system and adds a pooling layer. This is faster than its peers and the addition of a pre-processing procedure for night images enhances detection in darkness by removing highlights and modifying contrast and brightness. This new optimized O-YOLO algorithm executes an accuracy of 66% on a standard VOC dataset and 80.1% on a custom-curated dataset. Corovic [29] implemented YOLO to detect objects in real-time traffic and pre-trained the algorithm to detect them in five categories. These were cars, trucks, civilians, signs, and lights. Tests were conducted to prove that YOLO was suitable for real-time detection and in different weather. They deducted detection could be improved in place of obstructions by incorporating datasets that contain weather conditions into the training. After training of 120 epochs was conducted, the accuracy had a steady increase from 18.98% to 46.60% but failed to climb to higher rates due to many occluded objects in the dataset. Salarpour [30] realized an algorithm to track multiple vehicles using the Kalman filter and background subtraction. A region-based algorithm is then combined with the filter to track and predict the region of the vehicle in the continuing frame while also using its color and size to get an accurate result of 96%. This method helps detect issues such as occlusion and clutter with minimal loss of accuracy.

Occlusion makes it hard for vehicles to be distinguished for detection and therefore a procedure to reduce dense occlusion from surveillance cameras was put forward by Phan [31]. This is also a combination of background subtraction and detection but mixed with occlusion detection where each occluded vehicle is extracted from images based on their features. The method improves the accuracy of detection in occluded images at higher angles proven by its 85% accuracy score during high traffic. To address the problem of detecting vehicles at varying scales and distances, Lu [32] produced a modified version of the Region Proposal Network (RPN) which is tailored to be scale aware during detection. This system has two different sub-networks to detect large and small case proposals and inputs through two separate XGBoost (Extreme Gradient Boosting) algorithms to create final predictions. Both algorithms boasted scores of 64.1% and 84.8% respectively in terms of precision.

The most consistently accurate model out of the many commented on above is the YOLOv4 algorithm. It offers a

staggering 98.1% mean average precision when applied over a vehicle recognition system. YOLOv5, which currently lacks substantial research documentation, has data that exhibits improved accuracy and speeds over its previous iteration [33] which will be nothing but beneficial to our training.

To train a varied dataset such as this, we needed a sustainable system powerful enough to process and execute all the data. The model we used in conjunction with neural networks was built to enhance every aspect of its previous build and therefore the database was processed much quicker than expected. The database itself is a mixture of both common and unique vehicles found here in the South of Asia but the rarity in variety of some of these vehicles was a complication. 21 assorted classes were selected, collected, processed, and augmented to create a robust dataset for this research.

### III. ARCHITECTURE

The method of detecting items in an image as shown in Fig. 2 and calculating their location using bounding boxes is known as object detection. The classification of images is concerned with determining whether an object exists in each image based on calculative likelihood. Images have characteristics like distinct edges that an object recognition method must extract. Convolutional Neural Networks, Auto Encoder techniques, and others, can be used to automate this procedure. The most effective object identification strategy is one that assures that all objects of vivid size are given a bounding box to be recognized, as well as having high computational capabilities allowing for faster processing. Both YOLO and SSD promise good outcomes, but there is a speed/accuracy trade-off.

#### A. Proposed Methodology

In the South Asian region, we began gathering images of various vehicle items. The dataset was sorted and categorized after the image collections were completed to prepare it for the machine learning model. This dataset was then split at random using the standard splitting technique, with 80% of the data going to the training set for training and 20% going to the validation set for validation.

Fig. 2. Detection Process during a Training Phase.

This is done to assess the model's correctness while avoiding over-fitting. The prediction model was evaluated using the set developed for the validation procedure, whereas the training set provided the algorithm. We were given numerous metrics and statistics to evaluate because of the outcome. The whole process is outlined in Fig. 3.

The YOLO model is part of the Fully Convolutional Neural Networks (FCN) family that allows for the most optimally achievable outcome and real-time object recognition in every end-to-end model. YOLOv5 as shown in Fig. 4 contains a variety of internal models, each with its own set of complexity and architectures. The largest and most sophisticated network is YOLOv5l, which is followed by YOLOv5m and YOLOv5s.

Each of these models was trained to see how the various architectures influence the overall model's speed and accuracy. The three different and crucial aspects of YOLOv5's architecture can be outlined.

**Backbone** - The backbone is primarily responsible for resolving gradient information and incorporating changes into feature maps, hence lowering parameter numbers and the overall model's FLOPS (Floating Point Operation per Second).

**Neck** - The neck improves the data flow within the model. It includes a feature pyramid network with an upgraded bottom-up approach that can expose new low-level complicated features, as well as localization signals in lower layers that can improve localization accuracy. Through interconnection provided by Adaptive Feature Pooling, the feature grids, and levels produce useful data on all levels.

**Head** - The head contains algorithms for creating feature maps of many sizes with prediction procedures that the model employs to recognize objects of many sizes. Because vehicles might have components and add-ons of various shapes and sizes, this technique is critical for vehicle recognition. Each of these items can be easily detected using the multi-scale detection feature. When the training on the model is started in YOLOv5, the procedure begins.

Fig. 3. Block Diagram of Vehicle Detection & Tracking Process.

Fig. 4. YOLOv5 Architecture

The data is fed into the Sparked module, which extracts the features, which are subsequently transmitted to the PANet (Path Aggregation Network) [34] module to be fused.

It is all gathered in the YOLO layer, which is then processed to produce important analytic data like class, location, score, and size.

#### B. Data Annotation Format in YOLOv5

Each image was annotated in the form of an a.txt file, with each line of the content record depicting a bounding box. In Fig. 5, for example, there are four items (car, minivan, pickup, and bus).

Fig. 5. Bounding Boxes For Data Annotation.

### IV. DESIGN AND IMPLEMENTATION

On the vehicle dataset, three distinct YOLOv5 architectures – small, medium, and large were implemented and trained. Table I lists the dataset metaphors that have been defined. The total number of images and their respective classes are displayed in Fig. 7.

This dataset needed to be carefully sliced for training. There was no exact way to divide the dataset, so we employed the traditional slicing technique. We separated 80% of the data for training and a small 20% for the validation process which is required to reduce over-fitting. A random selection was made

from the main dataset to create the test set which was sufficient for the calculation of the accuracy of the model.

The final dataset contains 11,808 images of different classes of vehicles, out of which 9,749 images were used for training and 2059 images were used for validation. After splitting the dataset and annotating the images, the training set and validation set were fed into the machine learning model. The training set was used for the algorithm training process and the validation set was used for the prediction model which provided us with the different evaluation metrics and statistics.

The instances of some of the classes are higher than others and this makes the dataset non-uniform in nature. For example, the 'Car' class contains the highest number of appearances in our dataset with a total number of 10,680 whereas classes like 'garbage van' and 'Police car' appear less in the dataset.

**A. Dataset Preparation**

We used a custom data collection with about 21 types of automobiles in South Asian territory for our research. Most of the images were gathered from real-time data acquired by users, social networking pages, blogs, and other online sources, and the improper images were filtered out of the dataset.

Filtering the data collection is impressive, and as with any model preparation, it is required to increase the amount of relevant data that our model can extract from the dataset. Because there are images containing items that aren't supposed to be there, the dataset is full of noise.

**B. Dataset Pre-processing and Augmentation**

When it comes to improving the model's performance, pre-processing the dataset is essential. It is a necessary step toward improving the quality of data and the amount of useful information the model can derive from it. It is also critical to generate a balanced dataset to improve the accuracy of an

existing model. Before the dataset was supplied to the model for training, the images with their pixels had to be reshaped and resized. The images were resized using the `numpy.reshape()` method, and the pixels were replaced with `pixel/255` using vector scalar division.

Fig. 8 shows how the different augmentations were carried out and as a result, multiple different versions of the image were created. Balancing this dataset was a complex task as different categories of images had massive disparities in numbers.

Fig. 6. Sample Images from the Dataset.

**Dataset Visualization After Augmentation**

Fig. 7. Number of Instances Per Class before Augmentation.

Fig. 8. Different Types of Image Augmentations Applied to Our Dataset.

To solve this, only two different augmentations were carried out. The Contrast and Grayscale filters were utilized on our dataset to create augmented data with distinct differences that would be easily identifiable by the machine when trained. Because our original dataset was imbalanced and non-uniform, augmentation was used to increase the number of instances of classes in the dataset, particularly those that appeared less frequently like ambulances, bicycles, etc., thus improving the model's accuracy and performance by making the dataset more balanced.

After augmentation, a relative balance within the dataset was achieved which can be seen in Fig. 9 which shows the instances of different classes after augmentation was applied to it compared to Fig. 6 above which was before augmentation.

Fig. 9. Number of Instances Per Class after Augmentation.

### C. Model Training

YOLOv5 has multiple architectures such as YOLOv5s, YOLOv5m, and YOLOv5l in order of complexity and depth. We have implemented and juxtaposed each of these models on our dataset to determine the one which fits best. Each of the models was trained for 100 epochs which took around 12 hours per model. The model training process is illustrated in Fig. 10. The network is trained using a collection of training data, and it then learns to predict the target values. We have also improved the accuracy of the dataset for the YOLOv5l, YOLOv5m, and YOLOv5s designs.

An appropriate dataset is required to train a deep learning network. You may need to make a Train-Test Split depending on the available data. During the training phase, validation losses are tracked, and non-constant values are generated after several epochs. Otherwise, the model will be adjusted for hyper-parameters, and the validation loss value will be kept as low as possible.

The model with the largest validation loss is saved for testing on the real data. When a model obtains high precision and recall rates for new datasets, or when it demonstrates improved performance after training on an enriched dataset, it is said to perform satisfactorily.

### D. Dataset Demonstration

For model training, the entire vehicle dataset is provided. Table II shows the number of images evaluated for implementation, the number of images used to train the model, and the number of images used in testing.

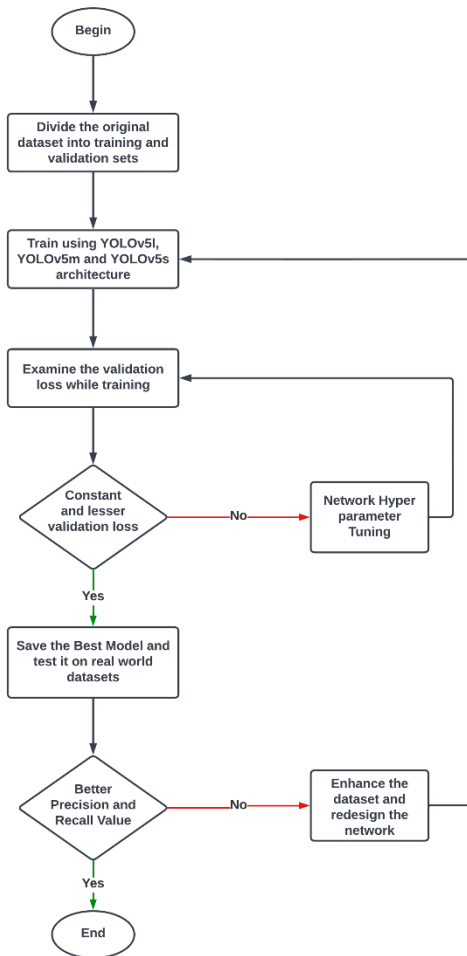

Fig. 10. Flow Diagram of Model Training.

TABLE II. DATASET DISTRIBUTION

Features	Before Augmentation	After Augmentation
Number of Classifiers	21	21
Total Input Images	11,808	88,818
Images to be Trained	9,749	55,956
Images to be Tested	2,059	32,862

## V. DISCUSSION

We were able to create a big dataset with over 21 unique classes and about 11,808 images. The dataset size increased to exactly 88,818 instances after the various Data Augmentation methods were applied.

### A. Performance Matrices

**Confusion Matrix:** Assists us in this by providing a comprehensive assessment of each model's performance, including faults.

- TP (True Positive) - When the anticipated value is equal to the actual value and the result is positive.
- TN (True Negative) - When the projected value is the same as the actual value, but the value is negative.

- FP (False Positive) - The anticipated value was incorrectly predicted as positive when the actual value was negative.
- FN (False Negative) - The anticipated value was incorrectly predicted as negative when the actual value was positive.

A variety of performance measures can be calculated using these numbers.

**Accuracy:** Measurement as a singular metric is invalid because it assigns equal costs to different types of errors and can only be used with a well-balanced dataset. The formula is as follows:

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+TN+FN} \quad (1)$$

**Precision:** Precision is a metric for how many accurately anticipated situations turn out to be positive, which can help establish a model's eligibility.

The formula for precision is as follows:

$$\text{Precision} = \frac{TP}{TP+FP} \quad (2)$$

**Recall:** Recall is the measure of the positive cases that were correctly classified by our model and is defined by the following formula:

$$\text{Recall} = \frac{TP}{TP+FN} \quad (3)$$

**mAP (mean Average Precision):** mAP is used to evaluate object detection models like Fast R-CNN, YOLO, and Mask R-CNN. It considers both types of errors, false positives (FP) and false negatives (FN), as well as the trade-off between precision and recall (FN).

$$\text{mAP} = \frac{1}{N} \sum_{i=1}^N AP_i \quad (4)$$

The mAP is calculated by averaging each class's Average Precision (AP) over several classes.

**F1 Score:** It combines the values of Precision and Recall into a single metric that must be maximized to enhance our model. However, interpreting the F1 score is challenging, leaving us oblivious to which of the metrics the model is optimizing. The formula is as follows:

$$\text{F1 Score} = \frac{2}{\frac{1}{\text{Recall}} + \frac{1}{\text{Precision}}} \quad (5)$$

**Loss function:** We will summarize YOLOv5 losses and metrics to help you better comprehend the outcomes. The three parts of the YOLO loss function are box loss, obj loss, and class loss.

## VI. RESULT ANALYSIS

For this research, three distinct YOLOv5 designs – small, medium, and large – were implemented and used. Before training, the dataset was pre-processed and supplemented. The complexity and depth of the three YOLOv5 architectures differ. Each model was tested against our dataset, and the results were compared to determine which model performed the best in terms of vehicle detection.

Mean average precision is a well-known and commonly used object detection evaluation metric. Faster R-CNN [35], YOLO [36], and MobileNet [37] are all state-of-the-art models that use mAP to evaluate their models. We tried to test the performance of the three YOLOv5 models – small, medium, and large – in our implementation.

### A. Mean Average Precision (mAP) Analysis

The mAP 0.5 of the three designs employed throughout 100 epochs is illustrated in Fig. 11 and Fig. 12. The YOLOv5l model achieves more accuracy in Fig. 11 and Fig. 12 than the other two models both before and after augmentation, as shown in the graphs.

### B. Training Loss Analysis

The training loss is a metric that measures how well a deep learning model matches the training data. That is, it evaluates the model's error on the training data. The training set is a subset of the dataset that was used to train the model originally. The training loss is calculated computationally by adding the sum of errors for each sample in the training set. It is also worth noting that the training loss is calculated after every batch.

According to Fig. 13 and Fig. 14, it showed that the training loss is minimal for the YOLOv5l model. The lesser the training loss, the faster a model's performance can be obtained.

Fig. 13. Train/Box Loss Comparison between Models before Augmentation.

Fig. 14. Train/Box Loss Comparison between Models after Augmentation.

Fig. 11. mAP Comparison between Models before Augmentation.

Fig. 12. mAP Comparison between Models after Augmentation.

### C. F1 Score Analysis

By comparing the F1 Score among the three models before and after the augmentation of the dataset as seen in Fig. 15 and Fig. 16, we can see that the large model has a higher score, followed by the medium model and the small model.

Fig. 15. F1 Score Comparison between Models before Augmentation.

Fig. 16. F1 Score Comparison between Models after Augmentation.

#### D. Augmented Vehicle Dataset Epoch Results

We have augmented our dataset and run for 100 epochs. At the end of the last epoch, the precision was 0.64, recall was 0.63 and mAP was 0.66 for an augmented dataset in YOLOv5 three architecture, Table III.

TABLE III. PERFORMANCE MEASUREMENT AND COMPARISON OF DIFFERENT YOLO MODELS

Model	Precision	Recall	mAP_0.5
YOLOv5l	0.64214	0.63763	0.66877
YOLOv5m	0.59261	0.60812	0.60112
YOLOv5s	0.58038	0.61149	0.57469

The performance is not up to the mark as our dataset was unbalanced and we have a higher amount of car dataset by comparing with other types of vehicles.

#### E. YOLOv5 Overall Performance Analysis

For analyzing the performance of YOLOV5 based on three different architectures, we have measured the performance based on before and after augmentation data. The outcome is presented in Tables IV and V.

Based on the findings, we can conclude that the YOLOv5l model does better out of the three architectures when it comes to vehicle detection for our dataset.

TABLE IV. RESULT COMPARISON OF YOLOV5S, YOLOV5M AND YOLOV5L BEFORE AUGMENTATION

Attributes	YOLOv5s	YOLOv5m	YOLOv5l
mAP_0.5	0.33505	0.35135	0.36361
mAP_0.5:0.95	0.20561	0.23274	0.24556
train/box_loss	0.03026	0.02182	0.01924
train/class_loss	0.01448	0.00737	0.00503
validation/box_loss	0.03443	0.03407	0.03309
validation/class_loss	0.02466	0.02801	0.02853
F1 Score	0.42211	0.43096	0.4438

TABLE V. RESULT COMPARISON OF YOLOV5S, YOLOV5M AND YOLOV5L AFTER AUGMENTATION

Attributes	YOLOv5s	YOLOv5m	YOLOv5l
mAP_0.5	0.57469	0.60112	0.66877
mAP_0.5:0.95	0.41897	0.43868	0.48071
train/box_loss	0.02711	0.0225	0.01574
train/class_loss	0.00977	0.013675	0.00158
validation/box_loss	0.02235	0.022442	0.02112
validation/class_loss	0.00952	0.009342	0.00802
F1 Score	0.59552	0.600264	0.63987

#### VII. CONCLUSION

The application of the different modules of YOLOv5 has significantly improved the detection of vehicular objects in traffic and on the road. The accumulated dataset has provided a vast amount of variety in vehicle classes which led to a richer and more accurate result across all the models. For performance comparison, we utilized different models with different nodes, layers, and speeds. After an extensive data training and processing, period was carried out, it was seen that YOLOv5l had outperformed the rest. Its deeper node complexity and increased number of convolutional layers make it the most efficient in terms of processing, but it was also seen that it takes the most time although by a short margin. The significant performance efficiency of the YOLOv5l model compared to YOLOv5s and YOLOv5m solidifies the real-world application opportunities for the detection of uniquely South Asian vehicles.

# Multi-method Approach for User Experience of Selfie-taking Mobile Applications

Shahad Aldahri, Reem Alnanih

Computer Science Department, Faculty of Computing and Information Technology  
King Abdulaziz University, Jeddah, Saudi Arabia

**Abstract**—Taking selfies is a popular activity in most social media applications and applying filters/lenses to these selfies has become one of the most demanded features of such applications. This paper aims to design an application for taking selfies to minimize the heavy use of beautifying filters. To understand the current user experience of selfie-taking and filter features, multiple user experience research methods were applied in two steps. In the first step, interviews were conducted with 10 participants to collect data. The key findings of interviews were (i) the need for saving memories as users' primary goal of using the applications, (ii) the need for using slightly beautifying filters as their preferred filter type, (iii) the need for a favorite filters list, and (iv) the need for the opportunity to edit selfies after they are taken. This output of the interviews was used as an input for determining the survey questions in the second step. A total of 340 respondents completed the survey and the findings were consistent with those of the interviews. Further pointing to the rising opportunity for a new selfie-taking application designed to save selfies quickly without sharing and only apply slightly beautifying filters. More studies should focus on increasing engagement and including a saved selfie categorization feature in the design.

**Keywords**—Filters; lenses; multi-method; research methods; selfie taking; user experience research

## I. INTRODUCTION

The Social media platforms have become indispensable Internet-based communication tools for daily life, in part due to the wide range of connectivity they provide. Social media and the Internet have caused the social participation rate to increase rapidly over time; in 2021, the number of Internet users worldwide reached 4.9 billion [1]. Furthermore, social media use is considered one of the most popular online activities [2]. In Saudi Arabia, active social media users represent 79.25% of the population, with an annual growth rate of 8.7% [3]. One of the most popular types of social media platforms are those that provide photo-sharing services—e.g., Instagram and Snapchat—and taking, viewing, and sharing selfies has become a daily habit for many people. Selfies edited with filters are an especially rising trend.

Snapchat is one of the fastest-growing selfie-taking social media applications, with a massive number of users that reached approximately 306 million in 2021 [4]. In 2016, Snapchat introduced a feature called Lenses to offer a range of filters to users, making it the first social media application to utilize augmented reality (AR) technology. Its facial recognition software allows users' mobile cameras to detect

their facial features and overlay a chosen virtual effect on their faces, which alters their facial features to look funny, scary, or more beautiful [5].

The problem with many existing selfie-taking applications that allow users to take selfies with filters is the heavy daily use of filters. People seeing each other from a distance may no longer know what their actual faces look like without filters. Social comparisons are no longer made between actual faces but between one's unfiltered face and the filtered faces of others. This may affect self-evaluation and self-esteem, especially because physical appearance is strongly related to self-esteem [6].

This paper aims to apply user experience (UX) research methods to better understand the current UX of selfie-taking and filter feature in order to minimize the use of heavily beautifying filters to help users accept the reality of their appearance. The UX was investigated through three different views—users' goals of using selfie-taking applications, their requirements for taking selfies, and their behaviors when taking selfies—to answer the following research questions:

- [Goal] Why are people using selfie-taking applications and using the filters feature?
- [Need] What is necessary for taking selfies and using the filters feature?
- [Behavior] How do users take selfies with existing mobile applications?

The strength of this paper lies in its use of several UX methods and techniques. Interviews and surveys were conducted sequentially to collect the requirements data. The findings from the interviews determined what to investigate in the surveys to produce clearer insights. Active listening and affinity diagrams were further used to analyze the collected data.

To the best of the author's knowledge, no existing study has conducted a multi-UX research methods approach to study the UX of selfie-taking and filters in order to minimize the reliance on heavily beautifying filters. The findings of the study should lead designers in this domain to consider the following implications in designing a new selfie-taking application:

- Design a selfie-taking application dedicated to saving memories.

- Allow only slightly and realistically beautifying filters in the application to encourage users to accept their looks without relying on heavily beautifying filters.
- Minimize the time required to take a quick selfie with quick reach, and provide a limited number of customized favorite filters.
- Minimize the time required to edit selfies with quick-adding capabilities for items such as gifs, emojis, text, and automatic date and time.

The rest of the paper is organized as follows: The second section highlights the related work in the field of UX, the third section provides the data collection and analysis, the fourth section presents the results of the study and discussion, and the fifth section concludes the current work.

## II. RELATED WORK

Many researchers have conducted UX studies dedicated to understanding, evaluating, and improving the UX of hardware and software products. One study of hardware aimed to understand the UX of unplanned smartphone use [7] via an ethnographic method that involved video recordings with wearable cameras on the chest to capture spontaneous smartphone use in everyday activities. According to the researchers, unplanned smartphone use leaves no memory of the actions in the past, presents no attributes of what it is, and projects no endings of what it will be in the future. Another study examined the UX of SmartTVs to identify UX factors that influence Smart TV UX factors over different periods [8]. Different UX methods were exploited in different stages, such as surveys, thinking aloud, and daily diaries.

The empirical evidence from each method suggests that the UX factors vary with respect to product temporality. Moreover, UX research has been conducted to design smart, wrist-worn digital jewelry [9]. The authors identified the requirements from the literature and conducted semi-structured interviews with jewelers and potential users. After data analysis and prototyping, they identified the final concept of the digital bracelet and implemented an operable and wearable prototype, which they then used to measure the UX and usability.

The participants' experience was positive. Another researcher used a survey to develop a storyline for an animated video to help generate empathy from the viewer for people with social anxiety disorder [10]. The viewers of the video were able to empathize with the main character in the animation even though the story did not have a defined ending.

Many UX studies have contributed to the UX of mobile applications and websites. For example, the gendered perceptions of and initial UX of Pinterest were studied to improve the binary disparity in its use between men and women [11]. The results of the surveys conducted in the study revealed significant differences in perceptions between users and non-users and between men and women. Another study evaluated the UX of Snapchat's onboarding process,

using a new multi-method approach that could be used to evaluate UX for any mobile application [12]. The new methodology consisted of three methods: a usability test interview, an affinity diagram, and a model of UX attributes. The UX attributes were applied to Hassenzahl's model to define which were most important and identify significant development points for the application management team. One researcher evaluated Facebook's UX and investigated the differences in experiences between frequent users and new users using electroencephalography (EEG) [13]. Their findings present a significant statistical difference between new and frequent Facebook users.

Table I summarizes the published date, type of studied product, UX method used, and domain of these studies.

The achievements of the above studies highlight that UX research can contribute to a theoretical background for the development and design of products and analysis of user behavior for various products and domains. Furthermore, different UX methods can be used to collect and analyze data in UX research to deliver reliable findings, and mixed methods can be used to gain more knowledge about UX [8][9]. The Smart TV study used different methods in different stages (i.e., before usage, during usage, after usage). Similarly, the digital bracelet study used one method before usage and another method during usage.

However, none of the above studies used 1) mixed methods in a single stage or 2) sequential methods where findings from the first method determined what to measure in the second method. Moreover, the only research that studied the UX of social media with selfie-taking focused only on the Snapchat UX in the onboarding process, and it failed to discuss Snapchat filters [12].

## III. DATA COLLECTION AND ANALYSIS

Multi-sequential methods of qualitative and quantitative were conducted to investigate the topic in more depth. The 2-step process of data collection and analysis is shown in Fig. 1.

Fig. 1. Two-step Data Collection and Analysis.

The first step of the methodology included interview data collection and analysis. Interviews were conducted first to develop a more thorough understanding with a small number of users. The outcome of the interviews and data analysis informed the topics explored in the survey, which were narrowed in scope to just a few key findings to allow for a deeper investigation. The second step was survey data collection and analysis, which sought to determine whether the interview key findings applied to a broader subset of Snapchat users.

#### A. Step 1: Interview Data Collection and Analysis

The interviews were designed with 9 opening questions to elicit initial responses to a specific topic, providing a useful springboard for follow-up questions. The questions explored the participants' demographic information, previous and current usage of selfie-taking apps, goals and motivations of using these apps, pain points and needs within the apps, and contexts for taking selfies with and without filters. Recruiting of interviewees ensured they met the following criteria: selfie-taking applications used at least once a week, filters used at least once a week, and at least 1 month of previous use of selfie-taking applications.

Ten participants were recruited for 30-minute interviews, which were conducted in the summer of 2021. Nine participants were interviewed by phone due to circumstances related to the COVID-19 pandemic and one was interviewed in person. Six participants were women and four were men. Their ages ranged from 19 to 32 years, and each had used some combination of Snapchat, Instagram, and TikTok for taking selfies.

The data collected from the interviews were analyzed using two UX methods: active listening and an affinity diagram.

1) *Active listening*: The active listening technique condensed the large amount of data gained from the interviews into smaller units that were easier to understand [14]. This technique involved listening to the important things said by the interviewees, then paraphrasing each response into a single quote that captured its essence. The digital tool Miro was used for this task [15]. The following sentences fragments are examples of the small-unit responses resulting from active listening of the interviews with Participants 1, 2, and 4:

- Participant 1: "I would like to reach my favorite filters quickly".

- Participant 2: "I use Snapchat 90% for saving memories".
- Participant 4: "I like using filters that beautify me but allow me to look like myself".

2) *Affinity diagram*: The affinity diagram technique was used to organize and analyze the large amount of data gathered from the interviews. Its purpose is to arrange many pieces of data into manageable clusters or groups that identify patterns in the data [16][17]. To construct the affinity diagram, the responses were categorized into three main groups—user behavior, user needs, and filters that users like or dislike—and further subcategorized into a total of 9 specific themes, as shown in Fig. 2.

The key findings of the affinity diagram are listed below. The finding names (e.g., F.A, F.B) correspond to Finding A, Finding B, etc., and were used to simplify the process of mapping the key findings from Step 1 to the survey questions in Step 2.

These findings are accompanied by supporting evidence, such as screenshots, quotes from the participants, and the number of participants that agreed on the finding.

Key findings:

F.A: Users take selfies primarily to save memories.

- "I use Snapchat 90% for saving memories" Participant 2.
- "Saving memories is my first goal, then viewing others' selfies." Participant 3.
- "I usually take selfies with others, mostly for saving not for sharing." Participant 7.

F.B: Users prefer slightly and realistically beautifying filters over beautifying filters that are unrealistic and over the top.

- Most participants (7 of 10) preferred to still look like themselves after using beautifying filters. They use them to look healthier, with smoother skin and a few realistic changes to their facial features.
- "I hate the beautifying filters that change me to look like everything but me, like I am another person" Participant 2.
- "I like filters that only give me a healthy look" Participant 5.

Fig. 2. Levels of Themes of Affinity Diagram.

F.C: Users want to reach their favorite filters quickly before taking selfies.

- “I would like to choose from my list of filters that I can reach quickly” Participant 6.
- “It would be helpful if only the favorite filters appear with one tap before taking the selfie” Participant 10.
- “I like that in Snapchat I can put stars on my favorite filters, but I have to go to explore filters to find my favorite filters” Participant 4, see number 1 and 2 in Fig. 3.

F.D: Users like adding items to their selfies, such as gifs, emojis, text, and the date and time.

- “I enjoy using gifs and emojis on selfies” Participant 1.
- “I like that Snapchat saves the date and time automatically” Participant 3.
- “I like to add music, stickers, text, time, and date to the selfies” Participant 6.

**B. Step 2: Survey Data Collection and Analysis**

The survey was divided into three sections: demographic questions, screening questions, and requirements questions. The demographic questions gathered demographic information that may affect users’ selfie-taking experience. The screening questions ensured that the respondents met the following qualifying criteria: selfie-taking applications used at least once a month, filters used at least once a month, and the device used for taking selfies is the mobile. Finally, five requirements questions were posed to investigate the key findings of the interviews. Table II presents the requirements questions, the corresponding key findings, and the rationale for the selection of these questions.

The survey data were collected in November 2021 in Saudi Arabia. The final sample consists of 460 participants. The quantitative data were analyzed using statistical procedures with SPSS. Descriptive statistics and charts were used.

1) *Demographic questions analysis:* Most respondents were in the 21–30 age group and the 10–20 age group had the fewest number of respondents. Furthermore, 35.2% were

men, 64.8% were women, and 81.5% held bachelor’s or graduate degrees.

Fig. 3. Reaching Favorite Filters in Snapchat.

TABLE II. REQUIREMENTS QUESTIONS

Requirements Questions	Key Finding(s)	Rationale
Which of the following is your goal of taking selfies?:	F.A	Understand the user’s goal
Which type of filter do you prefer to use?	F.B	Understand the user’s preference of filter types
Do you have any favorite filters that you usually use?	F.C	Identify if the user has a favorite filters list
How many favorite filters do you usually use?	F.C	Identify the usual number of favorite filters for users
Based on your experience with the selfie-taking app(s) you use, how essential were the following features?:	F.C , F.D	Determine what is necessary for users before and after taking the selfies

2) *Screening questions analysis:* The screening questions filtered out 120 respondents, leaving 340 to complete the survey.

Table III shows the percentages of male and female respondents who were frequent users of filters (i.e., used filters daily or weekly) and those who were infrequent users of filters (i.e., used filters monthly or less).

Most respondents (53.55%) used filters daily or weekly. The 21–30 age group had the highest daily usage of filters in selfie-taking applications, and women had higher daily filter usage than men.

TABLE III. FREQUENCY OF USING FILTERS BY GENDER

Gender	Frequent use of filters	Infrequent use of filters
Male	42.86%	57.14%
Female	59.12%	40.83%
All	53.55%	46.45%

3) *Requirements questions analysis:* The selfie-taking application used most often was Snapchat with 95.6% of responses. The results of the multiple-choice questions regarding the users' goals of using selfie-taking applications revealed saving personal memories as the most common goal (71.1%, n=241), followed by sharing with family and friends (64.9%, n=220). For most age groups and both men and women, saving personal memories was the most chosen goal; the exception is respondents over 40 years old, for whom sharing with family and friends was most chosen. Seeing one's face with a filter was the third most chosen goal, mostly by female respondents (76.62%, n=118) and respondents who used filters daily. Sharing with public users was the least chosen goal (9.4%, n=32); male respondents chose this goal more than female respondents. Fig. 4 shows the distribution of goals for each age group, and Fig. 5 shows these goals for men and women.

For the questions on filter type preferences, most of the respondents chose the slightly beautifying filter type (83%, n=284). The advanced beautifying filter type was chosen mostly by respondents who used filters daily.

The majority of respondents (58.1%) had favorite filters that they usually used, whereas the other 41.9% did not. The most common numbers of favorite filters were 3 (28.4%, n=56), 2 (24.4%, n=48) and 4 (19.8%, n=39).

Cronbach's  $\alpha$  (0.71) was calculated to test the reliability of the responses to the five questions on the essentiality of different features in selfie-taking applications. Most respondents (55.16%) considered accessing favorite filters quickly to be a must-have feature and 35.40% considered it a nice to have feature, as shown in Fig. 6.

Adding text and date features were mostly considered nice to have features. Adding the time, emojis, and gifs were mostly considered unnecessary or nice to have features.

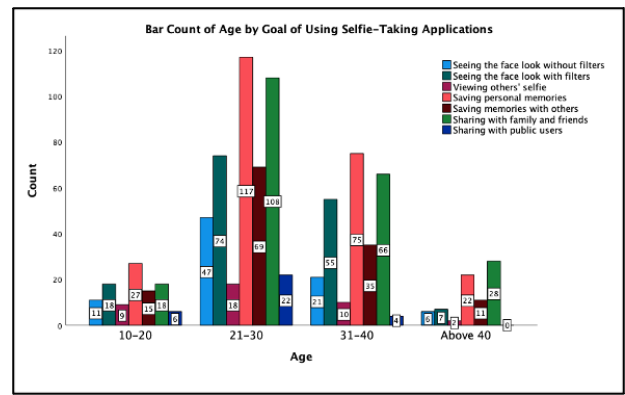

Fig. 4. Goal of using Selfie-taking Applications for Each Age Group.

Fig. 5. Goals of using Selfie-taking Applications for Men and Women.

Fig. 6. Percentage of Essentiality of Accessing Favorite Filters Quickly.

#### IV. RESULT AND DISCUSSION

By focusing on areas that were rich with respondents, the final key findings were identified and supported by evidence.

Final key findings are:

- Users prefer slightly and realistically beautifying filters over unrealistically and excessively beautifying filters.
- 83.8% of participants preferred slightly beautifying filters and only 15.6% preferred advanced beautifying filters.

- Users enjoyed adding text, the date and/or time, and emojis to their selfies.
- 75.2% of participants considered adding text as either a must-have or nice to have feature.
- 67.3% of participants considered adding the date as either a must-have or nice to have feature.
- 59% of participants considered adding the time as either a must-have or nice to have feature.
- 58.4% of participants considered adding emojis and gifs as either must-have or nice-to-have features.
- Users had favorite filters and wanted to reach them quickly before taking selfies.
- 58.1% of participants had favorite filters they usually used.
- 55.16% of participants considered quick access to their favorite filters as a must-have feature.
- Users take selfies primarily to save memories.
- 71.1% of participants chose saving memories as their goal of taking selfies.
- Saving memories was the most chosen goal for both men and women and all age groups, except >40 years.

The above result shows that the key findings of the survey align with those of the interviews. From this, an opportunity was identified for a new selfie-taking application that differs from the existing selfie-taking applications. The main points considered for the new application were:

- The ability to take a selfie just for saving, not for sharing.
- The ability to reach one's favorite filters with one click before taking selfies.
- A collection of slightly and realistically beautifying filters.
- The ability to add the time and date, gifs, emojis, and text on taken selfies.

Each research method has both positive and negative attributes. Surveys and interviews are two of the most used methods in UX studies. However, using a survey alone leads to a disconnection between the researcher and respondents to observe emotional concerns that may be evident in respondents' responses. Also, no possibility of correcting the misunderstanding which may be due to the wording or ambiguity in the survey. In other hand, using interviews alone has several cons such as sex, race, and class affiliation of the interviewee may play a role in the bias of the interviewer. Also, recruiting a large sample in the interview method will require higher costs and time. The limitation of a single-method approach was overcome by employing multiple research methods and the double diamond framework to understand the full UX. The sequential usage of these research methods allowed the researchers for a more in-depth investigation of the research topic. Rather than using the

survey to investigate every point or issue from the interviews, the scope was narrowed to the key findings of the interview that merited further investigation. The survey therefore focused on users' goals of using selfie-taking applications, their preferences for filter types, the need for a favorite filters list, and the essential features for taking selfies. This multi-sequential approach proved able to provide consistent findings.

The existing studies had a limitation in evaluating the UX of selfie-taking applications, especially the evaluation of filters feature. The contribution of this paper is using the benefits of multi-sequential research methods and the strength of the double diamond framework to evaluate the UX of selfie-taking and filters.

People's daily reliance on heavily beautifying filters motivated this research. However, the results of the research methods illuminated two new problems in selfie-taking applications. The first is that most selfie-taking applications focus on sharing selfies with other users because, like Snapchat, they are considered social media platforms. However, most of the participants of both the interviews and surveys chose saving memories as their goal in using these apps, which answers question 1 of this study. The second problem is that the excessive numbers of filters available mean that users must search through them to choose one for each selfie; this extends the time required to take a quick selfie. Many respondents expressed the need for a quick reach time to the favorite filters list, which answers question 2 of this study. Because people live busy lives, they sometimes wish to stop only for a second to take a quick and almost neutral selfie with slightly enhancing beauty—just to save the memory for themselves, not to share, which answers question 3 of this study. A new selfie-taking application could solve these problems by focusing solely on taking selfies instead of sharing them and by offering slightly beautifying filters and the option to quickly save the memories.

## V. CONCLUSION

Recently, applications that support people's interest in taking selfies by providing various features, such as filters, are in high demand. However, the consequences of daily reliance on beautifying filters have increased. Thus, to understand the current UX of selfie-taking applications, this empirical study investigated the goals, needs, and behaviors of their users in order to find opportunities for improvement and solve the rising reliance on heavily beautifying filters. The multi-sequential methods approach was conducted to collect and analyze data on two steps. The result of these analyses revealed an opportunity for a new selfie-taking application that focuses on taking selfies to save memories rather than sharing them, providing only slightly beautifying filters rather than heavily beautifying filters, and improving the speed and ease of the selfie-taking process to make it compatible with people's busy lives.

The multi-sequential approach of qualitative and quantitative methods combined is expected to be easily generalizable to similar applications and products. Also, this research can serve as guidelines for building new social applications with selfie-taking and filters features. Future

research can build on this study to determine new features for categorizing and handling the saved memories and increasing the level of engagement.

# Predicting Academic Performance using a Multiclassification Model: Case Study

Alfredo Daza Vergaray<sup>1</sup>, Carlos Guerra<sup>2</sup>, Noemi Cervera<sup>3</sup>, Erwin Burgos<sup>4</sup>

Professor, School of Systems and Computer Engineering, Universidad Nacional del Santa, Ancash, Perú<sup>1,2</sup>

School of Systems and Computer Engineering, Universidad Nacional del Santa, Ancash, Perú<sup>3,4</sup>

**Abstract**—Now-a-days predicting the academic performance of students is increasingly possible, thanks to the constant use of computer systems that store a large amount of student information. Machine learning uses this information to achieve big goals, such as predicting whether or not a student will pass a course. The main purpose of the work was to make a multiclassifier model that exceeds the results obtained from the machine learning models used independently. For the development of our proposed predictive model, the methodology was used, which consists of several phases. For the first step, 557 records with 25 characteristics related to academic performance were selected, then the preprocessing was applied to said data set, eliminating the attributes with the lowest correlation and those records with inconsistencies, leaving 500 records and 9 attributes. For the transformation, it was necessary to convert categorical to numerical data of four attributes, being the following: SEX, ESTATUS\_lab\_padre, ESTATUS\_lab\_madre and CONDITION. Having the data set clean, we proceeded to balance the data, where 1,167 data were generated, using the 2/3 for training and the remaining 1/3 for validation, then the following techniques were applied: Extra Tree, Random Forest, Decision Tree, Ada Boost and XGBoost, each obtained an accuracy of 57.41%, 61.96%, 91.44%, 59.65% and 83.3% respectively. Then the proposed model was applied, combining the five algorithms mentioned above, which reached an accuracy of 92.86%, concluding that the proposed model provides better accuracy than when the models are used independently meaning that it was the one that obtained the best result.

**Keywords**—Learning machine; prediction; academic performance; hybrid model; classification techniques; multiclassification; python

## I. INTRODUCTION

The performance of a student, over the years, has always been of great importance to the institutions that provide teaching, which is why much research is done on academic achievement.

On the latter, [1] he states that "it is of great importance to support the development of students and improve the quality of higher education, which ultimately improves the reputation of institutions" (p. 21). Therefore, education plays a very important role in the progress of any society, where learning outcomes are seen as an indicator related to better health, social and more effective careers and a factor of improvement of families and communities [2].

According to [3] they indicate that about 25% of every 100 students at the higher level abandon their training in the first semester. Most of them start with failed subjects and low

averages, in the third semester there is a dropout rate of 36%, a figure that increases semester by semester, until reaching 46%, which makes academic performance very transcendental and important. These results show that today's young people have the minimum of the skills needed to perform capable in contemporary societies; they have serious deficiencies to start their professional studies and of course they will have serious problems to successfully insert themselves both into the labor market and into the social, scientific, political and business groups that run the country.

Likewise, universities undertake to update their study plans and programs to adapt them to the needs of today's society; Unfortunately, while these efforts are important, modifying or changing the curriculum does not eliminate learning problems, but also presents new challenges. Similarly, according to [4] to consider a university as one of high quality it is necessary that it has an excellent record of academic achievement.

As an idea of solution to achieve this goal, is that the use of new technologies is becoming more and more frequent, as is the case of data mining.

According to [5] "Data mining is a process of automatically extracting useful information from large data set repositories, etc." In addition, the usefulness of this technology is that it can be used to train learning models, which from historical data can discover useful learning information and based on this, make a prediction [6].

Currently this technology is applied in various fields such as industry, banking, among others. Applied to the field of education, it is called Educational Data Mining (EDM), which, according to [7] "is an emerging area of research composed of a large set of psychological and computational approaches to provide a roadmap of how students learn." On the other hand, at present the existence and constant use of automated learning tools allow, according to [7] to store "a variety of data related to students and valuable characteristics that affect the performance of students and that can be used in the construction of the prediction model".

In Peru, the problem of low performance is frequent at different levels of education. The performance of the students of the different engineering faculties of the Universidad Nacional del Santa is medium low of the vast majority according to the report made by the [8], this affects both the university, since "its success depends on the success of its students" according to [9], and the students themselves, since

they opt for desertion, career change, or limit them when it comes to finding work in the future, where in their studio they developed a predictive model using the J48 technique, which obtained an accuracy of 60.9%.

Currently there are many learning models that are used to extract knowledge from a data set, some of these are those based on Naive Bayes (NB), Vector Support Machine (SVM), Decision Trees (DT), the Closest Neighbor (KNN), among others; but as stated [10], it is difficult to find an efficient classification model that can be used for various situations or problems. That is why the idea of combining several classifiers (multiclassifiers) was born.

The multiclassifiers according to [18] "belong to a recent area of data mining that has allowed to improve, in general, the accuracy of predictions through the combination of individual classifiers" and some of these multiclassifiers are Streaming Ensemble Algorithm (SEA), Coverage Based Ensemble Algorithm (CBEA), multiclassification based on CIDIM (MultiCIDIM-DS) and MultiCIDIM-DS-CFC.

Based on the problem that arises in the university and in search of improving the various solutions proposed by several studies, it was proposed to create a hybrid model that is capable of predicting academic performance so that students and teachers can opt for preventive measures to avoid that grades are deficient in the future.

This article aims to create a predictive model making use of multiclassification through the Stacking technique using new algorithms such as: Extra Tree, Random Forest, Decision Tree, Ada Boost and XGBoost to achieve better accuracy, taking into account that the studies that have been done so far, make use of a single prediction technique, thus generating a good precision, but that could be better if several techniques were applied together.

The rest of the work is structured in five sections. In Section II, a review of the literature of related works is presented. Section III contains the method, which outline the data mining process implemented in this study, which includes a representation of the collected dataset, an exploration and visualization of the data, and finally the implementation of the data mining tasks and the final results. Section IV shows the findings and discussion obtained after the creation and testing of the predictive model. Finally, Section V contains the conclusions reached after the development of the model.

## II. RELATED WORK

This section compiles various research conducted in recent years on the application of data mining in the education sector.

There are many studies or works carried out related to education, whose main theme is the academic performance or dropout of students such as the study carried out by [8] whose objective was to compare various data mining techniques when using them to predict the performance of students. The data they used was from the Kaggle repository and this comparison included the techniques: Decision Tree (C5.0), Naïve Bayes, Random Forest, Support Vector Machine, K-Nearest Neighbor and Deep Neural Network, this being the one that obtained a greater precision, reaching 84% accuracy.

Another work is also carried out by [11], aimed to perform a comparison and study of hybrid classification model and machine learning algorithms based on decision tree, clustering, artificial neural network, Naïve Bayes, etc., using the open source data mining tool Weka for a practical experiment on a student dataset, having as results that the hybrid method achieved the highest accuracy of 92.59% than individual classifiers, that is, J48, NB, IBK and ANN achieved an accuracy of 85.18, 81.48, 88.88 and 88.88%.

In [12], the authors developed a regression model to predict the score that a student would have, used the ALGORITHM KNN, Decision Tree, SVM, Random Forest and Multiple Linear Regression. After comparing the results of each algorithm, it was the Multiple Linear Regression Model that obtained the greatest accuracy. In [13], They conducted a study of student dropout to determine what were the causative factors and which classification algorithm is the most used to predict this problem. After reviewing several studies, they concluded that decision tree classifiers were the most commonly used, as they obtained good predictions.

A semi-supervised learning approach is the one they used [14] to rank the performance of first-year college students. The categories to classify were low, medium and high and the classifier was Naive Bayes, who obtained an accuracy of 96% and specificity of 100%.

In [15], they build a model that predicts the outcomes students will achieve in the semester. They used 13 learning algorithms, belonging to 5 categories, for the Bayes category, they used Naive Bayes, for the Function category they used SVM and Perceptron Multilayer, for the Lazy category, the IBK technique, for the Rules category they used Decision Table, JRip, OneR, Part and ZeroR and finally for the Trees category, they used the J48 techniques, Random Forest, Random Tree, and Simple CART. The data correspond to 50 students and they developed their model on the Weka platform, after the results of having applied each of these techniques, the one that had the best results was the J48 technique, which reached 88% accuracy in the prediction

In the same way the study carried out by [16], whose objective is to develop a prediction model based on Bayes, specifically Naive Bayes and Bayes Network. The data was collected through a questionnaire of 62 questions related to health, social activity, relationships and academic performance. They used the Weka tool in which they obtained as a result the algorithm Naive Bayes is better, since it obtained 70.6%, while Bayes Network obtained 64.3% accuracy.

In [17], the author in his research aimed to develop an algorithm with incremental learning to mine data flows that is capable of manipulating gradual, abrupt or recurrent concept changes, obtaining as results that the FAE algorithm achieved promising results in the tests, compared to well-known algorithms implemented also in the MOA work environment, taking into account the parameters: Accuracy (82.4%), execution time, behavior in the transition period from one concept to another and recovery time after a change of concept.

In the present study, five classification algorithms are used as the basis for the creation of a multiclassifier model, through

the Stacking technique, these algorithms being: Extra trees, Random Forest, Decision Tree, Ada Boost, XGBoost.

#### A. Extra Trees

It is the short name of Extremely Randomized Trees, which means Extremely Randomized Trees. This technique consists of a large number of individual decision trees. It is characterized because it uses the entire set of training data, to grow each decision tree [18].

The Extra Trees algorithm creates many decision trees at random, with the intention of finding a final answer, from the combination of the results of each tree. The difference with the Random Forest algorithm, which has the same procedure, is that the number of random processes used in Extra Trees is much higher.

#### B. Random Forest

A random forest consists of many decision trees. Each tree in the forest is a binary tree and its generation follows the principle of top-down recursive division [19]. For each tree, the root node contains all the training data and this is divided into two nodes, the left and right, according to certain rules and these in turn train with different samples of data. The division continues to occur based on certain rules until the fork stop is met.

#### C. Decision Tree

The decision tree is a tree-like structure that represents a series of decisions and the resulting decision takes the form of rules for classifying a given data set [20]; these are supervised algorithms that can be used for both classification and regression. The objective of this algorithm is to predict by learning decision rules. After the construction of a decision tree, these classify an instance from the root node of the tree then it is directed to a leaf of the tree that would be the intermediate node, depending on the value it takes and this is done successively until it reaches the last leaf of the tree that would be the terminal node.

#### D. Ada Boost

The Ada Boost algorithm stands for Adaptive Boosting and is one of the most popular techniques of the Boosting method. This algorithm is iterative and its operation consists of training different classifiers considered weak for the same set of training data, then combining them to form a stronger classifier [21].

Ada Boost classifiers represent a robust class of classifiers that aim to increase or improve the accuracy of an already built classifier [14].

#### E. XGBoost

XGBoost is an advanced software based on Gradient Tree Boosting that can efficiently handle large-scale machine learning tasks [22]. The XGBoost algorithm stands for Extreme Gradient Boosting and is a supervised algorithm based on the Boosting method. To achieve the strongest classifier, an optimization algorithm is used, Gradient Descent and each model generated is compared with the previous one and if a new model obtains better accuracies, this is taken as a basis for relicensing modifications. But, if in case, its accuracies are low, it returns to the previous model, making modifications based on this. The process is repeated until the differences between two consecutive models are negligible, which means that the maximum number of iterations was reached.

#### F. Stacking

Set learning algorithms are metaalgorithms that combine different machine learning algorithms into a single predictive model to reduce bias (boosting), variance (bagging) or improve the accuracy of predictions (stacking) [23]. Based on the study presented in this section a stacking method was developed (see Fig. 1). This technique involves using predictions from previous-level machine learning models as input variables for next-level models [5].

Fig. 1. Graphical Representation of the Stacking Method used in this Work.

### III. METHOD

For the development of the present study, the steps of the stacking method shown in Fig. 2 have been followed, it should be noted that XGBoost is an advanced software based on Gradient Tree Boosting that can efficiently handle large-scale machine learning tasks [14].

1) *Data integration*: The data of systems and computer engineering and agroindustrial engineering were integrated.

2) *Selection*: This work focuses on students of systems engineering, energy and agro-industrial of the Universidad Nacional del Santa. Data were collected using an online questionnaire, which included questions related to some characteristics about academic performance. The questionnaire contained a total of 25 characteristics and were answered by 557 students, of whom 135 were female and 422 were male. The characteristics considered in the questionnaire are detailed in Table I.

3) *Pre-processing*: This step is important to prepare the data before it is used in testing. In our case, the data required pre-processing, as there was empty data, inaccurate data and irregular or inconsistent data. Some of the tasks included in this step are: data cleansing, transformation data, reduction data, and integration data [19]. Another detail of the collected data set is that they are mostly categorical, and for this data to be used in the selected tool, Python, it must necessarily be numerical data.

a) *Removing attributes*: Initially, the characteristics SCHOOL, Cod\_student, CI\_ante, prom\_trans, NATIONALITY, FECH\_nac, RACE, TYPE\_viv, PLACE\_res and other attributes that do not necessarily have a great correlation with the student's performance were eliminated, as shown in Table II.

b) *Data cleansing*: Data cleansing required deleting records that contained empty or inconsistent data. In the first instance, there were 88 records that had at least one empty value, after their elimination, there was a record that contained an invalid data, finally leaving 500 records to be used in the model to be proposed.

c) *Creating the output class*: The focus of this report is classification, and taking into account that the collected data set had an attribute, AVERAGE\_ACU, which contained the academic averages of the students surveyed, the creation of 3 categories was considered so that the model can classify a certain student in one of those categories. These three categories were considered based on the following:

- Bad, whose rating is less than 10.5.
- Regular, whose rating is greater than or equal to 10.5, but less than 14.
- Regular, whose rating is greater than or equal to 10.5, but less than 14.
- Well, whose rating is greater than or equal to 14, but less than or equal to 20, this value being the maximum in Peru's rating system (vigesimal system).

Therefore, the final output class considered for the classification model is, CONDITION, the following attributes as shown in Table III.

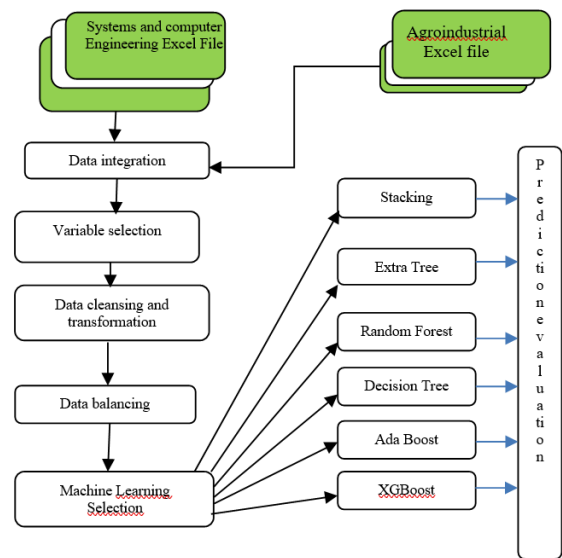

Fig. 2. Process of Prediction of Academic Performance through the Stacking Model.

TABLE I. LIST OF FEATURES USED IN THE QUESTIONNAIRE

Feature	Description	Feature	Description
SCHOOL	Academic school	ESTATUS_lab_padre	Employment status of the father
Cod_student	Student Code	ESTATUS_lab_madre	Mother's employment status
SEX	Gender	TYPE_viv	Type of housing
CI_ante	Previous cycle	INCOME_pa	Father's income
AVERAGE_acu_	Academic performance	INCOME_ma	Income of the mother
Prom_trans	Previous average	PLACE_res	Place of residence
NATIONALITY	Nationality	scholarship	Do you have a scholarship?
CURRENT_AGE	Current age	c_otra_carr	Do you have another career?
Anio_ingreso	Year of admission to the University	c_title_otra	Do you have another title?
AGE_estudiar	Age at which he began to study	DEPARTMENT	Department
FECH_nac	Date of birth	PROVINCE	Province
RACE	Race	DISTRICT	District
n_int_fami	Number of members in the household		

TABLE II. LIST OF FEATURES WITH THE HIGHEST CORRELATION

Feature	Domain
SEX	Nominal (Female, Male)
CURRENT_AGE	Whole
Anio_ingreso	Whole
AGE_estudiar	Whole
N_int_fami	Whole
ESTATUS_lab_padre	Nominal (Dependent, Independent)
ESTATUS_lab_madre	Nominal (Dependent, Independent)
INCOME_pa	Real
INCOME_ma	Real
AVERAGE_acu	Real

TABLE III. LIST OF FINAL FEATURE

Feature	Domain
SEX	Nominal (Female, Male)
CURRENT_AGE	Whole
Anio_ingreso	Whole
AGE_estudiar	Whole
N_int_fami	Whole
ESTATUS_lab_padre	Nominal (Dependent, Independent)
ESTATUS_lab_madre	Nominal (Dependent, Independent)
INCOME_pa	Real
INCOME_ma	Real
CONDITION	Nominal (Bad, Regular, Good)

d) *Data balancing*: Fig. 3 shows that the dataset is unbalanced, so accuracy could be affected. There is a lot of difference between the minority class (Good) and the majority class (Regular), so it was necessary to balance the dataset to ensure a better percentage of accuracy. The technique of oversampling has been used for data balancing as shown in Fig. 4, which generates artificial examples of the minority class, until reaching the number of records of the majority class.

Fig. 3. Output Class Records before Applying Data Balancing.

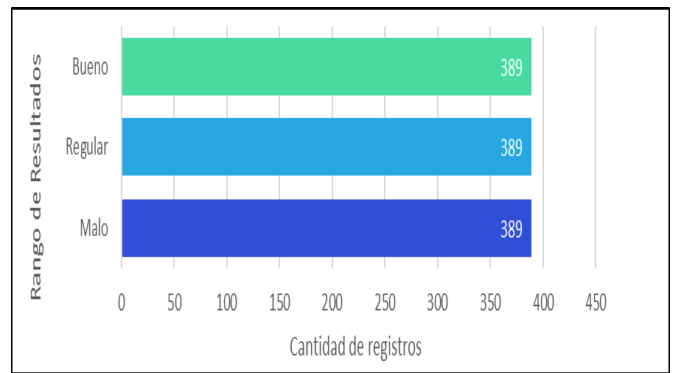

Fig. 4. Output Class Records after Applying Data Balancing.

4) *Transformation*: All development and implementation of the predictive model and data processing was done using Python software.

Due to the use of this tool, it was necessary for the entire dataset to have numeric values. That is why the data of the characteristics SEX, ESTATUS\_lab\_father, ESTATUS\_lab\_mother and CONDITION, had to be transformed into numbers according to conditions. Table IV shows the new values of the characteristics that were transformed.

5) *Data mining*: Python is a tool for data mining that offers many modules or libraries to be used professionally. These modules help the application of various classifiers.

For the application of data mining, one of the ways to increase the accuracy of the prediction made by a specific classification technique is the use of ensemble learning algorithms, one of them being stacking, which is what was applied for the construction of this predictive model.

According to the definition of [24] "it's the process of using different machine learning models one after another, where the predictions of each model are aggregated to create a new feature."

The techniques used as a basis for using stacking were: Extra trees, Random Forest, Decision Tree, Ada Boost, XGBoost.

TABLE IV. LIST OF FEATURES WITH NUMERIC VALUES

Feature	Numeric values
SEX	1 = Female 2 = Male
ESTATUS_lab_father	1 = Dependent 2 = Independent 3 = Deceased 4 = Live without a father
ESTATUS_lab_mother	1 = Dependent 2 = Independent 3 = Housewife 4 = Not working
CONDITION	1 = Bad 2 = Regular 3 = Good

The dataset was classified into two groups. The first group of data is for training and is made up of 2/3 of the total data. The second group is the test group and is made up of the remaining 1/3 of data. The application of the stacking algorithm was done using the training data to prepare the model, and then the test data. Model performance can be observed after application of the model to the test dataset.

6) *Interpretation and evaluation:* Python is used to import the dataset from an excel spreadsheet. The attributes with the highest correlation were selected to apply model training. The attributes sex, father's employment status, and mother's employment status were converted to numerical to avoid errors during the modeling process. Applied the different techniques to the final data set, each of these obtained different precisions.

To know the efficiency of the classifiers, these were evaluated using a confusion matrix, in which the number of records classified correctly and incorrectly is appreciated. 5 models were built to individually analyze the performance of the models and each of these obtained the following matrix confusion:

a) *Extra trees:* The first model to be built was the model based on the Extra Trees sorter. For its application in the Python tool, the ExtraTreesClassifier class of the sklearn.ensemble library was used and the following parameters were considered:

- random\_state = 0
- n\_jobs = -1
- n\_estimators = 100
- max\_depth = 3

Applied the algorithm to the dataset, the confusion matrix obtained was as follows:

As shown in Table V, is classified most students in the Bad category. These results show that the algorithm does not give good accuracy for this case.

b) *Random Forest:* For the implementation of this model, the RandomForestClassifier class of the sklearn.ensemble library was used and the parameters considered for its application were the following:

- random\_state = 0
- n\_jobs = -1
- n\_estimators = 100
- max\_depth = 3

TABLE V. CONFUSION MATRIX FOR THE EXTRA TREES MODEL

		Prediction		
		Bad	Regular	Well
Current	Bad	108	4	2
	Regular	96	16	22
	Well	97	2	42

The confusion matrix that was obtained from this model was as follows:

Based on the data obtained in Table VI, it can be said that the model has predicted well in terms of the classification of students in the Bad and Good categories, but for the Regular category, there is some uncertainty when classifying almost the same number of students for the three categories.

c) *Decision Tree:* To implement this algorithm, the DecisionTreeClassifier class of the sklearn.tree library was used and the parameters considered were the following:

- random\_state = 0
- min\_samples\_split = 2
- max\_depth = None

Running this model gets the following confusion matrix:

According to the values of the matrix, this is the model that has obtained a better precision, because as shown in Table VII, of 114 students correctly predicted the 114 within the Bad category, of 134 students correctly predicted 96 within the Regular category, and of the rest, 15 incorrectly predicted as Bad and 23 as Good. Finally, he correctly predicted 141 students as Good.

d) *Ada Boost:* This algorithm was implemented using the AdaBoostClassifier class of the sklearn.ensemble library and the parameters considered for its application were the following:

- random\_state = 0
- n\_estimators = 100

The confusion matrix that was obtained from this model was as follows:

Table VIII shown that of each dataset belonging to the three categories, the model was able to classify half of the students correctly, but not enough to be considered a good prediction, since it misclassified a large percentage of the students. So it is assumed that accuracy is not good for this model.

TABLE VI. CONFUSION MATRIX FOR THE RANDOM FOREST MODEL

		Prediction		
		Bad	Regular	Well
Current	Bad	87	9	18
	Regular	42	51	41
	Well	34	12	95

TABLE VII. CONFUSION MATRIX FOR THE DECISION TREE

		Prediction		
		Bad	Regular	Well
Current	Bad	114	0	0
	Regular	15	96	23
	Well	0	0	141

TABLE VIII. CONFUSION MATRIX FOR THE ADA BOOST MODEL

		Prediction		
		Bad	Regular	Well
Current	Bad	62	43	9
	Regular	27	77	30
	Well	9	45	87

e) *XGBoost*: For the implementation of this model, the *XGBClassifier* class of the *xgboost* library was used and the parameters considered for its application were the following:

- `random_state = 0`
- `n_jobs = -1`
- `learning_rate = 0.1`
- `n_estimators = 100`
- `max_depth = 3`

The confusion matrix obtained from this model was as follows:

This algorithm is the second most accurately after the decision tree. Table IX shown that of 114 students who belonged to the Bad category, it correctly ranked 108. Out of 141 students in the Good category, he correctly predicted 132. But of the 134 students considered regular, only 80 could predict correctly.

TABLE IX. CONFUSION MATRIX FOR THE XGBOOST MODEL

		Prediction		
		Bad	Regular	Well
Current	Bad	108	1	5
	Regular	23	80	31
	Well	0	9	132

What is part of a confusion matrix are the following four classifiers:

- True Positives (TP): These are the records correctly classified in the positive class.
- False Positives (FP): These are the records incorrectly classified in the positive class.
- False Negatives (FN): These are the records incorrectly classified in the negative class.
- True Negatives (TN): These are the records classified correctly in the negative class.

From these values, the following metrics can be calculated to evaluate the effectiveness of a predictive model:

- Sensitivity

This metric measures the positive values, in this case, correctly identifying students in the Bad, Regular and Good categories, according to the given parameters.

$$Sensitivity(TPR) = \frac{TP}{TP + FN}$$

- Specificity

This metric measures the negative or false values.

$$Specificity(TNR) = \frac{TN}{TN + FP}$$

- Precision

This metric measures the total number of items correctly classified as positive.

$$Precision(P) = \frac{TP}{TP + FP}$$

- Accuracy

$$Accuracy(ACC) = \frac{TP + TN}{TP + FP + FN + TN}$$

This metric measures the veracity of the prediction, that is, the difference between the predicted value and the actual one.

According to the results obtained from the application of the techniques individually, each of these obtained the following percentages in their precisions, shown in Table X:

TABLE X. METRIC RESULTS FOR INDIVIDUAL TECHNIQUES

Classification Technique	Metric			
	Sensitivity	Specificity	Precision	Accuracy
Extra trees	.4548	.7295	.5741	.6178
Random Forest	.6058	.8011	.6196	.7326
Decision Tree	.9054	.9509	.9144	.9348
Ada Boost	.5785	.7889	.5965	.7206
XGBoost	.8268	.9106	.8330	.8817

And after the application of stacking, the results he obtained were shown below in Table XI:

TABLE XI. METRICS RESULTS FOR STACKING

Classification Technique	Metric			
	Sensitivity	Especificidad	Sensitivity	Exactitud
Stacking	.9253	.9619	.9286	.9485

7) *Knowledge*: A graphical interface was created (Fig. 5) in which the previously developed predictive model was integrated, for the ease of use of teachers and in this way the performance of new engineering students can be predicted.

As a test, the following values were entered into the interface:

Age:

Sex:

Members:

And the result obtained concludes that the student will obtain a low academic performance.

#### IV. FINDINGS AND DISCUSSION

In this paper, the stacking technique was used to predict students' academic performance. In addition, as part of this technique, other classification methods such as Extra Trees, Random Forest, Decision Tree, AdaBoost and XGBoost were necessary, which are algorithms that obtain good results for a certain type of situation. During the modeling process, a cross-validation of 10 was required to ensure that each result is independent of division for training and test data.

The results obtained from the stacking technique (which is a combination of five algorithms) is 92.86% accuracy which is very encouraging with respect to the other results obtained by Extra Tree with 57.41% accuracy, Random Forest 61.96%, Decision Tree 91.44%, Ada Boost 59.65% and XGBoost with an accuracy of 83.3%, while authors such as [15], in their study show that the Naives bayes algorithm gave as a significant useful result an accuracy of 84%, being considered the best algorithm to predict academic performance and thus be able to arrive at solutions to improve the problem. On the other hand, in the study of the researchers [9], they developed a predictive model using the Rep Tree technique, which obtained an accuracy of 60.9%.

With regard to sensitivity, it is so that in the present study the Extra Trees technique was used, which reached a sensitivity of 45.48%, the Random Forest technique, 60.58%, the Decision Tree technique 90.54%, Ada Boost 57.85% and

finally XGBoost obtained a sensitivity of 82.68%, however when combining the aforementioned techniques through the Stacking technique a sensitivity of 92.53% was obtained, exceeding the percentage of sensitivity of the models; this is corroborated with the study of [16], which using the Naive Bayes technique, the model obtained a sensitivity of 66.7%.; they also [6] did a study in which a sensitivity of 88.7% was reached using Random Forest.

Likewise, with regard to specificity using the extra trees, Random Forest, Decision Tree, Ada Boost, XGBoost and each of these techniques, a specificity of 72.59%, 80.11%, 95.09%, 78.89%, 91.06% respectively was obtained and when performing the combination through the Stacking technique a specificity of 96.19% was obtained. In a study conducted by [14] they made use of the Naive Bayes technique, which obtained a specificity of 100%.

A limitation of the present study is that it was carried out considering the total average of the academic cycle of the students and in addition, they only belonged to the engineering schools. Results may vary for other schools or if a specific course or subject is considered.

Universities can employ the generation of a predictive model through stacking to predict the results of students' academic performance by cycle. Since it was demonstrated that its use and application can achieve a better accuracy in the prediction. This will help improve academic performance, as it will allow corrective action to be taken in advance and will also help reduce the percentage of students suffering from an academic delay.

#### V. CONCLUSION

The objective of this work is to develop a model that achieves better accuracy compared to the individual application of various techniques, through the stacking of different classification techniques, and in this way check if a better prediction is obtained.

The questionnaire applied to students to obtain the data set contains many questions, some of which have a greater correlation with academic performance than others. So maintaining the most important features benefits the accuracy of the prediction.

To achieve a good percentage of accuracy, it was necessary to have a process that involved cleaning the data, eliminating attributes less correlated with the output class, eliminating incomplete records or with invalid values. In this model, 5 classification techniques are used that are part of the multiclassification technique, stacking. The individual techniques were Extra Trees, Random Forest, Decision Tree, AdaBoost and XGBoost, after obtaining the predictions of each technique, XGBoost was used as a second-level technique to make the final prediction.

After having applied stacking it can be concluded that this has given better results than the application of the techniques individually.

# COVID-19 Disease Detection based on X-Ray Image Classification using CNN with GEV Activation Function

Karim Ali Mohamed, Emad Elsamahy, Ahmed Salem  
College of Computing and Information Technology, Arab Academy for Science  
Technology and Maritime Transport (AASTMT), Cairo, Egypt

**Abstract**—The globe was rocked by unprecedented levels of disruption, which had devastating effects on daily life, global health, and global economy. Since the COVID-19 epidemic started, methods for delivering accurate diagnoses for multi-category classification have been proposed in this work (COVID vs. normal vs. pneumonia). XceptionNet and Dense Net, two transfer learning pre-trained model networks, are employed in our CNN model. The low-level properties of the two DCNN structures were combined and used to a classifier for the final prediction. To get better results with unbalanced data, we used the GEV activation function (generalized extreme value) to augment the training dataset using data augmentation for validation accuracy, which allowed us to increase the training dataset while still maintaining validation accuracy with the output classifier. The model has been put through its paces in two distinct scenarios. In the first instance, the model was tested using Image Augmentation for train data and the GEV (generalized extreme value) function for output class, and it got a 94% accuracy second instance Model evaluations were conducted without data augmentation and yielded an accuracy rating of 95% for the output class.

**Keywords**—COVID-19; CNN; GEV function; image augmentation

## I. INTRODUCTION

In December 2019 less than four months after coming in Wuhan for the first time, the coronavirus has deteriorated into a public health calamity. As of March 30, 2021, there were 127.34 million reported diseases and roughly 2.78 million deaths on a global scale [1]. The illness COVID-19 is brought on by a virus source that irritates the lungs and makes patients develop pneumonia. These pneumonia cases are treated and medicated very differently from those caused by other viruses or bacteria. In addition to the diagnosis, specific preventative measures are implemented if a person exhibits COVID-19 signs. To prevent the infection from spreading, the COVID-19 patient is isolated for a predetermined number of days. Therefore, it is crucial to accurately and promptly identify COVID-19-related pneumonia in order to stop the virus's transmission. In the medical field, machine learning algorithms for automated diagnosis have recently gained traction as a tool for physicians [2], [3]. Deep learning algorithms have been used to correctly classify skin cancer [4], [5], Breast cancer diagnosis [6], [7]. Psychiatric disorder classification, detection of pneumonitis using chest x-rays, and image segmentation, COVID-19 is most commonly diagnosed

RT-PCR is the method used here. The early detection and treatment of this condition necessitates the use of chest CT and X-ray imaging. It's still possible to find symptoms on CT scans, even with test results that come back negative[8], because the RT-sensitivity of PCRs has dropped to 70% from 60% before [9], [10]. A good approach for diagnosing COVID-19 pneumonia when paired with CT has been demonstrated [11]. CT scans are often clear for the first two days or so after symptoms start to appear. When COVID-19 pneumonia survivors underwent CT lung examinations 10 days following the onset of symptoms, the most substantial pulmonary pathology was found [12], [13]. This is a black and white picture of the body's internal organs. The X-ray is a medical diagnostic tool that has been around for a long time and is still commonly used today. An X-ray image of the thoracic cavity can detect chest infections and other lung illnesses including pneumonia, making X-ray imaging a viable alternative diagnostic method for COVID-19, in light of the present healthcare crises throughout the world. In order to create a COVID-19 case identification system based on machine learning, we specified the following goals.

- Helping radiologists and other medical professionals identify minute, slow changes in X-rays that could otherwise go undetected.
- Because radiologists are so expensive, many people in developing nations do not have access to them. They might use this technology to identify their X-ray images as pneumonia, COVID-19, or normal; to build a model to scan complex data like CT and MRI scans for COVID-19 cases.

## II. RELATED WORKS

Classification and recognition jobs have been proven to be an effective machine learning method. Different deep-learning techniques have been used by researchers to detect COVID-19 in clinical pictures such chest CT scans and X-rays Alakwaa, Wafaa, Nassef, and Amr Badr [14]. For the detection of COVID-19, several of these radiological imaging techniques have recently gained popularity, The segmented CT images were initially fed straight into 3D CNNs for classification, but this proved to be insufficient. Instead, nodule candidates in the Kaggle CT scans were first identified using a modified U-Net trained on LUNA16 data (CT scans with tagged nodules). The U-Net nodule detection method had a high rate of false

positives, so regions of segmented CT scans of the lungs were used to feed 3D convolutional neural networks (CNNs) to determine whether the CT scan was positive or negative for lung cancer. These regions were where the U-Net output had identified the most likely nodule candidates. The test set accuracy produced by the 3D CNNs was 86.6%.

Hemdan Ezz, Marwa A. and Mohamed Esmail [15] using 25 confirmed positive COVID-19 instances on 50 chest X-rays serve as the study's validation data. Seven distinct deep convolutional neural network designs, including the updated (VGG19) and the second version of Google MobileNet, are included in the COVIDX-Net, experiments and evaluate the COVIDX-Net, 80–20% of X-ray pictures were used for the model's training and testing stages, respectively. With f1-scores of 0.89 and 0.91 for normal and COVID-19.[16] COVID-Net was developed by Alexander Wong, Linda, Wang and Zhong Lin ,COVID-19 identification is based on a deep model that achieved 93.2 percent accuracy rate in categorizing (COVID-19, normal and pneumonia). Tartaglione, Enzo, et al .[17] For COVID-19, we advocate a combination of Deep Learning and Transfer Learning, which has been the most thoroughly studied field of research these papers examine the extent to which COVID-19 identification may be improved by modifying popular deep models. Abdul Hafeez and Muhammad Farooq [18] are two such men. COVID-ResNet, Radiograph Detection, and more there are 5941 chest images in the COVIDx dataset, and the ResNet was trained with X-ray images of varying sizes and learning rates, resulting in an accuracy of 96.23 percent using COVID-ResNet. Tzani and Ioannis D .[19] used chest X-rays with different hyper parameter settings to test 5 different models for COVID-19 detection, all 1427 X-rays showed 224 people who had Covid-19 sickness, 700 people who had confirmed common pneumonia, and 504 people who were healthy. VGG-19, InceptionNet, MobileNetV2, XceptionNet, and Inception ResNetV2 are five conventional CNN designs that have been evaluated for the job of categorizing X-rays using various model parameters like the number of untrainable layers and the top layer neural network classifier settings achieve 96.78 %, 98.66 %, and 96.46 %, respectively, are the greatest levels of accuracy. Sultan Mahmud and Kh. Mustafizur Rahman [20] used Convolutional Neural Networks (CNNs) in a deep learning model that is proposed to automatically identify COVID-19 disease using CXR (Chest X-ray) pictures. Model was trained using 10293 X-ray pictures, 875 of which were from COVID-19 instances. The collection includes three separate types of tuples: pneumonia, COVID-19, and normal cases. The empirical results demonstrate that, while using a CNN with fewer layers than those works, the suggested model achieved 97% specificity, 96.3% accuracy, 96% precision, 96% sensitivity, and 96% F1-score, which are better than the works currently available. Junaid Latief and Asif Iqba [21] Exception's CoroNet deep neural network was used to identify and diagnose COVID-19 in chest x-ray images. ImageNet and a chest X-ray dataset generated by merging COVID-19 and other publically accessible X-ray pictures were used to train this. Accuracy was attained in the model with 98% recall and 93% accuracy in three of the COVID instances after conducting several tests (COVID vs. pneumonia vs. normal). Rajib Kumar and Sagar Deep [22] used CNN models to

identify COVID from chest X-ray images, the ensembles network is comprised of three CNN networks that have been trained. There was a 91.99 percent success rate for the NASNet, MobileNet, and DenseNet. Hasan K. Naji, Hayder K, Fatlawi,

Ammar J [23] implements classifiers using both ensemble classification algorithms (Adaptive Boosting and Adaptive Random Forest). The study of the data revealed a striking correlation between the patient's age, the presence of a chronic illness, and the rate of recovery. The experimental results show that adaptive boosting classifiers perform exceptionally well, reaching 99% accuracy, while adaptive random forest classifiers scored just 91% accuracy, Mahmoud B. Rokaya, [24]. The work emphasizes the value of bioscience in identifying recovered patients from mortalities. The decision trees (DT) could distinguish between recovered patients and mortalities with 94% accuracy even with little data. A shallow dense network attained a 75% accuracy rate. However, the net reached 99% accuracy when a 10-fold approach was used with the same data. They gathered the data for this study from King Faisal Hospital. Two parameters had the highest power to distinguish between recovered patients and mortalities, according to PCA analysis. When trained using only calcium and hemoglobin, the shallow net provides an accuracy of 92%.

Convolutional Neural Networks (CNNs) are used in a deep learning model suggested by Sohaib Asif, Ming Zhao, Fengxiao Tang, and Yusen Zhu [25] to automatically identify COVID-19 disease using CXR (Chest X-ray) images. They use a model to assess the performance of various pre-trained deep learning models (InceptionV3, Xception, MobileNetV2, NasNet and DenseNet201). Second, a lightweight shallow convolutional neural network (CNN) architecture with a low false-negative rate is developed for identifying X-ray pictures of a patient. The data set used in this study includes 2,541 chest X-rays from two separate public databases that have been confirmed as COVID-19 positive and healthy cases. The suggested model's performance is compared to those of pre-trained deep learning models. According to the results, the proposed shallow CNN has a maximum accuracy of 99.68% and more importantly sensitivity, specificity and AUC of 99.66%, 99.70% and 99.98%.

### III. MATERIAL AND METHODS

According to the guidelines in this section, chest X-rays should be classified as normal, pneumonia, or COVID-19. The issue with medical imaging is the lack of huge data sets. Because it isn't recommended to start from scratch and build a DCNN, the medical images can be categorized by using the features learned through a process called transfer learning [26]. The ensemble architecture suggested here will make sure that all of the descriptors needed for picture classification are there, so that the process can go smoothly. To get features from photos, a layer called "Filter" is used. These features are combined and then applied to a FC classification. We used features from two trained models as a starting point for the proposed model, with Global Average Pooling added to them. This layer is to cut down on feature length, which means that there will be fewer neurons in the last classifier input layer. This is good because it reduces the number of parameters,

which makes it less likely that the network will become over fit [27]. In this section, we will list the methods used in this model.

### A. Convolutional Neural Networks

A convolutional layer, which is made up of groups of kernels or filters, is the most important part of a CNN. During training, the layer parameters are learned. Filters are often smaller in size than the original image, and each filter constructs an activation map by combining with the image. The filter is moved over the image height and width, and at each spatial position we calculate the dot product between each filter element and the input. Fig. 1 depicts the convolution process. When a filter is applied to an image, the first layer of the activation map (shown in blue in Fig. 1) is formed via convolution with the image blue component. This method is repeated for each image element to create the activation map. Stacking the activation maps of each filter is used to enable convolutional layers to build their output volume along the depth dimension. The output of a neuron helps equalize each component of the activation map.

As the previous data led to the conclusion, the size of input image is equal to the size of the corresponding filter because each neuron is connected to a small local area of the input image. There are also factors that are shared by all neurons in an activation map. Because the convolutional layer has such a strong local connection, the network is forced to train filters that respond strongly to a specific portion of the input. The first convolutional layer looks for low-level characteristics like lines. The next convolutional layers look for high-level features like shapes and individual objects, as shown in Fig. 1.

### B. Data Augmentation

Accumulating fresh training data from previously collected data is known as "data augmentation". It is possible to improve photographs using simple image processing methods such as padding, cropping, rotation, and flipping. In order to train neural networks, these edited photographs are added to the original collection of photos, increasing the data set size. Data augmentation is used to artificially expand the training data set [28].

Imaging and labels are regularly altered in medical images to achieve this effect. Contrary to popular belief, data augmentation is a common practise in the training industry. It is simple to generate and decrease overfitting in CNNs using data augmentation and regression. COVID Image [29] is an excellent example of an image augmentation technique that uses only a little amount of training data to create modified copies of training data sets that belong to the same class as the original images.

Fig. 1. Convolution Layer Sample.

The training data set is often utilized for data augmentation rather than validation or testing of the data sets. However, this is distinct from other data settings, such as pixel and image scaling. Consistency must be maintained across all datasets with which the model interacts. CNN models for deep learning have lately proved the necessity of data augmentation, since data augmentation enhances outcomes when training CNN on sparse data, but only when the augmentation procedures utilized are appropriate for each dataset [30].

There are a number of simple data augmentation strategies that are being tested. Table I shows the parameters utilized in the picture augmentation process.

### C. Transfer Learning Features Extraction and Concatenation

Each layer of the CNN learns ever-more-complex filters. The initial layers demonstrate how to employ fundamental feature detection filters, such as corners and edges, to look for things. They learn how to use filters to look for parts of things, like eyes and noses. This is how the last layers work. They develop the ability to recognize complete things in a variety of shapes and orientations. For the time being, I'll briefly describe what transfer learning is and how it works. How can you train an image classifier in a few hours? Training image classification models might take many days or even weeks, depending on the size of the networks and datasets used.

As a result, why do not we use the work of dedicated data scientists working on in image classification projects at businesses like Google and Microsoft as a starting point for the image classification initiatives? Transfer learning is based on the concept of taking pre-trained models, i.e. known-weights models, and applying them to a new machine learning issue. You cannot simply replicate the model and expect it to operate, you must retrain the network using the new data. However, because the weights from earlier layers are more generic, they can be frozen for training.

Consider pre-initialized networks to be intelligently constructed networks rather than a randomly generated network. Because we are effectively tailoring the network, lower learning rates are often employed in transfer learning than in regular network training. Transfer learning may not be beneficial if high learning rates are applied and the network's early layers are not frozen. In many transfer learning cases, just the final layer or a few layers are taught. There are many free neural networks available online that can be used for transfer learning if the problem is fairly general and the user doesn't have enough data to train the network — this is common.

TABLE I. IMAGE AUGMENTATION PARAMETER USED

Parameter	Value
samplewise_center	True
width_shift	0.23
height_shift	0.22
shear	0.15
zoom	0.15
horizontal_flip	Ture
brightness	[0.4,1.5]

Fig. 2. Transfer Learning Model.

We may sum up this principle by saying that lower-level characteristics can be adapted to different environments by adjusting their weighting in later and fully connected layers, as we can see in Fig. 2, an example of a transfer learning model, as shown in Fig. 2.

The two-transfer model DCNN structures used in our model are described briefly below.

1) *DenseNet169*: In 2018, Huang et al. proposed densely linked convolutional networks, which interconnect each layer of a network in a feed-forward manner. A convolutional neural network with much more depth and accuracy was made feasible as a result of this groundbreaking achievement. Each layer of a dense network is linked directly to the next in a feed-forward method (inside every dense block). To create each subsequent layer, the feature mappings from prior layers are transferred to the new inputs.

2) *xception Net*: Deep detachable convolutions are used in the architecture of this CNN. A team of Google researchers came up with it. As a stepping stone between a regular convolution and a deep-separable convolution, Google has described the component units of convolutional neural networks. The input flow is the initial stop for data, followed by eight trips via the middle flow and a final stop at the outgoing flow. In addition, batch normalisation was used on all convolution and separable convolution layers in the final product.

#### D. GEV Activation Function

The majority of the data in a dataset is organized into a few number of classes, whereas several classes appear only sporadically. There is a considerable tail to the data in this example. Students who took classes with a larger number of students had a greater impact on their learnt traits. In this scenario, it's easier to simulate the more frequent classes than the rarer ones [31]. In both, binary and multiclass contexts, this problem exists.

When dealing with data that is very asymmetrical, with many instances in one class and few in the other, new techniques are needed. GEV distribution from extreme value theory yields a better activation function than sigmoid activation function when one class dominates the other. Binary and multiclass classification can be improved using

GEV activation functions rather than sigmoid or softmax activation functions. COVID-19 and other diseases with limited training examples may benefit from this new paradigm. When one side of the training dataset is much better than the other, or when the dataset is very imbalanced. CNN may then be used to extract the pictures' characteristics. The characteristics are then reduced to a single value by a liner combination in the fully linked layer. GEV (Generalized Extreme Value) is the activation function used to transform this single value into a probability [32]. GEV activation is provided by the function.

$$GEV(x|\mu, \sigma, \varepsilon) = \begin{cases} \exp\left\{-\exp\left(-\frac{x-\mu}{\sigma}\right)\right\}, & \text{if } \varepsilon = 0, \\ \exp\left\{-\left\{1 + \varepsilon\left(\frac{x-\mu}{\sigma}\right)\right\}^{-\frac{1}{\varepsilon}}\right\}, & \text{if } \varepsilon \neq 0, \end{cases} \quad (1)$$

Where  $\mu$ ,  $\sigma$ , and  $\xi$  are in the deep learning framework, parameters must be learned. According to the extreme value theorem the properly normalized maximum of a sample of independent and identically distributed random variables, can only converge to the GEV distribution. To give a probability, the GEV activation rescales the values between zero and one.

The parameters, on the other hand, enable the curve to better model the long-tail distribution that occurs with extreme data [33].

#### E. Evaluation of Performance

The most crucial metric for assessing how well our deep learning classifiers perform is accuracy. It's the sum of true positive and negative values divided by the total value

$$accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (2)$$

Precision is a measure of how many predictions in a certain class are really in that class.

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

Recall is a metric that measures how many correct class predictions might be produced given all of the data that was found to be correct.

$$Recall = \frac{TP}{TP+FN} \quad (4)$$

The F1 score is measurement accuracy metric. The F1 score is equal to twice the ratio of the accuracy and recall measurements multiplied by the total of the accuracy and recall measures.

$$F1 \text{ score} = 2 * \frac{Precision * Recall}{Recall + precision} \quad (5)$$

#### F. Data Collection

The images were captured from a number of publically available resources.

- <https://www.kaggle.com/prashant268/chest-xray-covid19-pneumonia>
- <https://github.com/agchung>
- <https://github.com/ieee8023/covid-chestxray-dataset>

Three sub-volumes comprises each of the two volumes (“training and testing”) in which the data is organized and labelled into (COVID19, PNEUMONIA and NORMAL). Which contains 6,432 X-ray pictures make up the dataset divided as follows 1583 image as normal and 576 labelled COVID-19 and 4273 as pneumonia, which 20% of the data are test images. As seen in Fig. 3 and Fig. 4, we can see the dataset is highly unbalanced, we used GEV function to solve this problem. We plot some samples of data in Fig. 5.

Fig. 3. Training and Validation Dataset.

Fig. 4. Test Dataset.

Fig. 5. Samples of Data.

#### IV. RESULTS AND DISCUSSION

COVID-19 detection is the primary goal of this investigation. We used a dataset that was organized into (COVID19, PNEUMONIA, and NORMAL) instances and used our model to classify the COVID-19 by employing features derived from two separate transfer learning models using GEV activation function to accomplish our study goal. In our models, we have a three-step process. Every step of the process will be described in depth, including pre-processing, categorization, and validation. Fig. 6 depicts the suggested framework. During the classification phase, we feed the proposed model the "feature maps" generated by two previously trained models (DensNet 169 and xception Net). Filters or feature detectors are applied to the input image, and the outcomes of those operations are calculated to produce these feature maps. Based on the model's design, a variety of feature maps was generated. Table II displays the feature maps generated by the DensNet 169 model, which were [7, 7, 1664].

Using the ImageNet dataset, the input of the 224x224x3 form is sampled down to 7x7x1664 at the conclusion of the model. Table III indicates the xception Net feature maps generated, which is [7, 7, 2048] (see Table III). 224x224x3 input is down sampled to 7x7x2048 at the model's conclusion. ImageNet-trained model structure was used to create this feature. Table IV's concatenation output feature that was generated from two preview Models [7, 7, 3712], is the input to our proposed model. In the form of a feature map created by merging two previously trained models, this layer significantly speeds up deep network training and boosts neural network robustness by normalizing data between neural network layers instead of normalizing raw data. Instead of analyzing the full dataset, a flattening layer reduces the result of normalization to a single-dimensional feature vector, which aids learning by speeding up training and increasing the pace at which information is absorbed. The flattening layer combines all the pixel data from convolutional layers into a single vector.

Once the model has received the vector, it uses it as an input layer. To feed data to each neuron in our model, we utilise the flatten function, which reduces multi-dimensional input tensors to just one dimension. Flattening layer output is shown in Table IV as [3712]. When the vector data has been flattened, it is transmitted to the CNN's layers, which are referred to as "completely linked" or "dense layers," where it is processed in one of two ways. Because of these interconnections between neurons at every level, the brain may function as a single unit. It is the initial responsibility of dense layers to categories the picture using the flattened output results of convolution and pooling layers as input.

As a result, the categorization determination is ultimately driven by the completely linked layer. We used three fully connected (FC) layers, which represent the global averaged attributes of the two models utilizing three neural layers, were used to solve the classification problem. There are 128 nodes, 32 nodes, and then 3 nodes in each layer of the brain. Every FC layer has a PReLU Activation Function applied. Neurons can be activated or deactivated using an activation function. It

will be determined whether or not the input from the neuron to the network is crucial, using simple mathematical approaches.

It is common for CNNs to include a "dropout layer," a mask that eliminates particular neurons from the next layer while keeping all others intact. It is possible to apply a dropout layer to an input vector in two ways: either to eliminate part of the vector's attributes, or to delete neurons inside a hidden layer. The value [0.5] of Dropout was utilized in the first FC layer in order to avoid CNNs being unduly dependent on the training data. This implies that 50% of the neurons in the input were randomly deactivated. This model relies heavily on the learning rate parameter. The rate at which we learn determines how frequently we need to adjust the settings we're working with. The model will take a long time to converge if the learning rate is too low, because the parameters will only change by modest amounts. If the learning rate is excessively high, the parameters may hop over the low spaces of the loss function, and the network may never achieve a convergent state. The inverse is also true. Learning Rate (0.0003 to 0.00005) was the range of the steps we utilized on this model schedule. Once the model has ceased improving, this callback method will attempt to change the model by decreasing the learning rate. Up to 13 epochs of training data were utilized with the validation data (validation loss').

Using a GEV function to forecast the output class improved performance in the imbalance class, when there are a lot of samples from one class and a few from the other, but only a few instances from the other. GEV distribution from extreme value theory yields a better activation function than sigmoid activation function when one class dominates the other. Binary and multiclass classification can be improved using GEV activation functions rather than sigmoid or softmax activation functions, as shown in Fig. 6.

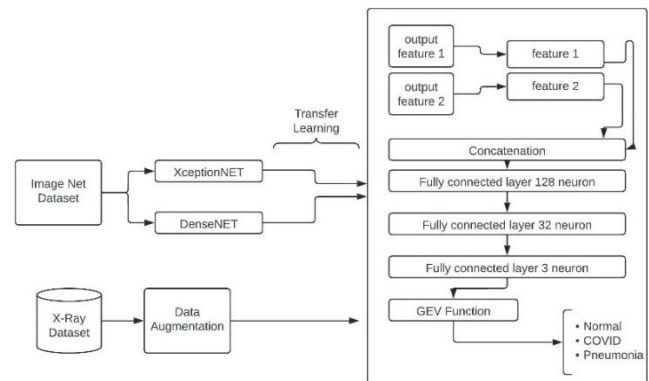

Fig. 6. Proposed Framework.

### A. Results and Evaluation Model

The effectiveness of the proposed model is also compared to that of Dense Net and xception Net as single classifiers. As illustrated in Table V, to compare model output, we repeat the model without the image augmentation parameter, as shown in Table VI.

When compared to two independent models, Xception-NET and DenseNet, without augmentation, the estimated model accuracy is 95.5%, and with augmentation, it is 94% as we can see in Fig. 11. As shown in Fig. 7 and 8, DenseNet achieves an accuracy of 93.2 percent with picture

augmentation and 94 percent without image augmentation, whereas Xception NET achieves an accuracy of 84 percent with image augmentation and 94 percent without image augmentation. 13 is the ideal number of epochs, as we can see in Fig. 12 based on intersection of the training line with validation line so we stopped the training model at epoch 13.

We can measure the metrics of the outcomes of our categorization investigation using the confusion matrix. The confusion matrix for the proposed CNN framework's test cases is shown in Fig. 13 with image Augmentation and Fig. 14 without, In addition, Fig. 9, 10 graphic representation of the CNN classifier performance evaluation shows loss both with and without image augmentation during the validation and training stages. Additionally, at epoch number 12, the validation and training losses attained by the suggested system are 0.1587 without image augmentation and 0.1777 with augmentation.

TABLE V. RESULT WITH IMAGE AUGMENTATION TECHNIQUE

Model Name	Precision	Recall	F1-score	Accuracy

## V. CONCLUSION

Using the GEV activation function, For the purpose of identifying and classifying COVID-19 occurrences from X-ray images, we suggested a deep learning model using two DCNN structures. 95 percent of the time, our model is able to handle jobs that include numerous classes. To process the COVID dataset without data augmentation, our model achieved 95% accuracy in just 13 learning cycles. The GEV Function surpasses a single classifier in terms of generalization performance when features are combined from the two DCNN structures without picture augmentation. Radiologists can benefit from the suggested strategy by learning more about COVID-19's important components. Accuracy is expected to increase better with more and more training data. The following are some of the most important discoveries from this research: For effective and more accurate image categorization, CNN models require a sufficient number of images.

When employing an existing dataset with a GEV activation function, picture augmentation parameters have little impact on the performance of a CNN model.

In a statistically significant way, the suggested CNN model improves the performance of other single CNN models. The medical sector may greatly benefit from CNN-based diagnosis using X-ray imaging when dealing with large-scale testing situations like COVID-19.

**Abstract**—One of the most prevalent cancers in the world, cervical cancer claims the lives of many people every year. Since early cancer diagnosis makes it easier for patients to use clinical applications, cancer research is crucial. The Pap smear is a useful tool for early cervical cancer detection, although the human error is always a risk. Additionally, the procedure is laborious and time-consuming. By automatically classifying cervical cancer from Pap smear images, the study's goal was to reduce the risk of misdiagnosis. For picture enhancement in this study, contrast local adaptive histogram equalization (CLAHE) was employed. Then, from this cervical image, features including wavelet, morphological features, and Grey Level Co-occurrence Matrix (GLCM) are extracted. An effective network trains and tests these derived features to distinguish between normal and abnormal cervical images by using EfficientNet. On the aberrant cervical picture, the SegNet method is used to identify and segment the cancer zone. Specificity, accuracy, positive predictive value, Sensitivity, and negative predictive value are all utilized to analyze the suggested cervical cancer detection system performances. When used on the Herlev benchmark Pap smear dataset, results demonstrate that the approach performs better than many of the existing algorithms.

**Keywords**—Cervical cancer; pap smear; time-consuming; contrast local adaptive histogram equalization (CLAHE); Grey Level Co-occurrence Matrix (GLCM); morphological features; wavelet; SegNet

## I. INTRODUCTION

A thin layer of tissues made up of cells covers the human cervix. Cervical cancer is the term used to describe a condition when a cell is transformed into a malignant cell that can divide and expand quickly to form a tumor [1]. Cervical cancer, which affects women worldwide and ranks as the second leading cause of cancer-related mortality, is fatal. If this cancer is found early enough, it may be treated [2]. Typically, a biopsy and screening procedure is used to make the diagnosis. Techniques for image processing can be used to determine where cancer has spread. The fourth-most frequent cancer-related cause of death in women is cervical cancer [3, 4].

Intelligent systems and medical image processing both contribute to the analysis of cancerous cells. They grow more time and money efficient as new approaches are developed [5-7]. They are currently gaining popularity in place of traditional

techniques including Pap smears, colposcopies, and Cervicography [8]. These methods are objective to the human experience, but it's important to note that they don't completely replace the professional doctor's subjective assessment, even though they can greatly aid it [9].

Analyses of the nucleus and cytoplasm are typically necessary for cell classification investigations to take cell type into account. Consequently, it is essential to develop algorithms that would aid in nuclei and cytoplasm segmentation [10-12]. The majority of feature extraction uses the same standards that specialists use to evaluate a cell. However, there is limited knowledge of cervical cytology [13]. Although this has not yet been researched, the cell might possess traits found in higher features. As a result, deep learning techniques have recently made representational learning more well-known. The automatic extraction of characteristics from input photos is a remarkable benefit of deep learning [14].

Analyses of the nucleus and cytoplasm are typically necessary for cell classification investigations to determine the type of cell. As a result, algorithms that can divide the cytoplasm and nuclei into separate parts must be developed [15-17]. The majority of feature extraction considers cells using the same standards as experts. Cervical cytology is, however, not well understood. The cell might possess traits found in higher forms, however, this has not yet been researched [18].

As a result, deep learning techniques have recently made representational learning more well-known. The automatic extraction of characteristics from input photos is a remarkable benefit of deep learning. As a result, automatic screening has made extensive use of deep learning [19]. In particular, DeepPap achieved a predictive performance of 98.6% on the Herlev benchmark Pap smear dataset and comparable effectiveness on the HEMLBC private Pap smear dataset using patch extraction from the nucleus ground truth mask and a transfer learning strategy to initialize weights with a pre-trained model.

The main cause of cervical cancer-related deaths in female patients is that the disease cannot be identified at an earlier stage, and patients do not experience any symptoms until cancer has progressed to its terminal stage [20]. Only if it is

discovered at an earlier stage can the death ratio for female patients be decreased. To prevent patient deaths, this research suggests a mechanism for detecting cervical cancer at an earlier stage.

The major key contributions of the research are as follows,

- The preprocessing stages are used to increase the classification efficiency, even more, here images can be resized, data augmentation strategies are used and CLAHE is employed to improve the image quality.
- Following that, features such as moment invariant features, GLCM features, and wavelet features are extracted from the preprocessed image.
- The EfficientNet classifier is trained using these features to categorize the cervical images as Normal or Abnormal.
- Finally, we propose a SegNet for segmenting the defected areas, it uses multi-stage architecture and attention blocks in each stage.
- The Herlev dataset has undergone various ablation experiments. Our proposed network outperforms the state efficiency concerning all other approaches, according to the experimental data.

The paper is organized as follows. In Section II, a few similar prior efforts are summarized. Section III describes the proposed system. Section IV presents experimental findings and a discussion. Section V contains the work's conclusion.

## II. LITERATURE REVIEW

In the literature, there is a lot of research comparing the effectiveness of various methods utilized to treat cervical cancer. ML and DL techniques were used in group studies. It is clear from studies on cervical cancer that deep learning techniques including CNN, stacked autoencoder, VGG19, and LASSO were applied.

Convolutional neural networks (CNNs) were introduced by Ghoneim et al. [21] for the identification and categorization of cervical cancer cells. To extract deep-learned features, a CNNs model is fed the cell pictures. After that, a classifier powered by an extreme learning machine (ELM) classifies the input photographs. Through transfer learning and fine-tuning, CNN's model is applied. Their accuracy is superior to others as compared to the current system. Comparatively, the level of complexity is higher.

To classify cervical cancer from Pap smears, William et al. [22] developed an improved fuzzy c-means method. Through the employment of a Trainable Weka Segmentation classifier, cells were segmented, and trash was eliminated sequentially. Wrapper filters were used to select features. The method surpasses several of the current algorithms in terms of false negative rate, false positive rate, and classification error, according to the results. The primary drawback of the recommended automated Pap smear analysis systems is their inability to handle the Pap smear architectures complexities.

Deep learning methods, such as softmax classification with stacked autoencoder, have reportedly been utilized to

categorize data sets, according to Adem et al. [23]. The raw data collection is transformed into a lower dimension dataset by applying a stacked autoencoder. In order to minimize the data dimension and create a classifier with high accuracy, the stacked autoencoder model was used. Comparatively speaking to the other machine learning method, it has higher classification success rates for data related to cervical cancer. It is necessary to increase accuracy by removing relevant information.

The VGG19 (TL) model and the CYENET were presented by Chandran et al. [24] to automatically classify cervical tumors from colposcopy pictures. By improving the VGG19 model, which is extensively used for medical image processing, the transfer learning method is applied to forecast accuracy. By utilizing an optimal architecture and an ensemble technique CYENET, the CNN created from scratch is intended to automate the screening of cervical pictures. The outcomes of the experiments demonstrate that the suggested CYENET had high performances. As a result of the dimension reduction, training process is very long.

The classification of cervical biopsy tissue images based on LASSO and ensemble learning-support vector machine (EL-SVM) was first presented by Huang et al. [25]. The average optimization time was decreased by 35.87 seconds while maintaining the classification accuracy when the LASSO technique was used for feature selection. Serial fusion was then carried out. 468 biopsy tissue pictures were identified and classified using the EL-SVM classifier. The ROC curve and error curve were utilized to assess the classifier's generalizability. The results of the experiment indicate that a superior categorization result was obtained. A two-step feature selection process that takes time and makes it challenging to distinguish between individual cells.

A smaller visual Geometry Group-like Network is used to classify the segmented entire cervical cell data by Allehaibi et al. [26] using a Mask R-CNN and VGG-like Net. The ResNet10 network serves as the foundation of the Mask R-CNN, fully utilizing geographical data and past knowledge. Mask R-CNN performs better in precision, recall, and ZSI than the prior segmentation approach during the segmentation phase when applied to the entire cell. The performance of the seven-class problem categorization produces excellent results. The suggested method uses a little volume of data and requires more research to fully understand cervical cells.

Allehaibi et al. [27] presented an Inception v3-based cervical cell categorization system with features that were intentionally extracted. The accuracy of cervical cell recognition has been significantly improved by the use of Inception v3 and artificial characteristics. Additionally, this research inherits the strong learning capability from transfer learning to produce an accurate and efficient classification of cervical cell images while addressing the under-fitting issue with a limited amount of medical data. The suggested algorithm offers great accuracy, good universality, and minimal complexity. The Suggested method had issues with certain cells having overlapping cytoplasm sections. Table I represents the merits and demerits of the existing papers.

TABLE I. MERITS AND DEMERITS OF RELATED WORKS

Reference	Year	Method	Dataset	Merits	Demerits
[21]	2020	CNN& Extreme Machine learning	Herlev database	More scalable and practical	Investigating cervical cells requires more research.
[22]	2019	fuzzy c-means algorithm	DTU/Herlev benchmark Pap smear dataset	Higher precision and smaller data dimensions	Due to the dimension reduction, training time is quite long.
[23]	2019	stacked autoencoder	Cervical cancer dataset	Acquire more complementing features	an increase in image fusion complexity
[24]	2021	VGG19 and CYENET	Intel ODT dataset	Better accuracy Efficient classification	More complexity Need more investigation
[25]	2020	LASSO- (EL-SVM)	Cervical cancer	Better sensitivity and specificity	Extraction of pertinent data is required to increase accuracy.
[26]	2019	Mask R-CNN	Herlev Pap Smear dataset	Improvements in accuracy and feature selection	The selection of features in two phases takes time.
[27]	2019	Inception v3	Herlev dataset	Excellent robustness and best performance	need development to change the parameter

It is possible to draw a conclusion using a few of the restrictions and potential improvements that may be learned from the existing research. The effectiveness of existing approaches was insufficient. The algorithm's complexity and potential are primarily responsible for this. Our proposed approach is used to address the gaps in the current body of research. The segmentation and classification method for cervical cancer that has been suggested is intended to enhance classifier performance.

### III. METHODOLOGY

The four essential components of the proposed methodology were preprocessing, feature extraction, classification, and segmentation. The preprocessing processes are used to increase the classification efficiency even more. The raw photos were prepared using the pre-processing method. Data compression and image enhancement were part of the pre-processing. By using the CLAHE approach the

image can be enhanced. Then, characteristics including GLCM features, wavelet features, and moment invariant features are extracted from the preprocessed image. By comparing the cervical picture with the taught features, the EfficientNet classifier is trained to determine if the image is normal or abnormal. Finally, SegNet is employed to segment the defected area. After that, the dataset is separated into three parts. The training model is then fed this dataset. A selection of test datasets is utilized to label the training model, which is then used to categorize cervical cancer. Fig. 1 demonstrates the architecture diagram of the proposed framework.

#### A. Preprocessing

Images are strengthened in resolution during the initial stages of pre-processing utilizing various filters. To prevent further distortions, several data augmentation methods, including shearing, scaling, and rotation, are also used. Images are also resized at various scales. The CLAHE algorithm can be used to improve the image.

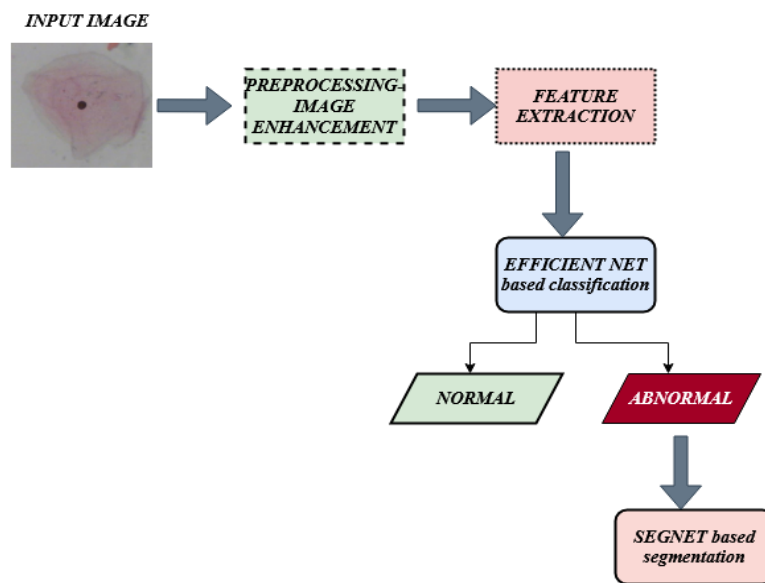

Fig. 1. Architecture Diagram of the Proposed Methodology.

1) *Contrast Local Adaptive Histogram Equalization (CLAHE)*: With the help of histogram clipping, the histogram-based image enhancement technique known as CLAHE can only amplify images to a certain degree. It is a technique that is efficient for assigning projected intensity levels in medical data. In order to adjust the brightness of a pixel's display to reflect where that pixel ranks in terms of intensity in its histogram, the method analyses an intensities histogram in a contextual region that is focused on each individual pixel. The histogram that is generated shows the image contrast created by the technique at every luminance. It is a modified version of the standard histogram.

It lessens contrast enhancement, which is typically achieved through the histogram equalization method, which also makes more noise. As a consequence, by reducing contrast augmentation in Histogram Equalization, the expected result was attained in situations where noise became particularly obvious by enhancing contrast, such as medical photos. To lessen contrast, one can restrict the slope of the linked function. The use of CLAHE in our work has helped to increase the accuracy rate overall.

#### B. Feature Extraction

The nucleus' and cytoplasm's essential characteristics, including texture, shape, and color, were retrieved at this stage. In an image, features stand for the traits of the pixel pattern. In this study, morphological, wavelet, and GLCM characteristics are retrieved from cervical images to distinguish between normal and pathological images. GLCM was employed to extract eight texture features. Normal and abnormal cells appear very differently in the cervical Pap smear image in terms of color and form distribution.

2) *Wavelet features*: Due to their speed and superior transformation capabilities compared to other transforms like Contourlet and Curvelet, Wavelets are beneficial in multi-resolution analysis of cervical images. This study decomposes the magnitude response Gabor image using the Discrete Wavelet Transform (DWT), which is applied to every row and column.

The LL, HL, LH, and HH sub-bands are produced by the first level decomposition. L and H stand for low and high frequencies, respectively. Additionally, the second-level decomposition of DWT is applied to the LL sub-band to create four additional subbands. The feature pattern for the cervical image classifications uses each of these subbands.

3) *GLCM features*: The feature extraction method known as GLCM is employed to extract the energy features of the cervical picture. Any single channel image can have one built. The GLCM is a square matrix with the same number of rows and columns as there were in the original image's grayscale. The GLCM matrix is created by counting the number of times a grayscale intensity pixel will be found next to a pixel with the value of the fused cervical picture at various orientations, such as 0°, 45°, 90°, and 135°. The GLCM matrix is built in this work at a 45° angle. The contrast, energy, entropy, and

correlation characteristics of the GLCM features are employed to distinguish the cancerous image from the healthy cervical image.

Contrast: It's described as,

$$Contrast = \sum(|i - j|^2 \times p(i, j)) \quad (1)$$

This texture feature calculates the difference in grayscale between adjacent pixels.

Correlation: It's described as,

$$Correlation(R) = \frac{\sum(i - \mu_i)(j - \mu_j) \cdot p(i, j)}{[\sigma_i, \sigma_j]} \quad (2)$$

The correlation between brightness in adjacent pixels is measured by R. The GLCM's row average  $\mu_i$  and column average ( $\mu_j$ ) are respectively. The GLCM's row  $\mu_i$  and column  $\mu_j$  corresponding standard deviations are denoted by  $\sigma_i$  and  $\sigma_j$ .

Energy: It is a second angular moment, calculated by adding the squares of all the GLCM's components.

$$Energy(E) = \sum p(i, j)^2 \quad (3)$$

Energy, a unit of measurement for homogeneity, runs from zero to unity for a picture.

Entropy: It is described as,

$$Entropy = -\sum p(i, j)[\log_2 p(i, j)] \quad (4)$$

The degree to which the GLCM's elements are near the diagonal is gauged by this metric. The value is between 0 and 1.

4) *Morphological features*: Cell size and form make up the morphological characteristics. For this study, eight connected chain codes were used to determine the morphological characteristics of cells. The eight pixels around the eight-linked chain code are the connected pixels.

a) *Area*: the number of pixels that each cell has taken up;

b) *Circumference*: The cell's circumference is equal to one week.

c) *Nuclear to cytoplasm ratio*: ratio of nuclear to cellular size:

$$\frac{N}{C} = \frac{Nucl_{area}}{Nucl_{area} + Cyto_{area}} \quad (5)$$

#### C. Classification based on EfficientNet

The EfficientNet group has eight variants, spanning from B0 to B7, and the quantity of estimated parameters does not increase much as the amount of models increases, even though accuracy increases. In contrast to previous CNN models, EfficientNet employs the Swish activation function rather than the Rectifier Linear Unit (ReLU) activation function. Deep learning frameworks seek to uncover more efficient methods using fewer methods. EfficientNet, unlike other state-of-the-

art approaches, achieves more efficient results by scaling depth, width, and resolution evenly while reducing the strategy's size. When resources are limited, the initial step in the compound scaling strategy is to discover the relationship among the various scaling dimensions of the network. This method determines an appropriate scaling factor for the depth, breadth, and resolution dimensions. After that, these coefficients are used to scale the baseline network to the target network. Table II represents the EfficientNet architecture.

CNN belongs to the EfficientNet group. In terms of layer width, layer depth, input resolution, and a combination of these criteria, EfficientNet methods scale well. EfficientNet is a recent deep learning approach that aims to improve model efficiency while also improving accuracy. From B0 to B7, there are various variants. The inversion bottleneck MB Conv is the basic building piece for EfficientNet. It was first presented in MobileNetV2, however, it is used significantly further than MobileNetV2 because of the larger FLOPS budget. Blocks in MBConv are made up of layers that expanded and then compress the channels, hence direct connections are employed among bottlenecks that connected far fewer channels than expansion layers. When compared to typical layers, this design has in-depth separate convolutions that minimize computation by almost a k2 factor. The 2D convolution window's height and breadth are determined by the kernel size, or k, which is the opposite.

EfficientNet presents a novel compound scaling model that scales network width, depth, and image size uniformly using a compound coefficient  $\phi$ .

$$\text{depth: } d = \alpha \phi \tag{6}$$

$$\text{width: } w = \beta \phi \tag{7}$$

$$\text{resolution: } r = \gamma \phi \tag{8}$$

$$\begin{aligned} \text{s.t. } & \alpha \cdot \beta^2 \cdot \gamma^2 \approx 2 \\ & \alpha \geq 1, \beta \geq 1, \gamma \geq 1 \end{aligned} \tag{9}$$

FLOPS are proportional to d, w2, and r2 in a standard convolution process. Because convolution operations account for the majority of the cost of computation in convolution networks, growing the network as indicated in Eq. (3.5) boosts the network's FLOPS by about  $(\alpha, \beta^2, \gamma^2) \phi$  in total.

The batch normalization (BN) restricts the final layer's outcome to a range, requiring a mean of zero and one SD. This adjustment shortens the training period and improves the model's stability. The compound scaling approach scales this system in two phases, starting with the baseline EfficientNet-B0.

Step 1: Considering double as many materials are allocated, a grid search with  $\phi = 1$  is used to find the best values for  $\alpha, \beta, \gamma$ .

Step 2: The generated  $\alpha, \beta, \gamma$  values are set as constants, and the baseline network is scaled up using Equation. (3.5) with varied values  $\phi$  to generate EfficientNet-B1 through B7.

#### D. Segmentation

Using morphological techniques, the cancerous regions of an aberrant cervical picture are segmented. An encoder network, a decoder network, and a final layer for pixel-wise categorization make up SegNet [28]. This configuration consists of four blocks, the final block of which does not execute pooling. To create feature vectors that correspond to each input, features from the input image are extracted using the encoder layers. A decoder network that consists of four blocks of upsampling, convolution, and batch normalizing layers is then applied after that.

TABLE II. EFFICIENTNET FRAMEWORK

Level	Operator	Resolution	Channels	Layers
<b>EfficientNetB0 architecture, the network baseline</b>				
1	Conv1×1/Pool/FC	7×7	1,280	1
2	MBCConv6, k3×3	7×7	320	1
3	MBCConv6, k6×6	14×14	192	4
4	MBCConv6, k3×2	14×14	112	3
5	MBCConv6, k5×4	28×28	80	3
6	MBCConv6, k5×5	56×56	40	2
7	MBCConv6, k3×3	112×112	24	2
8	MBCConv1, k3×3	112×112	16	1
9	Conv 3×3	224×224	32	1
<b>Additional layers</b>				
10	FC/Softmax	1	NC	1
11	FC/BN/Swish	1	128	1
12	FC/BN/Swish/Dropout	1	512	1
13	B.N./Dropout	7×7	1280	1

Segmentation mask is created by the decoder network using feature vectors, and output at high resolution is produced by upsampling layers using low features. The final layer is a classification layer that uses 2D convolution with a 1x1 filter size to do pixel-by-pixel classification. Throughout the training, a stride of one and a filter size of 3x3 are employed. Except for the final layer, where the sigmoid activation function is employed, ReLU is employed as the activation function. To reduce the size of the feature map, max-pooling layers with a pool size of 2x2 are employed [29]. After each batch, the weights are optimized by the Adam optimizer with a learning rate of 1e-4.

The model is trained throughout 10 epochs with a batch size of 32. For pixel-wise segmentation, a Softmax classifier is given the final decoder output feature maps. For quick and precise image segmentation, the decoder recovered spatial dimensions. Due to its memory and processing speed, the SegNet architecture is generally superior to other systems like U-Net and FCN.

#### IV. RESULT AND DISCUSSIONS

To illustrate the conclusion, using a benchmark dataset to compare the proposed method to existing techniques in terms of NPV, sensitivity, specificity, PPV, and accuracy. The materials and metrics that were employed to achieve the intended results will be described in this paper. The proposed experiment's performance was evaluated in PYTHON.

##### A. Dataset Description

Herlev dataset, which is made available to the public for disease detection, was obtained from Denmark Hospital to detect cervical disease. There are 917 total Pap smear images in the complete data set. The dataset is split into a training set and a testing set, with the training set including 643 photos and the testing set including 274 images. The classifications of Normal and Abnormal have been taken into consideration.

With a total cell count of 917, we have taken into account the various cervical cell types, including epithelial and dysplastic, which are divided into normal and abnormal classes. The sample smear cervical cells from the dataset shown in Fig. 2 were chosen at random.

##### B. Evaluation Metrics in Cervical Cancer Diagnosis

The effectiveness of the categorization model is explained by several evaluation criteria used by various authors. Confusion matrices are used to assess the model's efficacy for the majority of medical image classification. Sensitivity, Specificity, Accuracy, and F1 score are some of the distinctive metrics employed for the analysis. The prediction output includes four results: true positive, true negative, false positive, and false negative. The various performance criteria used to evaluate the mode are displayed in Table III.

Accuracy: The number of correctly identified images determines a technique's classification accuracy, which is evaluated as follows:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (10)$$

Sensitivity (Recall): It measures the percentage of positive samples that are accurately categorized. Sensitivity has a value between 0 and 1.

$$Sensitivity = \frac{TP}{TP + FN} \quad (11)$$

Specificity: It is a measurement of the percentage of incorrectly identified negative samples.

$$Specificity = \frac{TN}{TN + FP} \quad (12)$$

Positive Predictive Value (PPV): It counts the number of pixels that are positive and accurately identify cancerous regions.

$$PPV = \frac{TP}{TP + FP} \quad (13)$$

Negative Predictive Value (NPV): It counts the number of negative pixels that are associated with incorrectly identified cancer region pixels.

$$NPV = \frac{TN}{TN + FN} \quad (14)$$

Confusion Matrix: The Confusion Matrix summarizes the categorization problem's prediction results. The confusion matrix reveals not just the classifier's errors, but also the sorts of errors. Fig. 3 represents the output of cervical cancer.

##### C. Evaluation of Classification Performances

A comparison of classification techniques and current classifiers is provided in this section. Four classification methods AlexNet, LeNet, VGG and Inception V3 are used in this study. Table III displays the effectiveness of many strategies, including the one that is suggested.

The existing approaches like Lenet, AlexNet, VGG and Inception V3 are compared with the proposed approach. When comparing with the sensitivity metrics it achieves 89.73% in LeNet, 90.16% in AlexNet, 91.37% in VGG, 99.44% in Inception V3 and our proposed approach yield a greater solution which is 99.67%. The next comparison can be made in Specificity LeNet achieves 84.33%, AlexNet yields 87.34%, VGG gains 86.88%, 96.73% in Inception V3 and the proposed approach yields 98.39%.

Fig. 2. Sample Images from the Dataset.

Fig. 3. Output of Cervical Cancer Affected Image (a) Input Image (b) Contrast-enhanced (c) Segmented Defected Area.

TABLE III. PERFORMANCES COMPARISON OF PROPOSED WITH EXISTING APPROACHES

Approaches	Sensitivity	Specificity	Accuracy
LeNet	89.73	84.33	86.76
AlexNet	90.16	87.34	89.57
VGG	91.37	86.88	91.47
Inception V3	99.44	96.73	98.23
EfficientNet	99.67	98.39	99.05

TABLE IV. COMPARISON OF PERFORMANCES OF THE CLASSIFIERS

Approaches	Accuracy (%)	Specificity (%)	Sensitivity (%)	PPV (%)	NPV (%)
CYENET	92.30	96.20	92.40	92	95
DenseNet-121	72.42	76.83	59.86	48.39	84.52
DenseNet-169	69.79	71.48	65	44.84	85.31
SVM	63.27	71.85	78.46	70	76.87
Proposed	99.67	98.39	99.67	94.67	96.13

Fig. 4. Performances Comparison of Proposed with Existing Approaches.

Finally, a comparison can be made with accuracy metrics our proposed approach yields 99.05% which is the best solution then the worst solution appear in LeNet which is 86.76%. Performances comparison of proposed with existing approaches is represented in Fig. 4.

The metrics like Accuracy, Specificity, Sensitivity, PPV and NPV are used to compare the performances. To compare our proposed approach performances, the existing approach includes CYENET, DenseNet-121, DenseNet-169 and SVM utilized (Table IV).

Comparison can be made with the Accuracy metrics CYENET achieves 92.30% of accuracy, DenseNet-121 yields 72.42% of accuracy, DenseNet-169 gains 69.79% of accuracy, SVM achieves 63.27% of accuracy finally our proposed approach gains 99.67% of accuracy which is the greater one. Fig. 5 represents the Accuracy comparison of the proposed with existing approaches.

Fig. 5. The Accuracy Comparison of Proposed with Existing Approaches.

When comparing with specificity our proposed approach gains 98.39%, CYENET achieves 96.20%, DenseNet-121 yields 76.83%, DenseNet-169 gains 71.48%, and SVM achieves 71.85%. The figure represents the specificity comparison of the proposed with the existing. The Specificity performance comparison of the proposed with existing approaches is shown in Fig. 6.

Comparison can be made with the Sensitivity metrics CYENET achieves 92.4% of Sensitivity, DenseNet-121 yields 59.86% of Sensitivity, DenseNet-169 gains 65% of Sensitivity, SVM achieves 78.46% of Sensitivity finally our proposed approach gains 99.67% of Sensitivity which is the greater one. Fig. 7 represents the sensitivity comparison of the proposed with existing.

Fig. 6. The Specificity Performances Comparison of Proposed with Existing Approaches.

Fig. 7. The Sensitivity Performances Comparison of the Proposed with Existing Approaches.

Comparison can be made with the Sensitivity metrics CYENET achieves 92% of PPV, DenseNet-121 yields 48.39% of PPV, DenseNet-169 gains 44.84% of PPV, SVM achieves 70% of PPV finally our proposed approach gains 94.67% of PPV which is the greater one. Fig. 8 represents the PPV comparison of proposed with existing.

Fig. 8. The PPV Metrics Comparison of Proposed with Existing Approaches.

Comparison can be made with the Sensitivity metrics CYENET achieves 95% of NPV, DenseNet-121 yields 84.52% of NPV, DenseNet-169 gains 85.31% of NPV, SVM achieves 76.87% of NPV finally our proposed approach gains 94.67% of NPV which is the greater one. The Fig. 9 represents the NPV comparison of the proposed with the existing.

The confusion matrix for the end-to-end trained proposed method is shown in Fig. 10. 3% of Normal, 2% of abnormal samples were misclassified, while 97 % of benign samples, 98% of cancerous samples were classified correctly. As a result, the proposed approach acquires the best result.

#### D. Evaluation of Training and Testing

Train Accuracy and Validation Accuracy curves converge in the end, and after 50 epochs we received an accuracy of 99.56%, which is quite good. The validation Loss curve jumps up and down a bit. It means it would be nice to have more validation data. Fig. 11 represents the proposed training accuracy versus testing accuracy.

After about 25 epochs Validation Loss exceeds Train Loss, which means we have a bit of overfitting here. But the curve doesn't go up over epochs, and the difference between Validation and Train Loss is not that big, so this could be accepted. Fig. 12 represents the proposed training loss versus testing loss

Fig. 9. The NPV Metrics Comparison of Proposed with Existing Approaches.

Fig. 12. Proposed Training Loss Versus Testing Loss.

### E. Discussions

The success rate of treatment for cervical cancer is greatly impacted by early identification. The pathological study of microscopic Pap smear slide pictures is the primary cervical cancer screening tool. Automatic image analysis techniques are likely to defeat subjective justifications and lighten the workload. Due to the considerable unpredictability of cervical cell pictures, including overlapping cells, dust, contaminants, and uneven irradiation, effective nucleus image segmentation remains a difficult challenge. Furthermore, restrictions in feature design and selection make it difficult to classify cervical smear images.

The quantitative analysis of microscopic Pap smear slide pictures is difficult as a result. The absence of uninvolved photos from the public database of cervical images is crucial for the early detection of cervical cancer. Additionally, there are few cervical smear photos that have been labelled. The paper proposed an automatic cervical smear image categorization system based on EfficientNet to address the existing issues mentioned above. The usefulness of the proposed approach, which takes time to apply, is shown by experimental findings. Future research might focus on improving the method's efficiency and lowering computational complexity.

### V. CONCLUSION

In conclusion, a set of clinically relevant and biologically understandable features are used to offer an automated detection and classification approach for the identification of cancer from cervical pictures. The proposed methodology is based on a network for segmenting and classifying cancer. The CLAHE-based approach is utilized to improve the cervical pictures. EfficientNet classifier is employed to divide cervical pictures into normal and abnormal images. According to the simulation results, the suggested cervical cancer segmentation method can identify both normal and abnormal areas in images of the cervical region. The cervical cancer detection system's performance metrics are 97.42 percent sensitivity, 99.36 percent specificity, 98.29 percent accuracy, 97.28 percent PPV, and 92.17 percent NPV. The theoretical deep learning model will be tested on other datasets in the future. Combining a few sophisticated image processing techniques with the method can also improve it.

### ACKNOWLEDGMENT

We declare that this manuscript is original, has not been published before and is not currently being considered for publication elsewhere.

**Abstract**—Forecasting the quantity of waste growth in upcoming years is very much required for assessing the existing waste management system. In this research work, time series forecast model, ARIMA (Autoregressive Integrated Moving Average), is used to predict future waste growth from 2021 to 2028 for Bengaluru, largest city in Karnataka. Eight years old historical solid waste dataset from 2012 to 2020 is used to make predictions. This dataset is preprocessed and only time bounded variables like days, month, year and waste quantity in tons are used in this research work to obtain accurate prediction. The model is implemented in python in Google Colab free cloud’s Jupyter notebook. As ARIMA is time bounded, forecast made by the model is accurate and performance of the model is evaluated using metrics such as Mean Absolute Deviation (MAD), Mean Absolute Percentage Error (MAPE), Root Mean Square Error (RMSE) and Coefficient of Determination ( $R^2$ ). Outcomes revealed that ARIMA (0, 1, 2) model with the lowermost RMSE (753.5742), MAD (577.4601), and MAPE (11.6484) values and the maximum  $R^2$  (0.9788) value has a greater forecast performance. The outcomes attained from the model also showed that the total volume of yearly solid waste to be produced will rise from about 50,300 tons in 2021 to 75,600 tons in 2028.

**Keywords**—Cloud Computing; Machine Learning; Time Series Forecasting; Waste Management System; ARIMA; Predictive Modeling

## I. INTRODUCTION

Today’s global technologies are popularly driven by cloud computing and machine learning. Both of these are contributing to every organization’s business growth. Machine learning today facilitates users to create models which can be used to make predictions by training them to automatically learn from past data. Various machine learning approaches [7] such as supervised and unsupervised require huge amount of storage which is a challenging task for machine learning professionals. Cloud computing [9] contributes in such scenarios by providing all the resources and services required to ease the tasks. Machine learning makes brainy applications where as cloud computing provides storing and refuge services to access these applications. Cloud computing [2] thus helps in enhancing and expanding machine learning applications. Recently, these two technologies together gave birth to a new technology which is known as intelligent Cloud [15].

Cloud Computing (CC) [2] is one of the easy, flexible and quickly growing and most demanded technologies meant for delivering services requested by the users on demand over the Internet. The constraints such as cost, computational processing power, storage, analysis etc. involved in traditional approach have led to the raise of cloud computing [16]. It allows us to access various applications and data remotely without letting us install any software’s explicitly in personal laptops. The various services provided by CC “are generally categorized into Software as a Service (SaaS), Platform as a Service (PaaS) and Infrastructure as a Service (IaaS)” [2].

Cloud computing provides all the resources required to develop, run and deploy machine learning models on demand. Machine learning needs huge amount of data storage, computing power and many servers to concurrently work on models as presented in Fig. 1.

Fig. 1. Cloud Computing and Machine Learning.

Some of the key capabilities behind cloud with machine learning is that cloud’s pay per use service which is good for organizations who aspire to influence machine learning competences for their business without much spending. It offers the elasticity to work with machine learning features without having advanced data science skills. It helps us in ease of testing several machine learning skills and scales up as projects go into production and demand rises. Due to these capabilities, many cloud service providers today are offering lots of machine learning services for everyone without having background expertise of Artificial Intelligence (AI) and Machine Learning (ML).

Metropolitan cities today are loaded with huge population impacting solid waste growth such as food waste, plastics, bottles, sanitary waste, construction waste etc. impacting our surrounding environment. To minimize the effect of waste growth, it is necessary to understand and analyze the speed at which solid waste is being created. Existing waste management systems do not have automated techniques incorporated for exact prediction of solid waste growth [5]. Due to lack of data, incomplete data and other challenges such as poor strategies, they are not performing efficiently. To overcome this, machine learning approach can be used [1].

## II. EASE OF USE

Today's municipal waste management systems [8] are inefficient to perform waste analysis and take precautionary measures due to numerous loop holes such as lack of data, lack of technical expertise, lack of efficient strategies, lack of planning etc. Inaccurate prediction may be the reason for well-known shortfalls in waste administration arrangement such as unnecessary or inadequate disposal arrangement, waste collection, landfilling and recycling divisions. Accurate forecast is very much needed in case of metropolitan cities like Bengaluru, New Delhi etc. in India as they are highly populated impacting waste growth so that an appropriate action can be taken prior. These actions are not only to develop and improve existing systems but also help to alert the public so as to encourage decrease of waste and also recycle the solid waste produced. If the waste generated is not handled well, it may affect environment and living organisms' health. Due to noteworthy influence of waste growth on the environment, waste management systems [12] resulting minimal impacts on universe and zones required to be established. "Various methods of forecasting solid waste growth [6] can be generally categorized into five key clusters: descriptive statistical approach, regression approach, material flow approach, time series approach [13] and artificial intelligence approach" [5].

In [20], authors have used ANN for forecasting waste growth in Poland. Various explanatory variables were used to reveal the impact of socio-economic and demographic variables on the amount of waste generated. Performance of the models are measured using MSE (Mean Squared Error) and  $R^2$  metrics. The results proved that ANN is cost efficient approach in foreseeing the waste growth.

In [21], authors have developed hybrid Multilayer Perceptron (MLP) deep learning automated method to classify the waste dumped by community in the metropolitan area. Their experiments employed camera to capture images of waste and sensors to recognize the essential features. The experimental results proved that hybrid approach is capable to achieve more than 90% accuracy.

In [24], authors have carried out their research work to foresee waste growth for Mashhad city for different seasons using ANN on time series data. In [23], authors used weekly time series data to predict waste growth in Mashhad using SVM along with PCA (Principal Component Analysis). Kumar et al. used time series data which holds the yearly MSW (Municipal Solid Waste) [14] produced in New Delhi, India. Different models are used to predict waste growth and

the model's performance is assessed using RMSE and the IA values.

In [17], authors presented ARIMA model to foresee solid waste growth for Arusha city, Tanzania. Monthly generated waste data for the last few years 2008 to 2013 was used to carry out the research. The result proved that ARIMA (1, 1, 1) is well suited for forecasting "in terms of MAPE, MAD and RMSE measures".

In [18], authors presented "ARIMA model to forecast solid waste growth in the Kumasi Metropolitan Assembly (KMA)". The results showed that ARIMA (1, 1, 1) is well suited for predicting solid waste growth in the KMA.

In [19], authors presented "ARIMA model to forecast healthcare waste growth for the hospitals of Garhwal region of Uttarakhand, India". The performance of the model was analyzed using  $R^2$  value, MSE and MAE metrics and proved that ARIMA is best suited for forecast.

In [22], authors developed "ARIMA model to forecast the municipal solid waste growth of Abuja city, Nigeria. The results proved that an ARIMA (1, 1, 9) is the optimal model for forecast".

In [25], authors developed ARIMA model for forecasting amount of solid waste growth for Karur town, Tamil Nadu. Monthly based historical data was used for the year 2015 to 2017 and the results proved that ARIMA is best for prediction.

In [26], authors presented "ARIMA, Support Vector Regression (SVR) [4, 11], Grey model and Linear Regression (LR) model to forecast medical waste growth of Istanbul city, Turkey". Historical dataset used for forecast was from 1995 to 2017. Various performance metrics such as MAD, MAPE, RMSE and  $R^2$  were used to assess the models performance. Outcome showed that ARIMA (0, 1, 2) model is well suited for waste growth forecast.

## III. MACHINE LEARNING TIME SERIES FORECAST MODEL

Some of the key challenges in Statistics and Data Science today are time series and forecasting. A data is said to be time series data when it is bounded to time like days, months and years. When this data is used to predict future values, then it is called as Time series data.

ARIMA [3] is one of the popularly used machine learning algorithm for time series forecasting. It predicts future values using past data (autoregressive, moving average).

### ARIMA Model

It is a class of linear models that uses historical data to estimate forthcoming values. ARIMA [10] enclosing three components, Auto Regressive (AR), Integrated (I) and the Moving Average (MA) contribute to the ultimate forecast. Two of the Key concepts behind these models are Stationarity and Autocorrelation.

Stationarity tells that observations/data are time independent whereas autocorrelation relates the same set of observations but across diverse timing. The different components of ARIMA are explained as follows.

### Auto Regressive (AR)

This component uses autocorrelation concept, where the dependent features depend on the past values.

The general equation is:

$$X_t = \alpha_1 + \phi_1 X_{t-1} + \phi_2 X_{t-2} + \dots + \phi_n X_{t-n} \quad (1)$$

As shown in (1), an observation  $X$  at time  $t$ ,  $X_t$ , depends on  $X_{t-1}, X_{t-2}, \dots, X_{t-n}$ ,  $\phi_1, \phi_2, \dots, \phi_n$  determines coefficient of lags that the model evaluates,  $\alpha_1$  is the intercept term, and where  $n$  is called the lag order which represents the number of previous lag samples or observations to be considered by the model.

### Integrated (I)

This component of ARIMA transforms non-stationary time-series data to a stationary by accomplishing prediction on the difference between any two pair of observations instead directly on the data itself.

$$\begin{aligned} A_t &= M_{t+1} - M_t \dots c = 1 \\ B_t &= A_{t+1} - A_t \dots c = 2 \end{aligned} \quad (2)$$

As shown in (2), Differencing tasks which can be achieved many times levels ( $M \rightarrow A$  and  $A \rightarrow B$ ), depends on the hyper parameter  $c$  that is set while training the ARIMA model.

### Moving Average(MA)

This component performs some kind of aggregation on the historical time series data in terms of residual error epsilon ( $\epsilon$ ) thus reducing noise in the data.

$$X_t = \alpha_2 + \omega_1 \epsilon_{t-1} + \omega_2 \epsilon_{t-2} + \dots + \omega_n \epsilon_{t-n} + \epsilon_t \quad (3)$$

The terms  $\epsilon$  indicate the residual errors from the aggregation operation as shown in (3) and  $n$  is another hyper parameter that specifies the time window for the moving average's residual error.  $X_t$  depends on the lagged forecast errors.

Following is the generic steps followed for ARIMA.

- Step 1: Visualization of Time Series Data
- Step 2: If data is non stationary, then convert it to stationary
- Step 3: Make the Correlation and AutoCorrelation graphs
- Step 4: Build the model using data
- Step 5: Make predictions using the model

## IV. RESULTS AND DISCUSSIONS

The ARIMA model used here for waste growth forecast is implemented in python. Jupyter notebook from Google Colab which is a free cloud service is used for the implementation.

Autocorrelation (AC) and Partial Autocorrelation (PAC) graphs shown in Fig. 2 (a) and (b) respectively are used to analyse and forecast future waste growth. They basically indicate how many days of previous data need to be considered to forecast future values which is known as lags. To calculate AR, three values,  $p$ ,  $d$ ,  $q$  need to be chosen,

where,  $p$  represents AR model lags,  $d$  represents Differencing,  $q$  represents MA lags.

ARIMA model used here is to predict future trends of waste growth. The model needs stationary data to determine AR and MA components. Since the data used in this research work is non stationary,  $d=1$ , first order differencing was done.

Autocorrelation graph in Fig. 2(a) showed that the series is stationary after first differencing. The arrangements of the AC and PAC graphs of the differenced series were examined for the initial computation of autoregressive ( $p$ ) and moving average orders ( $q$ ) in ARMA ( $p, q$ ) model.

For an AR model, the number of nonzero partial autocorrelations gives the most extreme lag of  $x$  that is used as a predictor.

Once, AC and PAC computation and analysis was done, ARIMA model was invoked on the dataset which gave the results shown in Table I and the forecast graph obtained is shown in Fig. 3.

(a)

(b)

Fig. 2. (a) Autocorrelation and (b) Partial Autocorrelation after First Differencing .

Equations used to measure the performance of the model are RMSE shown in (4), MAD shown in (5), MAPE% shown in (6), and R<sup>2</sup> shown in (7).

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (W_{real_i} - W_{expected_i})^2}{n}} \quad (4)$$

$$MAD = \frac{1}{n} \sum_{i=1}^n |W_{real_i} - W_{expected_i}| \quad (5)$$

$$MAPE = \frac{1}{n} \sum_{i=1}^n \frac{|W_{real_i} - W_{expected_i}|}{|W_{real_i}|} \times 100\% \quad (6)$$

$$R^2 = \left[ \frac{\sum_{i=1}^n (W_{real_i} - \overline{W_{real_i}})(W_{expected_i} - \overline{W_{expected_i}})}{\sqrt{\sum_{i=1}^n (W_{real_i} - \overline{W_{real_i}})^2 \times \sum_{i=1}^n (W_{expected_i} - \overline{W_{expected_i}})^2}} \right]^2 \quad (7)$$

Where,  $W_{real_i}$  and  $W_{expected_i}$  denote the real and expected value of  $i^{th}$  data point value, respectively.  $\overline{W_{real_i}}$  and  $\overline{W_{expected_i}}$  are the average of the real and expected value of  $i^{th}$  data point value. Also,  $n$  indicates the total number of data values. The performance of the model was measured by computing  $R^2$  value. It accepts values between 0 and 1, and values very close to 1 which indicates better fitting.

TABLE I. ARIMA MODEL PERFORMANCE

Model	RMSE	MAD	MAPE	R <sup>2</sup>
ARIMA (1,0,2)	854.2914	635.4722	11.5771	0.9767
ARIMA (0,1,0)	960.1165	713.0000	13.5741	0.9690
ARIMA (1,2,1)	1045.2257	777.5254	15.3163	0.9683
ARIMA (0,1,2)	753.5742	577.4601	11.6484	0.9788

Various ARIMA models are also made for selecting the model and their performance analysis is done using various metrics. As shown in Table I, the ARIMA (0, 1, 2) model has the highest R<sup>2</sup> (0.9788) and lowest RMSE (753.5742), MAD (577.4601), and MAPE (11.6484) and hence it is chosen as best model.

Fig. 3. Solid Waste Growth Forecast using ARIMA.

## V. CONCLUSION

It is very important to contribute and enhance the existing condition and scenarios of waste management in the crowded smart city, Bengaluru which can only be attained with precise waste assessment. Hence, the goal of this research work is to deliver an appropriate model to assess the quantity of waste produced. In this context, ARIMA (0, 1, 2) was chosen as the best model and used to forecast the waste growth of Bengaluru based on eight years of historical data. The outcomes of this research work can help waste management authorities to develop a reliable waste forecast model, which can be a significant foundation of information for Bengaluru. In addition, previous data about the volume of waste produced can be used for both the planning and design of future services.

## VI. LIMITATIONS AND FUTURE RESEARCH WORK

This research work targets to the development and improvement of waste management practices in smart cities through forecasting waste generation. It shows the development of a systematic process where time based factors affecting waste generation in smart cities have been determined to study and forecast waste growth. Unavailability of the continuous waste data and also socio-economic and demographic variables affecting solid waste generation makes it difficult to foresee solid waste growth for the developing countries like India.

The research work can be extended in the future by incorporating more input features, more socio-economic parameters. Other ML, AI or deep learning techniques can be used in future to handle complex scenarios and to achieve better accuracy.

**Abstract**—This paper presents the results of our research carried out as part of the building of an Intelligent Tutoring System (ITS) to learn *Mooré*, a tone language. A word in tone language may have many meanings according to the pitch. The system has an intelligent tutor to personalize and guide the learning of the transcription of polysemous words in *Mooré*. This learning activity aims both to master the transcription and also to distinguish the lexical meaning of words according to the pitch used. A first step of this research has been the specification of the processes, inference and knowledge of the system. In this work we present the implementation and pedagogical assessment of the system. We designed the architecture of the ITS, the diagnosis of transcription errors and remediation approach. Then, we used the Petri net formalism to model the system dynamic in order to analyze its states and fix deadlocks. We developed the system in java and we evaluated its educational value by an experimentation with learners. This shows that the learning objectives can be achieved with this system.

**Keywords**—Intelligent tutoring system; petri network; evaluation; *Mooré* language

## I. INTRODUCTION

An Intelligent Tutorial System (ITS) is a computing environment for human learning that integrates artificial intelligence techniques and cognitive theories in order to provide guided and personalized learning to learners [1], [2]. It consists of four main modules: domain, student, tutoring and communication [26], [27]. In the literature, ITS for learning language research are mostly on European and Asian languages such as English, Japanese, Chinese [5], [10], [11], [12]. Our research contributes to the development of ITS for language learning. We aim to build an ITS to learn polysemous words in *Mooré* through transcription activities. *Mooré* is a tone language, the most spoken in Burkina Faso. This language is also spoken in some neighboring countries such as Côte d'Ivoire, Ghana, Mali and Togo.

The contribution presented in this paper follows a previous one where we presented a specification of an intelligent tutoring system to learn tone language [13]. We used CommonKADS a knowledge engineering method to specify the knowledge and processes of the system. The specification provides a common framework for the development of transcription-based ITS for any tone language.

In Burkina Faso, the learning of local languages is part of the non-formal education program of the government. So, only with the training centers, often of short-term projects, provide learning programs for local languages. Therefore, building

an ITS for *Mooré* learning is a significant contribution in the field of local languages ilearning in Burkina Faso. The building of such IT tools could not only help meet the needs to learn local languages in sub-Saharan Africa but also to ensure the continuity of local language learning during periods of pandemic such as COVID-19.

The rest of the paper is organized as follows. Section II presents the background. It contains important concepts used in this article. In Section III we present the architecture of the system and describe the approach to diagnostic transcription errors and the remediation to provide. Section IV shows the development framework and an overview of the system. Section V presents the evaluation results of the system experimentation. In Section VI we summarize the work done and gives some perspectives.

## II. BACKGROUND

In this section, we present important concepts that we used and related work on tone language. These concepts are the Petri net, Bayesian network widely used in the field of ITS research.

### A. Tone Languages

A Tone language includes pitch phonemes in addition to consonants and vowels, and pitch differences are used to distinguish one lexical item from another [15]. Tone languages are characterized by two types of tones: punctual tone and melodic tone. In punctual tones, only one aspect of the melodic curve is considered (highest or lowest) whereas in modulated tones, they are distinguished by successive directions of the melodic curve [16]. *Mooré* and most of the languages spoken by sub-Saharan African are languages with punctual tones [4]. The *Mooré* language has three tonal patterns:

- the high tone, represented by the acute accent ( )
- the medium tone, represented by the dash sign ( )
- the low tone, represented by the grave accent ( )

The Non-respect of tones leads to confusion, misinterpretation or nonsense.

The learning activities of the ITS are based on transcription tasks of polysemous words in *Mooré* language at the example of Fig. 1. To do this, taking account the tone in the transcription is very important because it allows us to distinguish the lexical meaning of words according to the pitch.

Fig. 1. Example of Two Words(Bread and Fall) Represented in Images. The First Image is Transcribed by the Word *Bûri* and the Second Image by the Word *Bûri*. The Word *Bûri* in *Mooré* without the Pitch, it' is Unclear whether that Word Alludes to the First Image or to the Second Image.

### B. Petri Networks

The Petri networks in short Petri nets is a mathematical modeling formalism introduced by Dr. Carl Adam Petri in 1962. This modeling tool is used to represent the dynamics of discrete distributed systems in computer science, engineering and so forth [8]. The petri nets formalism is borrowed from graph theory. Therefore, a Petri nets is a directed bipartite graph that has two types of node: places and transitions. Place is represented by circle and transition by bar or box. Places and transitions are connected by directed edges. Place represents system states, condition or resources that must be met before an action can be performed. Transition represents actions.

A mathematical definition of Petri net is a tuple  $PN = (P, T, Pre, Post)$  where:

- $P = \{p_1, p_2, \dots, p_n\}, n > 0$  a finite set of places;
- $T = \{t_1, t_2, \dots, t_m\}, m > 0$  a finite set of transitions;
- The places  $P$  and transitions  $T$  are disjoint ( $P \cap T = \emptyset$ );
- $Pre : (PxT) \rightarrow \mathbb{N}$  is an input function that defines directed edges from places to transitions;
- $Post : (TxP) \rightarrow \mathbb{N}$  is an output function that defines directed edges from transitions to places.

A marked Petri net is a five tuple  $G = (P, T, Pre, Post, M)$  where  $M$  can be viewed as a function, which assigns a natural number with each place, i.e.  $M : P \rightarrow \mathbb{N}$ .  $M$  can also be viewed as a vector given by  $M_k = \{M_1, M_2, \dots, M_i, \dots, M_n\}$  where the  $i^{th}$  entry of  $M$  is  $M_i$ , which is the marking of the place  $p_i$ . The execution of a Petri net causes its marking to change by removing tokens from its input places and depositing into each of its output places.

A transition is said to be enabled when each one of its input places is marked with at least one token. In mathematical terms, a transition,  $t \in T$ , is enabled if  $M(p) \geq Pre(p, t); \forall p \in P$ . If an enabled transition  $t$  fires then it causes a change in marking from  $M(p)$  to  $M'(p)$  given by the equation:

$$M'(p) = M(p) - Pre(p, t) + Post(p, t); \forall p \in P.$$

As for the usefulness of the Petri net, this approach is used to diagnose modeling errors of an application [9], [6]. In the field of ITS, Petri nets have been used to model systems

and to verify their consistency [7]. Thus, for our study, we used graphical representation of Petri net to model the operations(actions) and states of our system. The reachability graph will allow to represent the different firings of the marked Petri net. The purpose of the reachability graph is to remove possible deadlock states of the system.

### C. Bayesian Network

The Bayesian network is a graphical and probabilistic model for representing uncertain or incomplete knowledge of the learner in the field of learning [3]. It is a technique of artificial intelligence initiated by Corbett and Anderson in 1994. The graphical model is represented by two parameters  $\{N, A\}$ .  $N$  represents the set of nodes or vertices and  $A$  the set of arcs. The probabilistic representation of the Bayesian network is based on Bayes' theorem [28]. Bayes' theorem is translated by the following mathematical formula:

$$P(A|B) = \frac{P(B|A)P(A)}{P(B)}$$

In other words, this equation means: for two events  $A$  and  $B$ , what is the probability that  $A$  will occur given  $B$ .

In the field of ITS, the Bayesian network approach can be used to [17]: update the learner model [18]; diagnose the causes of learner errors [19]; or predict the actions of the learner in a problem-solving process [20]. Diagnosing misconceptions requires collecting and checking for buggy rules, which sometimes leads to overwhelming and impractical numbers of buggy rules, even for simple domains such as fractions [21]. Modern approaches, such as algorithmic debugging [22], automatically distinguish buggy rules. With reference to the study on the specification of knowledge and processes, the authors have determined two inference structures in the context of the design of ITS for tone languages learning [13]. These two inference structures are: the inference structure for Assessment and the inference structure for Diagnosis. The following Task-decomposition diagram (see Fig. 2) presents the different inferences used by the inference structure for Assessment.

Fig. 2. Task-Decomposition Diagram.

For this present study, we use the Bayesian network approach to trace transcription errors. This is a very suitable approach for the diagnosis of cognitive knowledge.

### III. SYSTEM DESIGN

In this section of our study, we first describe the different components of the intelligent tutoring system to learn *Mooré* polysemous word, then we show the approach used for the knowledge diagnosis and finally we present the approach used to design the operation of the system.

#### A. Architecture of the ITS

As most intelligent tutors, the intelligent tutoring system for learning transcription of polysemous words in *Mooré* language consists of four components namely the domain module, the student module, the tutoring module and the communication module. However, for the modeling of the components of our system, it was made taking into account the specificity of the domain of learning. Fig. 3 presents this architecture.

Fig. 3. Architecture of the System.

The different modules in Fig. 3 correspond to the following description:

- Domain module

The role of the domain module is to provide the system with all the information related to the knowledges of the learning area. The domain module consists of the learning tasks, transcriptions corresponding of learning tasks in *Mooré* and sounds in *Mooré* corresponding to the learning tasks. The Learning Tasks component of the domain module consists of all the learning tasks in the system. These tasks are presented in the form of images. The Tonal transcription in *Mooré* component contains the ideal transcriptions of the learning tasks. As for the Sound in *Mooré* component, it consists of sounds corresponding to ideal transcriptions in *Mooré*. The tutoring module uses this component of the domain module to provide didactic aid to learners. The didactic aid of our system allows learners to listen to the sound corresponding to the task selected in order to transcribe correctly.

- Tutoring module

The pedagogical strategy of the system is represented in the tutoring module. This module consists of the resolution, evaluation and remediation modules. With reference to the Petri network of our system represented by Fig. 6 in subsection III-C, the Resolution module is responsible for executing actions  $t_3$ ,  $t_4$  and  $t_5$  of the Petri network. As for the Assessment module, it is responsible for executing actions  $t_6$ ,  $t_7$ ,  $t_8$ ,  $t_9$  and

$t_{10}$ . For the Remediation module, it is responsible for executing actions  $t_{11}$ ,  $t_{12}$ ,  $t_{13}$ ,  $t_{14}$ ,  $t_{15}$ ,  $t_{16}$ ,  $t_{17}$ ,  $t_{18}$ ,  $t_{19}$  and  $t_{20}$  of the Petri network.

- Student module

It is composed of the learner's performance states in relation to his tasks solved and the data for the system login. The student module is responsible for managing all the information of learner's profile. It updates the profile of the latter, in particular the Student's performance component, after each resolution of a task.

- Communication module

The communication module consists of the different interaction windows between the system and the user. It allows the system to interact with users and vice versa.

We consider that the domain module and the tutoring module represent the most important modules of our ITS because domain module contains the knowledge that the system should taught and tutoring module the strategies that the system should use to evaluate learning and provide assistance.

#### B. Diagnostic

In the domain of ITS, some authors limit remediation to feedback [23], [24] and others perceive it as a process consisting of cognitive diagnosis and feedback [25]. We consider remediation as a process that consists of first detecting the sources of errors and then generating the appropriate feedback in relation to the error committed. So, for the diagnosis of knowledge, we have, using the graphic model of Bayesian network method, first proceeded to the representation of the uncertain and incomplete knowledge of the learners. This representation allowed us to make the causal links between this knowledge. We then developed the different algorithms for tracing transcription errors based on the Bayesian network representation. Fig. 4 below represents the Bayesian network model that we designed.

Fig. 4. Bayesian Network for Knowledge Diagnosis.

Fig. 4 presents the diagnosis of transcription errors. When the transcription evaluation made by the learner returns an erroneous transcription, the system performs tracing based on the above Bayesian network in order to detect the transcription error and generate the suitable feedback. The probable transcription errors listed in the graphical model of the Bayesian network above have been identified in collaboration with

the *Mooré* language trainers The flexibility of the Bayesian network approach allowed our collaboration non-computer scientists to easily understand the graphical model shown in Fig. 4. Also, this representation allowed the trainers of the *Mooré* language to participate in the validation of the study. Fig. 5 presents the flowchart model of our Bayesian network.

Fig. 5. Flowchart of Knowledge Diagnosis. This Represents the Bayesian Network Algorithm.

Fig. 5 shows a flowchart of the remediation algorithm that generates adaptive feedback according to the learner.

### C. Verification of the System Consistency

The Petri Network is an efficient tool for the verification of discrete event systems [14]. Since an ITS is a discrete event system, we use the Petri net formalism to model our system. This model is important to ensure that the system does not have any action or operation that would put it in a deadlock situation. Therefore, we can simulate the operation of the system and resolve possible blockage situations before implementation step.

Fig. 6 presents the Petri net of the system which models its different states.

In Fig. 6, the transitions ( $t_i$ ) represent the different actions performed by the system and the places ( $p_i$ ) represent the input or output data of the actions of system. Table I describes the different actions and states of the system.

Based on the description of places and transitions in Table I, the task solving, for example, is described as follows. The system first executes the action ( $t_3$ ). The learner selects one of the tasks presented ( $p_4$ ) and the system then executes the action ( $t_4$ ). From the data ( $p_5$ ), the system finally executes the action ( $t_5$ ).

To correct the possible blockages of the system, we made the reachability graph in order to analyze the different firings of the transitions. Fig. 7 presents the reachability graph of the Petri net.

The analysis of Fig. 7 shows that for each firing of  $t_i$ , the input place  $p_i$  goes from 1 to 0 and the output place  $p_{i+1}$  goes

Fig. 6. Petri Net Representation of the System States (Places) and Actions (Transitions).

TABLE I. DESCRIPTION OF THE PLACES (STATES) AND TRANSITIONS (ACTIONS) OF THE PETRI NET.

Places ( $p_i$ )	Transitions ( $t_i$ )
$p_1$ : app icon	$t_1$ : display login screen
$p_2$ : login screen	$t_2$ : check login and password
$p_3$ : home screen(Main)	$t_3$ : load tasks
$p_4$ : tasks presented	$t_4$ : load image and audio
$p_5$ : task selected, image and audio loaded	$t_5$ : read transcription
$p_6$ : transcribed word read	$t_7$ : produce success feedback
$p_7$ : transcribed word assessed	$t_8$ : mark task solved
$p_8$ : success feedback generated	$t_9$ : update learner's profile
$p_9$ : task solved marked	$t_{10}$ : return to tasks presented
$p_{10}$ : learner's profile updated	$t_{11}$ : detect spelling mistake
$p_{11}$ : spelling mistake detected	$t_{12}$ : display spelling mistake
$p_{12}$ : feedback spelling mistake displayed	$t_{13}$ : transcribe again
$p_{13}$ : tones error detected	$t_{14}$ : detect tones error
$p_{14}$ : feedback amalgamated tones displayed	$t_{15}$ : detect amalgamated tones and produce feedback
$p_{15}$ : feedback tones error displayed	$t_{16}$ : transcribe again
$p_{16}$ : sound emitted	$t_{17}$ : produce tones error feedback
$p_{17}$ : learner score displayed	$t_{18}$ : transcribe again
$p_{18}$ : system ended	$t_{19}$ : emit sound
	$t_{20}$ : end sound emitted
	$t_{21}$ : display score
	$t_{22}$ : return to the main menu
	$t_{23}$ : stop the system

from 0 to 1. From these results, we can say that the Petri net is 1-safe (or binary) which means that the system is deadlock-free. We can conclude that the designed system is coherent.

## IV. SYSTEM OVERVIEW

We implemented the system on the Java environment. We present in this section an overview of the system functionalities. An user can use this application to learn *Mooré* language by transcription tasks. Fig. 8 presents the system dashboard view.

Fig. 8 presents the system dashboard which provides main menu. A click on the "TACHES" button leads to the resolution

Fig. 7. Reachability Graph Corresponding to the Petri Net of Figure 6.

Fig. 10. An Example of Transcription. The Task Number 2 of Broom Image is Transcribed in *Mooré* by *saaga*.

Fig. 8. System Dashboard.

interface and user can select a task to transcribe, see Fig. 9.

The resolution interface displays a list of tasks to be solved by the learner. In Fig. 9, the selected task (number 2) is displayed as an image to be transcribed in *mooré*.

Fig. 9. Resolution Interface Presenting the Tasks. Each Task Corresponds to an Image to be Transcribed.

Fig. 10 gives an illustration of a resolution of task. The selected task shown in Fig. 9 consist of an image of broom. We suppose the user entered *saaga* in *Mooré* as the answer. We use this wrong answer that will allows to show some feedback generated by the system.

(a) Feedback of the Amalgamate

Fig. 11. Feedback Generated by the System when the User Enters the Word *saaga* as Answer. In this Case the Answer is Wrong Even if the Spelling is Correct.

The correct answer should be *saagà* with low tone on the last vowel.

## V. PEDAGOGICAL ASSESSMENT

To do the pedagogical assessment of our system, we proceeded with the experimentation of the application. A total of four *Mooré* trainers and seventeen learners were able to do the experimentation. For the questionnaires, we developed them via Google Forms.

The formulation of the questions addressed to the learners and the trainers aimed to verify the following aspects:

- The conformity between the content of the Knowledge Base (KB) of the system developed and the content of

the corpus of *Mooré* language, namely, the transcriptions and the sounds:

- The relevance of the learning tasks.
- The clarity of the resolution steps.
- The relevance of the feedback generated.
- The relevance of the sounds loaded.
- The ease of use of the system.
- And the contribution of the system in the field of the *Mooré* language learning.

Fig. 12 and Fig. 13 give an overview of some results of the users' feelings after the experimentation of the application.

Fig. 12. Learners' Opinions on the System

Fig. 13. Trainers' Opinions on the System.

We analysis the collection of the users' opinions and we present here some results in Fig. 12 and Fig. 13 for both learners and trainers.

For the verification of the conformity between the content of the Knowledge Base of the developed system and the content of the corpus of the *Mooré* language, the four trainers found an almost total conformity between the two contents. For the relevance of the learning tasks, fourteen out of seventeen learners found the different tasks at least enough relevant. For the clarity of the resolution steps, ten out of seventeen learners found the steps of resolution at least enough clear. As for the relevance of the feedback generated and the sounds loaded, fourteen learners affirmed that the feedback generated help in the correction of transcription errors and sixteen affirmed that the sounds emitted really help in transcription. And for the contribution of the system in the field of the *Mooré* language learning, all trainers answered in the affirmative that the system allows learning without human assistance.

Based on these results, we can say that the pedagogical assessment of the system allowed to show that the use of it could made it possible the learning of the transcription in *Mooré* without human assistance. Similarly, this system would be a great contribution in the field of education for local languages learning in Burkina Faso.

## VI. CONCLUSION AND PERSPECTIVES

In this paper, we presented the work on system design, the implementation of the system and the pedagogical assessment of the system. In the system design, we showed the architecture of the ITS, we described the Bayesian network approach that we used to trace the errors of transcription and we presented the Petri net approach that we used to design the operation of the system. The architecture proposed allowed to define the different modules of the system. The Bayesian network model made it possible to represent the uncertain knowledge and to develop the algorithms for tracing errors. As for the Petri net approach, it allowed to simulate the operation of the system and to correct the possible blockages. In relation to the implementation of the system, we presented some views of the system implemented. And as for the pedagogical assessment of the system, the experimentation of the application made it possible to collect the users' feelings. The analysis of these feelings shows, among other things, that our system is a great contribution for *Mooré* learning. For the future, we expect to develop a speech recognition activity to integrate into our system. This speech recognition activity will learn phonetics in *Mooré*. We also expect to develop a WordNet ontology for the *Mooré* language. The WordNet ontology for the *Mooré* language is a particularly promising avenue. It will constitute an online knowledge base and will be interoperable with our system and with other applications.

# Improving the Diabetes Diagnosis Prediction Rate Using Data Preprocessing, Data Augmentation and Recursive Feature Elimination Method

E. Sabitha, M. Durgadevi

Dept. of Computer Science and Engineering, College of Engineering and Technology  
SRM Institute of Science and Technology Vadapalani, Campus No.1, Jawaharlal Nehru Road, Vadapalani TN, India

**Abstract**—Hyperglycemia is a symptom of diabetes mellitus, a metabolic condition brought on by the body's inability to produce enough insulin and respond to it. Diabetes can damage body organs if it is not adequately managed or detected in a timely manner. Many years of research into diabetes diagnosis has led to a suitable method for diabetes prediction. However, there is still scope for improvement regarding precision. The paper's primary objective is to emphasize the value of data preprocessing, feature selection, and data augmentation in disease prediction. Techniques for data preprocessing, feature selection, and data augmentation can assist classification algorithms function more effectively in the diagnosis and prediction of diabetes. A proposed method is employed for diabetes diagnosis and prediction using the PIMA Indian dataset. A systematic framework for conducting a comparison analysis based on the effectiveness of a three-category categorization model is provided in this study. The first category compares the model's performance with and without data preprocessing. The second category compares the performance of five alternative algorithms employing the Recursive Feature Elimination (RFE) feature selection method. Data augmentation is the third category; data augmentation is done with SMOTE Oversampling, and comparisons are made with and without SMOTE Oversampling. On the PIMA Indian Diabetes dataset, studies showed that data preprocessing, RFE with Random Forest Regression feature selection, and SMOTE Oversampling augmentation can produce accuracy scores of 81.25% with RF, 81.16 with DT, and 82.5% with SVC. From Six Classifiers LR, RF, DT, SVC, GNB and KNN, it is observed that RF, DT, and SVC performed better in accuracy level. The comparative study enables us to comprehend the value of data preprocessing, feature selection, and data augmentation in the disease prediction process as well as how they affect performance.

**Keywords**—Artificial Intelligence (AI); Machine Learning (ML); Deep Learning (DL); Neural Network; Diabetes Mellitus; Recursive Feature Elimination (RFE); Synthetic Minority Over-sampling Technique (SMOTE)

## I. INTRODUCTION

A metabolic disorder known as diabetes mellitus is characterized by hyperglycemia brought on by the body's inability to create and utilize insulin.[1]. There are three forms of diabetes types. The human body cannot generate enough insulin when it has type I. The body is unable to produce or use insulin effectively in type II. During pregnancy, gestational diabetes can develop [2]. Both Type I and Type II diabetes are getting more and more prevalent worldwide, with

Type II diabetes being at epidemic levels. According to medical study, diabetes has been linked to the long-term degradation of vital organs. More concerning is its impact on pregnancies: diabetes affects roughly 7% of pregnancies each year, posing a dual life-threatening risk. Over half of the world's population is expected to have diabetes by 2045 due to the disease's rising prevalence. The WHO predicted that 463 million people will be diabetic worldwide by 2020, and these are just the cases that have been identified. In United States almost one in every 10 individuals is diabetic. Diabetes research is therefore essential, including studies of diabetes prediction and its effects on health [3].

Diabetes can be diagnosed by either an oral glucose tolerance test result or a fasting plasma glucose level. On the other hand, diabetes can be identified by Glycemic threshold levels. This is due to the fact that different ethnic groups have varied risk levels. Multiple blood sugar tests are taken both before and after a meal. By observing a relevant decision at a time, practitioners are faced with the difficult task for diagnosing diabetes. The diagnostic process, on the other hand, can be made more computationally simple [4]. The fields of technology and medicine have been profoundly affected by big data and data analytics approaches. Rather than depending on conventional methodologies, which are usually unable to handle massive data, cutting-edge technologies like ML, DL and cloud computing must be employed to fully utilize the data and automate computation processes in medical research. This paper provides a customised hybrid model of artificial neural networks (ANN) and genetic algorithms as a framework for accurately forecasting the onset of diabetes, replete with regularisation and prediction techniques created for diabetes prediction [5].

Numerous computational projects have been started recently, many of which are focused on the use of ML and DL algorithms in diabetes research with the goal of assisting physicians in making rapid and accurate diagnosis decisions. With the ongoing development of diabetes testing equipment, individuals can now take part in individualised examinations of their diabetes status for better lifestyle modifications. In comparison to existing methods, a dependable accuracy rate is categorized in recent studies. A higher accuracy rate in diabetes prediction is essential, as early diagnosis of diabetes mellitus is required. The researchers are presenting a range of DL and ML methods for diabetes forecasting. Despite a large amount of research on diabetic prediction, the accuracy still

needs to be improved. This is necessary since diabetes poses major health risks if it is not effectively treated or diagnosed in a timely manner. In this paper a comparative evaluation is done based on feature selection approaches and data augmentation techniques that increase prediction performance in this research. The main contribution of the paper is summarised as follows:

- 1) The significance of data pre-processing is demonstrated by comparing the outcomes of the proposed model with and without data pre-processing.
- 2) To emphasise the significance of feature selection in disease prediction, which improves model performance and boosts predictive power.
- 3) To overcome the issue of a small dataset, data augmentation is employed to enhance the dataset's size. Deep learning and machine learning typically require a large quantity of data to train the networks.

## II. RELATED WORK

The views of data pre-processing, data augmentation, and classification are the foundation of the current body of work. However, in this paper the review is limited to the recent publications. Diabetic research has recently begun to improve based on the performance accuracy. This article can be used by readers to learn about the past and present effectiveness of algorithms in diabetes research [6]. Table I illustrate the review on recent papers that work on the diabetic prediction. The review is based on the recent trends and papers that are suitable for the disease prediction. In diabetes research, the NN-based approaches have constant to increase accuracy. The problems of data standardisation, imbalance, and feature augmentation are addressed in this Min-Max Normalisation and a Variational Autoencoder [7]. MLP was then utilised for classification, with an accuracy rate of 92.31 percent. In [8], the accuracy of their Artificial Backpropagation Scaled Conjugate Gradient Neural Network (ABP-SCGNN), which was previously reported to attain 93 percent accuracy without data pre-processing, has significantly improved. The work of [9] demonstrates another impressive result with NN-based models. They looked at iterative imputers, k-nearest neighbour (K-NN), and median value imputation. In order to acquire an F1-score of 98 percent, MLP was then employed for classification. For feature selection and missing value imputation in [10], Pearson correlation and median value imputation were used. The authors used interquartile ranges to further normalise the data and eliminate outliers. DNN-based classification model, which contained a number of hidden layers, was 88.6% accurate. A deep neural network (DNN) model's accuracy was estimated to be 98.07 percent in [11]. Even though the authors claim to have used data cleansing, the process is not described in the article. In [12] used the median value for missing value imputation and principal component

analysis (PCA) for feature selection. MLP was then used to carry out the classification procedure, and it had a 75.7 percent accuracy rate. For feature selection and missing value imputation, PCA and minimum redundancy, maximum relevance (mRMR) was also used in [13]. Using an MLP, they were able to get a classification accuracy of 73.90%. Many different methods were employed [14]; implemented many assessment techniques, including Nave Bayesian, Random Forest (RF), KNN, and K-fold Cross-Validation. The technique has a 64.47 percent accuracy, according to K-fold Cross Validation. Nave Bayes, function-based multilayer perceptrons, and RF based on decision trees were all employed in [15]. The feature extraction method was utilised to extract reliable and illuminating properties from the dataset using the correlation method. According to the author, the Nave Bayes method outperformed the random forest and multilayer perceptron algorithms.

In [16] tested various machine learning methods for predicting early diabetes on the PID dataset. Using 20-fold cross-validation and a 70-30 train-test split, tree-based RF scored 75.65 percent, Nave Bayes (NB) 71.74 percent, and KNN 65.19 percent. A decision tree and the gradient boosting method were used by [17] for prediction. The technique has a classification accuracy of 90% and computes a correlation value to determine differences between a diabetic patient and healthy person. With 10-fold-cross validation and an enhanced K-Means cluster method, [18] obtained 95.42 percent accuracy. In [19] used 10-fold cross validation with machine learning techniques on patients who had a history of non-diabetics and a cardiac problem. In [20], which used machine learning as a prediction model for type 2 diabetes mellitus early prediction, Glnet, RF, XGBoost, and Light all shown improved clinical prediction. It is suitable for one dataset but inappropriate for another. A more advanced DNN-based diabetes risk prediction model that not only predicts but also identifies who will develop the ailment in the future was proposed in [21]. Before training on several classification models, such as NB, LR, RF, AB, GBM, and extreme gradient boosting, the mean of each column of data was pre-processed in [22] to remove missing values. With a precision of 77.54 percent, the XGBoost model was the most precise. The efficiency of the classification models SVM, K-NN, NB, Gradient boosting (GB), and RF were contrasted in [23]. With an accuracy of 98.48 percent, the RF prevailed. In [24] employed Pearson correlation for feature selection and mean value imputation for missing value. The authors assessed the performance of various classification models, including extreme boosting (XB), AB, RF, DT, and K-NN, using a K-fold cross-validation environment and the grid search strategy for hyperparameter tuning. With an accuracy percentage of 94.6 percent, the XB won. Linear SVM, Radial Basis function SVM, DT, and K-NN were employed in a stacked ensemble to achieve a classification accuracy of 83.8%.

TABLE I. OVERVIEW OF THE LITERATURE REVIEW

Authors	Feature selection (FS)	Classification	Comments
Benavides, C., et al .[7]	FS: none specified;removed missing values;	MultiLayer Perceptron	MLP achieved the best accuracy, 92.31%
Alkhamees, B. F et al.[8]	FS: none specified; MVI: none specified	ANN trained with ABS conjugate gradient neural network (ABP-CGNN)	Achieved 93% accuracy
Ahmad, M., et al.[9]	Median value, K-NN, and iterative imputer were used for missing value imputation	ANN	ANN achieved 98% accuracy
Foo, S. Y et al.[10]	FS: Pearson correlation MVI: Median value for missing values imputation.	DNN run with different hidden layers	Achieved 86.26% accuracy with 2 hidden layers.
Naz, H., & Ahuja, S. [11]	Method not stated	MLP and DL with 2 hidden layers	DL achieved best accuracy of 98.07%
Iqbal, M. A., [12]	FS: PCA; MVI: Median value	MLP	Achieved 75.7% accuracy
Qu, K., et al. [13]	FS: PCA; MVI: redundancy and minimum relevance	MLP	Achieved 73.90% accuracy
Halgamuge, M. N., et al.[14]	none specified	NB,RF,KNN,K-fold cross validation	Using K-fold CrossValidation, the method achieved 64.47% accuracy.
Singh, D. A. A. G., et.al.[15]	Correlation method	decision tree-based RF, function-based multilayer perceptron ,Naïve Bayes	Naïve Bayes algorithm achieved better results
Awais, M., et.al.[16]	none specified	RF,NB,KNN with 20 -fold cross-validation	RF achieved 75.65%
Selvan, K. A., et.al.[17]	none specified	DT,GB	Achieved 90% accuracy
Yang, S., et.al.[18]	none specified	K-Means cluster algorithm with 10 fold-cross validation.	Acheived 95.42% accuracy
Gnanadass [22]	none specified	NB, linear regression (LR), RF, AB, gradient boosting machine (GBM), and extreme gradient boosting (XGBoost).	XGBoost achieved 77.54%
Mounika, B., et al.[23]	none specified	SVM, K-NN, NB, GB, RF, LR	RF achieved best accuracy of 98.48%
Hasan et al [24].	FS: correlation; MVI: mean value	XB, AB, RF, DT, K-NN	XB achieved best accuracy of 94.6%

### III. MATERIALS AND METHODOLOGY

#### A. Dataset

The PIMA Indian Diabetes database was used for this study. The main objective of the dataset is to establish a patient's diagnostic diabetes status. The dataset contains one outcome variable and a number of medical predictor variables. Predictor variables for diabetes include age, number of pregnancies, BMI, BP, glucose, Skin thickness, Insulin, and Diabetes pedigree function. Particularly, all of the patients are females in PIMA who are at least 21 years old. The selection of these examples from a broader database was subject to several of limitations. Our proposed research compares data pre-processing, feature selection, and data augmentation techniques. The study aims to overcome flaws in early diabetes mellitus diagnosis that impair accuracy. The disadvantages are as follows: 1. A large number of missing values lead to erroneous predictions. 2. Imbalanced data has an impact on the model's performance. The suggested framework illustrates each stage of prediction work, including data pre-processing, Feature selection techniques incorporated with the Recursive Feature Elimination approach, and Smote

data augmentation with and without Smote data. The study compares model accuracy by applying the augmentation strategy to improve the dataset. The study compares not only on the basis of augmentation, but also on the basis of feature selection strategies. Fig. 1 shows a diagrammatic representation of the planned work.

#### IV. PROPOSED WORK

In this paper, a systematic framework is proposed for the diabetic prediction with different classifiers. The importance of the data preprocessing is elaborated by presenting the results obtained. The main contribution of the proposed work is to show the importance of data cleaning by using the data preprocessing strategies then by selecting the important attributes that highly correlate with diabetic prediction. Most important part is balancing the dataset by SMOTE data augmentation, the proposed work focus on the three part that improves the prediction accuracy. The six classifier algorithm are then used for classification. In the proposed system, inconsistent data is replaced, then suitable features are selected by using the RFE with the Random Forest Regression and finally the selected are augmented by SMOTE

Oversampling technique to improve the imbalance dataset problem.

Fig. 1. Proposed Work.

### V. DATA PRE-PROCESSING

The idea of data pre-processing refers to the conversion of unclean data into a clean data set. The dataset is pre-processed to look for missing values, noisy data, and other irregularities before applying the algorithm. These data are crucial for decision-making, thus accurate and effective estimate techniques are required. For this analysis, PIMA Indians Diabetes database is taken. The dataset has more missing values than null values. In the medical field, the problem of a database with missing values is very widespread. The Table II displays the number of zeros in each attribute, while Fig. 2 and Fig. 3 illustrate the proportion of missing data and the impossible value assigned in the pregnant feature, both of which reduce the model's performance. Using data pre-processing techniques, the study focuses on cleaning up the data by improving the values assigned to each feature. In this paper no specific strategies are followed to clean up the data in the suggested work, instead a few simple and easy ways to pre-processing is done to clean up and improve the quality of the data. The following are the methods that will be described.

TABLE II. MISSING VALUE IN DATASET

Features	Total	Percent
Insulin	374	48.697917
Skin Thickness	227	29.557292
Blood Pressure	35	4.557292
BMI	11	1.432292
Glucose	20	0.651042
Pregnancies	0	0.00
Diabetes Pedigree Function	0	0.00
Age	0	0.00
Outcome	0	0.00

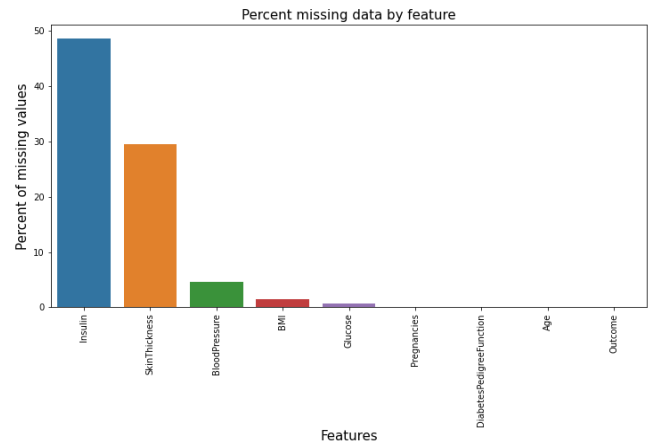

Fig. 2. Percent of Missing Data in Features.

Fig. 3. Outliers of Pregnancies Feature.

#### A. Treatment of Missing Values

If the behaviour and linkages with other variables are not adequately analysed, missing data in a data collection could reduce a model's power or fit or result in a biased model. The classification or prediction that results could be inaccurate. When the dataset's above mentioned attributes were evaluated, it was found that several of them had zero values and that the pregnancy variable had a maximum value of 17, which seemed to be impossibly high. There is a range for a typical healthy human being that is not zero, suggesting a missing value, hence these 0 column values are illogical. To make counting the missing integers simpler, we'll start by swapping out these zeros for NaN. Later, we'll swap them out for the proper values. There are a number different ways to handle missing values. The choices are displayed below. Simply deleting all instances where the variable being considered contains missing values is the simplest method to handle with missing values. However, this approach can mean losing actually valued data about patients. The calculation of mean is the second approach to complete all gaps in the data. In this approach the missing values are replaced by with the average value calculated in the same attribute. This method can reduce the loss of data instead of removing the missing values that reduces the quality of the dataset. In this method all the missing values are replaced by zero. The process of replacing by zero is simply by replacing any missing values with zero. Since the data in this study have been converted to values

between zero and one, substituting zero for missing values has the same result as substituting the attribute's lowest value. However this method leads to poor classification by missing data which are inaccurately appraised if they are necessary for clinical management. The K-nearest neighbour method is the fourth method which is used to replace the missing values in the dataset. The missing values are replaced with the value of nearest-neighbor column. The nearest-neighbor column is considered to be the closest column in Euclidean distance. The next closest column is used if the relevant value from the nearest-neighbor column also contains a missing value.

The Table I clearly describes the PIMA dataset. The features like Glucose, Blood Pressure, Skin thickness, Insulin, and BMI are with 0 values. In this study, we use second approach i.e. all missing values of an attribute are replaced by the mean by calculating the average of all accessible values of the same attribute. When all the zero values are replaced with mean value, the dataset was further split into training and testing data. The dataset as a whole is made up of 80% training data and 20% test data. The model performance is evaluated by the model accuracy, which is determined via machine learning algorithms. On two levels—one where the zero values were replaced with the mean and another where they weren't—we compared the model's performance. By contrasting the two, we can see how useful data pre-processing is in improving the dataset's suitability for subsequent operations. The comparison can be seen in upcoming session.

### B. Without Data Pre-Processing

The PIMA dataset is directly used in the machine learning algorithm to assess the prediction's accuracy without any data pre-processing. Some of the techniques used are Gaussian Nave Bayes (GNB), KNN, DT, Support Vector Classification (SVC), LR, and RF. The dataset is used in the classification approach to determine the degree of accuracy in disease prediction that may be made without any prior processing. Table III and Fig. 4, clearly represent the performance of the classification algorithm based on the accuracy. The accuracy for LR was 77.5 percent with 0.06 training time, for RF it was 76.5 percent with 0.77 training time, for DT it was 67.5 percent with 0 training time, for SVC it was 81.2 percent with 0.03 training time, and for GNB and KNN it was 75% with 0.02 training time.

TABLE III. ACCURACY OBTAINED WITHOUT DATA PRE-PROCESSING

S.no	Classifier	Validation accuracy	Training time
0	Logistic Regression	0.775	0.06
1	Random Forest	0.7625	0.77
2	Decision Tree	0.675	0
3	SVC	0.8125	0.03
4	GaussianNB	0.75	0.02
5	KNeighbors	0.75	0.02

Fig. 4. Accuracy Without Data Pre-processing

### C. With Data Pre-processing

1) *Dropout missing values*: The simple method to deal with missing values, is to simply delete any instances in which the variable being studied contains missing values. The loss of potentially relevant data regarding patients whose values are missing, however, could be a consequence of this strategy. The dataset is divided in an 80:20 ratio between training and testing data, after all missing values have been removed, and the features are chosen using RFE with Random Forest regression. An imbalance dataset generally speaking is the PIMA dataset. We can see that 268 people have diabetes and 500 people do not when we analyse the dataset by outcome.

The performance of the classification algorithm worsens when the data for training and testing are split due to the unequal size of the training and testing sets. Using classification techniques to determine correctness, we augment the dataset with additional data to address the imbalance issues. Table IV and Fig. 5 represent the result obtained. The accuracy scores are LR 69.04 percent with 0.05 training time, RF 85.7 percent with 0.62 training time, DT 73.8 percent with 0 training time, SVC 76.1 percent with 0.01 training time, GNB 73.8 percent with 0.02 training time, and KNN 71.42 percent with 0.01. When we focus on accuracy, RF has achieved the maximum score of 85.7 percent, but the training duration is 0.62 minutes. When it comes to training time, DT, SVC, GNB, and KNN take less time, but their accuracy is worse than RF.

TABLE IV. ACCURACY OBTAINED WITH DROP OUT MISSING VALUES

S.no	Classifier	Validation accuracy	Training time
0	Logistic Regression	0.690476	0.05
1	Random Forest	0.857143	0.62
2	Decision Tree	0.738095	0
3	SVC	0.761905	0.01
4	GaussianNB	0.738095	0.02
5	KNeighbors	0.714286	0.01

Fig. 5. Accuracy with Dropout Missing Values.

2) *Replacing missing value with mean*: There are no null values in the PIMA dataset, however there are more missing values, such as zero values in many characteristics, as previously indicated. As a result, the model's performance may be affected. To solve this problem, one option is to remove the zero values, but this reduces the algorithm's performance. Instead, in this study, we can replace the zero by calculating the attribute mean values and replacing the zero. One way to pre-process a dataset without reducing its size is by using this technique. Following pre-processing, the dataset is divided into train and test groups in an 80:20 ratio. The next stage is to assess the accuracy of the diabetic prediction using classification algorithms.

TABLE V. ACCURACY OBTAINED WITH MEAN VALUE

S.no	Classifier	Validation accuracy	Training time
0	Logistic Regression	0.725	0.04
1	Random Forest	0.7625	0.52
2	Decision Tree	0.7	0
3	SVC	0.7625	0.02
4	GaussianNB	0.7	0.01
5	KNeighbors	0.7625	0.01

Fig. 6. Accuracy with Replacing Mean Value.

The accuracy of classification algorithms when the inconsistent value is replaced by Mean value is explained in Table V and graphically presented in Fig. 6. When the dataset is pre-processed, we can witness a gradual improvement in accuracy in Tables IV and V. The dataset was pre-processed in this study by removing zero values and replacing them with the mean of the characteristics. There isn't much of a change, however pre-processing the dataset can help us gain a little more precision. Understanding the significance of data pre-processing in any research effort is made easier by this approach. Data pre-processing is essential for evaluating the model's performance or determining the algorithm's efficiency.

## VI. FEATURE SELECTION

Finding the most useful set of features for creating efficient models of the phenomenon being studied is the goal of feature selection. Feature selection strategies are divided into two categories: i) supervised techniques and ii) unsupervised procedures. The efficiency of supervised models is increased by using labelled data in supervised procedures to find pertinent characteristics. Unlabelled data is utilised in unsupervised approaches. In terms of taxonomic classification, these methods fall under the headings of A) Filter methods, B) Wrapper methods, C) Embedded methods, and D) Hybrid methods.

### A. Recursive Feature Elimination

To choose the features in the study, a Wrapper method based Recursive feature elimination (RFE) strategy is applied. RFE is a greedy optimization strategy that selects features by considering a reduced set of features iteratively. A variety of deep learning algorithms are provided and employed in the method's core to choose features. On the other hand, filter-based feature selections rank each feature according to its importance and choose the ones with the highest or lowest scores. The given algorithms, such as random forest, decision trees, and SVM, are used to score features, or a more general technique that is independent of the whole model is used. The importance of the features used in training the estimator is decided using the feature importance attribute. Until we get the required number of features, the least important feature is deleted from the existing collection of features.

#### Procedure

Step 1: Fit the RFE method to the model

Step 2: The feature importance attribute is used to rank features.

Step 3: Once the necessary number of features is collected, the least significant feature is deleted and the procedure is repeated.

#### RFE with five different algorithms

In this study feature selection done five different ways.

- 1) Manual feature selection
- 2) RFE with Logistic regression
- 3) RFE with Random Forest regression
- 4) RFE with Decision Tree regression

- 5) RFE with Decision Tree Classifier
- 6) RFE with 5-Cross validation

### B. Manual Feature Selection

The features for the prediction are manually picked in manual feature selection. The outcome is one of nine attributes in PIMA, eight of which are independent. We chose six attributes out of the eight for this research. The characteristics were chosen after reviewing a large number of research articles that were more accurate in diabetic prediction. We choose six attributes manually like Pregnancy, Glucose, Blood Pressure, Insulin, BMI, and Age. The dataset is then split in half, 80:20, into train and test sets. The classification algorithms such as GNB, KNN, DT, SVM, and RF are utilized, to analysis the performance quantified in terms of accuracy. The dataset, methodology, and accuracy achieved are all evaluated in the Table VI (also see Fig. 7).

### C. Recursive Feature Elimination with different Methods

In this research, RFE was used in conjunction with several methods such as logistic regression. The key characteristics from the dataset are selected using Random Forest regression, Decision tree regression, Decision tree classifier, and RFE with five-fold cross validation as an estimator. Pregnancies, BMI, DPF, and Glucose are the most common features selected by each feature selection technique. Pregnancies, BMI, DPF, and Glucose are four of the eight variables that are thought to be directly connected to diabetic prediction. The dataset is then divided into a train set and a test set in an 80:20 ratio based on the selected attributes. Classification algorithms like GNB, KNN, DT, SVM, and RF are used for prediction, and the performance of the algorithm is evaluated in terms of accuracy. The dataset, feature selection procedure, selected features, Classification Algorithm, and Accuracy are all detailed in Table VII

TABLE VI. MANUAL FEATURE SELECTION

Dataset	Classification Algorithm	Accuracy
PIMA	GNB	77.27%
	KNN	75.97%
	DT	70.10%
	SVM	79.87%
	RF	81.81%

Fig. 7. Accuracy with Manual Feature Selection.

RFE with Logistic Regression selected Pregnancies, BMI, and DPF features after observing several feature selection methods. The features are then divided into two groups: training and testing. For classification and accuracy evaluation, algorithms such as GNB, KNN, DT, SVM, and RF are utilized. GNB obtained 79.87 percent accuracy using the algorithms. RFE with Random Forest Regression, using Glucose, BMI, and DPF as selected features, has a greater accuracy of 81.16 percent when compared to DT. The same features were chosen from RFE with Decision Tree Regression and RFE with Decision Tree Classifier. KNN achieved 75.32 percent accuracy by using both selection methods. Pregnancies, Glucose, and BMI were chosen as characteristics for RFE with five cross validations. The KNN algorithm achieved 79.2 percent accuracy based on the features. When compared to other algorithms, RFE with Random Forest Regression utilizing DT has obtained greater accuracy of up to 81 percent, according to the detailed analysis using the RFE feature selection method and algorithm.

## VII. DATA AUGMENTATION

Data augmentation is a series of techniques for generating extra data points from existing data in order to fictionally increase the amount of data accessible. Simple data modifications or the use of deep learning models to generate more data are instances of this. Applications for machine learning are quickly increasing and diversifying, especially in the deep learning space. Approaches for data augmentation may be effective in the struggle against the drawbacks of artificial intelligence. One step in building a data model is cleaning the data, which is necessary for high accuracy models. The model won't be able to produce reliable predictions for inputs from the real world, though, if data cleansing limits representability. In order to increase the reliability of machine learning models, data augmentation techniques can be employed to replicate variations that the models would encounter in the actual world.

### A. SMOTE Oversampling

In many disciplines, unbalanced data has been a problem, causing most approaches to produce erroneous forecasts that strongly favour the dominant class. To decrease the harmful impact of unbalanced data, we can optimise the process using a variety of techniques: Certain techniques, like as oversampling, under sampling, or both, are employed to correct the unbalanced data set in order to generate a balanced distribution. A statistical method for equally expanding the number of cases in a dataset is called SMOTE (Synthetic Minority Oversampling Technique). Based on current minority conditions, the component creates new instances. The overfitting issue brought on by random oversampling is helped by the SMOTE algorithm. The working approach begins by setting up the total number of oversampling observations N. A binary class distribution of 1:1 is typically used to select it. This could be minimised, though, depending on the circumstances. After that, a positive class instance is randomly chosen and the loop starts. Then, the KNNs for that instance are obtained. In order to interpolate new synthetic

instances in the end, N of these K instances are chosen (see Fig. 8).

Fig. 8. SMOTE Oversampling.

**Algorithm**

Step 1: To interpolate new synthetic instances in the end, N of these K instances are chosen.  $x \in A$ .

Step 2: The uneven proportion determines the sampling rate N. N samples ( $x_1, x_2, \dots, x_n$ ) are chosen at random from  $x \in A$ . Set A1 is composed of the k-nearest neighbours.

Step 3: For each  $x_k$ , a new example is produced using A1 ( $k = 1, 2, 3, \dots, N$ ):  $x^{\wedge} = x + \text{rand}(0,1) * |x - x_k|$  in which  $\text{rand}(0,1)$  represents the random numbers between 0 and 1.

**B. SMOTE Oversampling with RFE with Random Forest Regression**

In the PIMA dataset, the result is in an unbalanced state. When examining the outcome, 1 counts to 268 and 0 counts to

500, resulting in false in excess of true. The model is trained with a higher percentage of false values than true values. SMOTE oversampling is used to reduce the data's complexity and balance it. The features selected through the RFE with Random Forest regression feature selection technique are subjected to oversampling. The Random Forest algorithm includes a feature importance calculation that can be done in two ways. The Gini coefficient is calculated using the Random Forest structure. Decision Tree algorithm with internal nodes and leaves make up each decision tree that makes up a Random Forest. The internal node uses the chosen characteristic to determine how to divide the data set into two sets with similar replies. For classification tasks, criteria like gini impurity or information gain, as well as variance reduction for regression, are used to select the internal node properties. The importance of a feature is determined by the average of all trees in the forest. There is also Mean Decrease. Accuracy is a method for calculating the importance of features on permuted out of bag samples based on the accuracy's mean reduction. The scikit-learn package does not include this function. The selected features from the RFE using Random Forest Regression are Glucose, BMI, and DiabetesPedigreeFunction. The features are then enhanced based on their results, and performance is measured using machine learning algorithms such as Logistic Regression (LR), RandomForest(RF), DecisionTree(DT), SVC, GaussianNB, and KNeighbor's for further classification. The accuracy attained with and without data augmentation is shown in the table VIII and IX.

TABLE VII. RFE WITH DIFFERENT FEATURE SELECTION METHOD

Dataset	Feature selection method	Selected Features	Classification Algorithm	Accuracy
PIMA	RFE with Logistic Regression	Pregnancies BMI DPF	GaussianNB(GNB) Knearestneighbor(KNN) Decision Tree(DT) SupportVectorMachine(SVM) RandomForest(RF)	GNB: 79.87 % KNN: 72.72 % DT: 62.98 % SVM: 72.07 % RF: 71.42%
	RFE with Random Forest Regression	Glucose BMI DPF	GaussianNB(GNB) Knearestneighbor(KNN) Decision Tree(DT) SupportVectorMachine(SVM) RandomForest(RF)	GNB : 74.02 % KNN : 72.77 % DT : 81.16 % SVM : 75.32 % RF : 75.97%
	RFE with Decision tree Regression	Glucose BMI DPF	GaussianNB(GNB) Knearestneighbor(KNN) Decision Tree(DT) SupportVectorMachine(SVM) RandomForest(RF)	GNB : 74.02 % KNN : 75.32 % DT : 68.27 % SVM : 74.67% RF : 72.72%
	RFE with Decision tree Classifier	Glucose BMI DPF	GaussianNB(GNB) Knearestneighbor(KNN) Decision Tree(DT) SupportVectorMachine(SVM) RandomForest(RF)	GNB : 74.02 % KNN : 75.32 % DT : 68.27 % SVM : 74.67% RF : 72.72%
	RFE with five cross validations	Pregnancies Glucose BMI	GaussianNB(GNB) Knearestneighbor(KNN) Decision Tree(DT) SupportVectorMachine(SVM) RandomForest(RF)	GNB : 74.02 % KNN : 79.2 % DT : 70.7 % SVM : 75.9% RF : 72.72%

TABLE VIII. WITH SMOTE AUGMENTATION

S.no	Classifier	Validation accuracy	Training time
0	Logistic Regression	0.80	0.03
1	Random Forest	0.7875	0.72
2	Decision Tree	0.725	0
3	SVC	0.825	0.03
4	GaussianNB	0.775	0.02
5	KNeighbors	0.7125	0.02

TABLE IX. WITHOUT SMOTE AUGMENTATION

S.no	Classifier	Validation accuracy	Training time
0	Logistic Regression	0.69	0.05
1	Random Forest	0.70	0.59
2	Decision Tree	0.72	0
3	SVC	0.7096	0.02
4	GaussianNB	0.6774	0.02
5	KNeighbors	0.6935	0.02

We can compare the accuracy gained with and without augmentation using the two tables above. The accuracy and training duration are shown in Table VIII with moderate improvement. The accuracy and training time are displayed in Table IX without any augmentation. When we compare the two tables, it's evident that by supplementing the data, we can improve accuracy. When compared to various machine learning algorithms, SVC with smote augmentation had the highest accuracy of 82.5 percent with a training time of 0.03. Whereas Logistic regression scored 80 percent with a training time of 0.03, Random Forest scored 78.75 percent with a training time of 0.72, Decision Tree scored 72.5 percent with a training time of 0, GaussianNB scored 77.5 percent with a training time of 0.02, and Kneighbors scored 71.25% with a training time of 0.02.

### VIII. RESULTS

The work is primarily focused on demonstrating the significance of data preprocessing, feature selection, and data augmentation in disease prediction that have a significant impact on the model's performance. Six distinct classification algorithms are used in the comparison analysis to highlight the impact with and without Data pre-processing, SMOTE Oversampling.

The work is divided into three sections:

- 1) With and without data pre-processing, and utilising classification methods to assess accuracy.
- 2) For feature selection, combining RFE with logistic regression, Random Forest regression, RFECV, Decision tree regression, and Decision tree classifier
- 3) Using SMOTE oversampling to improve accuracy by decreasing concerns caused by dataset imbalance.

In order to prepare the PIMA and diabetes type data for a deep learning model, data pre-processing is required. The PIMA dataset contains missing values, which means that many attributes have fewer values, such as zeros. The erroneous values reduce the model's performance. The number of null values in each attribute is shown in Table II. Properties including blood pressure, skin thinning, glucose, insulin, and BMI are all zero in Table II, along with other characteristics. Two data pre-processing strategies are used to replace zero values: one removes the zero values and the other replaces the values by finding the mean. Table III shows the results obtained without pre-processing the data. Tables IV and V show the outcomes of two different approaches to data pre-processing. We employ six classifiers in this work for data pre-processing: LR,GNB,KNN,RF,DT, and SVC. When comparing the results, we can see that when the data set is pre-processed, RF achieves an accuracy of 85.7 percent. Several algorithms, including LR, Random Forest Regression, Decision Tree Classifier, Decision Tree Regression, and RFE with cross validation, were used in our work to use the RFE feature selection approach. Following feature selection, the accuracy is determined using five classifiers. When we compare the results of the classifier based on feature selection RFE with Random Forest regression, we find that Random Forest regression has a better outcome DT: 81.16 percent. The third comparison is based on data augmentation with SMOTE Oversampling versus data augmentation without SMOTE Oversampling. The data augmentation method is used to alleviate the issue caused by an unbalanced dataset. Following feature selection, the SMOTE Oversampling technique is used to augment the selected feature dataset in our study. After that, six classifiers are used, and the accuracy of the classifiers is measured. When we examine the results of both methods, with and without SMOTE oversampling, we can see that with SMOTE oversampling, we can attain higher accuracy. Table VIII and Table IX explains the results obtained with and without SMOTE oversampling.

### IX. CONCLUSION

The comparison is based on three categories, which are elaborated in the study: (i) with and without data pre-processing, (ii) feature selection using five alternative algorithms, (iii) with and without data augmentation. The importance of data pre-processing, feature selection, and data augmentation can be seen in the three comparisons. When each category is examined separately, data pre-processing comes out on top since it significantly affects how well models or algorithms perform. When we pre-process a dataset, the dataset's quality improves, as does the performance of the models or algorithms. Tables III, IV, and V provide a comprehensive explanation of the contrast. In this study, pre-processing is done in two different ways, and the results of the two methods are compared. We used five different algorithms with RFE and compared the results in Table VII. Likely Feature Selection Importance was also thoroughly explained, and we used five different methods with RFE and compared the results in Table VII. When it comes to data augmentation, the goal is to solve problems that arise from an unbalanced dataset. The work utilised the SMOTE Oversampling technique and conducted a comparison with and without

# A Comparative Study of Unsupervised Anomaly Detection Algorithms used in a Small and Medium-Sized Enterprise

**Abstract**—Anomaly detection finds application in several industries and domains. The anomaly detection market is growing driven by the increasing development and dynamic adoption of emerging technologies. Depending on the type of supervision, there are three main types of anomaly detection techniques: unsupervised, semi-supervised, and supervised. Given the wide variety of available anomaly detection algorithms, how can one choose which approach is most appropriate for a particular application? The purpose of this evaluation is to compare the performance of five unsupervised anomaly detection algorithms applied to a specific dataset from a small and medium-sized software enterprise, presented in this paper. To reduce the cost and complexity of a system developed to solve the problem of anomaly detection, a solution is to use machine learning (ML) algorithms that are available in one of the open-source libraries, such as the scikit-learn library or the PyOD library. These algorithms can be easily and quickly integrated into a low-cost software application developed to meet the needs of a small and medium-sized enterprise (SME). In our experiments, we considered some unsupervised algorithms available in PyOD library. The obtained results are presented, alongside with the limitations of the research.

**Keywords**—Unsupervised anomaly detection algorithms; small and medium-sized enterprise; traceability; open-source libraries

## I. INTRODUCTION

The current societal landscape has seen an increase in the quantity and complexity of information processed daily. Such increasing use is required for effective management of current industrial processes and depends on the data acquired from the process itself, data that is cleaned and converted into information that can be used to create meaningful visualizations, be fed in complex control and prediction algorithms, or even stored for future reference and use. Moreover, data reliability is paramount. Correct information must be used to obtain correct responses from the managed processes and incorrect information can lead to inefficiency, loss of precision, data, or product that in turn can negatively impact the organization's reputation or the bottom line.

In general, the data is acquired from the process via sensors, manually or through automated systems. To eliminate acquisition errors, data is sanitized and, if possible, corrected. This prevents the propagation of errors further in the system. Data that does not meet the criteria for correction may appear anomalous compared with its dataset values or regarding the

median of the dataset. In any scenario, this might indicate either erroneous data or valid data signaling a potential problem with data acquisition or in the process itself. Therefore, isolating anomalous data is an important indicator of data health and a promising path in data analysis.

Anomalies are unexpected instances of deviation from a large part of the dataset. Thus, solving them will allow for improving the efficiency of the underlying process [1]. In fact, according to various studies (e.g., [2]), applications based on anomaly detection could help an enterprise detect possible issues in time, before they emerge by identifying anomalous behavior, thus minimizing the risk of data loss and streamlining business processes. Anomaly detection finds application in multiple industries and domains, including healthcare, finance, manufacturing, construction, logistics, cyber security, and many others [3], [4]. There are various specific applications of anomalies detection, such as, system health monitoring, early detection of sepsis [5], event detection, product quality, intrusion detection, energy optimization, various real-time applications, to name only a few.

The anomaly detection market is witnessing growth, thus, according to [2], “the anomaly detection market size is expected to grow from USD 2.08 Billion in 2017 to USD 4.45 Billion by 2022, at a Compound Annual Growth Rate (CAGR) of 16.4%”. This growth is being driven by the increasing development and dynamic adoption of emerging technologies such as big data analytics, data mining and business intelligence, machine learning and artificial intelligence.

According to scientific literature, there are three main types of anomaly detection techniques, depending on the type of supervision: unsupervised, semi-supervised, and supervised. Essentially, the choice of anomaly detection method can be made according to the labels available in the dataset [6].

Considering the extensive variety of available anomaly detection algorithms, how can one choose which approach is most suitable for a particular application? Clearly, performance in anomaly detection is a significant factor in algorithm selection. Unfortunately, there is no one approach that is best in every context and for all domains. Depending on the specifics, one algorithm may be superior to the others for a given user or dataset. Selecting an appropriate algorithm for a specific application is still a difficult design choice [7]. This is even more important in traceability systems that must ensure that the

product's lifecycle is correct, where the detection of an anomaly in the process can have a major impact on the production pipeline. However, these workflows can vary from company to company, which means that the use of supervised learning would imply higher costs to develop a custom model, whereas unsupervised learning and more precisely, anomaly detection would allow building a model that does not require human intervention, does not need prior knowledge about the process and, at the same time, can be very dynamic in terms of feature selection.

Reviewing the literature on machine learning-based anomaly detection algorithms reveals the diversity of algorithms evaluation and comparison approaches used by researchers. Consequently, the authors of [7] draw attention to the inconsistency in splitting between training and test datasets, in the selection of performance metrics and in the threshold used to indicate anomalies. Moreover, they point out the ambiguity in the definition of the positive class (i.e., the class of interest) utilized to evaluate the various models. Because of these inconsistencies, the authors find it difficult to understand the experimental evaluations presented in different papers [7].

To reduce the cost and complexity of a system developed to solve the problem of anomaly detection, a solution is to use machine learning (ML) algorithms that are available in one of the open-source libraries, such as the scikit-learn library [8], [9] or the PyOD library [10]. These algorithms can be easily and quickly integrated into a low-cost software application developed to meet the needs of a small and medium-sized enterprise (SME). Once the relevant features considered for anomaly detection are selected and pre-processed, the integrated algorithms can be applied within the specific software application.

In this paper, we will examine the viability of implementing anomaly detection in a traceability system by applying unsupervised anomaly detection algorithms. In this regard, we will study and compare the performance of some of the unsupervised anomaly detection algorithms applied on a dataset provided by the information technology (IT) department of a small and medium-sized software enterprise. We considered some un-supervised algorithms available in one of the popular open-source libraries, namely PyOD library. This library provides several benefits over comparable existing libraries. For instance, it contains more than 20 algorithms, it “implements combination methods for merging the results of multiple detectors and outlier ensembles which are an emerging set of models”, and “all models are covered by unit testing with cross platform continuous integration, code coverage and code maintainability checks” [10]. These benefits have led to its widespread adoption in academic and commercial applications [10]. According to [11], [12], the GitHub repository has more than 10,000 monthly visitors, and more than 6,000 monthly downloads for PyPOD.

The remainder of this paper is structured as follows. Section II provides an overview of machine learning-based solutions for traceability domain, methods and algorithms in anomaly detection and the evaluated anomaly detection algorithms. The methodology we relied on to conduct the presented research is also discussed. Section III describes the

experimental process and results obtained on a real dataset. Section IV is dedicated to presenting insights on the performance of the algorithms. The limitations and directions for future research are presented in Section V. The final section provides the concluding remarks of the paper.

## II. MATERIALS AND METHODS

In this section, we review prior work in terms of machine learning in traceability, and methods and algorithms in anomaly detection.

### A. Machine Learning in Traceability

By employing traceability systems, products can have better quality, or the workflow can be improved. Thus, this concept has been applied in a variety of domains, ranging from managing the food supply chain [13], [14] to the automotive industry [15]. Moreover, given the high volume of data, ML algorithms could be used to analyze and provide relevant information that can be used in the decision-making process.

Given that food safety is a critical concern, traceability has been used in this industry in order to follow the process taken by perishables to ensure safety and quality. For example, De Nadai Fernandes et al. [16] employed three supervised ML algorithms to determine the source of bovine meat in Brazil, where there was a loss of information during the slaughtering or marketing processes. On the other hand, Alfian et al. [13] used Radio Frequency IDentification (RFID) tags and Internet of Things (IoT) sensors to collect information regarding the environment and track when produce would pass through a space, for example, a warehouse door. They also employed supervised learning to identify the direction of the product and, thus, determine whether the products were safely stored. To prevent food safety incidents, Wang et al. [14] developed a traceability system that ensured quality at each stage of the production pipeline by developing supervised ML algorithms to determine the quality at each stage and establish the final quality, whereas Shahbazi and Byun [17] utilized ML and blockchain to detect counterfeits and ensure the validity of the expiration dates.

Sharma et al. [18] reviewed the use of ML algorithms in the agricultural supply chain and observed that these algorithms were implemented at each step of the production process to improve efficiency. For instance, in the preproduction stage, ML algorithms were used to predict the harvest, soil properties and irrigation management. In the production step, they were used to predict the weather, protect the harvest, detect weeds, manage animals, and overview the harvest quality. The processing step consisted of algorithms used to predict the demand and plan the production, while in the distribution phase they were used to improve transportation, analyze the consumers, and manage the inventory.

Other domains have also included ML algorithms to analyze performance, for instance, in the automotive industry [15], or to determine validity in software maintenance for traceability link recovery [19]. One important observation is the focus on quality control and preventing issues that could occur. However, most of the discussed systems used supervised machine learning algorithms that need labeled data as input, which means that the process must be firmly

established, and any change means having to reformat and revalidate the training dataset. In this context, we looked at unsupervised anomaly detection algorithms that could be applied to a more dynamic process to alert the user of any abnormalities in the system by using an unlabeled dataset.

The next sections provide brief descriptions of the algorithms used for anomaly detection.

### B. Methods and Algorithms in Anomaly Detection

Detection of anomalous instances in various datasets is of great importance in many processes. Outlier observations, records, recorded values, states, and devices can either affect the workflow of processes or can induce bias in computed values or scores. Removing the outliers is a valid and known technique, but the detection of the aforementioned anomalous values is not an easy process – especially when the data is not identified and tagged [6].

Anomaly detection techniques are employed in various working domains, but especially in supply chain management, where the capabilities of various techniques allow to manage complicated processes, using predictive algorithms and other use cases. For example, using blockchain technologies in supply chain systems allows for novel methods to manage all aspects of the process. However, to have a robust data model and verification mechanism to ensure the integrity of the processes it is required to implement mechanisms to correct anomaly signals in the acquired data required in verification processes for the business logic involving transactions (both resource intensive and critical for the wellbeing of the platform) [20], [21] between entities in the platform, for a better quality in supply chain management (not only from a performance point of view, but also from a security perspective).

In many applications that require anomaly data detection, ML algorithms are used to highlight the relevant data for future correction, removal, or analysis [22]. Many times, the detection algorithms are paired with traditional detection systems, usually rule-based, for better performance. In this regard, there are various application domains where these types of algorithms are used [6]: network security for intrusion detection (used for behavior analysis in enterprise settings for known and novel threats), surveillance for suspicious moves and actions (via visual and audio capture systems) [23], [24], detection of fraudulent transactions in banking industry (including transactions involving digital goods) [25], [26], energy optimization in smart buildings [27], medical smart equipment (capable of identification and analysis of anomalies to assist in medical diagnosis) [28], [29], and, generally, in use-cases where anomalous states can appear infrequently enough in the operating processes to be properly treated, but pose enough dangers to warrant such a system.

Even in processes that are tied to physical mediums, like, for example, nuclear radiation detection [30], telemetry data for spacecraft operations [31], traffic patterns analysis [32], sensor arrays and IoT systems [33], unmanned ground and aerial vehicles detection [34], edge computing systems and novel large-scale IT systems [35] or network quality of service assurance by using a Greedy algorithm [36] or even genetic

algorithms [37], such ML algorithms can be used for identification of anomalies. Moreover, similar algorithms are used in domains like supply chain management, where genetic rule-based and graph-based detection methods are employed to verify business transactions regarding their validity [20].

Anomaly detection domain can be classified in three types [6], based on the approach regarding labelling of the dataset content: supervised anomaly detection where the training data and the test data are fully labelled (in practice this is less used given that labelling the data is not always feasible or even possible), semi-supervised anomaly detection where the training is done on non-anomalous datasets (the anomalies being detected when they deviate from the “correct” model) and unsupervised anomaly detection that does not require labels to classify data (most flexible approach), the distinction being made on the internal properties of the dataset.

As stated in the introduction section, this paper has considered the evaluation of several unsupervised algorithms for anomaly detection in the context of traceability. According to [6], unsupervised anomaly detection algorithms can be roughly classified into the following main categories as illustrated in Fig.1 (1) Nearest-neighbor based techniques, (2) Clustering-based methods, (3) Statistical algorithms, (4) Subspace techniques, (5) Classifier-based algorithms.

In this paper, the evaluated algorithms are part of the first three groups.

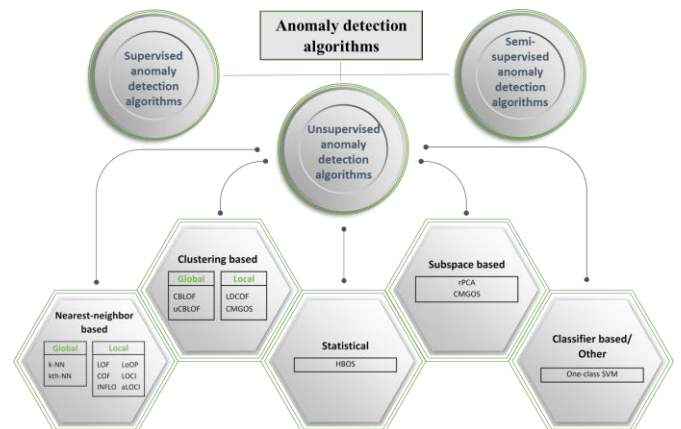

Fig. 1. Taxonomy of Unsupervised Anomaly Detection Algorithms (Adapted after [6]).

### C. The Evaluated Anomaly Detection Algorithms

In the following, it briefly presents the five anomaly detection algorithms that were evaluated. The k-nearest neighbor (k-NN or KNN) algorithm consists of finding the nearest neighbors and calculating the anomaly score based either on the distance to the nearest neighbor [38] or the mean distance to the k nearest neighbors [39]. One of the drawbacks of this algorithm is that it detects only global anomalies, an issue that was tackled in the Local Outlier Factor (LOF) algorithm [40], which was the first algorithm to detect local anomalies. The Cluster-Based Local Outlier Factors (CBLOF) algorithm [41] uses the grouping to determine the dense areas from the data and uses a heuristic to classify the groups,

whereas Histogram-based Outlier Score (HBOS) [42] is based on statistics and assumes that there are no dependencies between the features of the model. One challenge faced by clustering algorithms is choosing the number of groups, which was addressed by Local Correlation Integral (LOCI) [43] that uses a maximization approach.

The implementation of these algorithms in various software libraries, such as the PyOD library [10], facilitates their use in the development of software applications for anomaly detection.

#### D. Performance Criteria

In this paper, we have examined the possibility of employing anomaly detection in a traceability system by applying five unsupervised anomaly detection algorithms and compared their performance.

The algorithms evaluated in the considered scenario must be analyzed from a performance perspective. Given that not necessarily all algorithms can be implemented in the traceability platform (for performance reasons), usually the best algorithm will be employed in the final product, for best performance/accuracy ratio. Alternatively, two or three algorithms can be employed in certain circumstances, where their performance can compensate for their weaknesses in certain datasets configurations or certain limited cases. Thus, it is important to establish the performance of the potential solution in the given circumstances, including when adjusting the settings in the classifier model.

In this regard, a criterion that is often used to test the performance of algorithms in machine learning is the ROC curve (Receiver Operating Characteristics) [44]. ROC metric will help establish the performance of the model (higher the value, better the outcome) by plotting the rate of true positives compared (higher is better) with the rate of false positives (lower is better) and thus establishing a threshold for the performance of the model in classifying the input data [44]; this approach is important when deciding between various algorithms or when adjusting operating parameters of a given algorithm.

Another important criterion is the accuracy score. In performance metrics [45], the accuracy score is the measure by which the classifier will offer correct predictions compared with the total number of predictions made. Obviously, a greater accuracy is a highly desirable behavior of the model.

Finally, precision @ rank n represents the precision of the model up to n<sup>th</sup> prediction from the total number of predictions [46]. This metric helps usually in choosing a better model for a given type of problem, given that the goal is to obtain a good fit for our algorithm.

$$\text{Precision}@k = \frac{\text{true\_positives}@k}{\text{true\_positives}@k + \text{false\_positives}@k} \quad (1)$$

Training time is also an important factor in choosing a certain algorithm. Given that the time spent training the models can be an expensive proposition (for example in big datasets or when the datasets change in time, requiring re-training of the model), choosing an algorithm that is faster on training is better, as long as the performance metrics are not suffering.

As highlighted in [7], different splits of the training and test data can be used while comparing the performances of various algorithms. Thus, decisions have to be made regarding the splitting of training and test sets. For anomaly detection, it must additionally be decided whether one of these two sets will contain normal data, abnormal data, or both. Regardless of the decision taken, it must be used in a consistent manner when evaluating different algorithms [7].

In the next section, we present the considered use case.

#### E. Use Case

In order to perform the proposed comparison of some anomaly detection algorithms, we have considered the use case of the traceability of different equipment types in an IT department Fig. 2 presents the main steps of our process of evaluation.

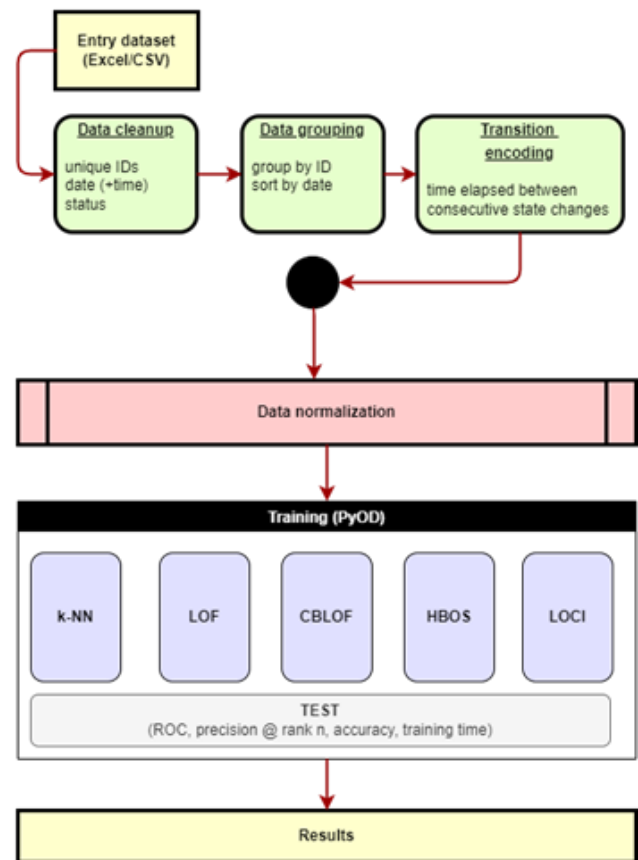

Fig. 2. The Workflow of the Experiment.

Next, we describe the data pre-processing and applied methods.

To perform the proposed anomaly detection comparison, we were provided with a set of data in the form of an Excel spreadsheet or a CSV (comma separated values) file that contained information regarding the management of equipment in an IT department. The spreadsheet was composed of records of items that were registered and then assigned to employees. There were cases when items malfunctioned, so they were sent back to the IT department for repairs and assigned back to an employee or had to be scrapped. The file consists of multiple

data columns, such as unique ID, date, equipment name, equipment type, employee name, status, etc. The dataset contained a number of 347 transitions for 130 items with 130 records for the acquired status, 177 instances of assigning an item to an employee for use, 22 cases of sending the item to the IT department for repairs, and 18 recorded for items being scrapped. It was considered that the data provided was valid and could be used for training a machine learning model, and that artificial anomalies could be added to the set of data for validation. It should be noted that this process can be applied to other types of items, regardless of their statuses as this process is generic and does not require any previous setup.

The first step of the pre-processing phase is extracting the relevant information, in this case from the Excel or CSV file, but other sources, such as databases, can be used. The significant attributes are the item unique identifier, and the date and status of the item when that record was made. Depending on how the data is stored, the status of the item may have a variety of formats, ranging from integers to strings. For example, we considered the coding of statuses presented in Table I.

Based on the previous coding of the statuses, Table II, illustrates the case of a monitor with the ID 132606, which was purchased (status with unique ID 1) on January 27<sup>th</sup> and given in use (status with unique ID 3) to an employee the next day, on January 28<sup>th</sup>. On June 25 of the same year, the item identified with ID 132606 is sent for repairs.

The date, and time if available, must have the same format and should be converted to a format that would allow for simple time difference calculations. Since the provided spreadsheet contained only the registration date, it was converted to the number of days since January 1st, 1900, in accordance with the ISO 8601:2000 YYMMDD format.

Secondly, to define the item transitions, all data must be grouped according to the unique identifier and sorted by date inside that group. If time is known, it should also be considered in the ordering, and this would be of greater significance in situations in which items transition multiple statuses on the same day. In our case, after going through these steps, the data for an item should reveal how an item was purchased and then assigned to employees with some cases where it was sent for repairs or was scrapped. A transition is represented based on the time elapsed between the current state and the previous state in the form of a number of days, or a number of minutes or milliseconds (depending on the granularity of the data), if the data contained time. The transition token is composed of the concatenation of the current and previous status identifier, which was defined in the previous step. A sample of the data is shown in Table III.

In this example, if item 132606 was purchased on the 27<sup>th</sup> of January and assigned (status with the three unique ID) to an

employee on the 28<sup>th</sup> of January that same year, then this transition will be characterized by a one-day time interval, resulting from the difference between the two dates, and the “13” token, which represents the concatenation of the unique identifiers assigned to the status attributes. These will be the two features that will be used to train the ML model, which were selected as relevant as a result of an analysis of what information is critical in a traceability system with the purpose of creating a trained model that could point out the incorrect transitions. Therefore, mistakes could be made while changing the status of an item, for instance, moving a monitor from acquired to scrapped would be invalid, whereas if, for example, the monitor is left in the in-repair state for a prolonged period reveals a different type of issue such as the lack of available employees to check the monitor. When an item is added to the system and is assigned its first status, the elapsed time should be set to zero and the token should consist of the doubling of the unique identifier status, in our case, the token for the first transition of item 132606 is “11”. If an item starts with a different status, then the ML algorithm should be able to signal it as an anomaly.

TABLE I. THE CODING OF THE CONSIDERED STATUSES

Status	Code
Purchased	1
Scrapped	2
In use	3
Maintenance	4

TABLE II. SAMPLE OF THE ENCODED DATA RECEIVED FROM IT DEPT.

Unique item ID	Status	Date
132606	1	January 26, 2021
132606	3	January 28, 2021
132606	4	June 25, 2021
132606	3	July 02, 2021
134338	1	April 29, 2021
134338	3	May 14, 2021
134338	2	July 30, 2021

TABLE III. EXAMPLE OF ITEM TRANSITIONS

Unique item ID	Transition token	Timelapse (days)
132606	11	0
132606	13	1
132606	34	148
132606	43	7
134338	11	0
134338	13	15
134338	32	77

The third step before training the models is normalizing the data, which in this case was performed using the preprocessing scale function from the scikit-learn [9] Python package. Normalization needs to be applied to each feature, because having overly broad scales could cause issues when training the ML model. This is avoided through the fact that the new values are smaller and at the same time they maintain the general distribution and data ratios, which means that the relevant information is preserved. Before applying this step, we also added a number of four artificial anomalies consisting of invalid transitions, new statuses, and prolonged periods of time, which should be signaled by the ML model. The added artificial anomalies had to be run through the same scaling process as the valid set of data to avoid inaccuracies. We added such a small number of anomalies, because, as per their definition, anomalies are events that occur rarely.

To analyze the performance of the applied algorithms the data has been formatted and split into a file that contains all the valid transitions, a file that contains 80% of the data and four artificial anomalies that can be used for training the model, and a file that contains the rest of the 20% of the data and other four artificial anomalies that can be used as the test data, which will be utilized to validate whether the model is overfitted. The split between the test and training data is done randomly by shuffling the item IDs and then selecting 20% of the IDs and their corresponding transitions for the test data. The rest of the items are assigned to the training dataset. In addition, when the data is split, it should be normalized separately to avoid any data leakage. Given that the IDs are separated randomly, this means that the data will be split differently when the process is run again on the same set of data.

### III. RESULTS

Next, the results of the training and tests processes for the ML algorithms having as input the datasets described in the previous section of this paper are presented. To evaluate and compare the anomaly detection methods we use the standard metrics of precision, ROC and accuracy. Also, it was considered the training time for each algorithm. The experimental evaluation is conducted on a laptop with i7-8550U CPU @1.80 GHz x 8, 16 GB of RAM, running Ubuntu 16.04 LTS. The code is written in Python 3.

In the experiments conducted, the split of data was performed considering normal and anomalous data, both in the training and in the testing phase. For the first analysis, we used the training dataset that had 80% of the whole data, and the test train dataset composed of 20% of the provided information. Each set contained the same four artificial anomalies that were used for validation. The first set of data was used to train five separate anomaly detection algorithms available in the PyOD Python package [10] by first initializing them and then applying the fit function that received the training set of data. This resulted in a list of prediction labels and outlier scores of the training data, which we used to compute the accuracy of the model based on the training dataset. To evaluate the model, the predict and *decision\_function* functions were used, which received the test dataset as input, whose results were used to calculate the accuracy of the test predictions. Accuracy was calculated based on the assumption that the received dataset contained only valid records and that there were four artificial anomalies. To calculate the ROC and the Precision @ rank n, we used the *evaluate\_print* function provided by the PyOD library. It was also recorded the time needed to train each model. Table IV contains the results of these metrics for the analyzed five algorithms. The evaluation results are shown in Fig. 3.

Given that the provided dataset was small, during the second analysis the complete dataset was used as the training data and some predictions were made based on four cases: normal record for item just being added to the system (N1), normal record for item being assigned to employee (N2) that was taken from the initial dataset, anomaly with non-existent states (A1), and anomaly with item assigned to employee but with an anomalous time (A2). Before sending these datasets to the algorithms for predictions they were processed by using the same normalization parameters used for the training set. Table V shows the results of training the five algorithms with the full set of data and using the previously described cases to validate the predictions. The evaluation results are shown in Fig. 4.

Nevertheless, in a normal setting, the prediction would be made based on a model that was trained using the full set of data, which could occur right when there is a request to predict whether a transition is anomalous or not, if the training is fast enough, or periodically, in which case it would contain only the records that were registered until the time of training.

TABLE IV. RESULTS OF ALGORITHM BASED ON TRAINING AND TEST DATASET

Metric/ algorithm	KNN		LOF		CBLOF		HBOS		LOCI	
	Train	Test	Train	Test	Train	Test	Train	Test	Train	Test

TABLE V. RESULTS OF THE ALGORITHMS TRAINED ON THE FULL DATASET AND VALIDATED BASED ON FOUR PREDICTIONS

Metric/algorithm	KNN	LOF	CBLOF	HBOS	LOCI
ROC	1.0000	0.9366	1.0000	0.9712	0.9323
Precision @ rank n	1.0000	0.0000	1.0000	1.0000	0.0000
Accuracy (%)	91.73	91.45	91.16	91.73	87.74
Time (seconds)	0.0042	0.0044	2.5900	2.5399	88.51
N1 prediction	Correct	Correct	Correct	Correct	Correct
N2 prediction	Correct	Correct	Correct	Wrong	Correct
A1 prediction	Correct	Correct	Correct	Correct	Wrong
A2 prediction	Correct	Correct	Correct	Correct	Wrong

#### IV. DISCUSSION

In this section we discuss and analyze the results of running the five machine learning algorithms, mainly k-NN (k-nearest-neighbor) - a nearest-neighbor-based unsupervised algorithm focused on detection of global anomalies (global relative to the dataset) with low computational impact [47], LOF (Local Outlier Factor) - a nearest-neighbor-based algorithm able to detect local anomalies alongside global ones [40], [48], LOCI (Local Correlation Integral) - a nearest-neighbor-based local algorithm with increased precision over k-NN but also with increased computational complexity [43], [45], CBLOF (cluster-based local outlier factor) - a clustering-based global algorithm [49] and HBOS (histogram-based outlier score), a very fast statistical algorithm almost an order of magnitude faster than k-NN [50].

By examining the results for the ROC scores from Table IV, it can be observed that most of the algorithms had good outcomes for the training values apart from LOCI with 0.6922, with the best being KNN (0.9982) followed by CBLOF (0.9657). On the other hand, the ROC values for the test sets show us that not all the models generalized well, for instance, the test ROC for LOF was 0.5, whereas HBOS had a lower score than the other algorithms with 0.8429. The best results were achieved again by KNN (0.9786) and CBLOF (0.9893), followed by LOCI (0.9643).

In terms of the precision @ rank n score, overall, CBLOF had the best results (0.75 for training and 1.0 for test) followed by KNN (0.75 for both the training and test datasets). Although HBOS had a low value of 0.25 for the training set, it had an exceptionally good score of 1.0 for the test set, whereas the other algorithms had low scores in general with 0.5 and 0.0 for train and test, respectively, for LOF, and 0.0 and 0.5 for train and test, respectively, for LOCI.

The accuracy score results revealed that HBOS performed the best with 96.44% for training and 98.64% for test with CBLOF being second with 91.10% for training and 82.43% for test. Even though KNN had a good result for the training dataset, 91.45%, it scored lower for the test dataset, 72.97%. Albeit having lower accuracy ratings, LOCI had similar values for both the train and test sets with 88.61% and 87.83%, respectively, whereas LOF had a considerable difference

between the test and train scores (90.74% and 52.70% respectively), which denotes that the model did not generalize.

Although the training time would not be a major factor to consider if the training is performed daily when there is no heavy traffic in the system, it can be still noted that LOCI had a significantly higher training time compared to the other algorithms. Its training lasted almost 45 seconds even if the dataset was relatively small while all the other models had times lower than a second, making LOCI definitively not a suitable candidate for such a system.

The second round of experiments displayed in Table V, which are closer to a real scenario, revealed some interesting results. Firstly, when using the full dataset for training, all algorithms had high scores for the ROC values with KNN and CBLOF having 1.0 followed by LOF and LOCI that had remarkably similar results, 0.9366 and 0.9323, respectively. On the other hand, the precision @ rank n was either exceptionally good with 1.0 for KNN, HBOS and CBLOF or bad with 0.0 for LOF and LOCI.

The accuracy scores were also higher in general, with KNN and HBOS having the same outcome of 91.73% followed by LOF at 91.45%, CBLOF at 91.16% and LOCI at 87.74%, which had a very similar result to the first experiment denoting a consistent pattern in the ability of this model to predict the anomalies for this dataset. In terms of the training time, KNN and LOF had the lowest results with times under a second. However, CBLOF and HBOS had significantly higher times (around 2.5 seconds), which can indicate a more rapid increase in time given that the training from the first experiment was performed on 80% of the data. LOCI still had the highest time with 88.51 seconds.

Regarding the four predictions, two normal cases and two anomalies, KNN, LOF and CBLOF correctly predicted all four cases, HBOS wrongly detected N2 as an anomaly, whereas LOCI was not able to detect the two anomalies. Although HBOS had similar results to KNN and CBLOF for the other evaluation conditions, it did not perform as well in terms of the test prediction. Thus, overall, the best results were achieved by KNN followed closely by CBLOF apart for the training time.

## V. LIMITATIONS

The size of the used dataset is a limiting factor in our work, however, even with such a small size we were able to demonstrate that anomaly detection can be applied to traceability with good results. Nonetheless, having a larger dataset could offer more insight, an analysis that could be undertaken in future work, where we could also include more algorithms in the comparison. The difficulty in creating a database for anomaly detection lies in the fact that the results will emulate the logic that was used in generating the data, thus, it is important to have access to a real dataset.

In future research, data splitting will be performed considering the normal data for training and all anomalous samples in the test set.

In terms of the discussed logic, adding a new process or status will automatically result in an anomaly detection. To solve this problem, the described logic could be adapted to add

a threshold, for example, there must be a minimum number of products that went through a status in order to send that transition to the anomaly detection algorithm. Another option would be to check if a generated group has lower elements than a set threshold. However, this could also mean that transitions that could be anomalous are not sent or are not taken into account by model. Handling this issue could be further investigated in future work.

In this analysis, only one process was considered. In order to improve the performance of the model, anomaly detection should be conducted for each type of process if the company workflow has various processes with different statuses. Obviously, for training a model there must be a minimum number of transitions for each category, which might be determined by user input or by involving a user in model validation. Once the model was able to properly detect anomalies, the threshold could be automatically set for future categories. Nevertheless, this could open the door to semi-supervised learning, which will be investigated in future work.

## VI. CONCLUSIONS

In recent years, there has been an increase in the number of artificial intelligence-based solutions for problems in various fields. Anomaly detection is an issue for which there are currently several approaches. One of the most widespread methods involves the use of ML techniques.

In this paper, the performance of five unsupervised anomaly detection algorithms regarding a traceability dataset that contains information on the management of devices from an IT department was analyzed and compared. The models used with anomaly detection algorithms based on machine learning do not require labeled data. Given the importance of reproducibility in research, we presented all the information regarding the implementation that allow double-checking the results and verifying whether they are reliable. By analyzing the precision, accuracy, ROC, and time we determine which algorithms tend to perform better or worse on the presented use case. We have demonstrated experimentally that these algorithms can be successfully applied to determine whether a new transition is an anomaly with an accuracy of up to 91.73%.

**Abstract**—Brain MRI (Magnetic Resonance Imaging) classification is one of the most significant areas of medical imaging. Among different types of procedures, MRI is the most trusted one to detect brain diseases. Manual and semi-automated segmentations need highly experienced radiologists and much time to detect the problem. Recently, deep learning methods have taken attention due to their automation and self-learning techniques. To get a faster result, we have used different algorithms of Convolutional Neural Network (CNN) with the help of transfer learning for classification to detect diseases. This procedure is fully automated, needs less involvement of highly experienced radiologists, and does not take much time to provide the result. We have implemented six deep learning algorithms, which are InceptionV3, ResNet152V2, MobileNetV2, Resnet50, EfficientNetB0, and DenseNet201 on two brain tumor datasets (both individually and manually combined) and one Alzheimer's dataset. Our first brain tumor dataset (total of 7,023 images-training 5,712, testing 1,311) has 99-100 percent training accuracy and 98-99 percent testing accuracy. Our second tumor dataset (total of 3,264 images-training 2,870, testing 394) has 100 percent training accuracy and 69-81 percent testing accuracy. The combined dataset (total of 10,000 images-training 8,000, testing 2,000) has 99-100 percent training accuracy and 98-99 percent testing accuracy. Alzheimer's dataset (total of 6,400 images-training 5,121, testing 1,279, 4 classes of images) has 99-100 percent training accuracy and 71-78 percent testing accuracy. CNN models are renowned for showing the best accuracy in a limited dataset, which we have observed in our models.

**Keywords**—Brain MRI; tumor; deep learning; classification; transfer learning

## I. INTRODUCTION

With the advancement of modern science and technology, brain diseases are still among the deadliest diseases. Magnetic Resonance Imaging (MRI) is a well-known term in the medical sector to diagnose cerebral complications. It is used to detect brain cells that differ from normal cells. There are some other methods such as X-radiation (X-rays), Computed Tomography (CT), Positron Emission Tomography (PET), Single-Photon-Emission Computed Tomography (SPECT), Magnetic Resonance Spectroscopy (MRS), etc. are also used for diagnosis of diseases. But among all of them, MRI is the most popular one to detect problematic cells accurately. MRI is a non-invasive and flexible clinical method that investigates the conditions of the brain and any other body parts in species [1].

\*Corresponding Author.

It uses magnetic fields and radio waves to generate images. For brain MRI, the images are taken from different planes to detect the actual area of the problematic cells of both pre-and post-contrast. Its scanned images provide high contrast and high spatial resolution images, which helps to understand the different characteristics of the soft tissues of a cell. Usually, brain abnormalities are easily found by MRI scans. After analyzing those images, medical experts can easily identify brain disorders such as Alzheimer's disease, schizophrenia, multiple sclerosis, brain tumors, cancer, and degenerative diseases [1]. Although, many neurological diseases need frequent analysis of the brain, in those cases MRI scan is essential.

In the past, segmentation done by humans was a time-consuming procedure and could not provide significant results [2]. On the other hand, automatic segmentation methods result in efficient and precise segmentation. Lately, deep learning methods have been given increasing attention due to their automation and self-learning techniques. Convolutional Neural Network (CNN) is one of the most popular deep learning architectures and it has shown outstanding impact on various industries, such as medical, electronics, robotics, etc. The main advantage of CNN is that it can learn abstract features of the image without having preceding acknowledgment compared to classical methods. This method is developing daily and has achieved numerous appreciations in brain segmentation and classification. Precise segmentation of a 2D and 3D image has always been a challenging task, and various approaches have been proposed for better accuracy in the past. But state-of-the-art deep learning architectures for image segmentation have managed to compute complex 3D models. For these reasons, automatic detection and classification are highly demanding attributes in the decision-making of medical science. Again, CNN models show high accuracy even in limited datasets which are also one of the reasons for choosing CNN models. As we have used transfer learning, the process has become faster. Most of the traditional supervised learning algorithms are not supportive of multi-class classifications as well as very few experiments have been done on recently developed deep learning algorithms for brain MRI classification. Therefore, the question remains what is an efficient way to classify brain diseases from MR images? Also, a comparison of different deep learning algorithms on different types of datasets is

missing, which raises the question of how well a model works on different types of images.

The main objective of this study is to find an efficient way to classify diseases from brain MRI using deep learning models and show a comparative study of them for multi-class brain MRI classification problems. Six CNN models which are commonly used in classification of brain MRI- InceptionV3 [3], ResNet152V2, MobileNetV2 [4], Resnet50 [5], EfficientNetB0 [6] and DenseNet201 [7][8][9][10][11][12][13][14][15][16][17][18][19]. We have implemented these models on three different datasets- one is an Alzheimer's dataset, and the others are brain tumor datasets, all of which are open-access datasets. This study contributes to the health sector, where it is crucial to act in a short time in case of any emergency. Our study can reduce the time to classify a disease from an MR image, which can also lower the occurrence of human error. Also, it can reduce the cost for the patients. As CNN models are getting developed day by day, we could improve our health sector services by finding the most efficient one.

The rest of the paper is organized as follows: In Section II, we have reviewed the related paper materials and their research analogy. A brief overview of publicly available brain MRI datasets, followed by a brain MRI analysis and overview of CNN architectures are discussed in Section III. We have analyzed the performance of our proposed architecture on three publicly available datasets and compared their performance with other methods in Section IV. In Section V, we conclude the paper.

## II. RELATED WORKS

Deep learning models are very recent but many research works have been done for the classification of brain tissues. A method for binary classification of brain tumors is proposed, where they took only the region of interest from MRI images by using Open source Computer Vision (CV) Canny Edge Detection technique and trained a CNN model of eight convolutional layers [20]. Multiclass classification of brain tumors is proposed by selecting features using Densenet201 Pre-Trained Deep Learning Model, Entropy-Kurtosis-based High Feature Values (EKbHFV), and a modified genetic algorithm (MGA), where Cubic SVM classifier is used to classify the selected features after fusing using a non-redundancy-based fusion approach [21]. Again, a CNN model of 18 layers is used for cropped lesions, uncropped lesions, and segmented lesion images for multiclass classification of brain tumors [22].

Some works have either pre-trained data or implemented a single model. MobileNetV2 is used to classify brain tumors with the accuracy of 94% [15], applied ResNet152V2 for classifying four types of brain tumors by using various pre-processing steps to achieve an accuracy of 98.9% [11], and used 29 different pre-trained models to classify Alzheimer's disease, achieved the highest accuracy of 92.98% by EfficientNetB0 [19].

In some literature, they have used multiple planes and multiple layers to detect the problem. A multi-pathway CNN architecture is proposed where the input images are processed

in three spatial scales: sagittal, coronal, and axial views [23] and implemented CNN model with small kernels and neuron weight to classify between tumor and non-tumor which brought 97.5% accuracy with very low complexity [24]. Some works have been done by summing up a few models. Using a method where pre-trained models are used for feature concatenation, it is found that features from the pre-trained model of InceptionV3 and DensNet201 can classify three-class brain tumor datasets better than existing state-of-the-art deep learning methods [8]. Using five CNN models, they used the weighted average of those models to get an accuracy of the 96% in classifying stages of Alzheimer's disease [12]. By removing the last five layers of ResNet50 and adding 8 new layers, achieved 97.2% accuracy in classifying brain tumors and also used Alexnet, Resnet50, Densenet201, InceptionV3, and Googlenet models to classify brain tumors [16].

In some, data are pre-processed in different ways, then models are applied to them. An automated brain disease classification model is created with four main phases, which are preprocessing, exemplar deep feature generator, feature selection, and classification using a support vector machine (SVM) [13]. By using Discrete Cosine Transform-based image fusion, which is combined with a super-resolution and classifier framework, a CNN model, ResNet50, achieved a 98.14% accuracy rate on an open-access dataset [18].

The literature demonstrates a handful of models which have the potential to be used in the brain disease classification sector. However, an in-depth analysis of the most popular and most efficient models on different types of datasets is not quite present in the explored studies.

In our experiment, we have implemented six different models- InceptionV3, ResNet152V2, MobileNetV2, Resnet50, EfficientNetB0, and DenseNet201 on two brain tumor datasets (both individually and manually combined) and an Alzheimer's dataset to visualize the difference of each model, compare their effectiveness by using four different measurements- Accuracy, Precision, Recall, and F1-score, and efficiency.

## III. MATERIALS AND METHODS

### A. Dataset

There is a total of three datasets from three different sources, each containing brain MR images of four kinds. Two datasets contain three variants of Brain Tumor, while one dataset contains three variants of Alzheimer's. We have combined two datasets of Brain Tumor to expand the size of the data and reduce biasness. For simplicity purposes, we have named the datasets respectively D1, D2, D3, and D4. D1 represents the Brain Tumor MRI dataset, D2 as Brain Tumor Classification (MRI), D3 as the manual combined dataset, and finally D4 as the Alzheimer's Dataset (4 classes of image). The datasets are publicly available and collected from Kaggle.

In Fig. 1, Fig. 2, and Fig. 3, glioma, meningioma, pituitary, and no tumor are the variations of brain tumor datasets and in Fig. 4, moderate demented, mild demented, non-demented and very mild demented are the four different classes of Alzheimer's dataset. The summary of all datasets is given in Table I.

Fig. 1. Sample Images from D1.

Fig. 4. Sample Images from D4.

Fig. 2. Sample Images from D2.

Fig. 3. Sample Images from D3.

TABLE I. SUMMARY OF DATASETS

Dataset	Classes	No. of Images	Total Images
Brain Tumor MRI Dataset (D1)	No Tumor	2000	7023
	Glioma	1621	
	Meningioma	1645	
	Pituitary	1757	
Brain Tumor Classification MRI (D2)	No Tumor	500	3264
	Glioma	926	
	Meningioma	937	
	Pituitary	901	
Manually Combined Dataset (D3)	No Tumor	2500	10000
	Glioma	2500	
	Meningioma	2500	
	Pituitary	2500	
Alzheimer's Dataset (D4)	Moderate Demented	64	6400
	Mild Demented	896	
	Non-Demented	3200	
	Very Mild Demented	2240	

### B. Preprocessing

At first, the images are converted into NumPy arrays, where each pixel of an image is assigned to a number, generating an array for each image. Image Augmentation is an important step in image processing. It creates multiple versions of one image to increase the size of the dataset. Each version has different properties that give more information and a new point of view of the image to train. The images are shifted both vertically and horizontally between -20px to 20px, randomly zoomed in and out by 20%. Then the categorical values are converted to numeric values. As there are four classes for each dataset, each class is given a numeric value in the range 0-3.

### C. Transfer Learning

Transfer learning is a machine learning technique where a deep learning model reuses the weights that have been generated from a different dataset. The reason for using this method is to use the patterns learned from a similar task to get a head start to avoid huge computational time and attain the best result possible for that model.

The models used in this experiment have already been trained with the ImageNet dataset, which provided us with the weights that we can utilize.

### D. Models

Six deep learning models are used train the datasets, these are InceptionV3, ResNet152V2, MobileNetV2, ResNet50, EfficientNetB0, and DenseNet201.

1) *InceptionV3*: InceptionV3 is the third version of Google's Deep Learning Convolutional Architectures series, Inception. It contains 42-48 layers, which include convolutions, max pooling, average pooling, dropouts, and fully connected layers, and has both symmetric and asymmetric building blocks. This model estimates the marginalized effect of label dropout during training to regularize the classifier layer by changing the label-smoothing regularization (LSR) which is defined by,

$$q'(k) = (1 - \epsilon)\delta_{k,y} + \frac{\epsilon}{k} \quad (1)$$

where the uniform distribution  $u(k) = \frac{1}{k}$  is used in the model.

Also by considering the cross entropy, LSR is

$$H(q', p) = (1 - \epsilon)H(q, p) + \epsilon H(u, p) \quad (2)$$

LSR prevents the largest logit or unnormalized log probabilities from becoming much larger than all others. It encourages the model to be less confident as it might cause over-fitting and reduce the adapting capability of the model. InceptionV3 gave more than 78.1% accuracy on the ImageNet Dataset [3].

2) *MobileNetV2*: MobileNetV2 has 53 layers, one average pool, and around 350 GFLOPs (Floating point operations per second). It has two types of convolutional layers: 1x1 Convolution and 3x3 Depthwise Convolution. It contains two main blocks, the Inverted Residual Bottleneck Block and Bottleneck Residual Block.

The inverted residual bottleneck layers are implemented in a memory-efficient way to it can be used for mobile applications. It builds a directed acyclic compute hypergraph G, where the edges are the operations and nodes are tensors of intermediate computation. The target is to minimize the total number of tensors stored in memory, so it selects the computation order  $\Sigma(G)$  which has the minimum memory,

$$M(G) = \min_{\pi \in \Sigma(G)} \max_{i \in 1..n} [\sum_{A \in R(i, \pi, G)} |A|] + size(\pi_i) \quad (3)$$

As for graphs with only trivial parallel structure, the memory needed to compute graph G is

$$\max_{op \in G} \left[ \sum_{A \in op_{inp}} |A| + \sum_{B \in op_{out}} |B| + |op| \right] \quad (4)$$

In the bottleneck residual block, a bottleneck block operator  $F(x)$  can be represented as  $F(x) = [A \circ N \circ B]x$ . As the chain of t tensors of size n/t are the inner tensor, the function can be written as

$$F(x) = \sum_{i=1}^t (A_i \circ N \circ B_i)(x) \quad (5)$$

When t is a small constant between two and five, this method is the most helpful as it can reduce the memory, but can still utilize most of the efficiencies of highly optimized deep learning frameworks [4].

3) *ResNet50*: ResNet50 is a variant of the Residual Network model. It contains 48 convolutional layers, 1 Max Pool, and 1 Average Pool layer with  $3.8 \times 10^9$  floating point operations per second (FLOPs).

The convolutional layers have 3x3 filters. The layers have the same amount of filters when the output feature map size is the same. However, the layers have the double amount of filters when the feature map size is half. By following these two rules, it performs downsampling. The final layer contains an average pool with a fully-connected layer of 1000 nodes with a softmax function. The total number of weighted layers is 34. Based on this network, shortcut connections are inserted which turn this network into its counterpart residual version. The identity shortcut is defined by

$$y = F(x, \{W_i\}) + x \quad (6)$$

Equation (6) can be directly used when the dimension of x and F are equal. But if the dimensions change, either identity mapping is still performed by the shortcut, or the projection shortcut is used to match dimensions, defined by

$$y = F(x, \{W_i\}) + W_s x \quad (7)$$

For both options, when the shortcuts go across feature maps of two sizes, they are performed with a stride of two. By replacing each two-layer block in the 34-layer net with a three-layer bottleneck block, it results in a 50-layer ResNet [5].

4) *EfficientNetB0*: EfficientNetB0 is the base model of EfficientNet family. It uses Model Scaling, where the existing model is scaled based on model width, depth, and resolution. This model introduces a new compound scaling method that uniformly scales the width, depth, and resolution to achieve better accuracy using a compound coefficient  $\emptyset$ . By considering depth,  $d = \alpha^\emptyset$ , width,  $w = \beta^\emptyset$ , and resolution,  $r = \gamma^\emptyset$ , this method is defined as

$$\alpha \cdot \beta^2 \cdot \gamma^2 \approx 2, \text{ where } \alpha \geq 1, \beta \geq 1, \gamma \geq 1 \quad (8)$$

For this principle in (8), for any new  $\emptyset$ , the total FLOPs will increase by  $2^\emptyset$  approximately. EfficientNetB0 is scaled up by using the compound scaling method where  $\emptyset$  is fixed at 1, and after doing a small grid search of  $\alpha, \beta$ , and  $\gamma$ , the best values are found to be 1.2, 1.1, and 1.15 respectively under the constraint of (8).

The model has a total of 237 layers. It consists of five different modules which are used in a certain way to create each block of the model [6].

5) *DenseNet201*: DenseNet201 is one of the models of the DenseNet group. It contains 201 layers, and it is divided into Dense Blocks with different filters and the same dimensions for each block. The network includes  $L(L+1)/2$  direct connections. The output of the previous layer becomes the input of the next layer by using composite function operations. The transition layer is added between the Dense Blocks, where it applies batch normalization using downsampling. The growth rate  $k$  controls how much information should be added to the next layer. At layer  $l$  the growth rate is defined by [7]:

$$k^{[l]} = \left( k^{[0]} + k(l - 1) \right) \quad (9)$$

The models are compiled for training by using the compile method of Keras Model Training API. The training data is fit into the model with 10% validation data, 15 epochs, and a batch size of 32. The categorical accuracy of each epoch is monitored to find the highest categorical accuracy by following (10).

$$\text{Categorical Accuracy} = \frac{\text{Number of Correct Predictions}}{\text{Total Number of Predictions}} \quad (10)$$

#### IV. RESULTS AND DISCUSSION

##### A. Result Analysis

We have implemented six algorithms on four different datasets and secured significant results. The maximum accuracy for each dataset was obtained by different models. As we have used various datasets, so the percentage of the accuracy was not consistent in every dataset.

Our models were trained by using 80 percent of the data for training, 10 percent of the training data for validation, and 20 percent for testing. We have used ImageNet as a pre-trained weight in every model and SoftMax for the pre-training classifier. We also included some hyper-parameters as well.

The following figures show how the training and validation accuracy/loss fluctuated per epoch in four different datasets for the models which gave the best results. The red line represents the validation accuracy/loss and the green one is for training accuracy/loss. Also, the final results of each of the models from different datasets are given in Tables II, III, IV, and V. The model with the best accuracy is highlighted in the tables.

TABLE II. ACCURACY SUMMERY OF D1

Model	Training Accuracy	Validation Accuracy	Testing Accuracy
<b>InceptionV3</b>	<b>100%</b>	<b>97.90%</b>	<b>99.54%</b>
ResNet152V2	100%	96.50%	98.63%
MobileNetV2	99.98%	94.58%	98.09%
ResNet50	100%	98.78%	98.63%
EfficientNetB0	99.98%	99.65%	99.47%
DenseNet201	100%	96.85%	99%

TABLE III. ACCURACY SUMMERY OF D2

Model	Training Accuracy	Validation Accuracy	Testing Accuracy
InceptionV3	100%	98.26%	76.65%
ResNet152V2	100%	100%	76.90%
MobileNetV2	100%	92.68%	69.04%
ResNet50	100%	99.30%	77.16%
<b>EfficientNetB0</b>	<b>100%</b>	<b>96.17%</b>	<b>81.47%</b>
DenseNet201	100%	97.56%	78.43%

TABLE IV. ACCURACY SUMMERY OF D3

Model	Training Accuracy	Validation Accuracy	Testing Accuracy
InceptionV3	100%	98.50%	93.45%
ResNet152V2	100%	98.38%	93.10%
<b>MobileNetV2</b>	<b>99.94%</b>	<b>98.75%</b>	<b>94.50%</b>
ResNet50	100%	98.13%	93.45%
EfficientNetB0	100%	99.38%	94.35%
DenseNet201	100%	98.75%	94.10%

TABLE V. ACCURACY SUMMERY OF D4

Model	Training Accuracy	Validation Accuracy	Testing Accuracy
InceptionV3	100%	99.42%	77.25%
ResNet152V2	100%	98.64%	71.07%
MobileNetV2	100%	100%	76.15%
ResNet50	100%	99.42%	73.50%
<b>EfficientNetB0</b>	<b>99.98%</b>	<b>99.03%</b>	<b>78.34%</b>
DenseNet201	100%	99.61%	75.45%

As we can see different model provides different accuracy based on different datasets. In the dataset D1 shown in Table II, we have achieved 99.54 percent testing accuracy using the InceptionV3 model and the minimum was 98.09 percent using MobileNetV2. In the D2 dataset shown in Table III, we have secured 81.47 percent testing accuracy using the EfficientNetB0 model and 69.04 percent was the minimum by MobileNetV2. After analyzing the second dataset we noticed that there was no equal distribution among the classes, which is why the accuracy might not meet its target. Therefore, we have combined D1 and D2 by maintaining the equal distribution of the four classes and have generated D3. D3 has received improved testing accuracy which is 94.50 percent using MobileNetV2 and ResNet152V2 provided its minimal 93.10 percent shown in Table IV. We have also implemented these models on a different dataset which consisted of the images of Alzheimer's disease and the maximum accuracy has been received at 78.34 percent by EfficientNetB0 shown in Table V. So, we can conclude that InceptionV3, EfficientNetB0, and MobileNetV2 these three models are working best CNN models so far according to our observation.

ResNet models are found to perform comparatively worse than other models. It focuses mainly on creating a deep neural network model without hampering the accuracy. As a result, it takes longer as it has a relatively deep architecture, i.e. more parameters to train. Furthermore, having a deep architecture can also be the reason for its consistent validation loss. In contrast, as we can see in Fig. 5 and Fig. 7 that InceptionV3 and MobileNetV2 take significantly less time for performance. They have divided the convolution layer into two distinct parts. Firstly, instead of separately applying the kernel to all the channels, they have applied depthwise convolution. It mainly applies the kernel to each of the channels individually. Secondly, they applied a convolution with one kernel size to combine the features of the newly generated channel, which directly contributes to the shorter training period. However, as it is apparent from our results, it also sacrifices the overall accuracy. In contrast to MobileNetV2 and InceptionV3, EfficientNet evaluates the scaling part of the neural network. Using a compound coefficient, they uniformly scale the width, resolution, and depth of the network simultaneously to find the best gains. As it is apparent from our results shown in Fig. 6 and Fig. 8, EfficientNetB0 provides significantly better accuracy while taking comparatively less training time. Table VI shows the training and prediction time taken by each model.

	DenseNet201	~ 748	~ 2.6
D3	InceptionV3	~ 2573	~ 13.3
	ResNet152V2	~ 5426	~ 15.1
	MobileNetV2	~ 17, 282 (Worst Case)	~ 23.2
	ResNet50	~ 2275	~ 9.8
	EfficientNetB0	~ 1812 (Best Case)	~ 9.4
	DenseNet201	~ 4020	~ 15.7
D4	InceptionV3	~ 591	~ 5.3
	ResNet152V2	~ 1670 (Worst Case)	~ 10.6
	MobileNetV2	~ 457 (Best Case)	~ 2.6
	ResNet50	~ 703	~ 4.6
	EfficientNetB0	~ 670	~ 3.8
	DenseNet201	~ 1276	~ 6.3

As we know validation of these models is very important to prove our performance for this research purpose, we have used some metrics to do so- precision, recall, f1 score, and confusion matrix. The mathematical notations of these terms are given below:

$$Precision = \frac{true\ positive}{true\ positive + false\ positive} \quad (11)$$

$$Recall = \frac{true\ positive}{true\ positive + false\ negative} \quad (12)$$

$$F1\ Score = 2 \times \frac{precision \times recall}{precision + recall} \quad (13)$$

The confusion matrices in Fig. 9 to 12, and the evaluation results calculated by (11), (12), and (13) in Tables VII, VIII, IX, and X of the models with the best results from each dataset are shown below:

Fig. 9. Confusion Matrix of D1.

TABLE VII. EVALUATION RESULT OF D1 (INCEPTIONV3)

Class	Precision	Recall	F1-Score	Accuracy
Glioma	0.99	1.00	1.00	1.00
Meningioma	1.00	1.00	1.00	
Pituitary	0.99	0.99	0.99	
No Tumor	1.00	0.99	0.99	

Fig. 10. Confusion Matrix of D2.

TABLE VIII. EVALUATION RESULT OF D2 (EFFICIENTNETB0)

Class	Precision	Recall	F1-Score	Accuracy
Glioma	0.78	1.00	0.88	0.81
Meningioma	1.00	0.42	0.59	
Pituitary	1.00	0.82	0.90	
No Tumor	0.72	0.98	0.83	

Fig. 11. Confusion Matrix of D3.

TABLE IX. EVALUATION RESULT OF D3 (MOBILENETV2)

Class	Precision	Recall	F1-Score	Accuracy
Glioma	0.98	0.85	0.91	0.94
Meningioma	0.88	0.99	0.93	
Pituitary	0.94	0.98	0.96	
No Tumor	1.00	0.95	0.97	

EfficientNetB0 Confusion Matrix

Fig. 12. Confusion Matrix of D4.

TABLE X. EVALUATION RESULT OF D4 (EFFICIENTNETB0)

Class	Precision	Recall	F1-Score	Accuracy
Moderate Demented	1.00	0.42	0.59	0.78
Mild Demented	0.87	0.51	0.65	
Non Demented	0.81	0.88	0.84	
Very Mild Demented	0.72	0.77	0.74	

### B. Performance

For comparison purposes, we have mentioned different types of models and their accuracy percentages in the relevant sector.

TABLE XI. COMPARISON TABLE WITH OTHER MODELS

Serial	Model	Dataset Size	Accuracy (%)
1.	DCT-CNN-ResNet50 [18]	70,220	98.14%
2.	ELM-LRF [25]	220,875	97.18%
3.	Multiscale Convolutional Neural Network [23]	3,264	97.30%
4.	Multiclass SVM cubic classifier [21]	335	99.8%
5.	InceptionV3 [10]	411	85%
6.	ResNet152V2 [11]	7,023	98.90%
7.	MobileNetV2 [15]	2,475	94%
8.	EfficientNetB0 [19]	6,400	92.98%
9.	InceptionV3 (Our model)	7,023	99.54%
10.	EfficientNetB0 (Our model)	3,264	81.47%
11.	MobileNetV2 (Our model)	10,000	94.50%
12.	EfficientNetB0 (Our model)	6,400	78.34%

From Table XI, we can see many other studies have used CNN models as well. In [11], the author found the highest accuracy of 98.90% by the ResNet152V2 model, where we have managed to use InceptionV3 to achieve 99.54% using the same dataset. However, our EfficientNetB0 model did not outperform the model used in [23] and [19], where both datasets were identical. Although for other models all of us did not use the same dataset, we cannot compare the accuracy for every model (e.g., [26]) entirely.

### C. Challenges

The study uses deep learning models, which is a very time-consuming procedure even with the help of transfer learning. The amount of data was not enough, generating some difficulties while getting a better result. Also, the use of medical datasets introduced its own challenges, because this sector has an extreme restriction on the time limit and the results have to be monitored as accurately as possible, as the application of these models in actual medical settings is expected in the future.

### V. CONCLUSION

Our goal was to find which CNN model or models can provide the maximum result. That is why we have implemented six models in four datasets of different types. Our datasets were not large enough to study in this field and not all datasets are suitable for every algorithm, which resulted in different accuracy in different datasets with the same algorithm. As we are using medical data, it is challenging to predict exact results, yet we have secured a remarkable accuracy of 99.54 percent. In medical science, time is one of the most crucial factors for any emergency. Therefore, by implementing the most promising CNN models, we can be able to analyze brain MRI images straight away. Mostly in our

country, doctors try to identify the types of tumors manually as well as any other brain diseases, so the risk of the occurrence of human error is high. Sometimes patients would have to use high-priced diagnostic methods to find the types of the disease. Health-related issues are way too sensitive, hence any type of mistake is unacceptable. Therefore, this study could save time and cost, and most importantly could save lives.

By using the most prominent model, we can develop software that can be used to detect a tumor or any other disease in an instant. We have only worked with brain MRI images, in the future, we would like to work with different types of MRI images as well.

### ACKNOWLEDGMENT

We are grateful to Dr. Bidyut Kumar Saha, MBBS, MD (India), Post Doctoral Training in Neuro Cardio Radiology (AIIMS, Delhi), Senior Consultant & Coordinator – Diagnostic & Interventional Radiology, Asgar Ali Hospital. He guided and collaborated with us and shared his medical knowledge regarding our dataset analyzing part. Without his help, we would not be able to do our tasks flawlessly.

Department of Cybersecurity, University of Jeddah, Jeddah 23890, Saudi Arabia<sup>3</sup>

**Abstract**—Network intrusion detection is a key step in securing today's constantly developing networks. Various experiments have been put forward to propose new methods for resisting harmful cyber behaviors. Though, as cyber-attacks turn out to be more complex, the present methodologies fail to adequately solve the problem. Thus, network intrusion detection is now a significant decision-making challenge that requires an effective and intelligent approach. Various machine learning algorithms such as decision trees, neural networks, K nearest neighbor, logistic regression, support vector machine, and Naive Bayes have been utilized to detect anomalies in network traffic. However, such algorithms require adequate datasets to train and evaluate anomaly-based network intrusion detection systems. This paper presents a testbed that could be a model for building real-world datasets, as well as a newly generated dataset, derived from real network traffic, for intrusion detection. To utilize this real dataset, the paper also presents an ensemble intrusion detection model using a meta-classification approach enabled by stacked generalization to address the issue of detection accuracy and false alarm rate in intrusion detection systems.

**Keywords**—Intrusion detection system; IDS dataset; stacking ensemble ids; stacking; security; ensemble learning

## I. INTRODUCTION

With the exponential growth of network-based applications globally, there has been a transformation in the business models of organizations [1]. Cost reduction of both computational devices and the Internet have led people to become more technology dependent. As a result of the increasing use of computer networks, new risks have emerged [2]. Therefore, the process of enhancing the speed and precision of security mechanisms has become crucial. Although abundant new security tools have been developed, the rapid evolution of malicious actions continues to be a demanding matter, as their ever-evolving attacks continue to create huge threats to network security [3]. Classical security techniques—for instance, firewalls—are used as a first line of defense against security problems but remain unable to detect internal intrusions or adequately provide security countermeasures [4]. Thus, network administrators tend to rely predominantly on Intrusion Detection Systems (IDSs) to detect such network intrusive actions.

During the past decade, it has become clear that the trend of using the cloud services model in preference to the old on-premises model is increasing rapidly for many reasons [5]. For

instance, the unique utilization/charging models offered by the cloud provider that gives customers the flexibility to adjust their expenses easily, based on their needs. Scaling processes would consume much more time, effort, and expense without the cloud model. With the cloud model, the Capital Expenditure (CapEx) is reduced to the minimum or removed. These elements are taken care of by the cloud provider, which reduces the time to market (TTM) of the services and facilitates hunting market opportunities. With these merits, and many more, adopting the cloud model enables the customer to focus on service development rather than infrastructure management, which helps in achieving customer satisfaction and maximizing revenue. However, using the cloud model comes with many implications and consequences, especially on the security side of the model. One such implication is the huge increase in the number of machines exposed to the Internet since the management of those remote servers, hosted over the cloud, by legitimate users, entails enabling remote access to the servers, which increases the number and kind of vulnerabilities that can be exploited by the attackers.

With the advances in the field of machine learning, studying the malicious traffic patterns and the attacker's behavior for the purpose of developing detection and mitigation/reduction algorithms has become a hot area of research [6]. A vital building block of most of the machine learning techniques is the dataset that is used either in the training phase in case of unsupervised learning or the training and testing phases in case of supervised learning. Due to the significance of the dataset (as shown later), many studies have been devoted to generating such a dataset using different techniques and setups [7].

Most of the time, the datasets used in different studies depend on a simulated dataset due to the lack of publicly available real datasets of the network attacks [8]. This is mainly attributed to the fact that organizations are usually hesitant to publicly share technical information with others about their computing assets, such as applications, network layout, or other information that can be extracted/guessed from a dataset. Doing so risks exposing confidential and sensitive data about the organization's computing assets from security and business perspectives and costs a lot more than taking the risk of sharing. Another reason for the scarcity of real datasets is that they would reveal valuable information about the organization's Intrusion Detection System (IDS) if the machine learning algorithm is trained on the same dataset, and this could help intruders to

bypass it. Although resorting to a simulated dataset seems to be a good solution, it could result in less accurate algorithms when applied in real-world systems [9]. Aside from being simulated or real, attack datasets used for machine learning models have a conceptual problem, which is the imbalance issue since the attacker would be trying to hide his traffic in the normal user traffic. Another shortcoming in the existing datasets is that most of them are a bit outdated, and most of the efforts focus on the attacks, but not the pre- or post-attack (attacker's behavior).

This paper produces a new network intrusion dataset based on real network attacks on up-to-date cloud-based infrastructure. It also offers an adaptive ensemble classifier model, which integrates the advantages of different Machine Learning (ML) classifiers for diverse kinds of attacks and achieves best results using ensemble learning. The proposed model uses a meta-classification method based on stacked generalization for network IDS. The advantage of ensemble learning is combining the predictions of numerous base estimators to expand generalizability and strength over that of a single estimator.

## II. RELATED WORK

### A. Dataset

The effectiveness of any study, or the accuracy of any algorithm that uses a dataset, greatly depends on the dataset quality in terms of both being correctly labelled and being up to date and able to capture the latest attacks [10]. Also, the more data instances there are in the dataset, the greater the accuracy of the experiments and the generalizability of the model. Network attack datasets are constructed by system logs, network logs, network flows, and memory dumps. A novel technique called generative adversarial networks is used to train a generator to create the dataset [11]. The dataset could be built using real or simulated data. The work of one group of researchers [12] provides a comprehensive overview of the existing datasets by analyzing 715 research articles. They focus on three aspects: the origin of the dataset (e.g., real-world vs. synthetic), whether datasets were released by the researchers or not, and the types of datasets that exist. They conclude that 56.4% of the datasets are generated via experiments, while 36.7% are real data. Also, 54.4% of the studies use existing datasets, while the rest created their own, and only 3.8% of them released their datasets. In another research project [13], the authors provide a comprehensive overview of the most used available datasets. Based on their research, the main limitations of the current datasets can be summarized as follows:

- Some of the datasets are old, so they do not help with the recent types of attacks.
- The dataset is not labeled, making it useless for training supervised machine learning models, unless manually labeled, which can be cumbersome.
- The dataset is limited to specific types of attacks or targets specific applications, reducing its generality.
- The dataset is small and does not contain enough data to generalize the trained model.
- The dataset contains redundant data, which could lead to biased models.

- The dataset is completely generated in the lab, making it less representative of the real-world attacks.
- The dataset consists of an imbalanced amount of attack data and benign traffic.

To address the above limitations, one study [14] proposed a dataset approach called CIDD (Cloud Intrusion Detection Dataset) for masquerade attacks. They developed a log analyzer and correlator system to parse and analyze the data from the network. These parsed data are fed to the log analyzer and correlator for processing and marking. The analyzer correlates the user audits in network and host environments using user IP and audit time. Then it assigns user audits to a set of VMs (Virtual Machines) according to their login sessions time and the characteristic of the user task. Finally, it uses the attack and masquerade tables provided by the MIT group to mark the malicious records. The drawback of this dataset is that it lacks the representation of real network traffic as well as actual attack simulations. Moreover, it is outdated for the adequate evaluation of modern IDSs on current networks, regarding types of attacks and the network infrastructure.

In other research [15], the researchers developed a testbed to generate their dataset. The testbed is composed of different machines in a Windows domain and each machine has different types of agents to collect logs and send them to the logger. These machines also have scripts to enable the simulation of some types of attacks, pushed by the logger server, as well as the generation of the normal traffic. The logger server is equipped with the necessary applications to play different roles. Examples of these are an elastic search to collect logs from the whole system, a Mitre Caldera Server to simulate various types of attacks using the installed agents on the hosts, an IDS Suricata for identifying network attack signatures in traffic that is used for labeling the dataset, and others. Unfortunately, the proposed testbed also does not represent real-world network traffic and lacks the actual attacks representation.

### B. Stacking Ensemble IDS

Ensemble learning based methods apply collections of ML procedures to obtain higher predictive performance than could be obtained from one classifier [16]. The core idea of ensemble methods is to combine several classifiers to exploit the power of each single algorithm used to obtain a more powerful classifier. Ensemble learning methods are mainly helpful if a problem can be split into subproblems so that each subproblem can be assigned to one module of the ensemble. Depending on the structure of the ensemble approach, each module can include one or more of the ML algorithms. During network attacks, because the signatures of different attacks are distinct from each other, having different sets of features as well as different ML algorithms to detect different types of attacks is preferable. A single IDS cannot address all types of input data or identify different types of attacks [17, 18]. Many researchers have shown that a classification problem can be solved with high accuracy when using ensemble models instead of single classifiers [19, 20, 21, 22].

### III. REAL CLOUD-BASED DATASET

#### A. Dataset Collection Setup

To collect real attack traffic, a testbed was built on AWS (Amazon Web Services) and was run for 10 days between the 8th and the 18th of March 2021. The system consists of three main subsystems: the Sensors, which is used as a decoy to lure the adversaries to try the system, The Collector, which gathers the data from different sensors, and the Visualizer, which parses, analyzes, searches, and extracts the collected data.

1) *The sensors subsystem*: Sensors are servers that are intentionally exposed to the public network, pretending to offer something interesting for the attacker. A lot of effort has been made to create such technology leading to what is known as a honeypot [23]. Which is a data framework asset whose esteem lies in unauthorized or unlawful utilization of that asset, which means that honeypots derive their values from the threats using them [24]. Honeypots, as a security approach, differ from firewalls and intrusion detection systems in the sense that they are implemented somewhere in the network intentionally with the hope of attracting hackers. If they are built the right way, with the right precautions, then the more they are attacked and the smarter those attacks are, the more valuable the honeypots are. A honeynet is a collection of high interaction honeypots on a tightly controlled and highly monitored network. A honeypot can be one of the three types:

- Low-interaction honeypot - This kind of honeypot gives the intruders the illusion that the system is running some services so that it has no risks and requires fewer resources, but it is easily discovered by the attacker [25].
- Medium interaction honeypot - This kind is a little more interactive as it simulates some services and enables the attacker to run commands on the system [25].
- High interaction honeypot - This kind can be a separate network of real running services for the sole purpose of deflecting the attacker from the actual services, collecting his data, and studying his behavior. It requires more resources and can be risky, but the collected data can be more valuable [26].

Besides using the honeypots as decoys to capture the attacker's data, they can also be of great value to trick and deflect the adversaries from the actual system, giving the administrators of the attacked system more time to harden the system and apply the necessary patches. In real enterprise systems, honeynets can be deployed either before or after the organization's firewall. When deployed before the firewall, they allow the most exposure to as many attacks as possible. On the other hand, they can be deployed behind the firewall for two reasons: first, to capture internal attacks originating from inside the organization by those who are trying to do things they should not be doing. This is important since internal traffic usually does not go through the firewall. Second, to give an early alert that the organization's firewall or IDS might need to be tuned after it was

successfully evaded by some non-legitimate attacker. In this experiment, the sensors subsystem is built as a honeynet of six honeypots to collect data from the attackers. Different honeypots have different purposes and run/simulate different services. In this section, a brief description of each honeypot is given.

- Dionaea: a low-interaction honeypot that captures attack payloads and malware. Dionaea listens on many different protocols, e.g., blackhole, epmap, ftp, http, memcache, mirror, mqtt, mssql, mysql, pptp, sip, smb, tftp, upnp.
- Cowrie: a medium/high-interaction honeypot that emulates SSH and Telnet services and gives the intruder the illusion of interacting with a real system and hence captures his actions against the system, e.g., commands and downloaded files. It works by running a fake filesystem with the ability to add/remove files where a full fake filesystem resembling a Debian 5.0 installation is included. It allows the addition of fake file contents so the attacker can "cat" files, such as /etc/passwd. Cowrie also gives the attacker the ability to download and upload files using wget/curl or sftp/scp and saves files downloaded for later inspection.
- Conpot: a low-interaction honeypot that is designed to work as a server-side industrial control system (ICS).
- AMUN: another low-interaction honeypot designed to capture malware that exploits server-based vulnerabilities. AMUN simulates a lot of protocols like RDP, SMP, telnet, FTP, and more to emulate many vulnerabilities e.g., Buffer Overflow, Buffer Overrun, and Stack Overflow.
- Snort: a honeypot, but it is used in this project as a sensor for the traffic. Snort is an intrusion prevention system that was developed by Cisco, who opened its source and made it available to the community.
- P0f: a tool that utilizes an array of sophisticated, purely passive traffic fingerprinting mechanisms to identify the players behind any incidental TCP/IP communications (often as little as a single normal SYN) without interfering in any way. P0f can recognize the operating system, measurement of system uptime, distance, and link type.

2) *The collector subsystem*: We used Modern Honey Network (MHN), a central server for the management and data gathering of honeypots [27]. MHN is the brain of the testbed as it facilitates the deployment of honeypots by wrapping all the necessary software for each honeypot in a script, collects data from sensors, and enables integration with the visualizer, as well as providing a RESTful API for integration with 3rd parties.

As shown in Fig. 1, MHN composed of two main components:

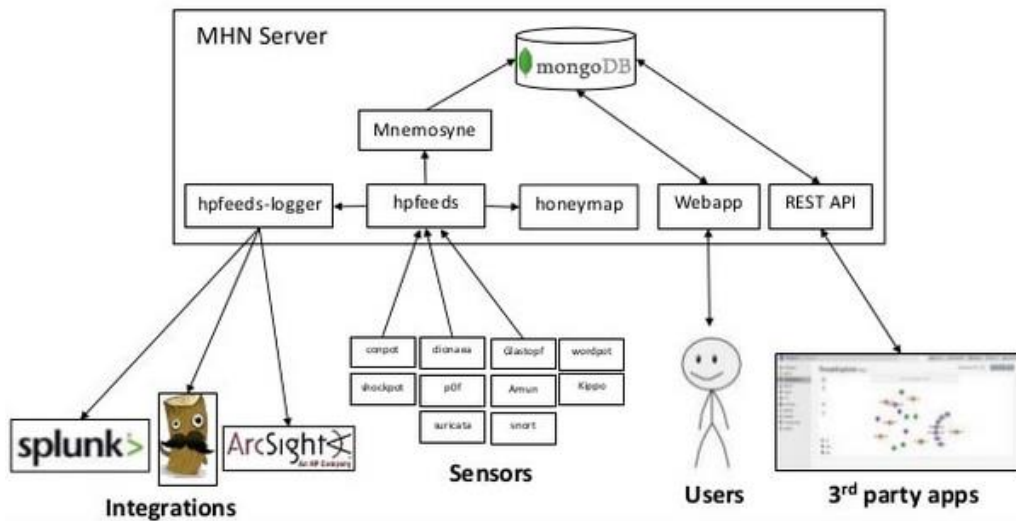

Fig. 1. MHN Server Architecture.

3) *Lightweight authenticated publish-subscribe protocol (hpfeeds)*. It has a simple wire-format so that everyone is able to subscribe to the feeds with their favorite language in very little time, so it is used as the landing point from all the honeypots, and as a data source for three other system components:

a) *Honey map*, which is a fancy map to show the geographical location of live attacks from some types of honeypots like Dionaea.

b) *Hpfeeds-logger* is a simple utility for logging hpfeeds events to files compatible with Splunk and ArcSight.

c) *Mnemosyne* provides immutable persistence for hpfeeds. It also provides normalization of data to enable sensor agnostic analysis and exposes this normalized data through a RESTful API.

4) *MongoDB is a general-purpose*, document-based, distributed database used to store all the indexed data feed from Mnemosyne. The Mongo database is used as the data source for two other system components:

a) *Web app*, which is the basic built-in visualization component of MHN unless a more complex analysis is needed by a 3rd party like Splunk.

b) *3rd party API*, which provides an API interface for 3rd party integration.

We built a testbed that consists of six sensors running different honeypots and one server running MHN and Splunk services. The honeypot servers were running on an AWS free tier t2-micro instance type, while the MHN & Splunk servers were running on a t2-medium instance during data collection, upgraded to t2-large instance type during data analysis and extraction.

5) *The Visualizer*: With the large amount of data collected by the sensors, it was better to use a third-party application to handle the data instead of the MHN built-in web app. Splunk is

used in this project, but MHN also supports integration with ArcSight software.

Splunk is a software platform to search, analyze, and visualize the machine-generated data gathered from the websites, applications, sensors, and devices that make up the IT infrastructure and business. Splunk is a great tool when it comes to the processing of a huge amount of data, as it can provide real-time processing and accept any data input format, e.g., csv, and JSON. It can also be configured to give alerts about the machine's states and predict if resource scaling is needed. To make integration with other systems easy, Splunk has the concept of apps that are an extension/addon of Splunk functionality. This gives the developers of any applications, e.g., MHN, who want to use Splunk the ability to develop their own application with a customized user interface and visualization dashboards to serve a specific need. They may then upload it to the Splunk marketplace (splunkbase) to make it available for the Splunk community. This makes it easy for the users to integrate those applications with Splunk by just importing the application extension into Splunk, and occasionally doing a few setup steps like licensing and data source configuration. For MHN, there is an app with the same name that can be downloaded from the splunkbase.

### B. The Dataset Collection Results

After the data was collected from the sensors by the MHN server and sent to Splunk for analysis and visualization, we used the Splunk query language, Splunk processing language (SPL), to extract the datasets. Table I summarizes the total amount of the collected data using the sensors subsystem, as well as the data collected per each sensor. In the section below, we present a sample of the dataset, a distribution of the data across the collection period, and a summary of the collected data per sensor.

By implementing a testbed hosted on Amazon's AWS cloud, we ran an experiment for 10 days and collected different attacks on different services. Using the data collected by different sensors, we created a real network attack dataset comprising

many interesting features that can be used to profile the attacker, e.g., source/destination IPs, source/destination port numbers (attacked service), ssh version, operating system name and version, link type, usernames and password tried by the attacker, tcp flags, ip ttl, and many more. A full list of the extracted features is shown in Table II. The dataset obtained can be used, or can be a seed, for a dataset that solves most of the common issues in the currently available datasets. It is real-world data by design, up-to-date, and can be kept up to date easily by running the testbed during specific periods. It can automate all the post-processing operations needed to get a ready dataset, thanks to the use of visualizers and query languages. The dataset represents different types of attacks and can easily represent more by deploying more honeypots.

Based on a 10-day experiment, the most attacked service was server message block (SBM), which might make sense as this service is used by the WannaCry attacks that have been spreading and active since 2017. SSH service comes second in the most attacked services as the attacker tries to exploit the lack of awareness of some users that use the default or weak credentials. The common username, “admin,” was the most tried username and “password” came second as the most tried passwords, while the less expected, “nproc” (a bash command to get the total number of cores/threads on the machine) was the most tried password. The most used operating system by the attacker was Linux version 3 or later, while Windows came next, which makes sense as a lot of the hacking tools used are Linux-based, e.g., Kali. Although most of the attacks originated from the United States, it might or might not accurately reflect the actual attacker’s location since a serious attacker might be using compromised machines to mount his attacks. These could be located anywhere, or be using any cloud-hosted machines, which the US has most. The data showed that the top attacking single IP was in Panama and generated around 34,000 attacks during the 10 days. The most used command is “uname,” which is used to get the operating system type, kernel version, and other information that is necessary to determine the suitable attacking scripts and tools. The second and the third most used commands are “echo” which is used to show whatever argument is used after it and “which ls” to get the full path of the “ls” command. The two commands might not be meant for actual use but just to check if this is a real system or a trap. This is good to know as it can guide the honeypot developers toward which commands, they need to simulate for a more deceptive honeypot.

TABLE I. TOTAL COLLECTED DATA

Sensor	Total Collected	Distinct SRC	Distinct SRC DEST_Port	Distinct SRC DEST_Port SRC_Port
Dionaea	177,000	10,000	72,000	158,000
Pof	369,000	24,000	108,000	212,000
AMUN	245,000	9,000	10,000	228,000
Cowrie	58,000	1,243	1,243	45,000
Snort	108,000	6,200	53,000	67,000
Conpot	3,780	444	444	544
Total	960,780	50,887	244,687	755,544

TABLE II. THE FULL LIST OF EXTRACTED FEATURES

#	Feature Name	Description
1	_time	time of traffic capturing
2	app	honeypot captured the traffic
3	dest	dest ip
4	dest_port	dest port
5	dionaea_action	either Dionaea honeypot accept or reject the connection
6	direction	the direction of the captured traffic either in or out
7	eth_dst	the dest mac address
8	eth_src	the source mac address
9	host	Splunk server ip or hostname
10	ids_type	the type of the used ids
11	ip_id	the packet id
12	ip_len	packet length
13	ip_tos	packet type of service
14	ip_ttl	packet time to live
15	linecount	the number of lines of the captured traffic
16	p0f_app	protocol used by P0f for fingerprinting
17	p0f_link	the connection type at the attacker side like modem or dsl
18	p0f_os	the operating system of the machine generating the attack
19	p0f_uptime	how long since the attacking machine is up
20	protocol	tcp or udp
21	sensor	id assigned by MHN per honeypot
22	severity	severity rank of the attack
23	signature	the signature of the attack as matched by snort
24	snort_classification	a number given by snort to classify the traffic
25	snort_header	the rule header
26	snort_priority	assigns a severity level to rules
27	source	input data source (needed by Splunk)
28	sourcetype	input data type (needed by Splunk)
29	splunk_server	Splunk ip or hostname
30	src	attack src ip
31	src_port	attack source port
32	ssh_password	password used by the attacker trying to get ssh access
33	ssh_username	username used by the attacker trying to get ssh access
34	ssh_version	attacker ssh client version
35	tcp_flags	indicate a particular connection state or provide additional information
36	tcp_len	packet length
37	timeendpos	at which byte into the event the timestamp ends
38	timestartpos	at which byte the timestamp starts
39	transport	transport protocol type tcp or udp
40	type	honeypot event type
41	udp_len	packet length
42	vendor_product	name of the honeypot that captures the traffic
43	_raw	raw (not parsed) event

Analysis of the collected data showed some interesting findings for each sensor. Dionaea not only listens on the opened ports but also allows the attacker to download and upload files. Fig. 2 shows a list of the top downloaded binaries expressed as their MD5. It is worth noticing that the same files came from different sources. Splunk's MHN application also adds a fast method to scan those files against different antiviruses via Total Hash and Virus Total websites. By clicking on the link, a web page will open automatically, search for the file, and show the scanning results, as shown below in Fig. 3. Fig. 4 to 8 show the most often attacked ports in different sensors. Fig. 9 shows the top link types, and Fig. 10 shows the operating systems. Fig. 11 shows the top URLs that were used by the attackers to download scripts, and binaries used to mount their attacks. Fig. 12 shows the top SSH versions, Fig. 13 shows the most used user/password pairs, and Fig. 14 shows the most often used attack commands. Fig. 15 shows the top attack types captured by Conpot.

#### IV. STACKING ENSEMBLE IDS

This section presents an ensemble learning model using a meta-classification method enabled by stacked generalization. A newly generated dataset that was captured from real network traffic was used for experimentation. Observed results indicate that the proposed stacking ensemble can generate superior predictions having 95% accuracy.

##### A. Methodology

As illustrated in Fig. 16, the stacking model comprises base and meta-classifiers—namely, Neural Networks (NN), k nearest neighbor (KNN), Decision Tree (DT), and Support Vector Machine (SVM), respectively.

Authors in [28] illustrated that the integration of a set of single algorithms leads to optimum predictions. Stacking or stacked generalization is a concept proposed by Wolpert [29]. Several ML algorithms define their subjective biases on a learning set, ultimately filtering out biases. The implementation of a stacked model involves two kinds of sub-models, base (level 0 classifiers) and metamodels (level 1 or meta). The main logic of a stacking model lies in using the meta-classifier to predict the samples by studying the level 0 classifiers. Yan and Han [30] illustrated the great advantage of using the stacking models. They have stated that stacking can enhance prediction accuracy while working with unbalanced datasets. A study [31] was conducted to emphasize the application of AI-based classifiers. The researchers in that study explained that ensembles were able to adapt to the robust behaviors of malicious and normal traffic effectively. Algorithm 1 shows the entire classification process implemented in the classification framework involving multiple classifiers.

##### B. Data Pre-processing and Feature Selection

Pre-processing was utilized to handle different data found in the dataset. To eliminate noise, and fix inconsistencies found in the data, a statistical transformation tool is needed. In our proposed work, missing data and outliers were compensated for by making the distribution normal. However, lost values rely on singular features. While some features can be assigned zero as a missing value, others are assigned zero as an actual value where binary data are considered. To maintain such predicaments, consideration of relevant features that guarantee ideal expectations is essential. Thus, an integration of hashing and information gain (IG) was applied to extract the maximum desirable features. Feature scaling was also utilized to assure that those features possessing a greater numeric range did not dominate the ones in smaller numeric ranges. The dataset has many features but not all appear to be important. Consequently, only 11 features were chosen from the dataset. The fundamental features were assigned weights to prioritize them, and only the best features were extracted. The dimensionality of the features was reduced using a hashing approach. The chosen features are direction, eth\_src, host, protocol, src, src\_port, ssh\_version, tcp\_flags, tcp\_len, type, and udp\_len.

##### C. Classification

The methodology to actualize the classification system included the application of different classifiers to resolve the basic complexities of information found in both packet-based and flow-based datasets.

Fundamentally, KNN count on a distance function that calculates the similarity or variance between two network occurrences found in the datasets under consideration.

The Euclidean distance  $d(x, y)$  can be calculated by via the following equation:

$$d(x, y) = \sqrt{\sum_{i=1}^n (x_i - y_i)^2} \quad (1)$$

where  $x_i$  is the  $i$ th feature of the instance  $x$ , while  $y_i$  is the  $i$ th feature of the instance  $y$ , and “ $n$ ” is the whole number of features found in the dataset. Let  $C = C_1, C_2, C_3, \dots, C_p$ . There are “ $p$ ” labels in the dataset. Let “ $x$ ” be the new sample to be predicted. The objective of KNN classifier is to determine “ $k$ ” vectors that are close to  $x$ . If most of the vectors belong to class  $C_m$ , then  $x$  will be assigned the class label  $C_m$ .

The radial basis function (RBF) is a preferred kernel function for many classification problems in ML. The following equation defines the RBF:

$$k(x, y) = \exp \left( -\frac{\|x - y\|^2}{2\sigma^2} \right), \quad (2)$$

Algorithm 1: Stacking Ensemble Strategy.

**Input:** Train data  $T = \{X_i, Y_i\}_{i=1}^m$  ( $X_i \in R^n, Y_i \in Y$ )  
**Output:** Predictions from the ensemble E  
*Step 1.* Impose cross validation in order to prepare a training set for meta-classifier  
*Step 2.* Randomly split  $T$  into “ $m$ ” equal size subsets, i.e.,  $T = \{T_1, T_2, T_3 \dots T_m\}$   
*Step 3.* for  $m \leftarrow 1$  to  $M$   
    Learn base classifiers namely NN, KNN, and DT  
    for  $n \leftarrow 1$  to  $N$   
        Learn a classifier  $P_{mn}$  from  $T$  or  $T_m$   
    End for  
*Step 4.* Formulate a training set for metaclassifier (SVM)  
    for each  $X_i \in T_m$   
        Extract a new instance  $(x'_i, y_i)$ , where  $x'_i = \{P_{m1}(X_i), P_{m2}(X_i), P_{m3}(X_i), \dots, P_{mN}(X_i)\}$   
    End for  
End for  
*Step 5.* Return  $y_{\bar{1}} = \{y_1, y_2, y_3, \dots, y_n\}$  from ensemble

Algorithm 1 shows the whole classification process implemented in the classification framework involving multiple classifiers.

D. Results and Discussion

The quality of any IDS can be measured by four performance metrics: true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN).

To accurately value the performance of the proposed approach and assure the results acquired from the stacked ensemble model, both binary and multiclass classification results are given in this section. Table III depicts the results acquired upon classifying the network instances of the dataset into either attack or normal. Moreover, to test the predictions and to assure that the models do not overfit, mean training accuracy (MTA), mean training precision (MTP), and mean training recall (MTR) values are also mentioned in Table IV.

The NetFlow traces found in the dataset contain genuine background network traffic for a substantial duration of ten days. As per the confusion matrix presented in Table V, all seven attack types found in the dataset were distinguished perfectly aptly by the stacking classifier.

The proposed ensemble model could identify the occurrence of SSH scan attack in the foremost effective way. In order to show reliable results, performance metrics like precision and recall were also considered in addition to accuracy. Recall is the ability of the intrusion detection model to correctly locate the positive instances, where precision is the model's capability to locate the percentage of positive instances that were identified correctly.

Table VI shows that the false alarm rate is extremely least regarding all attack classes, which is a signal that the general effectiveness of the proposed ensemble model is very good. The ROC curve also is shown in Fig. 17.

TABLE III. BINARY CLASSIFICATION RESULTS

Accuracy	Precision	Recall	F1 score	AUC	FAR (%)

## V. CONCLUSION AND FUTURE WORK

This paper has presented an ensemble methodology based on a newly generated dataset that was extracted from real network traffic. The extensive dataset that has been created provides valuable benefits for training ML models to detect current attack types efficiently and accurately. This is because it overcomes most deficiencies of the present available datasets and covers most of the essential standards with common updated attacks. Moreover, the produced dataset is fully labeled and includes different network traffic features that are extracted and calculated for all normal and intrusion flows.

To utilize the created dataset, we presented an adaptive stacking ensemble learning model that integrates the advantages of different ML algorithms for diverse kinds of attacks and achieves optimal results through ensemble learning. This combines the predictions of several base estimators (i.e., NN, KNN, DT, and SVM) to accelerate the processing speed and improve scalability with a larger amount of network traffic data. The experimental results have shown that the ensemble model was able to enhance the classification accuracy, increase the true positive rate, and decrease the false positive rate. The real dataset provided can help cybersecurity researchers and firms to better understand the recent networking environment traffic, and traits of recent attacks, in order to better detect and prevent them. It can also help law enforcement and digital forensics teams in investigating cyberattacks. The proposed ensemble model can also be utilized with the provided dataset as a training dataset to detect and classify potential network attacks. This can help service providers, like cloud service providers, to monitor and improve their infrastructure.

This work can be expanded in the future to cover more and/or new attacks by collecting more networking traffic in different environments such as the Internet of Things networks, fog, etc. In addition, we can investigate the effectiveness of the ensemble model against such new networking traffic and suggest different features and tuning for every type of environment. More experimental analysis and a complete comparison with literature would be considered as well.

## VI. DATA AVAILABILITY

The dataset generated in this work is publicly available and can be accessed from this link. Affiliated to Visvesvaraya Technological University  
Belagavi, Karnataka, India

**Abstract**—Author attribution is the field of deducing the author of an unknown textual source based on certain characteristics inherently present in the author's style of writing. Author attribution has a ton of useful applications which help automate manual tasks. The proposed model is designed to predict the authorship of the Kannada text using a sequential neural network with Bi-Directional Long Short Term Memory layers, Dense layers, Activation function and Dropout layers. Based on the nature of the data, we have used stochastic gradient descent as an optimizer that improves the learning of the proposed model. The model extracts Part of the speech tags as one of the semantic features using the N-gram technique. A Conditional random fields model is developed to assign Part of the speech tags for the Kannada text tokens, which is the base for the proposed model. The parts of the speech model achieve an overall 90% and 91% F1 score and accuracy respectively. There is no state-of-art model to compare the performance of our model with other models developed for the Kannada language. The proposed model is evaluated using the One Versus Five (1 vs 5) method and overall accuracy of 77.8% is achieved.

**Keywords**—Authorship attribution; Bi-Directional Long Short Term Memory; machine learning algorithms; parts of speech; stylometry features

## I. INTRODUCTION

Authorship Attribution (AA) finds the hidden patterns in an author's writing to identify the author of an unknown text. Not much work has been done for the same, especially for the texts in the Kannada language, which is a popular Indian regional language. The authorship attribution system works primarily to predict the probability of mapping the article to its author. Authorship attribution is a field with significant applications and a long history to present a solution to the same. Recent works in this domain for foreign languages have proven to be a powerful automated tool but in Indian regional languages, the absence of a state-of-the-art method leaves scope for improvement and research. Advancements in Machine learning techniques, Natural Language Processing (NLP) and Artificial Intelligence (AI) have helped in developing a model for author attribution by learning the distinct features in the author's writing style.

Kannada, the state language of Karnataka, belongs to India, is rich in literature and culture and the Kannada-speaking people are spread around the globe. Text processing is a challenging one. Deep learning algorithms [1] like Bidirectional Encoder Representations from Transformers, a transformer based model and a hybrid model [2] composed of

Recurrent Neural Network (RNN), Long Short Term Memory (LSTM), and Gated Recurrent Unit (GRU) proved effective in text classification.

Text Classification necessitates a significant amount of time spent analyzing the contents [3]. Several parameters like large vocabulary, semantic ambiguity, and words having meaningful relationships are used to classify the text.

Now-a-days text processing in Kannada is rapidly growing, AA can be found useful in predicting the ownership of a Kannada disputed text like threat letters, suicidal notes, literature work and so on. As per our knowledge, the proposed work is a novel approach. Till now no significant work has been carried out in the Kannada language on the authorship attribution of digital text. One can find a few works which emphasize handwriting analysis [4] so there is a lot of scope in this field, especially in the local languages. There are two main approaches to authorship attribution: Profile and Instance based approaches. The former is mainly suitable for short article samples and the latter is employed for lengthy articles. The proposed model uses a profile-based approach, in which the features are extracted from short samples to create an author's profile and then trained and tested with deep learning networks. To test the owner of a Kannada handwritten document, the handwriting styles [5-6] like cursive line, font size, the thickness of line, formation of characters, spaces between characters and words, and so on are considered but when the text is digital, then different parameters have to be used for the comparisons, these parameters are referred as Stylometric features. Stylometry features are those special features used to extract a person's writing style like lexical features, which include a total number of words/sentences/ special symbols/ usage of nouns and vocabulary richness, etc. Semantic features like POS tags and content-based features etc.

In our previous works [7-8], two AA models were developed based on lexical and syntactic features using classification algorithms and the N-grams technique respectively and observed that these models predict the probability of authorship pretty well. In the proposed work, semantic features are extracted using POS tags. Deep learning techniques are popular for many NLP applications. From the survey, it is found that Deep learning networks combined with N-gram is an efficient technique for many text processing applications and it improves the performance of a model to a great extent. Bidirectional Long Short Term Memory (Bi-LSTM) is the process of constructing a neural network that can

store a sequence of information in both directions forward (future to past) and backward (past to future). Inputs run in two directions in a bidirectional LSTM, which distinguishes it from a conventional LSTM.

The process for training and testing the proposed model using BI-LSTM is shown in the diagram below. The primary objectives for developing this model are:

- To extract semantic features of an author.
- To develop a Kannada POS tagger.
- To develop the Kannada AA model using deep learning techniques.
- Performance comparison of the proposed model with other languages models.

Fig. 1 shows the process of AA, the input to this model is the cleaned labeled Kannada dataset, quality features like POS and N-grams are extracted from this, which are later trained with machine learning models like Bidirectional LSTM and during the testing phase the anonymous text is questioned and the model predicts the most suitable author for the text.

Fig. 1. Authorship Attribution Process.

### Contributions

- The proposed work focuses on predicting the authorship of an anonymous Kannada text.
- The AA model accuracy mainly depends on the quality features, apart from extracting lexical features, semantic features are also extracted using the POS model, for this a POS tagger for Kannada tokens using the CRF model is developed.
- The work demonstrates the implementation of deep learning techniques like Bidirectional LSTM and using POS and grams approaches to perform AA task.
- The proposed work considers 50 authors of 500 documents and the overall accuracy of 77.8% is achieved.

## II. LITERATURE SURVEY

A survey will help us to analyze different techniques and methodologies explored by different researchers for Authorship attribution. This section will describe the same. A detailed survey on AA is done in [9], the authors described different dimensions of Authorship analysis including authorship prediction, verification, the importance of Stylometry features, ML algorithms and Deep learning techniques on AA. This work serves as a prerequisite for a researcher to start his work in the AA domain. Authors in [10] have explored an Instance based AA using deep learning based Artificial Neural Network on the Arabic Language. ANN (the proposed solution) produced an accuracy of 75.46% compared to 68.85%, 69.78%, 69.64%, and 69.78% attained by SVM, RF, DT and BNB respectively. Authors in [11] have explored a Cross-domain AA using Character sequences, Word uni-grams, and POS-tags features. Both the first and the second model extracts char 6-gram and 3-8-grams respectively. The third model was composed of content-based features based on POS tags. The results on the evaluation corpus are significantly lower and the three models seem to be overfitting. A different technique called Life-Like Network Automata for AA tasks is explored in [12]. This research represents network modeling texts as network automata (LLNA) with dynamics based on Life-Like rules. The LLNA method searches the whole rule space for an optimal solution to one problem. The best results were obtained with a partial lemmatization process, suggesting that this procedure is more adequate than just lemmatizing all words when text networks are used as the underlying model for this task.

Instance based and Profile-based approaches based on ensemble strategy to maximize the outcome by combining the probabilities of different feature sets by using SVM are discussed in [13]. AA task experiments on four different languages, researchers have also employed SVM with linear kernel and RBF kernel, K-nearest neighbors with K=3, and Random Forest and obtained an F1 score of 68%. Deep learning techniques proved to be very effective for AA tasks. Extracting the lexical features of an author and calculating projection for each file to predict the authorship [14] was found to be interesting. The result of the average projection shows similarities between the main author file and the summary file of each author. To recognize the true author of anonymous text written in the Russian language using deep learning networks is discussed in [15]. Authors have Extracted 33 to 5000 features and then trained and tested them using SVM and other NN features like optimizing algorithms, dropouts, loss function and various activation functions. SVM performed well with 96% average accuracy compared to a Deep neural network with 93% accuracy.

A convolution neural network based authorship model for the Bengali language is demonstrated in [16], authors have considered 6 author's 350 samples, and character level pre-trained embedding called fastText gives maximum accuracy of 98%, this work proves that pre-trained embedding outperforms compared to the non-pre-trained embedding of the text. The pre-trained models like BERT, Embeddings from Language Models(ELMo), Universal Language Model Fine-tuning and generation Generative Pre-trained Transformer -2

based authorship prediction on cross domain has been demonstrated in [17], a multi-headed classifier and DEMUX layer is created to handle different classifiers, BERT and ELMo outperform with more than 90% accuracy compared to other language models. Stylometry features play a vital role in the AA task, authors in [18] have explored a new technique of generating human-like sentences using a neural network and then various linguistic features are extracted to predict the authorship. the proposed model with an accuracy of 97.2% can predict the true author successfully.

AA for a very lengthy corpus is a tedious job, using a reduction model [19], the size of the candidate authors can be reduced. Doc2Vec reduction was found to be efficient compared to other models used for reduction. It is observed that Reduction in the candidate authors set and the corpus didn't significantly affect the performance of the AA model. Reduction of authors set with a minimum of 10% and a maximum of 90%, the model achieved 99% and 50% accuracy respectively. Lexical feature extraction is easy compared to semantic or content based features, but semantic features are more realistic. Researchers in [20] developed a content based model for AA by considering authors from different domains and also datasets with different genres. The proposed model learns the sentences from POS tags and the system is trained and tested with RNN, the model was able to achieve maximum accuracy of 78% accuracy on the PAN dataset. AA on Persian historical and literary works is explored in [21]. The authors have used a modified four parts of deep convolutional neural networks architecture and attention mechanism. The model outperforms other approaches with 72.59% accuracy.

Authors [22] have tried to predict the owner of the e-mail which has some dispute contents, a user with fake mail ids can write unacceptable contents that may damage the reputation of a person/ company. Prediction is mainly based on reasonable hypotheses; authors have strived to develop a mathematical model to successfully address this problem by combining the Analytic Hierarchy Process with SVM. Experimental findings demonstrate that the accuracy is greater than 95%.

In the proposed work Syntactic features are extracted from Kannada articles to understand the author's writing style. The basic concepts of POS tagging and the different methodology to implement it is discussed in [23]. Authors have served the complete POS tagging information for beginners to carry out research in this domain. They concluded that deep learning algorithms are more powerful compared to traditional methods for the English language.

The authors used deep learning methodologies [24] like RNN and LSTM to assign POS tags to the annotated Kannada words and achieved 81% accuracy. The limitation of this work is in getting the clear dataset in the required format since the same words are spoken and written in different ways due to this one word can have different inflections. This leads to ambiguity in assigning the POS tags.

The authors have explored both the Hidden Markov chain method and conditional random fields algorithms [25] to assign POS tags to the Kannada words. They achieved 79% and 84% for both methods respectively. The model suffers due

to cross domain dataset that is a dataset with different categories.

POS tags are assigned after analyzing each word in the text, authors have demonstrated POS tagging [26] using machine learning algorithms and deep learning algorithms. One of the machine learning algorithms SVM outperforms deep learning techniques with 85% accuracy. The lack of a clean dataset is the only demerit in this work.

Markov chain algorithm again proved to be efficient for a small Kannada dataset [27] of 18,000 words. researchers achieved 95% accuracy but their performance declines as the dataset increased.

Sindhi is one of the oldest languages and not much work have been done in the field of text processing [28], authors have designed rule based approach to assigning POS tags and they were able to assign POS tags successfully on 624 words. Performance comparison has not been focused on since there is no state of art models available for this language.

A large volume of data is flowing over the twitter media, and analyzing the data based on their POS tags are experimented with by the researchers [29]. They have used various classification algorithms to efficiently assign the POS tags to the Malay corpus. SVM yields a maximum accuracy of 95% compared to other algorithms. This approach can be implemented for various categories of Malay words.

Authorship attribution becomes a very important issue in today's time due to the increase in identity theft crimes. The text domain is in ranges from science, art, to philosophy-related texts. It is observed from the survey that, feature extraction plays a huge role in finding the source of a text (Lexical, Semantic and Syntactic features). Language Models (word/ character) and vocabulary of an author also are important parameters in performing the AA task. Few researchers have experimented on both Instance and Profile-based approaches for both global languages and a few Indian local Languages which include short and long texts. For the majority of the AA tasks, the deep learning technique [23] proved to be efficient but can't be claimed as a standardized technique since ML algorithms also outperformed well for other data samples.

There is a research gap in this domain for the Kannada language and this can be used as an opportunity by the interested researchers.

### III. METHODOLOGY

The overall description of the proposed work is given below:

- 1) Let A be the author set  $\{a_i, a_{i+1}, \dots, a_n\}$ .
- 2) Let D be the document set  $\{d_i, d_{i+1}, \dots, d_n\}$  written by the author  $a_i$ , such that  $d_i \in a_i$ .
- 3) Let S be the sentences in a document  $d_i$   $S = \{s_i, s_{i+1}, \dots, s_n\}$  such that  $s_i \in d_i$ .
- 4) Let T be the set of POS tags  $T = \{t_i, t_{i+1}, \dots, t_n\}$  for a sentence created using the CRF algorithm such that  $T \in s_i$ .
- 5) The model extracts semantic features using N-gram technique as  $\{t_1, t_2, t_3\} \dots \{t_i, t_{i-1}, t_n\}$  where it is a POS tag  $\in T$ .

6) Let  $A_t$  be the anonymous text during the testing phase, the authorship model extracts the POS features of the  $A_t$  and compares them with the extracted features and predicts the probability of a true author.

#### A. Dataset Source and Collection

The primary source of the dataset is the internet, from that we selected articles from the Kannada blogs/ websites, e-articles, e-books from Kannada Sahitya Paritshath which is a government-based website and also from other popular Kannada websites. Few authors have contributed their articles based on the request. Totally 500 documents from 50 authors have been considered. It is a cross-domain dataset that each author has written articles on various categories which include: Life skills, philosophy, folk, children's stories, politics and sports. The proposed work is implemented based on the POS and sequence model. The AA is based on the POS tagging to extract the hidden semantic meaning of the text, since there is no open access POS tagging application available on the internet, we created a POS model [24], and the summary of the overall implementation is briefed below:

- Preprocess the dataset by tokenizing the documents (articles/stories/poems) of each author and creating an array of sentences.
- Pass the tokens to a POS tagger developed using the CRF model [25,26]. For the sake of better results, the number of parts of speech is reduced and more generalized, then run the bag of words code into the POS tagger and assign a tag to each word.
- Created embedding vectors, since the model understands only the numbers, not the text.
- Designed a sequential neural network with two LSTM layers, dense layers, activation and dropout layers.
- Train and test the model by running each document sentence-wise.

POS tags are assigned to all the tokens of the author's samples, this gives information about the semantic structure of the language that is the author's usual way of using words to form a sentence. This knowledge helps the model to understand the context of the Kannada words used in a sentence. A word can have different meanings so different POS tags [27,28], the tagger in this case will help a reader to understand the correct meaning of the words based on the tags. The proposed work uses a CRF classifier for assigning the POS tags to the Kannada tokens. The overall implementation of POS tagging in the proposed work is given in Fig. 2.

Fig. 2. Working Flow of POS Authorship Model.

#### B. Document Parsing

Document parsing, the first stage consists of three distinct steps.

- Parsing the text document: To build a POS tagging, a separate dataset prepared by the International Institute of Information Technology (IIIT), Hyderabad (IIIT Hyderabad LTRCMT-NLP Lab) is used for training and testing the POS model and Kannada scripts are encoded in the UTF-8 format. Each document will have to be read in the same format to preserve the text. PDF files were not used because no existing tool parsed PDF files with Kannada text in them. The text documents parsed act as the raw source on which various pre-processing steps are carried out:
- Data cleaning: The raw text extracted from the parsing stage is analyzed to check if there are any English words present in them. This stage is executed using the understanding of the range of Kannada words in the UTF-8 encoded format and regular expression. Attempts to remove the stop words were made but not considered for the final evaluation as they would prove to be important in POS detection.
- Tokenization: The text after the previous stage is tokenized into indexes so it can be used later. This process is carried out using out-of-the-shelf methods provided by the Keras API tokenization method. OOV token is used to make sure non-existent words in the dictionary can be marked during model evaluation. Sample output for the same is shown in Fig. 3.

```
{ '<OOV>': 1, 'ಈ': 2, 'ಎಂದು': 3, 'ಬಂದು': 4, 'ಅ': 5,
12, 'ಅವರು': 13, 'ತನ್ನ': 14, 'ಎಂಬ': 15, 'ಅವನ': 16,
'ಬಂದು': 23, 'ಅವನು': 24, 'ನನಗೆ': 25, 'ಅವಳ': 26, 'ಹೆ
3, 'ಎರಡು': 34, 'ಬೇರೆ': 35, 'ಅವರಿಗೆ': 36, 'ಮನೆಗೆ': 37,
'ನಾವು': 44, 'ಜನ': 45, 'ಸ್ವಲ್ಪ': 46, 'ಅಲ್ಲಿ': 47, 'ಎಲ್ಲಾ':
'ಹೆಚ್ಚು': 55, 'ಸರಕಾರ': 56, 'ಕೈ': 57, 'ಬಂದ': 58, 'ಹೊಸ
```

Fig. 3. Sample Tokenized Kannada Words from the Article.

### C. Normalize Sentences

Once the data is parsed and cleaned for POS tagging. Normalizing the sentences on the other hand is used to preprocess the dataset used to train the POS model [11]. The dataset used for POS training comes in HTML format and thus, HTML tags (start tags, end tags, new line and parentheses) are removed to bring the data into raw text format. The raw text is then preprocessed to create a tag set where an index and a Part of Speech are attached to each word in a sentence. The first word of the sentence has index one and the index keeps increasing until a delimiter is found. The first word of the next sentence starts with index 1 again. This tag set contains complex parts of speech attached to each word. To reduce the number of classes for the classification model, we reduce the part of speech to its roots (11 categories: noun, verb, pronoun, intensifier, conjunction, adjective, demonstrative, quantifier, adverb, particle and punctuation). Table I shows the corresponding labels used in the datasets for various POS tags and Fig. 4 shows the output of the POS tagger.

```
[[1, 'ಅಹಂಭಾವವನ್ನು', 'N_NN'], [2, 'ಬಿಟ್ಟು', 'V_VM_VNF',
ಲಿಯಿರಿ', 'V_VM_VF'], [6, '.', 'RD_PUNC'], [1, 'ದೇವಿ',
N'], [5, 'ಪರವಾಗಿ', 'N_NN'], [6, 'ನಾನು', 'PR_PRP'],
C'], [1, 'ಇನ್ನೂ', 'JJ'], [2, 'ಮುಂದೆ', 'N_NN'], [3, '

ಲ್ಲಿ', 'N_NN'], [5, 'ಇದೋ', 'V_VM_VNF'], [6, 'ಸೋಮ
ತ್ತು', 'N_NN'], [10, 'ಅರಮನೆಯ', 'N_NN'], [11, 'ಪಕ್ಕದ
'ಹಾಕಿಸು', 'V_VM_VF'], [15, '.', 'RD_PUNC'], [1, 'ಸ
```

Fig. 4. POS Tagging for the Tokenized Words.

### D. Creating the embeddings

The identified tokens are used to create a word embedding matrix using the off-the-shelf Language Tokenizer [12]. This produces a 1\*400 vector for each word and an embedding matrix is created by stacking the vectors of each word based on their index from the tokenizer. Language\_tokenizer( )

returns two vectors for certain words as it recognizes the root word and the suffix as two different words. The root word is assumed to have the maximum importance and is retained while the vector for the suffix is discarded. This gives a 27046\*400 dimensions word embedding for the entire dictionary which is used as the first layer in the Sequence model.

TABLE I. KANNADA POS TAGS

Sl. No	POS tags in Kannada	Label
1	ನಾಮಪದ Noun	NP-Noun
2.	ಸರ್ವನಾಮ Pronoun	PR
3.	ಕ್ರಿಯಾಪದ MainVerb	V__VM__VF
4.	ತೀವ್ರಗೊಳಿಸುವಿಕೆ intensifier	RD__INTF
5.	ಸಂಯೋಗ conjunction	CC__CCS
6	ವಿಶೇಷಣ adjective	JJ
7	ಪ್ರದರ್ಶಕ Demonstrative	DM DMD
8	ಪರಿಮಾಣಕಾರಕ Quantifier	QT__QTC
9	ಕ್ರಿಯಾವಿಶೇಷಣ adverb	RB
10	ಕಣ Particle	RP_RPD
11.	ವಿರಾಮಚಿಹ್ನೆ Punctuation	RD_PUNC

### E. Create POS Tagging

The tag set generated in the normalize sentences section is used here. Each word in the POS tag set is processed to contain some features to use in the classification algorithm. The features considered are:

- The word itself.
- The length of the word.
- First 4 letters of the word.
- First 3 letters of the word.
- First 2 letters of the word.
- Last 4 letters of the word.
- Last 3 letters of the word.
- Last 2 letters of the word.
- Is the word a punctuation..
- Surrounding information
  - If the word is not the first word, the above mentioned features of the previous word.
  - If the word is not the second word, the features of the word that are two positions behind.
  - If the word is not the last word, above mentioned features of the next word.
  - If the word is not the last second word, the features of the word are two positions ahead.

The above features combined with N-gram predict the POS tag for a word based on the POS of the previous and the next word of that given word.

The performance of the POS tagger is given in Table II. With the proposed POS model, 91% accuracy is achieved.

TABLE II. PERFORMANCE OF THE PROPOSED POS MODEL

POS tags	Precision	Recall	F1 Score	Support
N	0.843	0.956	0.896	614
V	0.955	0.922	0.938	502
RB	0.444	0.316	0.369	38
CC	0.901	0.839	0.869	87
RD	1.000	0.997	0.998	317
JJ	0.806	0.532	0.641	47
DM	0.927	0.905	0.916	42
RP	0.647	0.333	0.440	33
PR	0.964	0.931	0.948	350
PSP	0.333	1.000	0.500	1
QT	0.913	0.808	0.857	26
Micro average	0.910	0.911	0.910	2057
Macro average	0.794	0.776	0.761	2057
Weighted average	0.909	0.911	0.907	2057
Final F1 score on the test dataset	0.9066			
Accuracy of the test dataset	0.9101			

The proposed POS model's performance is compared with those of other models identified during the survey. We were able to achieve a decent accuracy of 91% accuracy and a 90% F1 score since the model employs a clear dataset. The performance of the POS model is seen in Table III. The CRF model is one of the top models for assigning POS tags for Kannada words, according to the survey.

TABLE III. PERFORMANCE ANALYSIS OF VARIOUS POS MODEL

Reference No	Method employed	Accuracy in %
[24]	RNN+LSTM	81
[25]	Hidden Markov model CRF	79 84
[26]	SVM	85
[27]	Markov chain	95
[29]	SVM	95
<b>Proposed model</b>		<b>91</b>

#### F. Authorship model using Bi-LSTM

Once the author's dataset is prepared and the POS model assigns the tags for each token in the dataset, the next stage is, running the proposed authorship model. It is a classification problem and Bi-LSTM is employed to perform the AA task. Bi-LSTM model [13] reads the author's text in both directions and understands the syntactic features, especially how the sentence is formed using the POS tags. The Bi-LSTM architecture used for the proposed work is shown in Fig. 5 and the simplified architecture is shown in Fig. 6.

- Layer 1 composing 15 Bi-Directional LSTM Units: A Bidirectional LSTM, or Bi-LSTM, is a sequence processing model that consists of two LSTMs [10]: one taking the input in a forward direction, and the other in a backward direction. Bi-LSTMs effectively increase the amount of information available to the network, improving the context available to the algorithm (for example, knowing what words immediately follow and precede a word in a sentence).
- Layer 2 stacked on top of layer 1 consisting of 15 Bi-Directional LSTM Units.
- Batch Normalization for the sequence: It is a process to make neural networks faster and more stable by adding extra layers to a deep neural network. The new layer performs the standardizing and normalizing operations on the input of a layer coming from a previous layer.
- A densely connected neural network layer.
- ReLU activation: A linear function that will output the input directly if it is positive, otherwise, it will output zero.
- 64 Dense units with the 'ReLU' activation and a dropout of 0.5 32 Dense units with the 'ReLU' activation and a dropout of 0.5.
- Dropout: Dropout is a technique used to prevent a model from overfitting. Dropout works by randomly setting the outgoing edges of hidden units (neurons that make up hidden layers) to 0 at each update of the training phase.
- Sigmoid activation: A sigmoid function is a bounded, differentiable, real function that is defined for all real input values and has a non-negative derivative at each point and exactly one inflection point.

The model is compiled with the following hyperparameters:

- Loss: Binary cross entropy compares each predicted probability to actual class output, which can be 0 or 1. It then calculates the score that penalizes the probabilities based on the distance from the expected value. That means how close or far from the actual value.
- Optimizer: Stochastic Gradient Descent with a learning rate of 0.001 and momentum of 0.9. It attempts to find the global minimum by adjusting the configuration of the network after each training point. Instead of decreasing the error, or finding the gradient, for the entire data set, this method merely decreases the error by approximating the gradient for a randomly selected batch (which may be as small as a single training sample). In practice, random selection is achieved by randomly shuffling the dataset and working through batches in a stepwise fashion.
- Prediction: Each of the text documents is preprocessed similarly during the training and validation sets.

Fig. 5. Overall Bi- LSTM Architecture of the Proposed Model.

Fig. 6. The Architecture of the AA Model using Bi-LSTM.

All the documents with the labeled author's names are trained but testing is done in a different approach, that is 10 datasets are created such that, each dataset comprises articles written by five different authors so a total of 50 author's 10 documents are collected. Table III shows the dataset preparation for the proposed model. Finally, 500 articles are in the dataset, it is split into 70:20:10 for training, testing and

validation respectively. The model is trained using the N-gram approach by extracting the POS tag features of the authors. During the testing phase, if author 1's document is passed, then Model 1 is supposed to respond positively to the statements of author 1 and should predict 0 for authors 2,3,4 and 5's documents. Similarly, model 10 contains articles written by the authors 46,47,48,49 and 50. After predicting the author for each sentence in each document, the ratio of positive to negative statements is calculated. We used the 1v5 method for testing rather than having 5 neurons that associate a document to an author with a certain probability since this model produced more promising results.

#### IV. RESULTS AND DISCUSSION

The performance of 5 author sets of 10 models is tabulated based on the N-grams of POS tags. One of the metrics to measure the performance of the proposed model is the count of positive and negative statements.

The overall loss rate of all the dataset models is shown in Fig. 7, the loss rate is reduced after several epochs which indicates that the model is learning the writing style of the authors in a better way. After testing the author's samples with the different combinations, we obtained the accuracy of all ten author sets and tabulated them in Table IV and Fig. 8 to indicate the same.

We also observed that for a few articles authors are mispredicted. The performance is mainly depending on the efficiency of the POS tagger [12]. POS tagger is working fine with the training set but has average performance for the authorship dataset. The proposed work uses cross domain authorship that is an author can write political as well as scientific articles since the writing style differs, it has an impact on the accuracy and the N-gram technique extracting the POS tags is not sufficient to extract the writing style, N-gram combined with other stylometry features may work better. The performance of the model deteriorates when the anonymous text document is tested against the articles of all 50 authors. The accuracy was 10%-12% so a 1v5 approach is used. In the 1v5 approach, each time the dataset model contains different authors' articles.

TABLE IV. AUTHOR WISE ACCURACY

Dataset Models	Accuracy
Model-1	77%
Model-2.	78%
Model-3	77%
Model-4	78%
Model-5	81%
Model-6	77%
Model-7	81%
Model-8	78%
Model-9	72%
Model-10	79%
Average Accuracy	77.8%

Fig. 7. Loss Rate.

Fig. 8. Accuracy of All the Dataset Models.

Using LSTM one more approach called the sequence model is developed. This experimental model was used without convincing results. The text source created at the end of step 3 as shown in Fig. 5 is used for this model. After splitting the dataset as train, test and validation sets like the BI-LSTM model. All 50 authors were used for this model and the multi-class classification strategy was employed here. The prediction vector was in the form of a one-hot encoded vector where the index of the corresponding author was marked as 1 and the rest as 0. The sets from the previous stage are converted to indices using the tokenization from stage 4 of the Data Processing module. Both sentence level and document level sequences were considered with lengths 15 and 2500 respectively but this model yields overall accuracy of 15%.

#### A. Performance Comparison of Different Techniques

To assess the performance of our model, we have compared it with other AA models developed for other languages since no models are available for the Kannada languages. Table V shows the accuracy obtained by other AA

models. We observed that deep learning based models performed well with more than 90% accuracy, but we obtained 77.8% accuracy for the proposed work. Also, classification algorithms perform better in some cases. The reasons for the moderate performance of the proposed model are identified and listed below:

- The POS model is tested and trained successfully on a labeled dataset, but when it is used on a real authors dataset, it performs moderately since certain Kannada words have several meanings, which causes ambiguity.
- In the proposed work a cross-domain dataset is considered which has a variety of categories like life skills, science and health, sports, etc. It is common in foreign languages but is new to the Kannada language.
- A good dataset of more than 10,000 articles improves the model's performance, however building such a huge Kannada dataset is a challenging one.

TABLE V. PERFORMANCE COMPARISON OF AA MODELS

Reference No	Technique used	Accuracy / F1 Score in %
[9]	Artificial Neural Network	75.46
[10]	N-gram	61.1
[11]	Life Like Network Automata using Life-Like rules	70-75
[12]	SVM algorithm with linear kernel	68
[14]	SVM	96
	Deep learning	93
[16]	Convolutional Neural Network	98
[17]	BERT model	90
[18]	Neural Networks	97.2
[19]	Doc2vec Reduction model	99
[20]	Recurring Neural Networks	78
[21]	Convolutional Neural Network	72.59
[22]	SVM	95
<b>Proposed Model</b>	<b>Bi-LSTM</b>	<b>77.8</b>

#### B. Directions for Future Work

More powerful style markers can be introduced which can be used to classify a wide range of authors [30]. Right now, this work can classify 50 authors. The next step can be the development of general rules that should apply to almost every author. A near perfect classification can be achieved by training a meta-learner that will use both neural networks and decision trees, this is required because neural networks consider different sets of features than decision trees.

A combination of different sets of features may be tried to see if there exists a set that can be used by all learning algorithms. Also, feature extraction can be improved by using more powerful natural language tools. Features selection is an important criterion and the graph-based neural networks [14] can be used in the future where the network will itself select the features which contribute the most to the output.

## V. CONCLUSION

The model currently stands with an accuracy of 77.8%. According to our knowledge, the proposed model is a novel technique and a challenging one in recognizing the writing style of a Kannada author. The proposed work aims to increase the accuracy by tweaking the model and if possible, implementing the same model by extracting features other than syntactic. It is understood that lexical features, word length and sentence length do not often have enough descriptive power for any model to assign a document to an author with a sense of certainty. We aim to pursue further research in detail to pick only those features that will yield good results. We believe semantics is one of those.

# Flood Prediction using Deep Learning Models

Muhammad Hafizi Mohd Ali, Siti Azirah Asmai\*, Z. Zainal Abidin, Zuraida Abal Abas, Nurul A. Emran  
Centre for Advanced Computing Technology (C-ACT), Fakulti Teknologi Maklumat Dan Komunikasi  
Universiti Teknikal Malaysia Melaka, Hang Tuah Jaya, 76100 Durian Tunggal, Melaka, Malaysia

**Abstract**—Deep learning has recently appeared as one of the best reliable approaches for forecasting time series. Even though there are numerous data-driven models for flood prediction, most studies focus on prediction using a single flood variable. The creation of various data-driven models may require unfeasible computing resources when estimating multiple flood variables. Furthermore, the trends of several flood variables can only be revealed by analysing long-term historical observations, which conventional data-driven models do not adequately support. This study proposed a time series model with layer normalization and Leaky ReLU activation function in multivariable long-term short memory (LSTM), bidirectional long-term short memory (BI-LSTM) and deep recurrent neural network (DRNN). The proposed models were trained and evaluated by using the sensory historical data of river water level and rainfall in the east coast state of Malaysia. It were then, compared to the other six deep learning models. In terms of prediction accuracy, the experimental results also demonstrated that the deep recurrent neural network model with layer normalization and Leaky ReLU activation function performed better than other models.

**Keywords**—Deep learning; recurrent neural network; long short-term memory; flood prediction; layer normalization

## I. INTRODUCTION

Due to its impact on daily life, flooding is one of the most pressing issues that Malaysia has been dealing with recently. Floods are a type of natural geohazard that typically occur because of consistently heavy rain. This natural phenomenon causes massive damage to the country's property and Gross Domestic Product (GDP). According to Ashizawa et al. [1], the entire GDP of Japan impacted by flood damage is at least 1% of the overall GDP of the nation. Tiggeloven et al. [2] stated that the top 15 countries, such as India, Bangladesh, China, and others, are vulnerable to flood occurrence at the present day and could be worst if no action is taken. Indeed, floods can cause a massive amount of money to repair the damage. Hence, flood occurrence can affect every country, including Malaysia. Shaari et al., [3] stated that from 2006 to 2010, there was nearly 1 million USD damage caused by floods which affected the nation's economic growth. There are many classifications of floods namely coastal floods, flash floods, ponding (or pluvial flooding), and river (or fluvial) floods [4]. Floods often occur, especially in Southeast Asia, including our country, Malaysia. The general types of flooding in Malaysia include riverbank overflow, flash floods, high tides [5], and monsoon floods [6].

Floods are classified as natural disasters in Malaysia due to the monsoon season. In Malaysia, there are two distinct monsoon seasons: the Northeast Monsoon, which occurs from November to March, and the Southwest Monsoon, which occurs from late May to September. The Northeast Monsoon

can bring heavy rainfall. Due to the extensive network of rivers connecting several Malaysian states and the country's poor drainage, floods are expected in Malaysia during the monsoon season, especially on the West Coast and in Borneo. The populous region is flooded as a result of the river level rising significantly as a consequence of these strong rains. As a result, people are compelled to temporarily relocate to several relief. Floods halt economic progress since crops and animals are destroyed. Romali et al, [7] stated that Malaysian financial losses are estimated at nearly MYR 915 million annually on an average due to floods.

According to Zerara [8], time series is a statistical method that can be applied in a broad range of longitudinal research designs. Typically, this time series design involves a single subject that is measured repeatedly at regular intervals over a large number of observations. Time series forecasting aims to predict an outcome based on the collection of historical data that can be used to build a quantitative model that explains the variables under consideration [9]. For many years, time series forecasting has been an important research domain in meteorology [10], biology [11], and econometrics [12]. Generally, time series can have four characteristics: trends, seasonality, cycles, and noise [13]. Time series forecasting algorithms perform well with data that includes a time dimension and one or more properties [14].

Time series have been frequently utilized in flood forecasting and have shown excellent results for the global community [15]. Furthermore, according to Shen et al. [16], modern time series can be combined with deep learning models including Recurrent Neural Network (RNN), Artificial Neural Network (ANN), Long Short Term Memory (LSTM), and other models. However, the existing flood forecasting methods, for example, frequency analysis, rational method, and empirical formula, are not deemed suitable for a wide area. Those methods can only cover a small river flow area [17]. For example, Faruq et al. [18] used an LSTM model to predict the flood by using a Klang River lever dataset. Another study [19] used the ANN model to predict floods by using the Kelantan river lever and rainfall dataset in separate models. The LSTM model performs exceptionally well when the modelling has a large amount of time series data. Furthermore, according to the literature, the LSTM model outperforms the RNN in the number of previous time steps that can be considered. Additionally, Siami-Namini & Namin, [20] demonstrated that the LSTM model could predict time series much more accurate than the Autoregressive Integrated Moving Average (ARIMA) model in some cases. As a result, the LSTM model appears to be a likely top performer; although the study employs stock time series, it still has parallels to the current study since it focuses on time series forecasting. According to Jaiswal & Das

\*Corresponding Author.

[21], the ANN model works best with nonlinear problems whereas Šiljić Tomić et [22] stated that the ANN model can work with both nonlinear and linear problems. According to Y.f. Zhang et al. [23], despite being the most significant advantage of time series, long-term dependencies remain a considerable challenge. Besides, one of the most common drawbacks of the LSTM model and BI-LSTM model is the high computational cost during training procedures [24], where potential time series forecasting in floods has yet to be unfolded. Despite advances in developing models based on RNN, these models remain challenging to scale to long data sequences. Dhunny et al. [25] have proven that an ANN model can predict the flood water level well within 24 hours ahead of time by using the data from rainfall and present river level data. In this study, the flood was predicted for one day ahead.

The rest of this paper is structured as follows. Section II describes the related work and literature for this study. Section III presents the proposed models for flood prediction. Section IV covers the experimental procedure for the case study whereas the findings are discussed in Section V. Finally, Section VI concludes the paper, and a discussion of future works is included in Section VII.

## II. RELATED WORK

Artificial neural networks, often known as deep learning, are machine learning algorithms that have been influenced by the structure and operation of the human brain. Deep learning has dominated many uses and has proven to be superior to traditional machine learning algorithms because it can produce faster and more accurate results [26].

Deep learning enables computational models comprising multiple hidden layers of artificial neural networks with multiple linear and nonlinear transformations that learn the data representations with multiple abstraction levels [27]. In deep learning, multiple layers of nonlinear processing units perform feature extraction transformation in the deep learning model. Every layer in the previous layer input is used as its output and it is used in both supervised and unsupervised methods for classification problems and pattern analysis problems [28]. The characteristic of neural networks can be seen in Fig. 1.

Fig. 1. A Characteristic of Neural Network.

The human brain structure inspires the neural network architecture. Our brains can be trained to recognise patterns and classify various types of information. The possibility of detecting and displaying the correct answer increases with each layer of a neural network, which may be thought of as a kind of filter that operates from coarse to fine.

The neural network can begin to identify trends across the many samples it processes and classify data based on their similarities by using several layers of functions to decompose unstructured data into data points and information that a computer can use.

After processing a large number of structured data training samples, the algorithm has created a model of which elements in data and their relationships must be taken into account when determining whether structured data is present or not. The neural network compares new data points to its model based on all previous evaluations when evaluating new data. The model is then used to determine whether the data contains specific data.

The layers of functions that are present between the input and output in this example serve as a representation of deep learning. The interaction across layers is marginally enhanced in the following Fig. 2, however, the connections between nodes or artificial neurons might vary significantly.

### A. Long Short-Term Memory (LSTM)

Long Short-Term Memory (LSTM) networks can be considered as recurrent neural networks that are modified to improve from the RNN model with memory recall function. The LSTM classifier is ideal for processing, classifying, and forecasting time series with unknown time lags. Backpropagation is applied when training the model. There are three gates in the LSTM model as shown in Fig. 3.

Fig. 2. Interaction between Layers.

Fig. 3. LSTM Gates [29].

Forget gate - it analyses the previous state ( $h_{t-1}$ ) and the input content ( $x_t$ ) and returns the value ranging from 0 to 1 for each number in the cell state  $C_{t-1}$  by deciding through the sigmoid function. The forget gate equation of [30] can be referred to as (1).

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \quad (1)$$

Input gate - values from the input are applied to adjust the memory. The sigmoid function determines the value between 0 and 1, allowing through. The tanh function gives weightage to the values and then passes it, specifying their significant level ranging between -1 and 1. The input gate equation of [30] can be referred to as (2).

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i)$$

$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C)$$

$$C_t = f_t \times C_{t-1} + i_t \times \tilde{C}_t \quad (2)$$

Output gate - to determine the output, the memory and input of the block are applied. The sigmoid function determines the value between 0 and 1, allowing through. The tanh function gives weightage to the values and then passes it, specifying their significant level ranging between -1 to 1 and multiplying it by the sigmoid output. The forget gate equation of [30] can be referred to as (3).

$$o_t = \sigma(W_o [h_{t-1}, x_t] + b_o)$$

$$h_t = o_t * \tanh(C_t) \quad (3)$$

### B. Recurrent Neural Network

A recurrent neural network (RNN) is a simplified feedforward neural network with internal memory as seen in Fig. 4. RNN is recurrent because it works with the same function for each input data, and the current input as output is dependent on the previous computation. The output is produced, replicated, and then returned to the recurrent network. When making a decision, the current input and output might be seen as learned from the past.

By taking advantage of the internal state (memory) that the RNN model has, it can process the input sequence that is different from typical feedforward neural networks. As a result, the RNN model is suitable for speech recognition, unsegmented, or handwriting recognition tasks. However, there is one drawback in the RNN model: a vanishing gradient problem when dealing with long sequence data. The inputs are

completely independent of one another for other neural networks. On the other hand, all the inputs are connected in RNN.

Fig. 4. An Unrolled RNN [29].

The  $X(0)$  is taken from the input sequence at first, then the output  $h(0)$ , with  $X(1)$ , as the input for the next step. The  $h(0)$  and  $X(1)$  are the input for the next step. Similarly,  $h(1)$  from the previous step becomes the input for the next step of  $X(2)$ .

The formula equation of [31] can be referred to as (4) and this is the current state of the equation.

$$h_t = f(h_{t-1}, x_t) \quad (4)$$

Activation Function is applied:

$$h_t = \tanh(W_{hh} h_{t-1} + W_{xh} x_t) \quad (5)$$

The equation of [31] can be referred to as (5), in which  $W$  is the weight,  $h$  is the single hidden vector,  $Whh$  is the weight at the previous hidden state,  $Whx$  is the weight at the current input state, and  $\tanh$  is the activation function that applies a non-linearity squash of the activations to the range between [-1.1].

Output:

$$y_t = W_{hy} h_t \quad (6)$$

The equation of [31] can be referred to as (6), in which the output state is  $Y_t$ . The weight in the output state is  $Why$ .

Flood forecasting is a tool that allows flood control management to predict when local flooding is likely to occur with a high degree of accuracy. The river basin or watershed size can indicate the water levels and flow rates for intervals ranging from a few hours to days ahead; forecasted streamflow and precipitation data are used in the streamflow routing model and rainfall runoff. Flood forecasting can also use precipitation forecasts to expand the available lead time.

Flood forecasting is a crucial component of a flood warning system. The difference between flood forecasting and a flood warning is that flood forecasting produces a set of forecast time that profiles the river levels or flows channel at different locations. In contrast, "flood warning" refers to using forecasts to inform about flood warnings. A popular method applied for flood forecasting is hydrological modelling because this model is a simplified representation of a real-world system [32]. Although this model is good, the downside is that it is a scaling problem that faces a scale area parameter [33].

The existing flood forecasting method cannot be used with a traditional database based on a single source as the main data [34] and it requires a lot of data. With the current technology, flood prediction is more robust, and real-time flood forecasting in the provincial area can be accomplished quickly by utilising the technology of artificial intelligence (AI) and fourth

industrial technology (4IR). An effective real-time flood forecasting model may be helpful for disaster prevention, offering an advanced alert and mitigating the damage from the flood occurrence [35]. Flood forecasting has been improved by utilising deep learning models such as LSTM, RNN, and many others [18]. Many studies have applied a deep learning model in their study to predict flood occurrence and are proven to be an informative and accurate model as shown in Table I. Hence, for the deep learning model, there is always room for improvement with the use of uncertain data like flood data with a nonlinear characteristic. However, there are very few studies that build a deep learning model for flood prediction using multivariate data. In addition, the majority of past research has only used one variable or input as their main source of information to forecast the flood. In addition, the previous research already demonstrates a high level of accuracy. However, the majority of these studies utilize basic deep learning models without any additional characteristics, which can be seen as a discrepancy between the studies. The proposed models aim to get a dependable and more accurate prediction model while reducing the limitations of the previous study by using an additional characteristic as described in Section III. As previous studies are concerned with using a single data as primary data, this study proposed multivariate data as primary data to determine a correlation between several variables simultaneously and a deeper understanding of how the multivariate data relate to real-world scenarios like flood occurrence.

TABLE I. LITERATURE SUMMARY

Models	Title (Author and Year)	Goal	Country

### III. PROPOSED MODELS

The proposed enhanced models for flood prediction were formulated to increase the prediction accuracy. In this study two methods in the models were introduced as follows:

#### A. Layer Normalization

Inspired by the results of Batch Normalization, the Layer Normalization method is proposed by normalizing activations along the feature direction rather than the mini-batch direction. Hence, overcoming the disadvantages of batch normalization by eliminating the reliance on batches and making it easier to apply for RNN. Each activation feature is normalized to zero mean and unit variance through Layer Normalization.

In Batch Normalization, the statistics are computed across the batch, as for the spatial dimensions. In contrast, Layer Normalization (LN) computes statistics (mean and variance) across all channels and spatial dimensions. As a result, the statistics are batch independent. This layer was initially designed to handle vectors (mainly the RNN outputs).

Layer Normalization visually comprehends this as shown in Fig. 5:

Fig. 5. An Illustration of Layer Normalization [42].

When dealing with vectors with a batch size of NN, the 2D tensors of shape R N times K RNK.

Normalize with the mean and variance of each vector because it does not depend on the batch and its statistics. The normalize equation of [43] can be referred to as (7).

$$\begin{aligned} \mu_n &= \frac{1}{K} \sum_{k=1}^K x_{nk} \\ \sigma_n^2 &= \frac{1}{K} \sum_{k=1}^K (x_{nk} - \mu_n)^2 \\ \hat{x}_{nk} &= \frac{x_{nk} - \mu_n}{\sqrt{\sigma_n^2 + \epsilon}}, \hat{x}_{nk} \in R \end{aligned} \quad (7)$$

$$LN_{\gamma, \beta}(x_n) = \gamma \hat{x}_n + \beta, x_n \in R^K$$

When generalizing to 4D feature map tensors, it takes the mean across all channels and spatial dimensions, as shown below: The equation below based on [43] can be referred to as (8).

$$\begin{aligned} LN(x) &= \gamma \left( \frac{x - \mu(x)}{\sigma(x)} \right) + \beta \\ \mu_n(x) &= \frac{1}{CHW} \sum_{c=1}^C \sum_{h=1}^H \sum_{w=1}^W x_{nchw} \\ \sigma_n(x) &= \sqrt{\frac{1}{CHW} \sum_{c=1}^C \sum_{h=1}^H \sum_{w=1}^W (x_{nchw} - \mu_n(x))^2} \end{aligned} \quad (8)$$

### B. Leaky ReLU

To replace its saturated counterpart of Sigmoid or Tanh, the modern deep learning system employs a non-saturated activation function such as ReLU and Leaky ReLU. It solves the "exploding/vanishing gradient" issue and speeds up convergence.

ReLU reduces the negative component to zero while keeping the positive component. It has the desirable property of being sparse in activations after passing through ReLU. The equation of [44] can be referred to as (9).

$$y_i = \begin{cases} x_i & \text{if } x_i \geq 0 \\ 0 & \text{if } x_i < 0 \end{cases} \quad (9)$$

The gradient-based optimization algorithm will not change the weights of a unit that does not initially activate. Because the gradient is 0 when the unit is inactive, ReLU has a disadvantage during optimization.

If the neurons are not activated at the start of the ReLU, it is possible to end up with a neural network that never learns. The learning rate is slow when training ReLU networks with constant 0 gradients. The equation of [44] can be referred to as (10).

$$y_i = \begin{cases} x_i & \text{if } x_i \geq 0 \\ \frac{x_i}{a_i} & \text{if } x_i < 0 \end{cases} \quad (10)$$

Leaky ReLU adds a slight negative slope to the ReLU to sustain and keep the weight updates alive throughout the propagation process.

The alpha parameter was introduced to address the ReLU's dead neuron issues, ensuring that gradients are never zero during training.

The ReLU function and the Leaky ReLU function are nearly identical as seen in Fig. 6. During optimization, the Leaky ReLU foregoes hard-zero sparsity in exchange for a potentially more robust gradient. Alpha is a constant value (float >= 0).

Fig. 6. ReLU vs Leaky ReLU [45].

Unlike the ReLU function, the Leaky ReLU has a non-zero gradient across its entire domain. The Leaky ReLU activation function is only available in the form of layers, not activations.

## IV. EXPERIMENTAL PROCEDURE

As shown in Fig. 7, the experiment design started with data collection and ended with a model evaluation.

### A. Data Collection

A dataset of river level and rainfall at Rantau Panjang, Pasir Mas in Kelantan from 2013 until 2017 was used, as shown in Fig. 8 and Fig. 9. The data of these rivers were recorded every year with flood occurrence [46]. The data were provided by the Department of Irrigation and Drainage (DID) Malaysia, and the features variable is shown in Table II. The river at Pasir Mas station collected river level (m) and rainfall (mm) daily. This dataset contained one measurement per day. The dependent variable was observed as a single daily value; hence, these cloud values were summed, accomplished by taking the average between 00:00 and 24:00 as each day's value. Because there were fewer and more irregular observations, the cloud base was summarised by averaging an entire day.

The dataset was imported into pandas by using the read csv() function and saved in the Data Frame named "df". Because the dataset was in tabular form, it was automatically converted into a Data Frame when working with tabular data in Pandas. In Python, a Data Frame is a two-dimensional, mutable data structure. It is made up of rows and columns, much like an excel sheet.

### B. Data Cleaning

Data cleaning or filtering's main function was to correct (or remove) and detect inaccurate data in the dataset. The task involves identifying inaccurate, incomplete, incorrect or irrelevant parts of the data and then deleting the noise data, and replacing or modifying them [48].

**Data Collection**

Fig. 7. Experiment Design.

Fig. 8. Kelantan River Map [47].

AVERAGE AMOUNT RAINFALL PASIR MAS, KELANTAN  
IN 2014, 2106 AND 2018

Fig. 9. Average Rainfall in Pasir Mas [46].

TABLE II. SUMMARY OF VARIABLE DATA COLLECTION

Variable	Unit	Description
Date	Date/ dd/mm/yyyy	Describe the current date
River Stage	Meter/m	Describe the river level during the day
Rainfall	Millimetres/mm	Describe the rain during the day

Data cleaning is the most crucial task because having incorrect or poor-quality data can harm processes and analysis. Clean data boosts overall productivity and allows for the utilization of the highest quality data when making predictions.

First, the river of Pasir Mas dataset needed to be checked to determine whether the dataset had missing or null values. After reviewing the dataset, a missing or null value in this situation needed to be dealt with through two options: a) removed a row with a missing value; b) replaced the missing value by using one of the most fundamental methods namely linear interpolation method. The formula is as follows:

$$y = y_a + (y_b - y_a) \frac{x - x_a}{x_b - x_a} \text{ at the point } (x, y)$$

$$\frac{y - y_a}{y_b - y_a} = \frac{x - x_a}{x_b - x_a} \quad (11)$$

$$\frac{y - y_a}{x - x_a} = \frac{y_b - y_a}{x_b - x_a}$$

The equation of [49] can be referred to as (11), the new line slope between  $(x_a, y_a)$  and  $(x, y)$  is the same as the slope of the line between  $(x_a, y_b)$  and  $(x_b, y_b)$ . The advantage of linear interpolation is that it is easy and fast to be applied, but its accuracy is doubtful.

The river of Rantau Panjang Pasir Mas station had ten missing values in the river level variable because of the existence of the same reading of recording on certain days. Handling missing values was done by the python pandas.

The interpolate () function fills NA values or missing values in the series or data frame. Rather than hard-coding the missing value, various interpolation, and convenient techniques could be used to fill the missing value.

### C. Dataset Splitting

The dataset needed to be divided into training and testing sets to avoid any phenomenon such as overfitting. Besides, the size of the datasets as well as the train/test split ratios can significantly impact the model output, thus, affecting classification performance [50]. For example, if there are patterns in the training and testing set that do not exist in real-world data, the model performs poorly even though it cannot be seen in the performance evaluation. Dataset splitting is a practice considered indispensable and highly necessary to eliminate or reduce bias in training data for prediction models [51].

Based on the Rantau Panjang river dataset, 80% were training data, and the remaining 20% were testing data that would be optimally splitting the training and testing the dataset.

### D. Data Transformation

Normalization is a scaling, mapping technique, or pre-processing stage. For prediction or forecasting purposes, it can be useful when it distinguishes a new range from an existing one.

Normalization is a transformation process that utilises a standard scale to produce numerically and comparably input data. After collecting input data, the data should perform some pre-processing to make it worthwhile for decision modelling [52]. As previously stated, this pre-processing should take three critical factors into account: 1) removed missing values from the data; 2) converted all non-numeric data to numerical data to allow for normalization (standardisation); 3) Determined how to select a suitable normalization technique to ensure a standard scale, appropriate modelling representation (benefit or cost criteria), and aggregation comparability to obtain alternative ratings.

After the data cleaning process, river stage and rainfall data underwent a min-max scaler to get normalized data. Min-max scaler scaled the data between the minimum and maximum value of the data that ended up ranging between 0 and 1. Another function for normalizing the data was to speed up the learning time and performance of the model. The data were scaled down to a range between [0, 1] or [-1, 1]. The method's equation of [14] can be referred to as (12):

$$a_{\text{norm}} = \frac{(\text{high} - \text{low}) * (a - \text{minA})}{\text{maxA} - \text{minA}} \quad (12)$$

min A is the smallest value, and max A is the largest value of attribute A.

### E. Model Evaluation

1) MAE stands for Mean Absolute Error, which is

$$\frac{1}{n} \sum_{i=1}^n |y_i - \hat{y}_i| \quad (13)$$

Outliers are given less weight in this method, which is not sensitive to outliers. The equation of [53] can be referred to as (13).

2) MAPE stands for Mean Absolute Percentage Error, which is

$$\frac{1}{n} \sum_{i=1}^n |y_i - \hat{y}_i| \quad (14)$$

MAE is similar, but true observation is used to normalise it. The disadvantage is that this metric becomes problematic when true observation is zero. The equation of [53] can be referred to as (14).

3) MSE stands for Mean Squared Error, which is

$$\frac{1}{n} \sum_{i=1}^n (Y_i - \hat{Y}_i)^2 \quad (15)$$

MSE is a combination of variance of the prediction and measurement of bias, i.e.,  $MSE = \text{Bias}^2 + \text{variance}$ . The equation of [53] can be referred to as (15).

4) RMSE stands for Root Mean Squared Error, which is

$$\sqrt{\frac{1}{n} \sum_{i=1}^n (Y_i - \hat{Y}_i)^2} \quad (16)$$

It measures the standard deviation of residuals. The equation of [53] can be referred to as (16).

5) R2 stands for coefficient of determination, which is

$$1 - \frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{\sum_{i=1}^n (y_i - \bar{y})^2} \quad (17)$$

Representing the coefficient indicates how well the values fit in comparison to the original values. The equation of [54] can be referred to as (17).

### V. RESULTS AND DISCUSSIONS

The results between the proposed models and original models that share the same hyperparameter setting were compared as shown in Table III.

In the present study, the proposed models were evaluated and compared with the original RNN model proposed by Hochreiter and Schmidhuber [55], the LSTM model proposed by Rumelhart & McClelland [56] and the BI-LSTM model proposed by Graves & Schmidhuber [57] to get a better understanding of whether the proposed models could produce better results [58][59][60]. The proposed models had an extra layer called layer normalization and one activation function is known as Leaky ReLU. In contrast, the original models had a standard layer and used a sigmoid as its activation function. Each deep learning model needs to be compared to the proposed and original models to ascertain which deep learning models perform better [61][62].

TABLE III. COMPARISON RESULT

Models	MSE	MAE	RSME	MAPE (%)	R2	Training Time
DRNN + LN + Leaky ReLU	0.107	0.233	0.327	4.293	0.946	1.08 minute
DRNN	0.118	0.242	0.343	4.344	0.94	0.38 second
LSTM + LN + Leaky ReLU	0.125	0.231	0.353	4.117	0.936	1.33 minute
LSTM	0.122	0.236	0.349	4.296	0.931	1.32 minute
BI-LSTM + LN + Leaky ReLU	0.131	0.258	0.362	4.751	0.933	3.33 minute
BI-LSTM	0.123	0.243	0.351	4.432	0.937	2.39 minute

Table III shows that the proposed models produced a better accuracy result: for example, the Deep Recurrent Neural Network (DRNN) + LN + Leaky ReLU model produced the lowest MSE among other models whereas the BI-LSTM + LN + Leaky ReLU model produced the highest MSE. For MAE,

the LSTM + LN + Leaky ReLU model produced the lowest error and the BI-LSTM + LN + Leaky ReLU model produced the highest error among other models. For RSME, the DRNN + LN + Leaky ReLU model produced the lowest error whereas the BI-LSTM + LN + Leaky ReLU model produced the highest error. For MAPE, the interpretation was in percentage mode and the lower is better, where the LSTM + LN + Leaky ReLU model produced the lowest MAPE, and the BI-LSTM + LN + Leaky ReLU model produced the highest MAPE. For R2, the higher the interpretation is better, in which the DRNN + LN + Leaky ReLU model produced the highest R2 whereas the LSTM model produced the lowest R2.

Comparing the proposed models with the original models, the DRNN + LN + Leaky ReLU model produced a low error in terms of MSE, MAE, RSME, MAPE and R2 which indicated that the proposed models were good in making a prediction, but the drawback was that it took longer time to train the data. For the LSTM model, the LSTM + LN + Leaky ReLU model produced the lowest error in terms of MAE, MAPE and R2 which was slightly better than the LSTM model. For the BI-LSTM model, the BI-LSTM produced better results compared to the BI-LSTM + LN + Leaky ReLU model in terms of MSE, MAE, RSME, MAPE, R2 and training time. The proposed model could not work well with the BI-LSTM model.

Additionally, the BI-LSTM model required more training time compared to the other models. In addition to performance evaluation, training time must also be taken into account. For instance, it is clear that the proposed models needed more training time than the original model because it had an additional layer called the normalization layer.

In literature, the LSTM model is regarded as the best performer compared to other models developed with dependent variables. However, in this case, the DRNN model performance is better compared to other models. This result can be seen in Table III, in which the DRNN + LN + Leaky ReLU model outperform other models in terms of the MSE, RSME, R2 and training time. The LSTM model shows the second best among other deep learning models with the lowest MAE and MAPE with the LSTM + LN + Leaky ReLU model. The BI-LSTM model shows the lowest accuracy among other models, one thing needs to be highlighted the result has also shown that the accuracy among the models is about the same, the differences are just slight, and there is a considerable gap between them. The DRNN model is the first place in accuracy, followed by the LSTM model and the lowest is the BI-LSTM model. Because the LSTM framework uses backpropagation and a gate to train the model, it takes more time to train than the DRNN model, which uses sequential while training the data and has no backpropagation and gate in the architecture. The DRNN model ranks lowest in terms of training time, while the LSTM model comes in second. Contrarily, the BI-LSTM model necessitates that the training data move in both past and forward directions to train the data, which is why the BI-LSTM model takes longer to train the data.

Based on the result in Table III, only the proposed models with layer normalization and Leaky ReLU are deemed suitable for flood prediction with minimal missing value in the data usage which results in the lowest minimum error and good

accuracy. The missing value in the data can be filled by using the linear interpolation method to get the best possible clean data. The authorities may use these models as an alternative to anticipate flooding and make enough preparations prior to its occurrence.

## VI. CONCLUSION

In conclusion, the DRNN model performs relatively well compared to the LSTM and BI-LSTM models with the used dataset. From the literature, the LSTM architecture needs requirements for backpropagation and a gate to train the model. Therefore, the LSTM model is marginally more complicated than the DRNN model. Meanwhile, the BI-LSTM model performs with somewhat lower accuracy but is still able to deliver a good outcome. Additionally, the BI-LSTM model requires the training data to move backwards and forward in both directions which increases the training time needed. Even though the performance of proposed models performs well, there are still many improvements that can be made using deep learning approaches.

## VII. FUTURE WORK

For future work, it is suggested that additional experiments be conducted by combining a statistic model with the pre-processing models to ascertain how the combined model performs. Currently, these models produce a good accuracy for one day ahead but for future work these models need to be tuned to produce a good accuracy for multi-days ahead.

## ACKNOWLEDGMENT

The authors are grateful to Universiti Teknikal Malaysia Melaka for the financial support through the university's short-term grant PJP/2020/FTMK/PP/S01802.

# Recognition Method of Dim and Small Targets in SAR Images based on Machine Vision

Qin Dong

Yancheng Institute of Technology  
School of Information Engineering, Yancheng 224000, China

**Abstract**—Aiming at the problems of long recognition time and low recognition accuracy of traditional SAR image dim target recognition methods, a method of SAR image dim target recognition based on machine vision was proposed. SAR images are collected and preprocessed by machine vision, and the image information is processed by PCA dimension reduction considering the linear characteristics of the data to extract image features. Then, the SAR image target feature key frame frequency band is divided by the segmentation results, and the recognition model is established based on the image trajectory tracking and target analysis. The proposed algorithm is applied and analyzed. The simulation results show that the proposed algorithm has good recognition rate, average recognition rate and false detection rate are 99% and 0.9%, and can effectively ensure the data processing performance.

**Keywords**—Machine vision; SAR image; Weak target; PCA linear dimensionality reduction method; key frame frequency band

## I. INTRODUCTION

Synthetic Aperture Radar (SAR) is an active microwave imaging radar. SAR has high range and azimuth resolution, and can obtain two-dimensional high-resolution images. Since the electromagnetic waves emitted by SAR have a longer wavelength and can penetrate clouds, fog, rain, smoke, haze, etc., SAR has a certain penetration ability and can work all day and all day long. Based on the above advantages, SAR is widely used in the military field, mainly used for: military intelligence reconnaissance and tracking, military terrain mapping, navigation and guidance, damage evaluation, etc. [1]. In addition, with the further maturity of SAR technology, SAR is also widely used in many civilian fields, such as resource monitoring, environmental monitoring, forest vegetation cover detection, disaster monitoring, and ecology, hydrology, archaeology, and deep space exploration. With the continuous development of SAR technology, the resolution of radars is getting higher and higher, the quality of SAR images is getting better and better, and new SAR images are constantly being produced [2]. What does not match it is that the interpretation of SAR images has developed slowly. The initial manual interpretation is completely performed by personnel based on the shape, size, shadow, position, and hue of the target in the image to extract the information in the SAR image. This method is not only extensive, the knowledge and the deep background of SAR, and the efficiency is very low, it is greatly affected by the subjective experience of the observer, and it is far from satisfying the current situation of massive SAR images that need to be analyzed. Target recognition in SAR images does not require manual intervention, and relies on computers to run

related algorithms to automatically classify SAR image targets. The general target recognition step is: first extract the characteristics of the image target, and then recognize it through the corresponding recognition method [3].

Dim and small target recognition in SAR image is one of the core technologies in the automatic target detection system. When the distance is far, the imaging area of these targets on the focal plane is very small, generally not exceeding the size of the detector pixel. The target appears as dots in the image, and the signal-to-noise ratio is extremely low. The target is submerged by noise, which brings great difficulties to target detection. For more than ten years, the identification of small and dim targets in SAR images has been a research hotspot in the field of optics and infrared images [4]. The International Optical Engineering Society organizes an annual “Signal and Data Processing of Small Targets” conference to exchange new technologies for the recognition of small and small targets in SAR images. The International Optical Engineering Society defines the weak target as: the image size is less than 80 pixels, that is, less than 0.15% of 256×256. The research on the recognition of small and dim targets in SAR images originated from long-distance search and surveillance. For example, use wide-field telescopes to search for or track meteors, satellites or other moving targets in the sky, and use airborne or ground infrared (TV) search and tracking systems to search for long-distance targets. It uses image processing algorithms to automatically recognize targets in a cluttered background and strong noise environment. The performance of the algorithm is critical to the range and intelligence of the automatic target recognition system. Recognition of small and dim targets in SAR images is a difficult subject with important strategic application value [5].

At the same time, for the research of SAR target recognition algorithm, most scholars try to improve the algorithm from different angles to improve its target recognition accuracy, thereby reducing background clutter and noise interference factors in image recognition. Literature [6] proposed that the one-dimensional feature extraction of principal component analysis is used as the input data of the encoder, and then the SAR target image is used as the input of the neural network to realize the target recognition of two-dimensional data, and research has proved that the depth learning algorithm of fusion decision layer and feature layer has good adaptability and robustness. In reference [7], SAR image classification method based on target decomposition and support vector machine is used to decompose and combine features in polarization and establish polarization classification model. The experimental

results show that the improved polarization image classification method has better classification performance and application effectiveness. Literature [8] proposed a view tensor sparse representation model based on target recognition, and used JT-OMP algorithm to calculate the sparse representation error of SAR tensor image data and multi view SAR image after the construction of recognition dictionary. Subsequently, the effectiveness of the algorithm was verified in the target recognition database. In reference [9], considering the decline in accuracy of ship target image due to the motion of the target, it proposed to combine clustering algorithm with SAR image recognition, and proposed HCA ship target aggregation algorithm in airborne SAR image. The distance algorithm is used as the basis for the generation of a single image. The experimental results show that this method can have good application performance in simulation experiments. Reference [10] proposed a SAR target recognition method based on adaptive kernel dictionary learning, that is, extracting nonlinear feature information through data space mapping, information dynamic updating, and minimizing error reconstruction. Simulation results show that this method has good recognition performance. In reference [11], zero phase component analysis is used to achieve feature extraction, and sparse technology is used to optimize the convolutional neural network SAR target recognition algorithm. The results show that the algorithm has high target recognition ability and good noise robustness.

Literature [12] designed a multi-azimuth SAR image for target recognition convolutional neural network (Convolutional Neural Network, CNN), three SAR images of the same target are input into the network as a pseudo-color image, making full use of the characteristics of SAR image data acquisition are improved, and the flattening operation is replaced by a pooling layer, which reduces the number of network parameters. The experimental results show that even on a small-scale SAR data set, the convolutional network has the characteristics of high recognition accuracy. Targets of different models in the same category also have excellent recognition performance. Literature [13] proposed a two-dimensional principal component analysis (2DPCA) and L2 regularization constrained stochastic configuration network (SCN) for integrated learning SAR image target recognition method, 2DPCA not only It can effectively extract the feature information of the target and reduce the amount of data through sparse representation. The SCN regularization algorithm has fewer parameters and can effectively avoid the network overfitting problem and improve the recognition rate of the network. Although the above two methods realize the recognition of small and weak targets in SAR images, they take a long time to recognize and the recognition efficiency is low. Literature [14] proposes a synthetic aperture radar (SAR) image target recognition method based on random weighted fusion of single-level signal decision-making layers, and uses sparse representation classification (SRC) to implement the multi-level and multi-component single-level signal representation obtained from SAR image decomposition. For decision-making, the error vector is fused by a random weight matrix, which contains a large number of random weights. According to the fusion results, different types of error statistics can be obtained. The decision variables are defined to reflect the correlation of different types. Finally, according to the minimum error is used

to make category decision. Extensive experiments are carried out on the MSTAR data set and compared with many types of existing methods. The results show that the proposed method can effectively improve the overall performance of SAR target recognition. Literature [15] proposed a Capsule-based SAR image target recognition method, which uses multiple convolutional layers to achieve hierarchical processing, while using fewer convolution kernels, but the number of convolution kernels used in each layer gradually increases as the level deepens, which makes the extracted features more abstract. In the Primary Caps layer, the Capsule vector is composed of all the feature maps output by the last layer of the convolutional layer, so that the Capsule unit contains all the features of the target part or the whole to complete the complete instance of the target to achieve SAR image target recognition. However, the accuracy of the above two methods for small and weak target recognition in SAR images is low, resulting in poor recognition effect.

When the above methods are used for SAR target image recognition, they only focus on improving the accuracy of image recognition, but are difficult to analyze the characteristics of weak targets in SAR images. There are many factors involved in target weakening, including sensor itself, target scattering characteristics, background environmental factors and the amount of information about the target's environment. Based on the research limitations of previous scholars, the research proposes to use machine vision to recognize small and weak targets in SAR images. The image recognition is achieved through visual image acquisition - data preprocessing - feature extraction under linear dimension reduction - key frame division of target features. This not only ensures the effective detection of weak targets, but also considers the linear nature of data features, which improves the accuracy of algorithm recognition to a certain extent. At the same time, experimental simulation is used to verify the effectiveness of the algorithm, in order to provide a new idea for weak target image recognition.

## II. METHOD FOR RECOGNIZING DIM AND SMALL TARGETS IN SAR IMAGE

### A. SAR Image Acquisition based on Machine Vision

High-quality SAR images can better reflects the characteristics of the recognition target. In order to facilitate subsequent recognition operations and reduce the computational burden of the recognition algorithm, the use of machine vision imaging technology to collect SAR images enables the recognition algorithm to have relatively high recognition efficiency and recognition accuracy [16].

In the SAR image acquisition, the camera CCD is mainly used to convert the SAR signal into an orderly SAR signal and collect the target information to be identified. Considering the size of the target to be measured, as well as the imaging area, depth of field, working distance and other project requirements, the XF-5MDT05X65 telecentric lens is selected to cooperate with the camera to collect the image of the target to be recognized. The use of cameras to capture images has very strict requirements on the light source. When collecting SAR images, according to specific needs, choose a lighting plan to obtain the best lighting effect and obtain high-quality images. Considering

that the recognition target is a small and weak target in SAR image, the forward illumination method is selected, and the LTLNC100-W linear light source is used to light it [17]. For detection targets with complex structures and relatively large targets, it is easy to have uneven features during the acquisition process. In order to ensure that the characteristics of different regions in the collected SAR images are uniform, multiple light sources are used to illuminate different regions to improve the SAR image. The gray value is uniform level. Multiple light sources mainly illuminate the target in the form of superposition of light fields, as shown in Fig. 1.

The top light source shown in the upper part of Fig. 1 is mainly aimed at the center area of the target, and the imaging of the edge area is achieved through the bottom light source. When two light sources are used at the same time, the image gray value can be relatively uniform and improved. The quality of SAR images lays the foundation for the subsequent identification of small and dim targets in SAR images [18].

### B. SAR Image Preprocessing

Hu's invariant moments can solve the problem of image lens distortion in the image acquisition process, and improve the authenticity of image geometric moments. Then by inverting the radial distortion model of the image, the pixel coordinates of the image are restored, and the mapping relationship between the image pixel coordinates is grayed out [19].

Before determining the geometric shape characteristics of the SAR image, it is necessary to clarify the  $\alpha + \beta$ -order geometric moments contained in the SAR image:

$$m_{\alpha\beta} = \sum_{x=1}^M \sum_{y=1}^N a^\alpha b^\beta f(a,b); \alpha, \beta = 0, 1, 2, \dots \quad (1)$$

According to the calculation result of the above formula, it is known that the SAR image is  $M \times N$ , and  $f(a,b)$  is described as the actual gray value of the image, where  $a$  and  $b$  respectively represent the coordinate axis of the pixel point [20].

Suppose that in the discrete state of rotation, the sixth-order moments of translation, scaling, and rotation of  $\alpha + \beta$ , which contains geometric features, are derived from the ideal result of no distortion of geometric moments in the above-mentioned pattern. However, compared with the ideal result, the real SAR image must have a certain degree of distortion. This part of the error will make the pixel coordinate  $(a,b)$  and the gray level  $f(a,b)$  in the image unable to accurately correspond, resulting in geometric deformation of the SAR image after conversion [21].

To this end, this paper corrects the  $\alpha + \beta$ -order geometric moment of the SAR image by reversing the resolution of the radial camera distortion model.

Generally, the radial distortion model is defined as:

$$\begin{cases} a = \bar{a} + (\bar{a} - a_0)(O_1 r^2 + O_2 r^4 + \dots) \\ b = \bar{b} + (\bar{b} - b_0)(O_1 r^2 + O_2 r^4 + \dots) \end{cases} \quad (2)$$

According to the calculation results of the above formula,  $(a,b)$  is described as the actual pixel coordinate value due to the influence of distortion,  $(\bar{a}, \bar{b})$  can describe the ideal pixel coordinate unit, and  $(a_0, b_0)$  is described as the global center pixel coordinate [22]. Use  $O_i$  to describe the distortion coefficient produced by the  $2i$ -level of the image, and set the distortion influence range to be related to the distance  $r$  from the target point to  $(a_0, b_0)$ , and then:

$$r^2 = (a - a_0)^2 + (b - b_0)^2 \quad (3)$$

It is concluded that the geometric deformation in the SAR image collected by machine vision can be described by the second-order radial distortion coefficient  $K_i$ , without considering the influence of higher-order distortion terms [23]. Therefore, the ideal pixel coordinate  $(\bar{a}, \bar{b})$  is inversely solved by the simplified distortion calculation model obtained:

$$\begin{cases} \bar{a} = \frac{a + a_0 O_1 r^2}{1 + O_1 r^2} \\ \bar{b} = \frac{b + b_0 O_1 r^2}{1 + O_1 r^2} \end{cases} \quad (4)$$

Fig. 1. SAR Image Imaging Scheme.

Bring the ideal pixel coordinates into equation (1) to obtain the corrected  $\alpha + \beta$  -order geometric moment of the SAR image:

$$m_{\alpha\beta} = \sum_{a=1}^M \sum_{b=1}^M \left( \frac{a + a_0 O_1 r^2}{1 + O_1 r^2} \right) \left( \frac{b + b_0 O_1 r^2}{1 + O_1 r^2} \right) \quad (5)$$

The combination of formula (5) and formula (3) can obtain the Hu stock moment with translation, zoom and rotation functions, which can increase the influence factor of radial distortion during the acquisition process, and reduce the deformation caused by the acquisition of SAR images by the hardware device. The problem of reduced recognition accuracy is discussed in [24].

### C. SAR Image Feature Extraction

Feature extraction is an important research problem in SAR image target recognition. Choosing appropriate features can improve target recognition rate and timeliness. The definition of feature extraction can be divided into a narrow sense and a broad sense. Feature extraction in a broad sense refers to a transformation that uses various mathematical transformation methods to improve the distribution of original features in the feature space without changing the internal structure and parameters. It can compress feature dimensions, remove redundant features, and reduce calculations. Effect: Use the feature space transformation method commonly used in pattern recognition for feature extraction [25]. PCA is a commonly used linear dimensionality reduction method in pattern recognition. PCA takes the maximum change direction of the sample in a multi-dimensional space (that is, the direction of maximum variance) as the criterion for judging whether the vector is a principal vector according to the position distribution of the sample in the space. Realize sample compression and feature extraction. Suppose the projection of vector  $x$  is  $y$ ,  $w$  is the projection matrix, and D can be represented by the inner product of  $x$  and  $w$ , namely:

$$y = [w, x] = \sum_{i=1}^n w_i x_i m_{\alpha\beta} = x^T x m_{\alpha\beta} \quad (6)$$

The purpose of PCA is to find an  $w$  that maximizes the value of variance  $E[y^2]$ ,  $E[y^2]$  can be expressed as:

$$E[y^2] = E[(w^T x)^2] = w^T E(xx^T)w = w^T C_x w \quad (7)$$

According to the theoretical knowledge of linear algebra, if the value of variance  $E[y^2]$  is the largest,  $E[y^2]$  can be expressed as:

$$E[y^2] = E[(w^T x)^2 \lambda_i] = w^T E(xx^T) \lambda_i = w^T C_x \lambda_i \quad (8)$$

$E[y^2]$ , which maximizes the value of  $w$  according to equation (8), is the eigenvector corresponding to the maximum eigenvalue of matrix  $C_x$ . for the component of eigenvalue  $\lambda_i$ , the variance of the principal component is also  $\lambda_i$ , which represents the dispersion degree of the sample in the direction

of the principal component. Data dimensionality reduction is realized by controlling the contribution  $n_i$  of principal component  $\lambda_i$  to the data, and  $n_i$  can be expressed by the following formula:

$$n_i = \frac{\lambda_i}{\lambda_1 + \lambda_2 + \dots + \lambda_p} \quad (9)$$

Generalized feature extraction methods basically have mature implementation algorithms, which have been widely used in SAR image target recognition. In a narrow sense, feature extraction is the process of extracting features that can reflect the essential attributes of SAR image targets [26].

### D. Key Frame Frequency Band Division of Target Feature in SAR Image

According to the above extracted SAR image features, the key frame frequency band of SAR image target features is divided. Firstly, the template matching method is used to construct the pixel feature point block matching structure model of SAR image target, as shown in Fig. 2.

In the block matching structure model shown in Fig. 2, the pixel frame is used to match the template of SAR image target. For the target image collected in the  $k$ -th subband, the key frame fusion method is used to construct the frequency band division model of SAR image target. According to the correlation between key frames, the mean square error function criterion (MSE) of SAR image target block fusion is obtained. The calculation formula is as follows:

$$MSE(e_1, e_2) = \sum_{x=1}^{N_1} \sum_{y=2}^{N_2} \frac{f_i(x, y) n_i}{f_{i-1}(x + e_1, y + e_2) (l_x, l_y)} \quad (10)$$

Where,  $N_1 \times N_2$  is the high-frequency band coding bandwidth distribution of SAR image target extracted by video codec framework,  $(l_x, l_y)$  is the block fusion vector of SAR image template, and  $f_i(x, y)$  and  $f_{i-1}(x + e_1, y + e_2)$  represent the pixels of current frame and reference frame of SAR image target, respectively.

1	2	6	7
3	5	8	13
4	9	12	14
10	11	15	16

Fig. 2. Block Matching Structure Model of SAR Image Target.

The image pixel spatial fusion matching technology is used to realize the statistical analysis of weak and small target information in SAR image at each scale, and the statistical feature  $G(c_1, c_2)$  is:

$$G(c_1, c_2) = \frac{z \cdot \text{Length}(C) \text{MSE}(e_1, e_2)}{h \cdot \text{Area}(\text{inside}(C))} + \theta_1 |I - c_1| + \theta_2 |I - c_2| \quad (11)$$

Where,  $c_1$  and  $c_2$  represent the gray coefficient and brightness coefficient of SAR image target respectively, and  $z$ ,  $h$ ,  $\theta_1$  and  $\theta_2$  represent the sparsity feature distribution function, both of which are constants greater than 0. The key frame detection method is used to analyze the key frames in the target statistical feature. The calculation formula of frequency band division  $T$  of pixel key frames is as follows:

$$T = \frac{G(c_1, c_2)}{L_{\text{low}} \times L} \sum_{l \in \text{Lowfreq. } l=1}^L (E_k'(l) - E_k(l))^2 \quad (12)$$

Where,  $E_k'$  is the low-frequency band part of the similarity information fusion feature component,  $E_k$  is the low-frequency band part of the SAR image target pixel space,  $L$  is the number of DCT blocks of the SAR image target in each frame, and  $L_{\text{low}}$  is the number of low-frequency bands.

#### E. Dim and Small Target Recognition in SAR Image based on Intra Coding Function

According to the above obtained pixel key frame frequency band division results, track and analyze the weak and small targets in SAR image, mainly by constructing the intra coding function to realize tracking, and identify the weak and small targets in SAR image according to the tracking results. Firstly, the trajectory tracking function of each frame in the weak and small target area of SAR image is constructed, which is defined as follows:

$$v(g) = Tu^{-1}(u(1) - u(c(x))) \quad (13)$$

Where,  $c(g)$  is the neighborhood gray function of SAR image target, and  $u(\cdot)$  represents the trajectory tracking target function in key frame coding mode, which meets  $u: [0, 1] \rightarrow [0, 1]$ . Thus, the information feature quantity of weak and small targets in SAR image is extracted, and the expression of association rule coefficient  $P(w)$  of targets in SAR image is obtained as follows:

$$F(w) = \frac{\exp\left\{-\delta \sum_{I \in C} T_I(w)\right\}}{\sum_w \exp\left\{-\delta \sum_{I \in C} T_I(w)\right\}} v(g) \quad (14)$$

Where,  $\sum_{I \in C} T_I(w)$  is the total number of boundary pixels of weak and small targets in SAR image, and  $I$  is the spatial region neighborhood group of weak and small targets in SAR image. Then, the weak and small target recognition model of SAR image is constructed based on the intra coding function:

$$J = \sum_{k=1}^n \phi_r d(X_k, v_i) + F(w) \sum_{k=1}^n \phi_r d(\varepsilon, v_i) \quad (15)$$

Where,  $\phi_r$  represents a neighborhood of the target image collected in the  $r$ -th subband;  $\varepsilon$  represents the low frequency band part of the average similarity information fusion feature component. According to the sparse prior representation results, the high-resolution prediction value at frame  $m$  ( $x, y$ ) of the weak target  $F_m(x, y)$  in the SAR image is obtained, and the weak target recognition results of the super-pixel SAR image are obtained to improve the detection and recognition ability of the weak target in the SAR image.

### III. SIMULATION EXPERIMENT ANALYSIS

In order to verify the effectiveness of the weak and small target recognition method in SAR image based on machine vision in practical application, a simulation experiment is carried out by Vega software. Radar works is an important module in Vega software. It can produce real-time imaging radar simulation images based on physical mechanism. The operating environment of imaging radar is a comprehensive simulation environment composed of natural background, cultural characteristics and dynamic targets. One of the characteristics of radar works is that radar works runs in the same synthetic environment as Vega and sensor vision, and jointly provides fully correlated output windows and radar images. Before using the radar works module. It is necessary to set Vega basic modules (system configuration, window, channel, object, observer, motion mode, environmental effect, etc.), and then set the parameters of radar works module (radar type, resolution, frequency band, polarization mode, RCS range, surface side length, motion compensation mode, speckle noise level, carrier speed, image output mode, etc.) are set. The interface of radar works module in the visualization window Lyn X of Vega software is shown in Fig. 3.

The experimental parameter settings are shown in Table I.

Radar types in radar works module include real-time beam ground mapping, multi killer beam sharpening and synthetic aperture radar. The research in this chapter is only aimed at SAR. Radarworks supports six radar operating bands: K, Ku, x, C, s and l, and four polarization modes: VV, VH, HV and HH. The specific imaging parameter plan of SAR is shown in Fig. 4.

In this paper, a total of 8 SAR images are obtained through MSTAR database, including 26 ship targets, which are weak and small targets. They are used as the experimental samples for simulation test. The SAR image is shown in Fig. 5.

First, the algorithm proposed in the study is tested and applied for verification, that is, the loss value results of the algorithm with or without dimension reduction processing are counted. The results are shown in Fig. 6. The results of Fig. 6 show that before the algorithm is improved, the curve changes between the test loss value and the training loss value have a large difference, and when the epoch exceeds 200, the error trend of the two curves is large. However, the loss trend of the algorithm after dimension reduction is basically unchanged, and the difference affected by the value of epoch is small, indicating that the data loss has been improved.

Then, in order to further verify the effectiveness of this method, the SAR image dim target recognition method proposed in this paper, the multi azimuth SAR image target recognition method based on depth learning proposed in reference [12] and the SAR image target recognition method

based on 2dpca scn regularization proposed in reference [13] are used to identify dim targets in SAR images, and the recognition accuracy of the three methods is verified, The result data is compared from two aspects of recognition rate and false detection rate, and the comparison results are shown in Fig. 7.

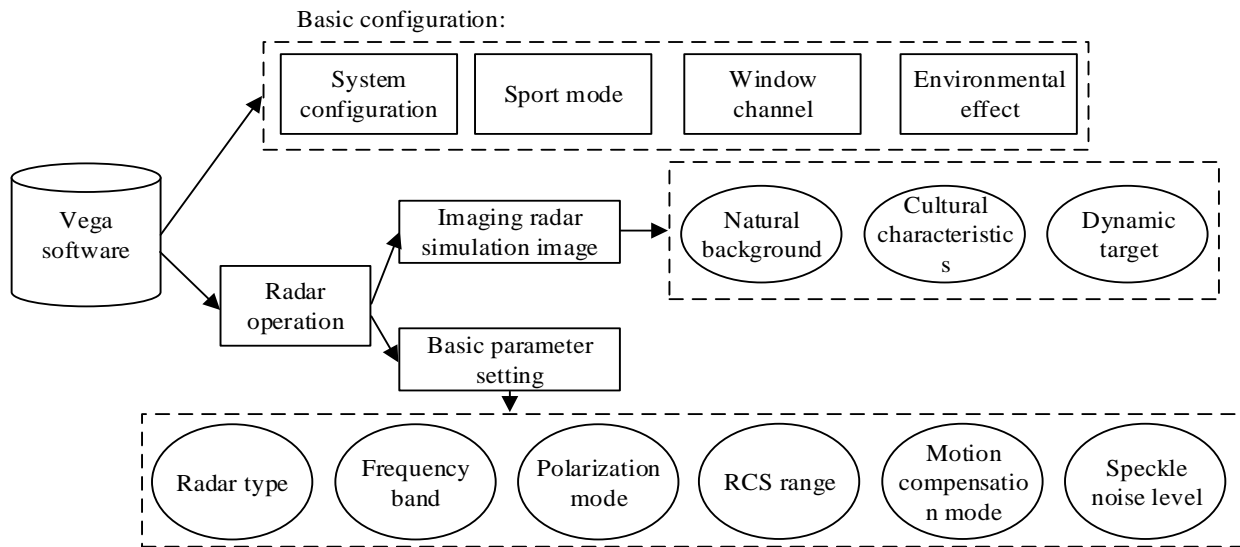

Fig. 3. Visual Operation Diagram of Vega Software.

TABLE I. EXPERIMENTAL PARAMETER SETTING

	Parameter
Frame frequency of visual sampling	12khz
Pixel set of image feature distribution	120
Identification interval	1.5ms

Fig. 4. Plan View of SAR Specific Imaging Parameters.

Fig. 5. SAR Image Samples.

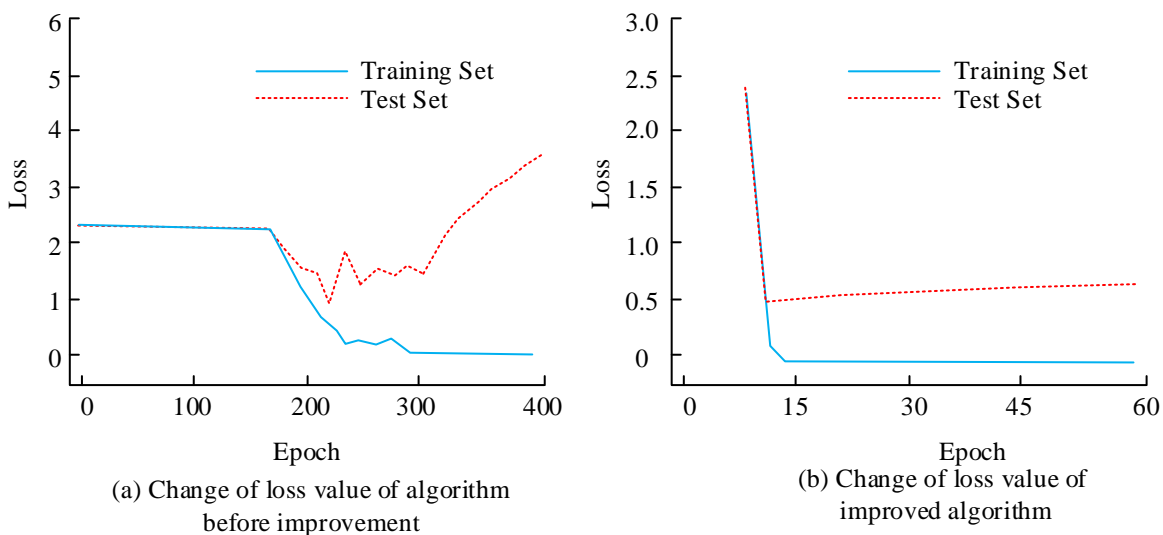

Fig. 6. Comparison Results of Weak and Small Target Recognition Accuracy in SAR Images of Three Methods.

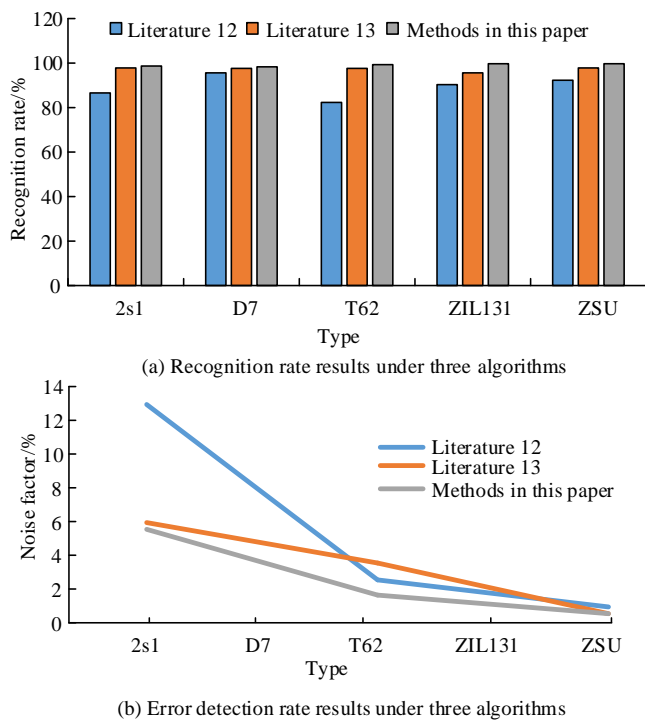

Fig. 7. Comparison Results of Recognition Rate and False Detection Rate.

Fig. 7 compares the algorithms from the two aspects of target recognition rate and false detection rate. It can be seen from Fig. 7(a) that the algorithms proposed in the study show good recognition rates in different types of test sets, with the recognition rates basically above 98%, and the average accuracy reaching 99%, far higher than the recognition rates shown in [12] and [13]. It can be seen from Fig. 7(b) that the false detection rate of the proposed algorithm is lower than that of the other two algorithms, with an average of less than 0.9%, while the average false detection rate of literature [12] and literature [13] is 6.9% and 2.1%. The above results show that the SAR image recognition method based on machine vision has good recognition rate and false detection rate, and the overall performance is good.

The above experimental results show that the algorithm proposed in this paper has a good recognition rate in weak target recognition, and effectively realizes the processing of image data information. Compare the research results with literature [27]. Literature [27] proposed to improve the accuracy of target recognition in SAR images by improving CFAR algorithm and operation algorithm. Its expansion and research of target data proposed that the dimension reduction of data considered the limited factors in target recognition process. The algorithm proposed in literature [27] has good inspection accuracy, which is similar to the algorithm results proposed in the research, which shows that the machine vision algorithm can improve the application performance of the algorithm.

#### IV. CONCLUSION

SAR is an active microwave imaging sensor. Its imaging principle is to install SAR on the radar platform, transmit electromagnetic waves regularly with the movement of the radar platform, and convert the received ground backscatter

signal into SAR image information. SAR uses pulse compression technology to obtain high resolution, can work all day and all weather, has multi band and multi polarization working mode, has certain penetration ability to soil, vegetation, clouds, etc., and can continuously image the observation area, so as to identify obstacles hidden in trees and forests. SAR is widely used in military, geographical and national economic issues. Automatic target recognition (ATR) of SAR image is a key research direction of SAR image interpretation. SAR image target recognition is the combination of SAR image manual interpretation and computer automatic recognition processing. Its working process can be described as: finding out the region of interest in SAR image, and then classifying each region of interest to determine its category. Therefore, this paper proposes a weak and small target recognition method based on machine vision in SAR image, and the effectiveness of this method is verified by simulation experiments. The algorithm proposed in the study considers the impact of linear characteristics on data when extracting image data information, so it uses principal component analysis to reduce the dimensions of data. Different from the improvement of previous improved algorithms in large dimensions, the study pays more attention to multi-dimensional consideration of data information.

In view of the limited ability and short time, in addition to making some progress, there are still many technical problems to be solved and improved, and the practical feasibility of the design scheme needs to be tested and corrected in the project. In order to obtain ideal detection results, there are still many aspects of technology to be studied.

1) This paper mainly studies the weak and small target recognition in SAR image under static background. In fact, the background may be dynamic. Further research is needed to realize the weak and small target recognition in SAR image under dynamic background.

2) In this paper, the target is not tracked after the recognition of weak and small targets in SAR images. Tracking the target is essential to realize the real-time monitoring or attack of the target. Further research is needed in this regard.

3) The engineering implementation of the weak and small target recognition method in SAR image studied in this paper needs further research, especially the setting of recognition method parameters. At present, the setting of parameters is mostly based on experience. After further research, artificial intelligence method can be used to set parameters.

# Information Classification Algorithm based on Project-based Learning Data-driven and Stochastic Grid

Xiaomei Qin, Wenlan Zhang\*

School of Education, Shaanxi Normal University, Xi'an Shaanxi 710062, China

**Abstract**—The adaptive partitioning algorithm of information set in simulation laboratory based on project-based learning data-driven and random grid is studied to effectively preprocess the information set and improve the adaptive partitioning effect of the information set. Using the improved fuzzy C-means clustering algorithm driven by project-based learning data, the fuzzy partition of information set in simulation laboratory is carried out to complete preprocessing of information set; The pre-processing information set space is roughly divided by the grid partitioning algorithm based on the data histogram; A random mesh generation algorithm based on uniformity is used to finely divide the coarse mesh cells; Taking the representative points of grid cells as the clustering center, the pre-processing information set is clustered by the density peak clustering algorithm to complete the adaptive partitioning of the information set in simulation laboratory. Experimental results show that this algorithm can effectively preprocess and adaptively partition the information set of simulation laboratory; For different dimension information sets, the evaluation index values of Rand index, Purity, standard mutual information, interval and Dunn index of the algorithm are all high, and the evaluation index values of compactness and Davidson's banding index are all low, so the algorithm has a high accuracy of adaptive partitioning of information sets.

**Keywords**—Adaptive partitioning; data driven; information set; project-based learning; random grid; simulation laboratory

## I. INTRODUCTION

Simulation experiments exist in the simulation laboratory, and the experimental environment, objects and equipment are provided by the simulation laboratory [1]. The simulation laboratory is a kind of simulation experiment environment supported by computer software and hardware technology and realized by software development tools [2]. By developing a series of simulation experiment components to simulate and reproduce the experimental environment, experimental equipment and experimental process, the experimenter can get rid of the bondage of the actual experimental conditions, feel the experimental information interactively, and realize the experimental process in a near real way under more convenient and fast conditions [3]. In the simulation laboratory, the experimental objects and equipment are either reproduced or simulated vividly, and the experimental process is completely controlled by the experimenter [4]. The simulation laboratory uses the powerful computing processing ability of the computer, with the help of graphics / images, simulation and virtual reality technologies, and has rich interface information,

friendly interaction ability and powerful data processing function. In addition, it is well compatible with various external devices, multi-media and Internet, forming a wonderful simulation experiment world. Project-based learning is a new teaching mode, which mainly focuses on the core concepts and principles of the discipline, and emphasizes that learners can solve practical problems, participate in some exploratory activities and other meaningful learning tasks [5]. In this process, learners learn independently and construct the meaning of the learned knowledge through practical operation, and apply it in the simulation laboratory. It can effectively improve learners' interest in simulation experiments and learning quality. Once the project-based learning simulation laboratory is established, it is a shared resource. Although it is not limited by the site and time, it greatly saves material resources, but it will generate a large number of project-based learning data and increase the difficulty of data search. The best way to solve this problem is to study a partitioning algorithm, which divides all information into several categories through the partitioning algorithm to facilitate information search. For example, Sutagundar, A., et al. proposed to use the function of sensor cloud and fog calculation to divide in a better way and minimize the delay problem. Using random forest classifier and genetic algorithm to divide the information and introducing Agent paradigm, not only saved the energy of physical sensor nodes, but also could quickly analyze and divide the information on the fog server. The results show that the algorithm has better effect in partition accuracy, delay and energy consumption [6]; Flisar, J., et al. used DBpedia ontology knowledge base to divide information. This algorithm can effectively divide information sets [7], but it cannot adapt to all data distribution well. The partitioning algorithm boundary is easily discarded as noise points, resulting in low partitioning accuracy. In order to achieve efficient, high-precision and high-speed information partition, Zheng, T., et al. designed a partitioning algorithm with low power consumption and high performance. In the training phase, a laser radar was simulated to collect the laser radar information, and then the designed neural network was trained using the information and the corresponding tags. In the testing phase, the new information was first divided into simple units using the range transformation watershed method, then, the trained neural network was used to divide the information. The average recall rate of the information partitioning of the algorithm was 0.965 and the average precision rate was 0.943 [8], but its complexity was high and it was difficult to meet the real-time requirements, and there were limitations in the processing of

\*Corresponding Author.

multidimensional information sets. The algorithm is susceptible to noise and the effect of boundary processing is not ideal. Data driving can be broadly defined as using the online or offline data of the system to realize various expected functions of the system such as data-based preprocessing, evaluation, scheduling, monitoring, diagnosis, decision-making and partitioning algorithm [9]. The random grid density clustering algorithm is insensitive to the input data and can adapt to different data distributions. Moreover, the algorithm has low complexity and fast calculation speed. It is suitable for partitioning different dimensional information and is not sensitive to the impact of noise [10].

In order to improve the precision of adaptive partitioning of information set, an adaptive partitioning algorithm of information set in simulation laboratory based on project-based learning data-driven and random grid is studied. First of all, the paper uses the fuzzy C-means clustering algorithm to carry out the fuzzy division of information, and preliminarily classifies the information. On this basis, the paper further uses the data histogram grid division algorithm to further roughly divide the information space, strengthen the classification of information, and avoid the problem of insufficient classification caused by the strong correlation between information; Then, the information is further clustered with the density peak clustering algorithm, which strengthens the aggregation of similar information and completes the information division. Finally, the experimental results show that this research method has the ability of adaptive partition, high precision of partition, and good overall application.

## II. ADAPTIVE PARTITIONING ALGORITHM OF INFORMATION SET IN SIMULATION LABORATORY

### A. Information Set Preprocessing of Simulation Laboratory by using the Improved Fuzzy C-means Clustering Algorithm based on Project-based Learning Data-driven

In the simulation laboratory, the project-based learning method is applied to carry out simulation experiments, so that students can explore the selected simulation experiment projects according to their own interests and learning needs. This learning activity emphasizes the students' hands-on operation and comprehensive application of various knowledge achievements, which can improve the learning quality of each simulation experiment project stage and make students more interested in the learning process of simulation experiments. In the process of simulation experiments using project-based learning, a large number of project-based learning data will be generated in the information of the simulation laboratory. In order to further improve the learning quality of each project stage in the simulation experiment process, it is necessary to self-adapt the project-based learning data in the information set of the simulation laboratory [11], accelerate the efficiency of students viewing the project-based learning data in the information set of the simulation laboratory, and facilitate the management of the information set of the simulation laboratory. In order to improve the adaptive partitioning effect of the project-based learning data in the information set of the simulation laboratory [12], it is necessary to obtain the fuzzy version of the project-based learning data in the original information set of the simulation laboratory (composed of

fuzzy attributes and fuzzy partitions). Fuzzy C-means clustering algorithm (FCM) generates fuzzy partitions by defining the value of fuzzy membership function ( $\mu$ ), which can solve the problem of hard boundary value caused by sharp partitions and protect the item learning data in the original information set. In addition, the fuzzy partition has obvious semantic relevance, which can well solve the inherent uncertainty of numerical data in the project-based learning data in the information set of the simulation laboratory.

An expression called fuzzy entropy is used as the cost function of the objective function of FCM algorithm. The definition of fuzzy entropy is roughly the same as that of information entropy, which is more suitable for fuzzy clustering analysis [13]. The function of fuzzy entropy can be defined as:

$$E(x) = - \sum_{i=1}^c \sum_{j=1}^n m_{ij} \mu_{ij} \ln m_{ij} \mu_{ij} \quad (1)$$

Wherein, the project-based learning data in the information set of simulation laboratory is  $x$ ; The fuzzy membership degree of the  $i$ -th attribute of the project-based learning data in the  $i$ -th information set of simulation laboratory is  $\mu_{ij}$ ;  $m$  is a weighted index, whose physical meaning is the fuzziness degree constant; The number of project-based learning data in the simulation laboratory information set is  $c$ ; The number of fuzzy attributes of the project-based learning data in the information set of the simulation laboratory is  $n$ .

The objective function of FCM can be defined as:

$$\begin{aligned} \min J(\mu, v) &= \sum_{i=1}^c \sum_{j=1}^n m_{ij} d_{ij}^2 \\ \text{s.t. } \sum_{i=1}^c \mu_{ij} &= 1 \end{aligned} \quad (2)$$

Where, the objective function of the sum of error squares is  $\min J(\mu, v)$ , and its value reflects the degree of compactness within the class under a certain difference definition [14]. The smaller the value of  $\min J(\mu, v)$  is, the tighter the clustering is; The clustering center of project-based learning data in the information set of simulation laboratory is  $v$ ; The Euclidean distance is  $d_{ij}^2$ .

Taking information entropy as the cost function, the minimum error square sum objective function of FCM algorithm is used to solve the problem of fuzzy partition of project-based learning data in the information set of simulation laboratory. The objective function of the improved FCM algorithm is:

$$L(\mu, v, \alpha) = \min J(\mu, v) + \alpha E(x) \quad (3)$$

Where the Lagrange multiplier is  $\alpha$ .

Substituting formula (1) and formula (2) in formula (3) can obtain:

$$L(\mu, v, \alpha) = \sum_{i=1}^c \sum_{j=1}^n m \mu_{ij} d_{ij}^2 - \sum_{i=1}^c \sum_{j=1}^n \alpha_j m \mu_{ij} \ln m \mu_{ij}^m \quad (4)$$

The Lagrange multiplier of the j-th attribute of the project-based learning data in the information set of the simulation laboratory is  $\alpha_j$ .

If  $\frac{\partial L}{\partial \mu_{ij}} = 0$  in formula (4), the following can be obtained:

$$\mu_{ij} = \exp\left(\frac{d_{ij}^2}{m \alpha_j} - \frac{1}{m}\right) \quad (5)$$

Since  $\sum_{i=1}^c \mu_{ij} = 1$ , the finishing formula (5) can be obtained:

$$\alpha_j = \frac{1}{\sum_{k=1}^c d_{kj}^2} \quad (6)$$

Wherein the attribute number of the project-based learning data in the information set of simulation laboratory is k.

Substituting formula (5) and formula (6) into formula (4), it can get:

$$L(\mu, v, \alpha) = \frac{m \mu_{ij}}{\sum_{k=1}^c d_{kj}^2} \quad (7)$$

It can be seen from formula (7) that in order to obtain the optimal value of  $\min J(\mu, v)$ , it is also necessary to process the project-based learning data in the information set of simulation laboratory [15]. By analyzing the physical meaning

of  $\frac{1}{\sum_{k=1}^c d_{kj}^2}$ , it can be seen that in fact it should be the distribution characteristics of project-based learning data in the information set of the simulation laboratory, representing a distribution characteristic of project-based learning data in the data space [16]. That is to say, taking information entropy as the cost function of the objective function, the objective function of the FCM algorithm needs to obtain the minimum value. In addition to the membership degree [17], the actual distribution characteristics of the project-based learning data in the data space in each cluster must also be considered. For the

convenience of later expression and calculation,  $\delta_j = \frac{1}{\sum_{k=1}^c d_{kj}^2}$  is specially used, that is,  $\delta_j$  is used to represent this distribution characteristic.

According to the above analysis, the objective function is adjusted accordingly to obtain:

$$J(\mu, v, \delta) = \sum_{i=1}^c \sum_{j=1}^n m \delta_j m \mu_{ij} d_{ij}^2$$

$$s.t. \sum_{i=1}^c \mu_{ij} = 1 \quad (8)$$

Then, according to the Lagrange function method, it can get:

$$J(\mu, v, \delta, \alpha) = \min \sum_{i=1}^c \sum_{j=1}^n m \delta_j m \mu_{ij} d_{ij}^2 + \sum_j \alpha_j \left(1 - \sum_{i=1}^c \mu_{ij}\right) \quad (9)$$

Let  $\frac{\partial L}{\partial v_i} = 0$ , then:

$$v_i = \frac{\sum_{j=1}^n m \delta_j m \mu_{ij} x_j}{\sum_{j=1}^n m \delta_j m \mu_{ij}} \quad (10)$$

Wherein the project-based learning data in the information set of simulation laboratory of the j-th attribute is  $x_j$ ; The clustering center of the project-based learning data in the i-th simulation laboratory information set is  $v_i$ .

Let  $\frac{\partial L}{\partial \mu_{ij}} = 0$ , then:

$$\mu_{ij} = \left(\frac{\alpha_j}{m \delta_j d_{ij}^2}\right)^{\frac{1}{m-1}} \quad (11)$$

The fuzzy partition of the project-based learning data in the information set of the simulation laboratory is generated by iteratively optimizing the objective function formula (8) by

updating the values of the membership function  $\mu_{ij}$  and the cluster center  $v_i$ .

In order to improve the fuzzy partition effect of the project-based learning data in the information set of the simulation laboratory, the fuzzy membership function of the FCM algorithm is determined by using the project-based learning data-driven method. The generation process of fuzzy partition of project-based learning data in the information set of simulation laboratory based on project-based learning data driven FCM is as follows:

It is defined that the project-based learning data in the information set of the simulation laboratory is  $D = \{x_1, x_2, \dots, x_c\}$ ,  $x_1, x_2, \dots, x_c$  is the data of different

numerical attributes, and D is the set of Boolean attributes and numerical attributes; The numeric attribute set is defined as  $A = \{q_1, q_2, \dots, q_r\}$ ; The fuzzy partition is defined as  $P = \{P_1, P_2, \dots, P_r\}$ , the fuzzy partition is the result of clustering the numerical attribute set A by FCM algorithm, and  $P_r = \{f_1, f_2, \dots, f_w\}$  is the fuzzy clustering partition set of the numerical attribute  $q_r$ .

The improved FCM algorithm is used to cluster the data in the numerical attribute set of project-based learning data in each information set of simulation laboratory, and then the corresponding fuzzy partition is obtained. Each numerical attribute data has its own unique fuzzy membership function. This process is repeated several times until the fuzzy partition of all numeric attribute values is obtained.

The whole preprocessing process of the project-based learning data in the information set of the simulation laboratory includes two steps: the first step is to generate fuzzy partitions for the values of the numerical attributes of the project-based learning data in each information set of the simulation laboratory through the improved FCM algorithm; The second step is to further process the project-based learning data in the original information set of simulation laboratory, and then obtain its fuzzy Version (composed of fuzzy attributes and fuzzy partitions). Pre definition: the Boolean attribute value

data set is  $B = \{b_1, b_2, \dots, b_{m'}\}$ ; The definition attribute set is

$\hat{A} = B \cup A$ . The fuzzy version generation process of the project-based learning data in the original information set of simulation laboratory is as follows: scan the project-based learning data in the original information set of simulation laboratory, classify the data attribute values, put the project-based learning data belonging to the Boolean attribute in  $B = \{b_1, b_2, \dots, b_{m'}\}$ , and put the project-based learning data

belonging to the numerical attribute in  $A = \{q_1, q_2, \dots, q_r\}$ , and then perform classification calculation. When an item learning data is a Boolean attribute, its fuzzy membership function  $\mu = 1$  or  $\mu = 0$  can easily divide the fuzzy partition, and then obtain the fuzzy version of the Boolean attribute value [18]; When a project-based learning data is a numerical attribute, each numerical attribute in the project-based learning data D can be converted into a fuzzy record according to the fuzzy partition  $P_r$ . Each fuzzy record contains the fuzzy attribute of the project-based learning data and the corresponding fuzzy membership function.

Thus, after selecting the data attributes in the first step, an intermediate version of the project-based learning data  $D_1$  in the information set of simulation laboratory can be generated; Then,  $D_1$  is updated iteratively [19], until all the attribute data in the attribute set  $\hat{A}$  are processed, and then the fuzzy version

of the original project-based learning data will be obtained. Therefore, by applying the FCM preprocessing technology driven by project-based learning data, any project-based learning data in the original information set of simulation laboratory with Boolean and numerical attributes can be transformed into a fuzzy set  $Q = \{\hat{x}_1, \hat{x}_2, \dots, \hat{x}_N\}$  with fuzzy records and fuzzy attributes.

### B. Adaptive Partitioning of Information Set in Simulation Laboratory based on Random Grid

1) *Random grid partitioning of information set in simulation laboratory*: The density peak clustering algorithm based on random grid partitioning is used to adaptively divide the fuzzy set  $Q = \{\hat{x}_1, \hat{x}_2, \dots, \hat{x}_N\}$  of the project-based learning data in the information set of simulation laboratory obtained in Section 2.1.

In order to better adapt to the best partitioning of the fuzzy sets of project-based learning data in different situations, first, the fuzzy sets of project-based learning data are roughly divided by the data histogram, and then the random grid is divided by the grid uniformity.

In order to adapt to the adaptive partitioning environment of fuzzy sets of project-based learning data, overcome the shortcomings of current grid division, and improve the efficiency and reliability of grid cell uniformity [20], firstly, rough partitioning of fuzzy sets of project-based learning data is carried out by using histograms. The steps are as follows:

Step 1: read in the fuzzy set  $Q = \{\hat{x}_1, \hat{x}_2, \dots, \hat{x}_N\}$  of the project-based learning data and normalize it. The normalization formula is:

$$\tilde{x} = \frac{\hat{x} - \hat{x}_{\min}}{\hat{x}_{\max} - \hat{x}_{\min}} \quad (12)$$

Wherein, the minimum and maximum values in the fuzzy set of project-based learning data in the information set of the simulation laboratory are  $\hat{x}_{\min}$  and  $\hat{x}_{\max}$ ; The item learning data in the fuzzy set after normalization processing is  $\tilde{x}$ .

Step 2: scan the fuzzy set Q of item learning data once, and draw the data histogram on each dimension within Q.

Step 3: according to the corresponding data histogram of each dimension, determine the high-density area and the low-density area of the fuzzy set of project-based learning data in the information set of the simulation laboratory, and divide the grid cells of the high-density area into fine ones and the grid cells of the low-density area into coarse ones. The specific operation is to use the number of data points contained in a grid to be equal to a given threshold  $\beta$  to divide, and the value of threshold  $\beta$  is related to the size of the entire fuzzy set Q.

Although the rough grid partitioning based on data histogram divides the regions with different densities of the project-based learning data fuzzy set in different scales, the

distribution of the project-based learning data of the grid cells with the same density may still be very different, so the boundary of the class cannot be effectively found and the class with arbitrary shape cannot be effectively found. Next, the random grid cells are finely divided by the uniformity index. The steps are as follows:

Step 1: calculate the uniformity of each random grid element obtained by rough division, and the formula is as follows:

$$S_l(u) = 1 - \left\{ \max \left( \frac{\phi_{i'}(u) - \eta_{i'}(u)}{\eta_{i'}(u)} \right) \right\} \quad (13)$$

Where  $\eta_{i'}(u)$  is used to represent the overall standard deviation of the  $i'$ -dimension of the random grid unit  $u$ ;  $\phi_{i'}(u)$  represents the standard deviation of the  $i'$ -dimensional project-based learning data samples of the random grid cell  $u$ , and  $S_l(u)$  represents the uniformity of the 1-dimensional grid cell  $u$ ;  $i' = 1, 2, \dots, l$ ; The closer the value of  $S_l(u)$  is to 1, the higher the uniformity of the random grid cells in the fuzzy set of item learning data is.

If  $S_l(u)$  satisfies the given threshold, i.e. it is a uniform mesh, it will not be divided; If the uniformity is less than the given threshold, i.e. non-uniform mesh, go to step 2.

Step 2: for each non-uniform grid, divide the random grid cell into two new grids of equal size along the worst dimension of  $S_l(u)$ , and judge whether the two new grids meet the stop criteria. If not, further divide them by the same method until the stop criteria are met.

Step 3: stop criteria. ① The grid element is a uniform grid; ② The grid cell is an empty grid; ③ The number of project-based learning data points in the grid is less than a given threshold.

2) Automatic selection of clustering center of information set in simulation laboratory: It is assumed that the center point of the grid unit  $u$  after random grid partitioning is  $g_u = (g_u^1, g_u^2, \dots, g_u^l)$  and  $u = 1, 2, \dots, K$ ;  $K$  is the total number of meshes; Where  $g_u$  represents the coordinate of the center point of the grid cell  $u$  in the 1-dimension, so the grid cell  $G_u$  can be expressed as:

$$G = \left[ \left( g_u^1 - \frac{side}{2}, g_u^1 + \frac{side}{2} \right), \left( g_u^2 - \frac{side}{2}, g_u^2 + \frac{side}{2} \right), \dots, \left( g_u^l - \frac{side}{2}, g_u^l + \frac{side}{2} \right) \right] \quad (14)$$

Wherein the side length of the grid cell is side.

The set of points in the grid cell  $u$  is  $Y = \{y_1, y_2, \dots, y_{h_u}\}$ , and  $h_u$  is the total number of project-based learning data points in the grid cell  $u$ , then the representative points of the grid cell are:

$$Y_u = \frac{\sum_{\hat{x}_i \in G_u} \hat{x}_i}{\lambda h_u} \quad (15)$$

Where the constant is  $\lambda$ ; The item learning data in the fuzzy set of the  $i$ -th information set in simulation laboratory after normalization is  $\hat{x}_i$ .

The local density of the grid cell's representative point  $Y_u$  is the number of project-based learning data points in the grid cell  $u$ , and the number of points in the grid cell  $u$  is:

$$h_u = \sum_{i=1}^N f'(\hat{x}_i, G_u) \quad (16)$$

Where, the function is  $f'(\cdot)$ ,  $f'(\hat{x}_i, G_u) = \begin{cases} 1 & g_u^l - \frac{side}{2} \leq \hat{x}_i < g_u^l + \frac{side}{2} \\ 0 & other \end{cases}$ , so the local density of

$Y_u$  is  $\rho_u = h_u$ .

The nearest distance between the grid cell's representative point  $Y_u$  and the higher density representative point  $Y_o$  is taken as the distance value of the grid cell's representative point  $Y_u$ , which is recorded as  $d'_u$ , and the formula is as follows:

$$d'_u = \min_{o: \rho_o > \rho_u} (D'_{ou}) \quad (17)$$

Wherein  $d'_u$  is the distance between the grid cell's representative point  $Y_u$  and the grid cell's representative point  $Y_o$ .

An improved adaptive method is designed to complete the automatic selection of cluster centers when the information set of simulation laboratory is adaptively divided, and the exact number of cluster centers is selected without manual intervention, so as to improve the accuracy of cluster center selection. The determination function is:

$$\rho_{C_i} - \sigma(\rho_i) \geq 0 \quad (18)$$

$$\frac{\xi_{C_i} - E'(\xi_i)}{2} \geq \varpi(\xi_i) \quad (19)$$

Wherein the density of the representative point  $C_i$  of the grid cell of the  $\hat{i}$ -th cluster center is  $\rho_{C_i}$ ; The mean value of the representative point density of all grid cells is  $\sigma(\rho_i)$ ; The minimum distance between the representative point of grid cell and the representative point of cluster center in the same cluster is  $\xi_{C_i}$ ; The expectation of all  $\xi_i$  is  $E'(\xi_i)$ . Formula (18) indicates that the local density value of the representative points of the grid cell is greater than the average value of the local density of all the representative points in the grid cell. This determination method satisfies the condition that the clustering centers of the project-based learning data in the information set of the simulation laboratory are often distributed in the relatively high density area in the density peak algorithm. The determination method of formula (19) satisfies the condition that the relative distance between the cluster centers is relatively long. Therefore, when the grid cell's representative point object meets the above two formula conditions, the grid cell's representative point is selected as the cluster center.

3) *Classification of project-based learning data points in the information set of simulation laboratory*: The nearest neighbor algorithm in the density peak clustering algorithm is used to classify the item learning data points in the fuzzy set of the remaining information set of simulation laboratory. After the selection of the representative points of the cluster center is completed, the remaining non cluster center representative points are classified into the class of the representative points closest to them and with local density greater than the point in  $\rho_i$ -descending order, and the data points in the project-based learning data in the fuzzy set of the original information set in simulation laboratory are assigned to the class of the representative points of the grid cells.

When the project-based learning data in the fuzzy set of the information set of the simulation laboratory is adaptively divided, the object of the boundary point is the representative point of the grid cell. Firstly, the set of boundary grid cell's representative points in the current cluster is calculated according to the density parameter  $\theta_c$ , to find the grid cell's representative points with the highest density in the boundary point set, and take the density of the representative points as the threshold to divide the core representative points and noise points, so as to reserve the representative points with the density greater than or equal to the density threshold as the core representative points in the cluster; The noise representative points in the current category that are smaller than the density threshold are removed, and the project-based learning data points in the grid where the noise representative points are located are also removed.

4) *Adaptive partitioning process of information set in simulation laboratory*: The specific steps of the adaptive partitioning of the information set in simulation laboratory are as follows:

Step 1: use the project-based learning data in Section 2.1 to drive FCM, preprocess the project-based learning data in the information set of the simulation laboratory, and obtain the fuzzy set of the project-based learning data;

Step 2: normalize the item learning data in the fuzzy set;

Step 3: roughly mesh the fuzzy set of project-based learning data according to the data histogram;

Step 4: perform random mesh refinement on the coarse divided mesh according to the uniformity to obtain several disjoint mesh elements;

Step 5: map the project-based learning data points to the corresponding grid cells, obtain the representative points of each grid cell from formulas (14) and (15), and count the number of project-based learning data points contained in each grid cell;

Step 6: calculate the local density  $\rho_u$  of the representative point  $Y_u$  of the grid cell according to formula (16);

Step 7: arrange the grid cell's representative points in reverse order according to  $\rho_i$ , and calculate the high density distance  $d'_u$  of each grid cell's representative point according to formula (17);

Step 8: adaptively determine the representative point of the cluster center by formula (18) and formula (19), classify it into the class of the grid representative point with the shortest distance and the local density greater than the point according to the p-descending order, and classify all data points in the project-based learning data in the original information set of simulation laboratory into the class of the grid representative point;

Step 9: calculate the boundary point set of the current class from the density parameter  $\theta_c$ , select the representative point with the highest density in the boundary point set, and use the density of the point as the threshold for dividing the core representative points and noise points of the current class, and eliminate the representative points in the current class that are smaller than the density threshold and other item learning data points in the grid cell where the representative points are located;

Step 10: return the final clustering result, that is, complete the adaptive partitioning of the simulation laboratory information set.

### III. EXPERIMENTAL ANALYSIS

Taking the sensor simulation laboratory of a university as the experimental object, the simulation laboratory realizes semi-automatic interactive control through animation, video or virtual reality technology. The structure of the simulation laboratory is shown in Fig. 1.

The simulation laboratory integrates the resources such as computers, instruments and equipment, tested points and their data into the network for sharing, and realizes the functions of

remote or remote testing, control, data acquisition, fault monitoring and on-site monitoring. The networked simulation instrument can obtain the measurement information from any place and at any time.

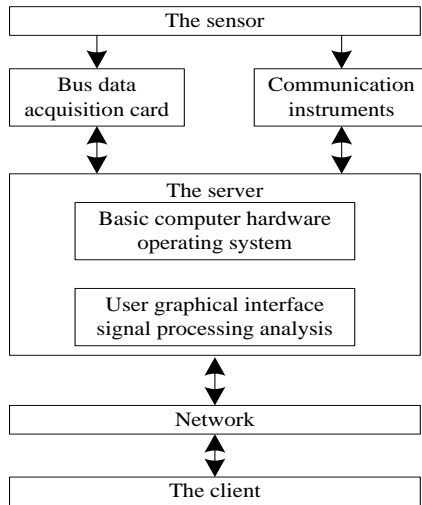

Fig. 1. Structure Diagram of Simulation Laboratory.

In the process of sensor simulation experiments in the project-based learning mode conducted by the university students in the simulation laboratory, tens of thousands of project-based learning data of different dimensions are generated, forming a high-dimensional information set in simulation laboratory and a low-dimensional information set in simulation experiment. Both information sets contain four types of project-based learning data, namely, carrier data, modulation data, excitation data and vibration data. Using the algorithm in this paper, the information sets of two simulation laboratories are divided adaptively, which proves that the algorithm in this paper has a good adaptive partitioning effect.

Taking the information set of low dimensional simulation experiment as an example, the information set is fuzzy partitioned by the algorithm in this paper, and the results of fuzzy partitioning are shown in Fig. 2.

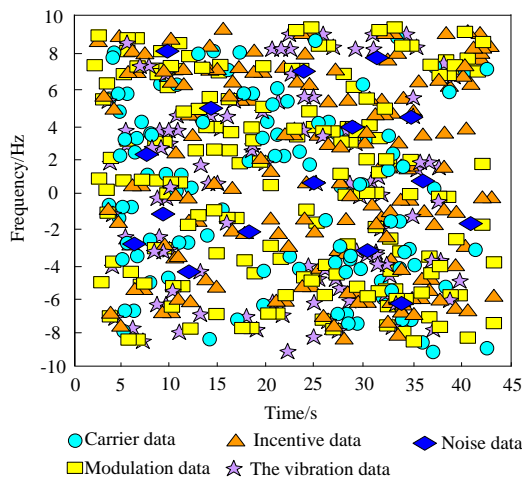

Fig. 2. Project-based Learning Data in the Original Low-dimensional Simulation Laboratory Information Set.

Using the quantitative attribute Income, the effect of fuzzy partition of the project-based learning data in the information of the low-dimensional simulation laboratory is analyzed. The value range of the Income attribute is  $Income \in [0, 9]$  (the unit is thousands). The number of fuzzy partitions of project-based learning data in the information set of simulation laboratory is defined as 4, which are "Around 1", "Around 3", "Around 5", "Around 7"; The analysis results of fuzzy partition effect of the algorithm in this paper are shown in Fig. 3.

According to Fig. 3, after preprocessing the project-based learning data in the original low-dimensional information set of simulation laboratory using the algorithm in this paper, the fuzzy partitions obtained are related to each other, that is, they have strong semantic relevance, and the curves of each fuzzy partition are relatively smooth, which solves the problem of "sharp partition", protects the boundary value, and thus protects the project-based learning data. The Income value corresponding to the highest value of the fuzzy membership degree of each fuzzy partition corresponds to the set Around value, which indicates that the algorithm in this paper has better fuzzy partition effect of the information set in simulation experiment, that is, better preprocessing effect of the information set.

The algorithm in this paper is used to adaptively partition the project-based learning data in the low-dimensional information set of simulation experiment. The adaptive partitioning results are shown in Fig. 4.

According to Fig. 4, the algorithm in this paper can effectively divide the project-based learning data in the information set of the simulation laboratory. After the rough division, the description between the project-based learning data is relatively fuzzy, and the noise points are not distinguished. After the random grid refinement, the boundary area between the project-based learning data is further refined, and the noise point data is effectively divided into isolated grid cells; According to the grid cells finely divided by random grid, four kinds of project-based learning data are obtained through clustering processing, and the noise data scattered outside the project-based learning data is better removed. Experimental results show that the proposed algorithm can effectively partition the information set of simulation laboratory.

Fig. 3. Fuzzy Partition Effect.

Fig. 4. Adaptive Partitioning Results of Project-based Learning Data in Low-dimensional Simulation Experiment Information Set.

The external evaluation indexes Rand index, Purity and normalized mutual information (NMI), internal evaluation indexes compactness (CP), separation (SP), and relative evaluation indexes including Davies bouldin index (DBI) and Dunn validity index (DVI) are used as evaluation indexes. The higher the value of Rand index is used to measure the

percentage of correct division, the higher the adaptive partitioning accuracy is, the value range is  $[0, 1]$ ; Purity represents the purity of the partitioning result, and the value range is  $[0\%, 100\%]$ . The higher the value is, the better the partitioning result is; NMI is to evaluate the consistency between the clustering results and the real categories through the mutual information between the clustering results and the real categories. The value is between  $[0, 1]$ . The higher the value is, the better the classification effect is; The lower CP means that the closer the clustering distance within the class is, the better the compactness is, and the value range is  $[0, 1]$ ; The higher the larger of SP is, the farther the cluster distance and the distance between clusters are, and the value range is  $[0, 1]$ ; The closer the intra class distance is, the farther the inter class distance is, the better the partitioning effect is; The smaller DBI means the smaller the intra class distance and the larger the inter class distance, the better the partitioning effect is, and the value range is  $[0, 1]$ ; The larger the DVI means the greater the distance between classes and the smaller the distance between classes, and the better the partitioning effect. The value range is  $[0, 1]$ ; The effect of adaptive partitioning of information set in simulation laboratory by the algorithm in this paper is analyzed. For high-dimensional information set of simulation experiment and low-dimensional information set of simulation experiment, the test results of adaptive partitioning of information set in simulation experiment by the algorithm in this paper are shown in Table I.

According to Table I, the RAND index of the algorithm in this paper is relatively high when adaptively dividing the information sets of low-dimensional and high-dimensional simulation laboratories, which is close to 1, indicating that the algorithm in this paper adaptively divides the information sets of different dimensions with high accuracy; The purity is also high, which is close to 100%, and the NMI is high, which is close to 1. This shows that the results of adaptive partitioning of different dimension information sets in this algorithm are very similar to the actual results; SP and DVI are both large, close to 1, CP and DBI are both small, and close to 0, which indicates that the algorithm in this paper adaptively partitions the information set with a large inter class distance and a small intra class distance, and has a better adaptive partitioning effect; Comprehensive analysis shows that for different dimension simulation laboratory information sets, the algorithm in this paper can accurately and adaptively partition the information sets, and has better adaptive partitioning effect of the information sets.

In order to further verify the performance of the algorithm studied in this paper, the algorithm in the literature [6] and the algorithm in the literature [7] introduced in the introduction are used as the comparison method to test the RAND index results in different dimensions, and the test is repeated five times. The results are shown in Table II.

It can be seen from Table II that under different dimensions, the lowest RAND index of this method is 0.96, close to 1. The RAND index of literature [6] method and literature [7] method is 0.89 and 0.88 respectively, which is far lower than that of this method. This shows that the adaptive division accuracy of this method is the highest and has certain applicability.

TABLE I. TEST RESULTS OF THE PROPOSED ALGORITHM FOR ADAPTIVE PARTITIONING OF SIMULATION EXPERIMENTAL INFORMATION SETS IN DIFFERENT DIMENSIONS

The evaluation index	Low-dimensional simulation laboratory information set	High dimensional simulation laboratory information set
Rand index	0.98	0.97
Purity	97.5%	98.2%
NMI	0.96	0.98
CP	0.01	0.02
SP	0.97	0.97
DBI	0.02	0.03
DVI	0.96	0.98

TABLE II. COMPARISON OF RAND INDEX RESULTS OF DIFFERENT METHODS IN DIFFERENT DIMENSIONS

group	Methods in this paper		Literature [6] Method		Literature [7] Method	
	Low-dimensional simulation laboratory information set	High dimensional simulation laboratory information set	Low-dimensional simulation laboratory information set	High dimensional simulation laboratory information set	Low-dimensional simulation laboratory information set	High dimensional simulation laboratory information set
1	0.98	0.97	0.89	0.87	0.88	0.81
2	0.99	0.96	0.88	0.88	0.81	0.75
3	0.97	0.98	0.85	0.84	0.86	0.78
4	0.98	0.97	0.86	0.85	0.72	0.79
5	0.99	0.97	0.89	0.82	0.83	0.82

#### IV. CONCLUSION

In order to deeply analyze the large amount of information generated by the simulation laboratory, it is necessary to accurately partition the information. An adaptive partition algorithm of simulation laboratory information set based on project-based learning data-driven and random grid is studied. The fuzzy C-means clustering algorithm in project-based learning data drive preliminarily divided the information, avoiding the constraints of time, space and other conditions. In the information space, the grid division algorithm of the data histogram was used to further divide the information, weakening the correlation between the data. Then, the grid division algorithm of the data histogram was used to cluster similar data, thus further enhancing the classification effect of the data. Through experiments, it is verified that the method can still maintain high classification accuracy in different dimensions, and has good application effect. However, there are still some shortcomings in this paper. Some heterogeneous data may appear in the data generated by the simulation laboratory, which is easy to be excluded as abnormal data when classifying. In future research, it is also necessary to strengthen the research on the classification and re clustering of heterogeneous data.

**Abstract**—The H1N1 virus, more commonly referred to as swine flu, is an illness that is extremely infectious and can in some cases be fatal. Because of this, the lives of many individuals have been taken. The disease can be transmitted from pigs to people. This research presents an artificial neural network (ANN) classifier for disease forecasting, as well as a technique for detecting people who are sick based on the geographic region in which they are found. The source codes for these two algorithms are provided below. These coordinates serve as the foundation for the GIS coordinates that are utilized in the method for assessing the extent to which the illness has spread. The ICMR and NCDC datasets were utilized in the study. They used Dynamic Boundary Location algorithm to detect swine flu affected person's location, the researchers discovered that the accuracy of the proposed classifier was 96 standard classifiers.

**Keywords**—Swine Flu; influenza; machine learning; GIS; classifiers; ANN; virus; algorithm

## I. INTRODUCTION

The swine flu is very contagious and spreads quickly. Potential vectors for the propagation of the disease include air and water. The influenza virus strain is also known as H1N1, which is another name for the H1N1 virus. Virus outbreaks might be global or local in scope, but they invariably end in the loss of human life. More than one country has reported human cases of influenza virus infection. It affects the respiratory system in humans. The WHO estimates that the influenza virus kills between 250,000 and 500,000 people each year, infecting 5 to 15% of the world's population and causing respiratory illnesses and other complications. Due to influenza-related infections, the United States of America loses between \$70 billion and \$170 billion. This has a huge impact on the economics of the rest of the globe [1] [2].

An artificial neural network (ANN)-based system for swine flu categorization and forecasting is suggested in this

paper. GIS coordinates of the person who is infected are acquired, and the second approach is used to locate the individual's position, as outlined in the article. The algorithm determines how far the sickness may spread, and it is constantly being updated as more people become ill. Confinement zones are defined by a set of boundaries generated by an algorithm. Machine learning may help in the analysis and exploration of patterns in a dataset. Machine learning-based classifiers take in data from training datasets and then use that data to make predictions.

Contribution from us: We present a cutting-edge technique that use machine learning to reliably forecast the incidence of swine flu in real time. Sore throats, chills, weariness, nausea, runny noses, body pains, coughs, and fevers are all common symptoms of swine flu infections. In certain cases, a cough may accompany these symptoms. ANN classifiers are able to predict whether or not a person has swine flu with a "Yes" or "No" answer, despite the difficulty of the task. We've come up with a supervised classifier as a solution to this problem. The classifier's output is sent into the proposed boundary algorithm, which generates the disease's sphere of influence's outer border.

## II. LITERATURE REVIEW

The Table I shows the Literature review of swine flu affected areas and the limitation of each paper. In this, we explain the main research gap of the latest significant state of the art approaches. Based on Table I we found research gaps in Machine learning for predicting location. We have seen various kinds of research papers and we conclude that most of the research papers are used Support vector machine, Random forest, Artificial Neural Network, NavieBayes, Ad boost and KNN. The main gap is quality of dataset is not used, accuracy and no comparisons are not made.

TABLE I. LITERATURE REVIEW

Ref No	Approach	Limitations	Gaps
[3]	Describe the use of social network plat forms to track people infected with swine flu based on their post on socialmedia like twitter	Social media data like twitter is not trustworthy	No detection method is discussed
[4]	Discusses the symptoms of the disease along with the hotspot detection	No comparisons made	No proper dataset And detection mechanism
[5]	Discusses 7 ML Classifiers for influenza detection	Dataset was randomly selected and consisted of 31268 records over a period from 2008-11	The number of records and time period both are less
[6]	Study and review of the Existing ML techniques that could detect other diseases were performed. The techniques like SVM, Random Forest, ANN, Naïve Bayes and Adaboost are used.	No classifier was proposed. Only standard base line algorithm were used	A quality dataset was not used for the study
[7]	Use deep learning neural network architecture for predicting thoracic disease using x-ray images. 50 layers Resnet architecture is used. Dynamic routing approach is used in between convolution layers	No classifier was Proposed. Data set is specific to application	Semi supervised approach not used in location information
[8]	Predicts and localization of disease done simultaneously. The use of deep learning classifier is used	Classifier is not explained	A quality dataset was not used for the study
[9]	Larger dataset are required to get better results	Gaussian distribution not used	No comparisons made
[10]	Images of pneumonia may be identified and pinpointed thanks to a model constructed using deep learning. Utilizes a segmentation-based approach.	Dataset was small	Average segmentation approach is used
[11]	It has been hypothesised that there exists a system that is capable of concurrently learning discriminative brain-region localization and sickness detection. The data came from ADNI, which was used as the source. The algorithm that will be used to categorise the data has been suggested.	The model works well for small patches	Classifier for prediction is not available
[12]	Proposed a classifier based on Random forest algorithm on individual symptoms of swine flu. Probability [reduction of each symptom was detected leading to the disease of swine flu	Dataset of GCI used is small	Did not perform proper clustering to detect hotspot of the disease
[13]	Create a concept for an artificial neural network (ANN) that loops back on itself. In comparative testing, the performance of the suggested method is Superior than that of SVM and Naïve Bayes.	Algorithm and dataset not described properly	No comparisons made
[14]	Discusses the methods like density estimation, Model based approaches to clustering	Detection process is not mentioned	A quality dataset was not used for the study
[15]	Uses Machine learning Techniques to find hotspot in fabrication technology. A combination of classification and feature extraction process are used	SVM kernel was used with an accuracy of 78%	Accuracy is low
[16]	Detects hotspot in online Forums. The proposed algorithm works in collaboration with K Means and SVM. The centre of the cluster is the hotspot	Apart from Detection. No proper algorithm is used to identify the hotspots	No comparisons made
[17]	Uses KNN algorithm to find hotspot with ML algorithm and	A proper dataset is not used	Segmentation of cluster region not specified
[18]	Applied a ML-based hotspot identification approach that includes lithography data into the development of the SM during the learning phase. True alarms are few and far between.	Did not detect all hotspots together	No comparisons made
[19]	Used feature extraction with tensor generation in CNN that has spatial relationships. The learning process is further extended to batch learning. Used gradient decent approach with low false alarm	Comparison Between different methods learning's not specified	A quality dataset was not used for the study

### III. METHODOLOGY

#### Dataset

The ICMR supplied the data utilized in the study. 122751 cases of swine flu have been verified and 115517 people have recovered from the infection, making up 1264443 entries in the database. Between 2015 and 2021, 7336 Americans lost their lives as a result of various causes around the country. Shown in Table II are the dataset's most essential features.

TABLE II. DATASET

No of Records	1264443
Positive Cases	122751
Recovered	115517
Deaths	137234
No of Training Records	1002200
No of Test Records	250551

The Table III shows the attributes that was selected for the study after performing a feature selection. 10 attributes were selected for the study.

TABLE III. ATTRIBUTES SELECTED FOR THE STUDY

Sl. No.	Symptoms/Attributes
1	Fever
2	Chills
3	Fatigue
4	Body/Muscle ache
5	Loss of Appetite
6	Headache
7	Dry Cough
8	Sore throat
9	Running/stuffy nose
10	Age

The Proposed System architecture of the system is displayed in Fig. 1. The ICMR and NCDC data sets supply the information that is used in the recommended technique. The recommended approach can determine whether or not a person is sick, and hence at danger, when GIS coordinates are used to find a likely hotspot for the Swine Flu. The purpose of this research is to identify cases of swine flu using the application of machine learning. This goal has been accomplished as a direct consequence of implementing the classifier that was recommended [30].

For the purpose of anticipating Swine Flu symptoms, this system makes use of an implementation that is based on artificial neural networks. Even though there are 10 separate tones being sent into the network in Fig. 2, it only produces two distinct tones. The missing layer, which is composed of two hidden levels, has had a total of eight nodes removed from it. The artificial neural network (ANN) is a type of classifier that sorts incoming data by employing a multilayer feed forward back propagation method. The technique of modeling

makes use of the activation function that is associated with the sigmoid function. Using this procedure, swine flu can be identified in one of two different ways: Training and tests are included in this package. Each individual neural network must be trained on all ten characteristics that comprise a record in order to function properly. Please be aware that this is an activity that will be logged.

The Table IV show the parameters of Artificial Neural Network(ANN), it takes 10 input nodes, two output nodes , two hidden layer( each hidden layer contain four nodes)and used backpropagation method. The Activation function is Sigmoid function.

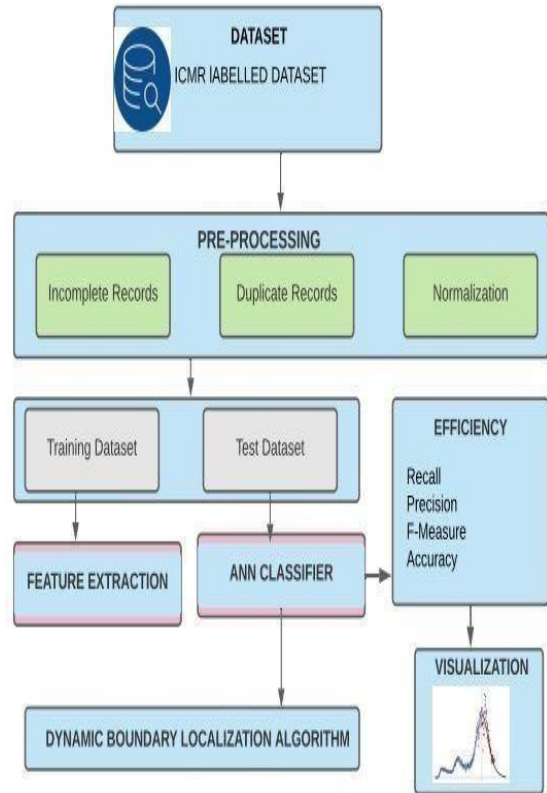

Fig. 1. Proposed System Architecture.

TABLE IV. PARAMETERS OF THE ANN

Number of input nodes	10
Number of output nodes	2
Number of hidden layers	2
Number of nodes in hidden layer	8
Paradigm	Multilayer Feed-Forward Network (Backpropagation)
Weight updating rule	Delta weight
Activation function	Sigmoid function

Fig. 2. Flow of ANN using Selected Features.

The Fig. 3 describes the how Artificial Neural Network(ANN) works.

If you go through the data set, you will learn about the classes. To categorise all records, this process is repeated as many times as necessary. Errors in training will be propagated backward and new penalties or delta error values will be applied if necessary. The figure shows how the algorithm for making predictions works in a visual way. Next, a random weight is supplied to each node in the artificial neural network to "initialize" it. Every node has been given a certain threshold. Calculating how much of a miscalculation occurred begins by determining the difference between projected and actual data. Efforts are taken to minimize the chance of making a mistake. An optimization condition must be met in order for checks to be performed. The output error can also be affected by errors that occur in the hidden layers. At every step of this procedure, it is necessary to use the gradient Descent function. It is important to meet the erroneous criteria in order to generate an accurate forecast for swine flu. A total of four data sets are available for training [31].

Fig. 3. Flowchart of the Proposed Algorithm.

### Proposed Predicting Algorithm

#### Algorithm Prediction Detecting Diseases Formation

L4  $W_i \leftarrow$  Random

L5  $Node \leftarrow$  Threshold

L6  $f = Output\ Expected - Output\ Observed$

L7  $f_1 =$  Set of  $f \leftarrow$  minimize error

L8 Repeat L6 to L7 until optimization criteria

L9 End

L10  $Output\ Error \leftarrow \frac{1}{n} \sum_{i=1}^n (Expected - Output)^2$

L11 Hidden error  $\leftarrow$  Back Propagation method

L12 If Error criteria checking  $\rightarrow$  False Go to Line 10

L13 Repeat Until Expected = Output

L14 }

L15 End

For the suggested classifier, a random seed is used to initialize the ANN network's weights. Each node has its unique threshold. The node is activated when the reset threshold is met. The total number of mistakes in each node's output is calculated. By using it, we may get an accurate estimate of the variance between what was expected and what was really achieved, which is known as the error value. Each

node in the network calculates the ANN's error. By utilizing the new value, we may achieve a reduced level of node-level inaccuracy. Errors should be kept to a minimum as the primary goal of the project. To determine hidden layer errors, the output error is first decreased.

The gradient descent function has been used to lower the total amount of error in our calculations. It is still possible for the gradient descent process to reach a point of convergence even while the data cannot be separated linearly. Each time an incorrect number is rectified, a little amount is deducted from the overall sum. When an error number rises, the error value that was there just before the rise is displayed on the screen as well. Because of this, the function is referred to as "decent." The gradient descent technique can be used to break out of a loop if an error continues to occur [32].

For starters, only 20% of the data is really used for training. Our second iteration uses the first 20% of data, as well as the remaining 20% of data. More than half of the records are still in use in the third iteration. We were able to use about 80% of the data in the final dataset. Approximately 20% of the entries in the database are taken from which a sample of the full database may be utilized for testing. At the conclusion of each cycle, the accuracy or detection rate is shown in the Table V. With a 96 percent accuracy rate, the classifier is clearly doing its job. For your perusal, Table 5 displays the matrix of perplexity. There were 39450 positive test findings, and 1861 27 negative test results were uncovered in this investigation. The values are shown in their proper

Training Data Accuracy Rate

TABLE V. SYSTEM ACCURACY RATE

Iteration	Upper value for -ve case	Lower value for +ve case	Required Threshold value	Number of Records per iteration	No. of correctly classified patterns	Accuracy for each partition

Fig. 7. Working of Proposed Dynamic Boundary Localization Algorithm.

This Fig. 7 article provides an explanation of the Dynamic Boundary Localization technique. To phrase it in a different way: Imagine that X is the location where the first case of the flu or swine flu was found. As a point of reference, Google Maps is utilized, and the value of the country/region/Distance area is selected based on the location of the point X. Let's say D represents a distance of 50 kilometers in this scenario. From point X, mark the locations of points B1, B2, and B3 at a distance of D/2 in the north, south, and east directions, respectively. This location houses the outermost cluster. The maximal possible spread of the illness. Find the data point that is geographically closest to each point (x1, x2, etc.) that makes up the triangulated region so that you may create tiny clusters or joint clusters. If a data point is located outside of the region that was triangulated, this indicates that the disease has spread to a location that is not included in the triangulation. In this stage, the algorithm will need to dynamically expand the area. This is accomplished by looking for the boundary point that is geographically closest to the data point that is located outside the boundary. The boundary points X3 and B3 are the ones that are located the most closely to one another. It is necessary to repeat the stages from B3 to B4 to B5 to B6 once more. The algorithm first creates a zone in the shape of a

triangle, and then it expands to the north, south, and east sides of the triangle. If it grows on just three of the globes or Earth's sides, then it will encompass all of the other four sides [35].

V. RESULTS AND DISCUSSION

The suggested classifier has a consistent upward trend over the length of the learning process. According to Table IV, there was a success rate of 78% in the first 20% of data that were looked at. The right classification was applied to a total of 197252 items. The accuracy of the classifier increases from 80 percent after the third iteration to 84 percent after the fourth iteration, and then to 92 percent after the fifth iteration. We can ensure that our classifiers continue to improve as we increase the number of iterations that we feed into them as well as the quantity of training data that we feed into them by utilizing the techniques of machine learning [36]. This is an easy assignment to do because the ANN classifier that was explained has an accuracy rate of 96 percent. Fig. 4 provides a visual representation of the ANN (artificial neural network) prediction classifier detection rate. Table V presents the matrix of ambiguity for your review and consideration. In the database, there are a total of 39450 positive entries in addition to 186127 negative records [37].

The Table VIII show the comparison of results with existing literature i.e., it will be compared with Machine learning algorithms and get the accuracy results. The Dynamic Boundary Location Algorithm (DBLA) and finally we get the 96 accuracy.

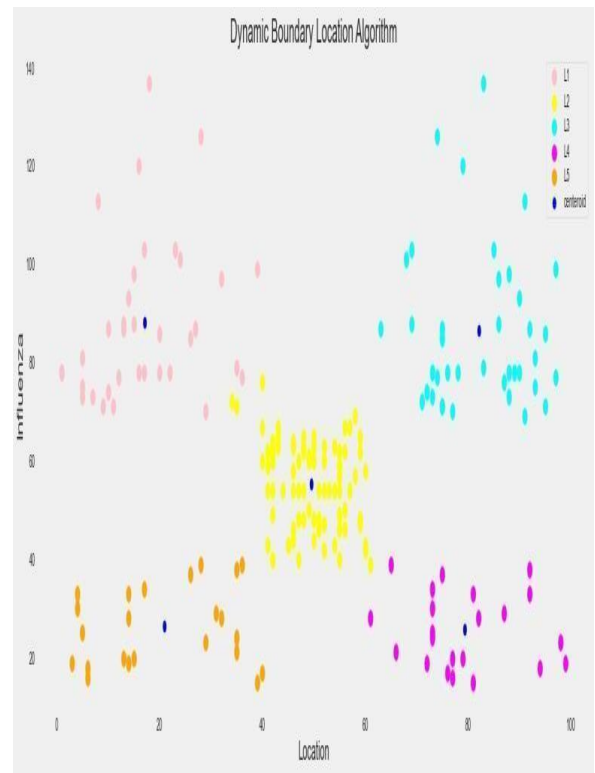

Fig. 8. Results of the Second Technique was Provided for Dynamic Border Localization.

Fig. 9. The Output from Both the Existing Standard Literature and the GIS Tools.

Fig. 10. Localization of Confirmed Swine Flu Cases using Proposed Dynamic Boundary Location Algorithm.

The total number of genuine positives was 9217, whereas the number of erroneous negatives was 10184. The method for predicting the spread of swine flu has an accuracy rate of 96 percent overall. According to the findings, the accuracy of the classifier is measured at 17.4 percent recall. According to the findings of the test, the accuracy was found to be 79.48 percent, and the F-measure was found to be 44.84 percent. The results of the experiments are presented in Table VII, which also serves as a comparison of the experimental outcomes of the recommended classifier with previously published research. The ANN classification algorithm that has been presented in this article cannot be compared in any way to the approaches that have been discussed in the previous paragraphs. Fig. 8 illustrates the results of the second technique that was provided for dynamic border localization. This method was proposed before [38]. The Fig. 9 and Fig. 10 show the output from both the existing standard literature and the GIS tools that are now available thanks to the method's superior area localization accuracy and GIS co-ordinate precision.

## VI. CONCLUSIONS

The use of localization for predictive purposes about swine flu is covered in great detail in the study. Both prediction and location may be accomplished with the use of algorithms. A back propagation classifier based on an artificial neural network should be considered as a first step. The Indian

Council of Medical Research (ICMR) is the source of the data that feeds the algorithm. The classification process is broken up into two distinct steps by the classifiers. In the first step, instances of swine flu are identified, and in the second stage, positive cases are localized with the use of an algorithm known as the dynamic boundary. The locations in the world where this extremely contagious virus is spreading may be easily identified, and containment zones may be set up in regions where the prevalence of the disease is high. Eighty percent of the data in the dataset is utilized in the training of the classifier. During the testing phase, there are an infinite number of potential combinations and permutations that might result in a record testing positive or negative. In order to assess the level of accuracy achieved by the methodology, a wide variety of well-established machine learning approaches were used as benchmarks. The recommended classifier has a detection rate that was significantly higher than the detection rates of the typical classifiers that are currently being utilized. The likelihood that the algorithm has gotten the answer correct is 96 percent. In order to evaluate the precision of the dynamic boundary method, many different GIS tools were utilized. It has been demonstrated that the localization accuracy achieved using the dynamic boundary technique is on par with that achieved using more conventional GIS tools.

# Taxation Transformation under the Influence of Industry 4.0

Pavel Victorovich StroeV<sup>1</sup>, Rafael Valiakhmetovich Fattakhov<sup>2</sup>, Olga Vladimirovna Pivovarov<sup>3</sup>, Sergey Leonidovich Orlov<sup>4</sup>, Alena Stanislavovna Advokatova<sup>5</sup>

Financial University under the Government of the Russian Federation, Moscow, Russia<sup>1, 2, 3, 4, 5</sup>

**Abstract**—Today the growing level of automation and the new concept of online technologies are transforming the traditional industry. Value is generated with the help of Industry 4.0 technologies that not only increase the efficiency and agility of supply chains, create new products and offer new ways of connecting businesses and consumers but also have a major impact on the traditional tax system. This study aims at determining changes in the modern industrial economy and substantiating possible directions for transforming the tax system to adapt it to the requirements of Industry 4.0. The objective is to identify the relationship between the digitalization of the economy, the use of blockchain technologies, robotics, automation, M2M technologies offered by Industry 4.0, and taxation. The article demonstrates how these technologies influence taxes and proposes measures to address possible tax issues. The authors of the article have concluded that the reasons (and goals) for transforming the current tax system as a result of the development of Industry 4.0 technologies are as follows: 1) to increase or stabilize tax revenues to compensate for tax losses and finance new education needs; 2) to introduce innovations for the development of Industry 4.0 and further digitalization of the economy; 3) to create an automatic tax administration system.

**Keywords**—Digitalization; cryptocurrency; blockchain; robotics; automation; innovation; tax

## I. INTRODUCTION

New technologies, principles, and approaches to production, automation, and robotics are influencing the level of employment [1], the amount of operating costs [2, 3], tax revenues [4], and the traditional taxation system as a whole [5].

The existing taxation system is built on the principles that have not changed over a long time, namely: fairness (all people pay taxes in proportion to their income and capabilities); certainty (the elements and overall organization of tax payments are clear); convenience (the mechanism for paying taxes should be as easy as possible for taxpayers); efficiency (the cost of administering taxes should be minimum) [6].

In our opinion, technological progress and globalization determine other priorities for socio-economic development, the specifics of production and sources of income [7], transforming the structure of tax systems, the organization of tax collection, shifting emphasis from one taxation object to another, expanding tax bases or reducing benefits [8, 9]. Thus, we want to answer the following questions: what are the consequences of the modern taxation system for introducing

Industry 4.0 and the digitalization of the economy as a whole? How will the introduction of Industry 4.0 affect the taxation system's organization? How will Industry 4.0 technologies affect the tax structure and will new taxes be introduced?

## Literature Overview

Different scholars are trying to answer these questions about the impact of the changes brought by Industry 4.0 on the development indicators of enterprises, households, and countries as a whole. Within the framework of studies [10, 11], an attempt was made to determine the potential tax implications for enterprises using new technologies and approaches to their production. The impact of Industry 4.0 on the tax strategy is analyzed in [12, 13]. Some studies conducted by specialists in taxation [14, 15] dwell on tax evasion in the digital economy. Recently, more and more scientific works have been prepared on the relationship between new technologies (such as robotics and the blockchain system) and taxes [15, 16]. Much attention is paid to electronic tax administration and control [17, 18].

Since digitalization, robotics, M2M technologies, and blockchain lead to significant changes both in national tax systems and in international taxation [19], some scholars offer several approaches to solving emerging problems: 1) to apply taxation to new technologies and their products and applications, for example, to extend traditional taxes to such objects as personal data, cryptocurrencies, and imputed income of robots [20]; 2) to replace digital transactions and shortfalls in revenues by traditional taxation objects in the form of tangible assets and/or increase tax pressure and the degree of progressive taxes already levied on such objects [21]; 3) to build a new tax system and transfer it to automatic taxation using blockchain technologies [22].

We believe that participants in global economic processes are entering a new technological era, therefore the development of Industry 4.0 does not affect individual spheres but rather concerns the whole world community.

Thus, the article aims at studying changes in the modern industrial economy and substantiating possible directions for transforming the tax system for its adaptation in the context of the development of Industry 4.0.

The research tasks are as follows:

- To reveal the main technological changes as a result of the development of Industry 4.0 and the digitalization of the economy as a whole;

- To identify economic changes in connection with the development of Industry 4.0;
- To analyze the consequences for the tax sphere, the impact on taxation objects and tax bases, which will cause economic changes in connection with the development of Industry 4.0;
- To propose measures in the tax sphere that need to be taken to solve the problems that arise.

The research hypothesis is as follows: economic changes as a result of the development of Industry 4.0 technologies affect (and will affect) the tax policy and tax system, which requires the transformation of the modern tax system and the use of both traditional and innovative tax tools.

## II. METHODS

To solve the above-mentioned tasks, we used theoretical and empirical methods of research, tested in scientific research devoted to the economic and information spheres of social development. Among the theoretical methods, we include the collection and analysis of scientific sources on the topic [23]. We used empirical research methods (expert survey) to collect quantitative data [24] with mathematical processing of results using the Kendall concordance coefficient (W) [25].

The study was conducted in three stages from February to April 2022 at the Financial University under the Government of the Russian Federation.

At the first stage of the study, we examined scientific and analytical works on the research topic.

The analysis of the relevant publications allowed us to identify the main technological changes as a result of the development of Industry 4.0: the digitalization of the economy, the use of blockchain technologies, robotics, automation, M2M technologies (machine-to-machine, data transfer directly between devices).

At the second stage of the study, we communicated online with the experts. The expert survey was carried out in Russian via e-mail.

The e-mails containing the above-mentioned questions were sent to 68 respondents, including 39 employees of high-tech companies from the top 15 of the Techuspekh 2020, 14 employees of analytical and information technology departments of the central office of the Federal Taxation Service of Russia, and 15 lecturers of the Financial University under the Government of the Russian Federation. The respondents were asked to justify their answers in a free form. As a result, we received answers from 61 experts.

In connection with the research topic, the experts were asked the following questions:

- 1) What are the consequences of digitalization, the use of blockchain technologies, robotics, automation, and M2M technologies for the economy and the tax sphere?
- 2) What measures should be taken in the field of taxation to offset the negative (positive) consequences of this influence?

All the respondents were informed about the purpose of the survey and that the authors planned to publish its results in a generalized form.

When receiving the answers, we asked the experts, depending on the significance of emerging problems, to arrange the consequences for the economy and the tax sphere on a scale of order, and to assign points. After that, each consequence of the economy and the tax sphere was ranked according to the points assigned by the experts.

For a more objective analysis of the data obtained during the expert survey, the consistency of expert opinions was measured through the mathematical processing of the results using the Kendall coefficient of concordance (W):

$$W = 12S/n^2(m^3-m),$$

where S is the sum of the squared deviations of all the ranks of each consequence for the economy and the tax sphere from the average value; n is the number of experts; m is the number of estimated economic/tax consequences.

Then the information obtained during the expert survey was processed to determine the impact of each consequence on the economy and the tax sphere, as well as to build a rank transformation matrix and calculate the arithmetic average of impacts for each consequence of the development of Industry 4.0 for the economy and the tax sphere, respectively.

The final impacts determine the significance of the consequences of Industry 4.0 for the economy and the tax sphere from the viewpoint of experts. All calculations were carried out using Excel 365 programs and the Stattech online service (<https://stattech.ru/>).

## III. RESULTS

The analysis of the expert survey has revealed the main consequences in the economy and taxation due to the introduction of new technologies and forms of doing business (Table I).

TABLE I. THE KEY ECONOMIC AND TAX CONSEQUENCES OF INDUSTRY 4.0

Changes	Consequences					
	Economy	Ranking	Impact	Taxation	Ranking	Impact
Digitalization	Increasing the purchase and sale of digital services and digitized goods	1	0.27	Reducing tax revenues on the consumption of traditional goods and services	1	0.36
	Protecting personal and corporate data	3	0.14	Protecting personal and corporate data	4	0.14
	Growing transnational stateless income	4	0.11	Erasing the tax base when taxing profits upon concluding agreements with citizens of other countries without their physical presence in these countries	3	0.16

Use of blockchain technology	Transparent operations	6	0.05	Possibility of a fundamental change in the tax administration system based on the automatic calculation of tax liabilities and their withdrawal from accounts	5	0.02
	Free access to transaction information	8	0.02			
	Minimizing the risk of losing documents	9	0.03			
Robotics, automation, M2M	Reducing the number of low-skill jobs	7	0.04	The need to compensate for the losses of social taxes that are currently paid by those employed in production	2	0.32
	Lack of personnel	5	0.10			
	Growing unemployment and income inequality	2	0.24			

Note: based on the results of an expert survey

According to the calculation of the Kendall's coefficient of concordance (W) ( $W = 0.69$ ), it can be argued that the expert opinions coincide since the value of  $W > 0.5$  indicates the objectivity of the survey results. This circumstance allows determining the impact of economic and tax consequences in connection with the development of Industry 4.0.

In conformity with the calculation results, digitalization has the greatest impact on the economy and taxation. Thus, the most important consequences are an increase in the purchase and sale of digital services and digitized goods (0.27), and the associated decrease in tax revenues on the consumption of traditional goods and services (0.36).

The robotics and automation of production which increase unemployment and income inequality (0.24) are no less important. As a result, it is necessary to compensate for losses in social taxes that are paid by those employed in production (0.32).

TABLE II. THE MEASURES TO BE TAKEN TO SOLVE TAX PROBLEMS

Changes	Consequences for the tax sphere	Measures to be taken to solve problems
Digitalization	Reducing the amount of tax revenues on the consumption of traditional goods and services	Introduction of a tax on digital goods and services or expansion of the existing tax base
	Protection of personal and corporate data	Introduction of a tax on the collection and use of personal data for Big Data owners
	Erosion of the tax base when taxing profits upon concluding agreements with citizens of other countries without their physical presence in these countries	Alignment of national legal norms with international tax legislation by improving transfer pricing for digital goods and services
Use of blockchain technologies	Possibility of a fundamental change in the tax administration system based on the automatic calculation of tax liabilities and their withdrawal from accounts	Development of a plan, tools and methods for implementing blockchain technologies for automated tax collection and unification of tax administration
Robotics, automation, M2M	Need to compensate for the losses of social taxes that are currently paid by those employed in production	Determining the possibilities of introducing new compensatory forms of taxes (tax on robots, universal basic dividend, etc.). Introduction of a tax credit for education and retraining loans

Note: based on the results of an expert survey

Further analysis of the expert survey determines the appropriate tax measures that need to be taken in order to

overcome possible consequences for the tax sphere in connection with the development of Industry 4.0 (Table II).

#### IV. DISCUSSION

As our analysis showed, the main technological changes caused by the development of Industry 4.0 are the digitalization of the economy, the use of blockchain technologies, robotics, automation, and M2M technologies (machine-to-machine, data transfer directly between devices), which has a direct impact on changes in the tax sphere.

The digitalization of the economy will manifest itself in various aspects of business sectors, which will affect the development and adaptation of the tax system both in the context of international cooperation and in the context of the development of taxation systems at the national level. Let us consider the typical examples faced in practice by taxation specialists and researchers. We presented all the examples taking into account the rank of the consequences for the economy and taxation received as a result of our study.

##### A. Digital Goods and Services and their Tax Administration

Under the research results [22], industrial enterprises will annually reduce costs by 3.6% and increase revenues by 2.9% over the next five years due to the digitization of products and services, and the development of new digital services. From a tax standpoint, this is a positive trend since income growth also increases tax revenues. However, scholars highlight [13] that digital goods reduce the tax base in several ways: firstly, the cost of digitized goods is lower (for example, books and audio albums); secondly, digital goods and services can be paid for not in cash but in the form of barter (subscription to advertising, newsletter, and other forms of generally B2B communication services); thirdly, digital goods are sold via the Internet (the buyer might be from one country, the seller from another), therefore there is stateless income that is less subject to the current tax laws.

Thus, some countries do not rely on growing revenues from the sale of electronic goods and services of domestic manufacturers and review their taxation systems in order to adapt them to the changes caused by total digitalization. This grants foreign IT companies more access to their markets [26]. However, as the results of our expert survey show, these trends may lead to a decrease in the level of protection of personal and corporate data, so the access of foreign IT companies will be severely limited by the national legislation of countries [27], thereby hindering the development of digital goods and services.

### B. The Use of Tax Instruments as a Way to Protect Personal Data

An additional way to protect information can be the use of tax instruments [28]. At the World Economic Forum of 2011, personal data was recognized as a new asset, whose possession and use can generate income [9]. In the EU, it is allowed to tax enterprises that collect, integrate, and use such data in their activities but this right has not been implemented yet [13]. In France, an attempt was made to introduce a tax on the collection of personal data for Big Data owners (the taxation of Google, Amazon, and Facebook was considered a pilot project) but the corresponding law was not adopted. The reasons include the lack of statistics and schemes for calculating the company's profit from owning such data: on the one hand, their collection and use generate income; on the other hand, it is rather difficult to calculate its share in total income [29].

Researchers [1] believe that work has begun to protect national tax systems and minimize the risks of tax non-payment by digital companies and platforms. One of the proposals is the introduction of specific taxes (a tax on purchases of goods and services via the Internet, or a turnover tax on commercial activities on the web) to prevent the liability of digital businesses.

Currently, additional provisions on the taxation of foreign supplies of digital services and goods are being introduced into the tax codes of some countries. Since 2017, all digital goods and services provided by foreign companies are subject to an indirect tax (Goods and Services Tax) of 10% in Australia; 15% in New Zealand, 8% in Japan; a 5% VAT rate on online purchases in Taiwan [2].

### C. Transfer Pricing of Digital Services

Another feature of the development of Industry 4.0 is transnationalization, therefore an important aspect for tax purposes is the transfer pricing of digital services [19, 30]. According to the experts [17], this can be either quite difficult (if the company's smart connection is installed between a data center located in one jurisdiction and factory floors located in another jurisdiction) or relatively simple (when the intellectual property developed in one jurisdiction (country) is licensed in another jurisdiction).

In the first case, the company's departments where the production facilities are located should, according to transfer pricing rules, pay for the asset (smart connection) the fair market price that a third party could pay for them. However, it is almost impossible to determine the price due to the uniqueness of the asset. Thus, the current transfer pricing models are not always useful. In the second case, when licensing, legal rights to intellectual property usually remain in the country where it was developed, and economic rights are transferred to a foreign jurisdiction. There are no changes in the location of investments: investors use transfer pricing and record the costs of a unit in the country where the property is developed, and the profit is received by a unit in another country that has economic rights [11]. Although it is quite easy to set the price, tax evasion is still possible since, on the one hand, the expenses in the country of the developer (the parent company) will reduce the tax base; on the other hand,

the affiliated party might incur minimum expenses and receive excess profits due to lower tax rates. Therefore, the transfer pricing of companies using new technologies remains open and requires additional research.

### D. Blockchain Technologies' Effect on the Organization of the Taxation System

According to the experts [21], the use of **blockchain technology** will provide internal revenue service field offices with free access to the operations of enterprises as it allows them to simultaneously and automatically calculate tax liabilities, withdraw funds from bank accounts to pay taxes, and eliminate the gap between reporting and paying taxes. Thus, the functions of tax authorities can be significantly reduced, as well as the number of the administrative staff of local tax offices. At the same time, the use of blockchain in order to obtain taxation data will reduce the likelihood of tax disputes and audits.

The first changes might be the elimination of tax returns and the transition to digital tax accounts, which allows one to view and update tax information, receive timely news, and pay tax liabilities. Consequently, society will have a single, centralized digital tax system or platform that will work in real time. Many countries have already been taking steps in this direction. They aim to create a modern and efficient internal revenue service field office, easy to use and with simplified administration in the form of digital taxation.

### E. The Impact of Robotization Processes, Automation, and M2M on Changing the Taxation Organization and System

The introduction of robots into industrial production is quite expensive [31]. To renew assets and maintain the competitiveness of industrial enterprises in the world, a tax credit (R&D) is used [32], which allows for a reduction of the tax base by the amount of an enterprise's costs for the development and implementation of innovations [19].

Besides the advantages of robotics and fully automated production (increase in productivity [33] or wages [34]), there are also disadvantages, in particular, a reduction in the number of jobs, a decrease in demand for low- and medium-skilled workers, an increase in the income gap, i.e. the risks of growing unemployment [12].

According to the study results [15], one of the solutions to growing income disparities can be the redistribution of income with the help of fiscal tools. It is worth mentioning that there are several ways in which such tools can be used for equalization purposes. For example, the introduction of progressive taxes: in the short term, a larger redistribution can be achieved by combining an increase in tax rates for property, the establishment of progressive income taxes, and government programs to support those affected by digitalization and globalization [22].

Another way to address the issue of income inequality with the help of fiscal tools is to introduce a tax on robots [35], i.e. taxing the contribution of robotics and artificial intelligence to the economic results of enterprises. According to scholars [15], such a tax can slow down (at least temporarily) robotics advancement and provide the income

necessary to finance the adaptation of people through retraining programs for dismisses. However, there is an opinion [4] that a serious disadvantage of taxing robots will be the erosion of the tax base and the very concept of robot for tax purposes because this category can include any semi-automatic mechanism. The scholars [4] emphasize that there is a high risk of evading such a tax since elements of robotics will be embedded into mechanisms that are not robots. A possible solution is to create a state trust and introduce universal basic dividends financed by income from the total capital. Thus, an increase in automation and robotics will cause an increase in the income of enterprises that implement them. The automatic distribution of profits in the form of universal basic dividends will be carried out through a state trust that owns a share of such enterprises, which will solve a complex social problem [4].

At the same time, it is impossible to digitalize, introduce robotics and use digital platforms without highly qualified specialists, retraining production personnel, and improving the digital skills of enterprise management [36]. In this regard, we believe it is necessary to introduce loans for students who obtain higher education in the field of science, technology, engineering, and mathematics and are employed in their specialty [16], or an earned income tax credit when taxing the income of teachers who train highly qualified personnel. In Russia, a preferential mortgage program for IT specialists has been developed and is being implemented [37].

## V. CONCLUSION

The study results have confirmed the hypothesis that economic changes as a result of the development of Industry 4.0 technologies affect (and will affect) the tax policy and tax system, which requires the transformation of the modern tax system and the use of both traditional and innovative tax tools.

Transformation of the tax system change the traditional instruments of taxation: the adoption of a progressive tax (for individuals and legal entities); the expansion of taxation objects that emerge due to the digitalization of the economy (electronic goods and services, personal data, Big Data); the introduction of R&D and/or investment tax credit, tax credit for student loans, and preferential mortgage mechanisms for young professionals.

Under the influence of Industry 4.0, innovative tax instruments are being created and introduced into the practice of taxation. In our opinion, the most promising are the introduction of a tax on robots as a tax on the contribution of robotics and artificial intelligence in the economic results of enterprises; taxes on the digital economy (on payments made for the purchase of goods and services via the Internet, or from the turnover from commercial activities on the web).

The limitations of the study include the limited sampling of experts and the geographical representation of experts, as well as the authors' deliberate limitation of focus on technological changes of a certain group: digitalization, blockchain technologies, robotics, automation, and the use of M2M technologies.

This study lacks expert sampling and geographical diversity. In this regard, further research should dwell on the

transformation of taxation as a result of the development of such digital technologies as 3D printing, virtual and augmented reality technologies, digital twin technology, artificial intelligence, Big Data, etc.

**Abstract**—The article aims to determine the nature of changes in the attractiveness of the labor market of megaprojects from the perspective of megapolis residents under the conditions of digitalization and the long-lasting pandemic of COVID-19. The paper develops a scientific-methodological and categorical-conceptual apparatus with the support of empirical methods with distance methods. The study shows that the attractiveness of the labor market of megaprojects has undergone certain changes for megapolis residents under the current conditions. The factors of the attractiveness of the labor market of megaprojects are of a stable nature in the minds of megapolis residents. The main advantage of the work is the identification of trends in the changes of the megaproject labor market and the relationships they have. The study reveals both general and private trends. The obtained results can be used for further study of the megaproject labor market and the improvement of the social policy of the state and megalopolises in the conditions of digitalization and the prolonged pandemic.

**Keywords**—Megaproject labor market; metropolitan residents; digitalization; COVID-19 pandemic; attractiveness factors

## I. INTRODUCTION

The fourth industrial revolution (4IR) and the digitalization of all spheres of life are conceptually changing the structure of the labor market and the system of socio-economic relations. The more rapid the digitalization, the more contradictions arise and the greater the resistance from certain segments of society. The complexities associated with the COVID-19 pandemic are added to this tangle of contradictions. The world economy is undergoing structural changes with an emphasis on mass digitalization and remote forms of employment. The global recession hits small and medium-sized businesses the hardest, service businesses suffer losses [1]. Transforming the market for goods and services, the introduction of artificial intelligence reduces customer confidence, worsens the labor market [2], and furthers social inequalities. The coronavirus pandemic worsens the plight of workers, increases their dependence on employers and the digital environment.

Megaprojects are implemented under special conditions. Recently, large projects are mainly social and concern water supply, social housing [3], and infrastructure development. Their effectiveness in a digital environment depends on the

management system that is created [4, 5], the adopted decision-making procedures, timing forecasting technologies [6], risks, and funding procedures. With weak management, megaprojects threaten regional ecology [7] and local communities [8] and conflict with the Sustainable Development Goals (SDGS). Amid the COVID-19 pandemic, several projects aim to curb the dangerous virus, while others try to make super profits by degrading the environment and the living conditions of the population. Such approaches adversely affect the labor market of megaprojects.

The introduction of digital services and artificial intelligence into the sphere of human resources (HR) only partially compensates for the effect of negative factors on the labor market. Innovative technologies based on digitalization contribute to the development of social partnerships [9], especially in megapolises. Young people find themselves in a contradictory situation. On the one hand, they are the most adapted to digitalization, constant change, and the application of themselves in new areas of business. They easily enter the labor market with the help of social networks, quickly obtain information about all kinds of changes. Young professionals change their views on employment in the international labor market, on the forms and content of work itself [10], their behavior in the workforce. Under these conditions, it is necessary to develop mechanisms to attract the attention of young people, to improve their motivation [11], and to create favorable working conditions for entering megaprojects [12]. Higher education [13] and the role and professionalism of recruiters are growing in importance. IT professionals are in a better position, as the demand for them is only growing in both megaprojects and megapolises.

At the same time, in the context of the pandemic, it is difficult for young professionals to compete with experienced workers in large companies who have earned the trust of employers and have a strong hold on their jobs. While at the beginning of the pandemic, it was mostly young people who sought remote work, by the second year, more and more age-matched residents of large cities had joined the ranks. Unemployment in various sectors of the economy is growing, which to some extent encourages young people and experienced workers to seek jobs in megaprojects in remote areas.

The acuteness of the problem of providing megaprojects with personnel has not yet led to the development of a precise method for promoting the attractiveness of the megaproject labor market among megapolis residents. This process is further complicated by the prolonged COVID-19 pandemic. The present paper may become an element in the system of measures to improve the effectiveness of megaprojects by means of competent and technologically advanced provision of the workforce for them with a focus on megapolis residents.

## II. MATERIALS AND METHODS

### A. Design and Hypothesis

The present study is part of a research project and the next stage in identifying the nature of the impact of the digitalization of the economy and the use of artificial intelligence on the social environment and labor market in general [14], and on the labor market of megaprojects in particular. The peculiarity of this work is that it takes into consideration the impact on the labor market of such a negative factor as the limitations of the pandemic. The work develops a scientific-methodological and categorical-conceptual apparatus, which allows achieving the goal of the study by solving scientific problems. The study puts forward hypotheses and develops a set of approaches and methods in the combination developed specifically for this study. The research team is formed with a specific allocation of tasks and functions, the order of the research is determined. The priority of the research team is the observance of scientific ethics in conducting the research.

The goal of the study is to determine the nature of changes in the attractiveness of the megaproject labor market from the perspective of megapolis residents under the conditions of digitalization and the long-lasting COVID-19 pandemic. To achieve the goal, the following research objectives are set for the study:

1) To determine the degree of readiness of megapolis residents to enter the megaproject labor market in the context of the digitalization of society and the prolonged pandemic of COVID-19.

2) To reveal the essence of changes in megapolis residents' assessments of megaproject attractiveness factors.

The hypotheses proposed by the team of authors are as follows:

H1. The attractiveness of the megaproject labor market has undergone significant changes for megapolis residents in the context of digitalization and the long-lasting pandemic of COVID-19.

H2. Megapolis residents' assessment of the megaproject labor market is contingent on their sex, age, and sphere of work and is predictable.

The comprehensive study consists of two stages: the first stage lasting from January 10, 2020, to June 10, 2021, with a sample of n=719 people (2021.1) and the second stage from July 1 to December 30, 2021, with n=1098 (2021.2) people with a general population of n=12'500'000. The sampling error is 3.75% with a 95% confidence level for the first stage

of the study and 3.5% with a 95% confidence level for the second stage. The main quota characteristics in the study when selecting respondents are gender, age, level of education, and work experience.

The decision to organize two stages of the study (two studies) is due to the possibility of differences in the views of megapolis residents at the start of the pandemic after a certain cycle of it and in the context of the prolonged pandemic, which has led to moral and psychological exhaustion, deterioration of health, pressure on the part of the government and the employer management, changes in the labor market, and the transformation of the structure of the market of goods and services.

Analysis of socio-demographic characteristics of the respondents (Table I) shows that in both studies, women are more active than men in almost the same ratio. It is natural both in view of the general ratio of the male and female population of the country and the higher activity of women in sociological surveys.

The age ratio of the respondents differs between the two stages to some degree. The proportion of metropolitan residents who participated in the sociological survey under the age of 25 has increased (from 67% to 76%). At the same time, the number of respondents under 18 years old has significantly increased (from 2% to 27%). Analysis of other age groups shows that the older generation, even among young people, is tired of numerous sociological surveys conducted on various occasions (health care, banking, political priorities...) by various state and commercial structures.

TABLE I. SOCIO-DEMOGRAPHIC CHARACTERISTICS OF THE RESPONDENTS (IN %)

Characteristics of respondents		Share	
		2021.1	2021.2
Sex	male	31%	30%
	female	69%	70%
Age	14 - 18 years old	2%	27%
	19 - 25 years old	65%	49%
	26 - 35 years old	22%	18%
	36 - 55 years old	9%	3%
	56 - 65 years old	1%	2%
	over 65 years old	1%	1%
Level of education	higher	39%	15%
	incomplete higher	38%	35%
	secondary special	15%	18%
	secondary	7%	31%
	elementary	1%	1%
Work experience	1 year	26%	68%
	1-3 years	35%	20%
	4-5 years	18%	7%
	6-10 years	11%	2%
	over 10 years	10%	3%
Nature of work activities	executive	13%	4%
	specialist	48%	59%
	government official	11%	14%
	blue-collar worker	15%	12%
	self-employed	9%	8%
	unemployed	4%	3%

The age shift also affects the level of education. The share of respondents with higher education is significantly lower

(from 39% to 15%), while the group with secondary education has grown (from 7% to 31%). The latter are interested in discussing their future with the opportunity to participate in megaprojects as a mechanism of upward social mobility. The labor market itself, in turn, is in dire need of a great number of specialists with specialized secondary education. The provision of the market with highly qualified personnel is also a problematic issue.

Work experience in proportion to age has shifted toward one year. A significant reduction is observed in the number of managers (from 13% to 4%) and respondents with over four years of experience (from 21% to 5%). This suggests that experienced employees and managers have become less active in discussing their future in terms of participation in megaprojects. They are more comfortable working in their positions in the metropolitan city of Moscow.

### B. Data Collection and Sample

The study is organized and conducted collaboratively by the Humanities Department of the Russian State Social University (RSSU) and the Department of Economic Sociology and Management of the Sociology Department at the Lomonosov Moscow State University (MSU).

The research methodology is based on the sequential use of a group of methods, beginning with empirical ones. The data obtained in the course of empirical research serves as a basis for statistical processing, systematization, comparative analysis, and discussion.

First, a questionnaire was prepared for a sociological survey, which underwent expert evaluation. The indicators are assessed using the Likert scale. The scaling went through five levels, from complete disagreement to complete agreement with the definition. Due to the pandemic restrictions, the sociological survey was conducted remotely using special programs (Google Form), cloud conference platform Zoom, and VoIP service Skype.

The cause-and-effect relations on the problems of selecting priority attractiveness factors and their antipodes are discovered in the course of in-depth interviews. The respondents for the in-depth interview are selected randomly. In the first study, the in-depth interview involves 18 respondents, in the second study – 21 respondents. The content and structure of the in-depth interview are developed taking into account the results of the conducted surveys.

Systemic conclusions to determine the nature of changes in the attractiveness of the megaproject labor market for megapolis residents in the conditions of digitalization and the prolonged COVID-19 pandemic are developed based on a focus group. The focus group consists of Russian and foreign experts in the field. In the first study, the focus group includes eight experts, and in the second study – nine experts.

In light of the changes in the social environment due to the digitalization of society in the context of the long-lasting COVID-19 pandemic, the categorical-conceptual apparatus on the issue is developed (finalized).

The term “megaproject” is composite. It refers to a set of projects that are aimed at achieving a specific goal,

interconnected by tasks, place, and time, and provided with the necessary resources. In this study, under the megaproject labor market, we understand the nature and totality of the supply of jobs by the composite employer uniting the set of organizations that offer jobs as part of a large project (megaproject) at all stages of its realization, as well as the totality of demand for those jobs by potential participants in the project. Due to the highest concentration of labor resources of different specializations and qualifications in megapolises, the paper will consider the possibility of their participation in the planned and ongoing Russian and foreign megaprojects. Digitalization of society is the process of introducing information and communication, digital technologies in all socio-economic structures and spheres of life. By artificial intelligence (AI), we understand intelligent computer programs, systems tasked with creating intelligent reasoning and actions. Sometimes, AI is designed to look like robots, including human appearance [15].

The attractiveness of megaprojects is determined by attractiveness factors, which include the most significant factors that ensure the desire (aspiration) of megapolis residents to participate in the megaproject. On the eve of the sociological survey, the expert group ranked the attractiveness factors to include them in the questionnaire. For this purpose, a matrix of pairwise comparisons is used. The sample consists of the 10 most significant factors, including such factors as gaining work experience in a large project, interest in communication with different people, opportunity to make a career, as well as receiving a good salary.

The draft of the survey is tested in a pilot study on the sample of the citizens of Moscow living in the Ostankinskiy District of the North-Eastern Administrative Okrug of the city. This study used the “snowball”, the respondents passed on the invitation to participate in the sociological survey through their social communication channels.

### III. RESULTS

The study demonstrates that the ratio of megapolis residents willing to enter the megaproject labor market and participate in megaprojects remains the same. The greatest part of the respondents is to a certain extent ready to leave the megapolis (or stay in it) to participate in megaprojects (Fig. 1).

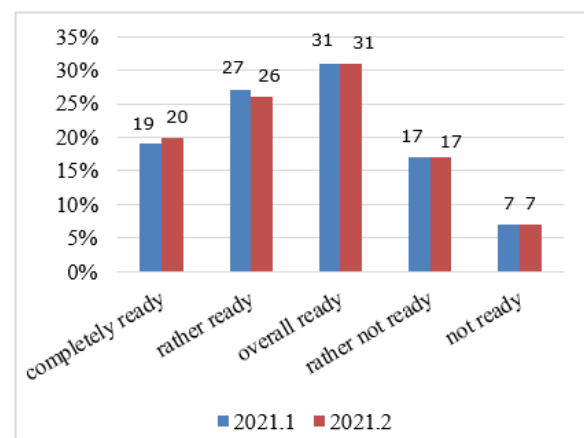

Fig. 1. Response Options to the Question, “Are you Ready to Offer Yourself in the Megaprojects Labor Market?” Source: Own Research, 2021.

It should be noted that the duration of the pandemic and the desire of the leadership to digitalize the private part of the people does not produce a significant effect on the position of megapolis residents. The share of the respondents completely ready to change the place of work (study) and take part in the megaprojects remains within 19-20%, and categorically refuse such opportunities the same 7% of the respondents. The rest of

the sample fluctuates between being partially ready or partially not ready to participate in megaprojects (57-58%).

The factors of attractiveness proposed for evaluation also remained approximately within the same limits of expert preferences. The changed conditions of the digitalization of society and the long pandemic have only partially changed the desires and aspirations of megapolis residents (Fig. 2).

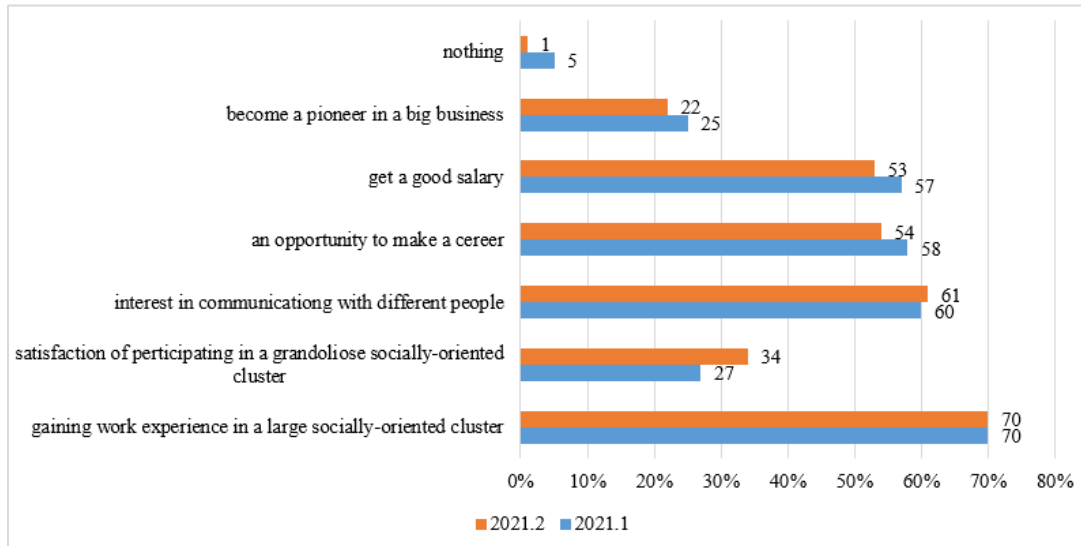

Fig. 2. Response Options to the Question, "What Attracts you most to a Megaproject?" Source: Own Research, 2021.

Among the leading **attractiveness factors** are the opportunity to gain experience working in a major project (70% of respondents), interest in interacting with different people (60-61%), the opportunity to make a career (54-58%), and getting a good salary (53-57%). Some changes are observed in the evaluation of the importance of other attractiveness factors. The importance of satisfaction with participation in a large megaproject is slightly decreased (from 34% to 27%). Total denial has increased with respect to the importance of megaprojects (from 1% to 5%), as well as of becoming a pioneer in a big business (from 22% to 25%).

At the bottom of the table of attractiveness factors, with less than 1% of the vote are the same factors, but with some changes in the values (Table II).

TABLE II. FACTORS WITH A LOW LEVEL OF ATTRACTIVENESS IN THE LABOR MARKET MEGAPROJECTS (IN %)

n/n	Factors of the attractiveness of a megaproject	%	
		2021.1	2021.2
1	Implementation of professional skills	0.1	0.1
2	If the company is international – the opportunity to communicate in a foreign language	0.1	0.2
3	Access to information	0.1	0.1
4	Any project is better than deployment in the army	0.1	0.2

At the same time, slightly higher is the importance of the opportunity to communicate and gain experience in a foreign language in an international company (from 0.1 to 0.2%) and to take part in a megaproject instead of serving in the army (from 0.1 to 0.2%).

In general, the study reveals the nature of the views of the residents of the Moscow metropolitan area on the megaproject labor market in the context of the digitalization of society and the prolonged pandemic.

#### IV. DISCUSSION

Comparative analysis of the sociological surveys reveals that the desire to enter the labor market of megaprojects generally remains unchanged among megapolis residents. However, taking into account changes in the age composition of respondents, their work experience, and professional skills, we can conclude that young people under 25 years old, mostly with secondary, specialized secondary, and incomplete higher education, are more favorable to megaprojects. They endured the pandemic digitalization with the least losses, being in educational institutions for the most part of it. The share of opponents of participation in megaprojects remains consistently small (7%).

The study also demonstrates a great number of those in doubt (over half of the respondents). This is explained by the instability of the situation: the economic crisis, the ever-changing restrictions, contradictory actions on the part of leadership to combat the COVID-19 pandemic, problems for small and medium-sized businesses, and increasing demands for skills and digital competencies on the part of employers. This group of respondents above all needs guarantees of the stability of employment in a big company in a decent position, as well as favorable working conditions. This is consistent with several studies [16].

The focus group experts are also sure of the hypothetical readiness of megapolis residents to enter the megaproject labor market under the condition of a high salary. This, however, applies mostly to young people with modest professional skills. Executives and highly qualified specialists will offer their services in this labor market reluctantly and involuntarily. Middle-aged and older respondents are least inclined to change the atmosphere of the Russian capital for dubious prospects in megaprojects. This is especially true for IT, logistics, and marketing specialists. These specialists were able to adapt to the constantly changing conditions and requirements of the megapolis administration and company management in the rich metropolitan labor market. They have developed several measures and implemented solutions to bypass (overcome) the next pandemic restrictions on movement, forced-voluntary vaccination, and remote labor and social activities. At the same time, they have the opportunity to partially or fully participate in megaprojects remotely, without leaving the megalopolis. The digitalization of the socio-economic sphere allows this to happen. This confirms the general **trend** of fragmented hypothetical desire and remote participation of megapolis residents in megaprojects.

Here it needs to be pointed out that a part of megapolis residents of various ages, being driven to despair by restrictions and oppression, openly and sometimes aggressively oppose such restrictions.

The in-depth interview reveals cause-effect relationships in determining the priority of attractiveness factors. The desire of megapolis residents to enter a new labor market to gain experience in a major project appears to be stable and strong. This seems logical for young people since, in the course of the pandemic, older workers have developed mechanisms for survival and retention of their positions. In megaprojects young professionals see an opportunity to rapidly develop their career, realize their creative potential, get a good salary, raise their social status, and get an opportunity to join a promising ambitious team. These findings correlate with several studies.

Work in a megaproject usually involves interaction with a large number of workers of different professions and areas of work. This arouses steady interest among megapolis residents. At the in-depth interview, they express their hopes to work with a good manager, in a favorable social and psychological climate with a friendly attitude to all employees regardless of their age, gender, social status, socio-ethnic features, and religious affiliation. The importance of these aspects in attracting and retaining employees in companies has been emphasized by various researchers [17, 18].

At the same time, in-depth interviews express concerns about entering the process of mass recruitment, the fear of "getting lost" in large teams, the difficulty of adaptation, especially on the part of talented young people.

The respondents' desire for good salaries is based on considerable and usually sustainable financing of large projects. This also implies high salaries in all positions of the megaproject. It should be noted that the concept of good wages among the megapolis residents differs significantly

from the views of the regional population. This acts as a deterrent to attracting megapolis labor resources to megaprojects. There is also a certain differentiation in the level of wages by age. For the majority of young people, the requests are lower than those of older age groups. These aspects are reflected in the works of researchers exploring the problem of personnel **motivation**.

The ambitiousness of work in the projects remains generally at the same level. For the most part, young people express their desire to be pioneers in the implementation of large-scale digital projects that would significantly advance the digitalization of the Russian economy. To a certain extent, the respondents point to the pandemic restrictions being lighter in the remote regions that could potentially become the site of the megaproject. However, these statements do not carry much meaning. Youthful enthusiasm, the desire to create the groundwork for a great career remain among the priorities.

The focus group experts conclude that in the second stage of the study, the main attractiveness factors have the greatest effect on the age group under 25 years old. This points to the emergence of a **private trend** of the decrease in age in assessing the effectiveness of the impact of the factors of the attractiveness of the megaproject labor market from the perspective of megapolis residents under the conditions of digitalization and the prolonged COVID-19 pandemic. At the same time, the results support the discovered **dependence** of the labor activity of megapolis residents in megaprojects on their age: the younger the age, the higher the communicability, labor activity, and readiness to relocate and change the place and conditions of work. This dependence was taken into account by the leadership of the Soviet state in the design and successful implementation of megaprojects.

The opportunities to apply professional skills in the megaproject and have access to its information remain in the zone of low demand. This is especially characteristic of young people who have only basic professional skills and limited work experience that had little to do with digital services and was rather a part-time job in the service sector in low-skilled positions, offline distribution of advertising. Focus group experts note young people's desires and simultaneous fears with respect to mastering new digital technologies and being socially secure. To some extent, this falls in line with the works of other researchers [10, 19, 20]. Somewhat higher is the share of proponents of communicating in a foreign language and military evaders. This comes as a result of the opportunity to gain greater career prospects by knowing a foreign language, as well as of a tougher approach to military personnel in the fight against the pandemic in the army.

Overall, it can be argued that there has emerged a common downward **trend** in the age of metropolitan residents willing to enter the megaproject labor market in the face of digitalization and the long pandemic of COVID-19.

## V. CONCLUSION

The study establishes that the attractiveness of the labor market of megaprojects has undergone certain changes for megapolis residents under the conditions of digitalization and the long-lasting pandemic of COVID-19. This partially

confirms the first hypothesis. The essence of these changes lies in the plane of age and the sphere of work. The work confirms the dependence of megapolis residents' employment in megaprojects on their age revealed in the first stage of the study: the younger the person, the higher their communicativeness and labor activity, readiness to relocate and change the place and conditions of work. To a certain extent, this confirms the second hypothesis that megapolis residents' assessment of the megaproject labor market depends on gender, age, and sphere of work and has a predictable nature.

Attractiveness factors have not undergone major changes in terms of significance, which points to the validity of the conducted expert assessments and the stability of opinions of megapolis residents. Those megapolis residents having real opportunities to enter the rich labor market of the capital are steadily attracted to megaprojects by the opportunity to gain experience in a major project, the interest of communicating with different people, the opportunity to make a career, and a high salary.

The study reveals (proves) general and private trends. Among the discovered **general trends** are the reducing age of megapolis residents wishing to enter the megaproject labor market in the context of digitalization and the prolonged COVID-19 pandemic, as well as the trend of fragmented hypothetical desire and remote participation of megapolis residents in megaprojects. Of private nature is the **trend** of the reduction of age in assessing the effectiveness of the impact of factors in the attractiveness of the megaproject labor market.

The results of the comparative analysis may be of interest for further research on the peculiarities of socio-cultural and socio-economic life in the context of the long-lasting COVID-19 pandemic with the concentration of digitalization on individual social aspects (QR codes). Furthermore, the results of the analysis may be used in covering the staffing needs of emerging and existing megaprojects, to be attentive to people, and to improve the social policies of the state and megapolises.

**Abstract**—The research peruses development of scientifically based toolkit to create and assess promising types of intellectual capital transformed into digital innovations for "open innovation" system. It is determined that in theory terms "intellectual, informational and digital capitals" are interrelated categories; efficient merge of informational and digital capitals minimizes information security risks; merge of informational and digital capitals provides a long-term multiplicative synergetic effect demonstrating constant transformation of innovative ideas into digital innovations. The following is suggested: structural and logical scheme method for creation and assessment of informational capital and scenarios for the synergetic development of informational and digital capitals.

**Keywords**—*Informational and digital capitals; informational security risks; synergy; open innovation; transformation*

## I. INTRODUCTION

In order to keep and maintain high financial corporate status, commercial organizations (corporations) should constantly develop promising trends of intellectual capital generation and its application according to the principle "intellectual capital available in corporation means future potential innovations" in the "open innovation" system. Modern digitalization of business processes calls for digital innovations development that first of all requires intellectual, informational and digital capitals synergy in the "open innovation" system. Timely transformation of intellectual, informational and digital capitals into digital innovations is hampered by the lack of inclusive understanding of the "informational and digital capitals" essence, as well as the processes of their generation, assessment and application. Poor methodological and practical background for creation of a toolkit for generating and assessing intellectual, informational and digital capitals - which could provide for development of digital innovations - limits corresponding

transformation. In this regard, substantiation of theoretical and methodological provisions and practical trends for creation and development of a toolkit for generation and assessment of intellectual informational and digital capitals with its subsequent transformation into digital innovations in the "open innovation" system is a key issue for foreign and national science and practice. Therefore, it determined relevance of the current research topic.

Achievement of the research goal suggests the following tasks: investigation of the essential characteristics of concepts - "intellectual informational capital" and "intellectual digital capital" identifying cross links; consider possibility to transform intellectual, informational and digital capitals into digital innovations in the "open innovation" system.

Working hypothesis of the study is based on the need to develop scientifically based toolkit for intellectual, informational and digital capitals generation and their assessment according to the principle, stipulating that intellectual capital available in corporations means future potential innovations" in the "open innovation" system, which is aimed at further digitalization of business processes in the moment in time and for long-term perspective. Theoretical significance of the study lies in deeper and more expanded understanding of intellectual, informational and digital capitals' generation and assessment, their transformation into digital innovations in the "open innovation" system. Some of the theoretical and methodological aspects of the research are proposed as tutorial and methodological materials for some disciplines of educational programs, as well as for retraining programs and advanced training of the corporations' employees working in the assessment, financial and innovation spheres, etc. Practical significance of the research lies in development and application of specific methods, models and practical provisions that serve to shape

methodological and practical basis for educational processes, assessments of intellectual, informational and digital capitals, and transformation of the latter into digital innovations; that will determine future implementation of a new methodological toolkit that ensures development and promotion of corporations' digital innovations in the "open innovation" system.

The role of intellectual capital in stimulating the transition of healthcare networks to digital technologies is reflected very well in the study of F. Schiavone et al. [1]. In particular they studied creation of an information panel to monitor key performance indicators (KPIs) in digital healthcare networks. It is aimed at improving health policy by means of developing an integrated meso-level structure based on the central role of intellectual capital components (structural, relational, human). In the context of pandemic uncertainty, which demonstrated the need for digital information technologies, the study of K.S. Al-Omouh, D. Palacios-Marqués, and K. Ulrich [2] on the interaction of intellectual capital, supply chain flexibility, collaborative knowledge creation and corporate sustainability during unprecedented crises such as Covid-19 is of high interest. The data was analyzed with the software for modeling structural equations with partial least squares (Smart-PLS). S. Kusi-Sarpong et al. [3] noted the connection of intellectual capital, including human, structural capital, and digital technologies capital - blockchain, embedded in supply chain management that ensures sustainable production.

In the study [4], special attention is paid to determination of the investments impact into intellectual capital as they describe the trends of industrial revolution 4.0 and intellectual capital in the era of FinTech.

E. García-Meca and I. Martínez [5] recognize how information influences intellectual capital while investment decisions making, and point out that certain characteristics of the firm affect the use of intellectual capital information.

Intellectual capital plays strategic role in achieving sustainable development goals and defining future, as noted by G. Secundo, V. Ndou, P.D. Vecchio and G. De Pascale [6]. A. Kalkan, Ö.Ç. Bozkurt and M. Arman [7] point to the connection of intellectual capital, innovation, organizational strategy and firm efficiency, revealing the impact of intellectual capital, innovation and organizational strategy on the activities of the companies operating in Antalya, Turkey.

F. Ricci, V. Scafarto, S. Ferri and A. Tron [8] insist that disclosure of information related to digitalization is a form of disclosure of information about intellectual capital that provides investors with potentially valuable data.

Taking into account the above, recognition of the connection between intellectual digital and information capitals becomes clear as it is the basis for digital innovations development in corporations in the "open innovation" system, which must be constantly improved and developed in the conditions of economic processes digitalization.

## II. METHODOLOGY

### A. Identification of Intellectual Capital and Innovations Cross Links

Considering that the best method for measuring intellectual, informational and digital capitals, which are the basis for digital innovations' development in corporations in the "open innovation" system, is the method that reflects their economic content and its generation is carried out in the following sequence of stages:

Stage 1: identification of the connection between intellectual capital and innovations. Its result is identification of the resource for innovative activity in corporations in the future, i.e. their intellectual capital.

Stage 2: ensuring the synergy of intellectual capital assessment and innovations, which is based on the principle stating that "intellectual capital available in the corporation is its future innovations". Its result is the determination of the factors for productive reproduction of intellectual capital that limit innovations including organizational innovations.

Stage 3: alternative direction for interpretation and evaluation of the intellectual information capital in corporations. Its result is provision of the characteristics for intellectual information capital in corporations, which is designed to ensure informational security of intellectual activity.

Stage 4: interpretation of the intellectual digital capital in corporations, its interaction with human and informational capital. Its result is justification of the fact that digital innovations represent interconnection of human, informational and digital capitals in "open innovation" system.

Theoretical and methodological foundation of the research: works of the international and Russian scientists and practitioners, Oslo Manual, internal regulatory corporations' framework. Methodological base of the research: system, process and logical scientific approaches to study processes of promising corporative types of intellectual capital generation and assessment aimed at subsequent transformation into digital innovations in the "open innovation" system.

Each stage of the research required general scientific and special methods to achieve proper efficiency, they were: analysis and synthesis, generalization and detailing, inductive and deductive, selective observation, grouping, formalization, analogy, abstract-logical, monographic, analytical, comparative, economic-statistical and economic-mathematical. Information sources were selected for the period of 1998-2022, taking into account the principles of complexity, relevance, transparency, materiality, comparability with the best international practices, consistency, preference, objectivity, reliability, relevance and up to date information .

J. A. Schumpeter [9] essentially connects initiation of innovations with generation of intellectual capital prerequisites. V. L. Inozemtsev [10] clearly names intellectual capital as opportunity for innovations, L.V. Yurieva et al. [11] highlight innovations as organizational intellectual capital element, V. P. Bagov et al. [12] consider it as an intellectual resource that predetermines organization’s ability to produce and sell its innovative products.

L. Edvinsson and M. S. Malone [13], B. Lev [14], A. Pulic [15] consider innovative component of organizational intellectual capital as a separate type of capital.

According to J.A. Schumpeter [9] determines practical implementation of scientific and technical initiatives and inventions as the essence of innovation, whereas underlining the meaning of an entrepreneur as a person of business amongst invention and innovation confirms importance of human capital.

Yu. V. Vertakova, E. S. Simonenko [16] point out that accomplishment of an invention or a discovery in a particular human activity area transforms underlying ideas of the invention into an innovation that contributes to new ideas emerge, eventually causing generation of new products (technologies). They associate invention with high-level innovation, defining products and technologies, social, economic, environmental and managerial processes as the subject of change. In the result there is an innovative spiral cycle: “scientific and technological progress - idea - innovation - scientific and technological progress - idea - innovation - ...”

In the Center for Economic and Social Research of the Republic of Tatarstan [17] new phenomenon, discovery, idea, method, etc., presented as a result of research, development / empirical work on increasing particular sphere of business efficiency is called innovation; its implementation creates innovation taking into account condition of human involvement that changes along with development of socio-cultural systems and regions. Innovation is shaped based on investment into new equipment, technologies, regulation

systems, labour organization and etc., that together shape intellectual organizational capital. In general, organizational capital of corporation is assessed according to the principle “inventions available in the patent portfolio mean future innovations”.

V.V. Platonov [18] recognizes innovation capital (industrial property, technological know-how) as a part of organizations’ intellectual capital along with the network, and human and organizational capitals.

B. Lev's model [14] “Value Chain Blueprint” describes intellectual capital on the basis of corporation's determination for innovations and integrates 9 parameters: internal renewal availability (research, personnel development, organizational processes); integrated acquired abilities (technologies, investment business); intellectual property; technological feasibility for innovations (clinical tests, approvals, prototypes); business networks (alliances, integrated corporations, customers and suppliers associations); customers (marketing alliances, brand value, value, customer drain); business on the Internet (website traffic, online orders, alliances on the Internet); performance (sales, including licenses, profit, market share, new products); future growth (periods for bringing new products to the market, planned initiatives, increase in results, etc.).

Human capital is described along with traditional qualities of a person: knowledge, skills, qualifications, competence, and other characteristics correlated with personality as well as innovations capability.

“Social innovation” term is always put together with the concept of “intellectual capital”, which comes up [19] when strengthening human factor via creation and introduction of systems for modernized personnel policy, professional retraining and growth of employees, social and professional adaptation of newly hired, bonuses and assessment of work results. It should be emphasized that K. Marx [20] when characterizing the economic category "capital" underlined its social aspect.

TABLE I. INFLUENCE OF FACTORS ON INTELLECTUAL CAPITAL FOR EVERY THREE PAST YEARS, ACCORDING TO FORM 4 - INNOVATION - ADAPTED FOR ORGANIZATIONS IN STAVROPOL REGION, UNITS

Factors	Factors' impact				
	1 – unessential	2 – essential	3 – crucial	4 – No clear answer	5 – Not applicable
<b>Human capital</b>					
Lack of qualified personnel	137	105	22	185	204
<b>Organizational capital</b>					
Uncertain economic benefits from intellectual property utilization	94	95	27	247	190
<b>Stakeholders' capital</b>					
Lack of own financial resources	66	181	94	157	155
Lack of State financial support	76	159	46	189	183
Lack of information on new technologies	150	70	22	197	214
Lack of information on sales markets	152	64	20	200	217
Underdeveloped cooperation networks	124	67	15	235	212
Underdeveloped innovations' infrastructure (intermediaries, information, legal, banking and other services)	143	68	25	237	180
Total	711	609	222	1215	1161

Source: calculation provided by the authors V.V. Manuylenko, G.A. Ermakova [19]

V.V. Manuylenko, A.A. Mishchenko [21] associate intellectual capital availability with personnel innovations emerge and regular improvement of erudition level with a professional team. Surely there is an opposite effect of intellectual capital sales and social or personnel innovations.

E.V. Petrukhina [22] recognizes following functions of organization's intellectual capital: education and future development of intellectual property; promotion of employees' innovative thinking, businessmen, scientists, and management teams that shape and test key models for reproduction within a single economic system or systems units.

Aggregated intellectual capital, as noted by V.V. Manuylenko, G.A. Ermakova [19], performs the function of corporations' innovative development. In terms of reproductive performance intellectual capital of corporations is simultaneously a prerequisite and result of innovations

creation process showing the result of previous or current innovative activities in the "open innovation" system. I.e., intellectual capital of corporations is a resource for future oriented innovative activities. Following the logics of the research, assessment of both intellectual capital and innovations in corporations is a challenging study issue.

#### A. Synergy of Intellectual Capital and Innovation Assessment

Considering available intellectual capital in corporations for future innovations, intellectual capital of corporations is assessed according to Form 4 – innovation (adapted). Still, in Form 4 – innovation "Information about organization's innovative activity" the following parts draw special attention: factors limiting innovation and organizational innovations.

Factors affecting each type of intellectual capital in organizations (human, organizational, stakeholders') – Table I.

TABLE II. ASSESSMENT OF POSSIBILITIES FOR CHANGES IN INTELLECTUAL CAPITAL DEVELOPMENT WITH ORGANIZATIONAL INNOVATIONS UTILIZATION IN CORPORATIONS OF STAVROPOL REGION, UNITS

Indicators	YY								
	2010	2011	2012	2013	2014	2015	2016	2017	2018
Number of corporations implementing organizational innovations during past three years	7	4	9	8	6	4	2	3	8
Number of corporations with no organizational innovations	435	459	455	449	438	450	690	650	811
<b>Organizational innovations / Human capital</b>									
Innovations concerning shift working hours	4	3	2	4	2	2	2	1	1
Introduction of corporative knowledge management systems	4	2	3	1	0	2	0	0	2
Personnel development means (corporate and / or individual trainings, creation / development of personnel training and advanced training institutions)	6	4	7	8	6	4	2	3	7
Introduction of new methods for employees motivation	0	0	0	0	0	0	1	0	1
<b>Organizational innovations / Organizational capital</b>									
Development and implementation of new or significantly corrected corporate (shareholders') strategy	5	3	4	5	4	4	2	2	2
Introduction of modern (IT-based) management methods in corporations	6	4	5	5	2	2	2	3	4
Development and introduction of new or significantly updated organizational structures in corporations	7	4	4	5	4	4	2	2	2
Application of modern systems for quality control, certification of goods, works and services	6	3	3	5	4	4	1	2	5
Creation of units specializing in research and development, implementation of scientific and technical achievements (technology and engineering centers, small innovation corporations)	3	2	1	3	2	2	2	1	2
Transferring certain functions and business processes to specializing contractors (outsourcing)	3	2	2	3	4	4	2	1	2
<b>Organizational innovations / Stakeholders' capital</b>									
Introduction of modern logistics and supply systems for raw materials, materials, components ("just in time", etc.)	4	3	3	3	2	1	2	1	4
New forms of strategic alliances, partnerships and other types of cooperation networks with product consumers, suppliers, Russian and foreign manufacturers	2	1	1	3	2	2	2	1	1

Source: calculation provided by the authors V.V. Manuylenko, G.A. Ermakova [19] as per data provided by Federal State Statistics Service for the North Caucasus Federal District [23]

Among the factors affecting intellectual human capital the following should be noted: lack of qualified workers, intellectual organizational capital, i.e. uncertain economic benefits from intellectual property utilization, intellectual stakeholder capital, i.e. factors associated with generation of financial resources: lack of own funds and/or State financial assistance; informational factors: lack of information about new technologies and sales markets; at the same time, such factors as underdeveloped cooperation networks and innovation infrastructure (intermediary, information, legal, banking and other services) should be also taken into account. Among significant financial nature factors that affect intellectual capital of organizations there is a lack of own funds and/or State financial assistance, which is followed by factors of underdeveloped innovation infrastructure, insufficient information about new technologies and sales markets as well as underdeveloped cooperation networks. No clear response was noted for such factors that affect intellectual capital of organizations as uncertain economic benefits from intellectual property utilization, underdeveloped innovation infrastructure and cooperation networks [19]. In general, when determining influence of factors on intellectual (human, organizational, especially stakeholders') capital, first prevail those corporations that have no clear response or with no applicable factors, then there are those that note insignificant, significant and crucial influence.

It should be noted that Form 4 – innovation – combines factors of efficient reproduction of intellectual capital (scientific and technological progress, the level of IT literacy, innovation and intellectual property policies, modern market infrastructure, institutional environment, etc.).

Alternative area for human, organizational and stakeholders' capitals development is organizational innovations. Merged application of intellectual capital and organizational innovation causes overturn of the principle: "intellectual capital existing in the organization means future innovations", ultimately creates opposite effect in the "open innovation" system. Intellectual capital in corporations influences creation and implementation of organizational innovations, which in turn affects intellectual capital, changing the demands, as well as its content (ratio between human, organizational and stakeholders' capital).

In the corporations of Stavropol Region, organizational innovations affect generation of human, organizational and stakeholders' capitals – Table II.

Organizational innovations mainly develop towards improvement of human capital in the area of personnel development (corporate and / or individual training, creation / development of personnel training and advanced training institutions). These organizational innovations serve to minimize risks with personnel insufficient scientific qualifications. From the standpoint of intellectual capital future development it is not good that in the region number of corporations with no organizational innovations prevails (435 - 811 units) over the number of corporations that have ones (2 - 9 units). Increase of corporations that do not carry out organizational innovations makes it difficult to reveal synergistic effect on the principle "intellectual capital

available in the corporation means future innovations" in the "open innovation" system.

In developing countries above human capital, resources and networks Oslo Manual [24] recognizes priority of information and communication technologies, their ownership and application by organizations. By the level of innovative development innovations are classified according to the criterion of technological parameters that takes into account essence of innovations, i.e. complex attraction of new digital, information and communication technologies. In the current environment, information and digital technologies become a priority issue demanding identification of characteristics for human, informational and digital capitals. According to KPMG research, factors hampering introduction of innovative technologies in Russia as well as in the world are insufficient maturity of processes / low automation, low level of IT-literacy of employees. Among the threats for digitalization Russian and world experts recognize the risks of information security, etc. [25-27].

### *B. Characteristics and Assessment of Corporations'*

#### *Intellectual Information Capital: Alternative Point of View*

V.A. Medvedev [28] puts together informational capital and level of control over information. V.L. Inozemtsev [10] designates databases as part of structural capital elements. B.B. Leontiev [29], L. Edvinsson and M.S. Malone [13] recognize information systems as constituent parts of organizational capital, and B.B. Leontiev [29] adds up accumulated knowledge bases.

In developing countries, information and communication technologies, their ownership and application by organizations are predominantly distinguished. In 1972, K.D. Arrow [30] identified link between special economic behaviour of intellectual resources and information creating and handling processes.

In existing environment, encoded and materialized information is represented in human capital. According to P.F. Drucker [31], knowledge is "information" that changes something or somebody or else is the cause of action that provides opportunities for different and more effective actions.

Corporations' financial managers should provide access to sources of knowledge and information, which are subsequently transformed into separate production resources for specific use. Constant monitoring of information relevance and demand serves its transformation into corporations' valuable resource, which is ensured only with creation of developed information and communications infrastructure, assumed that only up-to-date information processing technologies and information exchange are applied. IT-specialists categorized as intellectual workers are in demand.

Creation and development of corporations' intellectual capital is subjective to correctly built information exchange system. Paragraph 23 of Oslo Manual [24] pays special attention to information needs of analysts and politicians when they accumulate information about innovation activities or determine set of indicators. According to the golden rule of information mobilization, information exceeding value or its collecting costs makes its accumulation reasonable. At the

same time, it is important to take into account distinctive properties of corporations' intellectual capital, i.e. information asymmetry and liquidity. Processing of information results in knowledge that reflects human capital - when put together it represents powerful competitive tool. Science being one of the constituent parts of intellectual activity produces new knowledge, that is, new information; in order to transform it into knowledge it is advisable to present it and combine it with existing knowledge, establishing value of received information, attributing it to structure (superstructure), and providing guidelines for its application. Thus, knowledge existing in time interval  $t + 1$  is a complex functional relation of received information and human knowledge in corporations. As a result, importance of information in creation and development of intellectual capital in corporations, which should meet uniqueness requirement, is confirmed. The link between intellectual information and human capital of corporations becomes evident. In terms of liquidity degree information systems usually have medium liquidity, whereas databases and accumulated knowledge bases are low liquid.

As a result, it is fair to set aside intellectual information capital of corporations intended to ensure information security of intellectual activity; its functioning reveals risks of insufficiency and inconsistency of information capital in the existing environment, etc.

*C. Characteristics of Intellectual Digital Capital of Corporations, its Interaction with Human and Informational Capital*

Considering that corporations' "intellectual capital" concept is constantly changing over time, and accelerated introduction of digital technologies in economy and social sphere is one of the national development goals [32], intellectual digital capital is of great importance for Russian corporations. Information and digital technologies can ensure operation of corporations 24/7/365. Digitalization represents integration of digital technologies in order to improve project's performance by means of key processes adjustment [33]. Modern digital technologies are focused on transforming traditional business models and business processes in already existing industries. Innovations grounded in digital technologies create new electronic financial products and services and bring up to date their forms.

Technical financial industry having technological foundation shall incorporate provisionally basic end-to-end technologies: telecommunications, Big Data technologies, Internet of Things, industrial and simulated intellect, as well as interdisciplinary technologies: neuro-technologies, distributed ledger systems, elements of robotics and sensor technologies, quantum, new production technologies, technologies of virtual and augmented reality.

Hence, for most corporations, efficient digitalization process indicator represents "digital versions" of already existing conventionally traditional solutions, optimization results for actual business processes, whereas implementation of innovative changes in business models indicates future prospects. Corporations with limited digital technologies may provide basic services, such as balance sheet regulation, in the

"open innovation" system – Table III.

There are criteria for assessing satisfaction level of digital customers: regular compliance of requirements to provided services, timely receipt of information about digital products and services, assessment of the ratio between results and resources spent on digital products and services purchase, risk level at digital products or services receipt, overall satisfaction with digital products and services, digital customer feedback. Creation and development of digital stakeholders' capital in corporations should be aimed at exceeding stakeholders' expectations. It is true that digital stakeholders' capital in its essence represents digital asset value, expressed in relations with stakeholders, i.e. digital clients, which when efficiently managed by a corporation on the basis of special marketing activities maximizes value and ensures competitiveness, and in the quantitative aspect justifies amount of discounted cash flows obtained from real and potential stakeholders, i.e. digital clients, and excludes mobilization costs, that is lifetime value of real and potential stakeholders.

TABLE III. BASIC DIGITALIZATION AREAS FOR CORPORATIONS IN THE "OPEN INNOVATION" SYSTEM

Areas	Digital format functions	Financial technologies
Regulation and assessment of assets and liabilities	Assets and liabilities regulation in digital format	Big Data, block chain
Financial consulting	Financial consulting in digital format	Big Data, artificial intellect
Management Accounting	Online accounting	Cloud technologies
	Online reporting	SaaS
	System solutions	Cloud technologies, block chain
Infrastructure solutions	Identification solutions	block chain, artificial intellect, Big Data, SaaS
	distributed ledger and automated (smart) agreements	artificial intellect, block chain
	Information Security	computer education, artificial intellect, predictive analytics, block chain

Source: information provided by the author V. V. Manuylenko

One of the key corporation's competitive advantages is highly qualified personnel, namely central competence of corporation (capability to digital training and personnel development, infrastructure for long-term future growth) – employees with their own experience and qualifications, as well as unique abilities to digitalize economic processes. According American economist E. Denison study in 1929-1982, American economy growth occurred by 32% due to new labour force mobilization, 1.4% - due to increase of education level, 28% - progress in knowledge; 19% – new investment, 17% – modernization of production structure and labour organization [34]. Top three new key competencies of future demand include: flexible and critical thinking, creativity, emotional intelligence, which distinguish person from machine. Most demanded specialists for implementation of transformation programs are business analysts in process optimization and data analysis. Digitalization and innovation professional personnel should include IT specialists with different background (from data analytics, robotics and

interface design up to cyber security and integration), IT auditors with knowledge and skills in obtaining and analyzing digital information technology data [35], top risk management, internal audit, compliance, experts from other technological organizations that include various types of economic activities and research institutions. Creation, assessment of intellectual digital capital in the “open innovation” system should include professional judgment of specialists.

It is clear that initially digital intellectual capital causes risks of staff deficiency, insufficient level of scientific personnel qualifications and low scientific specialization. At the same time, introduction of financial technologies raises up threats of digital fraud in financial sector, leading to information security risks that also reveals links between intellectual, informational and digital capitals. Risks complementary to corporations’ intellectual digital capital functions are defined as possibility of wrong digital decision making. Synergy effect of merged intellectual, human, informational and digital capitals functioning should ensure development of digital innovations. Hence, digital innovations represent result of human, informational and digital capitals interaction, implementation of which results in relations and links rising up between corporations and digital clients in the “open innovation” system, that represents intellectual digital stakeholders’ capital.

### III. RESULTS

#### A. In Theoretical Block of the Research

- determined that innovative activity in the “open innovation” system derives from corporations’ intellectual capital elements;
- all types of innovations are based on technologies, among which - in the context of digital economy development - informational and digital technologies draw special attention; that makes necessary to research intellectual, information and digital capitals, i.e. basis of digital innovations development in the “open innovation” system;
- established connection between the concepts of organizations’ “intellectual capital” and “social”, “personnel” innovations, which mainly is reflected in strengthened human factor by means of development and introduction of modernized personnel policy systems, regular improvement of personnel / team education level, etc.;
- identified corporations’ intellectual informational capital function in the "open innovation" system, i.e. provision of information security for intellectual activity;
- described supplementary risks of corporations’ intellectual digital capital functioning at initial stage (staff deficiency, personnel scientific qualifications level, low scientific specialization) and subsequent threats caused by digital fraud possibilities in financial sector, leading to information security risks in the system "open innovation".

#### B. In Practical Block of the Research

- considering that available intellectual capital in corporations represents future innovations, Form 4 – innovation – was adapted to corporations’ intellectual capital assessment in the following areas: factors limiting innovations, organizational innovations;
- found that development of intellectual capital in most corporations is complicated by insufficient consideration of affecting factors (corporations with no answer or no factor prevail, organizational capital is affected by uncertainty of economic benefits from intellectual property utilization) that makes necessary call for professional judgment in assessment process in order to eliminate controversial interpretation of results, errors and manipulations, as well as decrease of corporations that carry out organizational innovations, whereas their influence is noted on building up human, organizational and stakeholders’ capital in corporations of Stavropol Region;
- based on corporations’ intellectual capital assessment according to adapted Form 4 – innovation, its key advantages and disadvantages are identified – Table IV;
- indicated sequence of intellectual capital assessment stages based on adapted Form 4 – innovation, as follows: 1) determination of the factors influencing intellectual capital, 2) assessment of changes possibility in intellectual capital development via organizational innovations, 3) identification of the key advantages / disadvantages of intellectual capital assessment by Form 4 – innovation, 4) generation of motivated professional judgment of specialists;
- found that most corporations consider digitalization processes efficiency indicator in the “open innovation” system as “digital versions” of conventionally traditional existing solutions, results of actual business processes optimization, whereas innovative changes in business models are taken for future projections.

TABLE IV. KEY ADVANTAGES AND DISADVANTAGES OF CORPORATIONS’ INTELLECTUAL CAPITAL ASSESSMENT ACCORDING TO ADAPTED FORM 4 – INNOVATION

Advantages	Disadvantages
Development of scientific level with actually obtained results of intellectual activity.	Lack of internal regulatory framework governing intellectual capital assessment process.
Development of inventive level represents a fact of created patented inventions, and good perspectives for inventing object	Based on non-formalized methods, expert assessments method with subjective nature, which do not represent importance of intellectual capital in added economic value and its impact on the market value.
Development of design level is demonstrated in patented industrial samples and applications of industrial design and exterior of commercial product submitted for patenting.	Tendency to collection of quantitative indicators, and their application without strict analytical dependencies.
Software creation represents	No mechanism for transfer of ideas

object for development of officially registered computer programs and / databases and / purchased applications for the official registration of computer programs and / databases	and high technologies into market products / or intellectual potential into capital
	No mechanism for transforming human and stakeholders' capital into capitalized assets, since market qualifications are recognized via certificates and licenses, reputation – via brands, knowledge – via intellectual property rights.
	No demo effect of ultimate goal from intellectual capital application that breaks main property of capital – its ability to generate income.
	Lack of tools for assessing and regulating risks associated with intellectual capital the functioning.

Source: research provided by the authors V. V. Manuylenko, G. A. Ermakova [19]

### C. In Methodological Block of the Research

- established link between human and informational capital, when knowledge in a time period  $t + 1$  represents complex function of received information and knowledge of a subject of business – i.e. a person in a corporation;
- determined that informational capital in the “open innovation” system reflects quality of information systems, databases, incorporating efficiency of information application, administrative systems and organizational structures, information products and technologies, etc., eventually performing a function of ensuring information security for intellectual activity;
- proposed that quality of information systems is assessed by means of satisfaction level of internal clients – employees of corporations, taking into account main theoretical and methodological provisions of the assessment – Fig. 1. The following are priorities for modernization projects: automation of information system, improvement of transparency and quality of information, availability of up-to-date information, regularity, efficiency and timeliness of information receipt, importance of regional aspect in information systems operation in terms of global trends. Assessment of satisfaction level with information systems by internal clients allows identify at relatively low costs wide range of problem areas, and represents efficient tool for development of informational capital. It is important that corporative cultures accept informational systems expressing affiliation of informational and cultural capitals;
- merged performance of intellectual, human, informational and digital capitals ensures development of digital innovations, causing synergy effect in the “open innovation” system. In digital economy environment, particularly these types of corporations' intellectual capital penetrating into each other create intellectual wealth, and obtain strategic national importance;
- outlined main areas of digitalization in traditional corporations in the context of functions revealed in digital format and financial technologies in the "open

innovation" system (management accounting - system solutions - cloud technologies, block chains, API; infrastructure solutions - information security - computer learning, artificial intelligence, predictive analytics, block chains, etc.);

- determined that at the initial stage digital intellectual capital is accompanied by risks of lack of personnel, low level of personnel scientific qualifications, low scientific specialization of personnel; subsequently introduction of financial technologies causes threats of developing digital fraud in financial sector, leading to information security risks in “open innovation” system.
- found that synergy of intellectual, informational, digital and human capitals in corporations contributes to development of digital innovations in the “open innovation” system.

### IV. DISCUSSION

The authors believe that developed toolkit for creation and assessment of intellectual, informational and digital capitals aimed at digital innovations development requires steady upgrade of information and digital technologies in the “open innovation” system. I. Kukhnin, specialist of Deloitte CIS Research Center [36], evaluated technologies in terms of their potentials as follows: artificial intelligence - 0.88, computer learning - 0.84, predictive analytics – 0.82, deep learning - 0.79, and Big Data - 0.78, block chain - 0.54, augmented reality - 0.58 and virtual reality – 0.55. The best effect of digital technologies application was brought by solutions on Big Data and predictive analytics - 40%, robotization - 38%. Big Data and predictive analytics are used in the following key areas - operational intelligence and analytics - 52%, customer service, sales and marketing - 35% [25-27].

It is important to take into account that information and digital technologies development has certain specifics in corporations in terms of their different business activity types. Analysis of cross sector integration of industrial CIOs from more than 90 countries, conducted by Gartner [37], shows the following ranking of economic activities according to potential impact of digital transformation: media – 30%, banking and investment services – 26%, telecommunications – 25%, insurance and transport – 22%, services – 19%, government – 18%, healthcare – 17%, retail – 15%, housing and utilities, industry – 14%, healthcare providers – 13%, education – 12%, wholesale trade – 11%, natural resources – 7%.

Corporations' digital innovations development implies:

- identification of logical links between the terms: “intellectual capital” and “social”, “personnel” innovations;
- identification of informational capital assessment stages;
- identification of risks linked with intellectual capital creation and application.
- Corporations' digital innovation development is possible in the following areas:

- corporations' digital strategy;
- intellectual capital development trends; separate research of intellectual stakeholders' capital of corporations was carried out by S.S. Galazova et al. [38];
- optimal combination of human, informational and digital capitals: E.A. Posnaya et al. [39], T.V. Shabunina et al. [40]; E.V. Rodionova et al. [41] – regional level;
- complex intellectual capital reproduction: E. Zhilenkova et al. [42];
- intellectual digital capital creation risk management: V.A. Kunin and D. Mikhailovsky [43].

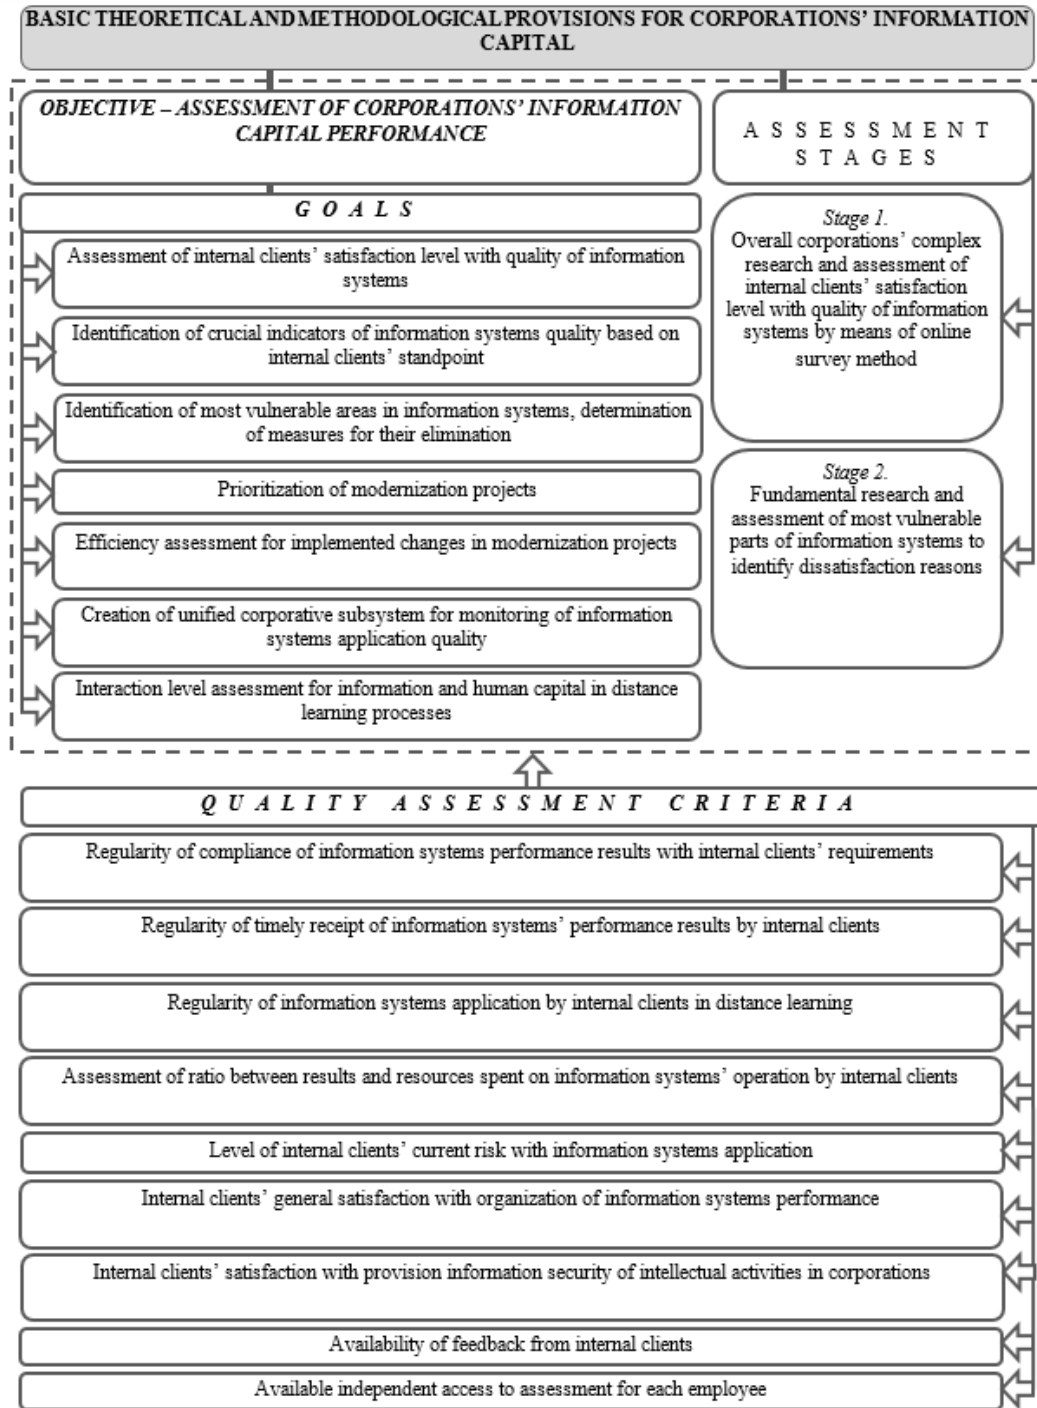

Fig. 1. Logical and Structural Chart for Creation and Assessment of Informational Capital in Corporations (Developed by Authors V. V. Manuylenko, G. A. Ermakova)

## V. CONCLUSIONS

It is important to note that development of digital innovations predominately on intellectual, informational and digital capitals foundation in the “open innovation” system serves to reduce research and development costs, create potential for efficiency improving as well as potential synergy between informational and digital innovations. Thus, conception was created and implemented as follows: intellectual informational and digital capitals functioning in corporations simultaneously with human and stakeholders’ capital represent future potential digital innovations in the “open innovation” system. Research possibilities are limited with underdeveloped legislation that regulates digital economics processes, which predetermine development of digital innovations in corporations. Different corporations may independently formulate guidelines for digital innovations development based on proposed scientifically grounded toolkit.

**Abstract**—Assistance humanoid robots (AHR) are the category of robotics used to offer social interaction to humans. In higher education, the teaching staff supports the acceptance of AHRs as a social assistance tool during the learning activities, with the whole responsibility of the correct operation of the device and providing a more comprehensive view of the objectives and significance of AHR use. On the other hand, students deal with AHRs either as a friend or control figures as a teacher. This paper presents an algorithm for AHRs in oral assessments. The proposed algorithm focuses on four characteristics: adaptive occurrence, friendly existence, persuasion, and external appearance. This paper integrates AHRs in higher education to improve the value of psychological and social communication during oral assessment where can assist students in dealing with challenges, such as shyness, dissatisfaction, hesitation, and confidence, better than a human teacher can. Thus, AHRs have increased students' self-confidence and enriches active learning.

**Keywords**—Algorithm; humanoid robot; social robots; oral assessment; assistance robots; higher education; adaptive behavior robot

## I. INTRODUCTION

Robots are becoming beneficial components of the educational ecosystem. With their different capacities, which range from the ability to see people and their environment to the ability to reason and explain circumstances and people's emotions, robots are becoming useful components of the educational ecosystem. These robots have a physical presence as well as multimodal interaction skills, which are equally crucial. With their human-like look, humanoid robots bring even another dimension to our understanding of social cues and body language: Keys to more intuitive and natural human-robot interaction and robots in education interacting [1].

As humanoid robots become more prevalent and people engage with them, the social intelligence of artificial agents is receiving attention. The important social skills presented by the standardized evaluation method for humans, Evaluation of Social Interaction (ESI), include approaches, speaking, turn-taking, gazing, and gesturing. When speaking to others, people employ co-speech gestures to accentuate their words, convey their intentions, or give detailed descriptions. Co-speech gestures have been shown to have strong impacts in numerous social science studies [2], and a neuroscience study supports motions are created by human professionals. The only movements that may be made are those that were considered during the design stage, even though hand-produced gestures

are natural and human-like. Furthermore, it takes significant human effort to create links between gestures and verbal phrases [4].

Due to their physical resemblance to humans, humanoid robots can give real-time feedback and interact with people more effectively. They have improved social abilities and are designed to show emotion through gestures, intonation, and facial expressions, as well as to respond with the right body language [5]. They can also display feelings, including shock, fear, rage, and disgust. Compared to human teachers, humanoid robots can assist in resolving issues connected to shyness, frustration, reluctance, and confidence. Humanoid robots are being widely employed in many nations, particularly for special education, and can assist students in dealing with challenges, such as shyness, dissatisfaction, hesitation, and confidence, better than a human teacher can. One of the factors contributing to humanoid robots' success in achieving learning objectives is that they never get tired, regardless of how many mistakes a pupil makes. Some humanoid robots support telepresence, which enables instructors to connect to the classroom remotely using display systems, which are typically built into the torsos of robots [6].

So, in the present paper, we focus on oral assessment to improve the value of psychological and social communications during oral assessment and to increase students' self-confidence and enrich active learning.

The remaining of this paper is organized as follows. Section 2 stated the problem statement. Section 3 is related to the work presented here. Section 4 presents an algorithm for AHRs. Section 5 describes the four recognized characteristics: adaptive occurrence, friendly existence, persuasion, and external appearance. These are described in Section 6. We conclude the paper and point future directions in Section 7.

## II. PROBLEM STATEMENT

Assistance humanoid robots (AHRs) in higher education have become an enriching teaching tool. They are different from portable devices such as smartphones, and tablets. AHRs have been described as human-looking forms with a head, arms, legs, and torso. Moreover, AHRs have characterized automation, repeatability, flexibility, digitization, anthropomorphism, body motion, and interaction [7]. Furthermore, AHRs encourage students to interact with reality in studying halls during the oral assessment process [8]. Consequently, AHRs have been characterized by personifying,

which provides more social interaction with students, such as instantly addressing them by name. In this environment, robots provide students with a more honest and realistic interaction than other technological devices [9].

On the other hand, dialogues support social interaction and create a shared experience of knowledge. Dialogue flow also provides a significant factor in increasing the quality of conversations [10]. As a result, a high degree of dialogue flow corresponds to favorable self-esteem, has an influence on the individual understanding of belonging, and can encourage solidarity [11].

Since dialogue flow can encourage social bonds and satisfy social conversation needs, education institutions should manage this knowledge when considering using AHRs in student oral assessments. Consequently, this can contribute to promoting dialogue between students and AHRs, especially in oral assessments. This paper has presented an algorithm for designing AHRs in higher education and put the main features of its external appearance and behavior.

### III. RELATED WORK

Artificial intelligence, sensors, mechatronics, and power are all components of humanoid robots. The main aim of modern humanoid robots is to acquire the ability to recognize visual expressions and perceptions to solve tasks, such as correctly predicting the emotion of a human by monitoring their visual facial expressions. Therefore, the only information that humanoid robots need supplied is the data that will supply enough relevant information to be processed, allowing them to do and expand the range of learning and performing activities that are already available to them. It will be up to the algorithms and other methodologies, such as deep learning and neural networks, to extract the features from photos that have been given to them. All these goals for humanoid robots present considerable difficulties and processing power needs, and it should be highlighted that a humanoid robot cannot employ this kind of enormous computing power alone. To install the cloud, which will further analyze the information and give it back to the humanoid robot, the humanoid robots must absorb, integrate, and collect the information from the environment [12].

Research in the disciplines of robotics that is currently considered critical technologies include multisensory perception, cognition, and man-machine interaction. Robotic systems are given theses and procedures from the field of artificial intelligence (AI). Significant biological principles can be used as recruiting tools and role models for robots. With remarkable accuracy, the human body is replicated in its greatest potential kinematic form. The main new area of research in AI is humanoid, complicated mechatronic systems inspired by biology. The psychological features of humanoid robots are just as fascinating as their technological ones [13].

More robots are being created for use in practical fields, such as education, healthcare, eldercare, and other assistive applications. For robots to have a positive impact on human life, there must be natural human-robot interaction (HRI). A human-like interaction is built on an understanding of the other person's needs and emotional condition at the time of the

interaction. To achieve this goal, Chiara and others proposed an ecological technology called thermal infrared imaging, which can give information on physiological characteristics related to the subject's emotional state. This ecological technology was presented and surveyed here. The technology can lay the foundation for the continued development of powerful social robots as well as for HRI. In the literature, thermal IR imaging has already proven effective for identifying emotions. This review can serve as a roadmap and encourage the usage of thermal IR imaging-based affective computing in HRI applications, which are meant to enable a natural HRI with a focus on people who find it challenging to convey their feelings [14].

Aburlasos et al. [15] proposed an organized and comprehensive modeling behavioral method to guide the activities of two interactive NAO robots with the goal of gradually evoking the Gestalt game in the mind of an autistic child. More specifically, the goal is to teach Gestalt's game first to robots and then to autistic children. In the end, children with autism will discover that playing with other children is more fun than playing alone with robots.

Teaching robots using hand gestures is now possible thanks to a framework developed by Mazhar et al. [16]. The background invariant robust hand gesture detector is the foundation of the suggested system. This was accomplished by applying a modern convolutional neural network that has already been trained, Inception V3, to the classification of 10 hand movements. The experiment validates the effectiveness of the suggested framework and guarantees a natural way to program robots. The combination of Kinect V2 and Open Pose allows the robot to understand its distance from the human worker to ensure the safety of nearby human coworkers.

Alemi, Meghdari, and Haeri [17] conducted a study in which they attempted to examine the attitudes of young EFL learners toward RALL. An experiment with a humanoid robot acting as a teacher's helper was carried out in a private kindergarten in Iran. They monitored the students' motivation, interaction, and anxiety as they studied with the humanoid robot. The outcomes demonstrated that the students' motivation increased because of their positive interactions with the humanoid robot. Additionally, they showed no indicators of nervousness while engaging with the humanoid robot during the learning process since it made the classroom feel welcoming. In conclusion, this study has served as a superb model for subsequent investigations using humanoid robots in second robots, which are seen as attractive and practical instruments in language learning and teaching circumstances. They can also accommodate the various needs of the students.

The field of social robotics is undergoing significant change because of neuroscience-based human-robot interaction, which is also improving our understanding of the human brain. Recent findings have demonstrated that more sophisticated analysis techniques and the trend of gathering data during real-time, embodied interactions with robots can deepen our understanding of the fundamental mechanisms underlying social cognition beyond simply perceiving robots in screen-based experiments. The development and design of the next generation of social robots, the same robots that may one

day function as social companions who support and care for their owners, stands to benefit from the additional (and natural) knowledge gained from this basic human brain research [18]. However, in less than 10 years, major problems about human-robot interaction have emerged from the field of neuroscience, such as: How can our relationships with these unique, mechanical companions benefit from the complex neural architecture of the human brain? How does the representation of social cognition evolve as robots become more pervasive in our social lives? Future research fusing human neurology and social robotics will shed light on how to live with autonomous robots that connect with us socially.

#### IV. HUMANOID ROBOT IMITATION LEARNING

Imitation learning refers to a humanoid robot's acquisition of skills or behaviors by observing a teacher demonstrating a given task. With motivation from neuroscience, imitation learning is a significant portion of AI, and human-computer interaction, and in turn, is taking a part in the future of robotics [19]. Another approach to imitation learning depends on trial and error, which introduces valuable models to understand desired behavior from a set of collected instances [20].

Imitation learning works by extracting features about the instructor's actions and the surrounding environment, including any manipulated objects, and understanding a mapping between the current position and revealed behavior. Traditional machine learning algorithms do not scale to high-dimensional agents with high degrees of freedom. Particular algorithms are therefore needed to build satisfactory representations and predictions to simulate motor processes in humans [21].

In the complete method of robotic imitation learning, demonstration teaching provides a teaching sample containing made options, operation characterization characterizes the options within the teaching sample as valid forms that the golem will acknowledge. The last word goal of imitative learning is to create the robot "master" behavior, which implies that the robot has got to reproduce the behavior and generalize the behavior into different unknown scenes. The method that robots use the teaching data to "master" behavior will be referred to as operation imitation. This thought methods of operational imitation are roughly divided into three categories:

activity biological research, inverse reinforcement learning, and adversarial imitation learning.

#### V. FROM HUMAN ASSESSMENT TO ROBOT

Although oral assessment has a wide record in examination practice in higher education and is a well-established component of such proceedings, concerns remain regarding its use. Therefore, there has been some move away from oral assessment for students, partly through a consideration of validity, trustworthiness, and justice [22].

Given the long history of oral assessment, which has some distinct advantages, it reflects the oral form document of communication that dominates professional practice. Also, it can test the limits of a student's knowledge and understanding. Moreover, it is thought to be an especially practical way of assessing individual types of capabilities. Furthermore, it supports intra-personal differences, such as trust and self-awareness [23].

AHRs have become an essential component of higher education infrastructure as teachers; they might take over assigned tasks that professors carry out. For example, AHRs deliver hints upon request to students [24].

In this case, the AHR keeps students' inspiration at a high level by prompting them. AHRs can be friends with students and share learning with them. Also, AHRs could assist in preserving student inspiration at a high level by encouraging them. Consequently, the AHR can play a valuable role in oral assessments. Oral assessment supports active learning through its empowerment of creating confidence among teaching staff and students during the oral assessment process of AHR technology [25]. That is, in turn, it may create more confidence for professors and higher education about the integration of AHR technology into their strategy.

#### VI. PROPOSED ALGORITHM

This paper presents an algorithm for AHRs, which is described by four recognized characteristics: adaptive occurrence, friendly existence, persuasion, and external appearance. This is detailed in this section.

##### Algorithm1: AHR generates gestures during dialogue acts information.

- Step 1: Start.
- Step 2: Collect speech datasets.
- Step 3: Determine the consideration of speech.
- Step 4: Define the dialogue acts based on speech consideration.
- Step 5: Classify the dialogue acts information into categories.
- Step 6: Discover the gestures happening combined with dialogue acts.
- Step 7: Extract main motion features.
- Step 8: Cluster these features to reduce dimensionality and increase the representability of gesture motions.
- Step 9: Develop conceptual models to connect dialogue information with gesture motion.
- Step 10: Analyze the intention of dialogue information related to gestures motion.
- Step 11: Discover the period of different gestures motion regarding dialogue information.
- Step 12: Determine the phases of gestures motion generation during dialogue information.
- Step 13: End.

Fig. 1. The AHR Generates Gestures during Dialogue Acts Information.

### A. Friendly Existence

Friendly existence expresses sociable presences. Students tend to humanize robots as technological devices, such as the AHR, and treat them socially when the technology shows social cues. The aim of this algorithm is to investigate the dialogue flow with AHR in the real oral assessment environment and to examine the extent to which oral flow is present in AHR–student interactions. Algorithm 1 described in Fig. 1 shows how AHR generates gestures. Dialogue acts as

information in oral assessments. This algorithm classifies dialogue gestures into categories and develops conceptual models to understand the intention of dialogue during oral assessment. Algorithm 1 can be compatible with generating hand gestures. It limits the whole arm's movements and manages the five fingers' movements. Also, there is a lack of head and torso motion. Another limitation can be indicated by eye gazing control issues. Algorithm 2, described in Fig. 2, generated laughing gestures during the dialogue assessment.

**Algorithm 2: AHR generates laughing gestures during dialogue information.**  
**Step 1:** Start.  
**Step 2:** Collect laughing speech dataset.  
**Step 3:** Analyze laughter types.  
(social, bitter, dumbfounded, and softening laughter).  
**Step 4:** Analyze laughter style.  
(secretly, giggle, guffaw, and sneer).  
**Step 5:** Analyze intensity level.  
**Step 6:** Analyze laughter function.  
(funny, amused, joy, mirthful laugh, social polite laugh, bitter/embarrassed laugh, self-conscious laugh, inviting laugh, contagious laugh, depreciatory/derision laugh, dumbfounded laugh, untrue laugh, softening laugh).  
**Step 7:** Detect the facial expressions during laughter.  
**eyelids**(closed, narrowed, open).  
**cheeks**(raised, not raised).  
**lip concerns**(raised, straightly stretched, lowered).  
**Step 8:** Detect the head and upper body motion during laughter.  
**head**(no motion, up, down, left or right up- down titled nod, others(including motions synchronized with motions like upper-body)).  
**upper body**(no motion, front, back, up, down, left or right, titled, turn, others(including motions synchronized with other motions like head and arms)).  
**Step 9:** End.

Fig. 2. The AHR Generates Laughing Gestures during Dialogue Information.

### B. Adaptive Occurrence

Adaptive occurrence represents adaptiveness as a key characteristic of oral assessment quality. Regarding AHRs in oral assessment, perceived adaptiveness may be expressed as the extent to which students consider the AHR to keep in touch with their individual learning assessment needs. For example, an AHR selects to begin a dialogue with the student to offer assistance, as depicted in Algorithm 3 in Fig. 3. According to Algorithm 3, student assistance suggests more known keywords to help the AHR understand the student-robot dialogue. Then, the AHR solves the problem itself, or student assistance can offer more additional information to enhance the

AHR's understanding. The problem includes understanding keywords or informing unclear messages not inserted into loaded sound files. This assistance provides an appropriate learning pace and introduces personal feedback during the oral assessment.

Furthermore, an AHR can address the unclear content in the oral assessment, as depicted in Algorithm 4 in Fig. 4.

Concerning the social behavior of AHR is a key facet of adaptiveness. The AHR stimulates social interaction in oral assessment with students by calling students by their name and capturing a photo, as depicted in Algorithm 5 in Fig. 5.

**Algorithm 3: AHR starts a dialogue for student's assistance**  
**Step 1:** Start.  
**Step 2:** AHR identifies a problem in student-robot dialogue.  
**Step 3:** AHR searches in loaded sound files on it.  
**Step 4:** If AHR finds the answer  
    **Then** AHR completes the student-robot dialogue.  
    **Else** AHR asks for student assistance.  
  
**Step 5:** Student's assistance provides AHR with the required support.  
**Step 6:** If AHR solves the problem  
    **Then** AHR completes the student-robot dialogue.  
    **Else** AHR requests additional support.  
  
**Step 7:** AHR tries again to solve the problem after student support.  
**Step 8:** AHR solves the problem thanks to Student assistance.  
**Step 9:** End.

Fig. 3. The AHR Starts a Dialogue for Student Assistance.

**Algorithm 4: AHR adapts the dialogue content.**  
**Step 1:** Start.  
**Step 2:** AHR greets students.  
**Step 3:** AHR introduces itself and the educational institution.  
**Step 4:** AHR explains its role in the dialogue which includes to clarify the aim of the dialogue.  
**Step 5:** AHR receives questions from students and provides them with answers.  
**Step 6:** If AHR detects any misunderstanding in the students' dialogue.  
    **Then** AHR alerts their attention and provides them with complete right explanations.  
  
**Step 7:** AHR supports its dialogue with suitable references from the university's library or internet resources or practical examples.  
**Step 8:** AHR updates its dialogue regularly to develop its skills in student-robot interaction.  
**Step 9:** AHR supports student dialogue by using gestures and expressing empathy motions.  
**Step 10:** End.

Fig. 4. The AHR Adapts the Dialogue Content.

**Algorithm 5: AHR adapts social behavior with students.**  
**Step 1:** Start.  
**Step 2:** AHR asks the student about his/her name.  
**Step 3:** AHR greets the student.  
**Step 4:** AHR captures a photo of the student.  
**Step 5:** AHR determines the student's face and performs face recognition.  
**Step 6:** AHR extracts the face features.  
**Step 7:** AHR predicts the student's age and emotional state.  
    (e.g. happy, unhappy, worried, sad, anxious).  
**Step 8:** If there is an academic database about the students' degrees or personal profiles.  
    **Then** AHR can be reached and collects the whole information about the student.  
  
**Step 9:** AHR confirms the learning processes(e.g. oral assessment process,  
    suggests some activities according to the social behavior of students or emotional state).  
**Step 10:** End.

Fig. 5. The AHR Adapts Social behavior with Students.

### C. Persuasion

According to Fig. 6, AHR provides students with more trust and persuasion through its physical shape like humans, which adds more flexibility and comfort during student-robot interaction. Also, the AHR design provides feedback based on social norms and friendship relations. Moreover, the AHR introduces a personalized service with the mutual gaze communicated along with contextual information.

Additionally, it incorporated traditional communicative processes, such as jokes. Through jokes, the AHR can deal with students with double-friendly interaction. Consequently, jokes can motivate students toward effective cooperation and create a community-centered learning environment. Also, jokes encourage students in the learning process and enrich social interaction.

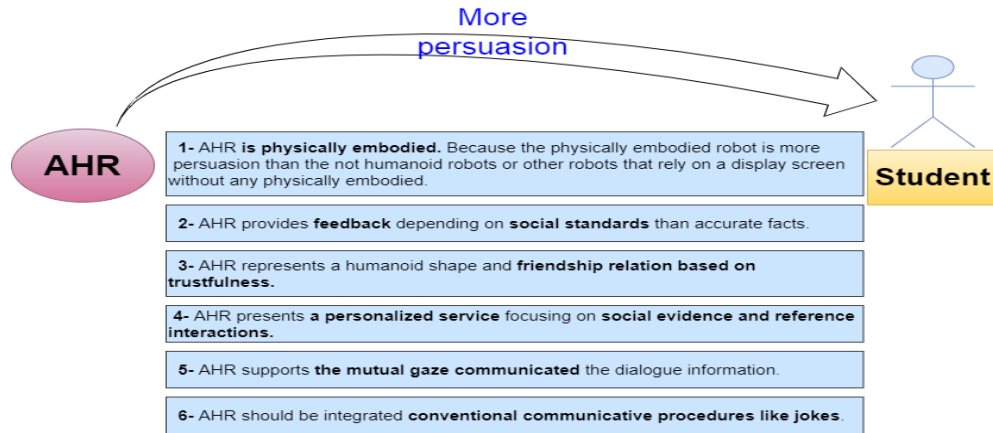

Fig. 6. Persuasion Features of the AHR.

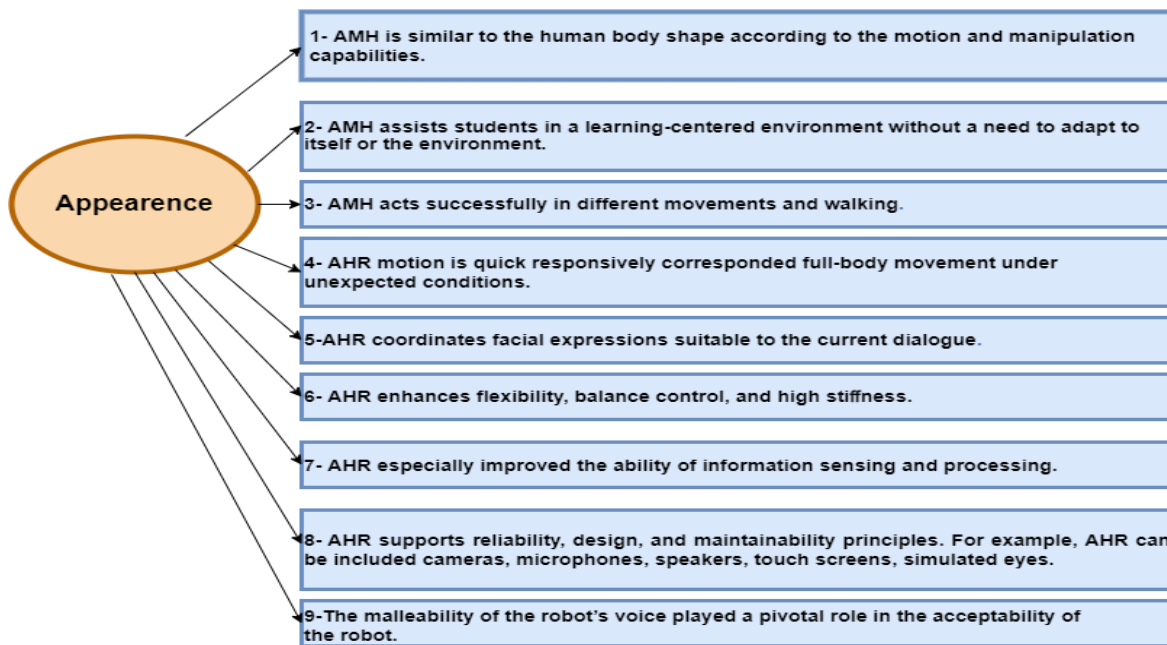

Fig. 7. External Appearance of the AHR.

#### D. External Appearance

AHR appearance should be designed to correspond to dialogue requirements in oral assessments. This appearance can be described as flexible. AHR dialogue contains different alternatives for each social interaction of dialogue, such as a greeting, end dialogue statement, jokes, and different keywords of various intentions. Fig. 7 explains the appearance of the AHR in detail.

### VII. DISCUSSION

To answer the research questions in this study according to the above analysis, we think it is possible for the robot to act as a tutor and automatically guide freshmen to conduct a group test.

We expect robots to judge students' answers fairly. In the past, when human teachers conducted oral tests, they sometimes let students pass the assessment with a looser standard. In addition, human teachers cannot maintain a certain concentration, objectivity and fairly for a long time, and robots can easily do it. However, we can find in the robot was not sensitive to students answers. In fact, sometimes the students should to try several times before the robot could receive the sound and recognize it. Although some monosyllabic words were heard by the robot, there may be some problems because of the pronunciation problems.

For example, since the pronunciation of numbers is very basic, this can be a blow to students. In the first case, students' pronunciation will affect the correct answer rate on the test. From the perspective of language teachers Technical problems can be overcome. Where, we suggest that when using a robot

to conduct the oral test, the robot need to practice pronunciation before conducting formal test. It also could give the students the opportunity to pronounce before the test. Besides, the teacher could modify the way that students answer questions (e.g., by answering with whole sentences instead of just numbers) to make up for the robot's lack of recognition of monosyllables. A further test can be conducted by native speakers to compare the reception of sound to find out if this situation is mainly due to the pronunciation of foreign language learners or the experimental environment. Also about the design of the test, the robot can say the correct answer after each question to let the students know the correct answer or pronunciation immediately.

On the other side, Human-robot interaction also can be enhanced peer-peer interaction. When someone answers right, the peers cheer. Through their peers' affirmation, students can improve self-confidence or reduce the sense of distrust of their own pronunciation. In addition, in group learning students can learn important lessons from the answers made by other students.

### VIII. CONCLUSION AND FUTURE WORK

Humanoid robots play a catalyst role in higher education because they include human-like forms that support student satisfaction. They also encourage students to generate contemporary fluencies. The prosperous performance of emerging AHRs in learning needs cognizance of the investment principles on the part of those carrying out the performance. Oral assessment is a critical process in higher education. Consequently, oral assessment supports active learning through its empowerment of creating confidence among teaching staff and students during the oral assessment process of AHR technology. That is, in turn, it may bring professors and higher education more confidence about the integration of AHRs technology into their strategy. This paper has discussed an algorithm for applying AHR in oral assessments in higher education. This algorithm also depends on four perceived characteristics: adaptive occurrence, friendly existence, persuasion, and external appearance. Moreover, it presents the experiences of human-robot interaction.

In future work, we intend to discover substantial distinctions between oral assessment guided by the teaching staff and AHRs. Also, we hope to develop the proposed algorithm by adding more characteristics. We desire to be able to use the AHR to direct oral tests so that professors can exchange roles and monitor and assess students' complete ability and change the way the oral test is conducted.

# Classifiers Combination for Efficient Masked Face Recognition

Kebir Marwa, Ouni Kais

Research Laboratory Smart Electricity & ICT, SE&ICT Lab., LR18ES44

National School of Engineers of Carthage

University of Carthage, Tunisia

**Abstract**—This study was developed following the upheaval caused by the spread of the Coronavirus around the world. This global crisis greatly affects security systems based on facial recognition given the obligation to wear a mask. This latter, camouflages the entire lower part of the face, which is therefore a great source of information for the recognition operation. In this article, we have implemented three different pre-trained feature extractor models. These models have been improved by implementing the well-known Support Vector Machines (SVM) to reinforce the classification task. Among the investigated architectures, the FaceNet feature extraction model shows remarkable results on both databases with a recognition rate equal to 90% on RMFD and a little lower on SMFD with 88.57%. Following these simulations, we have proposed a combination of classifiers (SVM-KNN) that would prove a remarkable improvement and a significant increase in the accuracy rate of the selected model with almost 4%.

**Keywords**—Masked faces; deep learning; AlexNet; ResNet50; FaceNet; classifiers combination

## I. INTRODUCTION

According to the World Health Organization (WHO) [1], there have been 517.648.631 confirmed cases of COVID-19, including 6.261.708 deaths, until May 13th, 2022. That is considered an astonishing number after three years of the virus's appearance and despite all precautions taken. Therefore, the Centers for Disease Control and Prevention (CDC) [2] emphasize social distancing and obligation to wear masks in order to minimize contamination and reduce the hazardousness of this virus. Except that, wearing a mask causes the performance degradation of security systems based on the identification of people by their faces, since the mask hides a large part of the face, hence the loss of a large amount of information. Thus, existent techniques for faces recognition implemented before this crisis, must have an improvement and some adjustment to live up to the expectations of users of face-based security systems, as stated by the National Institute Of Standards and Technology (NIST) [3]. The performance of facial recognition algorithms submitted before March 2020, when the World Health Organization declared a global pandemic, was examined in a previous NIST report published in July. The error rate of these pre-pandemic algorithms was found to be between 5% and 50% in this first investigation, which confirms that these systems have become ineffective.

The degradation of identification systems, causes several problems. So, frauds and wanted persons take advantage of the mask, for illegal immigration and crimes commitment without being recognized. Community access control and face

identification have become almost an impossible mission when a grand portion of the face is covered up by a mask. Due to these issues, face masks have essentially challenged existing face recognition strategies.

The epidemic situation, ensures the emergence of two new axes of research: [4]

- Face mask detection: consists of checking whether the individual is wearing a mask or not, and it is an interesting task in public squares and areas with fulls, where wearing a mask is mandatory.
- Masked face recognition (MFR): is used to identify people wearing masks on the basis of the remaining part of the face (the eyes and the forehead parts)

Our interest in this paper is the second axis. we have implemented a recent technique to identify masked faces using a deep learning-based method for extracting features. To train our model, two databases are used: Simulated Masked Faces Recognition database(SMFRD) and Real-World Masked Faces Database(RWMFD) presented in [5], specially designed to evaluate the performance of masked faces recognition methods.

An interesting preliminary phase in the recognition operation is the pre-processing of the images. However, the quality of the detection influences the accuracy of the identification, so we chose the MTCNN algorithm to have an exact and correct detection. Regarding the feature extraction task, we have opted for three pretrained models that are very recognized in the field of facial recognition, which are AlexNet, ResNet50 and FaceNet. For the classification process we have chosen a classifier which has proven a huge success in image classification, it is the Support Vector Machine(SVM). Finally, we have proposed, a classifiers combination (SVM-KNN) to enhance the performance of the classification process.

This study is organized as follows: The Section 2 provides the related works about masked faces recognition. While Section 3 highlights the motivation and the contribution of the paper. Section 4 discusses the state-of-the-art methods. Section 5 presents the used method. The remainder of the paper stated the experiments and the concluding statements based on experimental results.

## II. RELATED WORKS

Obviously, the issue of partially hidden faces has existed for a long time, since there are several factors other than wearing a mask such as a beard or mustache, sunglasses or

even makeup that changes the original features for masquerade reasons. But recently, the obligation to wear a mask makes the problem even worse and the dilemma of recognizing occluded faces has become at the head of research in computer vision. Consequently, significant increase in MFR research effort, extending existing MFR methods and yielding promising accuracy results. Then, search across major digital libraries to track growing research interest in the mission of occluded face recognition (OFR). A series of search strings are formulated to find leading repositories the article covers the use of deep learning techniques only in the context of face-based recognition. MFR article search results retrieved from Web of Science, Scopus, IEEE Xplore, Wiley, Ei Compendex, ACM Digital Libraries and EBSCOhost. These warehouses include articles on recent popular seminars, journals and conferences articles from five years.

Fig. 1. Diagram of Research Efforts on MFR from 2017 to 2022.

As shown by Fig. 1, the importance of research in the field of Occluded and Masked Faces recognition (OFR and MFR) witnesses a noticeable increase in parallel to exhausting researches [6] [7] [8].

Except that, this diversity does not mean the effectiveness of the applied techniques, because until now there is no masked face recognition method whose performance exceeds or equals that of unmasked face identification techniques. As a result, the achievement of the methods used post-pandemic remain unsatisfactory for real-time systems and high-traffic sites with high security requirements. As of late, researches have proposed many useful methods. They basically consist of three categories:[9]

- Generate a typical model of the occlusion issue(restoration model),
- Occlusion removal approach,
- Deep learning-based approaches.

#### A. Restoration Model

This approach consists of generating the hidden part of the face considering that the nose, mouth and chin carry a large amount of information. For the improvement of the recognition efficiency reasons and to generate the lost features of face, there are two restoration models: robust structured error coding and robust subspace regression [9].

- Robust structured error: The occlusion produced by the mask presents a spatial continuity. By this, an error caused has a specific spatial structure. This makes the reconstruction of the low-rank structure of the face image from the data damaged by occlusion necessary, to have a correct identification and minimize the rate of false positives and true negatives. For instances, authors in the literature [10] presented an improved robust principal component analysis (RPCA) method. At the beginning, the method consists in decomposing the learning matrix  $M$  by a lower rank matrix, which ensures obtaining a lower rank content matrix  $L$  and a sparse content matrix  $S$ . In this way, the recovery of the lower subspaces of the training sample is achieved. This method considers how to restore low-ranked structures from training samples that are error-prone but sparsely structured. This effectively suppresses the effects of sparse noise and provides strong efficiency. In order to increase interclass information between low-ranked matrices of different face categories, reference [9] has expressed all training patterns as observation matrix  $D$ . After decomposing the matrix  $D$ , we get a low-ranked matrix  $A$  with no occlusion and a sparse error matrix  $E$ . The RPCA is applied to the submatrix  $A$  and the resulting subspace is used as an occlusion dictionary for facial images. The image reconstruction was then identified and the error size was classified according to the sparse representation classification and occlusion dictionary.[9]

- Robust subspace regression: This model is generated by projecting high-dimensional feature data from different categories of facial images onto a low-dimensional subspace. Next, an independent subspace is set in the occlusion part, and the occlusion of the face image is expressed using the existing dictionary atom to realize a powerful recognition effect of the occlusion face. Currently, robust subspace solutions for occluded face detection primarily include sparse representation, collaborative representation, and obstruction dictionary learning.

#### B. Occlusion Removal Approach

This model aims to estimate the position of occlusion through two error indices. The first is in the form of local similarity error between the original image and the partially occluded image, while the second aims to the spatial local error caused by the occlusion. Otherwise, the method consists in locating the hidden areas of the face and eliminating them completely from the feature extraction and classification process. In this context, one of the most famous approaches is that based on segmentation. According to the literature [11], authors segmented the face in small local zones. These latter, contain the occluded part to be eliminated and which will be detected by the support vector machine (SVM). Then the last phase is to use a mean-based weight matrix for face identification.

Several techniques have been proposed to remove the concealed part of the face, including the exemplar based Image in-painting technique proposed in [12]. As well as, the

structural similarity index measure and principal component analysis technique [13].

### C. Deep Learning-Based Approaches

Currently, Deep learning has proven huge success in several areas, especially in FR. This comes down to the efficiency of deep features compared to others that are over shallow. The most recognized research works in occlusion face are based on this type of features, taking the example in [14], an efficient partial face recognition approach was proposed, this is Dynamic Feature Matching (DFM) approach, based on the combination of the Fully Convolutional Network (FCN) with Sparse Representation Classification (SRC). The method is intended to recognize partial faces of arbitrary size. Another model proposed to identify hidden faces called BoostGAN model [15]. The main idea of this model is to use the occluded face to elaborate the non-occluded face and this latter will then be used to recognize the person. Except that, in the case of large occluding surfaces such as face masks, GAN-based methods are hard to regenerate the details of the key points on the visage.

Table I presents the performance of some MFR methods.

TABLE I. SUMMARY OF SOME MFR METHODS PERFORMANCE

References	Model	Dataset	Accuracy
GuiLing, W.[9]	Mask separation	RMFRD	95.22
Priya, G.[11]	MBWM-SVM	GTAV	94.75
He,L.[14]	Dynamic Feature Matching	CASIA-NIR-Distance	94.96

### III. MOTIVATION AND CONTRIBUTION OF THE PAPER

The failure of current methods to correctly identify masked faces in the same way as non-masked face recognition techniques motivates us to explore a new solution to overcome this shortcoming. Drawing on the significant performance and strong light resistance of CNN-based methods, facial expression variations and face occlusion. In this study, we have proposed an occlusion removal approach with transfer learning model to solve the masked face problem noticing during the COVID-19 pandemic.

To the best of our knowledge, the restoration model approach isn't truly a great selection. This procedure endures from a few issues, particularly the difficulty of implementing it and culminating the comes about. As well as, it could be a prepare that devours an expansive execution time. With that, several researchers use this method as is the case in the literature [16], contrary of our choice. The disadvantages of this approach, inspired us to base our considerations on the occlusion removal approach since it is a compelling and simple strategy. As well as, pre-trained model for feature extraction.

Other side, face detection has a huge influence on the quality of recognition. As of late, a few face tracking strategies have shown up and have demonstrated tall execution, such as the viola and Jones detector, which has gotten to be a reference in object detection and particularly for face. A bit more recently, it appears the famous MTCNN detector [17] which has proven great efficiency and speed of execution. But that the major progression of machine learning recently, gives us with unused choices, like the modern finder which

made a boom in computer vision is the mediapipe algorithm [18]. MediaPipe face detector is an ultra-fast solution with six landmarks and multi-face support. It is an excellent detector for streaming videos, but it is not yet used for static images. What motives us to use the MTCNN detector.

So the contribution of this paper lies in three points:

The first consists in adapting models usually used for the recognition of unmasked faces for masked faces. This adaptation was made by training the three models AlexNet, ResNet50 and FaceNet by databases specially designed for masked faces and adjusting the parameters of each model in order to improve their performances.

The second contribution aims to improve classification task with the inserting of SVM classifier for each model.

While the third contribution consists in a classifiers combination (SVM-KNN) that considerably improves the obtained results.

### IV. STATE OF-THE-ART METHODS

The ordinary and common structure for all face recognition methods is composed of a face detection, a feature extraction and a classifier. Through this paper, we have presented the races that we followed, starting with face cropping.

#### A. Face Detector: MTCNN

Currently, MTCNN or Multi-task convolutional neural networks, is the most popular and rigorous face detection solution. It is composed of three cascaded neural networks known by P-Net, R-Net and O-Net [17].

- **P-Net** stands for **Proposed network**: It searches for faces in frames of size  $12 \times 12$ . The task of this network is to achieve rapid results.
- **R-Net** presents **Refined network**: Its structure is deeper than Pnet. Despite all candidates originating from the previous network will be fed to R-Net, a large number of candidates are already eliminated by the first network P-Net.
- **O-Net** comes from **Output network**: briefly returns the bounding box (face area) and face landmark locations.

These three cascaded neural networks are presented in Fig. 2.

Fig. 2. Architecture of the Three Cascaded Neural Networks of MTCNN [17]

The MTCNN model detects five landmarks on the face, which are the left eye, right eye, nose, and two corners of the mouth. This model proves high face detection accuracy.

### B. Masked Faces Databases

In this section, we have presented several benchmark datasets used in the literature to evaluate MFR techniques [19].

Starting with the most popular and used databases in this field which are the RWMFRD (Real-world masked faces recognition dataset), the Masked Face Detection Dataset (MFDD) and Simulated Masked Face Recognition Dataset (SMFRD) introduced in the same article [5].

As regards **MFDD**, it contains 24,771 masked face images, which allows the implemented model to accurately detect faces hidden by masks.

As for **RMFRD**, the largest existent database for MFR, since it contains 5,000 images of 525 people wearing masks, and 90,000 images of the same people without masks. This database was used in [20], in the context of face images that were not acceptable due to an incorrect match were manually removed. In addition, the right face areas have been cropped using semi-automatic annotation techniques, such as LabelImg and LabelMe, Fig.3 displays sample images from RMFRD.

Fig. 3. Sample Images from RMFRD.

For diversification reasons, **SMFRD** has been developed, it contains 500,000 images of synthetically masked faces of 10,000 people collected from the Internet and Fig. 4 illustrate some images from this dataset.

Fig. 4. Sample Images from SMFRD.

The Synthetic face-occluded dataset (**SFOD**) [21] was elaborated using published data records from CelebA and CelebA-HQ [22]. CelebA-HQ is a large-scale facial attribute dataset containing over 30,000 celebrities. Each face image is cropped and roughly aligned based on the eye position. The occlusions were aggregated by five common non-facial objects: hands, masks, sunglasses, glasses, and microphones. Over 40 different types of objects were used in different sizes, shapes, colors and textures. In addition, non-face objects were randomly placed on the face.

The Masked Face Segmentation and Recognition dataset (**MFSRD**) [23] is composed of two parts. The first part consists of 9742 images of masked faces that have been collected from Internet with hand-labeled masked segmentation annotation. The second part contains 11,615 images of 1004 identities, of which 704 are collected from the real world and the rest of the images are collected from the Internet, where each identity has at least images with and without masks. Celebrities in Frontal Profile in the Wild (**CFP**) [24] includes the faces of 500

celebrities in face and profile view. Two verification protocols with 7000 comparisons, each presented: one compares only frontal faces (FF) and the other compares (FF) and profile faces (FP).

Both, Masked Face Verification (**MFV**) and Masked Face identification (**MFI**) are presented in [25], the first one contains 400 pairs for 200 identities while the second includes 4916 images of 669 identities.

The **LFW-SM** [26] variant database contains a simulated mask that extends the LFW dataset and contains 13,233 images from 5749 individuals. Through Fig. 5, we have presented sample images from LFW-SM.

Fig. 5. Sample Images from LFW-SM.

Several MFR techniques used the VGGFace2 [27] dataset for training, which consists of 3 million images of 9131 people with over 362 images per person. From this database derives the Masked faces dataset **VGGFace2-m** [28], it contains over 3.3 million images of 9131 identities. Table II shows the main characteristics of the dataset used in the masked face recognition task.

TABLE II. SUMMARY OF THE MFR BENCHMARKING DATASETS

Database	Size	Identities	Type of masks
RMFRD	95,000	525	Real-world
SMFRD	500,000	10,000	Synthetic
MFSRD	11,615	1004	Real-world/synthetic
MFV	400	200	Synthetic
MFI	4916	669	Synthetic
LFW-SM	13,233	5749	Synthetic
VGG-Face2-m	3.3M	9131	Synthetic

### C. Feature Extraction

One of the most crucial steps in the facial recognition process is feature extraction. It consists of extricating a set of features that are discriminative enough to represent and learn key facial attributes such as eyes, mouth, nose, and texture. In the presence of partial occlusion, especially that produced by the face mask, this process becomes more complex and current facial recognition systems need to be adjusted to extract representative and robust facial features. There are two categories of feature extraction, the first is a **shallow feature extraction** which is a classical technique explicitly forming a set of features fabricated with low optimization or learning mechanisms. The most popular methods of this category are Histogram of Oriented gradient (HOG), LBPs and codebooks [29]. In recognition tasks for unmasking face, these algorithms achieve considerable accuracy and remarkable robustness against a variety of facial changes such as lighting, rotation, scaling and translation. But this is not the case for masked faces, great degradation was observed.

The second category is the **deep feature extraction**. One of the most efficient neural networks in the field of face recognition is the Convolutional Neural Network (CNN), it has shown preponderance in a wide range of applications, such as image classification, retrieval and detection of objects. CNN-based models have been widely deployed and trained on many large-scale face datasets [30] [31] [32].

Several pre-trained architectures are recognized in the field of FR and have proven remarkable success, especially for feature extraction. To choose the most suitable extractor for our application, we have made an overview of the most cited models in the literature. AlexNet [33] is a famous model that ensures to reduce the training time and minimize the errors even on large datasets [34]. Fig. 6 shows the architecture of AlexNet.

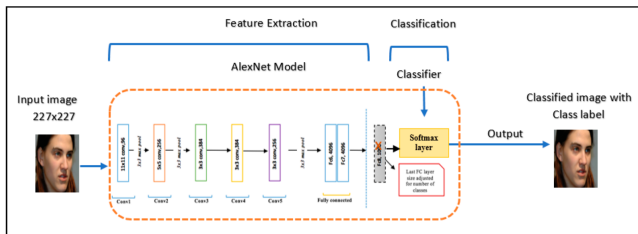

Fig. 6. Architecture of AlexNet [35].

Two other popular CNN-based models were presented in [36], VGG16 and VGG19 have been used in various computer vision applications, especially facial recognition. Despite achieving considerable accuracy, they endure from training time and complexity [37].

For the most complex identification missions, as in the case of masked faces, it is preferable to be processed by deeper neural networks like residual network (ResNet) [38]. This model achieves outstanding performance and accuracy, due to the stack of additional layers. These extra layers must be determined empirically to control for any deterioration in the performance of the model. The architecture of ResNet50 is presented in Fig. 7.

Fig. 7. Architecture of ResNet50 [39].

MobileNet [40] also is considered as one of the earliest deep neural networks, which mainly depends on a simple architecture. Its architecture exhibits high performance with hyperparameters and fast model calculations [41].

We cannot pass without mentioning Inception [42] and its variations [43], their innovation is that they use modules or blocks to build networks that contain folding layers instead of stacking them. Xception [44] is an extreme Inception

version that replaces Inception modules with deeply separable convolutions.

FaceNet [45], presented by Google researches, it is a famous pre-trained model that has proven very remarkable results. Fig. 8 shows the architecture of FaceNet.

Fig. 8. Architecture of FaceNet [45].

Through Table III we have presented a summary of the pre-trained CNN-based model.

TABLE III. SUMMARY OF THE PRE-TRAINED CNN BASED MODEL

Model	Variants	Trainable param	Conv layers	Total layers
AlexNet	-	62 M	5	8
VGG	VGG16	138 M	13	16
	VGG19	143 M	16	19
ResNet	ResNet50	25 M	48	50
	ResNet101	44 M	99	101
MobileNet	MobileNet	13 M	28	30
	MobileNet-v2	3.5 M	-	53
Inception	GoogleNet	7 M	22	27
	IncepV2	56 M	22	48
	IncepV3	24 M	22	48
	IncepV4	43 M	-	164
	Incep-ResNet-V2	56 M	-	164
Xception	-	23 M	36	71
FaceNet	-	140M	22	27

#### D. Classification

Many classifiers have been mentioned through literature, given the importance of classification in improving the performance of facial recognition systems.

As far as we are aware, the two most popular classifiers in facial recognition are Support Vector Machine (SVM) and K-Nearest Neighbour (K-NN) [46]

1) SVM: Support vector machine (SVM) is a supervised machine learning that can be used for classifications or regression problems. For the issues of multiclass classification it exists two distinguished approaches, the first is one-against-one and the second is one-against-all approach. Kernel functions are used for separation between classes for higher dimensional feature spaces. These Kernel functions are able to transform a non-linear distinguishable problem into a linear distinguishable one and projecting data into the feature space which ensure to find the optimal separating hyper plane [51].

2) KNN: K-Nearest Neighbor, a popular technique for classifying objects based on nearest training samples in feature space. This training samples are vectors with a class label for each one. The principle of the technique aims to compute the distance of the test sample to every training sample and keeping the k closest training samples (Where k designate positive integer). Then several distance functions used in the KNN algorithm, but the best methods are Euclidean distance [52].

3) *SVM-KNN*: Overall, the combination of classifiers is a relatively new technique. It can be considered as an optimization problem for minimizing classification errors and takes as input the outputs of M classifiers and generates the final N classes [53]. Classifier combination is more efficient, especially when the classifiers are different. There are two types of combination:

Features association using similar classifiers and decision association resulted from dissimilar classifiers [54]. The second type of combination is our choice since SVM and k-NN are two dissimilar classifiers.

On the other hand, classifiers can provide three types of outputs: The measure, class and rang types [55]. Depending on these types of output the combination may be:

- In the abstract stage built on voting methods.
- In the rank stage when the outputs are labels classified by a reducing weight.
- In the measurement level if the outputs are labels combined with confidence values.

For our work, we have used the majority vote in combination.

### E. Evaluation Metrics

In order to assess the cogency of implemented models for masked face recognition, we have opted for some evaluation parameters, such precision, recall, F1-score and accuracy metrics. These evaluation metrics were calculated as follow [49]:

$$Accuracy = \frac{T_N + T_P}{T_S} \quad (1)$$

$$Precision = \frac{T_P}{T_P + F_P} \quad (2)$$

$$Recall = \frac{T_P}{T_P + F_N} \quad (3)$$

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall} + score \quad (4)$$

Where  $T_P$ ,  $T_S$ ,  $F_P$ ,  $T_N$  and  $F_N$  designate respectively True positive, total samples, false positive, true negative, and false negative. For our work we have used Accuracy, precision and recall rate.

## V. USED METHOD

Our method consists of three primary scenarios (presented in Fig. 9), where we used three different pre-trained CNN-based models like feature extractors and the SVM is cascaded for classification. The model that has proven the best results will be improved by the combination of a second classifier which will be the K-NN.

Fig. 9. Architecture of our Primary Scenarios.

### A. AlexNet and SVM

We have used the well-known SMFD and RMFD databases specially designed to evaluate masked facial recognition systems. Data from each base were divided into 80% for training and 20% for testing and random distribution to avert biased results. Then, the images used are a mix of masked and unmasked faces which ensures good feedback.

Before we start, we need to preprocess the input images to fit the AlexNet model. Input image should be with a dimension equal to  $227 \times 277 \times 3$  pixels. For SMFD database, the image contains only the parts of the face we are interested in, so we don't need face detector, we just need to convert the size of the images from  $128 \times 128 \times 3$  to  $227 \times 227 \times 3$ . Unlike the RMFD base, we use MTCNN to frame the faces. It is important to note that the model is made up of many layers, but not all of these layers are essential for feature extraction. For instance, the first layer deals with the extraction of features such as edges and points. As it is presented in Fig. 10.

Fig. 10. Extracted Features by the First Layer of AlexNet from Original Image on RWMFD.

The table in Fig. 11 shows the different layers of the Alexnet model.

Layer	Number of Kernels	Kernel Size	Stride	Padding	Output Size
Input					$[227 \times 227 \times 3]$
Conv1	96	$11 \times 11 \times 3$	4	-	$[55 \times 55 \times 96]$
Max pool1		$3 \times 3$	2	-	$[27 \times 27 \times 96]$
Norm1					$[27 \times 27 \times 96]$
Conv2	256	$5 \times 5 \times 48$	1	2	$[27 \times 27 \times 256]$
Maxpool2		$3 \times 3$	2	-	$[13 \times 13 \times 256]$
Norm 2					$[13 \times 13 \times 256]$
Conv3	384	$3 \times 3 \times 256$	1	1	$[13 \times 13 \times 384]$
Conv4	384	$3 \times 3 \times 192$	1	1	$[13 \times 13 \times 384]$
Conv5	256	$3 \times 3 \times 192$	1	1	$[13 \times 13 \times 256]$
Max pool3		$3 \times 3$	2	-	$[6 \times 6 \times 256]$
fc6 Rel,U Dropout(0.5)	1				4096
fc 7 Rel,U Dropout(0.5)	1				4096
fc8 softmax	1				1000

Fig. 11. Details of AlexNet Layers [47].

After features extraction, we have equipped the SVM to perform the classification task. The output from ‘fc8’ layer was a 4096-dimensional feature vector. For the SVM kernel function, we used a linear kernel function without optimization. Kernel functions are used to take vector data as input and convert it into the optimal format. We were inspired by this network implemented mainly for unmasked faces as displayed by Fig. 12.

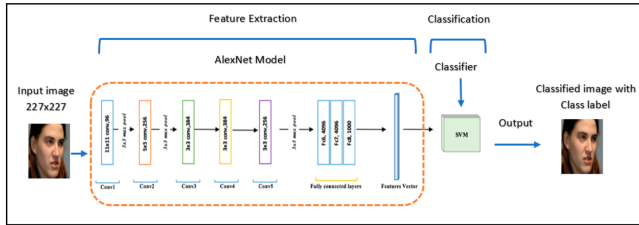

Fig. 12. AlexNet Convolutional Neural Networks with SVM.[35]

**B. ResNet50 and SVM**

Firsthand, Through the implementation operation, we have created an image data store that is useful for data management. Seeing that, the image was read and then loaded into the storage system. Then, the data was split into 80% training and 20% validation using random sampling for averting bias in the outcomes. On the other hand, the ResNet50 network can only process images with  $224 \times 224 \times 3$ , that’s why we resized images to be used in this size. Regarding the next phase, which is feature extraction, there is a final layer named fc1000 found just before the classification layer was used to extract features using the activation method. The activation outputs were aligned in columns to speed up afterwards the SVM training , and the optimizer Adam was used for the training instead of Stochastic Gradient Descent. Fig. 13 presents the ResNet50 model implemented with SVM.

Fig. 13. ResNet50 Convolutional Neural Networks with SVM.

We have adjusted manually different hyper parameter to obtain better outcomes. Starting with the batch size, it is tuned to 32 and we run our algorithm with cross-entropy for 50 epochs.

**C. FaceNet and SVM**

FaceNet model accomplished state-of-the-art results in several benchmark face recognition datasets, specially Labeled Faces in the Wild (LFW) and YouTube Face Database. The model requires as input images sizes  $160 \times 160$  and it contains 22 deep layers and 5 pooling layers, and a global average pooling is used at the end of the last inception module. The Fully connected layer will be used for face description. Elaborated

descriptors become an embedding module for correspondence descriptors. The max operator has been applied to features to develop a one feature vector from a template. The network must be properly tuned to expect a significant boost for the particular task of face recognition and verification. To retrain the FaceNet model, we have to bring a set of masked and unmasked faces[42].

The module includes four branches, the first contains a series of 1x1 local features from the input for learning. While The second branch implements 1 x 1 convolution in order to reduce the input dimensions until 1 x 1 convolution is achieved. This greatly minimises the quantity calculation the network desires. Third branch is coherent with the second branch with 5x5 learning filters. The last branch accomplishes 3x3 max pooling with a Stride of 1x1. Finally, all branches of the Inception module converge and Channel dimensions are linked to each other before being added to the next network, as displayed by Fig. 14 [48].

Fig. 14. Illustration of the Inception Module used for FaceNet Pre-Trained Model.

A crucial and next task in the FaceNet model is Face embedding, it consists of the representation of facial feature in the form of a vector. This latter, will be useful for comparison with the other generated vectors for identification of people. Embedding vector will be stored in order to be utilized as an input for the classifier. For this reason, we have to itemize each face in both training and testing database to have the classifier perform embedding and name prediction. It’s necessary that the pixels of the image are normalized to perform the prediction operation. FaceNet architecture contains a batch layer and a deep CNN network. This latter, was supported by the normalization L2 which results face embedding. The face embedding is performed Triplet loss during the training. The triple loss has a minimum distance between an anchor and positive when the identities are the same [49]. Fig. 15 displays the triplet loss training.

Fig. 15. The Triplet Loss Training[45]

Then, the validation process is integrated to recognize a candidate’s face by performing a classification task within an

integrated support vector machine (SVM). Since its inception, the SVM algorithm has been effectively applied to various classification-related problems. The SVM finds an Hyperplane that performs the classification task of the optimization issues. This maximizes the boundaries between the two classes of a particular input and target pair. The Classification is the result of certain robustness against over-fitting and margins represent class separation efficiency.

## VI. EXPERIMENTS AND RESULTS

### A. Implementation

Through this section, we have presented the experimental results acquired by face recognition using the three deep convolutional neural networks previously mentioned, after they are chained by the famous SVM classifiers, these implementations are based on both MFRD and SMFD databases. Three major experiments in our study were performed to compare performance differences between pre-trained CNN architectures. First, we evaluated the performance when extracting the learned image features from a pre-trained CNN AlexNet, followed by SVM as a classifier. Second, we have realised the same experience with ResNet50. Third, we have evaluated the performance of FaceNet model with SVM. The analysis and evaluation were carried out on the basis of the performance recognition accuracy, precision and recall rate.

Before beginning the training process for the convolutional neural network architectures, a previous pre-processing is required. For all datasets, a rescale is applied to resize the images to a  $227 \times 227$  as input for AlexNet,  $224 \times 224$  as input for ResNet50 and  $160 \times 160$  for FaceNet model.

All experiments were conducted using the platform of Windows with the configuration of AMD Ryzen5-GPU with 16 GB of NVIDIA GEFORCE RTX 3050 TI. Python tool was used to evaluate the method and perform the feature selection and classification task.

Table IV and Table V display the results obtained from the pre-trained models using two different databases.

TABLE IV. EVALUATION OF IMPLEMENTED MODELS USING RMFD

Model	Accuracy%	Precision%	Recall%
AlexNet	88.89	90.00	90.00
ResNet50	84.20	83.650	85.310
FaceNet	90	90	91.5

TABLE V. EVALUATION OF IMPLEMENTED MODELS USING SMFD

Model	Accuracy%	Precision%	Recall %
AlexNet	85.210	88.12	88.12
ResNet50	83.304	81.870	84.10
FaceNet	88.57	88.5	88.6

Since FaceNet has demonstrated considerable robustness with masked faces, we have opted this model to improve this performance by combining the used SVM classifier with the well-known K-NN classifier. The results obtained are presented in Table VI.

TABLE VI. FACENET MODEL WITH CLASSIFIERS COMBINATION

Model	RMFRD	SMFRD
FaceNet with SVM	90%	88.57%
FaceNet with SVM-KNN	94.46%	91.87%

### B. Discussion

As a first observation, the two databases are not simulated in the same way, RMFD provides more considerable results than the SMFD database for AlexNet, ResNet50 and FaceNet. The difference of results between the two databases comes down to the fact that in the SMFD database, mostly, masks are not really well placed on the face, since the masks are synthetic and are not real-world as in the case of the database RMFD database.

Regarding the models performance, FaceNet performed better on both databases. Although, AlexNet and ResNet50 models show significant results in unmasked face recognition, they present a remarkable degradation with masked faces. Even with the adjustment of some parameters for each architecture, as well as with the training of the models by a large number of masked faces.

According the authors in [35], AlexNet model reached higher accuracy of 100% on YTF datasets, 99.55% and 99.17% for the GTAV face and ORL datasets respectively. While ResNet50 has achieved high accuracy of 100% on GTAV face and YTF datasets. Similarly, FaceNet model presents a degradation compared to the results provided with the unmasked faces, let us quote the example of literature [50] where authors mentionned that FaceNet is highly efficient in non-masked faces recognition that it can reach 100% accuracy on YALE, JAFFE, AT&T datasets. Although the masked faces influenced the performance of the FaceNet model, it remains robust relatively to other models.

We have improved the classification process by a combination of voting-based classifiers which greatly improves the performance of the model, where we have reached an accuracy rate equals to 94.46% with RMFRD. This combination has been used in several works for different objects recognition other than masked faces recognition. Let's cite the example of the article [56], where the authors obtained an accuracy rate equals to 97.11% for Arabic-word handwriting recognition. In literature [57], classifiers combination for recognition of Arabic literal provides an accuracy rate equals to 98%.

It is obvious that these values exceed ours, this excess in values comes down to the fact that the models are less complex, the stains are easier and even the databases are much smaller.

To further appraise the proposed method, we have compared our model with several techniques destined specially for recognizing masked faces, such as the model implemented in [58] that just combined FaceNet with SVM and they got an accuracy rate equals to 91.304%. In the study presented in [59], authors used VGG16, the Multilayer Perceptron Classifier (MLP) and Bag-of-Features (BoF) paradigm, the accuracy rate obtained is equals to 91.3% . An efficient face recognition method presented in [35] using Transfer learning (ResNet50 and AlexNet) to fine-tune pre-trained models to the masked

face detection dilemma using an SVM classifier, authors have obtained an accuracy equal to 87%. Table VII summarizes this comparative study.

TABLE VII. PERFORMANCE COMPARISON WITH STATE-OF-THE-ART METHODS

Model	Dataset	Accuracy
FaceNet+Svm	RWMFD	91.304%
VGG16+BOF	RWMFD	91.3%
CNN+Svm	RWMFD	87%
Our model	RWMFD	94.46%

These methods achieve lower values than obtained by the proposed technique, which confirms the effectiveness of the classifiers combination. Then, the complementarity between the two classifiers increases the recognition accuracy and robustness of the model, this comes down to the fact that in image classification, the concept of ambiguity is particularly related to the presence of noisy pixels, mixed pixels and pixels from regions that have undergone changes. If some pixels are between two classes (such as those located on the boundaries of homogeneous regions), those pixels should be classified into a union of two classes rather than a single class. This case can be important when the spatial resolution of the sensor is high. Mixed pixels intervene in the image modeling of a single source whenever that source cannot distinguish between the two classes. In this case, only class related information is available. Pixels in areas with little change are difficult to distinguish from pixels in stable areas and must therefore use two classifiers to get more accurate results.

## VII. CONCLUSION

Today, the task of recognizing a masked face is a challenging process which makes it a focus of interest for scientific committees, given the importance of facial recognition for the security of various organizations and applications around the world. Models that intended for the recognition of unmasked faces have become helpless and unable to provide satisfactory performance to the expectations of security systems and real-time applications. Over the last two years, several techniques have emerged for this purpose but these techniques always remain less effective than the models destined of unmasked faces. This fact comes to several factors. First, the loss of the majority of facial details. Second, all the proposed techniques are based on models previously intended for unmasked faces by adjusting a few parameters to render the model adaptable with the new task. Third factor, the databases designed for the study of masked faces recognition systems, require more improvement. In this regard, we have proposed a model based on FaceNet with combination of classifiers (SVM-KNN) in order to have satisfactory results. This combination gives better results compared to the classification by a single classifier given the complementarity between SVM and K-NN classifiers. Finally, safety is vital at all levels (social, industrial, services, etc.) and security systems must reach a certain level of robustness, that's why our future work aims to develop a new model which does not consider masked faces as a barrier to having excellent results.

**Abstract**—Retailers have long sought ways to better understand their consumers' behavior in order to deliver a smooth and enjoyable shopping experience that draws more customers every day and, as a result, optimizes income. By combining various visual clues such as activities, gestures, and facial expressions, humans may fully grasp the behavior of others. However, due to inherent problems as well as extrinsic forced issues such as a shortage of publicly available information and unique environmental variables, empowering computer vision systems to provide it remains an ongoing problem (wild). In this paper, the authors focus on identifying human activity recognition in computer vision, which is the first and by far the most important cue in behavior analysis. To accomplish this, the authors present an approach by integrating human position and object motion in order to detect and classify tasks in both temporal and spatial analysis. On the MERL shopping dataset, the authors get state-of-the-art results and demonstrate the capabilities of the proposed technique.

**Keywords**—Deep convolutional neural networks; computer vision; object detection; object localization; temporal analysis; human shopping actions component

## I. INTRODUCTION

For years, the computer vision industry has been working on recognizing human actions. Many essential applications require the ability to recognize diverse behaviors from video data, such as fight identification from surveillance footage, human-robot interaction, video streaming analysis for online streaming services, and home security surveillance. Action recognition's main purpose is to recognize human actions in a video frame. For video-sharing services like YouTube and Twitch, action recognition is indeed a must-have feature. It can decipher a video's content and determine whether or not it should be made public. This tool can assist in the filtering of potentially harmful videos, such as bomb-making methods, choking activities, and the use of hard narcotics [1-3].

However, in areas like retail and shopping, the impact has been minimal. Using such technology in this context has a number of advantages, including efficient monitoring, consumer behavioral analysis, targeted marketing, and so on. Retailers will benefit from increased efficiency and revenue, as well as a more convenient shopping experience for customers if these strategies are used. Furthermore, the share of the worldwide trade market that these technological solutions occupy might be deduced from the rapidly expanding demand for them. The actual worth of such Artificial Intelligence (AI) based solutions relating to the retail industry is expected to be about US\$10 billion by 2025, according to research conducted by Grand View Research [2].

Applying AI, and particularly machine learning approaches, to the shopping sector is still difficult, due to the insufficiency of data, primarily because of security issues, expensive labeling, as well as the need to stay proprietary where data is gathered. In spite of the datasets being publicly available to the researchers, (e.g., The MERL shopping dataset [4]), applying deep learning techniques to those is difficult as the external challenges posed by distinctive environmental factors like camera view angle, quality of the video, interrelations between the goods and the customers, and high obstruction. However, success of the existing deep learning algorithms can be attributed partially to the utilization of largely available public datasets like ImageNet [5], UCF101 [6], or [4], which allow sophisticated methods with numerous variables to be optimally trained. The completed actions are the major visual clue in understanding human behavior, which when paired with additional indicators like facial expressions tracked over time can also provide detailed behavioral knowledge [1, 7, 8,]. To describe human actions, the initial efforts on action recognition adopted Three-dimensional (3D) models [9, 10]. However, creating a 3D model using videos is time-consuming and costly.

As a consequence, people rather employ global or local representations for action recognition. These methods are known as representation-based methods. Currently, deep networks-based algorithms have indeed been able to attain promising results in action detection, because of the fast evolution of graphics processing units (GPU). The task of activity detection and recognition from shopping surveillance footage inputs is used as the primary topic of this paper. The current study only focuses on categorizing the clipped video into the given activities during recognition, whereas categorization is practiced to a continuous video sequence of multiple activities during detection; i.e., the temporal location at the beginning and length of the actions are also unknown and desired [11].

The main contributions of this paper are

- For a less explored camera view angle, we present an innovative strategy powered by Generative Adversarial Networks (GANs) which uses partial body position in the lack of exact joint locations (top view).
- Using the proposed novel method along with the standard transfer learning, we train and test on the MERL shopping dataset, which has different challenges such as camera angle view, classifications of activity, and limited data for training.
- The authors propose a simple but successful technique for using our action-identifying network as an action detector that identifies and classifies action locations in real-time. This method divides the difficult detection task into identification and detection modules and uses a two-stream network to combine diverse sources in semantic space.
- The authors successfully combine two independent sets of features, one for recognizing or detecting the action, namely human body posture (incomplete) and object-of-interest motion, to direct greater network resources and attention to the most significant signals while ignoring the less important ones. This is performed through the use of self-attention, in which the video's relevant spatial regions are connected to other regions in adjacent frames for enhanced accuracy and/or precision.

The remaining sections of the paper are organized as follows: Section II - consists of the extensive literature survey; Section III - is the detailed explanation of the methodology used in the study; Section IV - is a detailed presentation of the results arrived at along with comparisons. We conclude the paper by providing future directions.

## II. LITERATURE SURVEY

Extraction through feature engineering algorithms that can effectively recognize and depict motion in the input pattern of image frames is the focus of this research. Many approaches of mixing optical flow (OF) and feature matching [12] have been introduced since the early phases of the space-time pyramid [13] until recent years, with the most current ones attempting to replace feature extractors using deep neural networks. However, predicting the flow of optical from succeeding video

frames has proven to be quite efficient. The literature on this subject contains a multitude of ways. Recently, there have been attempts to integrate these techniques with deep neural networks in order to achieve the best-of-both-worlds results, Horn et al. [14]. Many indigenous features have been facing this situation in recent years.

Pose estimation from single red, green, and blue (RGB) images has made substantial progress recently [6, 11, 15, 16, 17,], prompting its use as a high-level feature in movies to effectively represent diverse sorts of activities [18, 19]. Single image estimate is relatively reliable, even the tiniest mistake or disturbance in sequential posture estimation in videos is detrimental to activity interpretation utilizing existing futuristic techniques. With regards to missing joint locations in frames, as we will show factually, this occurs rather frequently irrespective of regular or low demanding settings. As a result, several techniques to utilize this vital information as an additional medium of data in combination with other resources such as optical flow and raw input frame have been presented. There are many alternative ways to take advantage of body posture characteristics while disregarding the faults. Indigenous approaches to cipher consecutive pose data into photos for classifying the actions are defined by some. There are numerous approaches to efficiently incorporate posture estimation into activity understanding in case of good pose prediction (for instance, 3D pose employing motion capture skeletal sensors or depth camera) [20]. However, because of a crowd, low range depth and occlusion, and costs, the use of depth cameras or signal fusion techniques is not viable in the shopping environment.

In computer vision, human-object interaction has long been a concern. However, the majority of the considered interactions revolve around sports [21], cooking [22], or ordinary activities [6, 9], which can sometimes be categorized from single photos [21]. Kim et al. [23] present an effective method for recognizing object-based activities. For action recognition from security cameras, the researchers make use of the graph neural networks for merging the object and human pose data. Their method, however, is largely dependent on the quality of the input posture data.

Multi-stream Convolutional Neural Networks (CNNs) have recently been popular for combining diverse modalities of data before generating decisions [4, 16]. It can be seen in most of the presented systems that one stream is dedicated to temporal understanding (usually utilizing a labeled training data and computed algorithm related to flow of optics [17]), whereas another is exclusively for diving into spatial features in the image.

Many academics have been attributed to the success of Two-dimensional (2D) CNNs in image interpretation to investigate the feasibility of doing so in videos. As a result, numerous ways to widen the convolution in time have been developed [7, 23, 24]. One of the issues with these techniques is that most of these are computationally costly, whilst moderately outperforming 2D CNN counterparts.

Several researchers have rethought their application, inventing sophisticated combinations of 2D and 3D CNNs to achieve the best possible outcomes [25, 26]. Nevertheless, the

work of exploiting pose data is still under-explored to our knowledge. Many other researchers integrate the two works and sort them concurrently [27]. Some techniques solely tackle the temporal detection element of the work, whilst others integrate both activities and sort them at the same time. Some are inspired by object identification techniques and use temporal region proposals [10, 18], while others are known as segmentation.

In the natural language processing (NLP) community, many unique strategies to replicate human attention in CNNs were first proposed on machine translation jobs. Some of them are used in sequential tasks to highlight key input frames [28], while others are used to simply focus on spatial regions of relevance [10, 9, 2]. Wang et al. [29] and combine them into one differentiable peripheral module. Moreover, there are works defining a representative capable of discovering the important areas or frames using sophisticated analytics like Reinforcement Learning (RL) [28]. The 3D modeling method was utilized extensively in early action recognition studies. The walker hierarchical model [9] uses a number of hierarchical levels to depict a person. To recognize pedestrians in a video, [10] employs linked cylinders and their progression. The kernel learned by CNN is visualized and found that the bottom layers learn low-level features while the upper layers learn high-level representations. This demonstrates that convolutional architecture may be utilized to extract features [29, 30].

Videos, unlike photographs, have a dynamic nature. Directly adding temporal features to a convolutional architecture is a typical approach of using deep networks for action recognition. To achieve this, Ji et al. [31] postulated the 3D CNN, which also uses 3D kernels to obtain both spatial and temporal information.

Many researchers have made contributions to the field of temporal information integration in CNNs. In the temporal domain, Ng et al. [30] discover that maximal pooling outperforms average and other pooling approaches. Karpathy et al. [32] present the slow fusion model, a new convolutional architecture that receives video clips and processes them via an identical set of layers (with common parameters) to provide outcomes for fully connected layers. The video description will then be generated from these completely connected layers. Tran et al. [33] combine the concepts of the visual geometry group (VGG) [9], Decaf [14], as well as the 3D CNN [29] to develop a 3-D graphics technique that can build 3D graphics out of 2D images (C3D), a generic video descriptor. They use the Sports-1M [32] dataset to train their network and extract video attributes from such a fully - connected layer. Learning temporal information from uncontrolled input is the purpose of a deep generative network [21, 26]. Xing Yan et al. [34]

present a deep Dyn encoder to capture video dynamics, based on the linear dynamic system modeling approach proposed by Doretto et al. [16]. The Long Short-Term Memory (LSTM) autoencoder model is created using the LSTM [26] cell.

The encoder LSTM and the decoder LSTM make up this model. Goodfellow et al. [35] propose an adversarial network to address the training challenges in deep generative networks. The competition between a generative and a discriminative model is referred to as adversarial. Mathieu et al. [36] use the adversarial principle where a multi-scale convolutional network is trained and highlight the benefits of pooling in a generative model. In this body of work, many databases have been added to aid in the development and testing of algorithms [28, 6, 24]. Kinetics [8], which is called the ImageNet [13] of videos, is among the largest. Only a few of these have untrimmed films that can be detected [22, 27]. More crucially, as previously said, the exclusive characteristic of statistics related to retail is the insufficiency of data on which to test frameworks to address the distinctive difficulties. As per our knowledge, the MERL [4] dataset is the only one available for human shopping actions. All of these aspects are addressed using Human Position and Object Motion based spatiotemporal analysis and are tested on the Recognition of Human Shopping Actions. Further details regarding the same are explained in the subsequent sections.

### III. METHODOLOGY

A GAN consists of two approaches: a generic model that is trained to comprehend the probability distribution of the input data and a discriminative model that seeks to distinguish real input samples from false ones [37]. Backpropagation is used to simultaneously train both models. GANs' success has been seen in their wide range of applications, which range from creative picture generation and super-resolution to semi-supervised classification. Using input pictures and noisy and imprecise joint heat maps, the authors propose a conditional GAN-based technique for regressing the precise location of six body joints. In the retail environment, we commonly encounter top-view (or near-top-view) recorded surveillance cameras, which exacerbate the difficulty of deciphering human activity by imposing extra occlusions of various body parts and components. Because of this distinct and demanding perspective, many deep learning professionals have avoided training on these sorts of input images. The posture estimator system that we implemented in our challenge suffers from the same problem, despite producing state-of-the-art results of different distinct activities that support traditional camera view angles Fig. 1 depicts the challenges encountered by the given strategy in the present working dataset.

Fig. 1. Illustration of the Issues Faced due to the Camera Angles.

To improve posture estimate accuracy, we present the GAN structure. It also ensures that the positions of the joints of interest in the dataset are predicted more accurately. The generator is in charge of learning the conditional probability of the joint locations given to the current noisy heat map that is extracted and the input frame, which is a CNN with an architecture similar to Inception-v4 followed by a multi-layer perceptron (stacked). The same has been summarized in Fig. 2.

In our scenario, only six joints are considered essential in the current shopping environment scenario, which are both the left and right shoulders, elbows, and wrists. To begin, consider human posture as a probabilistic heat map indicating the areas of joints that require better attention. Next, treating it as a high-level feature of the object which is moving in the scene, rather than treating pose data as a separate source of information for defining an action, instead of general features extracted with a massive proportion of unnecessary background data to acquire motion data without considering any other specific motion representation, forcing the deep learning architecture for feature extraction with a greater focus on these spots in each frame of the input images. Then, by implementing the GAN fine-tuning step, we reduce even more noise from the heat maps obtained from the input related to the six key joints and obtain its precise location, which is given to our pose stream network as a replacement for the pose heat map channel. The working of the same has been described in Fig. 3.

Refer to (1)

$$y_i = \frac{1}{c(x)} \sum_{\forall j} f(x_i, x_j) g(x_j) \quad (1)$$

where,  $i$  and  $j$  are indices of the locations in frames over the entire sequence (space-time),  $f$  refers to embedded Gaussian mapping of the input pattern, and  $g$  is a linear mapping function. Here  $x_i$  refers to weight for a single location in space-time input, and  $j$  is the set of all other potential places. The Embedded Gaussian Function is the function we're using here. The number of modules inserted into the network for optimal performance has been empirically determined to be two. The LSTM's hidden state vectors are subjected to the second attention mechanism. It actually assigns a scalar weight to every input frame based on the network's learned relevance. These weights were adopted to the LSTM's hidden feature vector as in practice. At every time the first step (relating to the feature vector of the frame is multiplied by the weight value supplied by the temporal attention), the LSTM has a hidden state. This is done in practice where a single fully-connected layer on the LSTM's hidden states is trained. The first of the two modules, in particular, has played a key role in advising us on how to strengthen our approach. The placement of joints is connected with a higher weight, notably the six joints that make up a part of the posture model, as shown in the representations provided in Fig. 3. By substituting the exact heat map of joint locations with the ones from our generator network, there was even more attention forced which improved our outcomes. In this case, by reducing the noisy heat, we were able to stimulate the concentration of network resources with more assurance maps.

Fig. 2. An Overview of the Proposed GAN Structure.

Fig. 3. A Summary of our GAN-Based Pose Fine-Tuning Method.

#### IV. RESULTS AND ANALYSIS

##### A. Experimental Setup

The authors used PyTorch for the implementation as it is open source. The fine-tuned network is then used with the remainder of the network, with no further training, to retrieve earlier data regarding item placements. To construct the weights for the generator in GAN architecture, we manually annotated additional thousand frames which are sampled uniformly with six joint-of-interest (e.g., wrists, elbows, and shoulders) positions. After that, the generator is supervised, and they are pre-trained using the Mean Square Error loss function across the ground-truth joint locations. On the other hand, the discriminator was built up at random using the Xavier approach.

After the GAN training has converged, the generator is used individually along the remainder of the network without

any more fine-tuning, as previously indicated. The pose and object mappings are created using binary maps in the following manner. The map has values of one in a circle of constant radius (here 10 pixels) around each joint center and 0 somewhere else for joint locations, and one in a rectangle area of fixed size (here 40 pixels) around the center of each identified item and zero otherwise for object locations. To reduce the Cross-Entropy loss over the Softmax class probability outputs, the entire recognition network is trained using gradient descent.

Adam is the optimizer that has been proven to perform better in terms of fast convergence in large-scale models like ours. This is achieved by making dynamic (or adaptive, as the authors call it) changes to the learning rate for each weight based on the gradient's higher and lower coefficients so far. The default hyper-parameter settings specified by the authors are = 0.001, 1 = 0.9, 2 = 0.999, and 1008.

It's difficult to train the spatiotemporal attention components in the intermediary layers of the two streams. These modules were given a contribution weight gamma (constant across the network) that was initially set to 0. The authors restart the training for a few epochs (9 to 11) once the main network has converged, starting with 0.1 and gradually increasing it to 1. Finally, because each stream has a similar design to the Inception v4 network, the authors initialize both streams using transfer learning from networks trained on COCO classification tasks. This allows us to drastically minimize training time; the full network training takes only 17-21 epochs to complete.

The detection sliding window and stride parameters must be fine-tuned in the final stage. A Brute Force search in two sets of values is used to accomplish this. As mentioned in the assessment section, the overall performance of each pair of window-stride size values is examined, and the top overall values are picked. Finally, because each stream has a similar architecture to the Inception v4 network, we initialize both streams using transfer learning from networks trained on COCO classification tasks.

This allows us to cut the training time in half; the total network training takes around 17-21 epochs. The detection sliding window and stride parameters must be fine-tuned in the final stage. A Brute Force search in two sets of values is used to accomplish this. As noted in the assessment section, the overall performance of each pair of window-stride size values is evaluated, and the top overall values are picked. Sliding windows range in length from 3 to 45 frames, with a stride of one to the length of the window. The PyTorch deep learning library is used to implement the entire training and inference process in Python.

### B. MERL Dataset Results

The MERL dataset was produced in response to a lack of relevant datasets in retail settings. The six activities are "reach the shelf," "retract from the shelf," "hand in the shelf," "inspect the object," "inspect the shelf," and the backdrop (or no action) class. It was photographed using a roof camera to look like a real retail mall, but not in any detail. There are 42 people in this dataset who work as shoppers. One of the dataset's challenges is that participants must complete a sequence of tasks, which can be easily exploited as a well-behaved transition probability matrix to produce good results on this dataset at the cost of simplifying it as a well-behaved transition probability matrix. Table I is an example of this challenge. This supplies the network with useful prior knowledge that may be used during inference to improve recognition accuracy.

TABLE I. MERL DATASET, ACTIONS, AND ITS CORRESPONDING DISTRIBUTIONS

Actions	Reach	Retract	Hand in	Inp. Product	Insp. Shelf
Reach	0.0	63.8	34.1	0.7	1.4
Retract	21.2	0.0	0.8	49.53	28.47
Hand in	0.12	85.7	0.0	6.32	7.86
Inp. Product	61.08	3.1	0.84	0.0	34.98
Insp. Shelf	98.9	0.094	0.67	0.34	0.0

Nonetheless, one of the key benefits of our technique is that we may get cutting-edge findings without relying on this extensive historical knowledge. This makes sense since, in real-world solutions, powerful priors are difficult to come by and impractical, therefore they can't be used. As a result, the authors eliminated these biases by ensuring that the participants do not follow a straightforward sequence of activities during the testing.

Unlike prior approaches that reported on the MERL dataset, we present results for both recognition and detection. The former believes that the input films only include single action, but the latter receives an untrimmed video with numerous actions as input. Table II displays our MERL recognition results, and Table III compares our detection results to those previously published because the recognition results for this dataset haven't been disclosed before by any other method, this presents a new challenge for future research, allowing other algorithms to compare their detection accuracy. As we've seen and as our results show, the accuracy of detection should be near to the precision of recognition for a decently good detection approach. As compared to other approaches, we significantly have higher Intersection over Union (IoU) (average 0.77 compared to 0.5 as the maximum reported) over previous methods while attaining better detection results, too.

TABLE II. RESULTS OF PROPOSED METHOD ON MERL DATASET

Details	In Percentage
Overall recognition Accuracy	71.14
F1 @ 50	67.11
Frame wise accuracy	71.41

TABLE III. COMPARISON OF RESULTS WITH PROPOSED METHOD (MERL DATASET)

Methodology	F1 {IoU = 0.5}	Accuracy in Percentage (Frame-Wise)
Multi-stream bi-directional RNN [4]	65.4	76.3
Temporal Convolutional Networks	72.9	79.0
Two stream CNN	74.8	77.1
Proposed methodology	77.46	75.13

### V. CONCLUSIONS

The authors have developed a framework for fine-grained activity recognition and detection in retail environments. Due to the short time between each action, considerable intra-class variance, and low inter-class variation, fine-grained detection is difficult; these difficulties contribute to the task's intrinsic complexity. Furthermore, the work is made more difficult by the extrinsic difficulty of a rare and unusual camera viewing angle. We developed a semi-supervised technique employing GAN to fine-tune posture estimate results when there is a discrepancy in the images present at different angles during training and prediction. We gave detailed experimental data to demonstrate the method's applicability in real-world scenarios, particularly in shopping contexts, which have their own set of characteristics and obstacles.

When direct estimation fails, we speculate that combining pose estimation with image sequences is one way to use the associated range of motion as background information for forecasting joint location in the next time step (e.g., occlusion). Furthermore, we believe that describing the attention process as a salient region localization job for an expert system might lower the computation cost of its training and prediction, given the recent success of deep reinforcement learning methodologies. Further attempts at face expression recognition and/or eye gaze prediction provide more data for deep customer behavior analysis.
