

Volume 13 Issue 9

September 2022

ISSN 2156-5570(Online)

ISSN 2158-107X(Print)

# Editorial Preface

## *From the Desk of Managing Editor...*

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

**Thank you for Sharing Wisdom!**

# Editorial Board

## Editor-in-Chief

### **Dr. Kohei Arai - Saga University**

*Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation*

---

## Associate Editors

### **Alaa Sheta**

#### **Southern Connecticut State University**

*Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems*

### **Domenico Ciuonzo**

#### **University of Naples, Federico II, Italy**

*Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things*

### **Dorota Kaminska**

#### **Lodz University of Technology**

*Domain of Research: Artificial Intelligence, Virtual Reality*

### **Elena Scutelnicu**

#### **"Dunarea de Jos" University of Galati**

*Domain of Research: e-Learning, e-Learning Tools, Simulation*

### **In Soo Lee**

#### **Kyungpook National University**

*Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning*

### **Krassen Stefanov**

#### **Professor at Sofia University St. Kliment Ohridski**

*Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design*

### **Renato De Leone**

#### **Università di Camerino**

*Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming*

### **Xiao-Zhi Gao**

#### **University of Eastern Finland**

*Domain of Research: Artificial Intelligence, Genetic Algorithms*

# CONTENTS

**Paper 1: ModER: Graph-based Unsupervised Entity Resolution using Composite Modularity Optimization and Locality Sensitive Hashing**

*Authors: Islam Akef Ebeid, John R. Talburt, Nicholas Kofi Akortia Hagan, Md Abdus Salam Siddique*

**PAGE 1 – 18**

**Paper 2: Remote International Collaboration in Scientific Research Teams for Technology Development**

*Authors: Sarah Janböcke, Toshimi Ogawa, Koki Kobayashi, Ryan Browne, Yasuki Taki, Rainer Wieching, Johanna Langendorf*

**PAGE 19 – 29**

**Paper 3: Fuzzy Image Enhancement Method based on a New Intensifier Operator**

*Authors: Libao Yang, Suzelawati Zenian, Rozaimi Zakaria*

**PAGE 30 – 34**

**Paper 4: Cooperative Multi-Robot Hierarchical Reinforcement Learning**

*Authors: Gembong Edhi Setyawan, Pitoyo Hartono, Hideyuki Sawada*

**PAGE 35 – 44**

**Paper 5: Differential Privacy Technology of Big Data Information Security based on ACA-DMLP**

*Authors: Yubiao Han, Lei Wang, Dianhong He*

**PAGE 45 – 52**

**Paper 6: A Reusable Product Line Asset in Smart Mobile Application: A Systematic Literature Review**

*Authors: Nan Pepin, Abdul S. Shibghatullah, Kasthuri Subaramaniam, Rabatul Aduni Sulaiman, Zuraida A. Abas, Samer Sarsam*

**PAGE 53 – 60**

**Paper 7: A Study on the Effect of Digital Fabrication in Social Studies Education**

*Authors: Kazunari Hirakoso, Hidetake Hamada*

**PAGE 61 – 66**

**Paper 8: A Blockchain-based Model for Securing IoT Transactions in a Healthcare Environment**

*Authors: Mohamed Abdel Kader Mohamed Elgendy, Mohamed Aborizka, Ali Mohamed Nabil Allam*

**PAGE 67 – 75**

**Paper 9: Study on Early Warning on the Financial Risk of Project Venture Capital through a Neural Network Model**

*Authors: Xianjuan Li*

**PAGE 76 – 81**

**Paper 10: Improving Privacy Preservation Approach for Healthcare Data using Frequency Distribution of Delicate Information**

*Authors: Ganesh Dagadu Puri, D. Haritha*

**PAGE 82 – 90**

**Paper 11: Attention-based Long Short Term Memory Model for DNA Damage Prediction in Mammalian Cells**

*Authors: Mohammad A. Alsharaiah, Laith H. Baniata, Omar Adwan, Ahmad Adel Abu-Shareha, Mosleh Abu Alhaj, Qasem Kharma, Abdelrahman Hussein, Orieb Abualghanam, Nabeel Alassaf, Mohammad Baniata*

**PAGE 91 – 99**

**Paper 12: Estimation of Recovery Percentage in Gravimetric Concentration Processes using an Artificial Neural Network Model**

*Authors: Manuel Alejandro Ospina-Alarcón, Ismael E. Rivera-M, Gabriel Elías Chanchí-Golondrino*

**PAGE 100 – 110**

**Paper 13: Risk Prediction Applied to Global Software Development using Machine Learning Methods**

*Authors: Hossam Hassan, Manal A. Abdel-Fattah, Amr Ghoneim*

**PAGE 111 – 120**

**Paper 14: HelaNER 2.0: A Novel Deep Neural Model for Named Entity Boundary Detection**

*Authors: Y. H. P. P Priyadarshana, L Ranathunga*

**PAGE 121 – 130**

**Paper 15: Face Recognition under Illumination based on Optimized Neural Network**

*Authors: Napa Lakshmi, Megha P Arakeri*

**PAGE 131 – 137**

**Paper 16: Transfer Learning for Medicinal Plant Leaves Recognition: A Comparison with and without a Fine-Tuning Strategy**

*Authors: Vina Ayumi, Ermatita Ermatita, Abdiansah Abdiansah, Handrie Noprisson, Yuwan Jumaryadi, Mariana Purba, Marissa Utami, Erwin Dwika Putra*

**PAGE 138 – 144**

**Paper 17: Effect of Random Splitting and Cross Validation for Indonesian Opinion Mining using Machine Learning Approach**

*Authors: Mariana Purba, Ermatita Ermatita, Abdiansah Abdiansah, Handrie Noprisson, Vina Ayumi, Hadiguna Setiawan, Umniy Salamah, Yadi Yadi*

**PAGE 145 – 151**

**Paper 18: Classification of Diabetes Types using Machine Learning**

*Authors: Oyeranmi Adigun, Folasade Okikiola, Nureni Yekini, Ronke Babatunde*

**PAGE 152 – 161**

**Paper 19: Criteria and Guideline for Dyslexic Intervention Games**

*Authors: Noraziah ChePa, Nur Azzah Abu Bakar, Laura Lim Sie-Yi*

**PAGE 162 – 172**

**Paper 20: The Effectiveness of Gamification for Students' Engagement in Technical and Vocational Education and Training**

*Authors: Laily Abu Samah, Amirah Ismail, Mohammad Kamrul Hasan*

**PAGE 173 – 180**

**Paper 21: Campus Quality of Services Analysis of Mobile Wireless Communications Network Signal among Providers in Malaysia**

*Authors: Murizah Kassim, Zulfadhli Hisam, Mohd Nazri Ismail*

**PAGE 181 – 187**

**Paper 22: Exploring Alumni Data using Data Visualization Techniques**

*Authors: Nurhanani Izzati Ismail, Nur Atiqah Sia Abdullah, Nasiroh Omar*

**PAGE 188 – 195**

Paper 23: The Performance Evaluation of Transfer Learning VGG16 Algorithm on Various Chest X-ray Imaging Datasets for COVID-19 Classification

*Authors: Andi Sunyoto, Yoga Pristyanto, Arief Setyanto, Fawaz Alarfaj, Naif Almusallam, Mohammed Alreshoodi*

PAGE 196 – 203

Paper 24: A Comprehensive Review and Application of Interpretable Deep Learning Model for ADR Prediction

*Authors: Shiksha Alok Dubey, Anala A. Pandit*

PAGE 204 – 213

Paper 25: Secure Cloud Connected Indoor Hydroponic System via Multi-factor Authentication

*Authors: Mohamad Khairul Hafizi Rahimi, Mohamad Hanif Md Saad, Aini Hussain, Nurul Maisarah Hamdan*

PAGE 214 – 222

Paper 26: Effective Multitier Network Model for MRI Brain Disease Prediction using Learning Approaches

*Authors: N. Ravinder, Moulana Mohammed*

PAGE 223 – 230

Paper 27: Application based on Hybrid CNN-SVM and PCA-SVM Approaches for Classification of Cocoa Beans

*Authors: AYIKPA Kacoutchy Jean, MAMADOU Diarra, BALLO Abou Bakary, GOUTON Pierre, ADOU Kablan Jérôme*

PAGE 231 – 238

Paper 28: SQrum: An Improved Method of Scrum

*Authors: Najih Soukaina, Merzouk Soukaina, Marzak Abdelaziz*

PAGE 239 – 249

Paper 29: Use of Interactive Multimedia e-Learning in TVET Education

*Authors: Siti Fadzilah Mat Noor, Hazura Mohamed, Nur Atiqah Zaini, Dayana Daiman*

PAGE 250 – 256

Paper 30: CBT4Depression: A Cognitive Behaviour Therapy (CBT) Therapeutic Game to Reduce Depression Level among Adolescents

*Authors: Norhana Yusof, Nazrul Azha Mohamed Shaari, Eizwan Hamdie Yusoff*

PAGE 257 – 264

Paper 31: Creating Video Visual Storyboard with Static Video Summarization using Fractional Energy of Orthogonal Transforms

*Authors: Ashvini Tonge, Sudeep D. Thepade*

PAGE 265 – 273

Paper 32: Denoising of Impulse Noise using Partition-Supported Median, Interpolation and DWT in Dental X-Ray Images

*Authors: Mohamed Shajahan, Siti Armiza Mohd Aris, Sahnus Usman, Norliza Mohd Noor*

PAGE 274 – 280

Paper 33: An End-to-End Big Data Deduplication Framework based on Online Continuous Learning

*Authors: Widad Elouataoui, Imane El Alaoui, Saida El Mendili, Youssef Gahi*

PAGE 281 – 291

Paper 34: Student's Performance Prediction based on Personality Traits and Intelligence Quotient using Machine Learning

*Authors: Samar El-Keiey, Dina ElMenshawy, Ehab Hassanein*

PAGE 292 – 299

Paper 35: Real Time Fire Detection using Color Probability Segmentation and DenseNet Model for Classifier

*Authors: Faisal Dharma Adhinata, Nur Ghaniaviyanto Ramadhan*

**PAGE 300 – 305**

Paper 36: Tissue and Tumor Epithelium Classification using Fine-tuned Deep CNN Models

*Authors: Anju T E, S. Vimala*

**PAGE 306 – 314**

Paper 37: Predicting University Student Retention using Artificial Intelligence

*Authors: Samer M. Arqawi, Eman Akef Zitawi, Anees Husni Rabaya, Basem S. Abunasser, Samy S. Abu-Naser*

**PAGE 315 – 324**

Paper 38: Using the Agglomerative Hierarchical Clustering Method to Examine Human Factors in Indonesian Aviation Accidents

*Authors: Rossi Passarella, Gulfi Oktariani, Dedy Kurniawan, Purwita Sari*

**PAGE 325 – 331**

Paper 39: A Framework for Crime Detection and Diminution in Digital Forensics (CD3F)

*Authors: Arpita Singh, Sanjay K. Singh, Hari Kiran Vege, Nilu Singh*

**PAGE 332 – 345**

Paper 40: Deep Learning and Classification Algorithms for COVID-19 Detection

*Authors: Mohammed Sidheeque, P. Sumathy, Abdul Gafur. M*

**PAGE 346 – 350**

Paper 41: Gamification on OTT Platforms: A Behavioural Study for User Engagement

*Authors: Komal Suryavanshi, Prasun Gahlot, Surya Bahadur Thapa, Aradhana Gandhi, Ramakrishnan Raman*

**PAGE 351 – 363**

Paper 42: Optimally Allocating Ambulances in Delhi using Mutation based Shuffled Frog Leaping Algorithm

*Authors: Zaheeruddin, Hina Gupta*

**PAGE 364 – 374**

Paper 43: Adopting a Digital Transformation in Moroccan Research Structure using a Knowledge Management System: Case of a Research Laboratory

*Authors: Fatima-Ezzahra AIT-BENNACER, Abdessadek AAROUD, Khalid AKODADI, Bouchaib CHERRADI*

**PAGE 375 – 384**

Paper 44: Analyzing the Relationship between the Personality Traits and Drug Consumption (Month-based user Definition) using Rough Sets Theory

*Authors: Manasik M. Nour, H. A. Mohamed, Sumayyah I. Alshber*

**PAGE 385 – 392**

Paper 45: Wavelet Multi Resolution Analysis based Data Hiding with Scanned Secrete Images

*Authors: Kohei Arai*

**PAGE 393 – 400**

Paper 46: Multiple Eye Disease Detection using Hybrid Adaptive Mutation Swarm Optimization and RNN

*Authors: P. Glaret Subin, P. Muthu Kannan*

**PAGE 401 – 410**

**Paper 47: Insect Pest Image Detection and Classification using Deep Learning**

*Authors: Niranjan C Kundur, P B Mallikarjuna*

**PAGE 411 – 421**

**Paper 48: Analysis of Noise Removal Techniques on Retinal Optical Coherence Tomography Images**

*Authors: T. M. Sheeba, S. Albert Antony Raj*

**PAGE 422 – 427**

**Paper 49: Analyzing the State of Mind of Self-quarantined People during COVID-19 Pandemic Lockdown Period: A Multiple Correspondence Analysis Approach**

*Authors: Gauri Vaidya, Vidya Kumbhar, Sachin Naik, Vijayatai Hukare*

**PAGE 428 – 439**

**Paper 50: SIBI (Sign System Indonesian Language) Text-to-3D Animation Translation Mobile Application**

*Authors: Erdefi Rakun, Sultan Muzahidin, IGM Surya A. Darmana, Wikan Setiaji*

**PAGE 440 – 450**

**Paper 51: A Review of Foreground Segmentation based on Convolutional Neural Networks**

*Authors: Pavan Kumar Tadiparthi, Sagarika Bugatha, Pradeep Kumar Bheemavarapu*

**PAGE 451 – 454**

**Paper 52: Multi-instance Finger Knuckle Print Recognition based on Fusion of Local Features**

*Authors: Amine AMRAOUI, Mounir AIT KERROUM, Youssef FAKHRI*

**PAGE 455 – 463**

**Paper 53: Detection of Credit Card Fraud using a Hybrid Ensemble Model**

*Authors: Sayali Saraf, Anupama Phakatkar*

**PAGE 464 – 474**

**Paper 54: Covid-19 and Pneumonia Infection Detection from Chest X-Ray Images using U-Net, EfficientNetB1, XGBoost and Recursive Feature Elimination**

*Authors: Munindra Lunagaria, Vijay Katkar, Krunal Vaghela*

**PAGE 475 – 483**

**Paper 55: Analysis of Privacy and Security Challenges in e-Health Clouds**

*Authors: Reem Alanazi*

**PAGE 484 – 489**

**Paper 56: Identification of Retinal Disease using Anchor-Free Modified Faster Region**

*Authors: Arulselvam. T, S. J. Sathish Aaron Joseph*

**PAGE 490 – 499**

**Paper 57: OpenCV Implementation of Grid-based Vertical Safe Landing for UAV using YOLOv5**

*Authors: Hrusna Chakri Shadakshri V, Veena M. B, Keshihaa Rudra Gana Dev V*

**PAGE 500 – 506**

**Paper 58: Gaussian Projection Deep Extreme Clustering and Chebyshev Reflective Correlation based Outlier Detection**

*Authors: S. Rajalakshmi, P. Madhubala*

**PAGE 507 – 515**

Paper 59: Efficient Decentralized Sharing Economy Model based on Blockchain Technology: A Case Study of Najm for Insurance Services Company

*Authors: Atheer Alkhamash, Kawther Saeedi, Fatmah Baothman, Rania Anwar Aboalela, Amal Babour*

PAGE 516 – 522

Paper 60: Virtual Communities of Practice to Promote Digital Agriculturists' Learning Competencies and Learning Engagement: Conceptual Framework

*Authors: Maneerat Manyuen, Surapon Boonlue, Jariya Neanchaleay, Vitsanu Nittayathamkul*

PAGE 523 – 528

Paper 61: Deep Q-learning Approach based on CNN and XGBoost for Traffic Signal Control

*Authors: Nada Faqir, Chakir Loqman, Jaouad Boumhidi*

PAGE 529 – 536

Paper 62: Automatic Text Summarization using Document Clustering Named Entity Recognition

*Authors: Senthamizh Selvan. R, K. Arutchelvan*

PAGE 537 – 543

Paper 63: Convolutional Neural Networks with Transfer Learning for Pneumonia Detection

*Authors: Orlando Iparraguirre-Villanueva, Victor Guevara-Ponce, Ofelia Roque Paredes, Fernando Sierra-Liñan, Joselyn Zapata-Paulini, Michael Cabanillas-Carbonell*

PAGE 544 – 551

Paper 64: A Monadic Co-simulation Model for Cyber-physical Production Systems

*Authors: Daniel-Cristian Crăciunean*

PAGE 552 – 557

Paper 65: A Machine Learning Model for Predicting Heart Disease using Ensemble Methods

*Authors: Jasjit Singh Samagh, Dilbag Singh*

PAGE 558 – 565

Paper 66: Novel Approach in Classification and Prediction of COVID-19 from Radiograph Images using CNN

*Authors: Chalapathiraju Kanumuri, CH. Renu Madhavi, Torthi Ravichandra*

PAGE 566 – 570

Paper 67: Machine Learning based Electromigration-aware Scheduler for Multi-core Processors

*Authors: Jagadeesh Kumar P, Mini M G*

PAGE 571 – 580

Paper 68: Sentiment Analysis on Acceptance of New Normal in COVID-19 Pandemic using Naïve Bayes Algorithm

*Authors: Siti Hajar Aishah Samsudin, Norlina Mohd Sabri, Norulhidayah Isa, Ummu Fatimah Mohd Bahrin*

PAGE 581 – 588

Paper 69: Partial Differential Equation (PDE) based Hybrid Diffusion Filters for Enhancing Noise Performance of Point of Care Ultrasound (POCUS) Images

*Authors: Deepa V S, Jagathyraj V P, Gopikakumari R*

PAGE 589 – 596

Paper 70: Smart Greenhouse Monitoring and Controlling based on NodeMCU

*Authors: Yajie Liu*

PAGE 597 – 600

Paper 71: Design of Accounting Information System in Data Processing: Case Study in Indonesia Company  
Authors: Meiryani, Dezie Leonarda Warganegara, Agustinus Winoto, Gabrielle Beatrice Hidayat, Erna Bernadetta Sitanggang, Ka Tiong, Jessica Paulina Sidauruk, Mochammad Fahlevi, Gredion Prajena  
PAGE 601 – 606

Paper 72: MOOC Dropout Prediction using FIAR-ANN Model based on Learner Behavioral Features  
Authors: S. Nithya, S.Umarani  
PAGE 607 – 617

Paper 73: Sentiment Analysis of Online Movie Reviews using Machine Learning  
Authors: Isaiah Steinke, Justin Wier, Lindsay Simon, Raed Seetan  
PAGE 618 – 624

Paper 74: Detection and Extraction of Faces and Text Lower Third Techniques for an Audiovisual Archive System using Machine Learning  
Authors: Khalid El Fayq, Said Tkatek, Lahcen Idouglid, Jaafar Abouchabaka  
PAGE 625 – 632

Paper 75: Data Recovery Comparative Analysis using Open-based Forensic Tools Source on Linux  
Authors: Muhammad Fahmi Abdillah, Yudi Prayudi  
PAGE 633 – 639

Paper 76: Advanced Persistent Threat Attack Detection using Clustering Algorithms  
Authors: Ahmed Alsanad, Sara Altuwaijri  
PAGE 640 – 649

Paper 77: Energy Efficient Node Deployment Technique for Heterogeneous Wireless Sensor Network based Object Detection  
Authors: Jayashree Dev, Jibitesh Mishra  
PAGE 650 – 659

Paper 78: Fine-grained Access Control in Distributed Cloud Environment using Trust Valuation Model  
Authors: Aparna Manikonda, Nalini N  
PAGE 660 – 666

Paper 79: BERT-Based Hybrid RNN Model for Multi-class Text Classification to Study the Effect of Pre-trained Word Embeddings  
Authors: Shreyashree S, Pramod Sunagar, S Rajarajeswari, Anita Kanavalli  
PAGE 667 – 674

Paper 80: A Hybrid Approach of Wavelet Transform, Convolutional Neural Networks and Gated Recurrent Units for Stock Liquidity Forecasting  
Authors: Mohamed Ben Houad, Mohammed Mestari, Khalid Bentaleb, Adnane El Mansouri, Salma El Aidouni  
PAGE 675 – 682

Paper 81: Visual Navigation System for Autonomous Drone using Fiducial Marker Detection  
Authors: Mohammad Soleimani Amiri, Rizauddin Ramli  
PAGE 683 – 690

**Paper 82: Design of a Mobile Application for the Logistics Process of a Fire Company**

*Authors: Luis Enrique Parra Aquije, Luis Gustavo Vasquez Carranza, Gustavo Bernnet Alfaro Pena, Michael Cabanillas-Carbonell, Laberiano Andrade-Arenas*

**PAGE 691 – 699**

**Paper 83: Intelligent System for Personalised Interventions and Early Drop-out Prediction in MOOCs**

*Authors: ALJ Zakaria, BOUAYAD Anas, Cherkaoui Malki Mohammed Oucamah*

**PAGE 700 – 710**

**Paper 84: An Intelligent Decision Support Ensemble Voting Model for Coronary Artery Disease Prediction in Smart Healthcare Monitoring Environments**

*Authors: Anas Maach, Jamila Elalami, Noureddine Elalami, El Houssine El Mazoudi*

**PAGE 711 – 724**

**Paper 85: Estimation of Varying Reaction Times with RNN and Application to Human-like Autonomous Car-following Modeling**

*Authors: Lijing Ma, Shiru Qu, Junxi Zhang, Xiangzhou Zhang*

**PAGE 725 – 730**

**Paper 86: Mobile Food Journalling Application with Convolutional Neural Network and Transfer Learning: A Case for Diabetes Management in Malaysia**

*Authors: Jason Thomas Chew, Yakub Sebastian, Valliapan Raman, Patrick Hang Hui Then*

**PAGE 731 – 737**

**Paper 87: Rethinking Classification of Oriented Object Detection in Aerial Images**

*Authors: Phuc Nguyen, Thang Truong, Nguyen D. Vo, Khang Nguyen*

**PAGE 738 – 747**

**Paper 88: TextBrew: Automated Model Selection and Hyperparameter Optimization for Text Classification**

*Authors: Rushil Desai, Aditya Shah, Shourya Kothari, Aishwarya Surve, Narendra Shekokar*

**PAGE 748 – 754**

**Paper 89: On-Device Major Indian Language Identification Classifiers to Run on Low Resource Devices**

*Authors: Yashwanth Y S*

**PAGE 755 – 760**

**Paper 90: Evaluating Hybrid Framework of VASNET and IoT in Disaster Management System**

*Authors: Sia Chiu Shoon, Mohammad Nazim Jambli, Sinarwati Mohamad Suhaili, Nur Haryani Zakaria*

**PAGE 761 – 766**

**Paper 91: A Novel Machine Learning-based Framework for Detecting Religious Arabic Hatred Speech in Social Networks**

*Authors: Mahmoud Masadeh, Hanumanthappa Jayappa Davanager, Abdullah Y. Muaad*

**PAGE 767 – 776**

**Paper 92: Modeling Multioutput Response Uses Ridge Regression and MLP Neural Network with Tuning Hyperparameter through Cross Validation**

*Authors: Waego Hadi Nugroho, Samingun Handoyo, Hsing-Chuan Hsieh, Yusnita Julyarni Akri, Zuraidah, Donna DwinitaAdelia*

**PAGE 777 – 787**

**Paper 93: Decentralized Access Control using Blockchain Technology for Application in Smart Farming**

*Authors: Normaizeerah Mohd Noor, Noor Afiza Mat Razali, Nur Atiqah Malizan, Khairul Khalil Ishak, Muslihah Wook, Nor Asiakin Hasbullah*

**PAGE 788 – 802**

**Paper 94: Research on Intelligent Control System of Air Conditioning based on Internet of Things Intelligent Control System of Air Conditioning**

*Authors: Binfang Zhang*

**PAGE 803 – 814**

**Paper 95: A Short Review on the Role of Various Deep Learning Techniques for Segmenting and Classifying Brain Tumours from MRI Images**

*Authors: Kumari Kavitha. D, E. Kiran Kumar*

**PAGE 815 – 824**

**Paper 96: Fish Species Classification using Optimized Deep Learning Model**

*Authors: J. M. Jini Mol, S. Albin Jose*

**PAGE 825 – 837**

**Paper 97: Environmental Noise Pollution Forecasting using Fuzzy-autoregressive Integrated Moving Average Modelling**

*Authors: Muhammad Shukri Che Lah, Nureize Arbaiy, Syahir Ajwad Sapuan, Pei-Chun Lin*

**PAGE 838 – 843**

**Paper 98: Extractive Multi-document Text Summarization Leveraging Hybrid Semantic Similarity Measures**

*Authors: Rajesh Bandaru, Y. Radhika*

**PAGE 844 – 852**

**Paper 99: An Efficient Hybrid LSTM-CNN and CNN-LSTM with GloVe for Text Multi-class Sentiment Classification in Gender Violence**

*Authors: Abdul Azim Ismail, Marina Yusoff*

**PAGE 853 – 863**

**Paper 100: Performance Analysis of Deep Learning YOLO models for South Asian Regional Vehicle Recognition**

*Authors: Minar Mahmud Rafi, Siddharth Chakma, Asif Mahmud, Raj Xavier Rozario, Rukon Uddin Munna, Md. Abrar Abedin Wohra, Rakibul Haque Joy, Khan Raqib Mahmud, Bijan Paul*

**PAGE 864 – 873**

**Paper 101: Multi-method Approach for User Experience of Selfie-taking Mobile Applications**

*Authors: Shahad Aldahri, Reem Alnanih*

**PAGE 874 – 880**

**Paper 102: Predicting Academic Performance using a Multiclassification Model: Case Study**

*Authors: Alfredo Daza Vergaray, Carlos Guerra, Noemi Cervera, Erwin Burgos*

**PAGE 881 – 889**

**Paper 103: COVID-19 Disease Detection based on X-Ray Image Classification using CNN with GEV Activation Function**

*Authors: Karim Ali Mohamed, Emad Elsamahy, Ahmed Salem*

**PAGE 890 – 898**

Paper 104: Deep Learning based Cervical Cancer Classification and Segmentation from Pap Smears Images using an EfficientNet

Authors: Krishna Prasad Battula, B. Sai Chandana

PAGE 899 – 908

Paper 105: Cloud based Forecast of Municipal Solid Waste Growth using AutoRegressive Integrated Moving Average Model: A Case Study for Bengaluru

Authors: Rashmi G, S Sathish Kumar K

PAGE 909 – 913

Paper 106: Building an Intelligent Tutoring System for Learning Polysemous Words in Moore

Authors: Pengwende ZONGO, Tounwendyam Frederic OUEDRAOGO

PAGE 914 – 920

Paper 107: Improving the Diabetes Diagnosis Prediction Rate Using Data Preprocessing, Data Augmentation and Recursive Feature Elimination Method

Authors: E. Sabitha, M. Durgadevi

PAGE 921 – 930

Paper 108: A Comparative Study of Unsupervised Anomaly Detection Algorithms used in a Small and Medium-Sized Enterprise

Authors: Irina Petrariu, Adrian Moscaliuc, Cristina Elena Turcu, Ovidiu Gherman

PAGE 931 – 940

Paper 109: Automated Brain Disease Classification using Transfer Learning based Deep Learning Models

Authors: Farhana Alam, Farhana Chowdhury Tisha, Sara Anisa Rahman, Samia Sultana, Md. Ahied Mahi Chowdhury, Ahmed Wasif Reza, Mohammad Shamsul Arefin

PAGE 941 – 949

Paper 110: Toward A Holistic, Efficient, Stacking Ensemble Intrusion Detection System using a Real Cloud-based Dataset

Authors: Ahmed M. Mahfouz, Abdullah Abuhussein, Faisal S. Alsubaei, Sajjan G. Shiva

PAGE 950 – 962

Paper 111: Authorship Attribution on Kannada Text using Bi-Directional LSTM Technique

Authors: Chandrika C P, Jagadish S Kallimani

PAGE 963 – 971

Paper 112: Flood Prediction using Deep Learning Models

Authors: Muhammad Hafizi Mohd Ali, Siti Azirah Asmai, Z. Zainal Abidin, Zuraida Abal Abas, Nurul A. Emran

PAGE 972 – 981

Paper 113: Recognition Method of Dim and Small Targets in SAR Images based on Machine Vision

Authors: Qin Dong

PAGE 982 – 990

Paper 114: Information Classification Algorithm based on Project-based Learning Data-driven and Stochastic Grid

Authors: Xiaomei Qin, Wenlan Zhang

PAGE 991 – 1000

Paper 115: Swine flu Detection and Location using Machine Learning Techniques and GIS

Authors: P. Nagaraj, A. V. Krishna Prasad, V. B. Narsimha, B. Sujatha

PAGE 1001 – 1009

**Paper 116: Taxation Transformation under the Influence of Industry 4.0**

*Authors: Pavel Victorovich Stroev, Rafael Valiakhmetovich Fattakhov, Olga Vladimirovna Pivovarova, Sergey Leonidovich Orlov, Alena Stanislavovna Advokatova*

**PAGE 1010 – 1015**

**Paper 117: Attractiveness of the Megaproject Labor Market for Metropolitan Residents in the Context of Digitalization and the Long-Lasting COVID-19 Pandemic**

*Authors: Mikhail Vinichenko, Sergey Barkov, Aleksander Oseev, Sergey Makushkin, Larisa Amozova*

**PAGE 1016 – 1021**

**Paper 118: Generation and Assessment of Intellectual and Informational Capital as a Foundation for Corporations' Digital Innovations in the "Open Innovation" System**

*Authors: Viktoriya Valeryevna Manuylenko, Galina Alexandrovna Ermakova, Natalia Vladimirovna Gryzunova, Mariya Nikolaevna Koniagina, Alexander Vladimirovich Milenkov, Liubov Alexandrovna Setchenkova, Irina Ivanovna Ochkolda*

**Abstract**—Entity resolution describes techniques used to identify documents or records that might not be duplicated; nevertheless, they might refer to the same entity. Here we study the problem of unsupervised entity resolution. Current methods rely on human input by setting multiple thresholds prior to execution. Some methods also rely on computationally expensive similarity metrics and might not be practical for big data. Hence, we focus on providing a solution, namely ModER, capable of quickly identifying entity profiles in ambiguous datasets using a graph-based approach that does not require setting a matching threshold. Our framework exploits the transitivity property of approximate string matching across multiple documents or records. We build on our previous work in graph-based unsupervised entity resolution, namely the Data Washing Machine (DWM) and the Graph-based Data Washing Machine (GDWM). We provide an extensive evaluation of a synthetic data set. We also benchmark our proposed framework using state-of-the-art methods in unsupervised entity resolution. Furthermore, we discuss the implications of the results and how it contributes to the literature.

**Keywords**—Entity resolution; data curation; database; graph theory; natural language processing

## I. INTRODUCTION

Entity resolution is critical in data cleaning, curation, and integration [1]. It also refers to finding duplicate records within the same table, across various tables, or multiple databases that might refer to the same entity. Traditional and rule-based entity resolution relies heavily on human input to guide the entity matching process using predefined rules. Defining those rules depends on handcrafting simple lexical, semantic, and syntactic conditions for matching records based on attribute similarity, such as in [2] and in [3]. However, moving toward automating entity resolution for data cleaning, curation, and integration has become a sought-after goal in many domains. Thus, unsupervised entity resolution methods have increased.

Nevertheless, unsupervised approaches suffer from higher inaccuracies than other methods due to relying solely on approximate string matching. Approximate string matching algorithms can quantify the similarity between strings based on character or token frequency and location [4]. String similarity metrics can vary in granularity from character-based to context-based. For example, character-based approaches such as Levenshtein's Edit Distance [5], Affine Gap Distance [6], Smith-Waterman Distance [7], Jaro Distance [8], or n-gram based algorithms [9] are better suited for data where the order

of the tokens matter in identifying unique entities [4]. On the other hand, token-based approaches such as Overlap, Cosine, Dice, Monge-Elkan [10], and Jaccard [11] rely on tokenizing the text into a finite set and then comparing the intersection and union between the sets, which makes them better suited for data characterized by typographical errors. The TF-IDF algorithm [12] is another type of string similarity metric, which is more context-based and depends on token frequencies in a corpus.

Unsupervised entity resolution methods typically follow an automated processing pipeline that consists of preprocessing, blocking, matching, clustering, profiling, and canonicalization. Preprocessing refers to multiple steps that involve merging and parsing data files, tokenizing, and normalizing the unstandardized documents. Blocking is the strategy used to mitigate the quadratic complexity of pairwise comparisons in unsupervised entity resolution. That strategy relies on quick and dirty techniques that divide the preprocessed unstandardized references into chunks or blocks, avoiding string matching across the whole dataset. As a result, each block can be processed separately, where pairwise string similarity can be applied with less computational cost.

Generally, unsupervised entity resolution systems resort to matching threshold setting and end the entity matching process at that stage, such as in [13]. Other systems further expand the pipeline to identify entity profiles generalizing the entity matching output to more than two entity clusters. The clustering process aims to resolve conflicts in pairwise matching and find records that indirectly match. Those conflicts typically occur due to the reliance on frequency-based blocking [1]. Thus, to increase automation, reduce the amount of human input, and increase efficiency in the unsupervised entity resolution process, we aim to reduce the number of input parameters needed and to step away from direct approaches in approximate string matching. We introduce a graph-based approach to entity profiling in unsupervised entity resolution systems that leverage graph clustering algorithms' maturity and autonomy.

More specifically, we address the following challenges in graph-based unsupervised entity resolution systems represented by [13] and iterative self-assessing systems represented by [1]:

- The processing pipeline in iterative self-assessing systems might need to be applied multiple times due to the low accuracy of relying on approximate string

matching alone without rules as in traditional methods. That is clear in approaches such as the Data Washing Machine (DWM) [1].

- Using approximate string-matching similarity measures that rely on heuristics, though providing robust results, sometimes undermines processing speed. Moreover, those algorithms are exhaustive with quadratic time complexity running time, such as in [14]. In addition, though [13] introduced a learned similarity function, the algorithm is relatively expensive and does not provide an entity profiling capability.
- Setting matching thresholds as in [13], and cluster quality thresholds as in [1] might be problematic for the user's perspective. Interpreting those thresholds depends on the fed data, and the user might not have a baseline reference to compare.

#### A. Contribution

Here we developed a solution that relies on exploiting the transitivity property characterized by the output of the matching process, allowing us to recast the matched documents as a graph of weighted edges. We expand on the work that our group has done, mainly the Graph-based Data Washing Machine (GDWM) [15] and the original Data Washing Machine (DWM) [1]. We address the previously mentioned problems as follows:

- ModER avoids the extra computational cost of iterating multiple times over the processing pipeline to maximize a similarity threshold and optimize a cluster quality threshold [1]. First, the recast graph is divided into smaller subgraphs using a connected component detection algorithm exploiting the transitivity property of pairwise matching. Second, a document-word bipartite graph is formed where an initial modularity optimization runs to initialize cluster memberships of document nodes on the block level subgraph. Finally, a conditional greedy modularity maximization algorithm further breaks down the detected clusters.
- Instead of costly computing token-based similarity measures, the weighted edges representing the approximated similarity between every two documents on the block level are estimated using a Locality Sensitive Hashing scheme [16]. The similarity weight is approximated using a MinHash Jaccard estimator [17]. In addition, we exploit the fact that documents or records almost always include highly discriminative terms representing a fingerprint for each document.
- Instead of relying on the user to set similarity matching and cluster quality thresholds, we overcome the need to set algorithm-related thresholds by using Modularity as an optimized cluster quality metric guiding the matching and linking processes. The only parameters that the user needs to input are data-related: the percentile of blocking words, the percentile of stop words, and the percentile of discriminative words. That allows the user to study the data before running our framework statistically. The user can then provide those parameters as a function of the statistical analysis of the dataset.

- To our knowledge, Modularity based graph clustering has not been adapted before to the problem of unsupervised entity resolution. Therefore, we make our code publicly available as a git repository through the link under the directory ModER<sup>1</sup>.

## II. RELATED WORK

There is a large number of entity resolution systems in the literature in general targeting many problems such as ZeroER [18], DITTO [19] and Swoosh [20]. In this literature review we focus specifically on papers that are within the scope of graph-based unsupervised entity resolution. Despite their sparsity in the literature, graph-based methods and algorithms have been adapted before to entity resolution.

### A. Token-based Graph Entity Resolution

In token-based graph entity resolution, the goal is to construct a bipartite undirected graph of token nodes and record nodes and cluster the record nodes into unique entities using methods such as SimRank [21]. In [22], the authors introduced a graph-based entity resolution model. The model transformed the input data set into a graph of unique tokens where connectivity reflects the co-appearance of tokens in references. The graph was clustered using a weight-based algorithm that considered three types of vertices: exemplar, core, and support vertices. The algorithm then constructed  $r$  radius maximal subgraphs from the original token graph to discover clusters related to unique entities. Token-based methods, however, are computationally expensive and memory intensive due to the lack of an integrated blocking strategy.

### B. Record-Record Similarity-Based Graph Entity Resolution

Record-record similarity graphs link structured unstandardized references in a weighted undirected graph where the nodes represent unique records. The connectivity represents the degree of similarity between individual references. That approach of constructing a record graph allows to directly utilize a whole set of graph clustering algorithms that graph theory and network science researchers have already developed. While [23] applied a graph clustering algorithm to optimize minimal cliques in the graph. The algorithms approximated the NP-hard graph clique problem through pruning. Moreover, [24] developed the FAMER framework to combine multi-source data using blocking, matching, and clustering schemes. The framework modeled the merged data as a similarity-record graph and then leveraged graph clustering techniques to resolve the entities.

Other work has leveraged the graph's structure instead of just the weights between records. In [25], the authors proposed three algorithms to cluster the similarity graph based on structure rather than edge weights. They argue that graph-based transitive closure, such as in [26], produces high recall but low precision because the graph's structure is not considered during clustering. They justified using maximal clique algorithms to leverage the graph's structure, which increases precision. There are also centrality and node importance-based methods where the edge weights are not considered, and node scores are propagated, such as in [27]. In addition, the authors introduced

<sup>1</sup><https://bitbucket.org/oysterer/dwm-graph/src/master/ModER/>

the notion of a node resistance score in a co-authorship graph to model entity similarity. Node resistance can be considered a PageRank score [28], where a random walker computes the probability of getting from the source node to the target node iteratively until convergence. Also, in [29], the authors introduced a graph-based model that linked two graph datasets by aggregating similarity scores from neighboring record nodes. However, record-record similarity methods are complicated and require extensive graph theory knowledge to tune the adapted methods.

### C. Hybrid Graph-based Entity Resolution

Hybrid methods that combine token-based bipartite graphs and similarity-based record-record graphs have been investigated in [13] and [30]. The authors proposed an algorithm that combines text similarity with a graph-based algorithm. They first partition the data into a bipartite graph of record pair nodes and frequent term nodes to learn a similarity score of the record pair nodes. Then, the result was used to construct a record-record graph and used to power the CliqueRank algorithm, which runs on the blocks of records identified by the first part, known as the ITER algorithm. The probability of a matching pair of records is then updated iteratively. The authors combined two distinct methods: the random walk-based approach and the graph clustering-based approach. However, the authors used the graph approach to match pairs of records without introducing any clustering approach that would resolve the entity profiles.

The following section describes the framework, method, and algorithm used in ModER.

## III. PRELIMINARIES

### A. Problem Definition

Let us assume that we have a collection of merged documents in one file where every single document has a unique identifier and a reference body. More formally, the set of merged documents are  $D$  consisting of tuples  $d_i = (u_i, r_i)$  where  $u_i \in U$  is a unique identifier that is either provided in the input file or is automatically generated by ModER and  $r_i \in R$  is the reference body. Let us also assume that there exists a latent variable  $\tau$  representing the underlying hidden unique entity profiles in the data file pointing to the probability  $P(\tau) = \sum_{i=0}^N P(d_i \in \tau)$  where  $N$  is the number of documents in the file. Hence  $|\tau| \leq N$ . That reformulates the problem as an estimation of  $P(d_i \in \tau)$  for each document  $d_i$ .

### B. Graph Formulation and Modularity

Consider a set of document unique identifiers  $u_i$  and their tokenized unique reference bodies  $r_i$ . Consider two ways of remodeling the input corpus as a graph. First a document-document graph  $G = (V, E)$  where each vertex/node  $v \in V$  represents a unique document  $u_i \in U$  where  $u \equiv v$ . While an edge  $e \in E$  where  $E \subseteq V \times V$  represents whether two records  $e_i = (r_i, r_j)$  are matched, and an edge weight  $w_e \in W(E) : E \rightarrow \mathbb{R}$  represents the normalized similarity between the two nodes. A graph  $G$  could be represented as an adjacency matrix  $A$  of size  $|V| \times |V|$ , where each cell in the matrix contains either a 1 if an edge exists between two nodes or 0 if an edge does not exist. Each cell value containing 1 could

be multiplied by the edge weight to represent a weighted adjacency matrix. We also define a set of clusters  $Q \subseteq P(V)$  where  $Q$  elements are a subset of  $V$  and  $P$  is a partition of  $V$ . The clustered graph conventionally can be seen as a graph of subgraphs where each meta-vertex represents each subgraph of vertices or records as follows:

$$V' = Q \quad (1)$$

$$E' = (Q_i, Q_j) : \exists (v_i, v_j) : v_i \in Q_i, v_j \in Q_j, (v_i, v_j) \in E \quad (2)$$

Second, the corpus of input data could be modeled as a bipartite graph  $G = (V, Y, E)$  with two types of nodes  $V$  and  $Y$  where an edge  $e \in E$   $E \subseteq V \times Y$  can only exist between two nodes of different types. In our case, the first type of node  $v \in V$  represents a unique document  $u_i \in U$  where  $u \equiv v$  and the second type of nodes  $y \in Y$  represents a unique token  $t_i \in T$  where  $t \equiv y$ . Edges can exist between a document node and a token node if the token exists in the document reference body. We also define the notion of node membership  $q_i$  where a node  $n_i$  can only be a member of one cluster  $q_i$ . Finding the best suitable cluster membership for a node  $n_i$  could be achieved through optimizing cluster quality heuristics such as Modularity [31] or Conductance [32]. Modularity quantifies the cluster quality in a graph by comparing the edge density in each cluster to a randomly rewired hypothetical network. Recall the notions defined in equation 1 and 2. Modularity can then be conceived as:

$$M = \frac{1}{2m} \sum_{i, j} \left[ A_{i, j} - \frac{k_i k_j}{2m} \right] \partial(Q_i, Q_j) \quad (3)$$

Where  $m$  is the number of edges in the graph and  $k$  is the degree of a node. In addition  $A$  is a weighted adjacency matrix constructed from  $E'$ . And,  $i$  and  $j$  are indices for each unique record in the file, represented as a vertex in the graph as  $vt \in V'$ . And  $e' \in E'$   $E' \subseteq V' \times V'$  and  $e' \equiv A_{i, j}$ .

### C. Similarity and Transitivity

Consider that if record  $a$  matches record  $b$  and record  $b$  matches record  $c$ , then by transitivity, record  $a$  matches record  $c$ . The former definition of transitivity is the notion that binds our assumptions that lead us to create a graph from a set of matched documents. This assumption can only hold if the probability of record  $a$  matching record  $b$  and the probability of record  $b$  matching record  $c$  are high enough [33]. A high enough probability in approximate string matching is considered above 50% [34]. we interpret normalized approximate string similarity measures such as the Jaccard index and Levenstein ratio as matching probabilities. Hence, a Jaccard similarity between two documents below 50% is not accepted as a link between two records, which is crucial for the transitivity assumption to remain valid. Note also that the transitivity assumption is what allows us to form a document-document graph; otherwise, it does not make logical sense to apply a transitive closure algorithm on a formed graph if transitivity does not hold or, in other terms, if the edge weight between nodes representing the matching probability is less than 50%. That assumption could also be corroborated by interpreting similarity at 50% as extreme uncertainty of whether the two documents are similar instead of the intuition that a 10% similarity indicates

uncertainty. On the contrary, a 10% similarity holds more certainty that the two documents are dissimilar. Hence a 50% similarity is an appropriate baseline for interpreting approximate string similarity measures as matching probabilities.

#### IV. METHOD

In this section we extensively describe the proposed framework as shown in Fig. 1.

##### A. Merged Input Corpus

The input corpus is defined in one file. The file is merged from multiple data sources. The user manages this step where the only requirement is a single merged file. In the future, we intend to address having to merge multiple data sources as part of the framework developed here. The assumption is that each line in the file represents a document containing a reference body where the number of latent entity profiles is less than or equal to the number of documents. In addition, as mentioned in the preliminaries section, it is assumed that documents share at least one token so that the assumption of transitivity is not broken III-C. Note that the unique identifier  $u_i \in U$  is either provided in the input file or is automatically generated by ModER.

##### B. Preprocessing

The parsing process includes normalization, cleaning, tokenization, and filtering and is central to the framework. Tokenization is preceded by the normalization and cleaning step, where the text from the reference bodies of the documents is cleaned from particular characters and converted to lowercase. If a unique character appears in the token's middle, it is removed, and the entire string is compressed. We use the standard approach to tokenizing text in English, splitting the text based on spaces between tokens. The parsed data are then loaded into memory, and unique token frequencies and length dictionaries are computed. Stop words are also removed if their frequencies exceed a parameter sigma  $\sigma$ . More formally, as referred to before in the preliminaries Section III-B, the corpus  $D$  consists of tuples  $d_i = (u_i, r_i)$  where  $u_i \in U$  and  $r_i = w_i \in W$  contains a unique distinct set of tokens  $T$  with different counts  $C$  given that  $t_i$  is a distinct unique token where  $t_i \in T \subseteq w_i$  and  $c_i$  is the corresponding count of each unique token  $t_i$  where  $c_i \in C$  and  $C = |t_i \in T|$ . In addition, a token length dictionary is computed where  $l_i \in L$  and  $L = \text{len}(t_i \in T)$ . First each document  $d_i \in D$  is processed using  $\sigma$  to filter out tokens  $t_i \in r_i$  with frequency  $c_i \in C$  and  $C = |t_i \in T|$  above  $\sigma$  to filter out stop words.

##### C. Blocking

The blocking process aims at reducing the potential number of pairwise matching across a data file as much as possible. We use a frequency-based blocking algorithm that assumes that two records that refer to the same entity share at least one token. We adapted the frequency-based blocking technique presented in the DWM [1]. The blocking method relies on the parameter beta  $\beta$ . For each reference token  $t_i \in r_i$  with frequency  $c_i \in C$  and  $C = |t_i \in T|$  below  $\beta$  and above 2 is considered a blocking token  $t_{Bi} \in T$ . Blocking tokens are identified for each reference in a list  $L$  where the filtered

records are repeated. The list is then grouped by blocking tokens regardless of reference. Each block includes all the references where the same blocking token appeared, and the number of blocks was equivalent to the number of unique blocking tokens in the dataset. This process is formalized in Algorithm 1.

---

**Algorithm 1:** Blocking

---

```
Input :  $C(T)$ ,  $R$ ,  $\beta$ ,  $\sigma$ : unique token frequencies,  
record set  
Result :  $B$ : list of blocks  
 $B \leftarrow \text{list}$   
for  $r \in R$  do  
  if  $c_i \in C$  for each  $t_{ij} \in r$  where  $t_i \in T \geq \sigma$   
  then  
     $r \leftarrow \text{remove } t_{ij} \text{ from } r$   
  end  
  if  $c_i \in C$  for each  $t_{ij} \in r$  where  $t_i \in T \leq \beta$   
  then  
     $L \leftarrow (t_{ij}, r)$   
  end  
end  
 $L_s \leftarrow \text{sort}(L, t_i \in T)$   
 $T_u \leftarrow \text{unique}(t_{ij} \in L_s)$   
for  $t_i \in T_u$  do  
  for  $l_s \in L_s$  do  
    if  $t_i = t_i \in l_s$  then  
       $b_i \leftarrow r \in l_s$   
       $B \leftarrow B + b_i$   
    end  
  end  
end  
return  $B$ 
```

---

##### D. Fast Matching using Locality-Sensitive Hashing

The goal here is to provide a quick, fast, and multilevel way of grouping documents that might belong to the same latent unique entity. However, matching every document in the corpus would result in an algorithm that runs as  $O(N^2)$  in time. So, our efforts are concentrated on reducing the number of possible matching operations through 3 steps. First, after the preprocessing phase, we apply a Locality Sensitive Hashing (LSH) [16] algorithm to allow for a quick approximation of a similarity function such as Levenshtein ratio, Cosine distance, or Jaccard index. Even at the block level, computing the former similarity metrics can be expensive for larger files. LSH aims at using a hashing algorithm to approximate a similarity function such as Jaccard index [11]. Jaccard similarity involves computing the set intersection and union across tokenized words between the two documents being compared. Computing both a union and an intersection could be computationally expensive, misaligning with our overarching goal of reducing string-wise comparisons as much as possible. An LSH algorithm operates on a metric, a threshold, an approximation factor, and a set of probabilities. The goal is to design a hash function that approximates a metric by optimizing a threshold. The approximation is achieved by making sure that the set of probabilities holds.

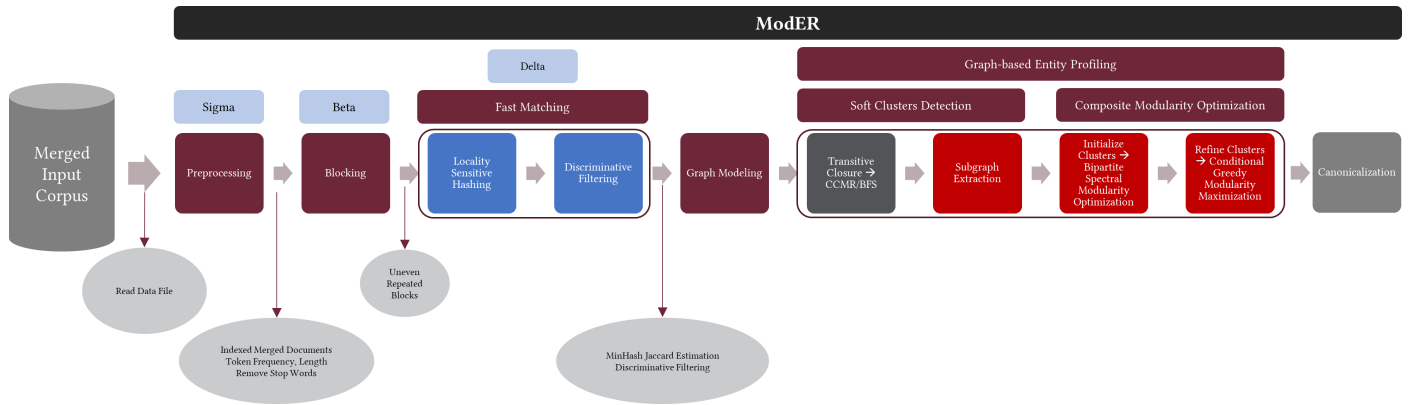

Fig. 1. An Overview of the ModER Framework.

Here we adapt the MinHash algorithm [17] to estimate the similarity between records in the same block. The MinHash algorithm is designed to approximate the Jaccard index between two sets. Sets are columns in a matrix where each row represents an element from the union of the two sets. A cell value of 1 represents the existence of that element in one of the two sets. The critical observation is that the Jaccard similarity could be approximated by counting the number of collisions between the two sets after hashing each element in each set. So counting the number of collisions of hashes between the two sets and normalizing them by the total number of hashes approximates the Jaccard similarity [35] [16]. That technique reduces the number of operations needed to compare two documents from  $O(N^2)$  to  $O(N)$  in time in best cases and  $O(N \log(N))$  in worst cases. we adapt MinHash by precomputing the approximating hash functions over the entire corpus. We provide a simple implementation of the MinHash algorithm in our code; however, while running experiments, we used the highly optimized implementation introduced by [36]. Each word is hashed for each document in the corpus using a 32-bit SHA algorithm [37]. The hashed unique tokens represented in each document are permuted and then drawn randomly from each document. A signature is then computed for each unique word in the documents, and the minimum signature is chosen to represent that word in the documents. The Jaccard index is then estimated linearly by counting the number of similar signatures in the same position over the total number of signatures appearing in the two documents according to the proof presented initially in [17]. We did not formalize MinHash here as formalizations of the algorithm are widely available.

The second part of our matching scheme, also done on the block level, is that we do not take the estimated Jaccard similarity at face value. We first filter the documents and extract what we call discriminate tokens. Those are tokens longer in length than a parameter delta  $\delta$ . Discriminate tokens represent tokens that, by looking at them, you can quickly determine whether two documents are similar. Those tokens might be social security numbers, credit card numbers, long street names, long last names, scientific names, product numbers, or models. Those tokens are usually highly discriminative in determining whether two documents are similar. Hence before estimating the Jaccard index on the block level, we check whether the two documents have tokens in common that are longer than

delta and their Levenshtein distance is less than 2. We consider 2 to be the threshold that defines a typo. The strength of our framework lies in the fact that we do not use a similarity threshold to match documents on the block level. Instead, we allow the data to automatically match the documents based on the characteristics represented in the parameters derived from the token frequencies and length. Hence, on the block level, we link documents with a similarity above 0 without any threshold setting. That process is described semi-formally in the pseudo-code presented in Algorithm 2.

---

**Algorithm 2:** Pairwise Matching using MinHash

---

**Input :**  $B, F$ : list of computed blocks, unique token lengths  
**Result :**  $E$ : linked weighted pairs  
 $E \leftarrow list$   
**for**  $b \in B$  **do**  
    **for**  $r1 \in b$  **do**  
        **for**  $r2 \in b$  **do**  
            **if**  $r1 < r2$  **then**  
                 $d1 \leftarrow f1 \in F$   
                 $d2 \leftarrow f2 \in F$   
                **if**  $d1 = d2$  **or**  $levenshtien(d1, d2) \leq 2$   
                    **then**  
                         $s \leftarrow 1.0$   
                    **end**  
                **else**  
                     $s \leftarrow minHash(r1, r2)$   
                **end**  
                **if**  $s > 0.0$  **then**  
                     $E.append((r1, r2, s))$   
                **end**  
            **end**  
        **end**  
    **end**  
**end**  
**return**  $B$

---

**E. Graph Modeling**

The unordered list of matched records can be considered an edge list or an adjacency matrix representing a graph of

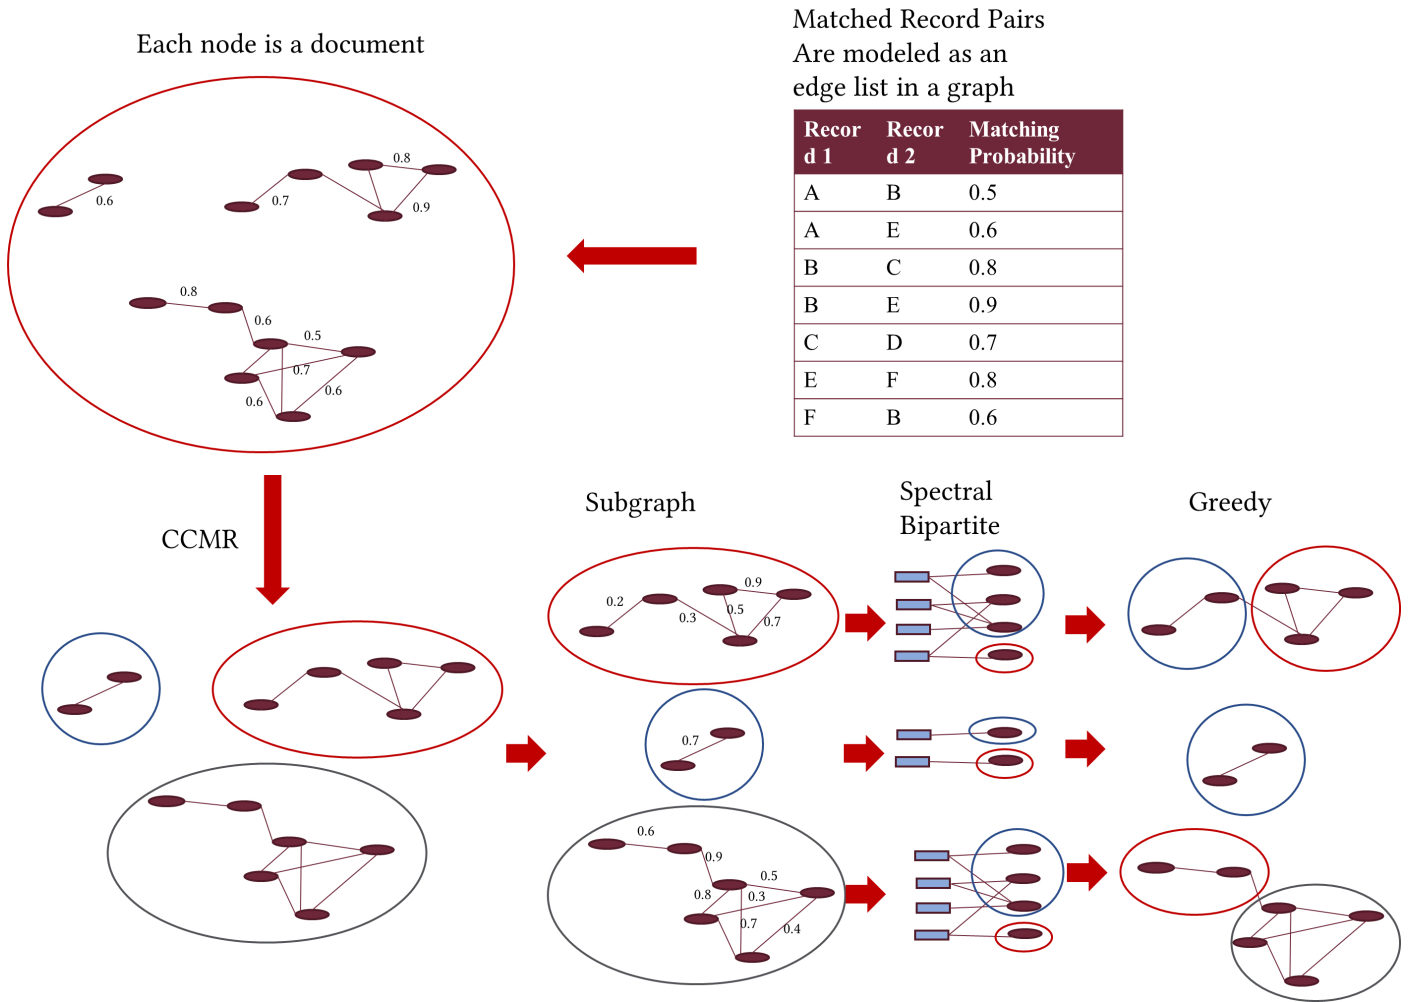

Fig. 2. Graph Modeling. First, the Matched Records are Modeled as One Large Weighted Graph with Expected Disconnected Components Due to the Transitivity Property. Second, Connected Component Detection Algorithms Output the Nodes in each Connected Component. Third, each set of Nodes is then Modeled as a Subgraph.

Fig. 3. The Typical Unsupervised Entity Resolution Approach Starts with Frequency-Based Blocking, Pairwise Matching, and Entity Clustering.

records. The blocking algorithm considers two similar records having a high probability of representing the same entity if

they have a minimum of one token in common. That increases the number of records representing one entity, as shown in Fig. 3. As a result, a record may appear in more than one entity, making clustering more expensive and the underlying graph of matched records more complex. In addition, the matching process also implies that one record might be similar in an indirect way to another record by transitivity, provided that the matching probability is above 50%. The output of algorithm two is modeled as a graph, as mentioned in the preliminaries in Section III-B and as seen in Fig. 2. A subgraph is then extracted on the block level.

#### F. Graph-based Entity Profiling

1) *Transitive Closure*: In transitive closure, the aim is to find the set  $C$  of sets  $V_i$  where each set represents a strongly connected component in the graph. A strongly connected component is a set of nodes where each node has at least one link to another node. Strongly connected components are separated by unlinked nodes. We also refer to strongly connected components as soft clusters. Here in ModER, one of two approaches could be used. First, an algorithm named CCMR was introduced by [26] and used and reimplemented in the original DWM [1] as a single-step clustering method. The algorithm starts by creating star subgraphs from the matched pair list. That is done by simply grouping the pair list by the smallest node. Then, the algorithm iteratively checks whether its vertices are assigned to subgraph components where the center of the subgraph component is the smallest vertex in its first-order neighborhood, relying on the MapReduce framework for scalability. The DWM provides an efficient implementation of the algorithm without relying on MapReduce. The algorithm is formalized and described thoroughly in [26] and [1]. The second approach that could be used is a simple breadth-first search algorithm [38] to extract the connected components or soft clusters. We provide implementation and describe both algorithms semi-formally in Algorithms 3 and 4.

2) *Subgraph Extraction*: The subgraph extraction process aims to avoid recomputing edge weights that have been computed before during the fast-matching process. A subgraph is simply the set of soft clusters that have been computed using the transitive closure process. Each soft cluster is represented by a set of unique nodes or documents. Each document or node can appear in only one soft cluster. To extract a subgraph from the larger graph, we find the edges where all the nodes in the current soft cluster are represented exclusively. Subgraph extraction is formalized in Algorithm 5.

3) *Composite Modularity Optimization*: In the Composite Modularity Optimization step, the goal is to initialize the cluster membership of each node in the extracted subgraph based on token memberships in each document. Next is to refine the clusters discovered in the initial clustering to more precise memberships. In the following two subsections, we outline how we implement that process.

a) *Bipartite Spectral Modularity Optimization*: This step exploits the relationship between documents and unique tokens across all documents. First, we project the unique document identifiers and unique tokens across all documents as a bipartite graph similar to Fig. 4.

---

#### Algorithm 3: Transitive Closure using Adapted CCMR

---

```
Input :  $S, \mu$ : pairs of matched records and their  
         computed similarity scores, similarity threshold

**Algorithm 5: Subgraph Extraction**

```

Input :  $V', A$ : component, adjacency
Result :  $G' = (V', E')$ : graph
 $E' \leftarrow list$ 
for  $v \in V'$  do
     $neighbors \leftarrow G.getNeighbors(v)$ 
    for  $nn \in neighbors$  do
        if  $nn \in V'$  then
             $E'.append((v, nn, A[v][nn]))$ 
        end
    end
end
return  $(V', E')$ 
    
```

Recall equation 3; we defined the Modularity heuristic  $M$  as the sum of the difference between the edges of the current graph versus a null model graph where edges are rewired randomly within clusters. Here we approach Modularity optimization on the bipartite network of documents and unique tokens or words using a spectral approach or, in other words using matrix form. The goal is to optimize Modularity across both types of nodes in the bipartite graph and extract only the optimized cluster memberships of document nodes. First, a clustered index matrix  $S$  is defined where the rows are the nodes in the graph, and the columns are the number of clusters in the graph. Initializing this matrix at the beginning means that each node has its cluster, so the number of rows equals the number of columns. The values in  $S$  are either 0 or 1, indicating node memberships. Recall from equation 3 defining Modularity, the term  $\frac{k_i k_j}{2n}$  defines the probability of an edge in the null model

and can be denoted by  $P_{i,j}$ . Hence the term  $[A_{i,j} - \frac{k_i k_j}{2n}]$  can be rewritten as  $[A_{i,j} - P_{i,j}]$  and can be referred to as  $B_{i,j} = [A_{i,j} - P_{i,j}]$ . According to [39], the previous matrix form can be combined with equation 3 to redefine Modularity in matrix form as:

$$M = \frac{1}{2n} Tr(S^T B S) \tag{4}$$

Where  $n$  is the number of edges in the graph since a bipartite graph is naturally partitioned into a minimum of two initial clusters [39]. That naturally help us derive a definition of Spectral Bipartite Modularity that penalizes any random choices of edges if the nodes belong to the same cluster, thus the bipartite Modularity in a non-matrix form could be defined as:

$$M = \frac{1}{n} \sum_{i=1}^p \sum_{j=1}^q \left[ \widetilde{A}_{i,j} - \frac{k_i d_j}{n} \right] \partial(Q_i, Q_{j+p}) \tag{5}$$

Where  $\widetilde{A}$  is the bi-adjacency matrix.  $k_i$  is the degree of node  $i$  from the document nodes and  $d_j$  is the degree of node  $j$  from the word nodes.  $n$  is the total number of edges in the graph and  $Q_i$  is the partition of a document node  $i$  while  $Q_{j+p}$  is the partition of a word node  $j$  indexed as  $j = i + p$ . Thus equation 5 in matrix form becomes:

$$M = \frac{1}{2n} Tr(R^T \widetilde{B} T) \tag{6}$$

Where  $R$  is the cluster index matrix similar to  $S$  but for document nodes, while  $T$  is the cluster index matrix similar to  $S$  but for token or word nodes.  $\widetilde{B}$  is the difference between

the biadjacency matrix  $\tilde{A}$  and the reformulated bipartite null model  $\tilde{P}$  where  $\tilde{B} = [\tilde{A} - \tilde{P}]$ . The goal is to maximize Modularity in matrix form as in equation 6. The term  $\tilde{B}T$  in equation 6 could be rewritten as  $[\tilde{A}T - \tilde{P}T]$  indicating that the bipartite null model is calculated on the token nodes only. We refer to this case as  $\tilde{T}$ . Or it could be written as  $[\tilde{A}R^T - \tilde{P}R^T]$  indicating that the bipartite null model is calculated on the document nodes only. We refer to this case as  $\tilde{R}$ . In terms of summation over the matrix in an optimization scheme, these two cases can be rewritten as:

$$M = \frac{1}{n} \sum_{i=1}^p \left( \sum_{k=1}^c [R_{i,k} \tilde{T}_{i,k}] \right) \quad (7)$$

$$M = \frac{1}{n} \sum_{j=1}^q \left( \sum_{k=1}^c [\tilde{R}_{i,k} T_{i,k}] \right) \quad (8)$$

Where  $c$  is the maximum number of clusters in the graph, note that this is equivalent to hypothetically assigning document nodes to clusters of word tokens and vice versa, similar to traditional modularity optimization approaches such as Louvain [40] hence the delta modularity, in this case, was the summation of both delta modularities from both node types. Given the previous formulation, we maximize Modularity using a greedy approach described in Algorithm 6.

*b) Conditional Greedy Modularity Maximization:* This second step aims first to recast the documents as a document-document graph as in Fig. 5. Second to break down the soft clusters in a hierarchical manner by maximizing Modularity  $M$  using a conditional modularity maximization algorithm as seen in Fig. 2. That step is seen as further filtering. The assumption here is that clusters in a graph are often defined by the density of edges between a set of nodes. Hence, the number of connections or edges between clusters characterized by high Modularity is often meager. Modularity is defined in equation 3 as  $M$ . It measures the difference between the actual number of edges and an expected number of edges between nodes. An expected number of edges between nodes can be considered a random rewiring of the graph given the same nodes. Optimizing Modularity through maximization in a graph is a complex problem and is often tackled through various ways to reduce the number of comparisons between all nodes in a graph. During maximization, we use the shorthand equation provided in [40] to reduce the computational cost of computing delta Modularity of all nodes as shown in equation 9.

$$\Delta M = \left[ \frac{\sum_{in} + k_{i,in}}{2n} - \left( \frac{\sum_{tot} + k_i}{2n} \right)^2 \right] - \quad (9)$$

$$\left[ \frac{\sum_{in}}{2n} - \left( \frac{\sum_{tot}}{2n} \right)^2 - \left( \frac{k_i}{2n} \right)^2 \right] \quad (10)$$

Where  $M$  is Modularity,  $in$  are incident nodes to cluster,  $tot$  all nodes inside cluster,  $k$  is the degree of the node,  $n$  is the total number of edges. We also apply a condition that a node is only assigned to the maximum Modularity difference cluster if the delta modularity is positive and the matching probability between both document references is 100%. That

ensures that precision is not compromised by breaking precise clusters discovered in the first step. In addition, that is also to assure that discriminative terms are factored into the composite Modularity optimization method. Our Conditional Modularity Maximization algorithm is formalized in Algorithm 7.

 $M_{final} \leftarrow computeModularity(V', E')$ 

```

G. Canonicalization

The clusters representing unique entity profiles are defined and persisted to the disk in this final step through a link index file. The link index file describes the final entity clusters of the unsupervised entity resolution framework as a list of ordered pairs where the first element of each pair represents the entity profile identifier to which the record is assigned. The entity profile identifier is simply the least recorded identifier in the cluster. The second element of each pair represents a member's unique record identifier.

V. EXPERIMENTS

A. Datasets

1) *Synthetic Datasets:* ModER is tested on a synthetic benchmark dataset. The reason lies in the fact that there is a lack of benchmark datasets for the task of entity resolution. Most entity resolution systems are evaluated against benchmark datasets [41] that are designed for an entity matching task and not an entity resolution task. Hence we use the synthetic dataset described in [42] as seen in Fig. 5 that is specifically designed for the task of entity resolution. This simulator-based data generator uses probabilistic approaches to generate coherent individual data for persons that do not exist except for S3 and S6, which both represents generated addresses and names of restaurants that do not exist and were introduced in [43]. The data fields are names, addresses, social security numbers, credit card numbers, and phone numbers mixed in several layout configurations. Some samples are labeled as mixed layout, meaning that each row might come with a different order of those attributes and might not be delimited. The standard label means that all the rows in the data file have the same order and attributes. The generator described in [44] used a probabilistic error model to inject various errors in the previously developed simulated dataset. For example, in this excerpt of a generated data file shown in Fig. 5, the first four records are almost

identical except for that record A956296 has a missing last name and the format of the phone numbers or whether they exist at all, all are errors injected and generated on purpose. In addition, the last two records are almost identical except for the first name, where an intentional error was introduced. A ground truth set recording the actual clusters of the simulated records is then sampled from the generated synthetic database. Next, the corresponding references are pulled from the generated synthetic database to create various sample files with different sizes, levels of quality, and layouts. Sizes of files can vary from 50 to 20K rows. For a more detailed description of the dataset please refer to [15].

2) **Benchmark Dataset: Abt-Buy** is an e-commerce benchmark dataset introduced and curated by [41]. Despite the lack of benchmark datasets that are designed specifically for the task of entity resolution rather than entity matching we used this dataset as a means to compare results with other systems. The dataset represents an entity matching task between products listed on 2 e-commerce websites<sup>2</sup>. The dataset appears as one data file containing attributes, product names, descriptions of products, manufacturer of the products, and price. The data set also is provided with a ground truth file containing a perfect matching between entities across both websites. The number of rows in this dataset is 1081 from the first source file and 1092 from the second data file.

3) **Benchmark Models: Data Washing Machine (DWM):** the Data Washing Machine (DWM) [1] implements a fully probabilistic, iterative, and token frequency-based approach. The DWM produces remarkable results on simulated datasets of various sizes, layouts, and qualities. The DWM is computational, iterative, and probabilistic; it follows a traditional data cleaning and merging pipeline, tokenization, blocking, matching, clustering, profiling, and canonicalization. The DWM relies on the idea of starting with a set of configuration parameters and then iteratively incrementing the parameters according to a self-administered evaluation of the quality of the clusters using an entropy-based metric. The DWM has been shown to provide robust results in large datasets. In addition, the current implementation is very modularized, allowing for room for improvement.

**Magellan:** Magellan, introduced in [45], is an end-to-end solution to entity resolution developed as a user-centric approach. It has been used and adopted widely. The model relies on providing guides that tell users what to do in entity matching scenarios. The framework also provides tools to cover the entire entity matching pipeline using a simple, approachable implementation.

## B. Evaluation Metrics

For evaluation we measured the precision and recall against the generated ground truth entity clusters. The ground truth is a list of each record and its membership cluster identifier. After canonicalization, the saved link index is grouped by the least record identifier in each cluster. Thus, all records belonging to the same cluster have the same record identifier as the first element in the link index pair. We then loop on each pair in the canonicalized link index and examine whether they belong together in the ground truth. Finally, we measure the following

statistics against the ground truth for each sample run as shown in Table I. That is also shown in the increased balanced accuracy [46], which is a valuable measure for problems such as entity resolution. Entity resolution is characterized by having a class imbalance as the number of matched pairs is usually way less than the number of unmatched pairs causing a very high number of true negatives.

## C. Results

We ran our model on an Intel Core *i7 – 4720HQ* CPU @ 2.60GHz and 32GB of RAM. We ran ModER and DWM first on the samples *S1* through *S18*, as described in Tables III and II. To determine optimal parameters for ModER relative to maximum F1-Scores, we ran each sample 10 times on incrementing beta, sigma, and delta and chose the parameters that gave the best F1-Scores. Please note that we do not set them directly as numbers when setting parameters beta  $\beta$ , sigma  $\sigma$ , and delta  $\delta$ . Instead, we set them using a percentile formula where the percentile of stop words is  $\sigma$ , the percentile of blocking words is  $\beta$ , and the percentile of word length is  $\delta$ . For running the DWM, we set the parameters to the equivalent in our model. For example, we assume that our baseline matching threshold  $\mu$  is 0.5 or 50% quantifying maximum uncertainty. Also, in the DWM runs, the quality epsilon  $\epsilon$  is tuned based on our previous work's data [15]. We also informed the setting of  $\beta$  and  $\sigma$  similar to what we did in the GDWM and set them to 6 and 7, respectively.

Table II shows the results from running the DWM on the 18 samples with equivalent set parameters. Even though it is challenging to compare both techniques due to their differences, it is helpful to compare both in relatively limited runs. Table V compares the final F1-Scores of both the DWM and ModER. On the other hand interpreting Table IV is tricky because more experimentation needs to be done to get a complete picture of the performance of the developed approach concerning what has already been done. However, ModER improves overall precision at the expense of recall from those results. Balancing precision and recall is challenging for most classifiers.

Composite Modularity Optimization as a technique for entity profiling is very efficient at detecting large clusters and breaking them down due to the reliance on a bipartite technique of modeling document nodes and unique words. That initialization is used in the second stage of Conditional Greedy Modularity maximization to refine the detected clusters further. Note that the conditional aspect of the greedy Modularity Maximization technique is intentionally injected into the algorithm to ensure that no nodes are assigned to new clusters if the delta modularity change is positive yet too little. That is also to ensure that we only see similarity at 100% or 1.0 as the most certain value indicating matching, and anything else below 100% is mere speculation and prediction and should be treated that way in other entity resolution systems.

In addition, when averaging all samples, as in Table V, ModER offers less F1-Scores performance than the GDWM and the DWM. Note that those averages were directly taken from [15]. Those values were for matching probabilities set at 70% and higher. That might not be fair because ModER does not rely on matching threshold settings. ModER could be seen as a quick and initial entity profiler before using other

systems or rely on a highly unsupervised system that does not require the user to set a matching threshold. In addition to a system that does not rely on matching threshold settings, unlike most state-of-the-art systems, the results are comparable and tell something about the need for matching thresholds. When a user uses such a system to detect entity profiles in a file, they have no experience with what a matching threshold might mean. Hence in ModER, we only let the user set 3 explainable parameters using percentiles, assuming they have studied their data statistically before running any entity resolution system.

In Table VI, we benchmarked ModER using the Abt-Buy dataset introduced in [41]. In addition, Table VII provides insight into multiple runs of ModER on the Abt-Buy dataset with different parameter configurations. Table VI

reports running ModER with parameters that resulted from 10 times increasing parameters with the best F1-Score. As seen, ModER outperforms our previous system, DWM, in addition to Magellan. That is mainly due to the Composite Modularity Optimization algorithm efficiency. In addition, our reliance on discriminative words has favored ModER since most data contain a higher percentage of discriminative keywords. In Table VII, it appears that the number of single nodes varied widely as with the number of edges in the graph formed after matching. That is due to the threshold of the varying parameter. In addition, those initial parameter settings affect the initial Modularity widely regardless of the final Modularity. A Higher F1-Score was tied to lower  $\sigma$  levels, suggesting that filtering stop words are always beneficial before running any entity matching algorithm.

TABLE III. RESULTS FROM THE SYNTHETIC DATA SET EXPERIMENTS ON MODER. BETA IS THE PERCENTILE OF BLOCKING WORD FREQUENCIES ACROSS THE WHOLE FILE. SIGMA IS THE PERCENTILE OF STOP WORD FREQUENCY ACROSS THE WHOLE FILE. FURTHERMORE, DELTA IS THE PERCENTILE OF TOKEN LENGTHS ACROSS THE DATA FILE. BA IS THE BALANCED ACCURACY AND IS COMPUTED AS DESCRIBED IN TABLE I. FINALLY, THE FINAL MODULARITY IS MEASURED ON THE FULL DISCONNECTED GRAPH AFTER ASSIGNING THE NEW MEMBERSHIPS AFTER THE COMPOSITE MODULARITY OPTIMIZATION STEP.

## VI. DISCUSSION

### A. Overall Effectiveness

Ideally, we need a better measure to quantify the balance between precision and recall, as seen in Fig. 6. The F1-score or the harmonic mean between precision and recall fails to differentiate between instances where recall or precision was very high and when they were balanced. A better entity resolution system always provides a balance between both. In that light, ModER appears to balance both precision and recall on S1, S2, S3, and S13. Despite their relative diversity, the common characteristic between those samples is relatively higher quality. That is, the difference between document references injected errors is not significant. They indicate that the first bipartite spectral Modularity optimization did all the work to detect entity profiles. The problem is that bipartite Modularity optimization is a memory-intensive optimization for more significant clusters even though its time complexity is at

$O(2N)$ , returning only two passes on the Modularity matrix to compute the difference. That points us to address this limitation in the future of balancing space and time complexities.

### B. The Effect on Modularity

Here we refer to the final Modularity as the Modularity computed on the final overall graph that has been projected before the entity profiling step. The final cluster memberships have been computed using our Composite Modularity Optimization approach.

In Fig. 7, modularity is more correlated with precision than recall. The more clusters are broken down during the entity profiling step, the higher the Modularity is. Note that Modularity is weakly correlated with the F1 score, meaning that higher modularity values do not necessarily mean higher F1 scores. Modularity is a comparison of edge densities between

TABLE IV. COMPARISON BETWEEN DWM AND MODER

Samples	DWM F1-Score	ModER F1-Score	Performance
S1	85.25	98.11	Improved
S2	73.05	91.3	Improved
S3	57.52	85.71	Improved
S4	77.98	81.54	Improved
S5	79.08	83.41	Improved
S6	78.66	40.28	Worse
S7	79.58	80.46	Improved
S8	47.45	28.45	Worse
S9	27.48	27.56	Improved
S10	40.01	27.71	Worse
S11	38.22	21.5	Worse
S12	38.78	16.2	Worse
S13	79.84	65.23	Worse
S14	76.92	65.54	Worse
S15	74.36	64.79	Worse
S16	39.4	23.76	Worse
S17	36.25	14.9	Worse
S18	42.28	14.0	Worse

TABLE V. THE AVERAGE SAMPLE RUNS ON DWM, GDWM, AND MODER

Method	Precision	Recall	F1-Score	Balanced Accuracy
DWM	72.43	57.82	62.97	76.89
GDWM	84.78	68.62	71.47	84.31
ModER	80.308	44.24	51.691	72.113

TABLE VI. BENCHMARK RESULTS ON THE ABT-BUY DATASET

Model	F1-Score
DWM	10.83
Magellan	43.6
ModER	58.82

TABLE VII. BENCHMARK RESULTS ON THE ABT-BUY DATASET. BA IS THE BALANCED ACCURACY AND IS COMPUTED AS DESCRIBED IN TABLE I. THE INITIAL AND FINAL MODULARITY IS MEASURED ON THE FULL DISCONNECTED GRAPH AFTER ASSIGNING THE NEW MEMBERSHIPS AFTER THE COMPOSITE MODULARITY OPTIMIZATION STEP.

Beta	Sigma	Delta	# Nodes	# Single Nodes	# Edges	Initial Modularity	Final Modularity	Precision	Recall	F1-Score	BA
5	819	9	2173	274	3477	0.0827	0.4577	0.0182	0.3292	0.0345	0.6604
5	92	34	2173	854	2173	0.505	0.647	0.138	0.0367	0.058	0.5183
5	26	8	2173	273	3407	0.083	0.31	0.1669	0.1905	0.1779	0.595
2	92	8	2173	428	1611	0.2697	0.76134	0.6686	0.525	0.5882	0.7625

the current memberships and hypothetical random memberships, also known as the null model.

### C. The Interplay between Precision and Recall

Finally, we plot precision as a function of recall, also known as the precision-recall curve in Fig. 8. The difference is that

precision-recall curves are usually interpreted in the case of binary classification. In our entity resolution system, we are not assessing a binary classifier. We are, however, assessing cluster quality. Nevertheless, plotting precision as a function of recall on the 18 samples arranged in an ascending order shows that recall tends to be more stable than precision affirming our conclusion that ModER provides higher precision but not

Metrics across Synthetic Samples

Fig. 6. A Bar Chart of Precision, Recall, f1-Scores, and Final Modularity after Running on ModER on the 18 Synthetic Samples.

necessarily recall.

#### D. Limitations

It is imperative and expected of course to understand the limitations of our approach here. First the 3 parameters that are controlled by the user  $\beta$ ,  $\sigma$  and  $\delta$  determine the sizes of the blocks. The size of the blocks eventually determines the sizes of the clusters in the modeled graph.

#### E. Takeaways and Future Work

In this work, we focused on the problem of unsupervised entity resolution for identifying unique entity profiles in ambiguous data. We defined ambiguous data as documents or records that do not adhere to a schema and come in unknown layouts and sometimes with inferior quality. In addressing this problem, We first focused on the meaning of similarity and matching. The problem lies in that if two documents are 100% similar, that does not mean that they refer to the same entity. In contrast, if 2 documents match at 10%, that does not mean that we are 100% sure that both do not refer to the same entity. Hence the inherent uncertainty and the nature of the problem. We started from the position that the only sure thing is that similarity between 2 documents of 50% is extreme uncertainty. Then assumed that below 50% of matches tend to ensure that the two documents do not refer to the same entity. On the other hand, two documents with a matching probability of more than 50% have some certainty that they might refer to the same entity. In the GDWM [15], we designed the system based on the later observation that higher mating probabilities should be detected with more certainty. While in

ModER, we generalized to all cases. That generalization came with some cost in performance, but it was not that significant, and compared with other methods in similar conditions, it gave respectable results. The point is that unsupervised entity resolution is a complex problem that needs to be addressed in a more sophisticated way. In addition, the concept of string similarity needs to be reconsidered as traditional similarity functions are the actual bottlenecks in this process. Some deep learning, machine learning, and graph approaches introduced learned similarities, such as in [13] and in [47]. In addition, this problem of unsupervised entity resolution could be generalized to other topics in natural language processing and information retrieval since it resembles the entity recognition problem and the search problem.

## VII. CONCLUSION

Here we introduced ModER, which stands for Modularity Composite Optimization for Entity Resolution, a framework combining multiple steps and algorithms. The method can quickly identify entity profiles in highly ambiguous data, overcoming the need to set matching thresholds. The method also limits user input to 3 parameters set using statistical percentile approximations. We based our work on the state-of-the-art unsupervised entity resolution, the DWM. In addition to the GDWM. To our knowledge, this technique has not been explored before. Our Composite Modularity Entity profiling step is innovative and can provide better results when benchmarked. In the future, we plan to address challenges such as the breakdown of high recall clusters even though they might not be imprecisely profiled. In addition, we address the memory-intensive bipartite approach posing a bottleneck for large

Fig. 7. A Scatter Plot of Values of Precision, Recall and f1-Score against Final Modularity Values on ModER after Running the 18 Synthetic Datasets.

profiles.

#### CONFLICT OF INTEREST STATEMENT

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

#### AUTHOR CONTRIBUTIONS

IAE created the ModER framework and wrote the article, JRT created the DWM framework and provided feedback and guidance on creating ModER as main PI, NH benchmarked the ModER framework and the GDWM framework and MAS tested the ModER framework and the GDWM framework on synthetic datasets and preprocessed the benchmark datasets.

#### FUNDING

This material is based upon work supported by the National Science Foundation under Award No. OIA-1946391.

**Abstract**—Scientific research teams often find themselves in remote working situations due to their internationality. Incredibly complex technological projects demand close collaboration and knowledge-sharing management. Remote teamwork, especially in cutting-edge scientific technology development, comes with various challenges that can negatively influence the overall team performance and commitment to the project. Within the EU-Japan (EU-/MIC-funded) project e-VITA, a consortium of 22 multidisciplinary partners and around 80 people work on research regarding a virtual assistant for healthy and active aging. We conducted qualitative data within the consortium after nine months of teamwork to understand the influence of collaboration on commitment, personal performance, efficiency, and work outcome. Based on this research's outcome, we built a framework for future scientific research projects and consortia to increase efficiency and quality of teamwork, thus researchers' well-being.

**Keywords**—Teamwork; technology development; international collaboration; scientific team performance; potential technology leverage; scientific commitment; team efficiency; team commitment; team performance; collaboration

### I. INTRODUCTION

Project e-VITA, e-VITA Virtual Coach for Smart Aging, is an EU-Japan project under the EU Horizon 2020 program and MIC funding regarding the Japanese Society 5.0 movement. 22 international partners research from 2021 to 2023 regarding new technologies and methods to help an aging society deal with specific problems of their older people. The aim is to combine sociological, medical, and technological excellence to produce an innovative coaching system based on the needs of older autonomous living adults. Thus, a virtual coaching system that can provide personalized recommendations and everyday help improve older adults' life quality in Europe and Japan while also delivering opportunities to SMEs and NGOs to derive knowledge, services, and products from this joint research force. The aimed impact scale is wide-ranged and ambitious for all partners and stakeholders in project e-VITA [1]. Thus, this project is a rare opportunity to research specific factors of scientific teamwork in complex technological research consortia, especially under the influence of the COVID pandemic and its specific influence on remote teamwork.

Team-wise we face a relatively rare challenge in project e-VITA. The team is brought together from different backgrounds without being orchestrated like an average team in, e.g., industry. There is no existing team that seeks an extension with a hiring process. The group is teamed together from various organizations and needs to get along no matter what; and it is faced with high expectations from the grant giver [2]. Building a team spirit in remote teams with no touching points is a rare situation [3]. A considerable challenge is establishing self-organizing sub-teams within the whole group [4]. The project e-VITA members come from a culture of waterfall hierarchy [5] and non-self-reliant work that needed to be changed to become a self-organizing team structure with agile aspects [4] to reach the complex aim of the project. When working in industry, we find a relatively clear understanding of the company, product, and job. In a research project like project e-VITA, the project start presents like a start-up without clear organizational structures [6] but also without a concrete product to gather around. It is a rather vague idea of what the research should look like compared to what a start-up business plan looks like when facing investors [7]. Installing rather formal business and strategy documents like an innovation roadmap [8], charter documents [9], and communicational guides were the first steps to meet the upcoming challenges in such a setting. The installment of a technological platform for data exchange, meeting organization, calendar set-up, and workstream organization in a remote setting [10] was also organized within the team and its members. Furthermore, the project e-VITA consortium coordinators tried to set up clear work structures [11] comparable to organizational structures in companies that were supposed to lead to more success without the expected friction losses in traditional and complex research projects [12] in science.

This research aims to collect data about the experienced work setting and culture significantly different from joint research projects. In the very first step, it is not the aim to quantitatively evaluate the used tools but to qualitatively get an impression on the work experience [13]. Positive work experiences are linked with employees' positive three-layered work commitment [14]. Furthermore, a high commitment is linked to more efficiency and qualitatively higher work outcomes [15]. Apart from wellbeing and health benefits due to a positive work and team culture [16], we aim to deeper

understand influencing factors and work on a recommendation framework for future research projects with similar complexity. Thus, our research approach is to understand which factors influence international collaboration and teamwork, if the experienced environment and climate influence the individual commitment and the quality of work outcomes, and which specific factors influence the personal performance.

## II. METHODOLOGICAL APPROACH

### A. Episodic Narrative Interview

We conducted 12 episodic narrative interviews with project e-VITA consortia members. The aim of an episodic narrative interview [17] is to better understand a phenomenon by generating individual stories of experience about that phenomenon. An episodic narrative interview participant provides nested narrative accounts of their experiences with a social phenomenon within the context of a bounded situation or episode. The episodic narrative interview is made to generate tightly focused, phenomenon-centered narratives reflective of bounded circumstances. We aimed to explore the deeper levels of experience linked to commitment and its effects and avoid the validity threat of social desirability by using a method that leads the interviewees to intuitive ways of reporting, in contrast, to merely answering explicit questions. We thoroughly followed the steps as presented by Alison Mueller.

### B. Interviews

We interviewed members that had to fulfill the delimitation criteria [17] of being part of the consortium for the whole period of nine months of bringing experiences from other research projects/ consortia, and of being actively involved in the project e-VITA in the specific episode in contrast to being a silent member that becomes active in later stages of the project. Furthermore, the sample was equally mixed from members of the EU and Japanese sides of the project. Thus, the primary interview language was English. To overcome possible language barriers, we also conducted five interviews in Japanese and professionally translated them to English for analysis purposes. The interviews were conducted remotely via Zoom without video streaming.

The 12 interviewees (Table I) were between 33 and 60 years old, with an average age of 46 years. Amongst the interviewees, we found six senior researchers from industry and science, four university professors, and two persons with high-ranking industry jobs (CEO/CTO). All interviewees have leadership experience ranging from 1 to 100 reports in technology science and industry, medical service and science, the housing industry, and political consultancy. Work experience ranged from 5 to 32 years at the interviews. All interviewees have a middle to high involvement in the researched project of project e-VITA.

### C. Analysis Process

As the method of Episodic Narrative Interview by Alison Mueller is relatively new and innovative, it does not offer extensive guidance regarding the used and proven analysis steps. We thus chose to be guided by the ideas of Grounded Theory Analysis and to follow the suggested three coding steps of open coding, axial coding, and selective coding to steadily

re-compare data and found phenomena to, in the end, derive a theoretical framework for the research questions of interest [18].

After the interviews were numerically coded to preserve anonymity, we mixed the Japanese and EU data by changing the numerical order to ensure an analyzing process without intercultural presumptions. We used five W-questions within the first coding step to define meaningful passages within the interviews and for the first theoretical abstraction. We focused on what was said, who was involved, what aspects were essential or influencing, why they were essential, and what solution was chosen for specific situations or problems. Thus, the aim was to detach the relevant passages from the overall interview to get an accurate impression of meaningful aspects not only in the context of one interview but in relation to the other interviews and relevant passages within.

Subsequently, we axially coded the defined text passages. We used the same codes to find connections, similarities, and differences. In an additional step of axial coding, we reduced our code system to capture different perspectives on particular issues. In a last coding step of selective coding, we started condensing our code system into a category network based on the found core categories from our previous coding steps.

We now were able to form theories and connections within a framework that could be the base for better cooperation in future international research projects.

TABLE I. INTERVIEWEE CHARACTERISTICS IN RANDOM ORDER FOR ANONYMITY, OWN DESIGN

Age	Position	Branch	Reporting Employees	Years of experience in expertise field
55	Senior Researcher	Real Estate Development	4	10
43	Senior Researcher	Research Institute	1-10	10
60	Professor	University	20-100	25
42	Senior Researcher	University	100	8
40	Assistant Professor	University	10	10
60	Professor	University	10-12	32
50	Manager	Start-Up	4	20
56	Senior Researcher	Research Institute	1	31
35	Senior Project Officer	Research Institute	1	5
39	Senior Researcher, Project Manager	Research Institute	2- 6	15
37	CTO	Start-Up/ Research Institute	4	14
33	Assistant Professor	University	7	4

#### D. Validity Threats / Methodological Limitations

The researchers of this study are part of the research object project e-VITA, i.e., potentially part of the phenomenon. This bears the danger of participant-answers according to the considerations of social desirability. We addressed this validity threat to meet the quality criteria by involving a supervision process to exclude the researchers own relevance system [19] from the data conduction and analysis phase during the research process, by using different interviewers, not only to meet language requirements and challenges but also to balance the personal factors that could arise social desirability answers. We focused on making the interviewees feel most comfortable to freely describe their experience with the phenomenon of interest. The validity threat of social desirability during the data conduction phase was also addressed by avoiding the video call and using a neutral screen whilst conducting the interview. Furthermore, we deliberately used the narrative interview style to lead the interviewees into phases of free talking and reminiscence without considering the interviewer and their relationship to each other [17] thus avoiding effects of social acceptance validity threats.

To distance ourselves from our own relevance system [19] during the analysis, we chose to present the data to a third-party researcher that was not involved in the project e-VITA so far, nor in planning the presented study or in conducting the data. The aim was to involve a perspective that adds an outer view on the data and results to avoid super exceeding expectations within the analysis [20] and research project of this study.

We considered a translator effect as another possible challenge [21] that we met by using the native language speaker on the JP side for data conduction. For the EU side we only used English as a common language for the interviews. We ruled out most of the common translator threats by using an algorithm-based translator software and a person fluent in both languages JP and English that professionally supported the study in the translation process.

### III. RESULTS

Within the following section we will present the found phenomena and directly compare them to the adjoining theoretical base. As no directly linked research can be found so far for our specific research questions in this application field, we draw links between adjoining fields and transfer them to our specific application interest. We combine the two steps of theoretical background/ comparison and result presentation for the sake of readability and length. We aimed our analysis to our above-mentioned research questions and could thus verify the following aspects as influencing factors for remote scientific work and international collaboration in research teams.

By the majority the interviewees addressed their need for change in various categories, but also their favor of certain aspects. Thus, we could define the topics communication, technical infrastructure/ remote work, organizational structure, personal information, cultural differences, commitment, workload, vision/ shared goal, personal development/ growth,

and shared values/ team cohesion as main categories for our analysis, i.e., most meaningful aspects for the interviewees.

The interviewees showed a great willingness to share deep insights of their experienced collaboration with us during the interviews. Throughout all interviews we could identify the most prominent topic, communication that was always addressed but was also always linked to all different categories mentioned above. Another specific phenomenon was the great wish to talk about commitment and to clarify specific forms of commitment throughout the whole consortium. The wish to enhance the organizational structure within huge projects like the researched one was also found in all interviews. Especially facing the affecting factors due to the COVID pandemic situation and remote working aspects left the interviewees with many expressed challenges.

#### A. Commitment / Shared Vision

Overall, respondents felt a strong commitment (compare [14], [15]) to the project and were motivated to achieve a good result. Especially the shared vision and shared common goal were named as important aspects to tackle the high complexity and workload of the project. However, many interviewees expressed the need to give more focus on a common vision and its communication within the whole team and to external partners and media streams.

“I think the positive thing is that we are very, very committed. So that's very new for me. And despite the fact we can't meet in the European countries or in Japan. ... Really, thanks to all the partners and namely the work coordinators, which are very, very involved and committed in this project, I think it is, this is also the guarantee of our success.” (Interviewee 6).

“I think that there is an overall goal in this project and that their people are working to, uhh, a lot of people working together on one goal with a certain amount of honesty and endurance and competence.” (Interviewee 2).

“...it would be good to find ways to at least in the beginning, to insist on this kind of vision.” (Interviewee 11).

The interviewees showed a solid normative and continuous commitment [14] when expressing the need to fulfill expectations to grant givers. Interestingly, they wished for more opportunities to expand their affective commitment [22] by getting deeper into the project's shared visions and getting deeply involved with their teammates throughout the whole consortium. Though all consortium members stemmed from different 'home' organizations and planned to build a research project like common in their field of work, they showed a strong interest in building an own organization for the project e-VITA. The tendency to form an own organization with all its effects like being committed to “one brand” gives a useful indication to the later framework but also to motivational aspects that can enhance innovative behavior for consortium members [7], [15], [23], [24].

#### B. Workload

The interviewees criticized the fact that they felt to only work for the deliverables of the project contract rather than the physical result, which aligns with the finding of a high

normative commitment mentioned above [25]. This sometimes put them under pressure and made them feel that the already high workload was even more significant or not feasible; they felt overwhelmed not capable of managing their own and other expectations. Thus, the interviewees expressed a decreased innovative capability aligned with first burnout tendencies [26]–[28].

In addition, some interviewees commented that they did not have the time to read through all the parts of the reports, even though they were interested in the progress of the other teams. The feeling of not being fully part of the team due to lacking information led the interviewees to want to enhance communication streams for deeper project involvement. This aligns with the wish to feel affectively committed [14], [22] to the project and gain a deeper understanding for the whole organization as well as the wish to be part of a 'bigger thing' to enhance self-efficacy [29], [30].

They also felt that the regular meetings of all the teams were too long and not very profitable because often everyone only gave their presentation, and there was barely any time for discussion and exchange. Thus, we can detect the need to deeper identify the leadership style and team cultural desires that are applied to the project. Discussion satisfaction among consortium members is a leading force in innovation behavior and employee satisfaction, furthermore a specific challenge in virtual teams [31].

The interviewees felt essential communication was missing; they expressed the need for an enhanced communication structure to cover specific information needs.

“...my first impression of this project for the initial months is that it has been very hard to do.” (Interviewee 4).

“(Person’s name) is struggling with a lot of deliverable workload.” (Interviewee 1).

“I’m sure it must be very difficult for the other researchers who are also working on top.

of their own jobs.” (Interviewee 3).

“I felt like I had to give 200% or 300% to finally I felt that ummm I was finally able to get an answer and wondered if I only resolved the issue because I had gone that far.” (Interviewee 1).

“I wish that days were 40, 48 hours long, but unfortunately they are not.” (Interviewee 5).

### C. Team Communication / Shared Goal

Some interviewees criticized that each team worked on its own and that there was too little collaboration as a whole group. As a result, a lot of knowledge was lost, even though the interviewees were basically interested in a team-wide overview.

“But the fact that we are working in silos we are working individually is not helping.” (Interviewee 9).

“But if we think that we need to cooperate, I found it really difficult to identify a cooperation with them.” (Interviewee 12).

“My impression is, that we haven't yet reached the point of real collaboration, which will become necessary in the future as we implement the system.” (Interviewee 7).

“Some do not work together at all. They don't know what. So European people do not know what the Japanese people do and the other way around...” (Interviewee 2).

In addition, each team within the consortium had different ways of working, so that it was difficult for non-team members to understand how the others worked and what insights could be gained.

“...it was always a bit of a feeling of not knowing what's going to happen next. All people on the same boat, so it was a bit like a kindergarten teacher to, uh, yeah, to, to take care of all the people involved in this project, are they all there? Are they going to be in the meeting? Are they doing their homework, so to speak?...” (Interviewee 2).

Again, we identify the consortium members' wish to be fully bound to the project, the desire to be given a broader base for their affective commitment. Obviously, this wish is connected to efficiency optimization but also to creating a work environment that offers wellbeing aspects [11], [22], [29], [32].

### D. Team Cohesion

The interviewees expressed a strong wish to feel as a whole and powerful team. They expressed the desire to be part of a big group capable of stemming this high workload and high complexity of such a technological research project. This is in alignment with the finding that the interviewees expressed the desire to find an environment that gives plenty of room for affective commitment in a work and research field that normally is rather conservative compared to brands that are classically connected to affective commitment like Adidas, Nike, Google, Apple etc. Interestingly the wish could be found without a cultural difference [33], [34].

“... a strong team is necessary, I think, to face the workload of project e-VITA.” (Interviewee 9).

“It's the team spirit. Yes, it's the team spirit and the team.” (Interviewee 6).

### E. Organizational Structure and Leadership

The interviewees wished for more apparent structures and task definitions, both within the team itself and across teams. They felt that time was lost, and the already significant amount of work was increased. More transparent structures would also enable more effective planning so that the workload and project flow could be managed continuously. This leads to the assumption to closely define work structures and streams in alignment with the team's socio-technical environment. This is true especially with regard to the used technological infrastructure that is applied to the project and the virtual team [35], [36].

“...a number of leaders and they all have a different way of a different style of leadership. Totally different. But there are a lot of people work with all of them or a couple of them, so they experience different ways of leadership, and some are more or less fair or more or less committed. Some are very committed.

So that's just a more heterogeneous way of leadership. And a lot of leaders next to each other.” (Interviewee 2).

“...if you're not involved as the leader. Because the project is so big and so many work packages are working next to each other simultaneously. You kind of get lost because you if you're not in every meeting that there is available, you will lose track of what's going on and other work packages. And therefore, you will not know what's going on there” (Interviewee 2).

“The needed structure to make all this thing run, um, well, of course, is necessary,…” (Interviewee 5).

“So, you have to do this strict organization, but also flexibility to change your objectives and your approach.” (Interviewee 10).

Some interviewees explained that they sometimes had too many tasks for which they lacked staff and skills. Hiring appropriate staff and giving room to these processes was expressed as a problem linked to the wish for enhanced organizational structures and better communication. Finding and keeping the right scientific personnel is well known as being a challenge. Especially the advanced skills needed in cutting edge technological projects demand a thorough selection process to ensure work quality results [37], [38]. Most managing persons in scientific projects were never trained in managing skills such as hiring and selection processes. These challenges were not mentioned but remained closely linked to this aspect. It is most likely that those persons demand a higher amount of time fulfilling the task of hiring than those who were specifically trained like industry managers and HR experts.

“Sometimes (team member's name) would ask me in meetings what I thought, but I couldn't say much, and I was a bit muddled, and I really didn't feel I could say much, even though I was the leader of Work Package...” (Interviewee 1).

“To be honest, there are many areas that are not my area of expertise,…” (Interviewee 4).

“In terms of my work, I have to deal with areas that I don't have the knowledge or experience to deal with,…” (Interviewee 8).

“...and we actually ask a temporary worker to do it for us.” (Interviewee 1).

“I think we need to ask a specialist for that, and we need to ask someone to support us in that area in the future.” (Interviewee 3).

We could also identify the wish to find a defined leadership style based on the findings. Interviewees described the current style and their wishes not only in terms of leadership in the project that defines certain tasks and work structures but also in motivation and guidance through the project's complexity. Thus, we can conclude the need to research appropriate leadership styles like transactional, transformational [39], or servant leadership [40] and follow basic principles based on the individual necessity of the team and project requirements (compare also [31]).

#### *F. Remote Work / Technical Infrastructure*

The ongoing COVID pandemic intensified many of the problems, as people could only work remotely with each other, which, on the other hand, is valid for many international projects even without the pandemic ongoing. This meant that the individual component was lost entirely for some interviewees because the international meetings could only take place online. They explained that as a result, they could not get to know their colleagues at all or only to a much lesser extent so that many aspects of communication such as facial expressions or the individual personality could not be conveyed. At the same time, a good team and support in the team were named several times as essential motivators to withstand these critical working conditions [7], [36], [41]. On the other hand, the remote work increased the wish to find enhanced organizational and communicational structures. The interviewees expressed several times the need to restructure classical work processes due to increased communication and alignment times to ensure efficient remote work [36], [42].

Furthermore, the interviewees described the wish for skilled personnel that deals with technical infrastructural questions that, on top of their research workload, needed to be tackled by themselves without the according expertise to do so. The remote working situation longed for specific technical solutions to ensure an efficient workflow, data exchange, video meetings, and a secure working environment for sensible information. According to the interviewees, the existing solutions on the market were not made for the specific context of scientific research projects, which left the members with many open issues that hindered their research work and work environment.

“I will say this is the first time that we are doing all the coordination in such a huge project, all by remote.” (Interviewee 5).

“...we didn't meet each other face to face also didn't help.” (Interviewee 9).

“I think it's something important. That the human interaction is it's important for the collaboration, for the cooperation and so on.” (Interviewee 9).

“...we never met face to face. And we could see that the...umm. It took more time, let's say to, to adjust our... there's an expression in xxx (my language) saying that we..., meaning that we have to adjust to the other person.” (Interviewee 9).

“...discovering that we can have a productive and efficient collaboration purely online was also quite a good thing.” (Interviewee 11).

“I also appreciate it a lot the selflessness in the Japanese partners in helping us...” (Interviewee 5).

“I really see a mutual help in this collaboration.” (Interviewee 10).

#### *G. Cultural Differences / Personal Information and Development*

The cultural differences between the teams were on the one hand seen as enrichment, but at the same time also led to some misunderstandings and problems, especially between the

European and the Japanese team. Since communication differs in many ways in all involved cultures, everyone had to adjust to each other first, which cost a lot of time that was not given within the planning structure. However, these misunderstandings could partly be solved through communication by individual team members explaining their behavior afterwards, thus creating an understanding. Again, this phenomenon is strongly linked to the expressed wish to rethink organizational structures and different communication behavior [36], [42].

“I think throughout the first nine months, it also changed a bit from the Japanese side. So, in the end, in the beginning, they were less vocal about their needs and also about their limitations. Now they are more vocal about it. So, they sometimes say they, I'm just referring to specific institutions I had contact with. ... I'm sorry, I don't know anything about it. Someone else has to do it. ... From my side point of view, they feel more comfortable to tell us if something is just not possible for them with regards to schedule, competence, or anything like that.” (Interviewee 2).

“... this kind of approach is something that has never been seen before in Japan, especially in technical projects...” (Interviewee 8).

“Challenges also is that we come from a different cultural context. ... But I feel like it's a cultural thing in Japan. Maybe I am not sure. Maybe they need more time to get the approval of maybe the hierarchy.” (Interviewee 9).

“...first difficulty was to try to understand each other, especially with our Japanese counterpart, because there were some small difficulties at the beginning and understanding each other.” (Interviewee 10).

“...it's not the same with the Japanese partner. Sometimes I think that the communication channels, it's completely different between us and them...” (Interviewee 12).

“There are three or four different European cultures that are packed together and in one side of the project, I would say, and it felt like the Japanese were between themselves, more in line with what they were doing then than the European side.” (Interviewee 11).

“That experience itself is something that I had never experienced before in my involvement with domestic projects in Japan. ... it was the first time that I had actually experienced this kind of emphasis in a project, and I think it was a great experience for me to be exposed to the values of this kind of team.” (Interviewee 8).

“I also started to understand how people work in such a mixed project and their habits.” (Interviewee 7).

As mentioned above, it was often expressed that more effective communication was desired. Particularly through remote work, some of the interviewees felt that communication was essential to create a team feeling, get to know each other and work effectively together. According to some of the interviewees, work-related conversations should occur more often and be shorter. On the other hand, the personal component should be strengthened by creating a framework for conversations without a work-related context. This aligns with

the idea to find an environment that leaves more room for affective commitment and its effects [43], [44].

“In the end, the only way to get along with a group of people who don't know each other is to talk to them. That's all there is to it.” (Interviewee 7).

“...it was really important to have these series of meetings and conferences. ... I think that this should be an added value for the future and which we will have more time and more space on board to talk together and to plan together. ... we really need to be in communication with more partners and also from the Japanese counterpart. That is something that we can do” (Interviewee 10).

“...because for myself, I think it's you can deal with everything if you talk about it. So, if somebody has someone has a hard time in his private life or I don't know and he can't do his parts at us, that's not a problem itself, because then just tell me and we can work around it.” (Interviewee 2).

Based on the various and extensive aspects that we gained throughout the interviews, we could identify two main pillars with a respective substructure that will be discussed in the following framework derivation section.

#### IV. FRAMEWORK DERIVATION

We derived a theoretical framework from the coded data and found the according information within the last step of theoretical abstraction. The framework will be a mixture of textual and visual overviews that shall aim to build recommendations to further contexts of remote scientific work.

We could identify two main pillars that headline the discussed categories – terms of commitment and organizational structure. Within standard research project organization, we find a discussion focus in research teams and their organizations on content-based aspects like research topic, research question, grant giver restrictions, deadlines, and deliverables (Fig. 1). Discussions around structural aspects and terms of commitment seem to be missing, which initiated the expressed need for change from the interviewees.

Fig. 1. Commonly Discussed Project Aspects and Missing Factors, Own Design.

Fig. 2. Framework Extension Visualization, Own Design.

Triggered by the interview style, we could identify meaningful aspects that the interviewees either wished to be realized or intensified. We thus could build Fig. 2 from which we can derive questions that future research teams in similar working situations like project e-VITA should address before starting the project (Fig. 2).

Under Terms of Commitment, we could identify six subcategories addressed with the interviewees' wish of change.

- 1) Code of Conduct
- 2) Shared Vision
- 3) Leadership Behavior/ Responsibilities
- 4) Team Spirit
- 5) Communicational Engagement/ Rules of Engagement
- 6) Team Planning

For Organizational Structure, we could identify six further subcategories.

- 7) Remote Working Aspects
- 8) Administrative Work and Timing
- 9) Leadership Structure
- 10) Staffing Issues
- 11) Technological Infrastructure and Maintenance
- 12) Workload

We will now present the questions derived from the interview material, which should be addressed in advance before starting a research project within the whole consortium. Based on the defined categories, the interviewees described meaningful aspects and questions, topics, and problems they favor to be addressed. We summarize those as follows.

1) Code of conduct / Shared values

a) How do we want to deal with competition? Knowledge-sharing?

b) To which extent do we integrate cultural differences as a beneficiary factor? Or do we just ignore them? Will we use them as learning aspect for personal development? Do we explicitly address them before or while working?

c) How do we deal with motivational aspects? Who is responsible for motivating the team, each one on his/her own or the consortium leader? How do we deal with missing motivation?

2) Shared vision

a) Which goals can we identify? Is it one goal for all, or can we combine various goals? Are there individual goals that are hard to integrate into the whole project? What do we want to achieve after our joint project time? Which result do we want to see in the end?

b) Is there any sort of a "brand message" that we can describe for our project, may be based on its name? For example: xxx (name of the project) stands for...

3) Leadership behavior/ Responsibilities

a) Do we have a leadership structure that can be clearly defined? Which responsibilities do we see for our possible leadership? Can we share responsibilities and leadership workload?

b) Which leadership style do we want to apply?

c) Who is filling the roles that we defined for our leadership?

4) Team spirit

a) How do we plan to work together? Do we see the project as a joint project by people from various organizations that meet every now and then? Do we want to build our own very close team, like our own little organization?

b) Can we all commit to the shared team spirit goals? How do we deal if individual positions do not align with our overall team spirit goal?

5) Communicational engagement

a) Can we define communicational rules? Which will be essential to us?

b) Which communication channels do we want to use? Chat, Mail, Telephone etc.

c) Can we define reaction times to different communicational media streams like WhatsApp, Mail, Chat, Kanban boards, phone calls, ToDo lists etc.?

d) Can we rate the consequences of chosen communication media streams? Can we use them and commit to our communicational rules and reaction times?

e) Can we define a timing range and content that needs to be discussed regularly? How often? When?

6) Team planning

a) Do we want to be one team or act in specific silos? Do we want to experience the benefits of getting to know researchers with diverse backgrounds, and how do we manage

this? How can we benefit from diverse backgrounds and integrate them?

b) How much time do we plan to set up and proceed with team planning sessions?

c) How do we deal with positions that do not align with our overall goal regarding team planning sessions?

7) *Remote working aspects*

a) Which experiences do we have with working exclusively remote? Which aspects of teamwork are essential and need to be included in the project?

b) Which benefits can we identify, which challenges? Which differences in contrast to face-to-face work do we need to consider?

c) Do we plan additional time to tackle the identified challenges?

d) How do we deal with missing answers to possible upcoming challenges?

e) How do we deal with knowledge/ result sharing aspects throughout the internal teams? How can we tackle information overflow vs. missing information? How do we share results, papers other information in a manageable way?

8) *Administrative work and timing*

a) How much administrative work do we expect from this project?

b) Which experience from previous projects can we share? Are they beneficial to our situation now?

c) Can we plan additional time for administrative work?

d) Who will be responsible for tackling administrative issues? Who is in charge, and can we delegate tasks?

9) *Leadership structure*

a) Can we define the leadership structure that we previously discussed in question 3a?

b) Can we sketch the leadership structure in one organigram that will be mandatory for all members?

c) How do we deal with changes in our project structure and according responsibilities?

d) How do we deal with missing commitment?

10) *Staffing issues*

a) Do we have the needed competencies already onboard, or do we need to expand?

b) Did we plan enough time to find the fitting team extensions and competencies?

c) How do we deal with missing competencies? How do we close possible gaps?

11) *Technological infrastructure and maintenance*

a) Which technical infrastructure do we want to use to work remotely? Which technological solution/ platform for which task discussed in 5b+c?

b) Which experiences can we share from other projects?

c) Who is responsible for setting up the technical infrastructure?

d) Who will maintain the chosen solution throughout the whole project, and do we have, or these persons have enough resources for fulfilling their task?

12) *Workload*

a) Did we realistically estimate the upcoming workload?

b) Can we identify gaps, challenges, overloads? How do we handle them?

c) Did we realistically plan the necessary time to tackle our workload? If not, how do we deal with upcoming problems?

d) How do we deal with various positions about workload manageability? Especially about aspects discussed in 1c?

Based on our findings we argue that beside content-based aspects future scientific research projects especially in remote working situations should address Terms of Commitment and Organizational Structure aspects to ensure efficiency, optimal team performance and researchers' wellbeing and commitment to the project. All three will be decisive for the later project's result and should stand equally beside each other in terms of importance (Fig. 3). This equality can be derived from our interview data. Thus, our orientation framework is of interest for future teams and grant giving stakeholders that review and proof project proposals, project flows, and results.

Fig. 3. General Framework Overview, Own Design.

## V. DISCUSSION

The presented study shows the need for additional planning when orchestrating a research project, especially in remote scientific, international collaboration. The high complexity of cutting-edge technological research projects is an additional complicating factor for the work environment. Based on the conducted data, we could show that the need to introduce additional aspects apart from content-based discussions is strongly given. Doing so will most likely positively influence team commitment and thus personal and team performance, efficiency, and work quality.

### A. Affective Commitment

International remote collaboration seems to be determined by many more soft factors than considered when planning projects. However, the team and individual performance can be positively influenced by the conscious planning of the soft framework factors. The possibility of living affective commitment in the projects is closely related to increased efficiency [45], [46]. In contrast to normative and continuous commitment, affective commitment is known to cause performance to skyrocket. A factor that should not be neglected in difficult working conditions such as remote work. A variety of framework conditions give the possibility of being able to form affective commitment. The interviewees described which organizational-psychological measures can be taken to bond emotionally to the project and thus create an environment of well-being. The sub-items of the found Terms of Commitment and the items of Organizational Structure are therefore sub-areas of the overall measure to create an environment for affective commitment. Employee commitment is widely researched for companies and their working environments.

In connection with employee identification, employee retention, and performance improvement, commitment is essential for regulating personnel processes. Organizational commitment, in general, is known as a critical driver to motivation and performance improvement of employees. However, it is advisable to distinguish the specific forms of commitment to deeply understand the influencing factors [46]. Continuous commitment is based on employees' cost-benefit calculation, i.e., leaving the company is associated with economic disadvantages for an individual that exceed the leaving benefit, a bond is created, and the employee tends to remain in the company. In contrast, normative commitment is based on an individual's values and perceived moral obligation to remain loyal to his or her company. The employee might feel committed to the company due to favors his/her superior might have given him/her in the past. On the other hand, affective commitment is defined by Meyer and Allen as a solid psychological bond that ties the individual to the organization. It describes the emotional attachment to the organization and has its origin in positive experiences with the company [47]. Affective commitment is declared to be the most potent form of employee loyalty to the organization and is not moderated by cultural country specifics [48]. A high level of affective commitment is associated with increased motivation, the will to take additional tasks, and employees' feelings of joy and pride for their organizational affiliation. Thus, affective

commitment correlates positively with higher individual performance and efficiency [49].

The found sub-items of our two main pillars, Terms of Commitment and Organizational Structure, describe with high agreement what organizational commitment research suggests applying for employee commitment improvement. Without explicitly knowing and naming aspects of what organizational research has known for decades, the interviewees described them for an entirely different setting. We argue that transferring organizational knowledge in the form of our framework to scientific research projects will increase affective commitment for remote researchers and the academic world and thus performance, efficiency, and researchers' well-being.

### B. Limitations

As discussed in the methodical section, we thoroughly tried to rule out possible limitations to the methodological approach. However, we cannot exclude the possibility that we did not get the full emotional range from the interviewees based on their cultural background or other personal influencing factors. This might give room for the fact that we did not record specific problems to the same extent as those mentioned by the persons who talked utmost limitation-free. However, this is true for every qualitative study since the researcher can never be entirely sure if the interviewees provide their whole knowledge or feelings. We thus trust our interviewees' expertise and professionalism, thus their given insight.

We mixed insights from university employees with those working in the industry. We deliberately did not separate those two sectors to gain a broad overview of multidisciplinary project structures in which industry and science mix. Knowing that the used work environment and standards most likely differ from science to industry, we consider a mixed sample approach as the most realistic one when seeking a framework for projects that combine science and industry partners most of the time.

Since we conducted data in Japan and Europe, specifically Germany, France, Italy, and Belgium, we cannot predict our conclusions transferability to other multi-cultural settings. However, some of the interviewees have extensive international experience, so we assume that the resulting framework can be adapted to other cultural standards and demands. We formulated the framework questions in an open manner that leaves enough room for individual cultural adaptations. Furthermore, since the suggested framework focusses mainly on increasing employees' affective commitment, we can also minimize the risk of cultural moderating factors [48].

We interviewed mainly persons with higher responsibility, i.e., higher hierarchical position. We cannot entirely be sure if the meaningful aspects found can be transferred to the emotional narratives of low-ranking employees. We considered the interviewed persons as experts for their field, including their lower-ranking staff. However, we cannot entirely rule out the difference in findings when replicating the study with a different sample and adapted delimitation criteria.

Deliberately we excluded researching the technological tools used and mentioned to ensure the technological infrastructure for remote work. This study focused on meaningful aspects to participants of remote international research projects, not on evaluating the technological solutions used.

### C. Future Studies

For the future, we see the open question of how the resulting framework described above can be implemented and used for prospective research projects. We see the danger that apart from focusing on the necessary content-based aspects, time is limited to concentrate on Terms of Commitment and Organizational Structure. Especially at the beginning of a project, when a consortium starts to find a joint base, additional time for such workshops might be missing or not considered relevant. After nine months of the project, the described challenges, obstacles, and problems are prominent for the interviewees. They might not have been prominent in the very beginning. However, since most partners in such projects come with experience from other research consortia, we can assume that the mere trigger to spend time on additional planning aside from the content-based aspects gives the suitable indication and priority. It might seem to add additional work at the beginning of a project. The possible reactance towards that must be overcome to later benefit from the positive effects of such a framework application. Especially the consortium leaders will oversee transporting the necessity and creating room for workshops, discussions, and fixation of framework questions like those mentioned above.

Next, we see a necessary evaluation of the framework. As a first step, we regard the opportunity to discuss the found framework and questions with experienced researchers and members from various projects and possibly adapt our recommendation according to those findings. A comparing evaluation might be possible for the far future, i.e., comparing projects and their results with and without applied framework.

### ACKNOWLEDGMENT

This work was partially supported by the joint EU and MIC project e-VITA. Project e-VITA received funding from the European Union H2020 Program under grant agreement no. 101016453. The Japanese consortium received funding from the Japanese Ministry of Internal Affairs and Communication (MIC), Grant no. JPJ000595. Special acknowledgment to the members of the project e-VITA consortium and Tohoku University, Smart-Aging Research Center, for their support.

# Fuzzy Image Enhancement Method based on a New Intensifier Operator

Libao Yang<sup>1</sup>, Suzelawati Zenian<sup>2,\*</sup>, Rozaimi Zakaria<sup>3</sup>

Faculty of Science and Natural Resources, Universiti Malaysia Sabah, Kota Kinabalu, Sabah, Malaysia<sup>1,2,3</sup>  
School of Mathematics and Information Technology, Xingtai University, Xingtai, Hebei, China<sup>1</sup>

**Abstract**—In recent years, fuzzy image enhancement methods have been widely applied in image enhancement, which generally consists of three steps: fuzzification, modify membership(using intensifier (INT) operator), and defuzzification. This paper proposed a new INT operator used in fuzzy image enhancement. The INT operator is adjustable for different test images. The image enhancement method is as follows, firstly, calculate the image threshold ( $T$ ) using the OTSU method. Secondly, calculate pivotal point  $p$  corresponding to  $T$ , and find the corresponding INT operator function. Finally, use the INT operator in fuzzy Image Enhancement. The INT operator is used multiple times in the image processing process to obtain multiple result images. Comparative experiments show that the proposed new INT operator has better image enhancement effect when INT operator is applied at the same number of times. On the other hand, more intermediate process result images can also be obtained through the proposed new INT operator. More result images can provide material resources for the subsequent image processing.

**Keywords**—Image enhancement; intensifier operator; threshold; pivotal point

## I. INTRODUCTION

Image enhancement's aim is to highlight useful information and remove useless information. The widely used image enhancement algorithms include gray transformation method [1]–[5], histogram equalization (HE) method [6]–[8], wavelet transform method [9]–[11] and basis algorithm Retinex method [12], [13] in color constancy theory. Gray transformation method is to directly apply the transformation function on the gray level to produce a new gray level. This method is relatively simple and easy to be implemented. HE method can increase image dynamic range and improve image contrast by making the probability density function of image gray level meet the form of approximately uniform distribution. The wavelet transform method divides the image into low frequency image and high frequency image, and enhances the different frequencies image to highlight the details of the image. Retinex method removes the influence of the illuminance component in the original image, and obtains the result image.

Image enhancement is widely used in many fields and many different types of images, such as infrared images, remote sensing images, underwater images, medical images and so on [14]–[17]. In recent years, fuzzy enhancement methods have been developed rapidly. Pal-King method [18] is the first proposed fuzzy image enhancement method, and has been applied in many fields until now. Generally, the fuzzy enhancement method consists of three steps: calculate

the image pixels' membership by fuzzification, adjust the membership using intensifier (INT) operator, and output new pixels' gray level by defuzzification. In the development of fuzzy image enhancement method, many functions of fuzzification, INT operator and defuzzification have been proposed. We introduce some common fuzzy enhancement methods. Li et al. [19] proposed a fast and reliable image enhancement technique based upon the fuzzy relaxation algorithm. Different orders of fuzzy membership functions and different rank statistics are attempted to improve the enhancement speed and quality, respectively. Hanmandlu et al. [20] used a Gaussian membership function to fuzzify the image information in spatial domain, and introduced a global INT operator which contains three parameters. Aiming at the membership cannot fill the interval  $[0, 1]$  and the pivotal point  $p$  of INT operator in Pal-King method is always the same ( $p \equiv 0.5$ ), Liu [21] proposed a fuzzification function based on tangent function and an INT operator with an adjustable parameter. Mahashwari et al. [22] proposed a defuzzification function. Hasikin et al. [23] proposed a new fuzzy intensity method to distinguish between the dark and bright regions. This method is computed by considering the average intensity and deviation of the intensity distribution of the image. The input image is enhanced using a power-law transformation. Singh et al. [24] proposed a new INT operator and a defuzzification method. Dawayet et al. [25] proposed a fuzzification and a defuzzification method. Yang et al. [26] proposed an INT operator based on cycloid arc length function. Fuzzy C-means clustering is also a good method for image enhancement [27]–[29]. More and more researchers are studying the fuzzy image enhancement method. The fuzzy image enhancement method has more and more unique advantages in the image enhancement field.

In existing methods, almost all fuzzification functions, INT operator functions and defuzzification functions are either piecewise functions or have a pivotal point  $p$  that cannot be adjusted ( $p \equiv 0.5$ ). In the realization of the algorithm (such as Matlab), the piecewise function needs to add the judgment statement in the coding, and use the judgment statement repeatedly in the calculation. This result will cause the computation time to increase. In view of pivotal point  $p \equiv 0.5$  and the possible shortcomings of piecewise function, this paper proposed an INT operator that is used in fuzzy image enhancement method. The INT operator function is made up by power function and has a variable parameter  $\lambda$ . For different test images, the parameter  $\lambda$  is determined prior to image enhancement. In Section 3, compare the image enhancement of the INT operator in [21] and the proposed INT operator using the same fuzzification function, and defuzzification function. The experimental results show that when INT operator process

\*Corresponding author

the same times, the proposed INT operator can achieve a better image enhancement, and even if the proposed INT operator is used many times, it still has a good enhancement effect.

## II. METHODOLOGY

Fuzzy image enhancement includes some steps: (1) using fuzzification to transform the image pixels' gray level to its membership, (2) modifying membership using intensifier (INT) operator, and (3) calculating pixels' new gray level by defuzzification. In this section, first, we introduce the common INT operators, and then propose a new INT operator.

### A. INT Operators

Although researchers have proposed many INT operators, there are two INT operators that appear most frequently in papers because they are simple to calculate and easy to manipulate. The first INT operator is a function made up of quadratic functions [18],

$$y = f(x) = \begin{cases} 2x^2, & 0 \leq x \leq 0.5, \\ 1 - 2(1-x)^2, & 0.5 < x \leq 1. \end{cases} \quad (1)$$

Fig. 1. The INT Operator  $y = f(x)$ .

Fig. 1 shows that the graph of INT operator  $y = f(x)$ . For all test images, the INT operator  $y = f(x)$ 's pivotal point (function piecewise point or inflection point)  $p$  is identically 0.5. This obviously has some limitations. In avoiding the shortcomings of INT operator  $y = f(x)$ , the improved INT operator is presented as follows [21]:

$$y = g(x) = \begin{cases} \frac{x^2}{p}, & 0 \leq x \leq p, \\ 1 - \frac{(1-x)^2}{1-p}, & p < x \leq 1. \end{cases} \quad (2)$$

The INT operator  $y = g(x)$  can adjust the point  $p$  according to the characteristics of the test image. Fig. 2 shows that the

INT operator  $y = g(x)$  can reduce the points which less than  $p$ , and enlarge the points which more than  $p$ . Both INT operator  $y = f(x)$  and INT operator  $y = g(x)$  are piecewise functions. The piecewise functions have some disadvantages in calculation, especially in the programming implementation (such as Matlab), judgment statements will be used many times in the program, which increases the amount of calculation. Now, we propose a new INT operator,

$$y = \varphi(x) = \frac{2x^\lambda}{1+x^\lambda}, \quad 0 \leq x \leq 1. \quad (3)$$

Where  $\lambda = 1 - \log_p(2-p)$ . The INT operator  $y = \varphi(x)$  is also can adjust the point  $p$  and its implementation procedure is more simplified. It does not need to use a judgment statement in the program. Fig. 2 shows that the graph of INT operator  $y = g(x)$  and INT operator  $y = \varphi(x)$ .

Fig. 2. An Example for of the INT Operators  $y = g(x)$  and  $y = \varphi(x)$  when  $p = 0.4$ .

### B. Fuzzy Contrast Enhancement

Image  $I = \{x_{ij} | i = 1, 2, 3, \dots, m, j = 1, 2, 3, \dots, n\}$ , where  $x_{ij}$  is gray level of the pixel in row  $i$  and column  $j$  of the image. To compare the effect of INT operators  $y = g(x)$  and  $y = \varphi(x)$ , we use the same fuzzification and defuzzification. Fuzzy contrast enhancement includes three steps as follow:

(1) Gray level fuzzification (Counting pixels' membership)

$$\mu_{ij} = \mu(x_{ij}) = \frac{x_{ij} - x_{min}}{x_{max} - x_{min}} \quad (4)$$

where,  $x_{max}(x_{min})$  is the maximum(minimum) pixel's gray level of the test image.

(2) Membership modification using INT operator:

$$\hat{y}_{ij} = I_t(u_{ij}) = I_1(I_{t-1}(u_{ij})) \quad t = 1, 2, 3, \dots$$

INT operator:  $I_1(u_{ij}) = g(u_{ij})$ ,

or INT operator:  $I_1(u_{ij}) = \varphi(x_{ij})$ .

In the Eq.(2) and Eq.(3),  $p = \mu(T)$ ,  $T$  is the test image threshold by the OTSU method.

(3)Pixels' new gray level by defuzzification

$$y_{ij} = (x_{max} - x_{min})\hat{y}_{ij} + x_{min}. \quad (5)$$

$I_{enh} = \{y_{ij} | i = 1, 2, 3, \dots, m, j = 1, 2, 3, \dots, n\}$  is the result image.

### III. EXPERIMENTAL RESULTS AND ANALYSIS

Structural similarity(SSIM) is commonly used to evaluate the image enhancement effect. This section also use the SSIM value as an objective evaluation criterion for image enhancement.

$$SSIM(x, y) = \frac{(2\mu_x\mu_y + c_1)(2\sigma_{xy} + c_2)}{(\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_2)}. \quad (6)$$

In equation (6),  $\mu_x$  is the mean of  $x$ ,  $\mu_y$  is the mean of  $y$ ,  $\sigma_x^2$  is the variance of  $x$ ,  $\sigma_y^2$  is the variance of  $y$ ,  $\sigma_{xy}$  is the covariance of  $x$  and  $y$ .  $c_1$  and  $c_2$  are constants [30].

Fig. 3. Test Images.

Fig. 3 shows the test images. INT operator  $y = g(x)$  and INT operator  $y = \varphi(x)$  processed test images for 2 and 8 times, respectively.

Fig. 4 shows that at the same number of processing times, the image processed by INT operator  $y = \varphi(x)$  is closer to the original image, and more intermediate process images can be obtained. When the INT operators are used the same number of times, the INT operator  $y = \varphi(x)$  has a higher SSIM value. It achieves a better image enhancement effect.

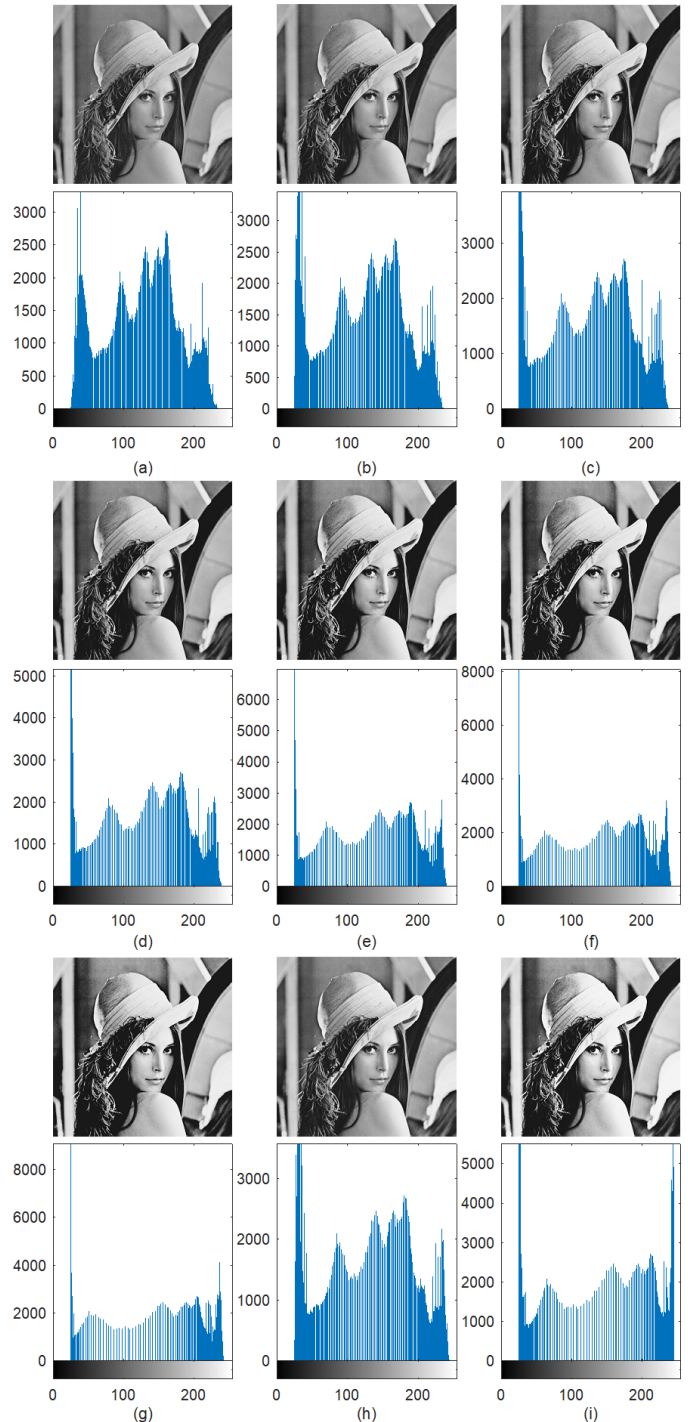

Fig. 4. Enhancement Results of the Lena and its Histogram. (a)-(g). Processed by Proposed INT Operator  $y = \varphi(x)$  Times:1-7; (h)-(i). Processed by Method with INT Operator  $y = g(x)$  Times:1-2.

TABLE I. STRUCTURAL SIMILARITY (SSIM) TEST RESULTS

Test images		Lena	Couple	Fishing Boat	Peppers
processed by INT operator $y = g(x)$	t = 1	0.9341	0.9000	0.9016	0.8871
	t = 2	0.7963	0.7125	0.7462	0.6793
processed by proposed INT operator $y = \varphi(x)$	t = 1	0.9916	0.9882	0.9863	0.9781
	t = 2	0.9681	0.9538	0.9485	0.9244
	t = 3	0.9325	0.9044	0.8987	0.8615
	t = 4	0.8911	0.8477	0.8514	0.7968
	t = 5	0.8485	0.7924	0.8117	0.7330
	t = 6	0.8090	0.7422	0.7785	0.6720
	t = 7	0.7725	<b>0.6990</b>	0.7503	0.6181
	t = 8	0.7398	0.6615	0.7238	0.5736

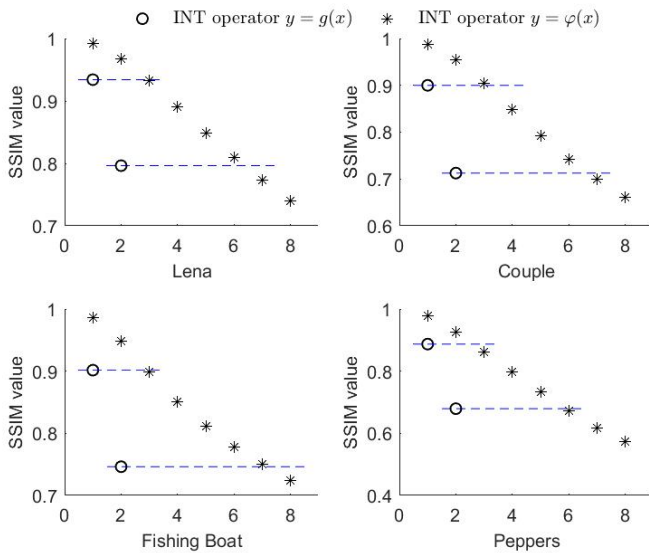

Fig. 5. The SSIM Values when the Test Images are Processed by Fuzzy Image Enhancement Method using INT Operators t Times.

In Table I, for the convenience of expression, denoted  $S(\text{image}, \text{INT operator}, t)$  means that the SSIM value of image and the image which is processed t times by INT operator. For example,  $S(\text{Couple}, y = \varphi(x), 7) = 0.6990$ . Table I shows  $S(\text{Couple}, y = \varphi(x), 1) > S(\text{Couple}, y = \varphi(x), 2) > S(\text{Couple}, y = \varphi(x), 3) > S(\text{Couple}, y = g(x), 1)$ . This means that when INT operator  $y = g(x)$  processed 1 time, the INT operator  $y = \varphi(x)$  can processed 3 times. All of the 3 result images' SSIM values are higher than the result image processed by the INT operator  $y = g(x)$  1 time. For other test images, a similar phenomenon exists. Fig. 5 shows this more clearly. For example, Fig. 5 (Peppers) shows that  $S(\text{Peppers}, y = \varphi(x), 1) > S(\text{Peppers}, y = \varphi(x), 2) > S(\text{Peppers}, y = g(x), 1) > S(\text{Peppers}, y = \varphi(x), 3) > S(\text{Peppers}, y = \varphi(x), 4) > S(\text{Peppers}, y = \varphi(x), 5) > S(\text{Peppers}, y = g(x), 2) > S(\text{Peppers}, y = \varphi(x), 6) > S(\text{Peppers}, y = \varphi(x), 7) > S(\text{Peppers}, y = \varphi(x), 8)$ . Fig. 5 is a visual representation of Table I.

#### IV. CONCLUSION

This paper proposed a new intensifier(INT) operator used in fuzzy image enhancement. It has the following advantages. First, compared to the INT operator which is made up by a

piecewise function, the proposed INT operator has an advantage in program implementation that it does not require writing judgment statements. Second, due to the range of change of the proposed INT operator is small (see Fig. 2), the result image with higher SSIM value can be obtained after the INT operator is multiple applied. This means that it achieves a better image enhancement effect. It can produce more process images. More images of the process can provide material resources for the subsequent image processing, and could help in other areas of research. In future work, we will investigate whether it can be used in other fields.

#### ACKNOWLEDGMENT

The authors would like to express their appreciation and gratitude to the Research Management Centre, Universiti Malaysia Sabah for granting this research study under Skim UMSGreat (GUG0540-2/2020).

**Abstract**—Recent advances in multi-robot deep reinforcement learning have made it possible to perform efficient exploration in problem space, but it remains a significant challenge in many complex domains. To alleviate this problem, a hierarchical approach has been designed in which agents can operate at many levels to complete tasks more efficiently. This paper proposes a novel technique called Multi-Agent Hierarchical Deep Deterministic Policy Gradient that combines the benefits of multiple robot systems with the hierarchical system used in Deep Reinforcement Learning. Here, agents acquire the ability to decompose a problem into simpler subproblems with varying time scales. Furthermore, this study develops a framework to formulate tasks into multiple levels. The upper levels function to learn policies for defining lower levels' subgoals, whereas the lowest level depicts robot's learning policies for primitive actions in the real environment. The proposed method is implemented and validated in a modified Multiple Particle Environment (MPE) scenario.

**Keywords**—Multi-robot system; hierarchical deep reinforcement learning; path-finding; task decomposition

## I. INTRODUCTION

Multi-Robot System (MRS) research has attracted significant attention recently due to its advantages over single robots. The benefits include (1) the decrease in time and the improvement in problem-solving efficiency due to the task decomposition, (2) an increase in problem-solving reliability, robustness, and resiliencies as the failures of single robots can be [1]–[3]. Using MRS, numerous prospective applications have been developed in which robots must be able to compete and cooperate, such as formation coordination [4], hide and seek [5], exploration and search [6]–[8], object transportation [9], disaster detection [10], communication networks [11], [12], etc. This study focuses on using MRS technology for exploration and search missions in unknown environments, where robots must collaborate to find the optimal path.

As shown in [13], [14], Reinforcement Learning (RL) is currently extensively employed as a robot learning algorithm that can automatically handle exploration and search problems in unknown environments, both in simulation and physical environments. Multiple robots undertake search and exploration operations in large and complex environments, such as in [15]–[17]. The objective of MRS is to distribute tasks between many robots to increase efficiency. Nowadays, applying RL is an important and challenging subject in MRS,

where robots must learn and adapt based on their individual strategies and collective behavior. Multi-Agent Deep Deterministic Policy Gradient (MADDPG) algorithm was proposed as an advancement of RL that may be used for multi-robot learning in which robots can collaborate to solve problems in unknown environments [18].

RL in complex environments is always challenging, hence it serves as the primary motivation for the proposed approach. This paper proposes Multi-Agent Hierarchical Deep Deterministic Policy Gradient (MH-DDPG) as an extension of MADDPG for solving search and exploration problems with many robots in finding the optimal path for each robot in various environmental complexities. Here, hierarchical learning is adopted to learn in complex environments efficiently [13].

The primary contribution of this paper is as follows: (1) MH-DDPG presents a framework that enables multiple robots to learn by sharing environmental information collectively. (2) MH-DDPG proposes a hierarchical learning strategy by assigning different abstraction levels to the problem space, where higher abstraction learnings supply the learning subgoal for the lower ones, which consequently execute automatic task decomposition.

The structure of this article is as follows: Section II examines the previous research and theories relevant to the proposed method. In Section III, the technical context and theory are explained. The proposed MH-DDPG is discussed in detail in Section IV. Sections V and VI present the conducted experiments and the validation of the results. Finally, section VII provides conclusions and potential future works.

## II. RELATED WORKS

Reinforcement Learning (RL) [19] is increasingly used as learning method to address complicated problems like games [20], [21], and robotics [22], [23]. Q-Learning [24], SARSA [25], and Temporal Differences (TD) [26] are RL algorithms that are predominantly applied to single agents within the Markov Decision Process (MDP) mathematical modeling framework [27].

Traditional RL faces various problems when attempting to solve real-world problems. This issue is known as the "curse of dimensionality", in which data grows exponentially, and computations become costly. Deep Reinforcement Learning (DRL) was introduced to solve this issue, for example, in [20].

---

This work was supported by JSPS Grants-in-Aid for Scientific Research on Innovative Areas (Research in a proposed research area) 18H05473 and 18H05895.

DRL models complex functions using the advantages of Neural Networks (NN), for example, Deep Q-network (DQN) [20], [28]. However, implementing DQN for robots with many degrees of freedom in action or continuous action space remains challenging. Policy Gradient (PG) [29] has been proposed to solve these issues; nevertheless, PG has its challenges, mainly that it requires extensive training. An actor-critic algorithm [25] combining DQN and PG's benefits was proposed to mitigate these problems. In the actor-critic algorithm, there are two networks: the actor-network, which employs a policy gradient to create optimal policies, and the critic-network, which contains DQN to evaluate the actor's policies. Deep Deterministic Policy Gradient (DDPG) [30] is an actor-critic [31] based algorithm that has been proposed to solve problems in continuous or high-dimensional action spaces.

Multi-Robot System (MRS) is currently attracting much interest because it can solve complex problems that are prohibitively difficult for single-agent systems. Although several attempts have been made to apply the prior algorithm in MRS, it is still not as successful as in single-agent systems. The recent development of MRS operates within the stochastic (Markov) games framework to model mathematical decision-making [32]. The difficulty of developing MRS is that the policies of one robot will impact a non-stationary environment generated by the policies of another agent. Recently, Multi-agent Deep Deterministic Policy Gradient (MADDPG) [18] was presented as a solution to this issue. For each robot, there is a DDPG in the MADDPG. The MADDPG is able to manage the problems of competitive as well as collaborative multi-agent systems.

One attempt to alleviate the learning difficulty is to design a mechanism for hierarchical learning. Hierarchical learning involves decomposing large and complex problems into more manageable subproblems. However, most algorithms need to fix the sub-problems that may hinder problem-solving flexibility. The Hierarchical Reinforcement Learning (HRL) approach of a single robot with discrete action has been proposed in [33], [34]; however, the subgoals need to be assigned manually, while [35] has been designed to be able to find subgoals automatically. Hierarchical Deep Reinforcement Learning (HDRL), [36], [37] proposed systems that can operate with continuous robot action. Algorithms in [33]–[37] work well with a single robot but are unsuitable for multi-robot implementation. Studies in [38], [39] presented a multi-agent hierarchy system with DRL for learning subgoals/skills at higher levels. However, the higher-level environment was manually defined using these approaches.

It is known that MADDPG can handle collaborative multi-robot system problems in a simple environment. However, an algorithm that can improve the learning performance of multi-robot systems is required for more complex environments. In this study, we propose MH-DDPG by developing MADDPG to perform under a hierarchical system. The proposed method is expected to be able to automatically discover subgoals, allowing it to perform better in a high-complexity environment.

### III. TECHNICAL PRELIMINARIES

This section highlights the theoretical basis for developing a hierarchical MADDPG method for cooperative multi-agent learning in handling complex problems.

#### A. Markov Decision Process and Reinforcement Learning

The decision-making process of a single robot is often based on Markov Decision Process (MDP). In RL, at each time step  $t$ , the robot perceives a state  $S_t$  from the environment's set of states  $\mathcal{S}$  ( $S_t \in \mathcal{S}$ ) and the robot selects an action  $A_t$  from the set of actions  $\mathcal{A}$  that may be executed in the state  $S_t$  ( $A_t \in \mathcal{A}$ ). Here, the next state is decided based on transition probability  $\mathcal{P}$  under the learned policy  $\pi$ , as shown in (1). The transition brings the robot to the next state  $S_{t+1}$  and gives reward  $R_{t+1}$ .

$$\pi(s', r|s, a) = \mathcal{P}(S_{t+1} = s', R_{t+1} = r | S_t = s, A_t = a) \quad (1)$$

where  $s \in \mathcal{S}$  and  $s' \in \mathcal{S}$  are particular states that occur at time  $t$  and  $t+1$ ,  $a \in \mathcal{A}$  is the action taken by the robot at time  $t$  ( $a \in \mathcal{A}$ ), and ( $r \in \mathcal{R}$ ) is the reward received by the robot at time  $t+1$ .

Typically, the Bellman Equation is used to optimize two functions in RL: the state ( $V^*$ ) and state-action ( $Q^*$ ) functions, for which the optimal equation is as follows:

$$V^*(s) = \max_{\pi} R(s, a) + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a V^*(s') \quad (2)$$

$$Q^*(s, a) = R(s, a) + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a Q^*(s', a') \quad (3)$$

Here, the discount factor ( $0 \leq \gamma \leq 1$ ) is used to express the significance of the future reward value.

#### B. Stochastic (Markov) Games

In contrast to MDP, which is utilized for a single robot, stochastic games are proposed as a mathematical framework for modeling decision-making in Multi-robot Reinforcement Learning. Stochastic games consist of  $N$  robots, a set of states containing the state of all robots ( $\mathcal{S}$ ), a set of actions  $\mathcal{A}$  from all robots ( $A = A_1 \times A_2 \times \dots \times A_N$ ), and a set of state transitions ( $T$ ) which are the transition probability ( $\mathcal{P}$ ) from the current state to the next state for a robot based on the actions taken by all robots ( $T: \mathcal{S} \times A_1 \times A_2 \times \dots \times A_N \rightarrow \mathcal{P}(\mathcal{S})$ ). The reward obtained by a robot depends on the actions taken by all robots ( $R: \mathcal{S} \times A_1 \times A_2 \times \dots \times A_N \rightarrow \mathcal{R}$ ). The reward function for each robot can be used to classify the type of games. For example, all robots share the same reward function if they play cooperatively. In contrast, when the robots play competitively, one robot aims to maximize the reward while the other attempts to minimize it. In stochastic games, the state value function ( $V$ ) could be written as follows:

$$V_{i,\pi}(s) = \mathbb{E}[\sum_{k=0}^{\infty} \gamma^k r_{i,t+k+1} | S_{i,t} = s_i] \quad (4)$$

#### C. Q-Learning and Deep Q-Network

Q-Learning is a RL mechanism based on Q-function. Similar to (3), the Q-function is used to compute the expected reward based on the action done by the robot in its current state. The optimum policy is found by maximizing the value of the Q-function. The Q-value is learned iteratively, as follows:

$$Q(s, a) \leftarrow Q(s, a) + \alpha \left( R + \gamma \left( \max_{a'} Q(s', a') - Q(s, a) \right) \right) \quad (5)$$

where  $0 \leq \alpha \leq 1$  denotes the learning rate.

The Q-value for all potential state-action combinations is stored in a Q-table, and thus high computational resources are required in a large number of states and large action space. The necessity for these costly computation resources can be alleviated by replacing the Q-table with a neural network for estimating the Q-value as in Deep Q-Network (DQN).

Q-Network and target Network are the two neural networks that constitute a DQN. The Q-network is used to train robots to predict the optimal Q-value, while the target network is used to forecast the next state based on the sample data and the optimal Q-value from all potential actions in the next state. In addition, DQN has a component called Experience Replay (ER) that stores and generates training data for Q-Network.

The optimal policy for DQN is determined by minimizing the Loss function in (6).

$$L(Q) = \mathbb{E}_{s,a,r,s'} \left[ \left( R(s, a) + \gamma \max_{a'} Q^*(s', a' | \bar{\theta}) - Q(s, a | \theta) \right)^2 \right] \quad (6)$$

where  $\bar{\theta}$  and  $\theta$  are the parameters for the target network and the Q-network.

#### D. Policy Gradient

Policy Gradient (PG) is used to enhance DQN's performance in generating optimum policies. In DQN, the robot chooses an action with the maximum Q-value, while in PG, the agent selects an action stochastically according to the probability distribution generated in the output layer.

The PG consists of a neural network known as a policy network, which predicts the probability distribution of actions given the current state. Here, the optimal policy is determined by maximizing the objective function defined as follows:

$$J(\theta) = \sum_{s \in \mathcal{S}} d_{\pi}(s) \sum_{a \in \mathcal{A}} \pi_{\theta}(a, s) Q_{\pi}(s, a) \quad (7)$$

where  $d_{\pi}(s)$  is the deterministic distribution of the states on  $\pi$ . Here, the objective function  $J(\theta)$  can be maximized by adjusting the parameter  $\theta$  by gradient  $\nabla_{\theta} J(\theta)$  as follows:

$$\nabla_{\theta} J(\theta) = \mathbb{E}_{s \sim d_{\pi}, a \sim \pi_{\theta}} [\nabla_{\theta} \log \pi_{\theta}(a, s) Q_{\pi}(s, a)] \quad (8)$$

#### E. Deterministic Policy Gradient and Deep Deterministic Policy Gradient

The policy function in PG is always modeled as a stochastic probability distribution of the agent's actions given the current state. The Deterministic Policy Gradient (DPG) has been proposed to model policy as a deterministic decision by the agent in the current state. The objective function in DPG can be written as follows:

$$J(\theta) = \mathbb{E}_{s \sim \rho_{\pi}} [R(s, \pi_{\theta}(s))] \quad (9)$$

where  $\rho_{\pi}$  is discounted state distribution. The gradient of the objective function in DPG can be written as follows:

$$J(\theta) = \mathbb{E}_{s \sim \rho_{\pi}} [\nabla_{\theta} \pi_{\theta}(s) \nabla_{\theta} Q_{\pi}(s, a) |_{a=\pi_{\theta}(s)}] \quad (10)$$

Deep Deterministic Policy Gradient (DDPG) is an actor-critic algorithm that combines DQN and DPG. DQN is for the actors that operate in discrete action space, while DPG is for the critics that work in continuous action space.

#### F. Multi-Agent Deep Deterministic Policy Gradient

Multi-Agent Deep Deterministic Policy Gradient (MADDPG) is an expansion of DDPG that adopt an actor-critic algorithm as its fundamental structure. The MADDPG contains multiple robots, each with its neural networks for the actors and the critics, while DDPG only uses a single robot. Similar to DDPG, the actors in MADDPG receive input from the robot's local observations and produce executable action recommendations for the robot. However, in contrast to the critical network in DDPG, the input of critics in MADDPG does come from not only the robot's local observations and actions but also other robots' observations and actions. The critic's output is the Q-value, which is used to evaluate the actor's actions by considering other robots' observations and acts. The network of agents may therefore learn both cooperative and competitive strategies.

### IV. MULTI-HIERARCHIES OF MULTI-AGENT DEEP DETERMINISTIC POLICY GRADIENT

This study proposes Multi-Agent Hierarchical Deep Deterministic Policy Gradient (MH-DDPG) as a new approach that enables learning robots to decompose complex tasks into more manageable subtasks at different time scales. Here, the robots train to learn several levels of policy, each of which has a specific task for the agents to do in parallel.

#### A. Architecture

MH-DDPG trains robots to hierarchically learn policies based on the architecture shown in Fig. 1. Here, MH-DDPG is comprised of DDPG and experience replay (ER). The number of DDPG and ER depends on the number of agents and hierarchy. For example, suppose  $N$  and  $K$  indicate the number of agents and hierarchies, respectively. Consequently, there are  $N \times K$  DDPG in MH-DDPG. Furthermore, the number of ER will equal the number of hierarchies,  $K$ . The bottom level represents the physical environment in which the robots physically operate. While the higher level, robots are presented by their abstraction.

Formally, the MH-DDPG with  $N$  agents and  $K$  levels are defined by the set of state  $\mathcal{S}$ ; the set of joint action  $\mathcal{A} = \cup_{i=1}^N \mathcal{A}_{i,t}^{\ell}$  and the set of joint observations  $\mathcal{O} = \cup_{i=1}^N \mathcal{O}_i^{\ell}$ , where  $\mathcal{A}_{i,t}^{\ell}$  and  $\mathcal{O}_i^{\ell}$  are actions  $A_i$  and observation  $O_i$  for each agent  $i$  at level  $\ell$  and time  $t$ . Each agent will optimize their respective policy at every level to estimate the transition probability  $\mathcal{P}$  for selecting an action at time  $t$ , such that  $\pi = \cup_{i=1}^N \pi_{i,t}^{\ell}$ , where  $\ell$  is the hierarchy level and  $0 \leq \ell \leq K - 1$ .

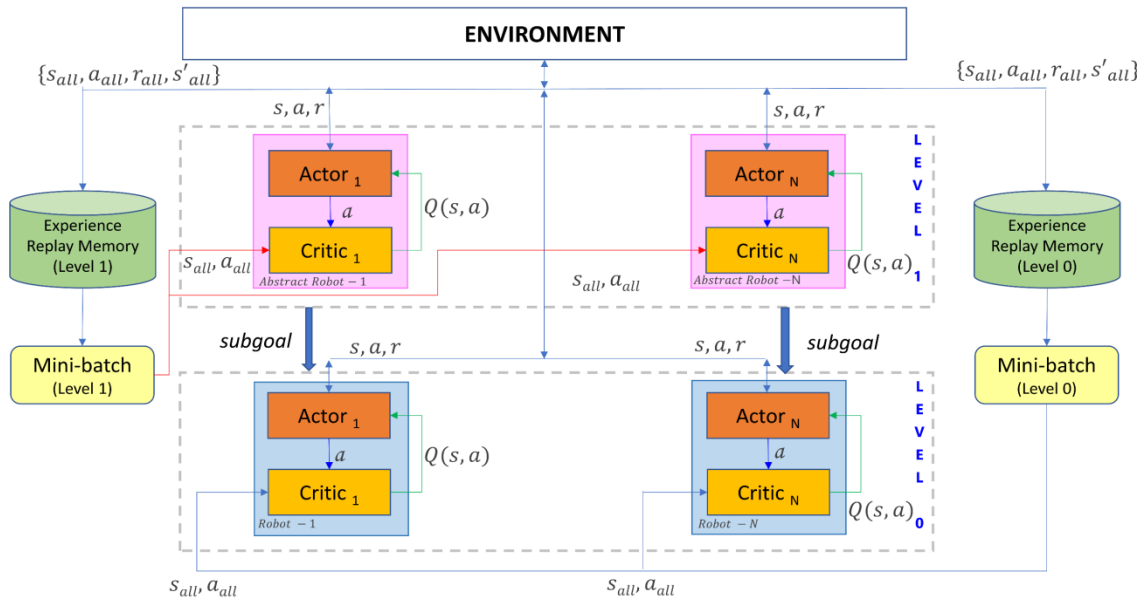

Fig. 1. Architecture of MH-MADDPG.

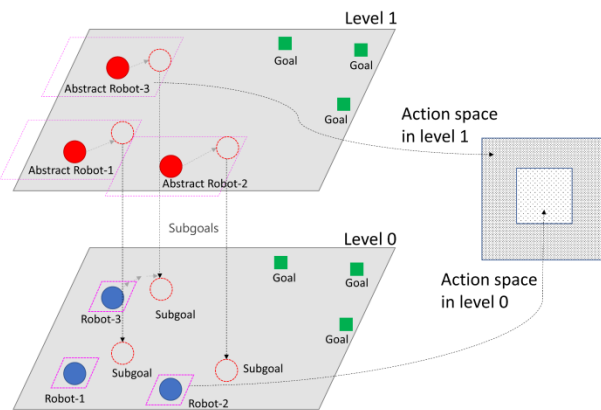

Fig. 2. Illustration Environment with Two Hierarchies.

For illustrating the dynamics of MH-DDPG multi-agent particle environment (MPE) environments will be utilized [40]. One of the MPE scenarios, "simple spread" has been modified here. For example, Fig. 2 depicts the problem that MH-DDPG must address. Simple\_spread is an environment with  $N$  robots and  $M$  goals (landmarks). Robots are expected to cooperate to accomplish a common objective while avoiding collisions with one another. There are three robots ( $N=3$ ), three goals ( $M=3$ ), and two hierarchies ( $K=2$ ). First, the real problem of the environment is illustrated at level 0, where a blue circle represents the actual robots, and a green rectangle represents the goals. Then, at level 1, an abstraction of level 0, the robots are referred to as abstract robots and symbolized by a red circle. Abstract robots at level 1 possess actions with more capabilities than those of actual robots at level 0. For instance, the actual robots at level 0 have a maximum velocity of 1 pixel per second, while the robot at level 1 is set with a maximum velocity of 10 pixels per second. As seen on the right of Fig. 2, the robot at level 1 has a greater range of distances than the actual robot for each action taken at each step.

The abstract robots are predicted to learn faster than the actual robots in achieving goals since they are less constrained than actual robots (for example, more quickly and with no obstacles). However, remember that abstract robots are only imaginative robots with no capacity to execute physical actions. The task of the abstract robot at level 1 is to learn how to accomplish the main goal best, while at level 0, the task is to learn how to achieve the subgoal optimally. MH-DDPG implicitly assigns different objectives for each level, in which the robots' objective at level 1 is to learn to achieve goals optimally, while the robots' work at level 0 is to learn to achieve subgoals optimally. The subgoal at level 0 is automatically determined from the higher level, which happens when the abstract robot chooses the action  $A_{i,t}^1$  based on the policy  $\pi_{i,t}^1$  in the current state  $S_{i,t}^1$  at time  $t$ . The robot will be transitioned to the next state  $S_{i,t+1}^1$  and will receive a reward  $R_{i,t+1}^1$ . Then, the learning shifts to the bottom level, and the next state at level 0 becomes a subgoal for the actual robots. In addition, robots at level 0 engage in learning to achieve these subgoals. When the robots get  $S_{i,t}^0$  at level 0, the agent will pick the action  $A_{i,t}^0$  based on the policy of  $\pi_{i,t}^0$ . The robots then transition to  $S_{i,t+1}^0$  and is rewarded with  $R_{i,t+1}^0$ . The learning process at level 0 will continue until the terminal criteria are satisfied. A terminal condition is defined by manually setting the maximum number of steps at level 0. If the terminal requirements are satisfied, learning returns to level 1 to execute the next step at the top level.

### B. Learning Dynamic

In MH-DDPG, the multiple robots learn in parallel at all levels. The process of robot learning will start at the top level and flows downward. Robot learning aims to provide optimum policies for each robot at all levels. According to the RL concept that the optimal policy is acquired by maximizing the rewards received by each robot. The reward obtained in the

future by each robot  $i$  at level  $k$  could be expressed by the following V-function:

$$V_{i,\pi}^k(s) = \mathbb{E}[\sum_{t=0}^{\infty} \gamma^t r_{i,t+1}^k | S_{i,t}^k = s] \quad (11)$$

$$V_{i,\pi}^k(s) = \sum_{a \in A} \pi_i^k(a|s) (R_i^k(s, a) + \gamma \sum_{s' \in S} \mathcal{P}_{ss'}^a V_{i,\pi}^k(s')) \quad (12)$$

where  $r_{i,t+1}^k$  is the reward earned by agent  $i$  at level  $k$  at  $t + 1$ , and  $\pi_i^k(a|s)$  is the agent policy. Here, the joint action is designed to make the robot's policy dependent on individual policies and joint policies. The definition of the Q-function is as follows:

$$Q_{i,\pi}^k(s, a) = \mathbb{E}[\sum_{t=0}^{\infty} \gamma^t r_{i,t+1}^k | S_{i,t+1}^k = s, A_{i,t}^k = a] \quad (13)$$

$$Q_{i,\pi}^k(s, a) = R_i^k(s, a) + \gamma \sum_{s' \in S} \mathcal{P}_{ss'}^a \sum_{a' \in A} \pi_i^k(a'|s') Q_{i,\pi}^k(s', a') \quad (14)$$

The optimal policy is determined by maximizing the value of all actions. According to the Bellman optimality equation, the optimal V-value ( $V^*$ ) and Q-value ( $Q^*$ ) could be written as follows:

$$V_i^k(s) = \max_{\pi_i} R_i^k(s, a) + \gamma \sum_{s' \in S} \mathcal{P}_{ss'}^a V_i^k(s') \quad (15)$$

$$Q_i^k(s, a) = R_i^k(s, a) + \gamma \sum_{s' \in S} \mathcal{P}_{ss'}^a Q_i^k(s', a') \quad (16)$$

If the environment consists of  $N$  agents and  $K$  levels, then the policy set  $\pi = \{\pi_1^k, \pi_2^k, \dots, \pi_N^k\}$  that is parameterized by  $\theta = \{\theta_1^k, \theta_2^k, \dots, \theta_N^k\}$ , where  $1 \leq i \leq N$  and  $0 \leq k \leq K - 1$ . Then, the gradient of the expected return for each agent  $i$  at level  $k$  could be expressed as follows:

$$J(\theta_i^k) = \mathbb{E}_{x,a \sim D} [R(s, \pi_i^k(s))] \quad (17)$$

$$\begin{aligned} \nabla_{\theta_i^k} J(\theta_i^k) &= \mathbb{E}_{x,a \sim D} \\ & \left[ \nabla_{\theta_i^k} \log \pi_i^k(a_i^k | \mathcal{O}_i^k) Q_{i,\pi}^k(x^k, a_1^k, \dots, a_N^k) \Big|_{a_i^k = \pi_i^k(\mathcal{O}_i^k)} \right] \end{aligned} \quad (18)$$

where  $Q_{i,\pi}^k(x, a_1^k, \dots, a_N^k)$  is the centralized Q-function at level  $k$  that accepts as input all agent actions at level  $k$ ,  $a_1^k, \dots, a_N^k$ , and observation  $x$  at level  $k$  of all agents,  $x = (\mathcal{O}_1^k, \dots, \mathcal{O}_N^k)$ , with the output being the Q-value for each agent  $i$  at level  $k$ . Experience Replay buffer  $\mathcal{D}$  contains  $(x, x', a_1^k, \dots, a_N^k, r_1^k, \dots, r_N^k)$  where  $x'$  is the next state obtained after the agent took action while in state  $x$ . The centralized Q-function  $Q_{i,\pi}^k$  will be updated by minimizing the following loss function:

$$\mathcal{L}(\theta_i^k) = \mathbb{E}_{x,a,r,x'} [(Q_{i,\pi}^k(x, a_1^k, \dots, a_N^k) - y)^2] \quad (19)$$

$$y = r_i^k + \gamma Q_{i,\pi',k}^k(x', a_1^{k'}, \dots, a_N^{k'}) \Big|_{a_j^{k'} = \pi_j^{k'}(\mathcal{O}_j^{k'})} \quad (20)$$

where  $\pi^{k'} = \{\pi_{\theta_1^{k'}}, \dots, \pi_{\theta_N^{k'}}\}$  is the set of target policy with delayed parameter  $\theta_i^{k'}$  at each level  $k$ . As the Q-function  $Q_{i,\pi}^k$  for each agent  $i$  is learned independently at all levels, the reward may be determined arbitrarily based on the issue. The algorithm of MH-DDPG is shown in algorithm 1.

#### C. State, Observation, and Action Space

Consider an environment with  $N$  robots and  $M$  goals. Robots and goals have a physical entity represented by  $X$ . Based on the original MPE,  $X$  is a two-dimensional object characterized by its position and velocity. Furthermore, the state contains polar coordinates that are utilized to identify the robot's relative position to the goals and other robots. An environment with  $N$  robots and  $M$  goals corresponds to a state space with  $N \times M$  polar coordinates of robots to the goals ( $d_{1,\dots,N \times M}^G$ ) and  $N-1$  polar coordinates to other robots ( $d_{1,\dots,N-1}^A$ ). However, it should be noted that the goals of the bottom level are the subgoals produced at the upper level.

Based on the preceding discussion, the state space  $\mathcal{S}$  is a mixture of each level state space:  $\mathcal{S} = \bigcup_{k=0}^{K-1} S^k$ , where  $S^k = \{X_{1,\dots,N}, d_{1,\dots,N \times M}^G, d_{1,\dots,N-1}^A\}$ .

Then each agent can only observe their own state of the entire state, called observation. The observation space of each agent at each level  $k$  is  $O_i^k(S) = \{X_i, d_{i,1,\dots,M}^G, d_{i,1,\dots,N-1}^A\}$ , where  $i$  indicates the  $i^{th}$  robot.

At  $k = 0$ , the output layer of the actor networks generates five outputs between 0 and 1 in which each one is associated with a particular action. The five outputs are denoted by  $u_n$ ,  $u_l$ ,  $u_r$ ,  $u_d$ , and  $u_u$  for no action, move left, right, down, and up, respectively. At  $k > 0$ , if the action of the abstract robot should have more capabilities than the actual robot, the range  $u$  is increased multiplied by the sensitivity rate, therefore  $u^k = u^0 x \mu$ , where  $1 \leq k \leq K - 1$  and  $\mu$  is the sensitivity with a value more than 1. The sensitivity of the upper level must be larger than the sensitivity of the lower level.

#### D. Reward Design

The reward is designed to correspond to the learning objectives of the robot. The distance between objects determines the reward design. Suppose that the positions of two object types, A and B, in two dimensions are known. A and B respectively add up to  $N$  and  $M$ , therefore  $A_i = (x_1^i, y_1^i)$  and  $B_j = (x_2^j, y_2^j)$ , where  $1 \leq i \leq N$  and  $1 \leq j \leq M$ . The following formula may be used to compute the total distance between two types of objects:

$$d(A, B) = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \quad (21)$$

$$d(A_{1,\dots,N}, B_{1,\dots,M}) = \sum_{i=1}^N \sum_{j=1}^M \sqrt{(x_2^i - x_1^j)^2 + (y_2^i - y_1^j)^2} \quad (22)$$

The design of the reward differs between the bottom and upper levels. The term for the rewards at each level is explained as follows:

1) *The goal/subgoal reward*: Designed to encourage agents to achieve the Goal/Subgoal. This reward is available at all levels. This reward is utilized at the highest level to promote the abstract robot to accomplish the main goal and at the lowest level to help the robot reach the subgoal. Reward calculations will be based on the distance between all robots and goals using (22) and (23).

$$R(\text{Agent}_{i,\dots,N}, \mathcal{G}_{j,\dots,M}) = -d(A_{1,\dots,N}, B_{1,\dots,M}) \quad (23)$$

where  $A = \text{Robot}$  dan  $B = G$  (goal/subgoal).

2) *Robot relative to other robots Reward*: for avoiding collisions between robots. This reward is only used at the lowest level because the abstract robot is unable to detect other robots. This reward term is calculated as follows:

$$R_c(A, B) = \begin{cases} -1; & \text{if } d(A, B) \leq A_{size} + B_{size} \\ 0; & \text{if } d(A, B) > A_{size} + B_{size} \end{cases} \quad (24)$$

where  $d(A, B)$  is the distance between two robots ( $A$  and  $B$ ) that can be calculated by (22) with  $i, j=I$ .

3) *Obstacle reward*: Aims to encourage robots to avoid obstacles. Due to the abstract robot's inability to detect obstacles, this reward is only applied at the lowest level. Similar to other robot rewards, the robot must compute the distance between itself and the obstacle to get reward.

$$R_c(A, B) = \begin{cases} -10; & \text{if } d(A, O) \leq A_{size} + O_{size} \\ 0; & \text{if } d(A, O) > A_{size} + O_{size} \end{cases} \quad (25)$$

where  $d(A, O)$  is the distance between robot  $A$  and obstacle  $O$  that can be calculated by (22) with  $i, j=I$ .

#### E. Neural Network Models

Each robot at each level of the MH-DDPG consists of actor and critic networks, structures of which are shown in Fig. 3. Local observations are the inputs for the actor-network, while robot actions represent the output. Therefore, the critic-network uses the observations and actions of all robots as inputs and Q-value as outputs. The Q-value is then used as the training basis for the actor networks. Every network employs the ADAM optimizer with a learning rate ( $\alpha$ ) and a discount factor ( $\gamma$ ).

Fig. 3. Neural Network Model.

#### V. EXPERIMENTAL ENVIRONMENT

We conducted experiments for comparing the DDPG, MADDPG, and MH-DDPG algorithms under the parameters listed in Table I. The experimental environment is set with three robots and three goals, with some obstacles to increase the environment's complexity. Fig. 4 depicts the environment for testing the proposed algorithm. The experiments were conducted on three types of environments with various complexities: low-complexity {Fig. 4(a)}, mid-complexity {Fig. 4(b)}, and high-complexity {Fig. 4(c)}.

Fig. 4. Illustration of the Experimental Environment.

Fig. 5. Block Diagram Comparison for DDPG, MADDPG, and MH-DDPG Employing 3 Robots. Q, O, and a Represent the Q-Value, Observation, and Action, Respectively.

TABLE I. EXPERIMENT-SPECIFIC PARAMETERS FOR DDPG, MADDPG, AND MH-DDPG

Parameters	DDPG	MADDPG	MH-DDPG
<b>Specific Parameters</b>			
The number of robots (N)	3	3	3
The number of levels (K)	-	-	2
The number of actors	3	3	6
The number of critics	3	3	6
The number of ERs	1	1	2
Sensitivity	5	5	5 (level 0), 30 (level 1)
<b>Actor and Critic Networks Parameters</b>			
Number of hidden layers	1	1	1
Number of hidden units	64	64	64
Activation Function	ReLU	ReLU	ReLU
Input Actor Network	Current Observations	Current Observations	Current Observations
Output Actor Network	Action	Action	Action
Input Critic Network	Current Observation and Action	Current Observation and Action	Current Observation and Action
Output Critic Network	Q-value	Q-Value	Q-value
<b>Training parameters</b>			
Optimizer	ADAM	ADAM	ADAM
Learning rate ( $\alpha$ )	1e-2	1e-2	1e-2
Discount factor ( $\gamma$ )	0.97	0.97	0.97
Replay buffer size	$10^6$	$10^6$	$10^6$
Minibatch size	1256	1256	1256

Fig. 5 compares the block diagrams of DDPG, MADDPG, and MH-DDPG, illustrating how the algorithm determines the parameter values for the specific parameters given in Table I, except for sensitivity. The values for the sensitivity and the training parameters are empirically determined. From the experiments, the determination of the training parameters in different environments demonstrates that the algorithms are not excessively sensitive to the chosen parameters.

Particularly in MH-DDPG, the designed environment can decompose into K levels. As a preliminary step in the proposed algorithm, this research performs a two-level investigation (K=2). Where the bottom level ( $k = 0$ ) is the real environment used for actual robots learning, and the top level ( $k = 1$ ) is the abstract environment used for abstract robot learning. In the environments, the robots must collaborate to accomplish the predetermined goals. The robots' mission will be accomplished if the robots can discover the optimal path for reaching all the goals.

## VI. RESULTS

The experiments compare the proposed algorithm against MADDPG and DDPG. The first step is assessing the robots learning performance based on the rewards obtained throughout the learning process.

Fig. 6 depicts the learning curve based on the robot's average reward in each episode. In this experiment, there were 150000 episodes in each environment. The average reward the robot obtains in a low-complexity environment is greater than in mid-complexity and high-complexity environments. A greater average reward indicates that robots in simple environments perform better than in other environments. A low-complexity environment without obstacles makes it easier for robots to reach their goals.

From Fig. 6, it can be observed that MH-DDPG converges faster to the maximum rewards and produces larger reward in each episode than DDPG and MADDPG, indicating that the robots that were trained using MH-DDPG reaches the goals

faster. Fig. 6 also indicates that the superiority of MH-DDPG over DDPG and MADDPG is consistent in complex environments. In a high-complexity environment, the graph also reveals that the average reward value is unstable for DDPG and MADDPG, whereas MH-DDPG remains robust.

Fig. 7 depicts the robot's behavior during the learning process compared to MADDPG and DDPG in a mid-complexity and high-complexity environment at  $t=0, 10,$  and  $40$ . The blue circle indicates the actual robot, the green rectangle represents the goals, and the red circle represents the abstract robot found exclusively on MH-DDPG. The abstract robots will generate a subgoal for the lower level. At  $t=0$ , the robot begins its first step of learning. Here, the locations of the abstract robot are identical to the positions of the actual robots.

At  $t=10$ , robots are learning to achieve all goals. Here, on MH-DDPG, a red circle indicates the presence of an abstract robot. At each instant  $t$ , the abstract robot generates a subgoal for the actual robot. In MH-DDPG, Actual robots will first learn to cover subgoals, but in DDPG and MADDPG, robots

will learn to cover main goals straight away since there are no subgoals. Abstract robots that cannot detect obstacles might occasionally be located in the same area as the obstacle, as shown in the high-complexity environment at time  $t=10$ . This condition is sometimes harmful to the actual robot when it learns to achieve the subgoal since the actual robot cannot reach the subgoal properly, which consequently decreases the associated state-action values.

Finally, at  $t=40$ , the final step of learning in a single episode occurs. In DDPG, it is evident that the robots have difficulty cooperating to reach the goal in both mid-complexity and high-complexity environments, which is also consistent with the successful rates shown in Fig. 8. In the mid-complexity environment, the robot tends to go toward one of the goals. Therefore the targeted objectives to cover all goals are often not achieved. This is because the robots work independently and do not share information. In high-complexity, obstacles tend to hinder the robot's ability to achieve the subgoals.

Fig. 6. Reward Graph.

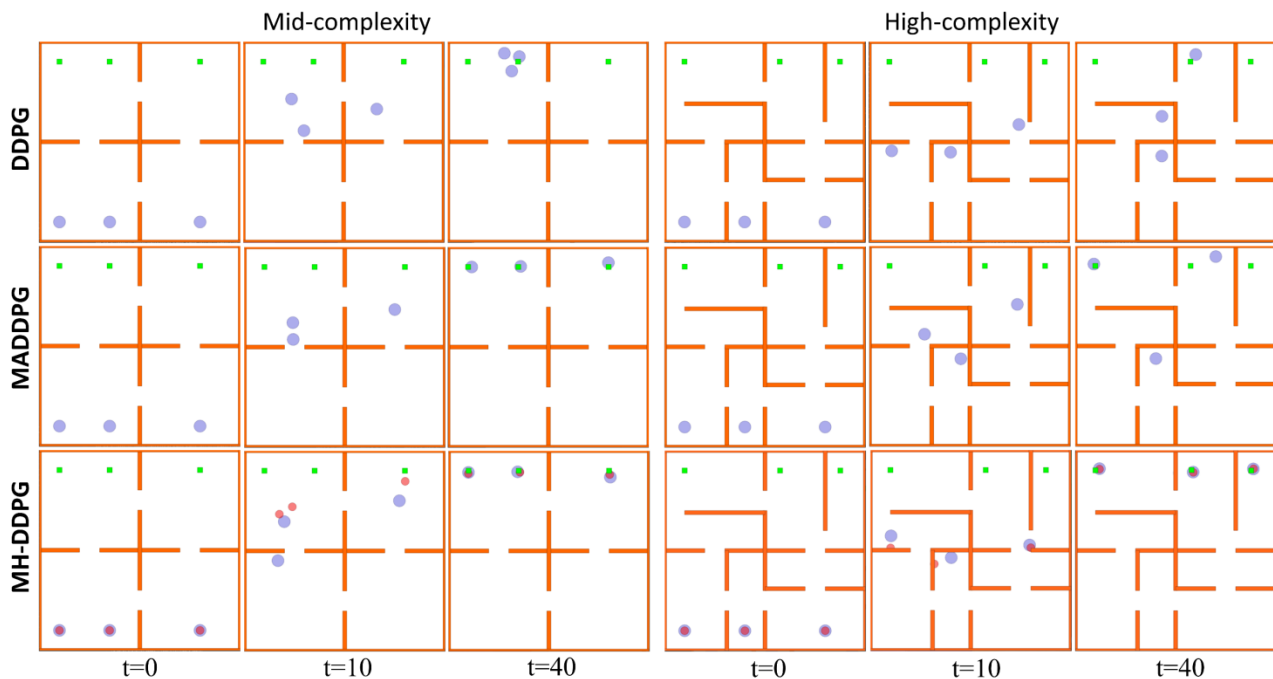

Fig. 7. Comparison between DDPG, MADDPG, and MH-DDPG on the Mid-complexity and High-complexity Environment.

Fig. 8. Success Rate.

From Fig. 7, for MADDPG, it can be observed that the robots can work collectively to achieve goals in a mid-complexity environment, while in high-complexity environments, due to the complex configurations of the obstacles, the robots faced difficulty in the early phase of the learning process as apparent from the fluctuating graph, but gradually stabilize as the learning progresses. In MH-DDPG, subgoals increase the robot's problem-solving ability as they are guided by intermediate objectives that consequently constrained the problem space.

Fig. 8 depicts the average success rate for the respective algorithm in each environment during the learning process. In all environments, the robots with MADDPG and MH-DDPG were able to cooperate and learn policies to achieve their goals, while the robots with DDPG failed to do so. The failure of the robots in DDPG is due to the lack of information sharing between robots; hence, the robots only learn independently and may repeat the failure of other robots. In the low-complexity environment, the average success rates for MADDPG and MH-DDPG are 74.18% and 82.15%, respectively. As the complexity of the environment increases, the average success rate for MADDPG and MH-DDPG decreases, as seen from the graphs for mid and high-complexity environments. MADDPG and MH-DDPG had respective success rates of 56.08% and 73.18% in a mid-complexity environment, while in a high-complexity environment, these success rates were 44.18% and 72.99%, respectively. The results show that MH-DDPG has a greater success rate than MADDPG. This indicates that decomposing the problem environment into many levels is advantageous for maximizing robot learning performance.

## VII. CONCLUSION

MH-DDPG is proposed as a novel framework for multi-robot learning with hierarchical Deep Reinforcement Learning. Here, the robots collectively learn by sharing information about state-action values from their individual runs. In addition, the proposed MH-DDPG provides a mechanism for creating multi-level abstraction, in which higher-level abstraction space allow the robots to execute a kind of "image training" where they may virtually explore the problem space without considering the physical constraints in real-world space. The virtual experiment in abstract space allows the robot to discover the real robots' intermediate goals rapidly. The intermediate goals

helps to limit the exploration for the real robots, thus alleviating the curse of dimensionality.

Through some empirical experiments, it can be observed that the proposed MH-DDPG outperforms DDPG and MADDPG in learning efficiency and success rate.

The weakness of the MH-DDPG is that an abstract robot at higher levels is incapable of detecting obstacles. Hence non-realistic subgoals are sometimes produced. This is the cost that needs to be paid for removing the physical constraints in the abstract space. In this preliminary experiment, the abstract robots are given higher speed but are constrained by their inability to detect obstacles, but it does not have to be so. In the following study, experiments will be conducted with various constrained conditions at the higher abstraction levels.

Immediate future research topics include investigating the effect of the number of levels and the number of robots in MH-DDPG. In addition, implementing the proposed learning method into physical robots is also of interest.

# Differential Privacy Technology of Big Data Information Security based on ACA-DMLP

Yubiao Han\*, Lei Wang, Dianhong He  
Shandong Information Technology Industry Development  
Research Institute, Jinan Shandong 250014, China

**Abstract**—Cloud computing and artificial intelligence have a deeper and closer connection with daily life. To ensure information security, most companies or individuals choose to pay a simple fee to store a large amount of data on cloud servers and hand over a large number of complex calculations of machine learning to cloud servers. To eliminate the security risks of data stored in the cloud and ensure that private data is not leaked, this paper proposes a collusion-resistant distributed machine learning scheme. Through homomorphic encryption algorithm and differential privacy algorithm, the security of data and model in machine learning framework is guaranteed. The distributed machine learning framework is adopted to reduce the data computing time and improve the data training efficiency. The simulation results show that the computational efficiency is improved while the user privacy security is guaranteed. The accuracy of model training is not reduced due to the improvement of privacy data security and computational efficiency. Through this study, we can further propose effective measures for the privacy protection of outsourced data and the data integrity of machine learning, which is of great significance to the security research of cloud intelligent big data.

**Keywords**—Big data; cloud computing; information security; distributed machine learning; differential privacy algorithms

## I. INTRODUCTION

The core technology of artificial intelligence is machine learning. Machine learning is mainly through the analysis of a large number of data, statistics, calculations, and other operations, from which to learn experience, build models, and step by step improve the accuracy of model training. In practice, machine learning is widely used for model prediction in medicine, banking, recommendation systems, threat analysis, and authentication technology. Over time, large amounts of data are collected to provide new solutions to old problems [1]. Large-scale Internet companies collect users' online activities and recommend services of interest to users in the future through the analysis of big data. Health data from different hospitals and government agencies can be used to produce new diagnostic models, while financial companies and payment networks can also combine transaction history, merchant data, and account holder information to train more accurate fraud detection engines [2]. Although the progress of technology at this stage makes the processing and computing of big data more efficient, it is still an important challenge to ensure the privacy and security of cloud data. Competitive advantages, privacy concerns, laws and regulations, and issues surrounding data sovereignty and jurisdiction have hindered the development of data training techniques by many outsourcing

companies [3]. The algorithm workflow of distributed machine learning can be summarized as follows: the system receives large-scale data and stores them in the cloud, and then communicates data in the distributed network. Each distributed computing node performs the corresponding computing task after receiving the required data, and the system aggregates the sub-models trained by each node [4]. The main bottleneck in the work is the privacy security during data training and the model security after each node trains the sub-model, and the efficiency and accuracy of model training cannot be reduced by improving the security. McMahan et al. employed a differential privacy technique on a distributed parallel architecture to enable a trusted server to add noise to the weighted average of user updates to guarantee the user-level privacy [5]. The aggregation scheme of Adadi et al. is proved to be secure in the semi-honest adversary environment, especially when the secure multi-party computation (MPC) computes the sum of individual local user model updates at the cost of computational cost and communication overhead [6]. Shakeel P. et al. proved that when the server is not trusted, differential privacy cannot rely on the server to complete the task of adding noise, and a small part of the original gradient can be used to explain the local data [7]. Li et al. used the federated learning method to protect the user's privacy, but it increased the cost of computation and storage while protecting the privacy security [8]. Elgabli et al. combined the distributed differential privacy with a three-layer encryption protocol and proposed an unbiased coding algorithm to reduce the mean square error to achieve a better trade-off and combination of security and efficiency [9]. This paper is based on the data analysis and calculation of cloud server ciphertext transmission and machine learning distributed training platform. A distributed machine learning scheme (Distributed Machine Learning Privacy-protection Against Collusion Attacks, ACA-DMLP) against collusion attacks is proposed. This comprises the following steps of: adding the Laplace noise disturbance to a ciphertext of a user by a cloud end, and performing disturbance processing on each piece of ciphertext data distributed to a training platform through a differential privacy algorithm. Through the unsolvability of the system of indeterminate equations in the algorithm, the collusion attack of the adversary is prevented. The security evaluation and efficiency performance analysis of the scheme is carried out through simulation experiments. The main innovations of this paper are:

1) This paper proposes a private data encryption scheme that supports multiple users to encrypt private data with

different public keys at any time and upload it to the cloud server to encrypt user data efficiently.

2) Establish a mechanism for the cloud server to add noise to the ciphertext data to efficiently protect the transmitted data.

3) An efficient distributed machine learning scheme is designed, and an anti-collusion attack algorithm is proposed to protect the privacy of each training node, which ensures the security of user privacy data and the training model of each node.

## II. RELATED WORK

### A. Distributed Machine Learning

Distributed Machine Learning is mainly used to study how to use multiple computers to train large-scale data models. Big data has a large volume of data, many types of data, and high commercial value. Big data and cloud computing cannot be separated. With the rise of big data, cloud computing is bound to develop. However, big data cannot be processed by a single computer, so users have to adopt a distributed computing architecture. Therefore, distributed machine learning has also been developed rapidly. However, before the theory and technology related to big data were proposed, there had been a lot of related research work in the industry. In order to make the speed of data calculation and model training faster in machine learning, multiple computers or servers are used to run at the same time. Parallel processing is generally called "parallel computing" or "parallel machine learning". Its main purpose is to decompose a large computing task into multiple small computing tasks, and then distribute them to multiple computers or processing nodes in a distributed architecture for processing and computing. Nowadays, under the dual challenges of large-scale data and large-scale models, there are newer and higher standards and requirements for the computing power and storage capacity of servers used in machine learning:

1) The calculation is more difficult and more complex, so that the previous simple parallel calculation may take a lot of time. Therefore, there is an urgent need for a processor or computer cluster with higher parallelism and computing power to complete the data training task.

2) The volume of data is large and the required storage capacity is large, which leads to the fact that a single machine cannot meet the data storage needs at all, so more and more schemes have to adopt the distributed cluster architecture for data storage.

### B. Differential Privacy Technology

Because of its strong background assumptions, differential privacy has become a mainstream security algorithm in the privacy protection schemes related to machine learning. It can even be said that in the field of cryptography, any algorithm related to privacy protection can use differential privacy [10]. Generally speaking, the most powerful thing about differential privacy is that as long as every step in the algorithm meets the requirements of differential privacy, it can ensure that the final output of the algorithm still meets the requirements of

differential privacy [11].

$m_1$  and  $m_2$  are two adjacent data sets with different records, which are called adjacent data sets (also known as brother data sets). Differential privacy uses the Laplace mechanism to add measurable disturbance to the ciphertext to ensure the security of data distributed by cloud servers [12].

Definition 1:  $\epsilon$ -DP :  $\epsilon$ -DP means that if there is a pair of adjacent data sets  $m_1$  and  $m_2$ , and  $K$  is within the range of  $R$ , then the mechanism  $R$  belongs to  $\epsilon$ -DP, then the following holds:

$$\Pr[R(m_1) = K] \leq e^\epsilon \Pr[R(m_2) = K] \quad (1)$$

Where  $\epsilon$  is the privacy budget, which refers to the number of bits of information that the data analyst DA can obtain. The smaller  $\epsilon$  is, the less bits of information that the data analyst DA can obtain. The stronger the secrecy of  $\epsilon$ -DP is, and the randomness of differential privacy ensures the robustness of differential privacy [13].

Definition 2: Sensitivity:  $f$  is a function in the input space of the data set, i.e.,  $f: m \rightarrow R^d$ , which is used to describe the mapping function of a data set  $m$  to a  $d$ -dimensional space [14].  $\Delta f$  represents the sensitivity of two adjacent data sets, and has the following calculation formula:

$$\Delta f = \max_{m_1, m_2} \|f(m_1) - f(m_2)\| \quad (2)$$

Where, on  $R^d$  with at most one different piece of data, the maximum value is on the pair of  $m_1$  and  $m_2$ .  $\|f(m_1) - f(m_2)\|$  represents the Manhattan distance from a point in the data set in the real domain to a point in the data set  $m_2$ , which is called the 1-norm. For various different pairs of  $m_1$  and  $m_2$  data sets, finding the maximum distance is the sensitivity [15]. Differential privacy means that for a data set with only one record difference, the probability obtained by query is close. The closer the probability is, the stronger the confidentiality of the algorithm to the private data is. If the results of two data queries are completely consistent, the data set has been completely randomized [16]. In this way, the data will lose its availability again and again to improve security. Privacy protection will lose its original role and significance. Most of the schemes make the query probability close, not exactly the same, hoping to find a balance between the security and availability of private data [17].

## III. BIG DATA INFORMATION SYSTEM SCHEME

### A. System Model

The system model diagram of the ACA-DMLP scheme is shown in Fig. 1.

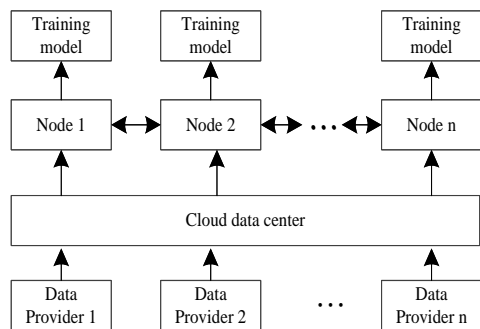

Fig. 1. System Model of the ACA-DMLP Scheme.

A DP is a group of a plurality of different data providers  $DP = \{DP_1, DP_2, \dots, DP_n\}$  in the scheme model, and provides data from a plurality of different sources for a cloud server. The data providers encrypt their own private data and submit the data to a cloud server. The cloud server adds a noise mask to ciphertext data and distributes the ciphertext data according to the requirements of a data analyst. Before the private data set is outsourced to the cloud server for storage, each data provider will use its own public key  $pk_{DP_i} (i = 1, 2, \dots, n)$  to encrypt the sensitive data in its data set, and then entrust it to the cloud server for storage and computation [18].

### B. Scheme Described

While the efficient training is distributed in the working nodes, the privacy data security and the sub-models trained by each distributed node are protected [19]. Fig. 2 is a system flow chart of that ACA-DMLP scheme.

The data provider DP uploads a large number of ciphertext data sets to the cloud server. The cloud server adds noise disturbance to the ciphertext data sets through the differential privacy scheme based on the Laplace mechanism and trains the logistic regression model through multiple iterations of multiple training nodes on the cloud platform. At the same time, it ensures that the adversary colludes with one or more computers in the distributed cluster and will not leak the encrypted data set distributed by the cloud server to the data analyst and the sub-model that has been trained by the computing nodes [20].

To improve the real-time and dynamic performance of data uploaded by users and ensure the security of data, this paper proposes a homomorphic encryption privacy protection scheme, in which each data provider has a public key. The privacy data is dynamically encrypted in real-time by combining the XOR operator of homomorphic encryption and the Diffie-Hellman theory of separable computation. Then upload it to the cloud server. Even if an adversary steals the cloud data, the plaintext cannot be cracked. A hash function is added to the algorithm to ensure the security of the ciphertext. Finally, through the security analysis and proof of the scheme, the feasibility and data security of the scheme are theoretically explained.

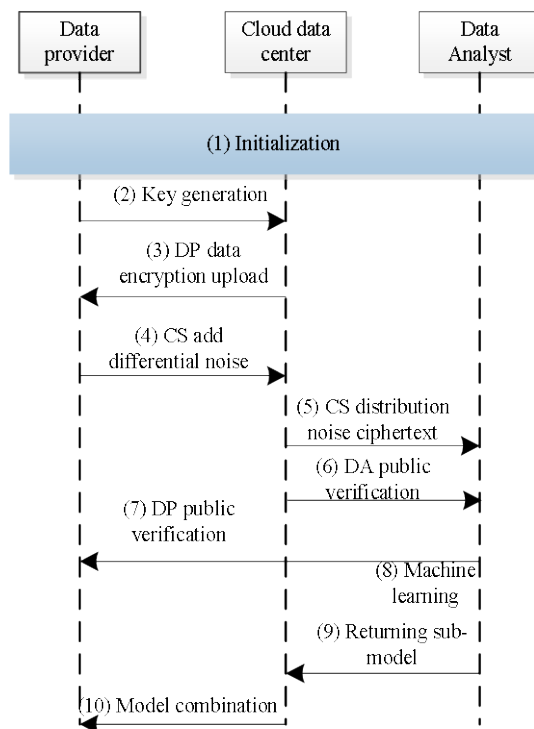

Fig. 2. System Flow Chart of the ACA-DMLP Scheme.

### C. Programme Framework Structure

The main content of the ACA-DMLP scheme is that the cloud server adds noise to the ciphertext data and then distributes the disturbing data to each working node of the data analyst. Due to the unsolvability of the indeterminate equations used by differential privacy to add noise, the adversary cannot theoretically steal the disturbed data through a reverse attack. Because of the particularity of the distributed architecture, the adversary cannot steal the trained sub-model of working nodes by conspiring with one or more hosts [21].

On the coordinate plane, the Manhattan distance between point  $i$  with coordinate  $(x_1, y_1)$  and point  $y$  with coordinate  $(x_2, y_2)$  is calculated as:

$$d(i, j) = |x_1 - x_2| + |y_1 - y_2| \quad (3)$$

If the scheme satisfies differential privacy, if and only if the following expression holds:

$$C(d) = f(d) + Lap\left(\frac{\Delta f}{\epsilon}\right) \quad (4)$$

$C(d)$  is the output function encrypted by the differential privacy algorithm, that is, each data set of the differential privacy algorithm outputs a ciphertext.  $f(d)$  is the ciphertext data received by the cloud server, that is, the cloud server adds noise to the ciphertext to execute the input function  $f(d) = (x_1, x_2, \dots, x_n)^T$  of the differential algorithm. T

represents the transpose of the vector [22]. Converts the input

data set to a vector.  $Lap\left(\frac{\Delta f}{\varepsilon}\right)$  is the noise perturbation added by the cloud server to the encrypted data. It is added in the form of a vector in the scheme. The form of adding noise disturbance is the vector addition operation between the vector of the original ciphertext data set and the noise vector, as shown in Formula 5:

$$C(d) = f(d) + \left( Lap_1\left(\frac{\Delta f}{\varepsilon}\right), Lap_2\left(\frac{\Delta f}{\varepsilon}\right), \dots, Lap_n\left(\frac{\Delta f}{\varepsilon}\right) \right)^T \quad (5)$$

Formula (4) is an algorithm formula for the cloud server to add noise to each piece of ciphertext data (n pieces of data in total) in the scheme. In differential privacy, as usual  $\mu = 0, b = \frac{\Delta f}{\varepsilon}$ , the Laplace function is written as:

$$Lap\left(\frac{\Delta f}{\varepsilon}\right) = \frac{1}{(2\Delta f) / \varepsilon} e^{\frac{-|x|}{(\Delta f) / \varepsilon}} \quad (6)$$

Simplified as follows:

$$Lap\left(\frac{\Delta f}{\varepsilon}\right) = \frac{\varepsilon}{2\Delta f} \exp\left(\frac{-\varepsilon|x|}{\Delta f}\right) \quad (7)$$

The initial ciphertext  $f(d) = (x_1, x_2, \dots, x_n)^T$  is differenced, that is, summed with the Laplace noise vector, to give the following equation:

$$C(d) = (x_1, x_2, \dots, x_n)^T + \left( Lap_1\left(\frac{\Delta f}{\varepsilon}\right), Lap_2\left(\frac{\Delta f}{\varepsilon}\right), \dots, Lap_n\left(\frac{\Delta f}{\varepsilon}\right) \right)^T \quad (8)$$

The following formula can be obtained by substituting the above formula (5) into the vector addition formula (6) and then transposing and expanding it:

$$\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} + \begin{pmatrix} Lap_1\left(\frac{\Delta f}{\varepsilon}\right) \\ Lap_2\left(\frac{\Delta f}{\varepsilon}\right) \\ \vdots \\ Lap_n\left(\frac{\Delta f}{\varepsilon}\right) \end{pmatrix} = \begin{pmatrix} x_1 + \frac{\varepsilon}{2\Delta f_1} \exp\left(\frac{-\varepsilon|x_1|}{\Delta f_1}\right) \\ x_2 + \frac{\varepsilon}{2\Delta f_2} \exp\left(\frac{-\varepsilon|x_2|}{\Delta f_2}\right) \\ \vdots \\ x_n + \frac{\varepsilon}{2\Delta f_n} \exp\left(\frac{-\varepsilon|x_n|}{\Delta f_n}\right) \end{pmatrix} = C(d) \quad (9)$$

Assume that there are N computing nodes in total in the data analyst, and each node allocates i (i is a random number in  $1, 2, \dots, n$ ) pieces of encrypted data. Then the noisy ciphertext data allocated by each working node is:

$$\begin{cases} C_1(d) = f_1(d) + Lap_1\left(\frac{\Delta f_1}{\varepsilon}\right) \\ C_2(d) = f_2(d) + Lap_2\left(\frac{\Delta f_2}{\varepsilon}\right) \\ \vdots \\ C_i(d) = f_i(d) + Lap_i\left(\frac{\Delta f_i}{\varepsilon}\right) \end{cases} \quad (10)$$

$C_N(d)$  is a noise data set allocated by the cloud server to each work node and added with the Laplace noise through differential privacy. Each work node in the data analyst executes related machine learning algorithms such as query, classification, calculation, statistics and the like on the noise data set, and trains a sub-model of each work node with the allocated data. Then the sub-models are submitted to the data center in the cloud server by the working nodes, and the next sub-model is trained, and finally all the sub-models of all the nodes are summarized by the data center to form a complete machine learning model to complete the machine learning task outsourced by the user.

#### IV. SAFETY ANALYSIS

##### A. Data Integrity Analysis

The adversary  $A_r$  attacks the ciphertext and training nodes distributed to the training nodes after the cloud server adds noise. Fig. 3 shows the security model of the ACA-DMLP scheme.

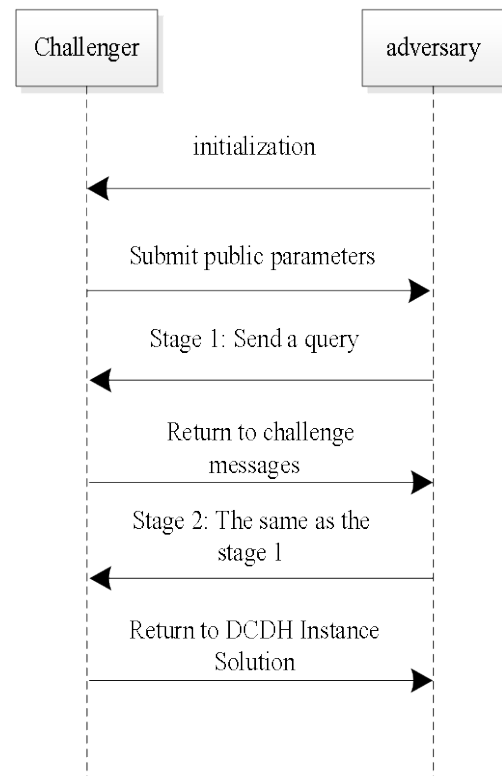

Fig. 3. Security Model of ACA-DMLP Scheme.

Setup:  $B_{tr}$  submits a public parameter  $(q, G, g, H_1, H_2, H_3, H_4, e_0, e_1)$  to  $A_{tr}$ .  $B_{tr}$  uses the list  $(L_{H_1}, L_{H_2}, L_{H_3})$  to simulate the random oracle model of  $H_1, H_2, H_3$  respectively, and guarantees their consistency.  $B_{tr}$  prepares a table  $L_k$  for the public and private keys.

Lemma 2: examine that communication between  $A_{tr}$  and the algorithm  $B_{tr}$  of the scheme in this paper according to the IND-PRE-CCA game.

Phase 1: the adversary  $A_{tr}$  issues a series of queries, and the algorithm  $B_{tr}$  responds to these queries according to the scheme algorithm.

Challenge: The adversary  $A_{tr}$  challenges  $B_{tr}$  to request a ciphertext message  $f(d)$  from the cloud server.  $B_{tr}$  responds to a series of queries from  $A_{tr}$  with a ciphertext  $C_N(d)$  that contains  $x_n$  and  $\frac{\varepsilon}{2\Delta f_n} \exp(\frac{-\varepsilon|x_n|}{\Delta f_n})$ . Due to the unsolvability of the indeterminate system of equations, the adversary cannot infer the initial ciphertext  $f(d)$  from  $C_N(d)$ .

Phase 2:  $A_{tr}$  continues to issue attack queries as in Phase 1, and algorithm  $B_{tr}$  continues to respond to adversary L's queries in the challenging manner described above.

Guess:  $B_{tr}$  returns a solution to the DCDH instance. In the random oracle model, the scheme is secure under the IND-PRE-CCA property. If an adversary  $A_{tr}$  corrupts CS or DA to obtain the outsourced data,  $A_{tr}$  cannot get the plaintext due to the IND-PRE-CCA nature of the scheme. In addition, if  $A_{tr}$  gains access to some data, the scheme achieves  $\varepsilon - DP$  due to the Laplace mechanism adding noise and the unsolvability of the algorithm equations. Therefore, the scheme is secure under the random  $\varepsilon - DP$  model.

### B. Collusion-Resistant Analysis

Due to the semi-honesty of the training nodes in the data analyst, suppose that there are  $\delta(1 \leq \delta \leq N)$  training nodes in the data analyst who collude with their training submodel  $R_i$  to steal  $R_e = (R_1, R_2, \dots, R_\delta)$ . Due to the strong background assumption of differential privacy, at least one training node does not participate in the collusion attack, and the adversary solves the logarithmic equation  $C(d) = f(d) + Lap(\Delta f / \varepsilon)$ . Because of its difficulty, the adversary cannot solve  $1 \leq i \leq n$  and  $\Delta f_i$ . Assume that the

adversary guesses  $\Delta f_i$  after several repetitions with a very low probability. According to equation (7), the adversary conspires to construct a system of equations with  $\delta$  equations and  $\delta + 1$  unknowns:

$$\begin{cases} C_1(d) = x_1 + \frac{\varepsilon}{2\Delta f_1} \exp(\frac{-\varepsilon|x_1|}{\Delta f_1}) \\ C_2(d) = x_2 + \frac{\varepsilon}{2\Delta f_2} \exp(\frac{-\varepsilon|x_2|}{\Delta f_2}) \\ \vdots \\ C_\delta(d) = x_\delta + \frac{\varepsilon}{2\Delta f_\delta} \exp(\frac{-\varepsilon|x_\delta|}{\Delta f_\delta}) \end{cases} \quad (11)$$

Since Equation (9) is an indeterminate equation system with infinitely many solutions, the adversary cannot solve all equation unknowns through the limited unknowns. The adversary cannot conspire to calculate all initial ciphertexts  $f(d)$  and all sub-models  $R_i$  through Equation (7).

## V. EXPERIMENTAL RESULTS AND ANALYSIS

### A. Experimental Setup

In the scheme, the data set is stored in the cloud server, so the user's local storage cost is small. The main analysis is not done in the scheme. The cost of the scheme depends on the time overhead, including encoding time, communication time, and computation time. To evaluate the time cost of the scheme in this paper, the test platform is shown in Table I.

The experiment examines the running time of the relevant scheme on the MNIST data set of size  $(m, d) = (12396, 1568)$ , where m is the sample size of the training data set and d is the test sample size. The distributed computing is simulated by the platform without considering the network delay. The time cost and accuracy of the proposed scheme are compared with the schemes in [23], [24] and [25].

### B. Efficiency Analysis

In the experiment, the total time cost of the scheme in this paper and the schemes in [23], [24] and [25] is simulated and analyzed by setting the number of training nodes  $N = (5, 10, 15, 20, 25, 30, 35, 40)$ . Fig. 4 compares the data calculation efficiency of the four schemes under different numbers of training nodes.

TABLE I. TEST PLATFORM CONFIGURATION

Type	Settings
CPU	Intel(R) Core(TM) i7-10700 4.8GHZ
RAM	32G DDR4
Hard disk	1T SSD
Operating system	Windows10
Data set	MNIST
Simulation platform	Python

In the experiment, the training time of different schemes is measured while the number of nodes is gradually increased. The following conclusions can be drawn: when  $N = 5$ , due to the small number of nodes and the small degree of parallelism between hosts, all schemes have almost the same performance; With the increase in the number of nodes, the difference in the time spent by different schemes to process the same amount of data sets is increasing, and the performance comparison between schemes is more obvious. Due to the distributed nature of the proposed scheme, the total amount of data sets are evenly distributed in each node. The more the number of training nodes is, the less time it takes to process the same task, and the shorter the total running time is. Thus, the time to process data sets decreases with the increase of the number of nodes. Compared with the scheme in the reference, the time cost of the scheme in this paper is smaller. Therefore, through the comparison of Fig. 4, it can be seen intuitively that the scheme adopted in this paper has obvious computational advantages. In the MPC scheme of [25], no matter how many hosts there are, each host repeatedly computes the entire data set to meet the needs of processing all tasks, so the computing time tends to increase. Through analysis, when the number of hosts is  $N = 40$ , it is found that the scheme in this paper has a significant improvement in efficiency compared with the schemes in [23], [24] and [25]. Fig. 5 shows the comparison of communication time (Comm), encoding time (Enco), computation time (Comp) and total time (Total) between the proposed scheme and the reference scheme when  $N = 40$ .

It can be seen from the images that the running time of each part of this scheme has been significantly improved compared with the reference schemes [23], [24] and [25]. The main reason is that the user encrypts the private data through the homomorphism in the scheme, which simplifies the algorithm and reduces the complexity. In the reference scheme [25], the data set size of each host is the same as the original data set, while the data set of each host in the present scheme is only 1/40 of the original data set. This is because the distributed machine learning provides a large parallelization gain for the scheme, while the reference scheme has a large computational overhead.

### C. Accuracy Analysis

MNIST data set is set in the experiment (12396 samples are used in the training set, and 1568 samples are used in the test set). Since [24] does not discuss the problem of training accuracy, the accuracy of this scheme is compared with that of the schemes in [23] and [25]. When the number of hosts is  $N = 40$ , the accuracy of this scheme is compared with that of the schemes in [23] and [25] under different iterations. Fig. 6 illustrates the experimental comparison results of the three schemes.

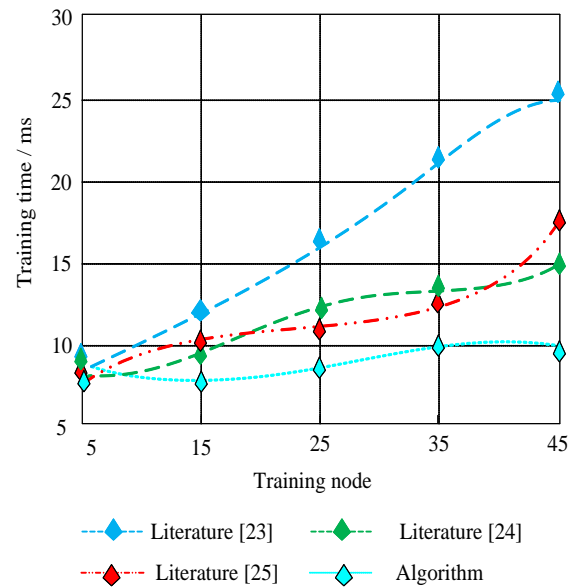

Fig. 4. Comparison of Running Time of Different Schemes.

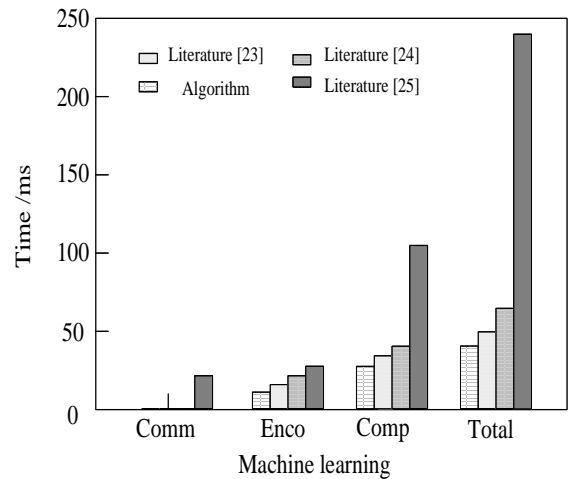

Fig. 5. Time Comparison of each Link of Different Schemes.

Fig. 6. Comparison of Accuracy of the Three Schemes.

It can be seen from Fig. 6 that during model training, compared with the reference schemes [23] and [25], this scheme has the same number of iterations, and the accuracy of model training of the two schemes is the same. When the number of iterations is five, there is a slight difference in the training accuracy of the scheme in this paper. The training accuracy of the scheme in this paper is slightly different from that of the comparison scheme, but the difference is kept within 2%. With the increase in the number of iterations, the accuracy between the schemes is getting closer and closer. The difference between the training accuracy of the scheme in this paper and that of the scheme in the reference is only 0.2%. This result shows that the scheme used in this paper almost guarantees the same accuracy as the reference scheme when the data set is unchanged and the number of iterations of the three schemes is the same. This scheme does not reduce the accuracy of model training because of the improvement of computational efficiency and data security.

#### D. Discussion

By comparing the functions of each scheme, it can be seen that [23] uses distributed architecture to improve the efficiency of data training, and uses homomorphic encryption algorithm and differential privacy to ensure the security of user privacy, and supports the public verification of ciphertext by each entity in the model. Appropriate measures are not taken to defend against the collusion between the adversary and the training nodes. The author in [24] uses a distributed model to speed up data analysis and improve the efficiency of training, but does not take security algorithms to protect the security of user data. The scheme in [25] can resist the collusion attack of the adversary and the training nodes in the distributed scheme, but it does not support ciphertext operation and public verification, and does not use differential privacy technology to protect the security of user privacy data. This scheme uses distributed structure to shorten the time of data analysis and improve the efficiency of machine learning, and uses homomorphic encryption algorithm to support the training platform to train on the ciphertext, uses differential privacy to strictly prevent the user's private data from being leaked in the process of transmission and training, and prevents the collusion theft of adversaries and distributed training nodes. At the same time, each role in the model is supported to download and publicly verify the data in the ciphertext domain at any time to ensure the integrity of user privacy data. Through the above analysis and comparison, the scheme in this paper has high feasibility, and strictly guarantees the integrity of user data, and improves the training efficiency of machine learning.

#### VI. CONCLUSION

In this paper, a collusion-resistant distributed machine learning privacy-preserving (ACA-DMLP) scheme is proposed.

1) The scheme adopts the architecture of distributed machine learning and improves the efficiency of data training through the cluster parallel systems.

2) A differential privacy encryption algorithm and a Laplace mechanism are used to add noise disturbance to the

ciphertext data in the cloud server to ensure data security in the ciphertext domain.

3) The feasibility and high efficiency of the scheme are objectively proved by simulation experiments on relevant platforms. The scheme in this paper improves the security and analysis efficiency of user private data in machine learning and can prevent adversaries from colluding with semi-honest working nodes within data analysts to steal data. The scheme in this paper only considers the safety of the model before training and the sub-model of the training node in machine learning but does not make an effective scheme analysis and demonstration of the data processing, model combination, and the safety of the overall model after machine learning. In future work, the data after training will be processed safely and the outsourcing agencies will be guaranteed to submit the machine learning results to users safely.

#### CONFLICT OF INTEREST

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

#### DATA AVAILABILITY STATEMENT

The data that support the findings of this study are available upon reasonable request.

**Abstract**—A reusable product line asset is a product or asset that can be reused for different purposes including charity. Smart mobile applications are one of several communication and information methods used in charitable activities. Web, mobile, or hybrid platforms can be used to develop charity applications. It takes design and purpose to build an application, whether methodology or software development is applied for the smooth design or development of an application. The data for this study were acquired from the appropriate literature between 2017 and 2021 in order to determine the application development on current charity applications. The Systematic Literature Review (SLR) was employed in this study. The SLR method is used to identify, review, evaluate, and analyze all available research on relevant topics, as well as research issues for philanthropic development. This study aims to answer the following research questions: identify the donation applications that are frequently developed by researchers; identify the methods that are commonly used in the development of charity applications; identify the application platform that is frequently used; identify the functions utilized to the developed application and identify the key users who are using the application. The findings show, charity donations app, structured method, mobile applications, authentication and charity centers and donors were the most often observed in this study.

**Keywords**—Application; charity; donation; reusable product line; systematic literature review

## I. INTRODUCTION

The advancement of information technology is very rapid nowadays. The growth of the telephone or mobile phone, as well as the internet's existence, has had an impact on many facets of life. Whether in one's personal life, socially, or in relation to the world of business or business. Information technology is used in philanthropic activities in addition to facilitating and speeding up communication and information processes. Humanitarian and social concerns can be carried out more quickly by taking advantage of technical advancements. This is because the internet, which has become a part of daily life, makes it easier to access information [1] [2]. The society has a role to play in the expansion of universal social and humanitarian concern activities. As a result, charitable activities have the ability to be done conveniently and quickly through the use of internet technology [3]. Many websites and mobile charity

applications have sprung up to function as a middleman, connecting people who want to help such campaign organisers and donors with people who need support [4]. With the growth of charity platforms nowadays makes it easier for everyone who wishes to donate or seeks donations with only access to the internet. Many communication and information technologies, like an application, are being created to assist users in undertaking donation activities. Application development is often classified into three platforms: desktop, online, and mobile. It takes a good planning to build an application, which must be examined to see whether the purpose, software development process used for the smooth design or development of an application. As a result, the objective of this study is to discover and examine prior studies relevant to the development of donation applications developed by previous researchers. The findings from this study will be used in the following phases for the proposed application SeekandHelp. Various stages should be evaluated before designing an application, including the area of focus, purpose, system user, method, or platform on which the application will run. The systematic literature review (SLR) strategy was applied to discover relevant findings and identify publications in a systematic way, with each procedure according to predefined phases or criteria [5]. This study is important to determine the application development on current charity applications so that it will give researchers to gain some insights on the application. The following sections in this study are organized as follows. Section II describes the methodology used for comparison study, Section III presents the result and analysis and lastly the conclusion.

## II. METHODOLOGY

This section will discuss and describe the phases of research process through using SLR method. SLR is a process of identifying, evaluating, and interpreting all research sources relevant to a research question regarding a research topic. Primary studies and secondary studies are studies and publications that contribute to SLR.

### A. Systematic Review Process

The systematic literature review method conducted will follow a specific process [6]. Each stage of this process will perform its respective tasks according to the order of research to obtain systematic research results. The process begins with

identifying research problems followed by formulating research questions and objectives. The next stage is the literature search strategy stage which process is to determine what keywords to use in article searching in the database and what searching criteria to include and exclude. In next stage, after search strategy completed is the process selection of the study which the process will including identifying, selecting, literature, extracting and evaluating the reporting research results obtained with followed by the last stage in this process. The systematic review process can be seen as Fig. 1.

Fig. 1. Systematic Review Process

### B. Problem Identification

The initial stage for systematic review is to identification of the research problems. Research problems are issues raised in related research which will be examined to be discussed and resolved. In this study, the research problem identified is that there is still a lack of research in the current study that provides a structured and comprehensive literature review regarding the development of applications in charity causes.

### C. Generate RQ and RO

In this stage, Research Questions (RQ) and Research Objectives (RO) are created. Research questions function to extract detailed information from each study conducted. Four research question formulations were made related to the study's namely the extent to which the implementation and development of applications related to charity were developed. The four questions have been generated and research questions are arranged in Table I.

TABLE I. RESEARCH QUESTIONS (RQ) AND RESEARCH OBJECTIVES (RO)

Research Question (RQ)	Research Objective (RO)
RQ1. What are the purpose and area of charity researcher focused in developing charity app?	Identify the purpose and types of topics focused on by researchers in developing the applications for charity donation.
RQ2. What methods were used in the app development of the study?	Identify method used by researchers. Knowing the method utilized in the various studies, this information can serve as a point of reference for designing a donation application for use in further study.
RQ3. What platforms are widely used in the development of the charity application?	Identify the platforms most frequently used to develop charity apps. Therefore, it is necessary to consider what platforms can be used for further studies.
RQ4. What functions and features are suggested in the charity app developed?	Identify the features used to develop charity apps
RQ5. Who is the focused user in system development in these studies?	To develop a system, it is necessary to identify who is the user will be involved.

### D. Literature Search Strategy

At this stage, the search process is carried out to obtain relevant sources to answer the Research Question (RQ) and other related references. The search process is carried out using electronic search journal databases, namely, Google Scholar and IEEE Explorer. This search on Google Scholar was chosen because Google Scholar provides a simple way to broadly search for scholarly literature and quickly gauge the visibility and influence of recent articles in scholarly publications

The keyword "local charity donation application" was used as the search query/search string. The search query or search string is what's utilized to find published material that explains the process of creating applications for charity causes. The keywords are formalized by using Boolean operators, namely the process of finding information from queries using Boolean expressions [7]. The Boolean expressions use the logical operators AND, OR and NOT in determining the calculation results only in the form of binary values. The Boolean retrieval result is only relevant documents or nothing. Thus, a Boolean retrieval overload does not result in the same document. Fig. 2 illustrates the search string.

1) *Literature inclusion and exclusion criteria:* Inclusion and Exclusion Criteria is performed to decide whether the data found is suitable for use in SLR research or not. Article search is selected based on criteria such as year of publication, type of journal article, books and proceedings. The Inclusion and Exclusion criteria's in this study is show as follows Table II.

### E. Study Selection Process

The procedure by which records identified in the preceding stage are evaluated for inclusion in the study is described as study selection. By objectively and methodically applying the predetermined eligibility criteria to each record to evaluate if the article should be included, selection bias can be avoided. This study selection process is shown in Fig. 3.

(Localized OR local )  
AND  
(Charity OR Charitable OR Donation)  
AND  
(Application OR System)

Fig. 2. The Finalized Search String/Sentence.

TABLE II. INCLUSION AND EXCLUSION CRITERIA

Inclusion Criteria	Exclusion Criteria
Literature publication from 2017 to 2021.	Literature publication year is below 2017.
Literature focusing on application development with related topics.	Literature which not discusses related topics in the study will not be selected.
Literature that uses only English.	Literature is not in English.

Fig. 3. Study Selection Process.

The selection process begins after obtaining literature search results in the database and obtained articles with details from Google Scholar with results with total of 19200 articles and in IEEE Explorer resulted in five literatures. Because of the large number of results, the first 250 literatures are selected for the screening stage. The first primary and second screening process is to exclude literatures based on duplicate literatures. The initial and second screening generated results of 137 and 98 literatures are excluded from non-English and year eligibility. The next screening is on study and understanding the abstracts of the literature to identify which articles are appropriate and which are not in accordance with the criteria for inclusion. Based on a comprehensive review of the title and abstract, there are 35 study literatures that meet the criteria relevant to the topic discussion. The following screening assessing of each literature for fully inclusion and exclusion criteria examines the literature in more depth. The process's inclusion and exclusion criteria finally resulted of 16 literatures accessible for this study.

1) *Data extraction and analysis:* The selected article then performed was data extraction to answer the research question (RQ). The data extracted from the research article discusses the development of charitable applications, whether the purpose, area, development methods, platforms used, features of the purpose app and system users of each application developed. By reading and analyzed the selected articles, an analysis will be produced that can answer the research questions. This process will be described in the results section and subsequent discussion in detail.

### F. Reporting the Result

Select Studies Overview indicates the distribution of selected literature through that source published. From 1320 literatures, 34 literatures were selected as shown in Table III.

## III. RESULT AND DISCUSSION

RQ1. What are the purpose and area of charity researcher focused in developing charity app?

The applications were grouped by the area focused by research in the literatures show in the Table IV divided into four groups: (1) Charity center donation, (2) Blood donation finder apps, (3) Food donation app, (4) Crowdfunding donation apps, and (5) Donation handling apps.

### A. Charity Center Donation

A total of six literatures were focused develop an app to find charity center for donation. The apps share the information of charity center to receive of donations and with information of center will be easier to find donors to meet the needs of the charity center. As studies by [13] focused on application to help the donor to find information about the non-profit organization available, [10] develop applications to facilitate donors and organizations to reach out directly and [8] reduce poverty. Study on [12] was not just to facilitate social institutions in making donations, but in [9] the apps were helpful to connect people to donate their used items and meanwhile, [11] help to reduce wastage and fulfil other items requirements of needy organizations. In the studies, an application was developed for further maximizing social services in the development of social welfare. The author of the literature focused on donation application design to facilitate the community in donating to the charity center in various forms, such as used good, volunteer, etc.

TABLE III. AREAS OF CHARITY DONATION APP FOCUSED

Focused donation area's	Ref. No
Charity donation center app	[8], [9], [10], [11], [12], [13]
Donation handling process app	[14], [15]
Blood donation app	[16], [17], [18], [19], [20]
Crowdfunding donation app	[21], [22]
food donation app	[23]

TABLE IV. DESCRIPTION OF SELECT STUDIES OVERVIEW

Literature	Purpose	Method	Platform	Area of Donation system focused	Features	User
[8]	To facilitate people and organizations to reach out easily in Bhutan.	Structured method	Web Application	Charity donation center app	Authentication	Charity organization and donor
[14]	To provide a better solution for donation handling in Sri Lanka during disasters.	Structured method	Hybrid	Donation handling process app	Authentication and Geolocation	Charity organization, donor and admin
[16]	To fill the knowledge gap about new technologies that can be developed to help the community in relation to blood finding.	Structured method	Mobile Application	Blood donation app	Geolocation	Donor and community
[9]	To facilitate and connect people in books donation.	Structured method	Mobile Application	Charity donation center app		Donor and seeker
[10]	To help people donate items in an easy way to the charitable organization in Malaysia.	Structured method	Mobile Application	Charity donation center app	Authentication	Donor and charitable organization
[21]	To design the crowdfunding platform specifically tailored to address food. insecurity problems in Indonesia.	Structured method	Mobile application	Crowdfunding donation app	Authentication	Charity organization, community
[20]	To improve the current existing system regarding the blood donation.	Structured method	Hybrid	Blood donation app	Authentication	Donor, patient, admin and authorize organization
[11]	To provides a platform for donation of useful items to the nearest NGO and reduce the wastage.	Object oriented	Mobile Application	Charity donation center app	Authentication and Geolocation	Charitable organization and donors
[12]	To help charitable organization and donor to raising/ giving donations.	Structured method	Mobile Application	Charity donation center app	Geolocation, Authentication and notification	Charitable organization and donors
[23]	To design and facilitate regarding food security issues.	Food donation	Mobile Application	food donation app	Authentication	Donor and community
[15]	To build an application program to reduce manual work of managing for the blood donation process	Object oriented	Mobile Application	Donation handling process app	Authentication and Geolocation	Charity organization, admin and donor
[17]	To develop a mobile blood donation management system and enhance the existing system.	Object oriented	Mobile Application	Blood donation app	Authentication and Geolocation	Authorize organization and donor
[18]	To solve the problem of searching for blood donors in the city of Lampung.	Object oriented	Mobile Application	Blood donation app	Geolocation	Donor, community and admin
[22]	To design, develop and test the decentralized crowdfunding web application in facilitating the donation process on Ethereum network.	Object Oriented method	Web Application	Crowdfunding donation app	Authentication	Charity organization and donor
[13]	to solve the problem by providing the donor complete information about the organization that accept the used item for donation.	Structured method	Mobile Application	Charity donation center app	Notification Authentication	Charity organization and donor
[19]	To develop blood donation app for handle emergency situation of blood availability.	Object Oriented method	Mobile application	Blood donation app	Authentication	Donor, Admin and authorize organization

### B. Blood Donation App

Research focusing on the development of applications for blood donation was obtained from relevant studies. This app focused on as an information tool to find blood donors or donate their blood. The blood application serves to provide information to users in facilitating the monitoring of blood supply and coordination of the processes involved. The availability of appropriate bloodstock is crucial for use during special medical condition [25]. Thus, various apps are design to solve the problems. Six articles were identified which researchers [16] and [18] develop an app to focus on blood donors to aid the community in relation to blood donation finders. A study by [20] focused to improve the existing system which was studied facilitating monitoring of blood supply and coordination of the processes involved. The research on [18] focused on to solve the problem of searching for blood donors based on the closest location. In [17], to the factor of authenticity, the apps develop focus to facilitate the work of the process of managing donors' information more quickly while [19] with organized blood bank donation data and information on bloodstock will facilitate people with easier access to bloodstock information without visiting a blood bank.

### C. Food Donation App

Researcher focused on food donation app which is a social movement themed application of donating food waste and foodstuffs to urban communities, in an effort to develop a digital community in reducing the amount of food waste. Research by [23] developed food donation applications as intermediaries to address food insecurity and eliminate food waste by using food sources available in local communities. This food -focused research is how to design an app with the theme of a social movement donating food and food waste to the community, in an effort to develop a digital community in reducing the amount of food waste.

### D. Crowdfunding Donation App

Crowdfunding is a fundraising practice for various types of businesses, whether in the form of product ideas, businesses or profits derived from donations from the general public or groups. There are two studies focusing on crowdfunding donations which researcher in [22] developed a decentralized crowdfunding focused application to facilitate the donation process on the network and record donation transactions securely. While researcher in [21] developed a platform specifically designed to address food insecurity issues that allow the public to make contributions to achieve targeted campaign funding. This type of development is different from regular donations, donations in crowdfunding are done online, where digital money is given for each campaign or project undertaken.

### E. Donation Handling Process App

Two studies found which focusing on developing an app for the process handling of donations, namely, researcher [14] which develops applications to improving the process of handling donations when a disaster strikes. It provides a better solution for handling donations when they are needed by the community. Meanwhile, researcher in [15] developed an application that focuses on the process of reducing the manual

work of managing donations in charity organizations in helping social organizations to run projects more transparently.

RQ2. What method were adopt in the development of application in the study?

Table V show structured methods which are the dominant method in the development of charitable applications. Structured methods in information system development, often known as the System Development Life Cycle (SDLC). In general, SDLC is sequentially divided into six stages, namely, planning, analysis, design, implementation and maintenance. This structured method is made up of many models, and in this study, we found as total 10 researchers who utilize it in the development of charitable applications.

An agile model is used in studies [13], in which the work process is repeated in an organized and systematic way. The prototype model has been utilised in studies [8], [14], [9], [20] and [23] which this model allows to understand the requirements at an early stage of development, helps get valuable feedback to understand what exactly to expect from the product under development. The authors in [16] and [21] utilise spiral model, which supports risk management and this model consists of multiple cycles, similar to a combination of waterfalls and iterations divided into each phase. The Rapid Application Development (RAD) paradigm is utilised in this study by [10] to emphasise rapid prototyping and quick feedback within an ongoing development and testing cycle, and it may produce multiple iterations and update software quickly with fast application development. In [12], the author utilised the waterfall model or known as classical method that follows a gradual regular pattern worked from top to bottom.

Object-oriented methods, as opposed to structured methods, total six researchers were utilized in their studies [11], [15], [17], [18], [19] and [22]. This object oriented method is used to simplify all kinds of problems that exist in a system by using many objects.

RQ3. What platforms are widely used in development of application in the studies?

The results shown in Table VI show that the dominant platform used in developing charity-based applications is the Mobile Application. Research focused on mobile platforms was carried out by [10], [16], [9], [21], [11], [12], [15], [17], [18], [13], [19], [15], [17], [18], [13] and [19].

TABLE V. METHOD USED IN SYSTEM DEVELOPMENT

Method	No. Ref
Structured method	[8], [14], [9], [20], [23], [16], [21], [12], [10] and [13]
Object Oriented method	[11], [15], [17], [18], [19] and [22]

TABLE VI. PLATFORM USED TO DEVELOP AN APPLICATION

Platform	Ref. No
Mobile Application	[10],[16], [9], [21], [11], [12], [15], [17], [18], [13], [19] and [23]
Web application	[8], [22]
Hybrid (Web and Mobile)	[14], [20]

A mobile app is an application that can be put into a mobile device and used at any time and from any place [21]. This is because mobile applications and their global influence show that they are used and impacted differently by individuals, businesses, and social groups [16]. Users can take advantage of the ability to use and benefit from mobile devices that can be accessible by mobile devices over mobile telecommunications networks [12], which helps users get to their desired place in their preferred time slot [11] and provides additional e-philanthropy experiences [10]. As a result of its simplicity of use, ubiquitous availability, and speed, smartphones have become more of a necessity than a commodity for most people [9][24]. Research on [8] and [22] applying web application development to the charities studied. Web application platforms, according to researchers, have lower communication costs. It can also encourage people to participate more often as there are no time constraints [22]. Meanwhile research by [14] and [20] focuses on both mobile and web application development. Implement a hybrid system makes it easier for users and organizations to gain access to the system [14]. Aside from that, mobile application and a website hosted on a cloud hosting that serves as an interface for system users and leverages the cloud to store and process data. This enables the system to take use of cloud hosting characteristics including rapid deployment, high availability, scalability, and management simplicity [20].

RQ4. What are the functionalities and features proposed in the development of charity apps?

This question is discussed by considering the results obtained from the implementation of 16 applications selected and answered the questions of RQ4 mentioned above. The features were evaluated for each of the selected literature. The results are presented in the Table VII.

#### F. Authentication

Authentication is the process of gaining recognition or gaining recognition. So this validation will verify who has actually interacted with the system. Authentication implementations can include what only the person knows [8], [10], [21], [12], [11], [15], [23], [17], [17], [19], a user who logs in with a username and password that only he knows, can be ascertained that that person is actually logged into the system when it comes to biometric authentication which involves part of body to be recognized by the user [26]. Researcher in [14] on the use of biometrics, for example, facial identification using the camera used to identify and record the faces of the people in an array for future accesses or [20] to identify and measure the health.

TABLE VII. COMMON FEATURES PROPOSED

Feature//Function	Ref. No
Authentication	[8], [10], [21], [12], [11], [15], [23], [17], [17], [19], [14]
Notifications	[12], [13]
Geolocation	[14], [16], [15], [17], [18], [12], [11]

#### G. Notifications

There are two applications that have been developed to provide users with a notification feature [12], [13]. This feature's implementation allows users to be notified in a variety of ways. Among those investigated, a notification could be an immediate alert the user receives about a reminder, news, or the next date on which event is possible. Users can also get push notifications for upcoming campaigns in their area as well as instant invitations to charitable events. Notifications are a potent tool that takes attention away the user's attention. However, if these notifications convey irrelevant and interesting messages, they can become annoying and leading to a negative perception of this feature.

#### H. Geolocation

The most significant element that should be added into a mobile app is geolocation, which allows users to identify their actual position by using a map that perfectly represents routes or other navigation data [27], [28]. Presently, GPS service for crises, or Location - based services, was among the most feature using in smartphone, making information sharing seamless and quickly [29]. Approximately 7 of the literatures analyzed [14], [16], [15], [17], [18], [12], [11] have built-in geolocation capabilities. Donor and centre locations are displayed on a visual map and optimised based on user real-time location data to identify the nearest one centre or donor. Since GPS services utilise users' personal information, harmful implications, as well as privacy and anonymity problems, might be crucial considerations that must be addressed to prevent data misuse.

RQ5. Who is the focused user of the system studies?

Based on 16 research articles reviewed, it was found that stakeholders who benefit from the use of charity applications are social organizations, donors, the needy, the community, authorized entities and patients. What can be seen from this study, researcher [8], [10], [11], [12], [26], [14], and [22] develop applications that focus on its main users involved in the system which are donors and charity centers and [15] develop similar systems but require an admin to manage donations from donors to social organizations before being sent to the receiver while [21], [23] involved with community. Researchers in [16] focus on the main users in the system which are donors and the community in blood finding. The author in [17] develops a blood finder between the donor and the authorizing party which is the hospital. As [16] in contrast to researchers [19], [18] [20] focused on connecting users and engagement between donors, admin, authorize the entity involved and the patient. Researchers in [9], [18] and [23] focused on the main users involved are donors and the needy who interact directly without an intermediary. As examined, the user is the component that determines how the user can communicate with the developed application. Therefore, indicating the system created is necessary to determine who will later be a user or users in the system in accordance with the system created.

#### IV. CONCLUSION AND FUTURE WORK

This literature review aims to systematically examine the extent to which charity application development and practice activities in the 2017-2021 range are based on the criteria exclusion and inclusion, 16 research articles were used for review. This literature review was carried out which is an approach to identify, collect and obtain information based on research question. Sixteen (16) articles were re-analyzed using five elements: the year, the article was published; the area of charity app develops that became the main focus of this research; the method used to conduct this study; the platform developed from the research; and the proposed feature and users who would use the system. In this finding, numerous academics have undertaken research to development of charity apps such as food donation, charity donations center, donation handle processing, crowdfunding and the search for blood donors. In literatures review resulted donation to charity center is the most discussing the topic. Furthermore, several methodologies are used in developing the apps, including structure method which consists of model waterfall, spiral, RAD, prototype, and object-oriented method. In this study, structured methods are the most commonly used and three platforms were discovered found in the literatures studies which mobile application development is dominance over web application and hybrid. From the aspects of functional, majority of apps installed include mobile features that could enhance the donation experience of the donors. Authentication, Notifications and Geolocation are the most interesting functionalities found in these studies. Research on system users, there are various users on each system developed, and it was discovered that donor users and charitable organizations are more in emphasis in the study. As a follow-up to this research, it is recommended in the form of suggestions, namely the need for further development and research on the application of charity in carrying out human activities and will be very useful during disasters or when times cannot be avoided.

#### ACKNOWLEDGMENT

This research was supported by Universiti Tun Hussein Onn Malaysia (UTHM) through Tier 1 Grant (Vot H937). The authors wish to thank Institute of Computer Science & Digital Innovation (ICSDI), CERVIE UCSI University which made this research endeavor possible.

# A Study on the Effect of Digital Fabrication in Social Studies Education

## Development of a Self-Learning Program for Creating 3D Educational Materials and Teaching Practice

**Abstract**—One of the learning methods that is increasingly being practiced in primary and secondary education is inquiry-based learning. This is not just a class to teach knowledge, but to practice activities to search for and discern the significance and essence of things. In social studies education, various trials and errors are being conducted, such as learning local history through fieldwork, and new approaches suitable for inquiry-based learning are being sought. In this study, as a new approach to social studies education, we developed a self-learning program that enables teachers to create original 3D educational materials using digital fabrication technology. We conducted an experiment in which students who wished to become social studies teachers participated in the program, created 3D educational materials, and taught a class using the materials. As a result, all the subjects who took the self-learning program could create 3D educational materials and give classes using them. The subjects' opinions suggested that practicing classes using 3D educational materials is effective for teacher education. This contributes to STEAM education, which has been spreading recently in the field of education, and this case study can be seen as a novel model.

**Keywords**—Digital fabrication; 3D educational materials; self-learning Program; social studies; STEAM education

### I. INTRODUCTION

In Japan, 3D printers are being promoted as school equipment in secondary education, making the use of 3D printers in school education more realistic. Usui et al. [1] report that the Ministry of Education, Culture, Sports, Science and Technology of Japan has added descriptions of 3D printers to its guidelines for developing educational materials for junior high schools and that 3D printer are now included in the curriculum guidelines for junior high-school technology and home economics courses and senior high school art, information, and industrial arts courses. There are already examples of 3D printers in science and technology education classes. Kurita et al. [2] use 3D topography created with a 3D printer as an aid in science classes to get an overview of the terrain, and they conduct classes that include on-site observation and fieldwork. Kadota et al. [3] incorporated the use of 3D CAD and 3D printers in a technology class to develop a radio-controlled car using a microcomputer, allowing students to learn multiple contents. Then, Muramatsu et al. [4] practiced and tested a learning curriculum for students

in a teacher training program for technology courses to build a model for introducing digital fabrication into school education. These precedents are probably due in part to the fact that digital fabrication is well matched to the content of these subjects.

However, the use of 3D printers in the classroom has been limited to a few subjects, and there are few practical examples, especially in social studies. This is probably because social studies teachers are far removed from technologies such as 3D printers and cannot imagine using them in social studies classes. Even if a 3D printer is close at hand, the opportunities that are not used well will limit the scope of inquiry-based learning.

In this study, we will develop a program that can practice digital fabrication, including 3D printers, in social studies education. It is a self-learning program that enables even beginners to create educational materials with a 3D printer and practice teaching with 3D educational materials. After class practice, we examine whether 3D educational materials are effective for social studies.

### II. PROGRAM DESCRIPTION

#### A. Previous Work

In developing the content to be used in this study, the teaching methods in e-learning in CAD were considered. Ahmed et al. [5] implemented a method for undergraduate students to demonstrate 3D modeling in an architectural 3D CAD class. As a result, students' motivation to learn and class understanding improved. Bodein et al. [6] indicated that in their survey of e-learning in CAD, they differentiated three types of instructional methods: awareness training (how to use the software), full training (how to operate the various functions), and performance support. In this study, we used teaching-by-demonstration and learning differentiated into steps.

#### B. Identification of the Teaching Content for beginner by Interview

The purpose of this program is to assist beginners in creating educational materials in history and geography through self-learning. We interviewed three teachers who teach digital fabrication to get an idea of the content needed for

beginners. All teachers have over eight years of experience teaching 3D CAD modeling and digital fabrication using 3D printers, CNC Milling Machine, etc. In the interview, we asked them to specify what beginners find difficult in the way of 3D model creation and digital fabrication. Furthermore, we found that beginners had difficulties when installing the software, so we made the program learnable from this point on.

C. Skills Required for Creating 3D Educational Materials and Self-Learning Program Contents

We identified the items required for the self-learning program. The content was designed so that beginners can learn step by step. Table I shows the skills needed to create 3D educational materials as a self-learning program. The process of creating 3D educational materials is divided into three steps, with each process consisting of detailed steps.

D. Selection of Contents of Social Studies Class

An example of a classroom practice studied in this program is the influence of topography on Japanese history. The 3D educational materials created by this program are modeled using a 3D printer with 3D topographic data provided by the Geospatial Information Authority of Japan (GSI) [7]. For more effective use of 3D educational materials, they can be used along with other educational materials.

E. Creation of Self-Learning Program

This self-learning program is built as a web system consisting of videos and an e-textbook. It consists of two parts. One is a method for creating 3D teaching materials composed mainly of videos, and the other is a classroom case study composed mainly of images and text. The 3D modeling software used was Fusion360 by Autodesk, Inc. [8].

Fig. 1 shows the screen where the 3D CAD operation method is explained. The instructor indicates the points to pay attention to in the voice while operating the software.

TABLE I. SELF-LEARNING PROGRAM CONTENTS FOR CREATING 3D EDUCATIONAL MATERIALS

Item No.	Step No.	Contents
1. What is 3D CAD and how to install it	1	What is 3D?
	2	What 3DCAD can do
	3	How to install 3DCAD and initial setup
2. 3D CAD Exercises	1	How to use key command operations
	2	2D sketching
	3	Geometric constraints
	4	3D modeling (Parametric modeling)
	5	Conversion to manufacturing data format
3. Features and Usage of Digital Machines	1	What is Digital Fab?
	2	Types of 3D printers and features of modeling
	3	Use 3D printer
	4	Features of CNC Milling Machines
	5	Use CNC milling machine
	6	Which machine to choose?

Fig. 1. An example of a self-learning program screen when explaining the operation of 3D CAD..

Fig. 2 shows an example of a class using 3D educational materials. The professor of social studies education explains key issues regarding specific classroom practices using 3D educational materials. The 3D educational materials created for the class are described with images and a written description of how to put them into practice.

Fig. 2. An Example of an Explanation of Key Issues in a Class using 3D Educational Materials.

Fig. 3 shows a mock class using 3D educational materials. The content is structured so that it can be implemented in class time.

Fig. 3. An Example of a Class using 3D Educational Materials.

III. EXPERIMENT

The following experiment was conducted over a total of eight weeks.

A. Self-Learning Program for Creating 3D Educational Materials

1) Overview of experiment: In this experiment, we asked subjects to take all the contents of the self-learning program in the correct order, up to the point where they completed the 3D educational materials. We investigated whether the subjects

could produce 3D educational materials without any problems after attending this program. After the experiment, subjects were asked the questions shown in Table II.

TABLE II. QUESTIONNAIRE FOR SELF-LEARNING PROGRAM FOR CREATING 3D EDUCATIONAL MATERIALS

Question	Level (1/2/3/4/5)
Q1. Were the self-learning program easy to understand?	1 – not at all 5 – very much
Q2. Were the speed of the explanation of the 3D CAD operation by video adequate?	1 – not at all 5 – very much
Q3. Were the content of the self-learning program sufficient for you to operate the 3D CAD?	1 – not at all 5 – very much
Q4. Did you find it stressful to understand the content of the self-learning program?	1 – very much 5 – not at all
Q5. If you were doing new class content, would you use a self-learning program like this one?	1 – not at all 5 – very much

2) *Subjects*: The subjects of this program are 20-year-old students: three males and three females, who aspire to become social studies teachers. Their PC skills are limited to daily use of Office software (Word, Excel, PowerPoint), and this is their first experience using specialized software such as 3DCAD.

3) *Experimental conditions*: Subjects took a self-learning program using their PCs. From the software installation to 3D data creation, the subjects used their PCs, and 3D educational materials were created at the Makers Floor (a fab facility equipped with 3D printers, CNC milling machines, and other digital fabrication equipment) located at Tamagawa University.

Fig. 4 shows the Form 2 [9] (Formlabs Inc.) 3D printer used in this study, which uses SLA printing: stereolithography, in which resin is cured by laser exposure for modeling. The software PreForm[10] (Formlabs Inc.) was used to convert 3D data (STL) to modeling data. The material used was Grey Resin. Fig. 5 shows an example of 3D educational materials. Fig. 6 shows the MDX-40A[11] (Roland DG Corporation) CNC-milling machine used in this study. The software SRP Player [12] (Roland DG Corporation) was used to convert 3D data (STL) to modeling data. The material used was chemical wood (SANMODUR MS-E). Fig. 7 shows an example of 3D educational material produced by a CNC milling machine.

Fig. 4. 3D Printer “Form 2 (Formlabs Inc.)”.

Fig. 5. An Example of 3D Educational Materials Modeled by 3D Printer.

Fig. 6. CNC Milling Machine “MDX – 40A (Roland DG Corporation).”

Fig. 7. An Example of 3D Educational Materials Modeled by CNC Milling Machine.

### B. Self-Learning Program for Teaching Practice in Social Studies Classes

1) *Overview of experiment*: Subjects first took the entire “Teaching Practice in Social Studies Classes” part of the self-learning program using their PCs. Then, each subject set their theme and reviewed the 3D educational materials they wanted to use in that class. Since the self-study program was also a collection of examples of classes using 3D educational materials, the subjects referred to it as needed when considering the content of their classes. After the experiment, subjects were asked the questions shown in Table III.

TABLE III. QUESTIONNAIRE FOR SELF-LEARNING PROGRAM FOR TEACHING PRACTICE IN SOCIAL STUDIES CLASSES

Question	Level (1/2/3/4/5)
Q1. Were the self-learning program easy to understand?	1 – not at all 5 – very much
Q2. Were the speed of the explanation of the 3D CAD operation by video adequate?	1 – not at all 5 – very much
Q3. Were the content sufficient for you to understand the significance of using 3D educational materials in your classroom?	1 – not at all 5 – very much
Q4. Have you been fully briefed on how to plan for implementing 3D educational materials in your classroom?	1 – not at all 5 – very much
Q5. If you were doing new class content, would you use a self-learning program like this one?	1 – not at all 5 – very much

2) *Subjects:* The subjects of this program are 20-year-old students: three males and three females, who aspire to become social studies teachers. These are the same subjects who attended the self-learning program for creating 3D educational materials.

3) *Experimental conditions:* After attending a self-study program on how to create 3D educational materials, the participants created and re-created 3D educational materials and discussed class content and class development over six weeks. After that, a mock class using 3D educational materials was conducted.

#### IV. RESULTS

All the subjects (n = 6) who took the self-learning program could create 3D educational materials and could practice teaching a mock social studies class for junior high school students using the 3D educational materials. Each experiment was conducted using questionnaires and interviews. The averages for each question are shown in Fig. 8 and Fig. 9. The results indicated high average values for both programs.

##### A. Self-Learning Program for Creating 3D Educational Materials

The results show that most subjects learned without stress and felt a slight deficiency in the amount of instructional content. Additionally, the following statements were made in the free response section of the questionnaire.

- After the experience, I felt a sense of joy and accomplishment when I created it came to me.
- I was relieved to find that with the self-learning program, creating 3D educational materials was easier than I had expected, even for someone like me who is not excellent with ICT.
- I could create the product by myself because I was carefully taught how to install the software and how to create the product using 3D CAD.
- I used to think that making things was something you did with your hands, but after the course, I learned that there is more than one way to make things.

- Using 3DCAD, I could create teaching materials like a game like Minecraft and produce them right in front of my eyes. This was especially interesting and fun for me.
- Although this program is for teachers, I thought it would be more accessible if there was a format that would allow children to experience it as well.

##### B. Self-Learning Program for Teaching Practice in Social Studies Classes

The results show that all items have high values, with easy-to-understand explanations rated especially high. Additionally, the following statements were made in the free response section of the questionnaire.

- I felt the significance of the advancement of technology and its use.
- I thought it was the knowledge I needed to know as a teacher.
- I created a 3D topography. I felt that the advantage of 3D topography is that it provides a bird's-eye view of the area through the senses of sight and touch.
- I thought the creator of 3D educational materials needs to understand the characteristics of what he or she wants to create and output it.
- I thought that a great deal of knowledge about 3D educational materials is needed both in terms of hardware at schools and among teachers themselves so that they can be used as educational materials in many schools in the future.

Fig. 8. Average Levels of Questionnaire Results of Self-Learning Program for Creating 3D Educational Materials.

Fig. 9. Average Levels of Questionnaire Results of Self-Learning Program for Teaching Practice in Social Studies Classes.

## V. DISCUSSION

### A. Potential of Digital Fabrication in Social Studies Education

As a result of the self-learning program, first, the purpose of creating 3D educational materials was generally achieved; all the subjects completed the 3D educational materials, although there were a few who experienced difficulties in operating the 3D CAD system. This indicates that even beginners can create 3D educational materials if they follow the appropriate instructions since the program deals with technical content.

However, there are issues regarding the practice of teaching with 3D educational materials. Excerpts from the actual evaluation comments are provided below.

- The content of what to create as 3D educational materials could not be decided.
- The lack of practical examples makes it difficult to realize in class and limits the scope of the concept.
- Without the support of social studies discipline-based epistemological approach, it is difficult to know what to express using 3D educational materials.

Many comments on classroom practice were about the implications of the class, such as what kind of 3D educational materials should be created and how to develop a class based on them.

However, many commented that they were deeply interested in the practice of teaching with 3D educational materials and wanted to practice it more. Participants who completed lessons using 3D topography using data provided by the Geospatial Information Authority of Japan showed great interest in the possibilities offered by these 3D educational materials.

These results indicate that the self-learning program developed in this study is effective in providing technological support, while improvements are needed in areas related to the "teacher's discipline-based epistemological approach" in classroom practice using 3D educational materials.

### B. Effectiveness of using 3D Educational Materials in Social Studies Education as Teacher Education

Consideration of the opinions of the subjects of the self-learning program suggests that to be able to create 3D educational materials optimized for inquiry-based learning and implement them in their classes, teachers themselves must be able to articulate "what they want to communicate to their students." For example, if a teacher wants to teach students about the geography of an area, "What kind of terrain can be created to highlight its features?" or "Will the students be able to notice the natural principles themselves?" ... etc., the teacher will have to deeply consider such questions, determine their perspective, set the task, and question their background knowledge. Additionally, empathy will be needed to imagine from the student's perspective.

Thus, the creation of 3D educational materials optimized for inquiry-based learning is beneficial not only for the

teacher's reflection but also for the acquisition of one's perspective and the formation of a new view of teaching that emphasizes a discipline-based epistemological approach. The self-learning program developed in this study will also enable teachers to create their tailor-made teaching materials, thereby realizing a learning environment that is optimized for everyone.

### C. Toward a Novel STEAM Education

After considering the results of the self-learning program and the process of implementation, we considered that the process for teachers to create effective 3D educational materials can be explained by the following new model, which includes design thinking in STEAM education. Fig. 10 shows the novel model. This is tentatively called the Hamada - Hirakoso model.

First, let us explain from outside the model illustration: we believe that the seeds of ideas for creating 3D educational materials are many across broad humanities. This means that the range of ideas itself would be limited if there is no intellectual activity such as consciously ingesting knowledge regularly.

However, knowledge is not enough to generate ideas. It is necessary to have one's perspective. This perspective can be viewed as an art of teaching. In this model, "one's perspective" and "sense of values" is "Art". It is only when one's perspective is established that one can decide what kind of educational material should be created, and having multiple perspectives allows one to consider various possibilities at the same time.

And the ability to access STEM expertise must create educational materials. This can be paraphrased as "the ability to implement. This ability of implementation is "Design thinking". The five steps of the process described in Design Thinking, "Empathy", "Define", "Ideate", "Prototype", and "Test", are used to link the seed of an idea to a solid basis. Additionally, through a process of trial and error, we searched for better educational materials. Without this process, good educational materials will never be completed. Design thinking will be used to access STEM, create educational materials, and implement classroom practices. We believe that teachers can use this model as a map for their daily practice.

Fig. 10. A Novel Model of STEAM Education.

## VI. CONCLUSION

In this study, we developed a self-learning program that enables students to practice digital fabrication, including modeling with a 3D printer, in social studies education.

In the experiment, subjects who were beginners in digital fabrication could create their own original 3D educational materials after taking this self-learning program. After considering the opinions of the participants in the self-learning program, creating 3D educational materials and teaching with 3D educational materials is a test of a teacher's ability. In other words, the results suggest that creating original 3D educational materials is effective for teacher education. This could be considered a novel model for STEAM education.

In the future, we intend to brush up on the program and expand the number of users by creating many examples of this program in practice. We would also like to verify whether the novel model we discovered was versatile enough.

## ACKNOWLEDGMENT

We would like to express our gratitude to the Makers Floor at Tamagawa University for their cooperation in the development of this program.

Cairo, Egypt

**Abstract**—A blockchain is a data structure that is implemented as a distrusted database or digital ledger. The transactions are saved to a block of transactions that is attached in turn to the blockchain after the verification process, in which each block in the chain contains a hash signature of the previous block in addition to the hash signature of the block itself. The blocks on the blockchain are chained as an immutable list using the proof-of-work procedure, where there is no way to alter or delete an attached block due to the strict security policy used for structuring the chain of blocks. Each node holds a copy of the blockchain in which the miners take the responsibility of verifying and attaching blocks to the blockchain. The Ethereum blockchain introduced the smart contract which holds logic to be processed once the contract is established. These smart contracts are developed via the Solidity programming language. This proposed paper exploits the Ethereum blockchain along with smart contracts as the base technology for implementing the proposed blockchain-based model. The paper aims to develop a multilayered blockchain-based model, in which the blockchain model is set up on a private blockchain Ethereum network where the nodes share the electronic medical records (EMR) among the P2P (peer-to-peer) network that will be used to secure the IoT medical transactions. Solidity smart contract, introduced by Ethereum, is deployed to handle the EMR “open-query-transfer” operations on the private network, whereas the miners are responsible to validate the transactions. Finally, the research conducts a performance analysis of the Ethereum network using the Ethereum Caliper, considering several performance factors, which are: Maximum Latency, Minimum Latency, Average Latency, and Throughput.

**Keywords**—Blockchain; ethereum; electronic medical records (EMR); iot secure transactions; smart contracts; proof-of-work

## I. INTRODUCTION

The blockchain technology has significantly contributed to putting an end to the interoperability challenges found in current and legacy healthcare IT systems, enabling individuals, healthcare service providers, healthcare entities, and medical institutions to securely share electronic healthcare sensitive data. Blockchains can enhance communication efficiency and increase security over the network, as the potential for using blockchain in healthcare is to overcome the challenges related to data security, privacy, sharing and storage [6], as well. It can also be applied in many software domains including financial and banking sectors, healthcare systems, and public services.

Although the blockchain-based models are increasingly used in modern software solutions, such models raised a significant number of challenges and objectives such as scalability, performance, processing speed over the network, data management on distributed nodes, and security breaches and attacks. Moreover, IoT network devices have been growing rapidly, as the number of installed IoT devices in the year 2022 is estimated to be 31 million devices. However, over the past few years, the blockchain model has become more stable and most of such issues and concerns have been resolved at most of the blockchain well-known platforms.

Thereby, as blockchains have become an excellent candidate to replace traditional transaction database systems, strict standards including acceptable behavioral guidelines must be laid out. These guidelines will facilitate the process of integrating the blockchain technology onto the healthcare domain systems, within the two blockchain main types: private and public blockchains. Thus, a blockchain network is basically either public or private, where a private blockchain is constructed for usage on a private network mainly used within a single entity such as a financial institution, for example. Generally speaking, blockchains are immutable, and thereby miners hold the responsibility of verifying the attached blocks to a blockchain on both private and public blockchains. But in the case of private networks, miners validate the blocks with a much stricter secured policy.

Miners create blocks of transactions, verify the blocks, and then attach every verified block to the blockchain. In blockchains, proof of stake or proof of work is being used to control the difficulty of the mining process. Thus, raising the complexity of the hash computations within the proof-of-work algorithm would increase the verification time of the newly attached block to the blockchain.

A block consists of five basic components: previous hash signature, nonce, transaction, timestamp, and the hash signature generated using proof of work or proof of stake. Data within the block attached to the blockchain is immutable; it is extremely difficult to be altered due to distributed nature of the blockchain structure. Furthermore, each block on the blockchain has a reference to the previous block hash signature, any change on the signature cannot be accomplished as in this case the hash has to be recalculated, and as a result, the blockchain will detect that change through the data verification process of the block.

Fig. 1. Blockchain Architecture [16].

A block, which is chained onto a blockchain, holds transactions. As shown in Fig. 1, a block data structure consists of a block header and a block body. The block header is formed using multiple parameters which may vary based on the blockchain network provider. For the sake of integrity and verification, the header contains the parent hash signature which points to the previous block, in addition to the hash signature of the current block. The block body holds the block transactions. The block size is defined by the blockchain network provider, as this may vary based on the blockchain network provider.

The natural properties of the blockchain technology can be used to face the challenges mentioned previously, (1) permission-based blockchain networks to enable granular access control for medical records can be achieved by supporting granular-level access mechanisms; (2) blockchain-supported smart contracts enable patient-centric and transparent data sharing and control; (3) the blockchain distributed consensus mechanism overcomes the limitation of centralization; and (4) the immutable block preserves the integrity of data, which enables a blockchain to be verifiable and provable [1].

Accordingly, this paper presents a multilayered blockchain-based model for securing IoT transactions in healthcare traditional transaction systems to overcome the aforementioned issues concerning the dispersed and unified patients' medical records. Thus, the contribution of the proposed research is twofold:

- 1) Taking advantage of the blockchain technology as an immutable database for operating multilayered architecture flexible pattern, designed using clusters with embedded nodes to enforce flexible security level and approval permissions for medical records transactions on the whole blockchain.
- 2) Exploit the power of the Solidity programming language for developing highly secured smart contracts to handle the operation messages between the nodes from one side and the IoT devices and regular PC devices on the other side.

Therefore, the proposed multilayered blockchain model develops an approach for maintaining and managing patient medical records assembled in clusters with the usage of blockchain-based systems. The presented model uses aggregation (i.e., clusters) on the level of networks via (1) the Network ID, as each network represents a mining facility with its separate miners; (2) private blockchains on the cloud services provider "AWS" with the aim of creating the blockchains, the nodes, in addition to the miners; (3) Ethereum as an open-source blockchain-based distributed computing application platform. Additionally, the efficiency and performance of smart contracts are measured with the

sophisticated certified tool "Caliper" which is used for measuring the core functions of the smart contract: Open, Query, and Transfer.

Experiments that are conducted to test the blockchain difficulty configuration, in addition to the number of total miners on the blockchain, shall prove the capability of the proposed model to work with high-security complexity, and with medium or low-security complexity, as well.

This paper is organized as follows: Section II will review the blockchain-based smart home architecture. Besides, it will compare the currently used dispersed healthcare models based on both, relational and NoSQL database architectures. Consequently, Section III will present two main contributions, first is designing the blockchain-based model used for securing and managing data immutable storage for healthcare multi-layered medical systems. Secondly, exploiting the smart contracts with solidity for managing the health organization transactions along with the verification of these transactions. Section IV deals with Implementation of model while Section V presents the experiments that demonstrate the effectiveness of the proposed architecture. At the end of the paper, Section VI will provide a discussion of open problems and will lay out a direction for the future work that could be done.

## II. RELATED WORK

Dorri, et al. [2] presented a blockchain-based smart home architecture, shown in Figure 2, which has been used as a core reference in the process of designing our proposed model. This BC-based smart home architecture consists of three tiers, the smart home, the overlay, and the cloud storage, in which communication within these tiers is carried out using block transactions. The smart home consists of IoT devices, local IL, and local storage as demonstrated in Figure 2; overlay is a P2P network with distributed capabilities in addition to cloud storage groups based on identical unique block numbers, where SHM has been used for authentication.

### A. Blockchain Systems Versus Traditional Systems

Table I draws a comparison between the features of the blockchain-based systems and the remote patient monitoring system which depends on traditional communication and data storage methods, such as relational databases and cloud computing [3].

Fig. 2. BC-Based Smart Home.

TABLE I. COMPARISON BETWEEN TRADITIONAL AND BLOCKCHAIN-BASED SYSTEMS

Factor	Traditional Systems	Blockchain-based Systems
Confidentiality	Security level based on the configuration which may vary	High level of security
Availability	Must be manually configured	High service availability
Immutability	Data is exposed for manipulation	Immutable; the attached block cannot be altered or deleted
Traceability	Manually configured with a complex configuration	Traceable
Speed	Depends on network speed and hardware configuration along with the data source provider engine	May vary based on the blockchain verification process

A blockchain-based system runs on a P2P network of computers where each node on the network has an identical copy of the blockchain. Blockchains types can be classified as public, private, or hybrid blockchains.

1) Public blockchain: it was first implemented by Bitcoin and other cryptocurrencies, and it has contributed significantly to the distributed ledger technology (DLT) structure. Issues due to centralization are handled with DLT as it distributes data throughout a P2P network rather than storing it in a single location. Because of its decentralized nature, it forces methods of authentication.

2) Private blockchain: it is set up on a closed private network or controlled by a single entity. Functionality goes on the same basis regarding connectivity and decentralization; however, is substantially smaller.

3) Hybrid blockchain: it includes private and public blockchain characteristics. It allows the creation of a private permission-based system along with a public permissionless system, in addition to regulations for access to specific data on the blockchain [4].

### B. Smart Contracts using Solidity

A smart contract can be defined as a piece of code that lives on a blockchain and is then executed automatically when one or more conditions are met. In the case of the Ethereum blockchain, smart contracts are implemented via the “Solidity” object-oriented language, in which users can execute the smart contracts through an application binary interface [6]. This property enables entities to perform their job functionalities such as access management, request handling, and data transmission. Ethereum enhanced the communication between a patient and a physician, as sharing medical prescriptions with the patients became much faster and easier. Accordingly, patients share their historical treatment data with doctors in a fast and accurate manner [5].

### C. Comparison of the Data Management Mechanisms

Traditional legacy medical records are paper-based medical records (PMR), making it very difficult to keep track of a patient’s health history. Thus, saving historical data in such a way will cause data loss in addition to increasing the potential of inaccurate historical data, which potentially may lead to maltreatment. This serious issue has been faced by utilizing electronic medical records (EMR), the digital transformation of paper-based medical records. Electronic access to historical health records significantly improved the quality of treatment in addition to better disease diagnosis and preventive care [6]. Thereby, blockchain-based systems played an important role in modern healthcare solutions. Table II reviews and compares these main blockchain-based research exploited in the healthcare sector.

TABLE II. REVIEW OF THE BLOCKCHAIN-BASED RESEARCH IN THE HEALTHCARE SECTOR

Research	Blockchain Characteristics	Type(s) of Data	Merits
Castaldo & Cinque [7]	A private blockchain that does not rely on proof-of-work	EMR	Sharing E-health data across the EU via audit logging
Yue, et al. [8]	Private blockchain	EMR & PMR	Smart App to manage and share healthcare data
Patel [9]	A private blockchain that guarantees proof-of-stake	Medical Image Records	Securely sharing medical images
Fan, et al. [10]	Hybrid consensus mechanism based on practical byzantine fault tolerance (PBFT)	EMR	Secure sharing of healthcare data
Ji, et al. [11]	Proof-of-work	Patients’ Locations	Multilayer location sharing schema
Azaria, et al. [12]	Ethereum blockchain with proof-of-work	EMR	EMR management and sharing of healthcare data
Zhu, et al. [13]	Ethereum platform	EMR	Data management in the cloud environment
Genestier, et al. [14]	Hyperledger platform	Medical Records	Managing personal data in the e-health environment
Wang & Song [15]	Consortium blockchain	Medical Records	Coupling encryption and signature for robust security

### III. RESEARCH METHODOLOGY

In this section, we propose and develop an approach for maintaining and managing patient medical records assembled in clusters with the usage of blockchain-based systems. Basically, the proposed model uses clusters on the level of networks using the network ID, as each network represents a mining facility with its separate miners. The proposed approach exploits the cloud services provider “AWS” to create the blockchains, the nodes, and the miners. Also, the proposed model uses “Ethereum” as an underlying base technology for managing the blockchain operations; the Ethereum platform is widely used as an open-source blockchain-based distributed computing application utility.

Moreover, the proposed model uses smart contracts developed with the “Solidity” programming language, which will be first deployed with the address to the blockchain, and then executed using its current hexadecimal address (Open-Query-Transfer).

It is worth mentioning that “Solidity” exploits the hashing algorithm KECCAK-256, as an alternative to the NIST standardized SHA-3 hash function, to verify the chained blocks (i.e., proof-of-work). The algorithm is defined as:  $(m,n) = \text{POW}(H_n, H_n, d)$  where  $m$  is the mixHash,  $n$  is the nonce,  $H_n$  is the new block’s header,  $H_n$  is the nonce of the block header, and  $d$  is the DAG (is a large dataset). The mixHash is a hash that, when combined with the nonce, proves that this block has carried out enough computation.

Thus, the proof of work (POW) controls the level of difficulty of attaching a block to the blockchain, and as a result, increasing the difficulty level will make the process of formulating the hash which matches the target hash more complex and will eventually consume more time.

### A. Proposed Model

This research introduces a novel blockchain-based model for securing IoT transactions in the healthcare environment; the model that simulates the blockchain workflow on healthcare-based systems contains the following main components:

1) *Hospital / Clinic Miners*: miners are responsible for creating block transactions and attaching them to the blockchain.

2) *Transactions*: each transaction in the blockchain holds internal logic pertaining to the relevant smart contract. Once the transaction processing starts, the smart contract gets executed and the final output is conducted. There are three types of transactions within the proposed model: the “Open”, “Query”, and “Transfer” transactions, each of which is responsible for executing operations on the patient EMR file.

3) *Local Blockchain*: in each healthcare entity (hospital or clinic), a local private blockchain holds the blocks with its transactions, where each block has its own signature in addition to the previous block hash signature. The very first block in the blockchain is called the “genesis block”; it contains the setup configuration which controls the behavior of the blockchain in addition to controlling the security measures. The genesis block parameters will affect the process of attaching the new block of transactions, as the hashing algorithm will get harder based on the genesis block parameters, and thereby such configuration will directly affect the performance of the transactions’ processing.

4) *Global Blockchain*: as the healthcare sector usually consists of more than one medical entity, peering between these entities is established to sync the mining operations on different entities, in which such a peering process shall establish the global blockchain scope. The peering process is achieved via the “addpeer” request, and once the two blockchains are peered, the mining process is synced between the two blockchains, as demonstrated in Fig. 3. Upon successful peering request process, the mining operation will

be the responsibility of more than one miner, as each blockchain has one miner, each of which works at the same difficulty level value of the two blockchains.

5) *Overlay Network*: it enables a distributed functionality on the proposed model architecture. Clusters, which are a group of network nodes, are used to decrease network overhead.

### B. Proposed Model Design

Figure 4 illustrates the proposed model which clusters the network using the Network ID that represents a mining facility with its separate miners. The model also consists of private blockchains on the cloud services provider “Amazon Web Services (AWS)” for the sake of creating the blockchains and the nodes in addition to the miners, utilizing “Ethereum” as an open-source blockchain-based distributed computing application platform.

### C. Proposed Model Transaction Structure and Flow

On each entity, the private Ethereum blockchain is set up with the predefined setup configuration found on the Genesis block, where the mining process on the blockchain is controlled according to the setup configuration parameters on the genesis block. In each mining operation, a new block is created, and the transactions are included within the newly created block, and at the end, the block is attached and added to the chain.

Fig. 3. Ethereum Blockchain Peering.

Fig. 4. Proposed Model Design.

Three main types of transactions are configured in the proposed model, namely, the “Open”, “Query”, and “Transfer” transactions, where each of them is executed via the smart contracts that contain the designated logic to be executed.

IV. IMPLEMENTATION

Fig. 5 is a flowchart that illustrates the steps of the addition and validation cycle in the proposed system.

A. Blockchain Initialization: The Genesis Block

The Genesis block contains the configuration of the private Ethereum network which will be used by all the miners, clusters, and nodes. The ChainId is used as the cluster identifier, where other configuration data inside the Genesis block will contain the following parameters/attributes:

- nonce: 64-bit string hash which, along with the mixHash, controls the amount of computation made for attaching the block to the blockchain.
- config: optional attribute which contains the ChainId unique identification of the private network; EIP150Block is used for fast sync, EIP155Block is used to reduce the probability of replay attacks, and EIP158Block controls how Ethereum clients handle empty accounts.
- timestamp: mainly used for verifying the order of the block within the blockchain.
- parentHash: a KECCAK 256-bit hash that points to the parent block.
- gasLimit: a scalar value that represents the limit of gas expenses of a single block in the blockchain.
- extraData: an optional parameter of 32 bytes at most, used for saving additional information if any.
- mixHash: a 256-bit hash which, together with the nonce, controls the level of computations used for verifying and attaching the block to the blockchain.
- coinbase: a 160-bit address, which is also called “etherbase”, holds all the successful mining operations amount.
- difficulty: a hexadecimal value that defines how hard it is to mine a block; the higher the value, the slower the mining process, since the mining operation will require more complex computations. Based on such difficulty value, hash computation is expected to run before obtaining a successful mining operation.
- alloc: optional parameters for predefining start balance on the mining account.

A typical example of the Genesis block structure:

```

# Study on Early Warning on the Financial Risk of Project Venture Capital through a Neural Network Model

Xianjuan Li

Hunan City University  
Yiyang, Hunan 413000  
China

**Abstract**—This paper aims to effectively reduce the financial loss of enterprises by accurately and reasonably making early warning of investment project risks. This paper briefly introduced the index system used for investment project risk early warning. It constructed a project investment risk early-warning model with a back-propagation neural network (BPNN) algorithm, and improved it with a genetic algorithm (GA) to solve the defect that the traditional BPNN is easy to fall into, over-fitting when reversely adjust parameters. An analysis was conducted on an electric power company in Hunan Province. Orthogonal experiments are performed to determine the population size and the number of hidden layers in the improved BPNN algorithm. The results showed that the improved BPNN algorithm had the best performance when the population size was set as 25 and the number of hidden layers was four; compared with support vector machine (SVM) and traditional BPNN algorithms, the GA-improved BPNN algorithm had better performance for early risk warning of investment projects. In conclusion, adjusting the parameters of a BPNN with a GA in the training stage can effectively avoid falling into over-fitting, thus improving the early warning performance of the algorithm; in addition, the improved BPNN has better early warning performance.

**Keywords**—Neural network; project investment; early risk warning; genetic algorithm

## I. INTRODUCTION

The rapid development of the economy has led to the emergence of various new enterprises, which further promotes the development of the economic market. In the process of enterprise development, the scale of an enterprise will be expanded, and during expansion, in addition to the existing profitable projects, the enterprise will also invest in other profitable projects [1] to further expand revenue and accelerate its development. However, there are few projects in the market that can make steady earnings, and more often than not, the projects available for investment carry different degrees of risk. Generally speaking, the higher the risk of an investment project is, the higher the ultimate return is, but the high risk of an investment project also means that the project is more likely to fail and lead to losses. The risk level of a project depends not only on the success probability of the project but also on the ability of enterprises to bear the losses after project failure [2]. When faced with the same project with a probability of failure, large enterprises that have more financial support than small

enterprises can still operate normally even if the project fails, while small enterprises may not be able to operate normally, i.e., small enterprises will take more risks when facing the project. Therefore, before investing in a risky project, an enterprise needs to make an early warning assessment of project risks in conjunction with its financial situation to minimize the loss of the venture investment. The early warning assessment of a venture usually requires the appropriate professional knowledge of the assessor, but the managers of enterprises generally do not have the relevant professional knowledge [3]. Relying excessively on expert experience and subjective judgment when making decisions on a venture will seriously affect early risk warning. Therefore, enterprises need a relatively perfect project venture capital model to objectively warn the risk of investment projects and guarantee the smooth operation of the projects. This paper briefly introduced the index system used for investment project risk early warning, constructed a project investment risk early-warning model with a back-propagation neural network (BPNN) algorithm, optimized it with a genetic algorithm (GA), and analyzed an electric power company in Hunan Province. The novelty of this paper lies in the use of the GA to adjust the parameters in the BPNN, avoiding falling into over-fitting when adjusting the parameters reversely. The organization of this paper is introduction, related works, the construction of the neural network-based early financial warning model, example analysis, discussion, and conclusion.

## II. RELATED WORKS

Zhu et al. [4] constructed a financial risk early-warning model based on the K-means clustering algorithm and found that the K-means clustering algorithm effectively avoided the negative subjective impact brought by artificially divided thresholds. Sun et al. [5] constructed a back-propagation neural network (BPNN)-based financial early-warning model, took mining listed companies as the research object, and found that the constructed early-warning model had a high prediction accuracy. Li et al. [6] introduced the L1 regularized support vector machine (L1-SVM) into the modeling of financial early warning systems as an effective feature selection technique and verified the feasibility of the technique in practical applications. Ouyang et al. [7] proposed a long short-term memory (LSTM) neural network under an attention mechanism for early warning of financial market risks. The final experimental

results showed that this neural network had good generalization ability and higher prediction accuracy compared with BPNN, support vector regression (SVR), and autoregressive integrated moving average (ARIMA) models. Qu et al. [8] put forward an improved kernel principle component analysis-based financial risk prewarning model for public hospitals, conducted experiments on the financial data of multiple public hospitals and listed companies, and verified the feasibility and effectiveness of the method. Ding [9] proposed to establish a fuzzy theory-based early risk warning management and intelligent real-time monitoring model system for financial enterprises and analyzed a listed company engaged in automobile sales. His study found that the use of fuzzy theory and modern network technology provided more accurate early warning and assessment of potential and apparent risks of financial enterprises. Feng et al. [10] constructed a BPNN-based enterprise financial risk prewarning model to predict financial crises and verified that the constructed prediction model could accurately predict the financial crises of the enterprises through predicting the finance of 200 manufacturing enterprises in 2018 and 2019. Qi et al. [11] proposed a variable precision rough set weighted k-nearest neighbor (KNN) network-based financial risk control algorithm and verified the algorithm's algorithm through experiments. Zhang [12] used fuzzy neural networks to warn the credit risk of financing platform loans, verified the effectiveness of the algorithm by example analysis, and gave relevant suggestions.

### III. NEURAL NETWORK-BASED EARLY FINANCIAL RISK WARNING

#### A. Constructing Early Risk Warning Indicators

Before warning financial risks of an investment project, it is necessary to build an indicator system that can determine the investment risks of the project, and these indicators will be used as input parameters of the project risk early-warning model [13]. Selecting early risk warning indicators generally follows the criteria of indicator criticality, data source accuracy, indicator relativity, indicator validity, and indicator simplicity. Indicator criticality means that the selected indicators are related to capital flow. Data source accuracy means that the selected indicators can be obtained from the data sources. Indicator relativity means that the selected indicators are relative indicators, ignoring the influence of company size as much as possible. Indicator validity means that the selected indicators need to be universal and valid. Indicator simplicity means that the selected indicators should be easy to calculate.

Different companies will invest in different types of projects due to their different positioning, and the risks possessed by different types of investment projects are also different. Therefore, only the general classification of indicators is given here, and the specific indicators will be given in the example analysis below. As shown in Fig. 1, the risk variables of project investment can be broadly classified into four types of risks: economic, technical, policy, and environmental risks. Project economic risk refers to the crisis faced by the investment project at the economic level. Project technical risk refers to the technical risk that arises during enterprise operation that can affect the project. Project policy

risk refers to the degree of influence that can be caused by laws and regulations in the project investment process. Project environmental risk refers to the degree of influence of the local environment during the operation of the investment project, and outdoor projects are more likely to be affected by the environment, which requires specific analysis in different cases [14].

Fig. 1. General Classification of Early Risk Warning Indicators for Investment Projects.

#### B. Neural Network-Based Project Risk Early-Warning Model

The evaluation indicators of investment projects will be input into the input layer of the BPNN algorithm [15]; therefore, the number of nodes in the input layer depends on the number of indicators used to evaluate the risk of the investment project. The output layer outputs the evaluation results of the risk level of the investment project. The risk level is represented by 1, 2, 3, 4, and 5. "1" represents a low risk, and the larger the value is, the higher the risk is. The hidden layer is the core structure of the BPNN algorithm, and its number is decided according to the demand. Usually, the more the layers and nodes are, the deeper the law can be mined, and the more accurate the model prediction is, but it will increase the amount of computation [16]. The basic process of constructing an early warning model for investment project risk is as follows.

1) The indicator data of different investment projects are collected according to the constructed financial risk early warning indicator system, as well as the risk assessment results of corresponding projects.

2) The collected data are pre-processed to eliminate the abnormal data. The indicator data of investment projects are input into the input layer of the BPNN algorithm.

3) The indicator data in the input layer are calculated layer by layer in the hidden layer [17]:

$$a = f\left(\sum_{i=1}^n \omega x_i - \beta\right), \quad (1)$$

where  $a$  is the output of every layer,  $\beta$  is the adjustment term of every layer,  $f(\bullet)$  is the activation function [18], and  $\omega$  is the weight between layers.

4) The output result of the last hidden layer is passed to the output layer. The softmax function calculates in the output layer. The risk level of the investment project is output according to the calculation result.

5) The risk level of investment projects calculated by the BPNN algorithm is compared with the actual risk level obtained when collecting data, and the error between them is calculated. The cross-entropy [19] is used as the calculation error. The calculation formula of the error is:

$$E = -\sum_i y_i \cdot \ln p_i \quad (2)$$

where  $E$  is the error,  $i$  is the label serial number, which is the risk level,  $y_i$  is the judgment parameter [20], whose value is 1 when the actual risk level of the project is  $i$  and 0 otherwise, and  $p_i$  is the probability that the project risk level is  $i$  in the calculation result.

6) Whether the BPNN algorithm reaches the termination condition is determined. If it does, then the training ends, and the construction of the early risk warning model ends; if not, then the weight parameter in the hidden layer is reversely adjusted. The termination conditions for training the model are that the number of iterations reaches the preset maximum value or the calculation error converges to the preset threshold. The training is stopped when either of the above two termination conditions are met.

The adjustment of the weight parameter in the hidden layer is based on the calculation error and learning rate. The output result converges in the direction of minimum error through the calculation error and learning rate. In this reverse adjustment process, the learning rate is crucial as it controls the convergence speed of the algorithmic model, and it is usually a fixed value; however, in the practical application process, there are a large number of local minima in the nonlinear error surface, and once the model training falls into the local minima, it is difficult to get out, which will seriously slow down the convergence speed [21]. Therefore, the GA is introduced to adjust the weight parameter of the BPNN algorithm.

The process of training the improved BPNN algorithm using the GA [22] is as follows. Firstly, the chromosome population is generated for the GA. Every chromosome represents a parameter scheme of the BPNN algorithm, and every gene in the chromosome represents a parameter to be adjusted. Then, the parameter schemes represented by the chromosomes are substituted into the BPNN algorithm for forward computation according to steps (1)~(5) described previously to obtain the error. Then, whether the training should be terminated is determined. If not, the genetic operation is performed on the chromosome population, including crossover and mutation [23]. The crossover operation refers to exchanging the data on the same gene locus of two chromosomes according to the crossover probability, and the mutation operation refers to changing data at a single chromosome locus according to the mutation probability. The genetically manipulated population is substituted into the BPNN algorithm again to repeat steps ①~⑤ are repeated until the model reaches the termination condition.

## IV. EXAMPLE ANALYSIS

### A. Analysis Object

An electric power company in Hunan Province was taken as an example. The work that this power company can undertake includes power engineering survey, manufacturing, design, and sales. The company has a relatively good organizational structure. The shareholders' meeting is the highest authority of the company and appoints other departments. The board of directors is the representative department elected by the shareholders' meeting to manage the company's business operations, and the operating management layer established under the board of directors manages 11 departments.

The basic process for project investment is to bid and process the winning project. The company's management department does not have a set of strict evaluation procedures. The department manager expresses his investment intention first, and then the financial department decides whether the project can be invested in after a simple qualitative analysis. The whole process is highly subjective and nonstandard.

In addition to qualitative analysis that can determine the presence or absence of project risks, quantitative analysis is also needed to determine the level of project risks to help the management layer make more scientific and rigorous judgments [24].

### B. Project Risk Early Warning Indicator System

The project data required for the case study were collected from the information disclosed on the official website of the company. A field survey was conducted on the company to collect project analysis information such as project investment plans and cost reports that are publicly available.

These data were pre-processed before formal use, which was because the data volume that the company could provide was limited and some projects were suspected of fraud. Pre-processing supplemented some data and eliminated the part that could not be supplemented. After pre-processing, the total number of samples was 500, of which 300 were randomly selected as the training set and the remaining 200 as the test set.

Before establishing the improved BPNN-based early risk warning model, the corresponding early risk warning indicator system was established. This paper analyzed the early warning indicators of this electric power company by referring to the general classification of the indicators given in the previous section. There were thirty-four second-level indicators under the four first-level indicators of economy, technology, policy, and environment. Although more early warning indicators were good for prediction accuracy, the calculation volume was also larger. Some indicators had low relevance and would not affect the prediction even if ignored. Thus, the 34 second-level indicators were screened to eliminate those with low relevance to reduce the computational effort.

Table I shows the early warning indicators screened after the KMO test, Bartlett test [25], and regression analysis, the KMO test statistic was 0.736, which exceeded 0.7, and the Bartlett test statistic was 276.35. In addition, the p-values of all 13 indicators in Table I were less than 0.01.

TABLE I. THE SCREENED-PROJECT RISK WARNING INDICATOR SYSTEM

The first-level indicators	The second-level indicators	P-value	Kaiser-Meyer-Olkin test	Bartlett's test
Project economic risks	Project cost-income ratio	0.001	0.736	276.35
	Net income ratio	0.000		
	Asset turnover ratio	0.003		
	Turnover of account receivable	0.000		
	Asset-liability ratio	0.003		
	Liquidity ratio	0.002		
	Sales growth rate	0.000		
Preservation and appreciation ratio	0.000			
Project technical risks	Payback period	0.002		
	Construction technology	0.000		
	Construction management	0.000		
Project environmental risks	Project approval method	0.001		
	Social conduct	0.002		

C. Parameter Setting

A BPNN algorithm modified by the GA was used to construct a project investment risk early-warning model. The number of nodes in the input layer of the BPNN algorithm was set as 13 according to the feature number of indexes that need to be input, and the sigmoid function was used as the activation function in the hidden layer for fitting nonlinear laws. For the GA-improved BPNN algorithm, factors that affected its prediction performance also included the population size of the GA used for adjusting the weight parameter in addition to the number of hidden layers in its structure. Therefore, orthogonal experiments were used to test the performance of the improved BPNN algorithm with one, two, three, four, and five hidden layers under the genetic population size of 10, 15, 20, 25, and 30. The population size and the number of hidden layers with the best performance were selected and used for the subsequent comparison experiments.

To further test the early warning performance of the improved BPNN algorithm for project risks, it was compared with SVM and traditional BPNN algorithms. The parameters of the SVM algorithm are as follows. The sigmoid function was used as the kernel function for mapping features to a high-dimensional space to linearize nonlinear features as much as possible, and the penalty factor was set as one. The number of nodes of input and output layers and the number of hidden layers of the traditional BPNN algorithm were the same as those of the improved BPNN algorithm, the activation function was used as the activation function, and the learning step length was 0.02.

D. Experimental Results

Table II and Fig. 2 show the results of the orthogonal experiments for the population size and the number of hidden layers of the improved BPNN algorithm. First, it was noticed from Fig. 2 that the overall accuracy of the improved BPNN algorithm for investment project risk prediction increased as the population size and the number of hidden layers increased,

but the overall accuracy of the improved BPNN algorithm tended to be constant after the population size reached 25, and the overall accuracy of the improved BPNN algorithm also tended to be constant after the number of hidden layers reached four. However, comparing the average single-project time consumption under different population sizes and hidden layers in Table II, it was found that the average single-project time of the algorithm always increased as the population size and the number of hidden layers increased. In other words, increasing the population size and the number of hidden layers could increase the overall accuracy of the improved BPNN algorithm and also increase the prediction time, but after they increased to certain levels, the prediction time still increased, but the overall accuracy of the prediction tended to be constant. Therefore, the population size of the improved BPNN algorithm was 25, and the number of hidden layers was four.

Fig. 3 shows the test results of the early risk warning performance of SVM, traditional BPNN, and improved BPNN algorithms for investment projects. It was seen that the accuracy, recall rate, and F-value of the SVM algorithm for early risk warning of investment projects were 75.3%, 70.1%, and 72.6%, respectively; the accuracy, recall rate, and F-value of the traditional BPNN algorithm for early risk warning of investment projects was 91.2%, 82.1%, and 86.4%, respectively; the accuracy, recall rate, and F-value of the improved BPNN algorithm for risk warning of investment projects was 97.5%, 96.6%, and 97.0%, respectively. It was seen from Fig. 3 that the accuracy, recall rate, and F-value of the SVM-based early-warning model were the lowest, and those of the GA-based BPNN model were the highest.

TABLE II. AVERAGE TIME SPENT BY THE IMPROVED BPNN ALGORITHM WITH DIFFERENT POPULATION SIZES AND NUMBER OF HIDDEN LAYERS ON A SINGLE PROJECT

	One hidden layer	Two hidden layers	Three hidden layers	Four hidden layers	Five hidden layers
Population size 10	98 ms	110 ms	131 ms	163 ms	205 ms
Population size 15	121 ms	140 ms	162 ms	184 ms	213 ms
Population size 20	176 ms	195 ms	211 ms	234 ms	252 ms
Population size 25	223 ms	241 ms	264 ms	287 ms	303 ms
Population size 30	251 ms	272 ms	295 ms	316 ms	339 ms

Fig. 2. Overall Accuracy of the Improved BPNN Algorithm under different Population Sizes and Number of Hidden Layers.

Fig. 3. Performance of Different Project Investment Risk Early-warning Models.

## V. DISCUSSION

Conventional enterprises will continue to expand their scales in the process of development, and they will make investments in different projects to obtain returns in the process of expansion. However, all project investments are risky. Usually, the greater the risk, the higher the return, but high risks also means that the probability of project failure. Once a project fails, the enterprise will suffer from huge losses, which is not conducive to its development. Thus, before investing in a new project, companies need to assess the risk to assist them in making decisions about the project investment. Traditional risk assessment is done manually, which is inefficient and subjective. In order to improve the efficiency of risk assessment and also to enhance the objectivity of the assessment results, intelligent algorithms are introduced into the early warning of project investment risks. This paper selects the BPNN algorithm, which can make a good fit to the nonlinear law, to warn the project investment risk and improved the traditional BPNN algorithm with the GA. Finally, an electric power company in Hunan province was analyzed, and the improved BPNN algorithm was compared with SVM and traditional BPNN algorithms. The experimental results have been shown in the previous section.

In the orthogonal experiments conducted by the improved BPNN algorithm on the genetic population size and the number of hidden layers in the BPNN, the early warning accuracy of the algorithm gradually increased but also stabilized as the population size and the number of hidden layers increased, and meanwhile the evaluation time also increased. The reason is as follows. The increase in the population scale made the parameters lead to more choices of parameters in the BPNN and increased the possibility of finding suitable parameters, and the increase in the number of hidden layers allowed the algorithm to fit the nonlinear law better, thus the early warning accuracy increased. However, both the increase in the population size and the increase in the number of hidden layers increased the computational effort of the algorithm, leading to an increase in computation time.

The comparison of the three early warning algorithms showed that the improved BPNN algorithm had the best performance, followed by the traditional BPNN algorithm, and the SVM algorithm had the poorest performance. The reason is as follows. Although the SVM algorithm could classify the risk level of investment projects relatively quickly and effectively,

the hyperplane it used was difficult to fit the nonlinear law; the traditional BPNN algorithm could fit the nonlinear law better, but the local minimum in the error surface in the training process could make the algorithm converge prematurely; after the improvement by the GA, the crossover and mutation operations adjusted the parameters to avoid falling into the local minimum, and the BPNN algorithm fully applied its nonlinear fitting to explore the laws, so it performed better in early warning.

## VI. CONCLUSION

This paper briefly introduced the indicator system used for investment project risk early-warning and used the BPNN algorithm to construct the project investment risk early-warning model. The BPNN algorithm was improved by the GA. An electric power company in Hunan Province was taken as a subject for analysis. The population size and the number of hidden layers in the improved BPNN algorithm were determined by orthogonal experiments. The results are as follows. (1) The increase in population size and the number of hidden layers in the improved BPNN algorithm improved the early warning accuracy; when the accuracy tended to be constant, the average time spent on early warning for a single project increased, so the final population size was set as 25, and the number of hidden layers was set as 4. (2) The accuracy, recall rate, and F-value of the SVM-based early-warning model were the lowest, those of the traditional BPNN algorithm-based model were higher, and those of the GA-improved BPNN algorithm-based model were the highest.

# Improving Privacy Preservation Approach for Healthcare Data using Frequency Distribution of Delicate Information

Ganesh Dagadu Puri, D. Haritha

Department of Computer Science and Engineering  
Koneru Lakshmaiah Education Foundation  
Vaddeswaram, AP, India

**Abstract**—In the modern world, everyone wishes that their personal information wouldn't be made public in any manner. In order to keep personal information hidden from prying eyes, privacy protection is essential. The data may be in the form of big data and minimization of risk and protection of sensitive data is important. In this research, a revolutionary customized privacy-preserving method is implemented that addresses the drawbacks of earlier personalized privacy as well as other anonymization methods. There are two main components that make up the proposed method's core. Delicate Information and Delicate Weight are two additional attributes which are used in the record table, are covered in the first section. The record holder's Delicate Information (DI) decides whether or not secrecy should be kept or if it should be shared. How delicate an attribute value is compared to the rest is indicated by its Delicate weight (DW). The second part covers a new representation used for anonymization termed the Frequency Distribution Block (FDB) and Quasi-Identifier Distribution Block (QIDB). According to experimental findings, the proposed system executes more quickly and with less data loss than current approaches.

**Keywords**—Privacy preservation approach; quasi identifier distribution block; frequency distribution block; big data; anonymization

## I. INTRODUCTION

Electronic Medical Records (EMRs) are currently widely used in healthcare networks. It makes it possible for people to easily and adaptably exchange their medical data. For instance, instead of needing to search through multiple physical records, a patient or his/her physician merely needs to access the data from a database to locate their diagnostic report. Advanced electronic medical record systems face a significant issue when it comes to securely storing and accessing electronic medical records because healthcare information is so sensitive [1]. Hadoop and big data analytics play a significant part in analyzing and processing the patient information in many forms to provide potential uses [2]. Investigation can leverage private data from several organizations to identify patterns. For instance, if a patient's private data is available across various hospitals, researchers can utilize it to better understand the patterns associated with a given disease and, as a result, make a more accurate diagnosis. The unprocessed information found in hospitals includes specific information on the patient, such as identity, address, date of birth, zip code, symptoms and

illness[3]. Before being delivered to the data receiver, the name and residential address information that are deemed private are stripped from the raw data which is also known as micro data. Furthermore, this micro data includes information like postal code and date of birth that can be connected to other external, publicly accessible data bases to re-identify sensitive value[4]. Linking attack refers to the process of re-identifying a record by connecting published data to publicly available data. Let us consider the patient records released by the hospital in Table I, for instance, which excludes data like name, residential data, and other private details. By joining the information from Table I with the publicly accessible external data base given in Table II, the intruder can disclose personal information. The query may appear like,

Select name, disorder from external\_table as A, patient\_table as B where A.postal=B.postal and A.age=B.age;

Since people are reluctant to volunteer their private data, it is extremely concerning that the answer to this query provides complete data about the illness and the name of the person. The join, which is referred to as Record Level Disclosure, may provide a value for age 36 and postal code 38677. Researchers employ techniques categorized as Privacy Preserving Data Publishing (PPDP) to hide confidential material from recipients. Quasi-Identifier (Q) attributes are characteristics found in Released Patient Data that can be connected to external, publicly accessible data bases, such as Postal Code, Date of Birth, etc. Data is modified in a way that leads to duplicate rows in the resulting table, limiting disclosure. Through the use of generalization, there has to be more than one implicit connection to the external data base. Thus, the k-anonymity algorithm is implemented for measuring this. Each entry in a table is indistinguishable from minimum k-1 other entries with regard to each and every set of quasi-identifier attributes if it fulfills the k-anonymity condition; such a table is known as a k-anonymous table.

With personalized anonymization, a guard node is utilized to determine if the record holder is willing to disclose the level of sensitivity upon which the anonymization will be carried out. As the record owner sensitivity is a generic one, the majority of the sensitive values that are included in the secret data base do not necessitate privacy protection. Therefore, just a small portion of the distribution's records need to be private. For instance, a record holder with malaria will not really mind

sharing his identity, in contrast to a record holder with HIV. The fact that some HIV-positive record owners are willing to expose their identities justifies this proposed privacy preservation strategy.

In other words, every group of quasi-identifier values needs a minimum  $k-1$  records, and they can be tricked by connecting a record from the disclosed data to a database with many entries that is publicly accessible. A two-anonymous generalization for Table I is shown in Table III. Assuming that the intruder uses a publicly accessible database and discovers that Ramesh is 36 years old with a postal code of 38677 and that he has a disorder, the intruder looks at anonymized Table III and learns that 38677 and 36 have been generalized to 386\*\* and [30-40] which can be associated with two entries of releases table and that the disorder cannot be derived from this information. Lung disease has been hidden and is not intended for publishing in this table ( $\langle 386^{**}, [50-60], \text{Lung Disease} \rangle$ ). Similar findings occur if the intruder attempts to infer Sitaram's illness, which belongs to category 3, but since every member of the category possesses the same sensitive property, the attacker deduces that Sitaram has fever.

Attribute level disclosure results from this release of confidential information. This occurs when a set of disorders are indeed symptoms of the same condition. To tackle this issue  $l$ -diversity was introduced. If the sensitive characteristic has at minimum 1 "well-represented" values, then an equivalence class has  $l$ -diversity. If each equivalence class in a table possesses  $l$ -diversity, the table has  $l$ -diversity. Additionally, skewness and similarity attacks are a drawback of  $l$ -diversity. Proximity was viewed as a method of overcoming this. The distribution of sensitive attributes in this strategy must match the anonymized chunk. Thus, there is a data loss.

In this paper, the research work is arranged into five sections. In Section 2, related work of various researchers and research limitations are described in detail. In Section 3, our proposed model is discussed. Experimental findings and discussion of each test is described in Section 4. Thus, in Section 5, research work is concluded and future scope of work is discussed.

## II. LITERATURE SURVEY

Two anonymous techniques were presented by Xingguang Zhou et al. [5] that not only ensure data secrecy but also realize anonymity for patient. When attackers select attack destinations before gathering data from the electronic health record, the first strategy obtains modest security. The second strategy ensures total security by having attackers select attack targets in an adaptive manner upon contact with the electronic medical record system. It also suggested a method for EMR holders to use an anonymous search engine to find their electronic health records. As per Safa Bahri et al. [6] enormous amount of information, especially clinical data, has recently been amassed as a result of the intensification of emerging innovations that the large majority of people in the globe have accepted. Medical associations have acquired and analysed this clinical information and gain information and ideas that may be used to a variety of clinical judgments, including recommendations for medications and improved diagnoses. This paper mentions the significant effects that Big Data has on healthcare stakeholders, including patients, doctors, pharmaceutical and medical technicians, and medical insurance companies. It also examines the various difficulties that must be overcome in order to maximize the advantages of all the Big Data and the software that are presently accessible. Such large data can be stored on the devices customized to application processing [7].

A Secured as well as Anonymous Biometric Based User Authentication technique is introduced by B D Deebak et al. in 2017 [8] to guarantee secure data transmission in medical applications. This study demonstrates that a hostile cannot pretend to be a registered user in order to get unauthorized entry to or revoke an intelligent mobile card. For the purpose of demonstrating security and energy efficiency in healthcare application systems, a formal study relied on the random-oracle approach and resource evaluation is presented. The suggested method also incorporates some efficiency study to demonstrate that it offers high-security characteristics for developing intelligent medical application systems in the IoM. In 2019, Jorge Bernal Bernabe et al. [9] conducted a thorough evaluation of the State-of-Art (SoA) for privacy-preserving research approaches and methods in blockchain, and also the primary connected privacy issues in this exhilarating and disruptive technology. The survey includes privacy strategies in permissioned and privatized blockchains along with privacy-preserving research report and methods in accessible and private blockchain, such as Bitcoin and Ethereum. The analysis of various blockchain use cases includes looking at areas including Electronic-Government, Electronic-Health, crypto currency, developed cities, and cooperative ITS.

A Privacy-Preserving-Reinforcement-Learning (PPRL) architecture for the cloud computing system is proposed by Jaehyoung Park et al. in 2020 [10]. The proposed methodology makes use of learning with errors based cryptosystem for completely homomorphic encryption. Various cloud computing dependent intelligent service contexts are used to carry out effective analysis and assessment for the developed PPRL architecture. A stateless cloud monitoring approach for non-manager adaptive group data with preserving the privacy is proposed by Xiaodong Yang et al. [11]. With the random masking approach, the proposed methodology not only achieves individual identity privacy preservation but also data confidentiality preservation. Marwa Keshk et al. [12] present a thorough analysis of the most recent privacy-preserving methods for defending Cyber Physical System (CPS) technologies and their data against online threats in 2021. The ideas of privacy preservation and CPSs are examined, with an emphasis on the parts of cyber physical systems and how these systems might be hacked physically or digitally. Abdullah Al Omar et al. [13] presented an approach for the healthcare system which ensures data security and transparency. Additionally, the Ethereum platform is used to integrate insurance policies into the suggested system's blockchain, and cryptographic techniques are used to protect private information.

A mathematical formulation for an identity-based encryption strategy for the protection of patient confidentiality during the gathering of clinical records for evaluation is presented by Kissi Mireku Kingsford et al. in 2017[14]. The submission of medical data for analysis is becoming an essential element of daily life. To protect the confidentiality of patient, the model dissociates the identity of the patient from the investigated data upon data submission. A thorough analysis of privacy protection in big data from the communication point of view is presented by Tao Wang et al. in 2018[15]. It focuses on privacy-preserving methods,

especially differential privacy, and the basic privacy-preserving paradigm. Additionally, it examines the difficulties with differential privacy as well as its variations and modifications for various novel apps. Muneeb Ul Hassan et al. [16] have performed a detailed analysis of differential privacy approaches for CPSs as presented in 2019. Specifically, it looks at how differential privacy is used and implemented in four key CPS uses: energy, medical, transportation, healthcare & industrial Internet of things. It also outlines unresolved problems, difficulties, and prospective research directions for CPS differential privacy approaches. This investigation can be used as the foundation for the creation of cutting-edge differential privacy methods to handle numerous issues and CPSs' data privacy contexts.

The privacy of Kim's approach was assessed by Kefei Mao et al. [17], who show that the plan is actually vulnerable to the stolen smart - card threat. The plan also has some impassable stages, and the privacy assumption is excessively rigid. In addition, a novel technique built on Kim's as well as the quadratic residue hypothesis is investigated. In contrast to the current plans, the latest proposal does not call for the electric medical record database to personally communicate different secure values with patients and physicians. As a result, it is more useful and practical. It demonstrates that the suggested approach can offer greater protection than Kim's earlier plan. A unique architecture to enable privacy-preserving Machine learning (ML) was proposed by Kaihe Xu et al.[18], where the training data are spread and every shared data chunk is of enormous volume. To accomplish privacy preservation, it actually makes use of the Apache Hadoop platform's data locality attribute and just a few cryptographic functions at the Reduce functions. The comprehensive simulations used to show the presented strategy's robustness and consistency demonstrates that it is safe in the semi-honest framework.

In 2017, Tanashri Karle et al. [19] focused on protecting privacy by utilizing an anonymization methodology and a thorough investigation of two anonymization techniques are discussed namely - Datafly Technique and the Mondrian Algorithm. While Mondrian method is more suited for real datasets, Datafly technique is better suited for synthetic datasets. By using privacy preservation on a medical dataset in 2017, Balaji K. Bodkhe et al. [20] preserve a person's identity and any associated disorders (sensitive feature). The techniques including slicing, generalization, suppression and bucketization are utilized. These techniques guarantee privacy preservation while maintaining the usefulness of the data. The goal of S.Sathya et al. [21] is to take advantage of the new privacy difficulties posed by big data and focus on effective, privacy-preserving computation in the big data era. In order to address the effectiveness and privacy needs of Data Mining (DM) in the big data era, it first formalizes the overall framework of big data analytics, identifies the related privacy requirements, and introduces an effective and Privacy-Triple-DES as an instance.

To minimize and protect the data from unwanted parties, S. Shimona et al. [22] offer the PPDM strategies in a concise manner together with other privacy preservation measures in 2020. In 2020, Suneetha V et al. [23] introduced a unique concept called spark that uses Apache Spark to manage big data in the health care industry quickly and effectively while

using K-anonymization as well as L-diversity to disguise private data. The suggested method ensures that shared information will not reveal the actual information and that sensitive data is separated before being sent to Hadoop distributed file system. In 2019, Hui Jiang et al. [24] highlighted the fundamental steps of Hadoop-based big data analysis and included technical recommendations for common actual and off-line application scenarios. These recommendations were based on a review of the ecological structure of Hadoop. In order to have some reference value for the development of a big data platform and for the analysis and processing of huge data, Hadoop was utilized to construct the application context and the WordCount scenario was merged to assess the MapReduce calculation procedure.

A cooperation privacy preservation strategy for wearable technology was developed in 2018 by Hong Liu et al. [25] with id validation and data access control concerns in the space and time-aware settings. To obtain a secure healthcare pathway query under e-medical cloud servers without disclosing the secret data of patients like name, sex, age, location and also the information of hospitals like diagnosis, medication, and cost. Mingwu Zhang et al. [26] suggested a Privacy Preserving Enhancement of medical pathway query method. To maintain confidentiality in the e-Healthcare system, the suggested methodology first develops a number of privacy-preserving protocols like privacy-preserving medical comparison, privacy-preserving phase selection, and privacy-preserving phase update. It then implements the greedy approach in a secure way to carry out the query as well as the Min-Heap innovation to make it more efficient. This approach is feasible and effective with regard to computational time and cost, according to test findings. In 2018, Abdulatif Alabdulatif et al. [27] set out to propose a cloud-based solution for real-time patient monitoring that protects user privacy by spotting changes in a variety of important health indicators of participants of smart communities. IoT-enabled wearable devices' produced vital sign information is analysed in real-time on the cloud. The construction of a predictive method for the smart community while taking into account the sensitivity of information processing in a third-party context is the main topic of this paper (e.g., cloud computing). For enabling data prediction with patterns, it designed a crucial sign change detection method employing Holt's linear trend approach, where completely homomorphic encryption technique is applied to carry out calculations on an encrypted area that may protect data privacy. Additionally, a parallel strategy for encrypted operations using the MapReduce method of Apache Hadoop was proposed in order to minimize the burden of the completely homomorphic encryption technique across massive healthcare data.

The difficulties and needs of creating frameworks and procedures for globally distributed data processing are investigated and discussed by Shlomi Dolev et al. in 2017 [28]. It categorizes and studies the overhead problems associated with batch, stream and SQL-style processing using geo-distributed architectures, methods, and techniques. Using differential privacy, Miao Du et al. [29] present and put into practice a ML technique for smart edges in 2018. In a wireless big data situation, anonymization in training datasets is the

main priority. Additionally, it designs two distinct techniques, Output and Objective Perturbation which fulfill differential privacy, and guarantees privacy and security by including Laplace techniques. Additionally, for correlated datasets, differential privacy preservation algorithms are offered, providing privacy through theoretical inference. Ultimately, tests were conducted using TensorFlow and the effectiveness of the technique was assessed using the four datasets STL-10, SVHN, MNIST and CIFAR-10. The suggested approach effectively ensures accuracy upon benchmark datasets while safeguarding the confidentiality of training datasets.

A scalable approach to the local-recoding issue for big data anonymization over proximity privacy violations was investigated by Xuyun Zhang et al. [30]. The study proposes a proximity privacy framework that provides the semantic proximity of sensitive values including numerous sensitive attributes. It also models the local recoding issue as a proximity-aware clustering issue. It presents a scalable two-phase clustering method that combines the proximity-aware agglomerative clustering technique and the t-ancestors clustering technique. The methods were created using MapReduce to provide good scalability using cloud-based data-parallel processing. Numerous tests using real data sets show that the method greatly outperforms existing methods in terms of scalability, time efficiency, and capacity to fight against proximity information leakage.

As per Haiping Huang et al. [31], Electronic-healthcare has substantially benefited from the industrialization of cloud computing, Internet of things and Wireless-body-Area-Networks (WBANs). Furthermore, there are still several obstacles standing in the way of e-Healthcare's growth, especially issues with data security and privacy protection. Healthcare system architecture is formulated to overcome these issues. It gathers health information from WBANs, transfers it across a substantial wireless sensor network, and then releases it into Wireless-Personal-Area-Networks (WPANs) through a gateway. Additionally, healthcare system uses the Homomorphic Encryption Dependent on Matrix scheme to assure confidentiality, the Groups of Send-Receive Model strategy to accomplish key distribution, and an intelligent system capable of autonomously analyzing the encrypted health data and reporting the findings. The confidentiality, privacy, and improved efficiency of healthcare system are evaluated theoretically and experimentally in comparison to existing systems or techniques. Lastly, the practicality of the healthcare system prototype implementation is examined. A privacy-preserving approach is put forth by Marwa Keshk et al. in 2019 [32] in order to obtain both safety and confidentiality in intelligent power networks. A two-level privacy component and an anomaly detection component are the framework's two core components. Using open datasets, the outlier detection module trains and validates the outcomes of the two-level privacy component using a Long-Short-Term-Memory DL approach. In contrast to various cutting-edge methodologies, the experiments demonstrated that the proposed architecture can effectively secure data of intelligent power networks and identify anomalous behaviors. The term "optimal distributed estimate" refers to a conceptual framework created by Jianping He et al. in 2018 [33] to examine how to maximize the

assessment of a neighbor's original data using the collected local data. The disclosure probability is then looked into as part of the best estimation for the data privacy evaluation. The privacy-preserving average consensus method's data privacy has been further examined using the established framework, and the best noises for the technique are identified.

In 2018, Weichao Gao et al. [34] used the idea of homomorphic encryption as well as secured network protocol development to tackle the issues of privacy preservation for information auction in CPS. A general Privacy-Preserving Auction Strategy is put forth, in which an unreliable third-party trade platform is made up of the two distinct entities of the auctioneer and interim platform. A winner in the auction procedure is defined and all bidder data is hidden by using homomorphic encryption as well as a one-time pad. However, it also suggests an Enhanced Privacy Preserving Auction Method that makes use of an extra signature verification technique in order to increase the overall security of the privacy preserving auction. Each strategy's viability is confirmed through in-depth theoretical analysis and thorough performance tests, which also include an examination of attack tolerance. A unique privacy-preserving anomaly - based detection methodology, known as PPAD-CPS, is suggested by Marwa Keshk et al. in 2018 [35] for safeguarding private data and identifying hostile findings in power technology and associated network traffic. There are two primary components in the architecture. In order to meet the goal of privacy preservation, a data pre-processing component is first proposed for filtering and changing original information into a new format. Secondly, an anomaly-based detection component utilizing a Kalman Filter as well as Gaussian Mixture Model for accurately predicting the posterior probabilities of normal and malicious events is proposed. Two open datasets, the Power System as well as UNSW-NB15 dataset, are used to test the efficiency of the architecture.

### III. PROPOSED SYSTEM

The privacy-preserving method we propose overcomes the drawbacks of existing techniques and other anonymization methods. There are two main parts that make up the proposed method's core. The first part of the equation concerns with additional attributes utilized in the table namely Delicate Information and Delicate weight. The DI indicates whether the privacy of the record owner's private data should be protected or released. DW determines the sensitivity of the attribute. DW is necessary for DI.

When the person provides their data, DI can be accessed easily from them. DW could be based on previously acquired sensitive attribute information. The same level of protection is provided for every sensitive attributes by conventional privacy approaches, which has been addressed in this approach by the implementation of DI and DW. The flag  $DI=0$  indicates that the entry holder is not willing to share his confidential attribute, while  $DI=1$  indicates that he has no problem doing so. The publisher has highlighted DW for any sensitive attributes where confidentiality is crucial. For instance, a record holder with the fever or gastroenteritis is less reluctant to expose his identify than a label owner with cancer. Whenever the sensitive attribute is a very common disorder

like the fever or mouth ulcer,  $DW=0$  is being used; for a sensitive attribute like brain cancer, which is uncommon,  $DW=1$  is utilized. For  $DW=0$ , DI has a default value of 1, and for  $DW=1$ , the record holder's DI values are accepted.

TABLE IV. DW FOR DISORDERS

Disease	DW
Mouth ulcer	0
Brain cancer	1
Fever	0
Lungs Disease	1

The second section discusses a novel approach for evaluating the distribution known as the FDB and QIDB. Each disorder's spread in the FDB is based on original, personal data. QIDB is formed for each entry with  $DW=1$  and  $DI=0$ . Several QIDB chunks will exist. These chunks are needed to make sure that each particular QIDB and distribution of FDB is synchronized.

TABLE V. PATIENT RELEASED DATA WITH DW AND DI

Postal Code	Age	Disorder	DW	DI
38677	36	Mouth ulcer	0	1
38602	38	Brain cancer	1	0
38678	42	Fever	0	1
38685	46	Fever	0	1
38905	52	Fever	0	1
38906	56	Fever	0	1
38909	53	Fever	0	1
38673	58	Lungs Disease	1	1
38607	65	Lungs Disease	1	0
38655	68	Brain cancer	1	1

TABLE VI. FREQUENCY DISTRIBUTION BLOCK

Disease	Probability
Mouth ulcer	0.1
Brain cancer	0.2
Fever	0.5
Lungs Disease	0.2

#### A. Model and Terminology for Proposed Personalized Privacy

Let R be a connection providing personal information about a set of people. There are four groups of attributes in R.

- Unique Identifiers  $U_j$  - It can be used to identify individuals who are eliminated from R.
- Quasi identifiers  $QI_j$  - its value can be combined with publicly available information to determine a person's identity.

- Delicate attributes  $D_j$  – It is secretive or delicate to the record holder.
- Non quasi identifiers  $NQI_j$  – It doesn't fall into any of the three categories.

The goal of proposed method is to obtain a generalized table  $R^*$  such that distribution of every QIDB is comparable to the diversity of the entire distribution as seen in FDB. For ease of use, the full set of quasi identifiers is denoted by  $QI$ , and its values by  $q$ . In a similar manner, there is a single delicate attribute  $D_i$  and its value  $d$ . Relation  $R$  comprises of  $m$  number of tuples  $R = \{r_1, r_2, \dots, r_m\}$ . Record holder data can be obtained by referring as  $r_j.d$  to represent delicate value and  $r_j.q$  for quasi identifier value  $1 \leq j \leq m$ .

1) *Delicate Weight*- for every tuple  $r \in R$ , its delicate weight is added. This value is derived from Relation  $W(ds, dw)$  where  $ds$  indicates disorder and  $dw$  indicates delicate weight.  $W$  contains  $p$  records

$$r_j.dw = \{ w_j.dw \text{ if } w_j.ds = r_i.d \mid 1 \leq i \leq p \} \text{ for every } 1 \leq j \leq m$$

Table IV provides the  $dw$  value for every disorder. Table I is used to create this distribution.

2) *Delicate Information* - for every tuple  $r \in R$ , its Delicate Information is indicated as  $r.di$ .

$$r_j.di = \{ 1 \text{ if } r_i.dw = 0 \text{ and } r_j.dw = 1 \} \text{ for every } 1 \leq j \leq m$$

The value of user defined ( $ud$ ), is either 0 or 1. If the value of  $r_i.di$  is zero, the user is not prepared to share his information, and if it is one, the user agrees.

Table V shows the values of  $dw$  and  $di$  assuming that the record holder will approve  $di$  value for  $DW=1$ . Additionally, it can be seen that if  $dw=0$ , the corresponding  $di$  is set to 1, showing that the entries' sensitivity is not really important.

3) *Thresholds* - To improve and enhance effectiveness of disclosure, generalization, and suppression, values of threshold are established for a number of personalized privacy aspects.

- $T_n$  - It indicates minimum number of entries in  $R$ .
- $T_{itr}$  - It indicates maximum number of required iterations.
- $T_{sup}$  - It indicates minimum number of delicate values for suppression.
- $T_{dis}$  - It indicates minimum number of delicate values for disclosure
- $T_{acc}$  - It indicates minimum number of thresholds for addition or subtraction.

Several threshold values are suggested because the dispersion aspect is being taken into account. The first value, which was never specified in the earlier representations, denotes the bare minimum number of item sets that must be provided in order to execute anonymization.  $T_{itr}$  is calculated using information of the Value domain hierarchy's height. The generalization is greater and information loss is correspondingly greater when the value of  $T_{itr}$  is high.  $T_{sup}$

denotes the absolute minimal amount of sensitive distribution that could exist in QIDB for that block's deletion following  $T_{itr}$ . The threshold value  $T_{dis}$  represents the amount that can be added or removed from every frequency distribution for every disorder in order to make it equal to the FDB distribution. The frequency of QIDB and FDB will not be completely the same, thus while examining the distribution of every disorder is examined if the frequency in that  $qidb.v.d \pm T_{acc}$  always  $T_{dis} > T_{acc}$ .

4) *Frequency Distribution Block* - Distribution of every  $w_j.ds$  in regards to the original distribution  $r_i.d$  is stored in relation  $FDB(ds, p)$  where  $d$  represents disorder and  $p$  represents probability distribution of it Every  $p$  for  $ds$  is computed by mapping every  $ds$  in  $R$  (values of  $r_i.d = fdbv.ds$ ) to the total no. of tuples in  $R$ , for every  $1 \leq v \leq k$ . Considering there are  $m$  entries in the relation.

5) *Quasi - Identifier Distribution Block*- for every  $r_j.d$  where  $r_j.dw=1$  &  $r_i.di=0$  a new QIDB is generated comprising  $r_i.s$  for every  $1 \leq j \leq m$ . The relation  $QIDB.V(q, d)$  where  $qidb.vl.q = r_j.q$  &  $qidb.vl.d = r_j.d$ . Considering there are  $m$  QIDB chunks.

TABLE VII. QIDB.1 DATA

Postal Code	Age	Disorder
38602	38	Brain cancer

TABLE VIII. QIDB.2 DATA

Postal Code	Age	Disorder
38607	65	Lungs Disease

Table VI illustrates the frequency distribution of every disorder. This distribution demonstrates that the fever is a widespread disorder with a higher frequency—roughly 50 percent in the reported data. Every QIDB maintains the exact similar distribution. Due to the fact that the quasi values  $\langle 38602, 28 \rangle$  and  $\langle 38607, 55 \rangle$  have the  $DW$  and  $DI$  values of 1 and 0 respectively, in the first cycle 2 blocks of QIDB will be produced for these values as shown in Table VII and Table VIII. Table VII shows Brain cancer disease probability is 0.2 in distribution block. In the same way Table VIII shows Probability of Lungs disease is 0.2 in the frequency distribution block. It is calculated from delicate weight of delicate information.

6) *Generalization* - A generalization function provides the general domain of an attribute  $R.Q$ . Function will return a generalized value in the domain provided a value  $r.q$  in the original domain.

7) *Check Frequency*- for every QIDB, examine  $CF_q(QIDB.V)$  with  $QIDB.V$  FD which is equal to the FD in FDB. It is performed as follows

Let  $c$  be the total number of entries in  $QIDB.V$  for every  $UNI_q(qidb.vl.d)$  obtain total number of mappings which match  $qidb.vl.d$  to the total number of entries that is  $x$  in  $QIDB.V$ , thus  $CF_q$  will return true if

For every  $1 \leq v \leq m$  such that  $fdbv.ds=qldb.vl.d$

$$fdbv.p = (\text{unique}(qldb.vl.d) / x) \pm Tacc$$

This is examined in each cycle if a QIDB satisfies the FD then this chunk won't be taken into account for the next iteration.

8) *Suppression*- After  $Titr$  iterations,  $SUP(QIDB.v)$  remove the chunk if it meets the following criteria

For every  $1 \leq u \leq m$  such that for every  $fdbu.ds=qldb.vl.d \wedge fdbu.ds=wj.ds \wedge wj.dw=1$  for every  $j \ 1 \leq j \leq k$

$$\text{Count}(qldb.vl.d) \leq Tsup$$

9) *Disclosure* - After  $Titr$  iterations,  $DIS(QIDB.v)$  adds extra records if it meets the following criteria for every  $1 \leq l \leq x$  such that for every  $fdbu.ds=qids.vl.d \wedge fdbu.ds=wi.d \wedge wi.dw=1$  for some  $i \ 1 \leq i \leq k$

$$(\text{unique}(qldb.vl.d) / x) = Tdis \pm fdbv.p$$

### B. Personalized Privacy Breach

Assume an attacker who tries to estimate important information from a record holder  $h$ . In the worst situation, the attacker only pays attention to the tuples  $r^* \in R^*$  whose  $Q$  value  $rj^*.q$  covers  $x.q$  for all  $j$  such that  $1 \leq j \leq n$  since it is assumed that the adversary knows  $Q$  of  $H$ .  $Q$ -group is formed by these tuples. That is, if  $rj^*$  and  $rjp^*$  are two such tuples then  $rj^*.q=rjp^*.q$  for all  $j$  such that  $1 \leq j \leq n$ . The adversary cannot deduce a sensitive attribute of  $h$  if this group is not established.

1) *Required Q-Group/ Actual (h)* - Given an individual  $h$ , the Required  $Q$ -group  $ReqG(H)$  is the only  $Q$ -group in  $r^*$  covers  $h.q$ . Considering  $Actual(X)$  represents those records which are generalized to  $RG(H)$ .

The attacker has no knowledge about  $Actual(H)$ . To acquire  $Actual(H)$ , the adversary must locate some external data base  $External(H)$  that should be covered in  $ReqG(H)$ .

2) *External DataBase Ext (x)*-  $External(H)$  is a collection of individuals whose value is covered by  $ReqG(H)$ .

$$Actual(H) \subseteq External(H)$$

The adversary uses a combinational strategy to deduce sensitive attribute of  $h$ . let us consider that  $h.s$  is present in one of  $ri^*$  and  $h$  is not repeated. The possible reconstruction of the  $ReqG(X)$  contains  $h$  different record holders  $h1, h2, h3, \dots, hr$  who belong to  $External(H)$  but there can be only  $y$  in  $ReqG(H)$ . This can be seen by the probabilistic nature and can be represented as  $perm(x,y)$ .

$perm(x,y)$  is Possible Reconstruction that can be created by with  $h$  holders and  $y$  mappings. Breach Probability represents the probability of inferred information. Let us consider  $Actual N$  represents actual number of entries with sensitive attribute from which  $h$  can be deduced.

$$\text{Breach probability} = \text{Actual } N / perm(x,y)$$

Breach probability will decide the privacy factors, If it is 100 percent then  $h$  can be deduced; if it is poor then the inference will be tough for the adversary.

### C. Quasi-Identifier Distribution Block - Anonymization Algorithm

Since it is assumed that the sensitivity distribution in every location is typically fairly uniform, this technique processes quasi values sequentially. Consider the following algorithm of QIDB.

---

#### Algorithm 1: QIDB-Anonymization

---

**Input:** personal data  $R$  with DW-DI, threshold values  $T_n, T_{itr}, T_{sup}, T_{dis}, T_{acc}$  and initialized  $FDB(ds,p)$

**Output:** Released table  $T^*$

**Step 1:** if  $(n < T_n)$  then return value 1

**Step 2:** for each  $rj.s$  where  $rj.dw=1$  &  $rj.di=0$  a new QIDB is generated comprising  $rj.d$  and  $rj.q$  for every  $1 \leq j \leq n$ .

**Step 3:**  $initial\_iteration=0,$   
 $receive\_flag=0$   
 $gen=Initial G(R)$

**Step 4:** while  $(initial\_iteration < T_{itr}$  and  $receive\_flag=0)$   
QIDB chunks are deleted if  $CFq()$  returns true then examines the value of QIDB if it is 0 then  $receive\_flag=1$   
 $Iteration = iteration + 1$   
 $gen = next G(R)$

**Step 5:** if  $receive\_flag=0$  then  
execute  $sup()$  and  $dis()$

**Step 6:** Examine value of QIDB if it is 0 then  $receive\_flag=1$

**Step 7:** release  $R^*$  if  $receive\_flag=1$

---

The resultant anonymization after implementing Personal Anonymization of one of the QIDB with  $T_{acc}=0.1$  chunk is depicted in Table IX.

TABLE IX. RESULTANT DW-DI BASED QIDB ANONYMIZATION WITH  $T_{acc}=0.1$

ZIP Code	Age	Disorder
386**	[30-50]	Brain cancer
386**	[30-50]	Mouth ulcer
386**	[30-50]	Lungs Disease
386**	[30-50]	Fever
386**	[30-50]	Fever

## IV. EXPERIMENTAL FINDINGS AND DISCUSSION

Effectiveness of proposed method in comparison to  $k$ -anonymity as well as  $l$ -diversity is obtained. The investigation made use of a common dataset. 400-records of adult dataset are taken into account with the relevant quasi-attributes: age, gender, marital status, and profession. Age is the only attribute that is numerical; all other attributes are categorical. For  $DW=1$ , probability is utilized to determine the DI value.

In Fig. 1, it is shown that data loss for proposed method is less than  $k$ -anonymity and  $l$ -diversity. Number of records can be increased in the proportion to see the information loss in three methods and compare it.

Fig. 1. Information Loss of DW-DI Proposed Personal Anonymization Technique Compared with l-Diversity and k-Anonymity Technique.

Fig. 2. Minimal Distortion Parameter of DW-DI Personal Anonymization Compared to l-Diversity k-Anonymity Technique.

Fig. 3. Discernibility Metric Parameter of DW-DI Personal Anonymization Compare to l-Diversity and k-Anonymity Technique.

For quasi identification, a generalization hierarchy is created and employed and a distance vector is produced and is used in this approach. The generalization hierarchy can go up to a maximum level of 10. In Fig. 1, the information loss factor is displayed. The data quality improves when there is less data loss. The concept of minimal distortion centers on penalizing every value that has been generalized or repressed. When a hierarchy inside the domain generalization hierarchy is extended to the next level, it is given a penalty. In Fig. 2,

minimum distortion is displayed. A penalty of 10 is applied in test for each generalization. Fig. 3 illustrates how this Discernibility Metric determines the cost by penalizing every tuple for being unrecognizable from other tuples. In Fig. 4, runtime is displayed. For the test, the threshold values  $T_n = 400$ ,  $T_{itr} = 10$ ,  $T_{dis} = 0.01$ ,  $T_{sup} = 1$ ,  $T_{acc} = 01$  was used.

Fig. 4. Run Time of DW-DI Personal Anonymization Compare to l-Diversity and k-Anonymity Technique.

## V. CONCLUSION AND FUTURE WORK

Since the runtime and quality of the data are better with personalized privacy, it is an essential research direction. Because all entries do not need to be private, using DW not only enhances the signal of sensitivity but also increases the usefulness of the data. Since many of the record holders are willing to expose their identities, DI is an extra flag that increases the quality of the data in the DW record. Therefore, DW-DI is a better solution for personalized privacy than employing a guarding node alone. Using anonymization depending on QIDB, several quasi groups can be separately generalized. This method improves confidentiality by checking each QIDB chunk for a FD of sensitive values that is roughly equivalent to the FD of sensitive values in the original contents. Additionally, it defeats probabilistic assault, attribute connection and record connection. When a specific sensitivity's frequency distribution is localized in a small area of an individual pattern, this method performs effectively.

Future research can go in a number of different ways as it examines QIDB anonymization of DW-DI personal privacy. Firstly, the impact of sequential and multiple distributions of released data have not been taken into account. Research on sensitivity weighting can be taken into consideration. In this method, records are processed sequentially to see if the generalized record fits the QIDB generalized value, and if they do, the record is added to the block. Different techniques can be investigated as an option to sequential processing. Multi-dimensional data and unorganized schema can both be used with this technique.

**Abstract**—The understanding of DNA damage intensity – concentration-level is critical for biological and biomedical research, such as cellular homeostasis, tumor suppression, immunity, and gametogenesis. Therefore, recognizing and quantifying DNA damage intensity levels is a substantial issue, which requires further robust and effective approaches. DNA damage has several intensity levels. These levels of DNA damage in malignant cells and in other unhealthy cells are significant in the assessment of lesion stages located in normal cells. There is a need to get more insight from the available biological data to predict, explore and classify DNA damage intensity levels. Herein, the development process relied on the available biological dataset related to DNA damage signaling pathways, which plays a crucial role in DNA damage in the mammalian cell system. The biological dataset that was used in the proposed model consists of 15000 records intensity – concentration-level for a set of five proteins which regulate DNA damage. This research paper proposes an innovative deep learning model, which consists of an attention-based long short term-memory (AT-LSTM) model for DNA damage multi class predictions. The proposed model splits the prediction procedure into dual stages. For the first stage, we adopt the related feature sequences which are inserted as input to the LSTM neural network. In the next stage, the attention feature is applied efficiently to adopt the related feature sequences which are inserted as input to the softmax layer for prediction in the following frame. Our developed framework not only solves the long-term dependence problem of prediction effectively, but also enhances the interpretability of the prediction methods that was established on the neural network. We conducted a novel proposed model on big and complex biological datasets to perform prediction and multi classification tasks. Indeed, the (AT-LSTM) model has the ability to predict and classify the DNA damage in several classes: No-Damage, Low-damage, Medium-damage, High-damage, and Excess-damage. The experimental results show that our framework for DNA damage intensity level can be considered as state of the art for the biological DNA damage prediction domain.

## I. INTRODUCTION

Mammalian cells have a complicated organism system. Specifically, each cell has a sequence of response procedures through a parent cell which is split into binary offspring cells; this is termed the cell-sequence-cycle with a total time of 24 hours. It consists of five phases, as shown in Fig. 1(a), Gap1

(G1) 8-10 hours, DNA synthesis (S) 6-8 hours, Gap2 (G2) 4-6 hours, Mitosis (M) around 4 hours and Quiescence (G0) silent mode. Furthermore, the mammalian cell has substantial impact on living cell dynamics, involving cell proliferation with differentiation [1]. However, mammalian cells usually stay in the early state or resting state, either Quiescence the G0 phase or initial G1phase, but the cell cycle developments to S phase further than the check point when actual growing influences motivate a cell necessarily. After DNA duplication through the S phase, the cell cycle developments complete the G2 phase to the final phase called the M phase. At the end of the cell cycle, specifically through M phase, the cell is necessarily separated into two new cells, called daughter cells. It signifies the complete progression process in the cell cycle as illustrated in Figure 1(a), (b). Also, this progression process is controlled by several complex networks. These networks enclose several biochemical species such as genes and proteins [2].

A mammal cell is commonly damaged and harmed by different resources like ultraviolet (UV)-irradiation, also ionization-radiation (IR), or other toxic chemical elements that are able to influence and cause breaks inside double-stranded DNA. This leads to DNA damage, and simulates an exceptional signal in the cell. Precisely, this DNA damage signal fires a DNA damage signaling pathway. The signaling pathway cooperates with the cell cycle controlling system to tentatively stop the cell cycle evolution in order to repair damaged DNA. Naturally, DNA damage is organized through a sub-network with five components, as shown in Fig. 2, and they cooperate over these steps (1) double significant elements at the launch are activated such as Ataxia telangiectasia mutated (ATM) and Rad3-related (ATR) protein kinases are activated via DNA damage, (2) ATM and ATR prompt p53 and checkpoint kinase 1 (Chk1), (3) initiated p53 stimulates the synthesis of p21, (4) then p21 prompting cell cycle halt. Accordingly, the signaling pathway for DNA damage takes straight action on the cell cycle arrangement mechanism, supporting cellular homeostasis and genetic constancy. Besides, any cell that has significant DNA damage might prompt apoptosis and perform planned cell death [3], [4].

The influence of DNA damage in mammalian cells is one great cause of human illnesses, and as such has gained much interest in research since the mid-1990s. DNA damage and oxidative stress are identifying factors for the source,

\*Corresponding Authors.

development, aetiology and progression of numerous different types of human disorders and diseases, such as cancer. Therefore, an abundance of present-day investigation in the DNA damage domain is dedicated towards sympathetic mechanisms and natural allegations of harmful DNA. This harmful DNA can go through alterations, such as mutations on its genetics; these types of mutations ultimately prime the expansion of tumors. DNA damage is also concerned in the growth of further prevalent human illnesses ranging from neurodegenerative disorders, such as Alzheimer’s illness, to chronic obstructive pulmonary disease (COPD). Further, they have also been linked to diverse illnesses, such as pulmonary illnesses, brain injury and other chronic inflammation related to disorders [5].

Essentially, biological discoveries have shown that mammalian cells are able to approximate the intensity-concentrations of DNA damage and choose a suitable cell fate, like applying DNA repair; otherwise, cell cycle arrest, or apoptosis death. Nevertheless, it is uncertain the manner in which a cell decides the suitable cell destiny. A confirmation of the affiliation among the intensity (proteins concentration) for DNA damage and the energetic behavior of the biochemical elements implicated in cell cycle controlling techniques and the signaling pathway for DNA damage is crucial for clarifying the techniques of cell destiny purposes.

DNA damage has a number of intensity-concentration levels; these levels of DNA damage in malignant cells and in further diseased cells are significant in the assessment of the lesion stages that appear in normal cells. A wealth of laboratory research has been concerned with distinguishing and comprehending DNA damage levels and DNA repair capacity, as well as the techniques employed through mutually abnormal and normal cells. In addition, since certain significant diseases, such as cancer, are the essential reason of premature mortality over the globe, there is a predominance and rapid assertiveness of research on illustrative DNA damage in cancer cells [6]. Mainly, as mentioned before, clarifying the DNA damage level will be helpful for treatments and research purposes, even if there is a scarcity in the available data. Consequently, this article aims to present a novel artificial deep learning model to classify and predict DNA damage levels based on available DNA damage intensity-concentration levels from a bench mark model. The bench mark model delivers a novel dataset for DNA signaling network and classifies the DNA damage into several levels. We rely on this dataset to train and test the novel proposed model to predict the weather of the DNA damage and classify them in several classes.

The research introduces and validates the novel model to predict and classify DNA damage levels. To achieve the goals, outcomes have been investigated with DNA damage datasets. The research objectives and contributions are represented as follows:

- 1) This research aims to propose a novel deep learning model by employing an Attention – Long Short Term Memory.
- 2) Experiments are to be applied on DNA damage datasets.
- 3) The ATT-LSTM deep learning classifier for DNA damage is to be employed, and the efficiency of the ATT-LSTM deep learning classifier is to be determined.
- 4) The developed framework not only solves the long-term dependence problem of prediction effectively, but also enhances the interpretability of the prediction methods established on the neural network.

The paper is structured as follows. Section II offers a literature review. Section III encloses the utilized method and model architecture and implementation. Section IV encompasses the results and investigation. Section V presents the conclusions.

## II. RELATED WORK

Declaration and quantification of DNA damage is an actual substantial topic in biological and biomedical study areas, which requires further influential and active methods. Defining the DNA damage level is a significant point to decide the fate of the cell, such as if the cell recovers the DNA damage, or kills itself, or develops into an abnormal cell and forms into a serious diseases such as cancer [7]. Besides, the defining level can help to get more insight over drug treatment experiments. Several attempts have been made to classify DNA damage levels. For instance, numerous classical machine-learning methods have been employed in classifying the data that were related to gene expression, involving Fisher linear discriminant analysis [8], decision tree, k nearest neighbor [9], multi-layer perceptron [10], support vector machine [11] [12], boosting, and self-organizing map [13]. In addition, concerning clustering gene expression data, various machine learning techniques have been utilized [14]; they include hierarchical clustering [15], graph theoretic approaches [16] [17] and self-organizing map [18]. Concerning disease and treatment for DNA damage also, another attempt is available in the literature based on use of the machine learning classifiers on illness datasets, like Leukemia disease dataset, Lymphoma malignance data set and colon tumor dataset. Researchers have also attempted to explore many features by utilizing classical methods, like multi-layer perceptron neural network, k-nearest neighbor, structure adaptive \_SOM- self organizing map and SVM (support vector machine); these have been employed for classification [19]. In addition, they have joined the classifiers to increase the performance of classification. The experimental consequences indicate that the ensemble with some basic classifiers produces the greatest classification rate on the benchmark dataset.

Other researchers have established an SVM classifier exactly for mtDNA missense variants [20]. Therefore, in the process which is associated in the training and validation of the model, they employed 2,835 mtDNA damaging and neutral amino acid replacements. In the abovementioned dataset, each instance is well-defined through a fixture of three attributes created on evolutionary preservation in Eukaryote modified amino acids. Consequently, the proposed classifier achieved better than other web-available tested predictors. However, lately, a Deep learning model has been offered [21]. The model is based on a weak label learning method; they used this method to investigate the whole slide images (WSIs) of Hematoxylin besides Eosin (H&E). Their occupation was Self-supervised pre-training technique and heterogeneity aware deep Multiple Instance Learning (DeepSMILE) and they engaged it on cancer tissue images. Their model improvements recommended the genomic label classification performance without collecting larger datasets. There is also a deep learn pipeline based open source, called FociNet [22]. It is interested in image classification and was established to mechanically segment full-field fluorescent images and divide DNA damage of each cell. The outcome from the model indicated that FociNet reached satisfying performance in classification. Since it classifies a solitary cell in a normal, injured, or no signaling (no fusion-protein expression) state, and it also shows exceptional matching in the assessment of

DNA damage, contingent on fluorescent foci images from different imaging platforms [23]. Evaluation of the performance of convolutional Neural Network was done to examine the amount of DNA damage by means of comet assay images and was matched to further approaches in the literature. The novelty of their work was employing convolutional Neural Network as a novel scheme to classify the comet objects on segmented comet assay inside the images. Additionally, numerous deep learning models were applied on DNA damage images [24] [25] [26]. However, almost all the available deep learning models in the available literature are based on image datasets for DNA damage, while few available deep learning models are based on DNA damage intensity – concentration datasets; this is due to a scarcity in experimentally observed data concentration datasets. Therefore, while it is challenging to envision these complicated relationships using only DNA damage, investigators can systematically confirm these associations with a mathematical-numerical model that incorporates data from experiments toward a kinematic mathematical model which includes the cell cycle regulation techniques with the DNA damage signaling pathway. Various scientists have developed valuable kinetic mathematical models. These models are associated with the cell cycle regulation mechanism to estimate the exchanges of natural species [1], [7], [27], [28], [29], [30], [31].

A mathematical model was proposed as a benchmark model of the DNA damage-signaling pathway and mimic cell fate selection [30]. The outcome from the novel model was that it offers a dataset for the DNA damage signaling pathway. This dataset exposes the proteins' concentration levels and activities to deal with DNA damage level. For instance, the researchers presented the DNA damage signaling pathway-proteins set-concentrations without DNA damage [30]. These observations from the delivered dataset qualitatively match with biologically appropriate facts. In addition, diverse intensities of DNA damage were found, such as Low-damage, Medium-damage, High-damage, and Excess-damage. These aforementioned DNA damage levels bear a resemblance to actual DNA damage, and are triggered by several values such as 100, 200, 400, and 800 J/m<sup>2</sup> doses of UV-irradiation. Further explanation will be clarified in the dataset preparation and analysis section and how we utilized this dataset to train and test the proposed artificial deep learning model to predict the DNA damage level into several classes.

## III. PROPOSED WORK AND OVERVIEW OF SYSTEM ARCHITECTURE (ATTENTION – BASED LSTM) – AT-LSTM MODEL

Currently, there is no effective computational model, neither a machine learning nor a deep learning model that can be utilized to validate the influence of the intensity-concentration of DNA damage on cell cycle system progression. Consequently, the crucial contributions of this paper essentially comprise the following: we employ the attention model to effectively extract the features of DNA damage big and complex dataset and the LSTM layer in the proposed model performs additive interactions, which can help improve gradient flow over long sequences in training [32]. Matched with classical models, AT-LSTM can

competently maintain and work with non-stationary sequences and detect the nonlinear relationships [33]. Furthermore, compared with deep learning models like RNN, the AT-LSTM can avert the long-term dependence issues and give rise to superior interpretability [34]. The mechanism for the attention in the proposed model makes it simple to recognize how the information in the input sequence influences the final created sequence through the model output process [35]. This might assist in discovering the interior operation mechanism of the model and debug certain precise inputs and outputs. Further, the experimental results on DNA damage datasets determine that AT-LSTM accomplishes more enhanced tasks than standard models.

1) *The architecture of the AT-LSTM model:* The proposed attention-based LSTM (AT-LSTM) model for DNA damage dataset multiclass prediction comprises two parts: the attention model and the LSTM deep learning model. The attention mechanism is able to adaptively choose the furthest related input features and provide higher weights to the corresponding original feature sequence. Then and there, we utilize the outcomes of the LSTM deep learning model as input for the attention model to predict the DNA damage level and assign it to several classes.

2) *LSTM model:* For a stated input raw,  $X = (x^1, x^2, \dots, x^n)^T = (x_1, x_2, \dots, x_m) \in R^{(n \times m)}$ ,  $n$  represents the numeral of feature orders -sequences,  $m$  stands for the length of the window.  $x^k = (x_1^k, x_2^k, \dots, x_m^k)^T \in R^m$  is utilized to denote a sequence (vector) of length  $m$ . For biological DNA damage, this sequence can be a protein concentration measurement for the sub-network, which represent the DNA signaling network. We use  $x_t = (x_t^1, x_t^2, \dots, x_t^n)^T \in R^n$  to represent a set-group of vectors of  $n$  features at time  $t$ . Long Short-Term Memory (LSTM) model is declared as follows: Let  $x_t, h_t$  and  $C_t$  stand for the input, control state, and the cell state on time step  $t$ . Delivering a sequence of inputs  $(x_1, x_2, \dots, x_m)$  the LSTM calculates the group of sequence  $(h_1, h_2, \dots, h_m)$  and the C-sequence  $(C_1, C_2, \dots, C_m)$  as follows:

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \quad (1)$$

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \quad (2)$$

$$c_t = \tanh(W_c \cdot [h_{t-1}, x_t] + b_c) \quad (3)$$

$$C_t = f_t * C_{t-1} + i_t * c_t \quad (4)$$

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \quad (5)$$

$$h_t = o_t * \tanh(C_t) \quad (6)$$

such that each equation has a set of special symbols, and identify several functions. For occurrence,  $\sigma$  represents the function of logistic sigmoid,  $*$  is a component wise multiplication, and  $C_t$  is the weather of the cell that is required to be changed. Also,  $W_f, W_i, W_c, W_o$  and  $b_f, b_i, b_c, b_o$  are a set of parameters for the model. Besides, these parameters can be learned over the processing. Additionally,  $f_t, i_t$  and  $o_t$  are likewise christened as a gate for the forgotten, along with an input gate and output gate. In actual fact, the architecture for

the LSTM unit includes a memory cell, this mean that every LSTM unit that contains a memory cell has state  $C_t$  at time  $t$ , which is structured by the three overhead gates.

3) *The attention model:* A significant part of human artificial is that it does not directly contract with all feedbacks from the outside world. As a substitute, human's first attention is on the significant sections to acquire the information they require. Correspondingly, the significance of several proteins concentrations in the biological data set is also different, big, and complex, and the other may be critical. It is also essential to emphasize key features first and remove repeated features. Accordingly, with the operative information inspired through the overhead information, we propose an attention model, and this model can apply the optimization part for the input feature sequence in DNA damage level prediction. An attention mechanism [35] can be defined as mapping an enquiry. Moreover, a set of key-value couples to an output, and similarly, the components in the system such as keys, query, values, including output are all defined as vectors. The outcome of the model is calculated as a weighted sum for the values, where the weight given to every value is calculated through a function related to the compatibility for the query with the equivalent key, as shown in Fig. 3.

The method of producing attention weights and the new input features established on attention is illustrated in Fig. 3. In the first fragment,  $x_t$  maps to  $h_t$  through the following.

$$h_t = f_1(h_{t-1}, x_t) \quad (7)$$

where the non-linear activation function is represented by  $f_1$ , while  $h_t \in R^s$  stands for the hidden state on time  $t$ , and  $s$  indicates the size of the hidden state. LSTM is implemented as  $f_1$ . The main aim for this implementation is to evade the long-term dependence problem, which typically arises in data prediction.

In the second fragment, we generate an attention mechanism by using specifically the deterministic feature in the attention model. For an exact feature sequence like  $x^k = (x_1^k, x_2^k, \dots, x_m^k)^T \in R^m$ , by relying to the aforementioned hidden state  $h_{t-1}$  and the cell state  $C_{t-1}$  in the LSTM unit, we express

$$\alpha_t^k = v^T \tanh(W_1 \cdot [h_{t-1}, C_{t-1}] + W_2 x^k) \quad (8)$$

$$\beta_t^k = \text{softmax}(\alpha_t^k) = \frac{\exp(\alpha_t^k)}{\sum_{i=1}^n \alpha_t^i} \quad (9)$$

Fig. 3. The Architecture of the Proposed Attention-LSTM Model.

The vector  $v$  and the two matrices  $W_1, W_2$  signify the learning abled parameters of the proposed model. The vector  $a^k$  has a length called  $m$  and its  $i$ -th item measures the significance of the  $k$ -th input feature sequence at time  $t$ . The aforementioned items must be normalized through softmax.  $\beta^k$  represents the weight in attention, which encloses a score, and the score shows the amount of attention that should be put on the  $k$ -th feature sequences. We are able to likewise acquire the outcome of the attention model at time  $t$ , i.e., the sequence of the weighted input feature named as  $z_t$  can be presented as follows:

$$z_t = (\beta_t^1 x_t^1, \beta_t^2 x_t^2, \dots, \beta_t^n x_t^n)^T \quad (10)$$

$x_t$ , in the equations from (1) to (7) swapped via a new calculated  $z_t$  to keep up the attention model. However, classical prediction frameworks that enclose recurrent neural networks usually utilized dataset input features as input, besides treating all input feature sequences in an equivalent fashion. Nevertheless, the recently acquired  $z_t$  can pay further attention to the particular input feature sequence, mining the key feature sequences efficiently, and based on attention weight, we reduced the influence of the redundant feature sequences. Hypothetically, there would be an improvement in prediction exactness with  $z_t$  as the input to the softmax layer.

#### IV. RESULTS AND DISCUSSIONS

##### A. Data Analysis and Simulation

This section explores how we apply experiential research on data sets with an aim to elucidate the validity of our DNA damage level prediction framework. First, we will introduce the dataset that was utilized in training and testing of the proposed model. We relied on available biological datasets related to DNA damage signaling pathways, which plays a crucial role in DNA damage in mammalian cell systems [30]. This Biological dataset consists of 15000 records intensity – concentration-level for a five-proteins set which control DNA damage. The DNA damage signaling pathway- proteins set-concentrations without DNA damage was previously presented [30]. These observations from the delivered dataset were qualitatively analyzed with biologically appropriate facts. In addition, diverse intensities of DNA damage were performed, such as Low-damage level, Medium-damage level, High-damage level, and Excess damage level. Herein, we studied and analyzed the aforementioned dataset and proposed a novel model which consists of an attention based on long short term memory- Neural Network named as LSTM (AT-LSTM) model for DNA damage multi-classification prediction.

##### B. Dataset Analysis

Researchers have assembled a new kinetic based mathematical – ordinary differential equations (ODE's)-model that assimilates the G1/S in cell cycle system models, and they measured compatibility to the biological credibility of the suggested model by confirming numerous mathematical mimicry time progression courses of the intensities of individual biochemical elements [30]. Furthermore, they as well quantitatively recognized the intensity – concentration level of DNA damage and provide experimentally observed data.

Certainly, when DNA damage has occurred, numerous protein kinases are involved at the location of damage and launch a special signaling pathway that forces cell-cycle to be arrested. The chief kinase at the damage location is ATM/ATR, which is activated and established on the type of damage and another protein of the gene regulatory protein p53 is also triggered. Mdm2 usually connects to p53 and stimulates its ubiquitylation and destroys the proteasomes. Phosphorylation of p53 stops its binding to Mdm2; consequently, p53 becomes accumulated to maximum levels and inspires transcription of the gene that encrypts the protein p21 and arresting of the cell in G1 [30].

Mainly, in the evolution process for the model, first, we extracted the observation from a base model deprived of DNA damage (DDS = 0) to get the time course for selected cell cycle regulators. Second, we extracted from an expermental dataset of the benchmark model the required obseravtion with four diverse levels of DNA damage: (Low-damage) with DDS = 0.002, (Medium-damage) with DDS = 0.004, (High-damage) with DDS = 0.008, and (Excess-damage) with DDS = 0.016. If DNA damage has certainly not arisen, the p21 with p53 stop over instead, and with a low level, as illustrated in Fig. 5 and 6. DNA damage drives p53 activation which prompts p21 [2].The character of p21 is to prevent the activity through inhibition of phosphorylation of Rb [1].

With the elimination of DNA-damage, [2]p53 and Mdm2 have a negative feedback loop which is completely reinstated, and p53 returns back to a low-slung level. The reduction in p53 decreases the scale of p21, as shown in Fig. 4 and 5 when DDS=0.004. Likewise, Figure 4 shows all the protein tensity for the protien P21 response in all DNA damage states. For instance, it shows the values for the P21 tensity in the case without DNA damage occurrence as a light-blue line. It provides roughly 3000 instances. On the other hand, it shows the concentration values for the P21 when DNA damage occurs,; for instance, in case of Low DNA damage, the P21 can be presented in an orange line, medium damage with a gray line, and a high DNA damage level P21 values and behaves to recover the DNA damage represented in a yellow line, while the P21 response in extreme DNA damage is represented in a dark blue line. We have to be aware about the values for each figure, specifically that each element in each DNA damage state has roughly 3000 different instances in response to DNA damage recovery.

Fig. 4. Time Courses of P21 responses with and without DNA Damage over the Simulation of Mammalian Cell.

With respect to High DNA damage with a rate of  $DDS=0.008$ , the time progressions of p21 and p53 are revealed in Fig. 5 and 6. The p53 is activated and presented in oscillation behavior, which were in settlement by means of those previously experimentally detected [30, 6, 29]. Furthermore, when DNA damage is presented, the DNA-damage signal in the sequence triggers p53 instead of Mdm2. The triggered p53 similarly can stimulate the synthesis of p21 which acts as an inhibitor. Meanwhile, p21 stops the phosphorylation of Rb. Fig. 6 indicates all the protein tensity for the protein P53 response in all DNA damage states. For example, it explores the values for the P53 tensity in the case without DNA damage incidence, the light blue line. On the other hand, it displays the concentration values for the P53 when DNA occurred, such as in the Low DNA damage, in which case the P53 is presented with an orange line, and the medium damage is represented with a gray line. In the case of high DNA damage levels, P53 values and behaves to recover the DNA damage that is represented in a yellow line, while the P53 responds in extreme DNA damage cases, represented in a dark blue line.

Fig. 5. Time Courses of P53 with and without DNA Damage over the Simulation of Mammalian Cell.

Fig. 6- 8 illustrate the responses of Mdm2, ATM/ATR and Im respectively in cooperating to handle the DNA damage cases. Each figure, as explained before, shows how the values in protiens tensity of each element will change during the DNA damage, whether it occurred or not. As demonstraed before, we have to be alert that the values for each figure of each ellement in each DNA damage state has around 3000 different instances in response to DNA damage recovery.

Fig. 6. Time Courses of Mdm2 with and without DNA Damage over the Simulation of Mammalian Cell.

Fig. 7. Time Courses of ATM/ATR with and without DNA Damage over the Simulation of Mammalian Cell.

Fig. 8. Time Courses of Im with and without DNA Damage over the Simulation of Mammalian Cell.

Herein, we revealed a brief examination of biological background, specifically cell cycle, with more deliberate focus on DNA damage pathways as a complicated system. As demonstrated before, the novel proposed deep learning Attention based LSTM model is trained and tested depended on the obtained dataset delivered by [30].

### C. Experiments

We performed several experiments on the proposed attention-based LSTM model for DNA damage classification. The proposed model was trained on 12000 samples and was tested on 3000 samples. The dataset is in-of-domain for DNA damage classification and the tested dataset that was used is also from the same dataset. There are three cross-validation methods which are often employed to evaluate the success rate of the predictor; namely, the K-fold cross validation, sub-sampling and jackknife test. The Jackknife test is the least arbitrary and most objective, and it has been mostly assumed by researchers to inspect the quality of diverse predictors. This method is source and time consuming. Therefore, in this paper we utilized an early stopping choice to elude a model's overfitting through setting the patience option to three epochs, and we utilized k-fold cross validation where K was set to 1, such that a single train/test split is generated to evaluate the attention-based LSTM model for DNA damage classification.

### D. Training

The framework developed by Keras and Python was used to train the attention-based LSTM model for DNA damage classification. For the classification task, SGD optimization algorithm was used with learning rate values set to 0.01 and

momentum set to 0.0, and the model's batch size set to 6. The model initially incorporated 331,525 parameters. The model used 256 LSTM units and the attention dimension was set to 255. Also, the proposed model size proved to require 1.7 seconds per epoch for the classification task. The training data was randomly shuffled at each epoch for the classification task. The proposed attention-based LSTM model for DNA damage classification task was trained to minimize the categorical-crossentropy validation loss for the DNA damage classification task while maximizing validation accuracy for the same classification task.

### E. Results Investigation

On performing experiments, it can be assured that the researchers have done extensive experiments on the attention-based LSTM model by testing different hyper-parameters. The proposed model was also experimented using three different configurations, such as BiLSTM with Attention layer, LSTM with Attention Layer and LSTM with Attention and Dropout layers. The classification performances measured will be listed in an accuracy score automatic metric evaluation. The results in Table I show the efficiency of the proposed Attention-Based LSTM model for DNA damage classification. It can be noticed from Table I that the proposed model obtained an excellent result when we used LSTM with the attentional approach, such that the model obtained an accuracy of 93.43. In comparison to other configurations listed in Table I, the proposed model (LSTM with Attention) obtained a better accuracy than the other configurations. These results suggest that the proposed model is effective and accurate in classifying DNA damage in a validation dataset. Also, as seen from Table I, the BiLSTM with attention configurations has obtained a competitive result, such that it obtained an accuracy of 93.13, which indicates that the BiLSTM performs very well in classification tasks. Adding a dropout layer to the model's design negatively impacts the model's performance and quality, such that the model obtained an accuracy of 75.43, as illustrated in Table I. Therefore, it can be summarized that the proposed model outperforms the models that used BiLSTM and Dropout layer. More importantly, results presented in Table I and Fig. 9 show the performance of the model that exploited the attention approach, and LSTM is higher than the other models. In addition, as shown in Fig. 10, it can be seen that the error on the training data decreases as the learning continues, and at the same time, the error of actual validation data decreases as the training continues, and this pattern proves that the proposed AT-LSTM model is not facing the problem of overfitting.

Moreover, as shown in Fig. 11, plot of accuracy, we found that the model is trained very well, as the trend for accuracy on both training and test datasets were still rising from epoch 100 till epoch 213, and this is an indication of the proposed model's performance and accurate classification.

Fig. 12. (a,b,c,d,e) illustrates how the AT-LSTM model classifies the responses of P21, P53, Mdm2, ATM/ATR and Irf, respectively in cooperating to handle the DNA damage. Each figure shows how the values in protein density of each element changes during DNA damage, and how it occurred in each class. The x-axis represents the diverse classes for the

DNA damage level while the y-axis represents the amount of each protein concentration during the DNA damage.

## V. CONCLUSION

DNA damage in mammalian cells causes genetic illnesses and a diversity of cancers. Therefore, more investigation and analysis can help the therapeutic process. Almost all classification prediction models that are used to explore DNA damage are based on DNA damage images, while few studies and models are based on DNA damage intensity. In this paper, we developed a novel deep learning model; in essence an Attention-based LSTM model to perform classification tasks of DNA Damage Levels. The proposed model was able to overcome other models and obtained an accuracy of 93.43%. These results confirm that the proposed model is effective and accurate in predicting and classifying DNA damage on a validation dataset. The attention approach was able to extract the complex features from the dataset and enhanced the proposed model quality and performance. The proposed model is considered as a novel work since AT-LSTM has never been applied in the DNA damage field, and can be employed to assist the investigation and studies of DNA damage since it provided a promising prediction of results.

**Abstract**—The concentrate process is the most sensitive in mineral processing plants (MPP), and the optimization of the process based on intelligent computational models (machine learning for recovery percentage modelling) can offer significant savings for the plant. Recent theoretical developments have revealed that many of the parameters commonly assumed as constants in gravity concentration modelling have a dynamic nature; however, there still lacks a universal way to model these factors accurately. This paper aims to understand the model effect of operational parameters of a jig (gravimetric concentrator) on the recovery percentage of the interest mineral (gold) through empirical modeling. The recovery percentage of mineral particles in a vibrated bed of big particles is studied by experimental data. The data used for the modelling were from experimental test in a pilot-scale jig supplemented by a two-month field sampling campaign for collecting 151 tests varying the most significant parameters (amplitude and frequency of pulsation, water flow, height of the artificial porous bed, and particle size). It is found the recovery percentage (%R) decreases with increasing pulsation amplitude (A) and frequency (F) when the size ratio of small to large particles (d/D) is smaller than 0.148. An empirical model was developed through machine learning techniques, specifically an artificial neural network (ANN) model was built and trained to predict the jig recovery percentage as a function of operation parameters and is then used to validate the recovery as a function of vibration conditions. The performance of the ANN model was compared with a new 65 experimental data of the recovery percentage. Results showed that the model ( $R^2 = 0.9172$  and  $RMSE = 0.105$ ) was accurate and therefore could be efficiently applied to predict the recovery percentage in a jig device.

**Keywords**—Empirical modeling; dynamic gravimetric concentration model; gravimetric concentration; machine learning for recovery percentage modelling; mineral processing

## I. INTRODUCTION

Recently more and more attention is paid to the methods of increasing the amount (yield) of gold concentrates obtained in separation by gravimetric processes that have an undesired gangue minerals (commercially worthless minerals) content. The purpose of gravity separation processes in jigs is to produce maximum amount of concentrate having desired gold content. This problem has been discussed during fifty last years in many research papers [1]–[32].

The mineral concentrate zone is a highly nonlinear process that requiring control; its parameters vary with time and

depend on the mineral feed rate and its size and density composition [30]–[34].

Although the use of neural network models is well established in the literature, it should be noted that such models, that depend on a large amount of data in the mineral processing industry is not very frequent, seeing the need to require such intelligent systems for further planning of design and optimization tasks, with which it is possible to understand, explain and test without the need to intervene in the real process [24], [35]. Machine learning models in general and artificial neural network models in particular, can be used to design and optimize control systems of concentrate discharge in jigs without the need to require a complex model that describes in detail the phenomena involved inside the equipment.

Regretfully, the lack of knowledge about all the phenomena that occur in this type of process is a frequent condition in practice in the mineral processing industry. Such situation occurs due to the low availability of phenomenological studies and due to some difficulties in modeling, inherited from past experiences; insufficient computational power led to the false appreciation that neural network models are complex. In addition, future research is needed to implement advanced control functions through the use of computer vision and multivariate data analysis. Such situations are directly reflected in the low availability of accurate models, which causes, for example, design problems in mining-metallurgical processes that must vary their operating conditions due to the heterogeneity of the ore to be processed. Today, it is possible to overcome such difficulties and use machine learning models such as neural networks to predict and describe the behavior of these processes, exploiting the capabilities of the model to analyze large amounts of data on the operational variables of the process while works with the process itself [32]–[34], [36].

Over the years, DEM and CFD models with a more detailed description of the gravimetric concentration phenomenon are being used more often [16], [29]. However, in spite of that progress, some challenges remain. For instance, one of the main goals that has not been accomplished so far is an agreed mathematical description of the percentage of mineral recovery (%R) and the operational parameters of the equipment (amplitude and frequency of pulsation, water flow, height of the artificial porous bed and size distribution). The %R turns out to be of paramount importance since it is directly

related to the amount of grams of gold per tons of ore concentrated (gpt): ideally, the gold percentage recovered from the concentrate stream should be equal to 100%.

Currently, the literature provides different ways to determine the %R, depending on the final application. As mentioned before, in some DEM and CFD models the authors use constant or linear approximations for %R [2], [13], [37]. Some other authors use empirical correlations describing the %R in terms of parameters mainly related to the geometry of the equipment and granulometric distribution of the mineral [31], [32], [38]. In spite of the many available ways to determine the %R in gravimetric equipment, the main observed concern about the above approaches is that they are only useful in the systems from which they were developed [2].

The fundamental purpose of this work is to apply and promote the use of artificial neural network models (ANN), in the analysis of gravimetric concentration processes for the design and control of equipment. The motivation for a work like this arises from the evident need to include the dynamic behavior of this type of process as fundamental elements in the design tasks in mineral processing engineering. In this regard, there is a large number of computational tools that already offer assistance for CAD (Computer Aided Design) without having written support that justifies such uses. Therefore, the inclusion of the concept of "machine learning" as the foundation of intelligent modeling is imperative, leading to the best use of the model as an analysis tool and support for process design and control tasks [2], [16], [24]. Since the existing works on gravimetric concentration equipment such as the jig, so far focus directly on a statistical analysis and describe the recovery percentages through experimental equations, and the mathematical models that currently describe the phenomenon are highly computationally demanding, making them unattractive for rapid tasks of optimization and control of equipment.

In this work, an accepted methodology for obtaining ANN is used in the modeling of the gravimetric concentration stage in the mineral processing industry. The efficient design and optimization tasks of the jig (which is the main equipment of the concentration stage in a mineral processing plant for gold extraction) require the process model to be able to study its behavior. Therefore, a good effort is dedicated here to the deduction and validation of an ANN model for the jig, counting on data available from a real pilot jig. This paper aims to develop a model to study the %R in a gravimetric pilot plant and its interaction with other internal process variables. First, an artificial neural network model is obtained to describe the dynamic behavior of the pilot plant. Then, the model is tested and assessed in terms of their ability to predict %R in the studied pilot plant.

The rest of the work is organized as follows: in Section II, a review of modeling in mineral processing is presented. In Section III, the ANN model is defined, mentioning the procedure for obtaining it, while in Section IV, said procedure is applied to the jig. Section V shows the simulation results of the obtained model and discusses its qualitative and quantitative validation, ending with a Section VI of conclusions and future work.

## II. RELATED WORKS

Jig is a gravimetric concentration equipment where mineral particles move in a flow of water pulsating, resulting at the end of the process in a stratification of particles of different densities and sizes. The stratification of the particles inside the jig occurs in a complex multiphase flow field. The particles are subjected to different hydrodynamic forces caused by the movement of the fluid, giving rise to different trajectories that depend on the velocity field of the fluid and particle properties. Various variables operations affect the motion of particles among which can be included the flow of fluid from water and mineral, the amplitude and frequency of pulsation of the fluid, among others [2].

Over the past decades, considerable efforts have been made to design and modify the jiggling process to increase gold recovery percentages and optimize processes [1]–[32]. Early in 1970s and late 1990s, mono-size small particles separation through a packed bed of mono-size large particles was studied by physical experiments [18], [39]–[48]. Later numerical models were also employed and the studies were extended to a much wider range of controlling variables on particle separation [3], [5], [9], [11], [15], [16], [19]–[21], [25]–[27], [29], [36], [37].

From the percentage recovery point of view, a jig can be classified as a complex system with multivariable nonlinear dynamics, large uncertainty according to external disturbances and both model structure and parameters, and multiple space and time scales dynamics [4]. Therefore, controlling recovery in jigs is, in general, not a straightforward task. These issues motivated the study of recovery behavior of jig by means of modeling and simulation tools. As pointed out by Dong *et al.* [4], there are several benefits to modeling jig: plant design and optimization, experimental design, testing research hypotheses, design and evaluation of control strategies, forecasting, analysis of plant-wide performance, and education [4], [28].

For design and optimization purposes of jig, the PET (potential energy theory) [8], [47] and DEM (discrete element method) [25], [38] simulation models are widely used to try understand the gravimetric concentration process in jigs. However, the above contributions don't address the recovery to the concentration of mineral particles widely distributed in size and density. Therefore, the investigations of Ospina and Usuga [15] and Ospina *et al.* [16] were the starting point. In these previous works, the authors evaluate the sensitivity of the mineral recovery through the variation of the operational parameters of the equipment, from a statistical and numerical analysis, using descriptive models, in the present investigation it is intended to model the jig through predictive intelligent systems.

Intelligent systems are in many places, from vehicles to cell phones and even in some common household appliances such as refrigerators and microwave ovens. This is nothing more than a black box that includes input/output. Among the scopes that can be achieved with this type of systems are the following: System identification techniques applied in real processes, investigating the current methodologies that are being studied; implement parameter estimates by means of neural networks to different systems, taking into account the

variables to manipulate and the data collected; validate with experimental data in real time the results obtained with the neural network model against using a mathematical model to confirm if there is a significant decrease in error and general improvements in the automatic control of processes, and encourage research and learning of neural networks for use in different areas of knowledge.

Artificial neural networks arise within the field of artificial intelligence, simulating the behavior of a biological neural network, in order to solve complex problems that would be very difficult to solve using conventional algorithms [49]–[52]. There are different types of artificial neural networks, which are used for different applications depending on their development. These networks are widely used for tasks such as: data classification, pattern detection, obtaining models of the retina of the eye and brain function, probability assessment, optimization, computer vision, and in the case of this research it was used for the prediction of variables in the mining industry.

However, in the field of modeling systems for mineral processing (grinding, classifying and concentrating), artificial neural networks are relatively recent, but their use is increasing in this type of systems due to the efficiency of the results that they can generate, avoiding the implementation of complex calculations with better performance [16], [24]. Currently, the intelligence systems by means of artificial neural networks can be summarized into four structures: i) supervised learning: the neural network learns a set of inputs and the desired outputs to solve the problem [53]–[56], ii) direct inverse learning: the neural network learns from the feedback of a system, so that, when the signal is obtained, it determines the parameters to be performed [52], [57]–[60], iii) utility backpropagation: this structure optimizes the mathematical equation that represents the system, where its main disadvantage is that it requires a model of the system to be analyzed [61]–[65] and iv) adaptive critical learning: similar to the utility backpropagation structure, but without the need for a model of the plant [66]–[68]. Although this type of structures are present and well accepted in different industrial processes, it is evident that in mineral processing applications and especially in the prediction of variables of interest such as mineral recovery, the existing studies of this type of design are based on simulations, this research being a starting point for the implementation of intelligent systems in gravimetric concentration equipment where experimental data obtained from a pilot scale jig is worked on.

This paper aims to use an ANN model to study the recovery percentage (yield) in a pilot jig and its interaction with other internal process variables (pulsation amplitude and frequency, water flow, particle size distribution and height of the artificial porous bed.). First an ANN model is obtained to predict recovery percentage by experimental data from the pilot jig. Then, the model is tested and assessed in terms of their ability to predict recovery with 65 other experimental tests different from those used for training the neural network.

### III. METHODOLOGY

Mineral processing is considered fundamental to the mining industry. Classically, the term mineral processing or

mineralurgy is used to describe the transformation operations involved in the upgrading and recovery of minerals [69]. These operations are carried out sequentially to obtain a raw material useful in subsequent processes or a final product desirable in the market. The operations that are grouped under the name mineral processing can be divided into four groups: size reduction, classification, concentration, and refining. Each stands out within a mineralurgical process, according to the mineralogical characteristics of the feed and the specifications of the final product. In a gravimetric concentration equipment a stream called feed is divided into two: a stream called concentrate, which has a high content of the species of interest and another stream called tails, in which this content is substantially decreased [2], [19]–[21]. Different operational parameters such as amplitude and frequency of water pulsation, bed thickness and feed flow characteristics affect the stratification process. In the following, the methodological application to obtain an artificial neural network model of a pilot-scale jig is shown.

The following methodology was proposed and followed step by step. This methodology attempts to bring together the theoretical component, the practical component, and the planning of the work.

- 1) Approach of an Experimental Design. Development of the Experimental Design. Assembly of jig at laboratory scale.
- 2) According to the proposed experiment design, the procedures to carry out the experimental tests on the laboratory scale jig and the data collection are planned.
- 3) Conducting tests in the jig at laboratory scale with alluvial ore sample suspensions to observe the concentration process in jigs, varying the proposed conditions. Sample collection and characterization.
- 4) Analysis of the results of the tests carried out.
- 5) Formulation of the ANN model that better predict the recovery percentage in jigs.
- 6) Validation of the obtained model with jig data at laboratory scale. The model was simulated in MATLAB®9.11(R2021b) using own code installed in a computer with an 8-core processor and 12GB of RAM. We used 216 samples (with sampling time  $T_s = 0.1$  s) for model identification and validation.

The aim is to estimate the percentage recovery of high-density minerals from low-density minerals in a jig according to a stratification of the particles present in a feed stream ( $F_a$ ) whose solids load is less than 10% in volume. The stratification is produced by the transmission of mechanical energy which is generated by the movement of a plunger that exerts pressure on the water ( $F_{h_2o}$ ) in the internal chamber of the jig in a harmonic way, generating a movement in pulses (ascent and descent) of the particulate system that enters the separation chamber of the jig, so that a stratification of the bed formed by the particles is obtained, which is later used to produce the separation of the minerals. The separation chamber of the jig is open to the atmosphere. Inside it there is a screen where a bed of particles is deposited with an intermediate density with respect to the minerals to be separated. The particle bed has an initial height  $H_0$  (packed bed) that rises to a height  $H_{max}$ , (fully fluidized bed)

according to the upward and downward movement of  $F_{h_{2o}}$ . The  $F_{h_{2o}}$  current contains water at a flow rate greater than or equal to the minimum fluidization velocity of the particles to be separated. The anharmonic motion of  $F_{h_{2o}}$  generates a hydrodynamic interaction between the two phases present in the process (solid-solid, solid-liquid interaction). This interaction alters the movement of the mineral particles in the separation chamber of the jig. The upward movement of water and mineral particles is called the fluidization stage. In this stage the mineral particles rise from a height  $H_0$  to a height  $H_{max}$ , initiating the stratification of the particles. At the beginning of stratification, the mineral particles with higher density and larger size tend to be deposited in the lower part of the bed, while the particles with lower density and smaller size are in the upper part of the bed. When the descent stage begins, the denser particles have a higher sedimentation velocity than the less dense particles, this allows that before the compaction of the bed, the heavier mineral particles are deposited quickly below the screen, obtaining after several cycles of pulsation, a complete separation of the mineral particles in two streams:  $F_{rejection}$  and  $F_{concentrated}$ . The process is carried out under ambient temperature conditions and no chemical reaction is present. A diagram of the general process is shown in Fig. 1. The jig from which actual data were taken to train and validate the model has the conditions reported in Table I.

A full factorial experimental design was developed involving the variables that exert the greatest control in the operation of the equipment (water flow, pulse amplitude, pulse frequency, granulometry, APB height) by means of an experimental matrix. This factorial design consists of five factors where the frequency, water flow and granulometry each have three levels (high, medium, low) and the amplitude and APB height each have two levels (high and low) resulting in a total of 108 tests plus replicates, a total of 216 tests. Table II summarizes the values considered for the different operating parameters. The response variable is the main metallurgical index (Recovery percentage (%R)).

Regarding the method of data collection and analysis. Primary data were used, which were collected through each of the ore samples generated from the experimental design (see Table I) by quantifying the gold mineral content in each of the 151 samples for identification and the 65 samples for validation, through two methods known as fire assay and time sequence analysis [7]. The effect of the operational parameters (see Table 2) on %R could be predicted from a sequential order of recovery percentage values (trend at equal time intervals).

The neural network method was selected because of its great capacity to adapt to different types of problems, the previous experience with the use of neural networks [70]–[73], and the ease of implementation of this type of technique, in addition to being a technique with great potential that is causing a revolution by proving to be the future of technology.

An artificial neural network (ANN) is an automatic learning and processing paradigm inspired by the functioning of the human nervous system [58], [59], [65]–[67], [74]. A neural network is composed of a set of neurons interconnected by links, where each neuron takes as inputs the outputs of the preceding neurons, multiplies each of these inputs by a weight

and, by means of an activation function, calculates an output. This output is in turn the input of the neuron it precedes. The union of all these interconnected neurons the artificial neural network [50], [51], [54], [55].

Fig. 1. Jig Diagram.

TABLE I. PILOT SCALE JIG CHARACTERISTICS

Feature	value
Mineral Feed Flow ( $F_a$ )	200 g/min
Water flow ( $F_{h_{2o}}$ )	[1.5-2.5] gal/min
Mineral size (granulometry)	[125-850] $\mu\text{m}$
Artificial porous bed height (APB)	[2.5-3.75] cm
Pulse amplitude	[5-7] mm
Pulse frequency	[5-9] Hz
APB particle diameter	3 mm

TABLE II. OPERATING PARAMETERS AND RESPECTIVE OPERATING LEVELS

Levels	High	Medium	Low
Frequency (Hz)-F	9	7	5
Pulse amplitude (mm)-A	7	-	5
Granulometry (mesh series Tyler)-T	+50 (1)	-50 +100 (2)	-100 (3)
Water flow (gal/min)-H	2,5	2,0	1,5
Artificial porous bed height (cm)	3,75	-	2,5

The artificial neural network as well as biological networks learn by repetition, and the more data you must train and the more times you train the network the better results you will get [62], [63], [67]. Training an ANN is a process that modifies the value of the weights associated with each neuron, so that the ANN can generate an output from the data presented in the input [52]. The weights are really the way the neuron learns. These weights will be modified in a certain way to adapt the value of the output in such a way as to minimize its error with respect to the real result that the artificial neuron should produce [55], [75].

Based on the above arguments, the following questions arise for this methodological development: What data are relevant for the management of the problem to be addressed?, which variables are relevant to address and manage this problem?, where can the data be obtained?, how to prepare and encode the data?, what type of network should be chosen?, how many hidden layers and how many neurons are necessary to manage the possible solution to the proposed problem?, what learning rule to choose?, and what initialization is given to the weights?. These data will be acquired by means of experimental tests using the pilot plant of the jig. The data obtained from the experimental tests will be organized in a spreadsheet to be later entered into the software that will be used to code the neural network (Matlab@R2021b)). The network to be designed will be initially selected with a configuration of one hidden layer with 13 neurons in each layer, five inputs, one output and a learning coefficient of 0.3 and random weights. However, once implemented, several tests will be performed to determine if a change in any of the parameters is necessary to obtain better results. The structure intended to be implemented for this proposed model is shown in Fig. 2. This structure has the possibility of being changed if a better alternative is discovered in the future during the process of development, research, and implementation.

As regards the activation functions, several functions were tested, among them the logsig, the ReLu, the softplus, the hardlim and the tansig, choosing in the end the logsig since it is the function that reaches a low margin of error in the shortest time for this specific process with the input data obtained.

Finally, it is possible to observe that the neural network was developed with its own code (the Matlab library was not used) along with the database with which it would be trained. The Matlab program consists of three parts: i) Network configuration: This is the main part, where the neural network is configured and trained. This was done using arrays of cells, so that it was possible to store arrays of different sizes in a single variable. Each row of the network variable is a different type of data, such as the weights of each layer, biases, errors, and so on, ii) Feedforward: In this file the forward propagation stage of the network was performed, where all the elements of the database are passed through the neural network, obtaining an output, and iii) Backpropagation: The backpropagation algorithm implemented for this network was gradient descent, where the aim is to minimize the error by calculating the partial derivatives of the error or cost function (mean squared error in this case), in terms of the weights of each neuron, modifying them in order to reduce the error in the output.

Fig. 2. Neural Network Configuration for Intelligent System.

Several tests were performed to verify the learning of this network and that the data delivered by it were consistent even with parameters that it had not received in the training stage, obtaining more than acceptable values, and thus proceeding to the implementation stage.

To assess the performance of ANN model, was followed the procedures suggested by Cruz et al.[58]. After visual evaluation and tests for fitting the behavior, the two criteria: Root Mean Square Error (RMSE), and coefficient of determination ( $R^2$ ) were applied [31], [32], [34] (see Eqs. (1) and (2)):

$$RSME = \sqrt{\frac{\sum_{t=1}^n (x - x_t)^2}{n}} \quad (1)$$

$$R^2 = 1 - \frac{\sum_{t=1}^n (x - x_t)^2}{\sum_{t=1}^n (x - \bar{x})^2} \quad (2)$$

where  $x$  is experimental data of the recovery percentage,  $x_t$  is ANN output,  $n$  is the sample size and  $\bar{x}$  is the mean of experimental data for the recovery percentage.

#### IV. RESULTS

This section presents the results obtained in this research, which includes the description of the intelligent implementation. The neural network was trained from plant experimental data, using the database "JigRNA.xlsx", which have 151 rows of data, the first column being the pulsation frequency value, the second the pulse amplitude value, the third the ore size, the fourth the water flow value, the fifth the APB value, and the sixth to the mineral recovery percentage value (output). Table III shows a portion of the recorded data.

Once the results of the experimental tests were obtained, the variables values were normalized in the interval 0 to 1, this in order to work with less uncertainty the data that would be entered into the neural network and have a free response of

engineering units. Eq (3) shows how the data were normalized and Table IV shows a portion of the normalized data.

$$Normalized_{value} = \frac{(value_{real}-value_{min})}{(value_{max}-value_{min})} \quad (3)$$

After normalization, a multilayer perceptron ANN with five inputs (corresponding to the five parameters used in Table IV) was created using proprietary code in a Matlab® script. The program identifies the five input and the output (%R). From the simulations performed, errors of less than 2% were obtained with 13 neurons in the hidden layer and starting the training process for 200 epochs. The results of the network without training and the training performance are shown in Fig. 3 and 4 respectively.

Fig. 3 shows the unsorted distribution of the data for the untrained neural network, once the training algorithm is started, it converges in only 40 epochs (see Fig. 4), making the network follow the input patterns that have been provided.

The performance of the ANN model was compared in two stages. In the first stage (Fig. 5), the identification data are shown with the absolute errors (maximum, average and minimum) that are reported in Table V.

Fig. 5. ANN Performance.

In the second stage the model is compared by means of the validation data (Fig. 6) with their respective R<sup>2</sup> and RSME presented in Table VI. Additionally, Fig. 7 shows the histogram of the errors made by the Neural Network for the validation data.

Fig. 6. Relationship of the Validation Data with the ANN Output.

TABLE VI. ERRORS IN VALIDATION

Model	R <sup>2</sup>	RSME
ANN	0,9172	0,105

Fig. 7. Histogram of ANN Errors with Validation Data.

It can be seen from Fig. 5 to 7 and Tables V and VI that the performance of ANN model may be suitable for prediction of recovery percentage in gravimetric concentration equipment in the mineral processing industry, both in identification and validation, yielding errors of less than 2%, which is adequate for engineering purposes, especially to implement an optimization strategy for the jig concentration process.

The ANN model result in its matrix form can be expressed according to Eqs. (4) to (9). In the hidden layer Eq. (6) the inputs to the network  $X_{5 \times 1}$  were shown one by one (see Table 4). These result in an output  $Y_{13 \times 1}^1$  (Eq. (7)) for each neuron from applying the activation function  $f^1(a_{13 \times 1}^1)$  (logsig). Subsequently, the outputs of the neurons of the hidden layer are fed to the neuron of the output layer (Eq (8)) to obtain the output of the whole network or each input supplied (Eq. (9)).

$$a_{n \times 1}^k = W_{n \times p}^k \cdot Y_{p \times 1}^{k-1} + b_{n \times 1}^k \quad (4)$$

$$Y_{n \times 1}^k = f^k(a_{n \times 1}^k) \quad (5)$$

$$a_{13 \times 1}^1 = W_{13 \times 5}^1 \cdot X_{13 \times 1} + b_{13 \times 1}^1 \quad (6)$$

$$Y_{13 \times 1}^1 = f^1(a_{13 \times 1}^1) \quad (7)$$

$$a_{1 \times 13}^2 = W_{1 \times 13}^2 \cdot Y_{13 \times 1}^1 + b_{1 \times 1}^2 \quad (8)$$

$$Y_{1 \times 1}^2 = f^2(a_{1 \times 1}^2) \quad (9)$$

In Eq. (4) to (9), the  $W^k$  are the weights of each of the connections of the neurons with the upstream and downstream layers and the  $b^k$  are the biases of each of the neurons. These two parameters are trained for each input supplied to the network and are updated epoch by epoch until the neuron output is as close as possible to the experimental data. The values of these parameters after training and validation are shown in Tables VII to IX.

13	4,9074

In Table VII, each row represents a neuron of the hidden layer, and each column represents the connection to each of the inputs (corresponding to the five operational variables of the jig). Similarly in Table VIII, each row corresponds to an output of the hidden layer neurons, and each column is the connection from the hidden layer to the output neuron of the network. Finally, Table IX can be interpreted as follows: each row corresponds to the bias of each of the hidden layer neurons. The bias value for the output layer neuron was  $b_{1 \times 1}^2 = 6,4373$ .

## V. DISCUSSION OF RESULTS

In this paper we proposed as a contribution an ANN model for the estimation of the recovery percentage in a gold gravimetric concentration equipment known as a jig, which was based on the development of its own code in Matlab®, based on experimental data from a laboratory-scale jig (see Figure 1). With respect to traditional empirical and DEM-CFD modelling [15], [16], [20], [25], [26], artificial intelligence applications can become more efficient than the conventional techniques still used in the mineral processing industry as the ones proposed in this research and supported by [24] where is emphasized that in the ANN model, the input variables can include other controlling variables, such as other particle properties and system dimensions, feature that is very similar to phenomenologically based models.

Comparing both the identification and validation errors. It can be said that the performance of the ANN model adequately predicts the response variable (RSME=0.105), despite the great dependence and sensitivity of the recovery percentage with respect to variability. Of the five main operational parameters of the equipment (frequency and amplitude of pulsation, water flow, height of the artificial porous bed, and size of the mineral to be separated). The error in the ANN model could be decreased by two orders of magnitude if more delve into the number of neurons and hidden layers in the network that give a better fit with respect to the data provided. The above was evidenced in [58] where it is ratified that the use of different neural networks, whether they use the gradient method or the

convolutional ones, converges to a global minimum of the error.

The prediction performance of the model is compared by experimental data (see Fig. 5 and 6). Note that, since the validation data were recorded from laboratory-scale jig, It is necessary to be able to validate the model taking into account more ore samples and on a full-scale jig, as there could be a significant lag between the result of the pilot plant and the data recorded on an industrial-scale jig [3]. This type of inconvenience can be easily compensated with the application of scaling techniques, integrating the total plant and control design [3], [32].

The average prediction errors that were estimated using the validation data sequence for the model, are shown in Tables V and VI. We see that the ANN model fits well, but one of the limitations of these prediction errors is that a significant number of dynamics (Particle-particle interaction and particle-fluid interaction) remains unmodeled. This may be since when employed models that depend heavily on data (empirical), built through experimentation and observation, the interpretability of many other phenomena that occur in this type of process is limited to the little knowledge that this type of structures present, in addition to other effects that can only be adequately modeled in a phenomenological mathematical structure.

This paper has shown that the modeling framework based on ANN models may give models that are as useful, accurate, and reliable as with phenomenological modeling, even if the system is well understood. Such models may serve as an alternative that may be attractive especially for systems that are not well understood, as in the case of jig. Moreover, we believe ANN model developed in this framework has significant advantages over many other non-linear empirical modeling frameworks. The reason is that it admits interpretability of the model through the intuitive and easily understandable operating regime concept, and the fact that the machine learning models can be interpreted independently.

## VI. CONCLUSIONS

In this work, ANN model was developed, and their performance was evaluated by means of absolute errors. It can be said that the application of this type of model in real mineral processes can guarantee an adequate optimization of highly dynamic processes, since the expected results can be obtained in a shorter time without the need to use complex mathematical models, which are often difficult to obtain, or the phenomena involved in most of them cannot be understood in depth.

ANN models have a wide use in present day engineering. In this contribution, special attention is paid to control oriented models. As is well known, chemical, biochemical, and mining-metallurgical models are complex and nonlinear due to the multiple interacting phenomena, making them hard to implement in process control tasks. Although an ANN model (a type of black-box model) is not able to capture and predict the essential phenomena (mass, energy, and momentum transfer), gives significant rapid response with respect to the variables that are intended to intervene, thus providing strategies to rationally optimize and to control industrial scale

jigs since in this type of process a large amount of data can be obtained from both input and output variables.

With the implementation of this type of advanced modeling strategy, there was a significant reduction in the error when comparing the conventional empirical data against the experimental data using neural networks and, in turn, a better response to the operational variability of the processes was evidenced. Considering the results obtained, it can be affirmed that neural networks can be the pillar of the so-called fourth industrial revolution, proving to be useful in multiple fields, offering high efficiency and reliability in the optimization of industrial processes.

It is concluded from the identification and validation performed that the ANN model is very sensitive to the data provided. Further simulations on the ANN model, changing the number of neurons in the hidden layer could show very significant changes in the errors of both the identification and validation data.

As a future work derived from the present research, it is intended to complement the architecture of the proposed system by including other artificial intelligence models for the analysis of recovery percentage, using, for example, fuzzy logic, in order to enable the implementation of early warning systems and particle-particle interaction and particle-fluid interaction for monitoring recovery percentage.

#### ACKNOWLEDGMENTS

The authors would like to thank the Universidad de Cartagena – Colombia, the Instituto Tecnológico Pascual Bravo - Colombia for their support in the development of this research through the research project with ID: IN202204, and the Instituto Tecnológico Metropolitano - Colombia for their support through the research project entitled "Diseño y modelamiento de un concentrador gravimétrico con campo eléctrico para la recuperación de minerales" with ID: P20221.

# Risk Prediction Applied to Global Software Development using Machine Learning Methods

Hossam Hassan<sup>1</sup>, Manal A. Abdel-Fattah<sup>2</sup>, Amr Ghoneim<sup>3</sup>  
Information Systems Department, Helwan University, Egypt<sup>1,2</sup>  
Computer Sciences Department, Helwan University, Egypt<sup>3</sup>

**Abstract**—Software companies aim to develop high-quality software projects with the best global resources at the best cost. To achieve this global software development (GSD), an approach should be used which adopts work on projects across multiple distributed locations, and this is also known as distributed development. When companies attempt to implement GSD, they face numerous challenges owing to the nature of GSD and its differences from traditional methods. The objectives of this study were to identify the top software development factors that affect the overall success or failure of a software project using exploratory data analysis to find relationships between these factors, and to develop and compare risk prediction models that use machine learning classification techniques such as logistic regression, decision tree, random forest, support vector machine, K-nearest neighbors, and Naive Bayes. The findings of this study are as follows: in GSD, the top 18 factors influencing the software project are listed; and experiments show that the logistic regression and random forest models provide the best results, with an accuracy of 89% and 85%, respectively, and an area under the curve of 73% and 71%, respectively.

**Keywords**—Global software development; distributed development; risk prediction model; machine learning

## I. INTRODUCTION

The entire software development approach has permanently changed in the last two decades to support distributed development environments with distributed teams [1]. This strategy can be described as a contract between two parties, with the client representing advanced countries and the vendor representing developing countries, with the goal of achieving mutual interests [2]. Therefore, the main reason for the widespread use of global software development (GSD) is that clients worldwide need highly specialized resources and tools at a reasonable price [3].

In addition, GSD has seen a considerable increase in contracts and business in recent years. The use of distributed development teams in various time zones and geographic locations may be referred to as the ‘new age’ of development projects employing GSD [4]. The affordable price of GSD is a significant factor contributing to its appeal. Consequently, there has been great success in the mutual benefit between clients and vendors [5], [6]. Some benefits of adopting GSD include sharing knowledge, using the most recent technologies, access to resources, economic benefits, lower expenses, and successful overall project completion [7], [8].

In addition, the challenges and limitations that have a significant effect on GSD should be pointed out. For example,

it can be difficult for distributed teams to communicate with each other and work together due to language barriers, cultural norms and limits, time zones, leadership, team capabilities, and project management [9]–[11]. One of the most serious issues confronting GSD is the location, distance, and communication between the distributed teams [12]. In addition, the problem of team communication has been solved owing to the benefits of using agile methods such as scrum [8].

However, risks remain when clients attempt to adopt and use this approach in their projects. It can also yield the opposite results if it is misused. In the beginning, the term "risk" can be identified as a collection of software project characteristics, situations, and regulations that present a hazard to a project's overall success. It is also important to determine how often these risks occur, and how to prepare for them [13].

The Project Management Institute (PMI) shows that most risk management methods and procedures are ignored and thrown out, especially in the IT industry, because they are too general or only work in a specific situation [14]. Despite this, software projects that use techniques and tools to predict risk can detect approximately 70% and avoid 90% of harmful risks [15].

So, companies need to know the benefits and the risks of adopting the GSD approach, in an early stage of the development, to avoid any financial loss. In addition, companies need to also know if adopting GSD approach is suitable for their project or it will have negative results. Therefore, a software risk prediction model using the machine learning classification techniques was provided in this study, to make a prediction of the success or failure of the software project in the domain of GSD.

In this study, the following are discussed: First, previous systematic literature reviews were reviewed to identify the top software risk factors affecting GSD. Second, a dataset was collected from software projects in various regions of the world. Third, exploratory data analysis (EDA) was conducted to find different insights and correlations between these factors and each other. Fourth, software risk prediction models were built using different supervised machine learning classification techniques. Finally, software risk prediction models were evaluated and represented to determine the best model suitable for the GSD approach.

As a result, this study answers two main questions in the section between parentheses. RQ1: Which software risk factors

are essential to the GSD domain and significantly affect the software risk prediction? (Section III-A)

RQ2: What are the best machine learning techniques for software risk prediction in GSD? (Section V)

The remainder of this paper is organized as follows. Section II presents related work. The methodology is described in detail in Section III. Section IV presents an examination and measurement of the precision. Section V presents the results of the proposed model. Section VI discusses the validity threats. In Section VII the conclusion is presented, finally, in Section VIII, additional work is listed to be considered in the future.

## II. RELATED WORKS

This section presents two types of studies. The first one concerns a systematic literature review related to GSD factors, and the second one is related to software risk prediction using machine learning and other techniques.

### A. Systematic Literature Review for GSD Factors:

In [5], an empirical investigation was conducted to figure out the top requirements of engineering (RE) practices in GSD. Among the 66 practices, the results showed that only six key factors play an important role in GSD, as listed below:

- 1) Identify and consult with system stakeholders.
- 2) Prioritize requirements.
- 3) Define system boundaries.
- 4) Define standard templates for requirements.
- 5) Check if requirements document meet your standards.
- 6) Uniquely identify each requirement.

The dataset was collected by conducting an online survey questionnaire. For the evaluation of these factors, 56 experts from GSD were involved. Limitation and future work: the questionnaire relied only on closed questions and focused only on the company size, testing these factors, and trying to develop a framework to be used in the future.

In [16], the authors tried to prioritize the success factors that affect requirement change management (RCM) in the GSD. Fuzzy logic analytical hierarchy progress (FAHB) was used to conduct the prioritization. The result of this study was to find out the RCM success factors and categorize them into four groups: team, technology, process, and organizational management. The dataset was collected by conducting a questionnaire survey and retrieved around 81 responses. Evaluation metrics for the prioritization were conducted by using experts' responses. Limitations and future work: sample size of the dataset needs to be widened, and organization size and types should be considered, in addition, success factors, barriers, and best practices need more investigation and analysis.

The authors in [17], focused on scaling agile projects in the domain of GSD. They mapped 44 agile practices to the SAFe Framework. Instructions were given for how the SAFe practices can be used in agile global software development (AGSD) projects. The dataset was collected by reviewing 86 studies. Of these studies, only 24 papers discussed the scaling of agile, from which the authors selected 44 practices to be mapped on the SAFe Framework. Limitations and future work:

(AGSD) practices need to be evaluated and should also be tested in the real industry. In addition, the mapped process of these practices needs to be evaluated.

### B. Software Risk Prediction Models:

In [15], a software risk prediction model was created based on risk analysis of the project by using its context history and project characteristics in the software development life cycle (SDLC) as shown in Fig. 1. The model is called the Atropos model and consisted of six main phases listed below:

- 1) Data Gathering through interface and bulk uploading.
- 2) Similarity by characteristics of the project.
- 3) Store context histories of the project.
- 4) Similarities by context histories.
- 5) Recommendation of any potential risks.
- 6) Risk management and monitoring.

The dataset was collected based on 153 software projects from a financial company. Evaluation metrics of the model showed an acceptance rate of 73% and an accuracy rate of 83%, and these results were assessed by 18 experts. Limitations and Future work for the model are to improve the model's accuracy, to improve the proposed model and methodology, additional use of prototype, the number of practitioners, and the duration of the study (5 weeks only).

In [9], artificial neural network (ANN) model was created to predict the risk factors in GSD. The model used algorithms such as Levenberg–Marquardt, Bayesian Regularization, and Scaled Conjugate Gradient. The dataset was collected by sending 760 questionnaires to companies. 390 were received, and 116 were rejected, leaving 274 responses that were used as the primary data set. Evaluation metrics of the model were conducted by using least mean square error (MSE), and the results showed that Bayesian Regularization gave better results as compared with the other two approaches and matched the results from these studies [18], [19]. Limitations and Future work for the model are the sample dataset needs to include many companies and random data collection should be used to generalize the model, also the author recommended to use deep learning to get more insights and accurate results in the future.

Fig. 1. Shows the Atropos Six-Stage Model [15].

In [20], the authors provided a software reliability prediction algorithm. They used fuzzy logic and ANN in their model. The dataset was collected from John Musa of Bell Laboratories and received from the IEEE repository. Evaluation metrics of the model were conducted by using root mean square deviation error (RMSE) and showed that the fuzzy-neural method was the best compared to other algorithms. Limitations and future work for the model: the model is restricted to one factor (time to failure). In addition, many software risk factors should be used to evaluate this model better.

The authors in [21] developed a fuzzy logic hybridized framework for software risk prediction models during the decision-making process. Technique for order of preference by similarity to ideal solution (IF-TOPSIS), fuzzy decision-making trial and evaluation laboratory (DEMATEL), and crow search algorithm (CSA), optimized adaptive neuro-fuzzy inference system (ANFIS) were used for the software model prediction. The dataset consisted of 93 software projects, 70% used for training and the remaining used for testing and validating the model. The results showed that integrated fuzzy was accurate in software risk prediction. Limitations and future work: make a set of decisions and use many software factors and advanced machine learning techniques to improve and validate the results.

To reduce cost risks, the authors of [22] amplified the constructive cost model (COCOMO-II) in the GSD context. The dataset was collected by conducting a questionnaire and

receiving around 175 responses. Evaluation metrics of the model were conducted by using Magnitude of Relative Estimates (MRE) and experts' judgment. Limitations and Future Work: the model is in an early stage and needs more validation and evaluation. In addition, mathematical or machine learning (ML) techniques may be used in the future.

In [23], the authors developed ML models for defect prediction in the domain of software reliability and performance. The models were built using ANN, random forest (RF), random tree (RT), decision table (DT), linear regression (LR), Gaussian processes (GP), SMOreg, and M5P. The dataset for these models was from the NASA promise repository. The results showed that the combination of different ML algorithms is effective in the prediction of software defects. Evaluation matrices used were correlation coefficient ( $R^2$ ), mean absolute error (MAE), (RMSE), relative absolute error (RAE), and root relative squared error (RRSE). Limitation and Future works: different datasets and ML algorithms can be used to evaluate the results. In addition, more investigation into software factors should be conducted to improve these results.

Most previous studies concentrated on a limited number of factors, as summarized in Table I. In addition, the dataset needs to be enlarged to include more regions, and (ML) techniques need to be improved and evaluated using real data from software companies, as will be provided in the subsequent section.

TABLE I. OVERVIEW OF PREVIOUS RESEARCH STUDIES FOR SOFTWARE PREDICTION MODELS

Reference	Dataset	ML Techniques and algorithms	Evaluation metrics	Limitation and Future work
(Filippetto et al, 2021) [15]	The dataset was collected based on 153 software projects from a financial company. ### III. RESEARCH METHODOLOGY

This section describes the methodology used to develop the GSD-applicable software risk-prediction model. Fig. 2 illustrates the six phases of the proposed model. Systematic Literature review (SLR) analysis (Section III-A), dataset selection (Section III-B), dataset preprocessing (Section III-C), modeling (Section III-D), experimental evaluation (Section IV), and risk prediction results (Section V).

#### A. Systematic Literature Review Analysis:

The proposal to build the software risk prediction model was based on many systematic literature reviews (SLR) that collected the software risk factors that affect the software in GSD. SLRs included empirical studies published between 2018 and 2022. After reviewing these studies, a list of 145 factors essential to software project success was created. (Available in Appendix "I").

Then, these factors were analyzed and reprocessed to determine the most significant factors in the GSD domain. To do this, the following three steps were followed:

1) *Merging step*: There were several duplicates; therefore, the first step in removing these duplicated factors was to merge the duplicates, which helped lower the total number by more than half.

2) *Filtration step*: After the merging stage, the factors were ranked and filtered by selecting only those with a frequency rate of greater than 50 percent. In this manner, the top 18 factors that affect software in the GSD domain can be collected.

3) *Categorization step*: In this phase, the top 18 factors were categorized into four categories: requirements, management, technical, and cultural, as shown in Table II to answer RQ1.

#### B. Dataset Selection

This subsection describes the data collection procedure and descriptive analysis of the dataset used to construct the model. The dataset was collected through a questionnaire survey and interviews with software companies and experts from various global regions. The main target was to focus on organizations that had extensive experience with outsourcing and were already using the GSD method. The dataset consists of information from 140 software projects in the GSD domain. Then, the data was gathered by conducting a questionnaire survey and interviews with companies and experts. The questionnaire is based on the top 18 factors listed in Table II. The data were collected from various regions that support a wide range of clients and vendors, including western Europe, central and eastern Europe, Africa, and the Middle East.

The dataset attributes were project ID, region, job, experience, company type, requirement clarity, project scope, requirement changes, project planning, project size, project management, communication, cost, commitment, modern technologies, roles and responsibilities, skilled staff, organizational stability, language and culture, time difference, progress, team size, methodology, and project status.

Then, the attributes were classified into numerical and categorical categories. The independent and dependent attributes were then determined. The dependent attribute is "Project Status." The remaining 23 attributes were independent attributes. Table III presents a more detailed description of the attributes of the dataset. In addition, Appendix "II" provides a sample of the questionnaire with attributes represented as questions.

TABLE II. TOP 18 SOFTWARE FACTORS THAT AFFECT GSD

Requirement Factors	
1.	Requirement ambiguity
2.	Requirement changes
3.	Requirements scope
4.	New technologies
5.	Project size
Management Factors	
6.	Competence level of project manager
7.	No planning or inadequate planning
8.	Low commitment of stockholders
9.	Progress measure
10.	Cost balance
11.	Lack of roles and responsibilities
12.	Team size
Technical factors	
13.	Staff does not have required skills
14.	Unstable organizational environment
15.	Methodology followed
16.	Communication infrastructure and process
Cultural factors	
17.	Language and culture differences
18.	Time zone difference

TABLE III. DATASET VARIABLES AND DESCRIPTIVE STATISTICS

n	Attributes	Type	Description	Mean	Std	Min	50%	Max
1	Project ID	Numerical (int64)	Project unique ID, which starts with one and ends by 140	—	—	1	—	140
2	Region	Categorical (object)	Region attributes lie in 5 main regions: Western Europe, Central, and Eastern Europe, Asia, Africa, and the Middle East.	—	—	—	—	—
3	Job	Categorical (object)	The job role of the person/company developer who filled the form	—	—	—	—	—
4	Experience	Numerical (int64)	Team/individual experience measured in years	3.925	4.171	1	3	30
5	Company Type	Numerical (int64)	company types measured by (national, international, and startup)	0.535	0.528	0	1	2
6	Requirement Clarity	Numerical (int64)	the level of requirements clearness is measured as (clear, moderate, unclear, and ambiguous)	2.1	0.798	1	2	4
7	Project Scope	Numerical (int64)	the project scope is measured as (clear, moderate, unclear, and ambiguous)	2.071	0.810	1	2	4
8	Requirement Changes	Numerical (int64)	the project scope is measured as (minor, normal, heavy, and messy)	2.55	0.798	1	2	4
9	Project Planning	Numerical (int64)	the project planning is measured as (clear, moderate, unclear, and ambiguous)	2.214	0.863	1	2	4
10	Project Size	Numerical (int64)	the project size is measured as (Enterprise, large, medium, and small)	2.185	0.918	1	2	4
11	Project Management	Numerical (int64)	Project manager's quality is measured as (Expert, Moderate, Basic, and None)	2.142	0.844	1	2	4
12	Communication	Numerical (int64)	communication is measured as (Excellent, Moderate, need enhancements, and worst)	2.028	0.804	1	2	4
13	Cost	Numerical (int64)	cost is measured as (balanced, moderate, and not balanced)	1.842	0.626	1	2	3
14	Commitment	Numerical (int64)	stakeholders' commitment is measured as (High, moderate, and low)	1.75	0.669	1	2	3
15	Modern Technologies	Numerical (int64)	modern technologies are measured as (many, normal, and few)	1.75	0.613	1	2	3
16	Roles and Responsibilities	Numerical (int64)	responsibilities are measured as (clear, moderate, and unclear)	1.721	0.74	1	2	3
17	Skilled Staff	Numerical (int64)	skilled staff are measured as (Agree, moderate, and disagree)	1.485	0.64	1	1	3
18	Organization Stability	Numerical (int64)	organizational stability is measured as (stable, normal, and unstable)	1.607	0.716	1	1	3
19	Language and Culture	Numerical (int64)	language and culture are measured as (reasonable, can be handled, and unreasonable)	1.55	0.627	1	1	3
20	Time Difference	Numerical (int64)	Time Difference is measured as (reasonable, can be handled, and unreasonable)	1.7	0.675	1	2	3
21	Progress	Categorical (object)	Progress level Measured by (task level, module level, sprint level, and delivery level)	—	—	—	—	—
22	Team Size	Numerical (int64)	Team size measured by team members	0.807	0.855	0	1	4
23	Methodology	Categorical (object)	the methodology was measured as (waterfall, scrum, Kanban, extreme programming, feature-driven, lean development, crystal, and dynamic system development, and rapid development )	—	—	—	—	—
24	Project status	Numerical (int64)	Project status represents this project is success or failed	0.814	0.39	0	1	1

### C. Dataset Preprocessing

In this subsection, the data preprocessing techniques are presented. This phase can be considered as the initial phase for building the machine learning model. Real-world data are often incomplete, inconsistent, or incorrect (because they have outliers or mistakes). Thus, preprocessing techniques must be conducted to help refactor the dataset to keep it clean, formatted, and organized [24]. This subsection includes four steps of dataset preprocessing: identifying the dataset, finding,

and handling missing values, encoding categorical attributes, and feature selection.

1) *Identify dataset:* During data preparation, it is essential to identify insights into the dataset because improper handling may lead to misleading software model results and serious model risks. Table III shows that the dataset is divided into two main types: categorical and numerical. It also provides a full picture of the dataset's characteristics, such as its type,

description, mean, standard deviation (Std), and minimum and maximum values.

2) *Finding and handling missing attributes:* Incomplete data can lead to inaccurate results. Consequently, these situations may be addressed by finding the mean of the attributes using numerical data. This is more efficient than the usual methods of treating missing values, which include omitting the entire row or column, as this might lead to data misrepresentation or bias in the dataset. Alternatively, mean, median, or mode can be used.

3) *Encoding categorical data:* As it is known, machine learning deals with numerical attributes only. Thus, categorical attributes can't be used until they are transformed into numerical data. As a result, only four categorical attributes which are: "Region," "Job," "Progress," and "Methodology" should be transformed into numerical attributes. The Python scikit-learn library label encoder technique was used to transform the categorical attributes into numerical attributes. In this technique, each label is assigned a unique integer based on the alphabetical ordering [25].

4) *Feature selection:* From the list of 24 attributes in Table III, Independent attributes that are significant to the model must be chosen. Therefore, weak attributes or attributes that do not have a relationship with the model should be excluded. To determine these relationships, a correlation analysis was conducted, which is a common multivariate (EDA) that relies on statistical techniques to measure the linear relationship between attributes and each other to obtain a better insight into the factors and their relationships [26]. The correlation coefficient is the unit of measurement used to calculate the intensity between the two variables. It has three types:

- a) *Positive correlation:* (0 to 1) means that both attributes are in the same direction; an increase in one will increase the other, and vice versa
- b) *Negative correlation:* (-1 to 0) means that both attributes move in the opposite direction; an increase in one will decrease the other, and vice versa.
- c) *Weak/zero correlation:* (0) means that the two attributes do not affect each other.

The formula for the correlation coefficient can be written as:

$$R = \frac{\sum(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum(x_i - \bar{x})^2 \sum(y_i - \bar{y})^2}} \quad (1)$$

where R is the correlation coefficient, usually from -1 to 1,  $x_i$  is the value from the X dataset,  $\bar{x}$  is the mean value of the X dataset,  $y_i$  is the value from the Y dataset, and  $\bar{y}$  is the mean value of the Y dataset. More details regarding the dataset attribute correlation are presented in Fig. 3.

Fig. 3. Correlation Analysis for Dataset Attributes.

Fig. 4 represents the independent attributes that have  $R \geq 0.4$  ("Project Scope," "Project Planning," "Responsibilities," and "Skilled Staff") and independent attributes that have  $R \leq 0$  ("Region" and "Experience"), which will be excluded from the dataset so as not to affect the proposed model.

Fig. 4. Correlation Coefficient (R) between Attributes.

#### D. Machine Learning Model Builder

In this subsection, the implementation of ML models is discussed. The category for the proposed ML model is called a "supervised problem" because the dataset is labeled (one with the correct answer) which can be used to teach the model how to predict software risk [27]. The model is based on the top six machine-learning classification algorithms: logistic regression, (DT), (RF), support vector machine (SVM), K-nearest neighbor (KNN), and naïve Bayes.

1) *Logistic regression:* The logistic regression algorithm is a classification technique based on statistical procedures. Logistic regression is a widely used ML algorithm for binary classification that makes predictions based on the sigmoid function [28].

The sigmoid function can be defined as a mathematical procedural function that takes any real number and maps it to a probability between one and zero. The formula for the sigmoid function can be expressed as:

$$\sigma(x) = \frac{1}{1+e^{-x}} \quad (2)$$

where  $\sigma(x)$  is the sigmoid function that returns values ranging from zero to one,  $x$  represents the sample,  $e^{-x}$  represents the inverse of the exponential function  $\frac{1}{e^x}$

2) *Decision tree (DT)*: The decision tree algorithm can be represented as a hierarchical or flowchart which represents the data with decisions [25]. The decision tree has many branches created by splitting the dataset into subsets based on the essential attributes, and each branch can be considered as an if-else statement. To create the hierarchical structure in the decision tree, the Gini index algorithm was used to select the best attribute selection measures (ASM) to split the data. The Gini index algorithm can be written as:

$$Gini(D) = 1 - \sum_{i=1}^c P_i^2 \quad (3)$$

where  $c$  is the total number of classes, and  $P_i$  is the probability of picking the data point with class  $i$

3) *Random forest (RF)*: An RF is a collection of decision trees. It is a common ensemble method that aggregates the results of multiple models. RF uses the bagging technique, which allows each tree to be trained on random dataset sampling and takes the majority vote from the trees [25].

4) *Support Vector machine (SVM)*: SVM is a machine learning algorithm that can be used for classification and regression analysis [26]. The purpose of SVM is to classify data based on hyperplanes in an N-dimensional (number of attributes) space, which is the border between positive and negative classes, maximizing the distance between data points from different classes.

5) *K-Nearest Neighbour (KNN)*: The KNN is an analogy-based ML algorithm. In general, it uses the Euclidean distance to calculate the distance between points and each other and then assigns the label of new data based on the labels of the nearest data points. The Euclidean distance can be written as

$$d(y, x) = \sqrt{\sum_{i=1}^n (x_i - y_i)^2} \quad (4)$$

where  $d$  is the Euclidean distance;  $(y, x)$  is the two-point Euclidean N-space;  $x_i, y_i$  represent the Euclidean vectors;  $n = N$ -space (attribute numbers).

6) *Naïve bays*: The naive Bayes algorithm depends on Bayes' theorem, which describes the probability of an event based on prior knowledge. Naive Bayes assumes that each feature is independent of the other [27]. The calculation of naive Bayes can be represented as:

$$P(A|B) = \frac{P(B|A) * P(A)}{P(B)} \quad (5)$$

where  $P(A|B)$  is a conditional probability, that is, the probability of an event A occurring given that B is true.

$P(B|A)$  is also a conditional probability: the probability of event B occurring given that A is true,  $P(A)$  and  $P(B)$  are the probabilities of observing A and B, respectively, without any conditions.

#### IV. EXPERIMENTAL EVALUATION

For model evaluation, different techniques and algorithms are described in this section. The essential part of any model is to determine whether it is accurate. Five evaluation metrics were used to measure the confusion matrix, accuracy, recall, precision, and area under the curve (AUC).

1) *Confusion matrix*: A confusion matrix is the best way to solve binary classification problems [35] because it shows the actual and predicted values and summarizes them in a matrix, as shown in Table IV.

2) *Accuracy*: Accuracy is the most important indicator for measuring a model's performance [29]. The purpose of the accuracy was to measure the percentage of the total number of correctly classified examples predicted over the total number of examples. The metric equation can be written as.

$$ACC = \frac{TP+TN}{TP+TN+FP+FN} \quad (6)$$

3) *Recall*: The recall evaluation metric, also known as the true positive rate (TPR), is used to determine the proportion of correctly classified positive classes [29]. The metric equation can be written as

$$R(TPR) = \frac{TP}{TP+FN} \quad (7)$$

4) *Precision*: The primary purpose of precision metrics is to measure the positive patterns from the total predicted patterns in a positive class [29]. The metric equation can be written as

$$P = \frac{TP}{TP+FP} \quad (8)$$

5) *AUC*: The area under the ROC curve (AUC) is a popular metric for comparing and optimizing machine-learning models [25]. A higher AUC indicates a better model performance. For classification evaluation, the AUC is more accurate than the accuracy metric, although the computational cost is high compared to the accuracy metric [25]. The AUC metric equation can be expressed as follows:

$$AUC = \frac{S_p - T_p(T_n + 1) / 2}{T_p T_n} \quad (9)$$

where  $S_p$  is the summation of all the positive examples,  $T_p$  is the number of positive examples, and  $T_n$  is the number of negative examples.

TABLE IV. CONFUSION MATRIX VALUE SUMMARIZATION

	Predicted (0)	Predicted (1)
Actual (0)	True Negative (TN)	False Positive (FP)
Actual (1)	False Negative (FN)	True Positive (TP)

V. RESULT AND DISCUSSION

In this section, the results of the software risk prediction model were discussed using six classification machine learning algorithms: logistic regression, DT, RF, SVM, (KNN), and naïve Bayes, and by using the dataset of 140 software projects in the real industry of global software development. Algorithm I present the pseudocode for the risk-prediction model using training data of 80% and 20% of the testing data.

**Algorithm I:** Pseudo-Code for Risk Prediction Model

- Input:** Import the dataset from a CSV File.
- 1: **Data Preprocessing Phase:** [ data cleaning, missing values]
  - 2: **Feature Transformation and Categorical Feature Encoding:**
  - 3: **Apply EDA and Feature Selection**
  - 4: **Dataset split: 80% for training and 20% for testing.**
  - 5: **Set:** Model = Logistic Regression, SVM, KNN, DT, RF, and Naïve Bayes
  - 7: **for each Model do**
  - 8:     **Select:** the ML model to use
  - 9:     **Use:** the training dataset to feed the proposed model
  - 10:    **Apply:** Testing the model using a training dataset
  - 11:    **Calculate:** confusion matrix
  - 12:    **Calculate:** The Accuracy metrics
  - 13:    **Calculate:** The Recall metrics
  - 14:    **Calculate:** The Precision metrics
  - 15:    **Calculate:** the AUC metrics
  - 16: **end for**

The software risk prediction model was constructed using the top six classification techniques: logistic regression, SVM, KNN, DT, RF, and naïve Bayes. Five evaluation metrics were used to find the most optimal ML algorithms to fit the risk prediction model. The model was conducted using the programming language Python and other third-party packages such as NumPy, Pandas, Scikit-Learn, Pandas, Matplotlib, and Seaborn, running on the MacBook Pro with the following specifications: Intel Core i5, 2.0Ghz, 16GB, and 512GB SSD. Table V presents a comparison of the six ML classification techniques using different evaluation metrics. Finally, the following research question was answered:

RQ2: What are the best machine learning techniques for software risk prediction in GSD?

Table V indicates that the top three techniques with the highest accuracy, AUC, recall, and precision were logistic regression, random forest, and SVM, with accuracy percentages of 89%, 85%, and 82%; AUC percentages of 73%, 71%, and 48%; recall percentages of 96%, 92%, and 96%; and precision percentages of 92%, 92%, and 85%, respectively.

TABLE V. SUMMARIZATION OF CONFUSION MATRIX VALUES

Model Name	Accuracy	AUC	RECALL	Precision
Logistic Regression	0.89	0.73	0.96	0.92
SVM	0.82	0.48	0.96	0.85
KNN	0.71	0.52	0.79	0.86
DT	0.71	0.62	0.75	0.90
Random Forest	0.85	0.71	0.92	0.92
Naïve Bayes	0.71	0.62	0.75	0.90

Therefore, logistic regression can be considered the optimum ML algorithm for software risk prediction in the domain of GSD, with an accuracy rate of approximately 90%. Further details regarding the algorithm’s confusion matrix showing the four values of true positives, true negatives, false positives, and false negatives are shown in Fig. 5.

Fig. 5. The ML Confusion Matrix for the Six Algorithms.

In addition, to improve the results of other algorithms, another technique was applied for splitting the dataset called cross-validation, which is a statistical method for splitting data to test and train a model on different iterations. In other words, cross-validation split the training dataset into k smaller sets. This technique helped us improve the accuracy of most of the six algorithms, obtain better insights, and solve overfitting classification problems.

Table VI Shows a comparison of the six ML classification techniques after applying the cross-validation technique using five k-fold; four of them were used for the model training, and the remaining fold was used for validating the model.

TABLE VI. ML ALGORITHMS ARE SUBJECTED TO CROSS-VALIDATION

Model Name	Accuracy	AUC	RECALL	Precision
Logistic Regression	0.80	0.72	0.92	0.85
SVM	0.81	0.75	1	0.81
KNN	0.80	0.74	0.93	0.85
DT	0.78	0.65	0.85	0.90
Random Forest	0.80	0.81	0.92	0.84
Naïve Bayes	0.80	0.84	0.84	0.91

After applying the cross-validation technique, the accuracy of the KNN, DT, and naïve Bayes were increased by 9% to reach 80%. Thus, from Table VI can be observed that the accuracy of the six algorithms is approximately 80%, and the top three algorithms are Support Vector Machine, KNN, and logistic regression, with accuracy percentages of 81, 80, and 80%, respectively.

## VI. THREATS TO VALIDITY

This section discusses the reality of the study, based on internal and external threats and construct validity [30].

Internal validity relates to whether the investigated software risk prediction model is affected by other factors, such as Python Scikit-learn library parameters. Unfortunately, there is no standard method to choose this parameter, but the standard parameters and best practices was used in the Scikit-learn library to solve this problem [25]. The standard parameters, best practices, and configuration related to ML implementation for the six classification algorithms are provided in Appendix "III". Another internal threat is the split of the dataset; the dataset was divided into training and test sets at proportions of 80% and 20%, respectively. Random assignments were avoided to avoid influencing the model results. In addition, another preferred technique was used, called cross-validation, which splits the dataset into smaller datasets to train and test the model and calculate the average of these results to determine the most accurate result for the risk prediction model.

External validity is related to the generalization of the software risk-prediction model [30]. Dataset samples were tried to obtain from most of the companies that outsource and apply the GSD concept in different regions; however, with a limited number of datasets, some difficulties in generalizing the findings appear. In addition, there were difficulties in obtaining the data set because outsourcing companies often had to pay for their data, which limited the size of the dataset that could use.

The final threat is related to the reliability of the proposed model, this point was considered when conducting the model to validate and analyze its performance using the confusion matrix, accuracy indicator, recall metric, precision metrics, and AUC metrics. Also, these results were compared with those of the top six classification algorithms to determine the best one for the proposed model.

## VII. CONCLUSION

Obtaining a solid and accurate software risk-prediction model has always been difficult in global software development. The applied model will help software companies, experts, project managers, and developers predict software risk, which will reduce the amount of time and money spent on this approach.

A dataset of 140 software projects in different regions was used to build the model, and was collected using 18 software factors, which were carefully collected from past studies and reviewed by experts. The data preprocessing phase consisted of four steps: identifying the dataset, handling missing values,

encoding categorical attributes, feature selection, and conducting EDA analysis. Two techniques were used for the dataset splitting. The first technique is the common traditional technique, which uses 80% for training and 20% for testing without using any random or shuffle to avoid influencing the results of the model. The other technique is cross-validation using 5-k folds, with 4-folds used for model training and the remaining used to validate the model.

The results show that the top two algorithms were logistic regression and random forest with accuracy percentages of 89% and 85%, respectively. Also, cross-validation was used technique to improve the accuracy of the other models by approximately 80% and obtained better results.

## VIII. FUTURE WORK

Below are suggestions to improve the proposed model and the dataset that can be considered in the future:

- 1) The dataset needs to be expanded, by gathering the dataset from distributed locations that adopt the GSD approach.
- 2) Generalization of the findings.
- 3) Enhancing the accuracy of the ML algorithms.

# HelaNER 2.0: A Novel Deep Neural Model for Named Entity Boundary Detection

Y.H.P.P Priyadarshana, L Ranathunga

Department of Information Technology, University of Moratuwa, Moratuwa, Sri Lanka

**Abstract**—Named entity recognition (NER) is a sequential labelling task in categorizing textual nuggets into specific types. Named entity boundary detection can be recognized as a prominent research area under the NER domain which has been heavily adapted for information extraction, event extraction, information retrieval, sentiment analysis etc. Named entities (NE) can be identified as per flat NEs and nested NEs in nature and limited research attempts have been made for nested NE boundary detection. NER in low resource settings has been identified as a current trend. This research work has been scoped down to unveil the uniqueness in NE boundary detection based on Sinhala related contents which have been extracted from social media. The prime objective of this research attempt is to enhance the approach of named entity boundary detection. Considering the low resource settings, as the initial step, the linguistic patterns, complexity matrices and structures of the extracted social media statements have been analyzed further. A dedicated corpus of more than 100,000 tuples of Sinhala related social media content has been annotated by an expert panel. As per the scientific novelties, NE head word detection loss function, which was introduced in HelaNER 1.0, has been further improved and the NE boundary detection has been further enhanced through tuning up the stack pointer networks. Additionally, NE linking has been improved as a by-product of the previously mentioned enhancements. Various experimentations have been conducted, evaluated and the outcome has revealed that our enhancements have achieved the state-of-art performance over the existing baselines.

**Keywords**—Computational linguistics; deep neural networks; natural language processing; named entity boundary detection; named entity recognition

## I. INTRODUCTION

Named entity recognition (NER) is an active research area and a prominent computational task under the key area of natural language processing (NLP) [1]. Further, NER can be recognized as a semantic level sequential labelling task in terms of identifying textual spans into the specified categories such as Person, Location and Organization. Several textual spans can be categorized under the above-mentioned predefined categories which are known as named entities (NE). Named entities can be categorized into two main different aspects such as named entity type and the named entity boundary. When it comes for the NE type aspect, two variations can be established such as fine-grained NERs and coarse-grained NERs. Fine-grained NERs typically consider much larger scopes and its contribution towards the NE boundary aspect would be slightly low. When it comes for coarse-grained NERs, which is considered as high potential capabilities in demonstrating the NE boundary related aspects

on the basis of specific niche NE types. The specific niche NE types have already been taken into the consideration under the flat NE boundary aspects [2]. Considering the NE boundary and type aspects still there is a potential vacuum under NE boundary avenues compared to the other variation, NE type component.

A novel approach has been invented through a recent prominent research activity to detect the respective boundaries of named entities [2]. The solution has been focused on the domain of Sinhala statements which have been extracted from social media such as Facebook, YouTube, and Twitter. This solution has been further enhanced from HelaNER 2.0 where an enhanced algorithm has been demonstrated to determine the respective named entity mention boundaries. These novel enhancements would be worthwhile to showcase the importance of addressing the social linguistic issues specially for low resource language settings. Named entity boundary detection still can be recognized as an unknown area considering Sinhala language. In terms of manipulating the social media contents which have been published in Sinhala, it is really worthwhile to undercover these types of niche domains. Compared to the other available benchmarks for NE boundary detection, several novel avenues and enhancements have been identified and showcased from this research attempt. The main contributions of this paper consist of the following:

1) The size of the combinational multi-layer classifier which is dedicated for NE head word detection along with the NE type detection has been increased. Additionally, the NE head word detection loss function has been further improved. Due to these enhancements in HelaNER 2.0, the performance of detecting the NE head words has been increased.

2) The stack pointer network which has been used for NE boundary detection under [2], has been further tuned up and improved. Specially, the 2nd and 3rd hidden layers which are dedicated for deriving character level representations have been further enhanced. These enhancements have been critically demonstrated and evaluated in the respective sections of this paper. Due to this enhancement, the overall accuracy for NE boundary detection process has been increased in a considerable margin compared with the other existing benchmarks.

3) As a by-product, the overall NE linking process has been further improved due to the above-mentioned enhancements. These novel enhancements have been critically analyzed and showcased under the methodological section.

4) Those main contributions have been critically evaluated considering the state-of-the-art benchmarks. The corpus has been increased compared to our previous research attempt [2]. The results have been demonstrated under the experimental results section.

The ultimate motivation of this research attempt is to develop a novel framework for named entity boundary detection for social media analysis. Detecting both NE boundary and NE type for named entities as an aggregate mechanism will eventually tune up the accuracy and performance of NE linking to knowledge bases. This proposed novel framework allows to capture the named entity boundary detection along with their respective named entity types by filling out the research gap which has been identified where the overall solution is capable of handling multiple domains including Sinhala. This framework can be further introduced as a specialized niche version for the domain Sinhala and is capable of enhancing up to a more generalized version considering multiple domains.

The rest of this paper is organized as follows. Related work about named entity (NE) boundary detection along with the specific NE type is given in Section II. Section III presents the scientific methodology of the overall approach in detail manner. Section IV introduces the experimental results of this entire solution along with the comprehensive evaluation procedure which has been conducted considering the existing prominent baselines. The discussion and future avenues of this novel mechanism have been discussed in Section V.

## II. RELATED WORK

Multiple deep neural and non-neural based computational systems have been established to showcase the usage of detecting NER in social media analysis in the recent past. Some of such systems have shown promising results over the existing benchmarks. The overall literature review would be separated into two sections such as analyzing the existing NE boundary detection systems along with the respective algorithms and critically analyze the statements which have been circulated in the social media platforms.

### A. Analyzing NE Boundary Detection

Due to the low language resources settings, deep transfer learning has been adapted to determine the starting and ending indices of name entities [3]. Such a system has been introduced to overcome certain issues such as removing the noisy data and avoiding hand-crafted feature settings. Due to the noisiness of the corpus, the system has failed in determining the respective NE types along with detecting the boundaries. In terms of enhancing NER, multiple NE linking mechanisms of detecting boundaries have been introduced considering the lexical and morphosyntactic features [4]. Classifying textual segmentations into text span identification has been identified as a significant drawback of this approach. A novel stack pointer networks-based approach along with deep adversarial transfer learning which is capable of detecting the NE boundaries has been demonstrated [5]. This system has a unique capability of deriving both starting and ending NE boundary tags but still has failed in detecting the respective NE type. In terms of addressing the issue of [6], a

context encoding neural model has been invented [7]. A combination of Bi-LSTM (Long Short-Term Memory) model with a CNN (Convolutional Neural Network) to capture character-level features relates to NE type and boundary aspects can be identified as the main contribution of the above-mentioned approach. Even though this model has performed well in capturing NE boundaries still the NE type capturing has to be improved further.

BDRYBOT, a neural based model for detecting NE boundaries has been demonstrated considering the NE linking procedures [1]. The model has been consisted with a CNN in terms of enhancing the character level contextual representations. The encoding phase has been enriched with a Bi-GRU (Gated Recurrent Units) model instead of Bi-LSTM considering low computational consumption. When it comes for the NE type detection along with NE boundary detection, still the system has not been improved to achieve up to that level and can be stated as a future avenue. A novel multitasking learning neural based boundary detection model has been introduced considering the nature of inner and outer layers of nested entity mentions [8]. This approach has been enriched with sequential classification tasks in terms of reducing the computational costs hence it has demonstrated some promising results in nested NER over the existing benchmarks. Even though this model has shown some promising results, still it has been limited for extracting implicit NE mention regions. Another hybrid NE tagging architecture has been showcased considering dual neural models, Bi-LSTM, and stack LSTM [9]. Here, a special NE tagging pattern, IOBES scheme has been adapted [10]. Though the NE identification performance has been boosted up due to this novel NE tagging pattern still this has been limited to NE explicit variations.

A novel deep neural network based exhaustive approach has been invented for nested NE mention recognition [11]. Here, both NE boundary related information and NE type related information have been considered. Additionally, inner NE feature representation also has been considered under this approach. Bi-LSTM model has been developed to fulfill the objectives by visualizing the character-based feature representations on top of contextual word vectors. Compared to the other well-known approaches which have been dedicated for nested NE tasks [12] [13] [14], the exhaustive model has shown promising outcomes under the time related complexities as well. Still there is a vacuum for entity mention outside feature representations apart from only limiting to inside feature mappings. A recent deep neural based approach, anchor region networks, has been demonstrated to showcase the value and impact of nested NEs [15]. The primary assumption has been set off as the head or main words would govern the whole structure of entity mention nuggets considering the respective boundary aspects. These fundamentals have been used to determine the benchmarking models with some major enhancements. Span based models [16] [17] [18] have been considered as a revolutionary approach for determining NER. Classification of sentence nuggets into the respective subsequences using span-based architecture [19] has been exhibited recently. Both multitask learning and BERT based classifications have been used to

play with the boundary level aspects of NEs. Even though this has been accepted as a novel methodology, still the conducted experiments have been revealed that the performance of detecting NE boundaries through span-based models is poor.

An enhanced Machine Reading Comprehension (MRC) model has been introduced in terms of addressing both flat NERs and nested NERs scenarios [20]. This novel model has focused on the theoretical approaches under the sequential labelling domain. In nature, MRC models are dedicated for extracting NE mention spans regardless of flat or nested nature [21]. The text classification objective has been accomplished using BERT based models [22]. Even though this model has been performed well enough for coarse-grained NER types, still there is a demand for such an advancement for considering fine-grained NER types as well. There is a trend of adapting object detection and mapping techniques in the theory of computer vision for extracting NE mentions. One of such advancements has been exhibited as NE boundary regression model [23]. In this approach, Nested NE mention detection has been conducted considering the overlapping of each NE mentions in the context by applying a concept called NE bounding boxes. A deep neural network model called convolutional feature maps has been invented for NE boundary detection. The same technique has been used for textual information extraction and information retrieval from movie reviews recently [24] [25]. Even though this model has showcased some promising results over the existing benchmarks still NE type detection aspect has been missed.

#### B. Analyzing Social Media Statements

Even though Sinhala is a morphological rich language, very limited amount of NLP resources has been introduced considering both micro level and macro level tasks in computational linguistics. Hence, very minimum facilities can be observed for accomplishing major activities like named entity boundary detection for Sinhala context. The paradigms of Sinhala social media statements analysis can be listed down as lexicon-based approaches and machine learning approaches [26]. The lexicon-based category has been specialized in applying for scenarios such as catering online forums, online blog posts and comments which have been extracted from online channels [27]. A specific speech lexicon has been adapted in terms of capturing verbs and nouns in the context [28]. Here, a NE recognizer has been used to detect the related nouns in the context. Since the whole procedure has been dominated under a particular lexicon, the approach can be recognized as a restrictive limited approach. In the recent past, an overwhelming demand has been experienced for the adaption of machine learning based models in capturing hate speech related contents. A novel approach has been introduced to pick out hate speech related content from German corpus [29]. This approach has been enriched with the adaption of transfer learning, web scrapping mechanisms and usage of Bag-Of-Words (BOW). Another similar approach has been conducted to extract speech related content from Indonesian language [30]. Here, a random forest classifier has been adapted to showcase the value of word n-gram feature representations in classifying social media statements.

When it comes for the avenues in deep learning for classifying social media statements, the linguistic level

matrices under micro level and macro level should be examined. A significant corpus is essential for implementing a valid supervised type of deep neural based model for accomplishing the analysis of extracted statements. Crowd sourcing can be identified as a handy approach to fulfill the issue of corpus unavailability [31] [32]. Those extracted data would be used to determine the respective word embeddings since it has been identified as the state of the art which has been discovered under textual processing [32] [33]. A unique classifier which has been invented adapting ensemble fundamentals has shown some promising results in classifying sexist and racist corpora [34]. Another novel LSTM based model has been introduced in terms of classifying speech related content in Italian language [35]. Those attempts can be identified as the fundamentals in deep neural models which have been invented for classifying social media content.

### III. RESEARCH METHODOLOGY

The overall methodological approach can be categorized into two main components such as discovering the Sinhala related posts, comments, and statements which have been spread out in social media context through mandatory features, complexity measurements and other related aspects and constructing a novel framework for capturing named entity boundary detection considering the respective named entity type.

#### A. Sinhala NE Boundary Detection

The ultimate goal is to turn up with a neural based methodology to discover and analyze the Sinhala related social media context analysis based on a supervised approach. As the initial phase, Sinhala social media related corpus has been constructed. A specific web crawling mechanism has been used to extract the social media statements from Facebook, Twitter, and YouTube platforms. Once the statements have been crawled, those have been collected to a pool to be distributed among multiple set of annotators who are responsible for conducting manual annotations. More than 100,000 social media statements have been crawled for this purpose. Once the annotated statements have been constructed, then the next sets of preprocessing tasks have been determined. Several important intermediate steps have been followed such as preprocessing, stemming, parts-of-speech (POS) tagging to filter the dataset in terms of using it in the next phases. Considering the Sinhala POS tagging, due to the unavailability of a standard Sinhala POS tag set, a special pseudocode has been implemented and demonstrated under the Fig. 1.

Then as per the final step under this section, the specific neural model has been designed and implemented. A recurrent neural network (RNN) LSTM has been used as the foundation for implementing the deep neural model since RNN has been accepted as the state-of-the-art in processing sequential representations. Some optimal hyper-parameter settings have been enriched for obtaining better results under the training procedure. The hyper-parameter settings can be identified as a vital component of the entire procedure where some of the critical evaluations have been conducted considering different value adjustments. The deep neural model which is dedicated for NE boundary detection can be showcased as per Fig. 2.

```

Algorithm 4.1: POS Tagging

        SET layer TO Dense(1, name='out_layer')(layer)
    
```

Fig. 2. Pseudocode for LSTM based Deep Neural based Model for Sinhala NE Boundary Detection.

**B. Determining NE Boundary Detection**

Once the initial methodological step is ready by identifying and classifying the named entity identification for Sinhala, then the second phase which is determining the NE boundary detection can be initiated. The proposed architecture of the entire procedure for deriving named entity boundary detection can be showcased as Fig. 3. As per the word representation, word level embedding, and character level embedding have been followed. Since the embedding process is at a basic stage for Sinhala, Glove word embedding which has been developed based on English corpus will be used as the platform. The obtained embedding values have been fed to a Bi-LSTM layer in terms of generating the backward and forward value sets.

Fig. 3. Proposed Architecture for Named Entity Boundary Detection.

Special LSTM based deep neural model has been developed as the overall NE detection end to end framework. A Bi-LSTM layer would be used to derive the word level classifiers to obtain the respective head word which acts as the dominant words of the pre-defined context. As an example, considering English context, “Dilan Perera has been elected as the Secretary of the Colombo Sports Club”, Dilan Perera acts as a PER mention type while Colombo Sports Club takes ORG mention type. Additionally, Colombo could be recognized a LOC type. Considering the whole nugget, even though there are three main NE mentions, PER mention can be considered as the main or the head NE which governs the overall semantic contextual representation. So, the first step is to determine the head word of each unique sentence nugget. Once the head words have been obtained, the relevant contextual level representations have been fed into a structured classifier called multi-layer perceptron (MLP) along with the conditional random fields (CRF). MLP is capable in nature to derive the inner representations of the word level contextual representations. A combined classifier has been used to improve the level of accuracy and this combined mechanism can be mentioned as a unique approach which has not been used for any of the previous NE boundary detection frameworks. The whole process can be visualized as Fig. 4 as follows.

Once the head words have been obtained, the next step is to locate the specific entity mention nuggets per each dominant word. Here a novel theory called boundary bubbles has been introduced. Boundary bubbles (BB) are abstractive level contextual representations which are used to visualize the NE mention nuggets along with their respective identified NE head words. Fig. 5 shows the demonstration of boundary bubbles for the previously given example (Dilan Perera has been elected as the Secretary of the Colombo Sports Club).

Fig. 4. Main System Architecture of NE Type Detection.

Fig. 5. Abstract Level Representation of Boundary Bubbles.

In terms of capturing mention nuggets, a special algorithm has been developed. Several parameters and assumptions have to be considered when declaring the specific algorithm. Two main such assumptions would be like, at least one word must be declared as the head word for that specific mention nugget and such a word should be found through the specific boundary bubble. The left boundary region and the right boundary region of the respective bubble should be determined for identifying the mention nuggets. Considering left and right boundary related values, two value tuples have been defined. A unique loss function has to be determined since it's mandatory to define the loss value under head word detection procedure. The head word detection loss function can be obtained as:  $-\log P(c_i|x_i)$ . The collective loss function would be determined as a weighted average loss value considering the respective scenarios including the head word detector would be resulting to NILL. The NE mention nuggets identifier can be recognized as per (1) as follows.

$$\tau(x_i; \emptyset) = v_i \cdot [-\log P(c_i|x_i) + L^R(x_i; \emptyset)] + (1 - v_i) \cdot [-\log P(NIL|x_i)] \quad (1)$$

$$L^R(x_i; \emptyset) = L^{left}(x_i; \emptyset) + L^{right}(x_i; \emptyset) \quad (2)$$

The respective above stated (2) would determine the identical structure for NE mention nuggets along with the respective starting and ending boundary regions. Additionally,  $v_i$  under (1), states the respective correlational value of the underline boundary bubble, in which the higher the value determines the stronger association considering the type of the bubble. The whole process would be complex if multiple head words per mention nuggets have been established. With all of these assumptions and decisions,  $v_i$  can be further demonstrated as:

$$v_i = \left[ \frac{P(c_i|x_i)}{\max_{x_t \in B_i} P(c_i|x_t)} \right] \alpha^v \quad (3)$$

Here  $\alpha$  can be showcased as a specific hyper-parameter. Different values can be assigned with the intention of analyzing the outcome behavior of the overall procedure. As the basic value assignment,  $\alpha = 0$  could generate a scenario where the determined NE mentions would be annotated with the respective boundary bubble type. When it comes for extracting the inner most head words,  $B_i$  determines the region of the extracted mention nuggets.

The final segment of the whole process of named entity boundary detection and type determination will be the boundary region classification. From the previous step, the respective NE mention nuggets have been derived and the next step is to determine the boundary detection using the obtained mention nuggets. In terms of deriving the NE boundary detection, a novel NE scope deriving mechanism which is called as IOBE (Inside, Outside, Beginning, End) pattern has been used. Even though IOB (Inside, Outside, Beginning) pattern has been adapted for NE boundary detection, usage of IOBE pattern can be identified as the first-time approach of adapting IOBE pattern along with stack pointer networks in terms of deriving the boundary detection. Plenty of other different patterns have been used for accomplishing different avenues under the named entity recognition and named entity boundary detection domains. Specially, BEO (Beginning, End, Outside) pattern has been used for one of the previous approaches under NE boundary assembling mechanisms for named entity recognition in biomedical domain [36]. As per our understanding, this is the initial attempt of using IOBE pattern for named entity boundary detection purposes under the named entity recognition domain. Further, this can be mentioned as one of the scientific core novelties of this research work. The respective design architecture related to NE boundary detection can be exhibited as follows under Fig. 6.

Fig. 6. Stack LSTM Architecture of NE Boundary Detection.

NE linking is a crucial task under information retrieval from the respective knowledge bases. Enhancing NE linking can be identified as a sub product of this overall procedure. Considering the three different components under the NE linking, our intention is to enhance the direct mapping through

the identification of NE boundaries. An explicit novelty will not be achieved from NE linking but a performance increment would only be expected due to the enhancements which have been exhibited under NE boundary detection. The respective enhanced algorithm which is dedicated for NE direct mapping purposes can be exhibited as (4). In the respective algorithm,  $p(c_{ij}|e_i)$  determines the respective contextual level probabilistic distribution of each entity mention denoted as  $e_i$ . The Laplacian smoothing has been adapted to avoid the zero probability values.

$$p(c_{ij}|e_i) = \frac{t(e_i, c_{ij}) + 1}{\#e_i + |C_i|} \quad (4)$$

The overall implementation has been carried out in a well constructive manner. Python 3.7.4 has been used as the primary programming language to implement the overall system including all the components. Frameworks such as TensorFlow 1.15 and Flask 2.1 have been adapted to deliver the whole application in a much standard way. The mandatory natural language processing and computational linguistics libraries such as Torch 1.7, Spacy 2.1.9, Keras 2.2.4, NLTK 3.4.5 have been adapted to fulfill the overall implementation procedure in a smooth manner. After the system has been implemented, the experimentation can be carried out, and the related experimental results can be described in detail manner as follows.

#### IV. EXPERIMENTAL RESULTS

The overall testing procedure has been conducted considering all the required aspects. An extensive experimental process has been carried out considering all the implemented components which have been mentioned earlier. Considering the overall experimental settings, several existing baseline mechanisms have been considered such as regional based models, conventional CRF models and hypergraph based computational models. A unique Sinhala NER corpus has been obtained which consists with 120,000 tuples as per training purposes, 100,000 tuples as per validation purposes and another 80,000 set as per accomplishing testing purposes. As per the hardware requirements, a high-performance graphics processing unit (GPU) machine has been acquired. Major sets of hyper-parameters have been set off for obtaining the competitive edge. Experimentations and the respective evaluation process have been focused with several sub-components such as evaluation on Sinhala NE identification, evaluation on word embedding, evaluation on NE head word detection, evaluation on NE mention boundary detection and evaluation on NE linking.

##### A. Evaluation on Sinhala NE Identification

Several annotators have been employed for constructing the main corpora such as classifying social media statements and grouping the identified named entities into NE categories. Hence, the Fleiss' Kappa [37] values have to be measured to evaluate the reliability of the corpus which has been used in the entire system. Once the annotation process has been accomplished, the inter annotator agreement has been processed to evaluate the relevant Kappa statistics. These respective individual Kappa statistics can be showcased under the Table I as follows.

TABLE I. KAPPA VALUES FOR NE CATEGORIES

Kappa Values for Individual NE Categories					
NE Class	Conditional Probability	Kappa	Standard Error	Z Value	P Value
PER	0.84	0.76	0.12	5.12	0.04
LOC	0.76	0.64	0.12	4.87	0.04
ORG	0.67	0.62	0.12	4.28	0.03
DES	0.48	0.57	0.12	3.72	0.02
PRO	0.43	0.52	0.12	3.24	0.02

Once the Kappa values have been obtained for the respective individual NE categories, then the overall Kappa statistics can be obtained and demonstrated as follows.

According to the values of Table II, the overall Kappa value for NE identification and categorization can be recognized as 0.72. Considering the overall value and according to the classification of the Fleiss' Kappa, it can be concluded that the generated Kappa value has represented a good strength in the inter annotator agreements.

TABLE II. OVERALL KAPPA VALUES FOR NE CATEGORIES

Overall Kappa					
NE Class	Conditional Probability	Kappa	Standard Error	Z Value	P Value
Overall	0.78	0.72	0.11	4.86	0.02

In terms of evaluating the model on NE type classification, set of main parameters have been defined and discussed in the previous chapter. The obtained results have been critically evaluated with the available benchmarks as per the Table III. The newly introduced unique model has been demonstrated as BB2022 (boundary bubbles).

TABLE III. EVALUATION ON NE TYPE CLASSIFICATION

Model	Precision (%)	Recall (%)	F1 (%)
SH2016 <sup>1</sup>	75.9	70.1	72.8
KBP2018	72.6	73.0	72.8
ARN2019	75.2	72.5	73.9
<b>BB2022</b>	<b>76.2</b>	<b>73.6</b>	<b>74.9</b>

As per the exhibited comparison outcomes, it can be concluded that the proposed novel model performs better than the existing NE type detection benchmarks in a competitive edge.

##### B. Evaluation on Word Embedding

Due to the low level of language resources settings, a transfer learning mechanism must be adapted to derive the Sinhala related word embeddings. Specific four main hyper-parameters have been used in terms of deriving the training procedure such as dev detect, test detect, dev all and test all. Once the overall testing process has been designed, a unique set of 500 tuples have been used for testing procedure

<sup>1</sup> Existing benchmarks which have been implemented and available for NE type identification purposes.

considering the above-mentioned testing related hyper-parameter settings. As per the Table IV, the respective highest performance has been demonstrated once the value settings have been set to 0.6.

TABLE IV. RESULTS ON WORD EMBEDDING

Set	Dev Detect	Test Detect	Dev All	Test All
500	84.68	84.27	84.39	84.76

Once the word embeddings have been obtained, respective evaluation has been conducted considering the most prominent word embedding techniques such as Glove, Word2Vec, ELMo and BERT. The respective comparison can be exhibited under Fig. 7 as follows. As per the comparison when the k value gets 1.4 a performance increment can be observed considering all models except ELMo. When Word2Vec, Glove and BERT models have been considered, the highest outcome has been demonstrated by our approach which is the Glove model. Even though BERT has shown some promising results in most of the previous scenarios as per the constructive literature survey, the Glove model can be mentioned as an optimal alternative approach, especially for low resource language settings.

Fig. 7. Performance Comparison on Word Embedding through Transfer Learning.

Later, with the introduction of cross-lingual word embeddings, some state-of-the-art word embedding models have been invented. One of such prominent mechanisms would be the usage of XLM-R for obtaining word embeddings considering major text classification tasks [38] [39]. Hence, another evaluation approach has been applied to compare the proposed model and the XLM-R model where the results can be demonstrated under the Fig. 8 as follows.

As per the comparison between the GloVe and XLM-R models, it can be concluded that the maximum outcome has been showcased by GloVe even though XLM-R has performed well in most of the sections in the graph distribution.

Fig. 8. GloVe and XLM-R Performance Comparison on Transfer Learning.

### C. Evaluation on NE Head Word Detection

NE head word detection has been identified as one of the scientific core novelties of this entire research attempt. Considering the major evaluation matrices which have been stated under the word embedding and the head word loss value, the testing procedure can be determined. Considering the key factors such as NE mention identifier and the head word detection loss value, the respective experimental results can be obtained and listed under Table V as follows.

As per the evaluation purposes, the existing NE head word detection mechanisms related to the flat NEs have been considered. Those existing benchmarks models have already been critically analyzed and reviewed under the comprehensive literature survey and the evaluation procedure has been conducted respectively. The respective evaluation results for the NE head word detection process can be showcased as per Table VI. Our novel model has been denoted as BB2022 (Boundary Bubbles). As per the competitive analysis, the most prominent deep neural based NE detection models such as Sohrab et al. 2018 [11], Ju et al. 2019 [16] and ARN2019 [15] have been used. These models have been recompiled and re-generated using the openly available source code in the respective code repositories. Considering the evaluation results it can be concluded that our novel model has performed well against all the prominent baselines which are available for NE head word detection.

TABLE V. RESULTS ON NE HEAD WORD DETECTION

Metric	Precision (%)	Recall (%)	F1 (%)
Dev Detect	85.973315	78.53125	82.083945
Test Detect	78.783828	81.76144	
Dev All	0.2187500	0.239808	
Test All	0.2338790	0.253577	
Dev Gap	85.707962	78.31259	81.844137
Test Gap	84.696074	78.54994	81.507865

	2	78.24	76.97	78.13
	3	78.88	77.31	78.24
	4	78.65	78.03	78.59
	5	79.16	77.68	78.88
	6	79.14	77.21	78.92

#### D. Evaluation on NE Boundary Detection

This component has already been mentioned as the next scientific core novelty of this overall research procedure under the methodology section. In other words, this component would be the core driving force of the entire solution. The respective performance related matrices have been generated for the five most prominent NE categories and the respective results can be demonstrated under Table VII as follows.

TABLE VII. RESULTS ON NE BOUNDARY DETECTION

NE Type	Precision (%)	Recall (%)	F1 (%)
ORG	0.84	0.89	0.86
DESIG	0.85	0.85	0.85
LOC	0.96	0.96	0.96
PER	0.96	0.95	0.93
DATE	0.88	0.91	0.89

Additionally, the accuracy also has been calculated considering the major hyper-parameters. Several hyper-parameters have been set off such as word embedding rate to be 25, output dimension to be 4 and the dropout rate as 0.1. Once the results have been obtained, the evaluation has been conducted. For evaluation purposes, as per the benchmarks, the systems which are dedicated for detecting NE boundaries have been used. The obtained evaluation results can be tabulated under Table VIII as follows. Considering the evaluation-outcome it can be concluded that our novel model, BB2022 (Boundary Bubbles), has performed well than the existing baselines.

TABLE VIII. EVALUATION ON NE BOUNDARY DETECTION

Model	Precision %	Recall %	F1 %
Sohrab2018	76.61	69.20	72.71
Ju et al2019	79.90	67.08	71.36
ARN2019	81.34	68.20	72.83
<b>BB2022</b>	<b>82.18</b>	<b>71.34</b>	<b>76.54</b>

#### E. Evaluation on NE Linking

Conducting the evaluation on NE linking can be described as the final phase of the overall evaluation procedure. In terms of accomplishing the NE linking procedure, several major topics under the Sinhala speech knowledgebase have been used. As per the methodology, only the direct mapping technique of the NE linking has been used so that the direct mapping technique should be evaluated as the evaluation criteria on the overall NE linking. Considering the major NE linking benchmarks, several prominent systems such as DBpedia Spotlight<sup>2</sup>, SOTA<sup>3</sup> and VCG<sup>4</sup> can be listed. Our model has been evaluated with those existing benchmarks and the evaluation results can be showcased under Table IX as follows. As per the overall comparison, it can be concluded that our novel approach, BB2022 (Boundary Bubbles), has performed better than the existing benchmarks.

TABLE IX. EVALUATION ON NE LINKING

Model	Precision %	Recall %	F1 %
DBpedia Spotlight	52.64	52.48	52.53
SOTA	57.26	51.24	55.24
VCG	61.25	58.26	60.18
<b>BB2022</b>	<b>62.47</b>	<b>60.15</b>	<b>61.27</b>

#### V. DISCUSSION AND CONCLUSION

NE boundary detection in Sinhala context can be introduced as the core of this entire research attempt. The usage of social media for various different kinds of purposes has been increased in an alarming rate [8] [9]. There is a high demand for a sustainable computational framework for identifying and extracting such kind of various inputs which have been spread out in social media, especially in low NLP resources-based contexts like Sinhala [2]. Considering the overall approach of HelaNER 2.0, various enhancements have been designed, implemented, and evaluated. Major enhancements have been applied under the methodological components of word embedding through deep transfer learning, NE boundary detection and NE linking. All the predefined objectives such as Sinhala social media analysis, obtaining word embedding through transfer learning, NE head word detection, NE boundary detection and NE linking have been achieved. The novelties have been achieved in NE head word detection and NE boundary detection components. Respective evaluations have been conducted and the outcome has revealed that the novel approaches have outperformed the existing baselines in the market. Several points can be summarized as follows.

<sup>2</sup> <https://www.dbpedia-spotlight.org/api>

<sup>3</sup> Exploring Neural Entity Representations for Semantic Information, A Runge, E Hovy - arXiv preprint arXiv:2011.08951, 2020 - arxiv.org

<sup>4</sup> <https://paperswithcode.com/task/entity-linking>

Compared to the performance dimensions of the previous approaches, several avenues have been identified as the key performance indexes (KPIs) for HelaNER 2.0. Firstly, word embedding through deep transfer learning has been tuned-up in terms of considering character level feature representations. Secondly, NE head word detection has been improved by enhancing the NE head word detection loss function. Also, multiple MLP and CRF layers have been adapted as another major improvement. Several experimentations have been conducted based on different hyper-parameter value adjustments. Thirdly, NE boundary detection has been further enhanced by introducing stack pointer networks which can be identified as the core scientific contribution for the domain of NE boundary detection. A constructive evaluation process has been followed taking the most prominent approaches which have been established as baselines. The overall evaluation procedure has been strengthened further through increasing the overall evaluation cycles. As per the evaluation outcome, it can be concluded that our novel avenues which have been introduced under HelaNER 2.0, have outperformed the existing benchmarks. As it's been mentioned earlier, even though this approach can be mentioned as a niche specialized solution for Sinhala domain, the generalized version of this would make a real impact for NE boundary detection in other domains.

Considering all these aspects, few potential avenues can be introduced as possible future enhancements under the whole process of detecting Sinhala related NE boundaries along with the considered NE type. It has been assumed as a particular head word would not be shared among more than one sentence nuggets under the section of dominant word detection considering MLP on top of CRF along with NE type detection in the constructive methodological approach. Therefore, sharing a given respective head word among several multiple sentence nuggets has been considered as a possible future enhancement under the overall methodological approach. Experimenting on the applicability of sharing a particular head word among multiple different sentence nuggets would be a major scientific research advancement of this entire domain.

#### ACKNOWLEDGMENT

**Abstract**—Face recognition is a significant area of pattern recognition and computer vision research. Illumination in face recognition is obvious yet challenging task in pattern matching. Recent researchers introduced machine learning algorithms to solve illumination problems in both indoor and outdoor scenarios. The major challenge in machine learning is the lack of classification accuracy. Thus, the novel Optimized Neural Network Algorithm (ONNA) is used to solve the aforementioned drawback. First, we propose a novel Weight Transfer Ideal Filter (WTIF) which is employed for pre-processing to remove the dark spots and shadows in an image by normalizing low frequency and high frequency of illumination. Secondly, Robust Principal Component Analysis (RPCA) is employed to perform efficient extraction of features based on image area representation. These features are given as input to ONNA which classifies the given input image under illumination. Thus we achieve the recognition of the face under various illumination conditions. Our approach is analyzed and compared with existing approaches such as Support Vector Machine (SVM) and Random Forest (RF). ONNA is better in terms of high accuracy and low error rate.

**Keywords**—Face recognition; illumination; neural network; robust principal component analysis

## I. INTRODUCTION

Face recognition is an interesting research area in computer science and information technology since 1990 [1] with several applications such as biometrics, law enforcement and surveillance video systems. Various face recognition methods have been developed during the previous two decades, and significant progress has been reached. Consequently, the efficiency of facial recognition systems under controlled conditions has already achieved a sufficient level. Unfortunately, the recognition rate of the existing FR system needs to be enhanced, also in real-world conditions like noise, illumination changes, pose and disguise. Because the accuracy of a face recognition technique varies a lot depending on the type of illumination and lighting used, illumination is one of the major aspects to consider when creating a human face recognition system. Due to the 3D geometry of human faces, it is noted that variations in illumination conditions form various shading and shadows on the face. This may make some facial characteristics appear weaker, or it may cause bright or dark areas in face images.

Face recognition accuracy is now quite high under perfect illumination; however, there are still issues to be solved under varying illumination [2, 3]. Several approaches have been developed in recent decades to improve the accuracy of facial

recognition in different illumination conditions, which can be divided into three groups: illumination modeling, illumination extraction of invariant features, and face image normalization [4]. The Retinex illumination model [5] describes the apparent illumination at every spot on the face in terms of that point's inherent reflectance, as well as the amount and angle of incident illumination. According to this concept, the low spatial frequency elements of the face image convey information on illumination, but the components with a high spatial frequency indicate inherent sensitivity of the face that ought to be retrieved for recognition.

As a result, self-quotient imaging [6] is used to estimate the illumination on a smoother version of the image of the face that reduced the logarithmic of the actual face image to produce an unchangeable representation. Similar filtering can be done in the frequency to normalize the low-frequency illumination and high-frequency illumination components using a logarithmic Gaussian Band Pass Bilateral Filter [7]. As previously established, the way faces are represented in the actual world is always flawed, as well as the images contain significant flaws. As a result of its extreme sensitivity to the flaws and inability to cope with information that is lacking, the traditional PCA estimation may be distant from the underlying real distribution of the facial image.

To address this issue, a significant sparse learning framework named Robust Principal Component Analysis (RPCA) is used to extract the features [8] [9]. Some modern technologies take advantage of the similarities that every human face possesses. To find the most matching area at each face location, the area representation is achieved using a 2D Fourier magnitude spectrum [10].

In this research, we propose a Weight Transfer Ideal Filter (WTIF) for face recognition that is robust to illumination variation. It is employed to remove dark spots, shadows and reflections in an image. Further, Robust Principal Component Analysis (RPCA) is used to extract features based on image area representation. The proposed WTIF method is used to recognize the face accurately based on a position-based voting scheme by increasing the features matching. The Optimized Neural Network Algorithm (ONNA) improves the classification accuracy under illumination and the proposed method is analyzed and compared with existing methods such as Support Vector Machine (SVM) and Random Forest (RF). Consequently, ONNA is better in terms of Accuracy, Equal Error Rate.

## II. RELATED WORK

Kim et al. [11] presented a method in which ground truth image could be employed to train the Illumination Normalization (IN) method using a convolutional neural network to convert the illumination variant face image into a feature map. The result showed that the IN-Net achieved better Face Recognition (FR) accuracy. Wu et al. [12] discussed the face recognition method across the posture and illumination issue, given a modest collection of training samples and one sample per gallery. The different illumination samples and deep neural network capacity to perform nonlinear transformations make multitask deep neural network ideal for posture and illumination normalization. Results show that this algorithm achieved better results on MultiPIE dataset less training data and also verified the effectiveness of introduced method.

Xiangpo Wei et al. [13] developed a face recognition approach based on a convolutional neural network (CNN) and a local binary pattern feature extraction method (LBP) that overcomes the impacts of illumination, posture, and expression. Local Binary Pattern (LBP) represents the local texture features of an image. CNN is capable of extracting image features and reducing their dimensionality. The experimental result demonstrated that the method could significantly increase the rate of accuracy and also has better robustness of illumination and posture.

Khan et al. [14] presented Particle Swarm Optimization (PSO) to optimize textural and wavelet features. The Discrete Wavelet Transform had the benefit of isolating significant characteristics, which reduced processing time and improved recognition accuracy. The results showed that the suggested technique is superior and resistant to illumination and has good accuracy rate. Han et al. [15] discussed the Accelerated Proximal Gradient (APG) technique and illumination regression filtering that was applied to remove the illumination effect. The results showed the introduced technique was robust to illumination.

Liang et al. [16] presented a method where Wavelet transform images of the Low Frequency Sub-Band (LFSB) and High Frequency Sub-Band (HFSB) were boosted and denoised, which frequently resulted in a loss of information due to less attention of HFSB. Furthermore, the Particle Swarm Optimization-Neural Network (PSO-NN) was used to classify the data. The suggested network can effectively create a robust visual impact under varied illumination and greatly increase recognition performance, according to experimental results.

Zhang et al. [17] presented the Expected Patch Log Likelihood (EPLL) algorithm that extracted illumination weight and used Neighboring Radiance Ratio algorithm (NRR) which optimized the initial vector of the Gaussian mixture model that utilized redundant data in image. Dewantara et al. [18] presented a novel optimized fuzzy based illumination constant approach that overcomes the influence of illumination for photometric based face recognition. It efficiently eliminates the impact of illumination on facial images and has a high level of robustness. Output proved that the introduced algorithm improved computational time and also that improve the face detection performance.

Baradarani et al. [19] presented the multi resolution analysis and sub band filtering the Double-Density Dual-Tree Complex Wavelet Transform (DD-DTCWT) was helpful and easy for illumination invariant face recognition. Principal Component Analysis (PCA) was employed for feature extraction and the Extreme Learning Machine (ELM) was used for faster classification. The result proved that the introduced method has high recognition rate and computational complexity.

Vidya et al. [20] used Discrete Wavelet Transform (DWT) that aided in the efficient extraction of features and the introduced Selective Illumination Enhancement Technique (SIET) which has high incidence of recognition. The result showed that the introduced method has average recognition rate for Color FERET database. Yang et al. [21] presented Nuclear Norm based Matrix Regression (NMR) for face recognition and categorization. Result showed that the NMR was more reliable for recognition with illumination changes.

## III. PROPOSED METHODOLOGY

Face recognition consists of three sections such as preprocessing, feature extraction, and classification. Fig. 1 explains the proposed methodology. Optimized Neural Network Algorithm (ONNA) is used to improve the classification accuracy under illumination conditions and also recognizes the face accurately. The scheme comprises preprocessing using the proposed method Weight Transfer Ideal Filter, to find the most matching area at each face location using a 2-D Fourier magnitude spectrum. Robust Principal Component Analysis (RPCA) is used for feature extraction. ONNA along RPCA gave better results in terms of high accuracy and low error rate.

### A. Weight Transfer Ideal Filter

The main purpose of pre-processing is to improve image quality so that it can be processed further by removing or minimising unrelated and surplus components in the illumination images. Weight Transfer Ideal Filter (WTIF) is employed to remove dark spots, shadows and reflection and also it reduces low frequency illumination and high frequency illumination. WTIF technique is used to recognize the face accurately based on a position-based voting scheme by increasing the features matching. A Weight Transfer Ideal Filter is a complete filter that combines spatial domain and range domain filtering to remove noise while preserving edge characteristics using (1) and (2).

$$\mu = \frac{1}{ab} \sum_{n_1 n_2} m(n_1, n_2) \quad (1)$$

$$Z_i = \sum_{k=0}^i P_{i,j} \cdot Q_{i,j} \cdot y_i \quad (2)$$

In Weight Transfer Ideal Filter, weights of the pixel decay as a function of distance from the filter's center, as provided by,

$$G_\sigma(a, b) = \frac{1}{2\pi\sigma^2} e^{-\frac{(a^2+b^2)}{2\sigma^2}} \quad (3)$$

$$I_F(B) = \frac{1}{W} \sum_{q \in S} G_{\sigma_s}(\|P - Q\|) G_{\sigma_r}(|I(P) - I(Q)|) I(Q) \quad (4)$$

Fig. 1. Proposed Methodology.

The Weight Transfer Ideal Filter is used for smoothing nonresponsive noise from two-dimensional signals while maintaining image quality. As a result, it's particularly well-suited to improve the illumination of the face image. The pre-processing technique is utilized in illumination improvement, artifact removal, and alignment. The pre-processing technique involved, creates masks for pixels with the greatest amount of effort to reduce dark spots and reflection and Fourier Magnitude Spectra as Image Area Representation Features.

Due to slight changes in a person's facial features and head position, even with properly matched face images, matching local pixel areas on the faces may not correlate to the same spatial structure. We employ a 2-D Fourier magnitude spectrum as the feature to describe each local image area to limit the outcome of modest mismatch errors in recognition [23]. We use the shift-invariance of the Fourier magnitude representation to enhance the ability to withstand minor mismatch errors and variations in face expression by taking the magnitude spectrum instead of the phase spectrum. When the 2-D Fourier transform is applied to an area in a Nonlinear Active Band pass Filter testing image, the magnitude spectrum of the resulting testing image may be represented as

$$|\tilde{I}_{\delta(a,b)}(m, n)| \cong \beta_{\delta(a,b)} |\widetilde{R}_{\delta(a,b)}(m, n)| + \delta(m, n) \alpha_{\delta(a,b)} \quad (5)$$

Where  $|\tilde{I}_{\delta(a,b)}(m, n)|$  and  $|\widetilde{R}_{\delta(a,b)}(m, n)|$  indicate the spectral magnitudes of the Gaussian band pass bilateral filter pixel value and intrinsic reflectivity of the area,  $\alpha_{\delta(a,b)}$  indicate the residual constant illumination background and the  $\delta(m, n)$  is the Kronecker delta function.

### B. Feature Extraction using Robust Principal Component Analysis

The output of the matching area representation is given as the input to the feature extraction. The Robust Principal Component Analysis (RPCA) method is used to extract textural features accurately by reducing the sparse error.

Consider a huge data matrix  $H \in \mathbb{R}^{m \times n}$  has a reduced layout  $I$  but is contaminated by sparse errors element  $M$ , i.e.,  $H=I+M$ . The goal is to reclaim a low-rank element  $I$  from the substantially corrupted matrix  $H$  in a reliable manner. Unlike in conventional PCA, the noise is small, the entries in  $M$  might have any magnitude and their support is believed to be simple but uncertain. The following is the original concept of Robust Principal Component Analysis (RPCA) [24]:

$$\min (\text{rank} (I)+ \gamma \|M\|_0), \quad \text{s.t. } H=I+M \quad (6)$$

Where  $\|M\|_0$  represents the matrix  $\ell_0$  norm that is collecting nonzero components in the matrix  $H$ . Due to the rank measure's non-smoothness and non-convexity as well as the zero-norm penalty, (1) is hard to solve. Principal Component Pursuit (PCP) is solved in the relaxed form using tractable convex optimization:

$$\min (\|I\|_* + \gamma \|M\|_1), \text{ s.t. } H=I+M \quad (7)$$

Where the rank procedure in (6) is nuclear matrix has taken its place  $\|\cdot\|_*$ , the matrix  $\ell_1$  -norm estimates the matrix  $\ell_0$ -norm and  $\gamma$  is regulation variable for balance and has been fixed to  $1/\sqrt{\max(m, n)}$ . It has been demonstrated both

mathematically and practically that the resolution of (7) properly retrieves the low-rank and sparse elements under very weak conditions, as provided as the rank of  $I$  is not too great and the errors  $M$  is sparsely maintained [22].

### C. Optimized Neural Network (ONNA)

An Optimized neural network is used to improve the classification accuracy under illumination. Firstly, search space algorithm is used to extract the features of the image. A search in a search space method is an example of a possible solution to the problem of determining the relevance of each characteristic. Suppose there are  $n$  search  $k$  dimensional space, then the position of search  $i$  can be represented as  $X_i = (x_{i,1},$

$x_{i,2}, \dots, x_{i,k}$  ( $i=0,1,2, \dots, n$ ). The velocity and position of each search are updated as follows:

$$V_i(t+1) = \omega V_i(t) + C_1 r_1 [pbest(t) - x_i(t)] + C_2 r_2 [gbest(t) - x_i(t)] \quad (8)$$

$$x_i(t+1) = x_i(t) + V_i(t+1) \quad (9)$$

Where  $C_1$  is the cognitive coefficient and  $C_2$  is the social coefficient and matching values  $r_1$  and  $r_2$  are two independently generated random numbers and  $\omega$  is the inertia weight. The maximum generations or the better position of the object in the cluster is no more included in the search algorithm, which cannot be improved even after a many number of generations. Therefore, the proposed searching algorithm has proved its efficiency and robustness in overcoming complex optimization challenges.

The range of  $C_1$  and  $C_2$  are  $C_1 \in (2.75, 1.25)$  and  $C_2 \in (0.5, 2.25)$  respectively. The learning factor function expression of linear change is described as given below using (10) and (11).

$$\Delta Pbest = g_1 * rand(0,1) * (Pbest_{i,j} - x_{i,j}) \quad (10)$$

$$\Delta Gbest = g_2 * rand(0,1) * (Gbest_{i,j} - x_{i,j}) \quad (11)$$

Where  $C_1$  and  $C_2$  are learning factors; rand is a positive random number between 0 and 1 distributed normally. This search algorithm is mainly used to learn the features. Given the face images  $q_1, q_2, \dots, q_m$ , the average face of these given face images is defined by (12).

$$\varphi = \frac{1}{s} \sum_{i=1}^s q_i \quad (12)$$

The difference between each input face and the average face is calculated as follows

$$\Psi_i = q_i - \varphi \quad (13)$$

The covariance matrix CM can then be computed using

$$CM = \sum_{i=1}^N \Psi_i \Psi_i^T = AA^T \quad (14)$$

The component effective method is used to train the learned sample. Finally, the error-reduced training sample is sent to the classification phase; here the neural network is issued to classify the training sample. It classifies the face accurately and finalizes feature matching and recognition. Finally, the feature matrices that correlate to numerous facial images are sent to the neural network as training data. The neural network driven feature learning framework, consists of 3 layers i.e., input layers, an output layer, and a hidden layer. For the Facial illumination Recognition problem, the right multiplication projection matrices in the hidden layer are also employed to get more discriminative characteristics among the high-level characteristics.

Let  $G_i = \{G_{i,j}^t, j = 1, \dots, E_i\}$  ( $t = 1, \dots, P_t$ ) indicate the  $t^{th}$  multi-channel projection matrix set consisting of  $C_i$  channels of projection matrices, where  $G_{i,j}^{(t)}$  denote the  $j$  th channel matrix of  $G_i$ ,  $P_i$  indicate the number of multi-channel projection matrix sets, and  $E_t$  indicate the number of channel matrices in

$G_i$ . The hidden layer can therefore be represented in the following way:

$$C_i = \sum_{j=1}^{E_t} G_{i,j}^{(t)} Q_j, (i=1, 2, \dots, P_t) \quad (15)$$

Where  $C_i$  indicates the matrix in  $t^{th}$  channel of the output and  $Q_j$  is the  $j$ th channel of the input matrices. If the input layer performs proper multiplication,

$$C_i = \sum_{j=1}^{E_a} Q_j G_{i,j}^{(a)}, (t=1, 2, \dots, P_a) \quad (16)$$

Then each row of the input matrix is projected onto a different feature area, resulting in a dimension reduction result at the same time. The resulting error by the given mode or result, i.e., the weight of the present related edge in the network is computed by combining the hidden layer and output layer results. The error of the hidden neuron is also calculated using the correlation weight and the error of the next layer's neuron. The network weight is updated with each neuron's error computed. Finally, the optimized neural network algorithm classifies the images. Fig. 2 shows the steps in ONNA.

---

### Algorithm steps

---

Input: Dataset, image size  $P$ , inertia feature  $\omega$ , cognitive coefficient  $c1$ , social coefficient  $c2$ , and matching value

Step 1: Initialize the parameters  $x_i$ , pbest, and gbest

Step 2: Determine the best face feature value selection

Step 3: Determine and pbest and gbest value

Step 4: Update  $x_i$  for each feature using (17)

$$V_i(t+1) = \omega V_i(t) + C_1 r_1 [pbest(t) - x_i(t)] + C_2 r_2 [gbest(t) - x_i(t)] \quad (17)$$

$$x_i(t+1) = x_i(t) + V_i(t+1) \quad (18)$$

Step 5: If the matching value is not met, go to step 2

Step 6: Steps 5 and 6 should be repeated until the set minimal error or the matching value is reached.

Step 7: Take the global best value of the training process.

Step 8: Set the learning rate, maximum iterations, number of hidden layer neurons, features and thresholds between the input and hidden layers, between the hidden and output layers, and the algorithm termination minimal allowable error.

Step 9: The training samples should be normalized.

Step 10: Start the training process by dividing the images into sub-images to match with the corrupted images and enhance the classification decision.

Step 11: Validate the original data by the trained process, and restores the output data to the original order of image.

Step 12: Testing Process

Step 13: Hybrid Weight Transfer Ideal Filter is used to recognize the face under illumination and matches the features. After that, the neural network is used to classify the image and implement the Optimized Neural Network Algorithm (ONNA) techniques to improve the classification.

Step 14: In this manner, a deep neural network classifier based on a position-based voting scheme is used to recognize the face accurately.

---

Fig. 2. Steps in Optimized Neural Network Algorithm.

#### IV. RESULTS AND DISCUSSIONS

All the experiments are performed in the Extended Yale-B dataset [25] and CMU Multi-PIE dataset [26]. Extended Yale-B database consists of 16128 images of 28 people under 64 different illumination conditions. CMU Multi-PIE database consists of 750,000 images of 337 people taken under 19 different illumination conditions. The Optimized neural network is introduced in this paper. Compared with SVM and RF the proposed method achieves high accuracy and low error rate.

The first column in Fig. 3 shows the input images full of dark spots. The proposed Weight Transfer Ideal Filter method enhances the low frequency images by removing the dark spots as shown in column 2. Column 3 images show the most matching area at each face location and the area representation is achieved using a 2-D Fourier magnitude spectrum. RPCA algorithm is applied to the images in column 3 to extract the features. Then the extracted features are given as an input to

the Optimized Neural Network Algorithm which improves the classification accuracy and by increasing local area matching, this method recognizes the face under illumination conditions. The recognized faces are shown in column 5.

The proposed method is compared with the existing classification methods such as support vector machine (SVM) and Random Forest (RF) in terms of accuracy and Error Rate as shown in Table 1 and Table 2. The accuracy of the proposed method is high compared to the existing classification methods because of the optimized neural network. Table 1 shows the results of face recognition under varied illumination on the Extended Yale-B database and Table 2 shows the results face recognition under varied illumination on the CMU-PIE database.

To prove the success rate of the introduced technique, it is essential to compare the Optimized Neural Network Algorithm with SVM and RF method, and the results are shown in Fig. 4.

Fig. 3. Dark Spot Removal and their Result.

TABLE I. PERFORMANCE ANALYSIS OF FACE ILLUMINATION IMAGE FOR OPTIMIZED NEURAL NETWORK ALGORITHM AND EXISTING METHOD ON EXTENDED YALE –B DATABASE

S.No	Performance analysis	SVM	RF	Proposed method
1	Accuracy	0.92	0.88	0.95
2	Error rate	0.037	0.074	0.03

TABLE II. PERFORMANCE ANALYSIS OF FACE ILLUMINATION IMAGE FOR OPTIMIZED NEURAL NETWORK ALGORITHM AND EXISTING METHOD ON CMU-PIE DATABASE

S.No	Performance analysis	SVM	RF	Proposed method
1	Accuracy	0.935	0.902	0.97
2	Error Rate	0.035	0.063	0.028

Fig. 4. Graphical Analysis of Optimized Neural Network Algorithm and Existing Classifier on Extended Yale-B Database.

Finally, the results showed that the performance of the proposed system is high in comparison to the existing methods.

## V. CONCLUSION AND FUTURE WORK

In the presence of varied illumination conditions, recognizing a face with good accuracy is the main challenge. In this paper, the Optimized Neural Network Algorithm (ONNA) is proposed to improve classification accuracy in varied illumination. Firstly, a pre-processing technique Weight Transfer Ideal Filter is proposed to reduce the dark spots, shadows, and reflection in the input image. Secondly, Robust Principal Component Analysis (RPCA) is applied to extract efficient features based on image area representation and the output of the RPCA is given as an input to the optimized neural network algorithm (ONNA) which improves the classification accuracy under illumination. Experiments are conducted on Extended Yale B and CMU-PIE datasets. According to the findings of the experiments, the ONNA outperforms the existing method such as SVM and RF in recognizing the faces under varied illumination in terms of high accuracy and low error rate. The future work is to use deep neural architectures such as Siamese Neural Network to improve the recognition rate.

**Abstract**—Plant leaves are another common source of information for determining plant species. According to the dataset that has been collected, we propose transfer learning models VGG16, VGG19, and MobileNetV2 to examine the distinguishing features to identify medicinal plant leaves. We also improved algorithm using fine-tuning strategy and analyzed a comparison with and without a fine-tuning strategy to transfer learning models performance. Several protocols or steps were used to conduct this study, including data collection, data preparation, feature extraction, classification, and evaluation. The distribution of training and validation data is 80% for training data and 20% for validation data, with 1500 images of thirty species. The testing data consisted of a total of 43 images of 30 species. Each species class consists of 1-3 images. With a validation accuracy of 96.02 percent, MobileNetV2 with fine-tuning had the best validation accuracy. MobileNetV2 with fine-tuning also had the best testing accuracy of 81.82%.

**Keywords**—Medicinal leaf plant; transfer learning; deep learning; phytomedicine

## I. INTRODUCTION

Leaves have characteristics such as shape and texture to be identified with the help of image processing technology and deep learning. An object sees identification as geometric information with boundaries [1]–[10]. The identified leaf object is limited to the boundary identified as leaf size and leaf shape, while the leaf texture or pattern is seen from the leaf surface [11]. Generally, the size of the leaves can be different, but the surface pattern of the leaves does not differ from one another [12]–[15]. This study aims to identify medicinal or phytomedicine plant species by processing leaf imagery using image processing and deep learning [15]–[21].

Research on the identification of phytomedicine plant leaves has been carried out by several previous studies, for

example Naresh and Nagendraswamy in 2015 [22], Mukherjee and his team in 2016 [23], Venkataraman & Mangayarkarasi in 2017 [24], Gao & Lin in 2018 [25], Sivaranjani et al. in 2019 [26], Pechebovicz et al. in 2020 [27], Bhuiyan et al. in 2021 [28].

In a study by Naresh and Nagendraswamy in 2015, the authors employed local binary patterns (LBP) to classify medicinal leaf plants. In a study conducted in 2016 by Mukherjee and his team, the classification of medicinal plants was accomplished with the use of Back Propagation Multi-Layer Perceptron (BP-MLP) [22], [29].

A study on the classification of medicinal plants also was carried out by Venkataraman and Mangayarkarasi (2017). They utilized the Histogram of Oriented Gradient (HoG)-Support Vector Machine for their research (SVM) [24]. Moreover, Gao and Lin (2018) used the OTSU approach in their classification of leaf plants for medicinal purposes. The OTSU approach involves using each manually marked edge point of the leaf to precisely detect the following outside points of the leaf located next to it [25]. The ExG-ExR index and the Logistic Regression (LR) classifier were utilized by Sivaranjani et al. to classify medicinal plants, and the researchers discovered that this method was successful. Based on each extracted leaf's color and texture characteristics, the Logistic Regression (LR) classifier is utilized to classify the various plant species [26].

In this study, we propose transfer learning models VGG16, VGG19, and MobileNetV2 to study the distinguishing features to identify medicinal plant leaves according to the dataset that has been collected. We also improved algorithm using fine-tuning strategy and analysed a comparison with and without a fine-tuning strategy to transfer learning model's performance.

## II. RELATED WORKS

Research on leaf image classification has been carried out for the last few years. To see the development of research in this field, we conducted a literature study on leaf image classification research from 2015 to 2021. The overview of related works is depicted in Fig. 1.

Fig. 1. Related Works

Local binary patterns (LBP) were used to classify medicinal leaf plants in a study by Naresh and Nagendraswamy in 2015 [22]. Back Propagation Multi-Layer Perceptron (BP-MLP) and Gray Level Co-occurrence Matrix (GLCM) were used to classify medicinal plants in a study by Mukherjee and his team in 2016. Results show that combined GLCM features can classify things better than basic single GLCM features. [23].

Venkataraman & Mangayarkarasi (2017) conducted a study for classification of medicinal plants using the Histogram of Oriented Gradient (*HoG*)-Support Vector Machine (SVM) [24]. Gao & Lin (2018) used the OTSU method to classify leaf plants that are used for medicine. OTSU method is to use each manually marked edge point of the leaf to accurately detect the next outer points of the leaf next to it [25].

Sivaranjani et al. (2019) used the ExG-ExR index and the Logistic Regression (LR) classifier to classify medicinal plants, and they found that this worked well. The Logistic Regression classifier is used to classify the plant species based

on the color and texture features of each extracted leaf. This classifier has a 93.3 percent accuracy rate [26]. Convolutional Neural Networks were used in a study by Pechebovicz et al. (2020) to classify medicinal plants [27]. Bhuiyan et al. (2021) used Convolutional Neural Networks to conduct research for the identification of medicinal plants (CNN) [28].

## III. RESEARCH METHODOLOGY

This research was conducted by applying several protocols or stages, including data collection, data preparation, feature extraction, classification, testing, and evaluation, as shown in the Fig. 2.

The first phase is data collection. The dataset used in this research is a public dataset called Medicinal Leaf Dataset. This dataset will be made public by Roopashree & Anitha in 2020 [30], [31]. The dataset collected is the result of photos using the Samsung s9+ Model Camera and Canon Inkjet Printer. Leaf photos are from leaves picked from different plants of the same species available at the study site. Healthy and mature leaves were selected for the dataset. The dataset consists of 1500 images of thirty species. Each species consists of 60 to 100 high quality images. An example of a dataset can be seen in the Fig. 3.

Fig. 2. Research Phases.

Fig. 3. Example of Dataset.

The dataset consists of 30 species of healthy medicinal plants such as *Alpinia Galanga* (Galanga Leaves), *Amaranthus Viridis* (Green Spinach Leaves), *Artocarpus Heterophyllus* (Jackfruit), *Azadirachta Indica* (Neem), *Santalum Album* (Sandalwood), *Muntingia Calabura* (Jamaica cherry), *Plectranthus amboinicus* (Indian Mint), *Brassica Juncea* (Oriental mustard), and many more.

The next stage is data preparation. The first sub-phase of data preparation is image normalization. This process is done by multiplying each pixel value by 1./255. The second data preparation stage is image augmentation. This stage is carried out by applying several image augmentation techniques to obtain additional synthetic data [32], [33]. The augmentations performed are `horizontal_flip`, `vertical_flip`, `width_shift`, `height_shift`, `rotation`, `fill_mode = 'reflect'`, `zoom`, `brightness_range = [0.5, 1.5]`, `featurewise_std_normalization = True`, `shear` and `featurewise_center` [34]–[37]. There are two stages of feature extraction carried out, as shown in the Fig. 4.

In data preparation phase, the dataset folder is named according to the scientific name of the species. The dataset is broken down for data training, validation, and testing. The entire dataset has been segmented to free from the background. The distribution of training and validation data is 80% for training data and 20% for validation data, with 1500 images of thirty species. The 80/20 dataset composition is based on previous research [38]–[45]. Data testing uses new data outside the dataset for training and validation. The testing data consisted of a total of 43 images of 30 species. Each species class consists of 1-3 images.

The third phase is feature extraction. This study conducted experiments to compare three pre-trained models for feature extraction on medicinal plant image datasets, namely VGG16, VGG19, and MobileNetV2.

Fig. 4. Feature Extraction Methods.

The fourth phase is classification. The data that has been extracted features a pre-trained model, then training and model validation is carried out using training and validation data. In order to obtain better accuracy results, experiments were also conducted to compare the model with fine-tuning and without fine-tuning. The VGG16, VGG19, and MobileNetV2 model architectures study leaf shape information to differentiate different plant species. The input leaf size and color channel used are adjusted for the VGG16, VGG19, and MobileNetV2 models.

The fifth phase is testing that is done using new data outside the dataset. The testing data obtained by searching through Google using the keyword species name of plant. The data selected on Google is only focused the leaves object, if there is a background in the image, only the leaves are taken (cropped). The testing data consisted of a total of 43 images of 30 species. Each species class consists of 1-3 images. The following Fig. 5 is an example of testing data.

The final phase is evaluation. The evaluation is carried out by comparing the experimental results to find the best suitable model in the dataset. We evaluated the VGG16, VGG19, and MobileNetV2 models for leaf identification on medicinal plant leaves by conducting experiments on the collected datasets. The evaluation method used is the accuracy method. The evaluation was carried out in two stages: evaluation at the training stage and evaluation at the validation stage.

Fig. 5. Example of Data Testing.

#### IV. RESULT AND DISCUSSION

This study used the VGG16, VGG19, and MobileNetV2 classification models for leaf identification on medicinal plant leaves. Two different processes are carried out on the same classification model and dataset, namely with and without fine-tuning implementation. From the implementation results, we want to know how the effect of implementation on the accuracy results during the training, validation, and testing processes using the same dataset and classification model.

The first stage is the training process. The training process is carried out by conducting experiments on 80% of the data from the dataset as a whole. The dataset consists of 1500 images (for 30 classes), meaning that there are about 1200 data used in this experiment. The experimental results can be seen in the Table I.

TABLE I. ACCURACY RESULTS ON TRAINING DATA

Model	Training Experiment	
	Without Fine Tuning	With Fine Tuning
VGG16	99.24%	95.72%
VGG19	93.85%	95.51%
MobileNetV2	98.89%	98.41%

Based on the data in Table I, the model without fine-tuning obtains an accuracy of 99.24% for the VGG16 model, 93.85% for the VGG19 model, and 98.89% for the MobileNetV2 model. In contrast, the models with fine-tuning get 95.72% accuracy for the VGG16 model, 95.51% for the VGG19 model, and 98.41% for the MobileNetV2 model. Moreover, the difference Value of training experiment of model implementation using the fine-tuning and without fine-tuning is depicted in the Fig. 6.

Based on the data in Table II, the model without fine-tuning obtains an accuracy of 95.17% for the VGG16 model, 89.49% for the VGG19 model, and 87.50% for the MobileNetV2 model. While the models with fine-tuning get 93.75% accuracy for the VGG16 model, 92.90% for the VGG19 model, and 96.02% for the MobileNetV2 model. Moreover, difference value of validation experiment of model implementation by using fine tuning and without tuning is depicted Fig. 7.

Fig. 6. Difference Value of Training Experiment.

The second stage is the validation process. The validation process is carried out by conducting experiments on 20% of the data from the dataset as a whole. The dataset consists of 1500 images (for 30 classes), meaning that about 300 pieces of data are used in this experiment. The experimental results can be seen in the Table II.

TABLE II. DATA ACCURACY RESULTS ON DATA VALIDATION

Model	Validation Experiment	
	Without Fine Tuning	With Fine Tuning
VGG16	95.17%	93.75%
VGG19	89.49%	92.90%
MobileNetV2	87.50%	96.02%

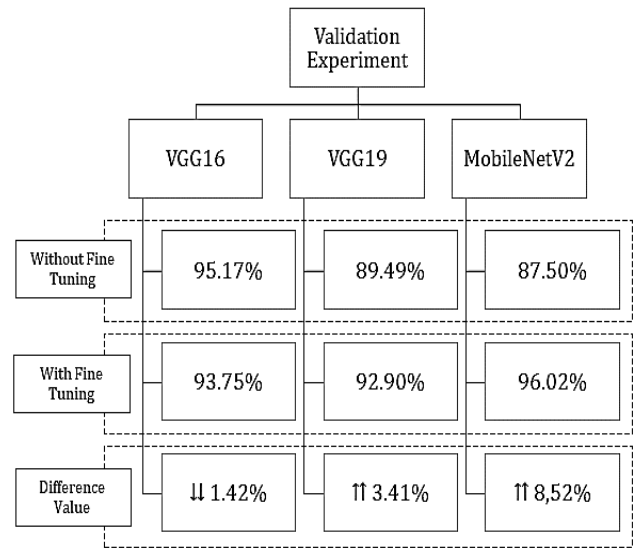

Fig. 7. Difference Value of Validation Experiment.

Based on the Fig. 7, MobileNetV2 and VGG19 with fine-tuning can significantly increase the validation accuracy, while in VGG16 with fine-tuning, it reduces validation accuracy. The third stage is the testing process. Testing data is new data that the model has never processed. After the model is obtained, then testing is carried out on the model using data testing and the result can be seen in Table III.

TABLE III. ACCURACY RESULTS ON TESTING DATA

Model	Testing Experiment	
	Without Fine Tuning	With Fine Tuning
VGG16	22.73%	36.36%
VGG19	15.91%	31.82%
MobileNetV2	43.18%	81.82%

From the experiment results, the models with fine-tuning both VGG16, VGG19, and MobileNetV2 experienced an increase in testing accuracy compared to the model before fine-tuning and the result can be seen in Table IV.

MobileNetV2 obtained the best model by fine-tuning with 96.02% validation accuracy, 81.82% testing accuracy, precision, recall, and f1-score values 0.73, 0.82, and 0.76. The following Fig. 8 is a classification report and confusion matrix obtained by the MobileNetV2 model by fine-tuning.

Overall, VGG16 obtained the highest accuracy compared to other models during the experiment of training without fine tuning (99.24%) and validation without fine tuning (95.17%). While in other experiments the MobileNetV2 model is superior to other models, as shown in the Table V.

Based on the experiment result, we recommended MobileNetV2 model to identify medicinal plant leaves according to the dataset that has been collected. MobileNetV2 was chosen for further research because it got the best accuracy and shorter computation time in recognizing the image of medicinal plant leaves [46]–[48].

TABLE IV. DETAIL OF RESULTS ON TESTING DATA

Class	Precision	Recall	F1-Score
Alpinia Galanga	1.00	1.00	1.00
Amaranthus Viridis	0.67	1.00	0.80
Artocarpus Heterophyllus	1.00	1.00	1.00

VA	FT	93.75%	92.90%	96.02%
TE	WFT	22.73%	15.91%	43.18%
TE	FT	36.36%	31.82%	81.82%

\*WFT = without fine tuning, FT = with fine tuning, TR=training, VA=validation, TE=testing

## V. CONCLUSION

MobileNetV2 obtained the best validation accuracy with fine-tuning with a validation accuracy of 96.02%. MobileNetV2 also obtained the best testing accuracy with fine-tuning of 81.82%. In other models, the testing accuracy obtained is far below MobileNetV2. This condition is likely to happen because the dataset for training and validation used is less diverse and general to build a good model, so the resulting model overfits the dataset. In this case, MobileNetV2 with fine-tuning is quite able to overcome the weaknesses of the dataset used so that when new testing data is given, the accuracy results obtained are quite good. In addition, based on the experiment results, fine-tuning the model can improve the accuracy of the validation and testing produced.

The limitation of this study is that it ignores the background problem of the leaf image. Further research will be carried out using a dataset with a complex background by adding a segmentation method before being processed by the MobileNetV2 model.

## ACKNOWLEDGMENT

The authors would like to thank Universitas Sriwijaya and Universitas Mercu Buana that have been supported this research.

**Abstract**—Opinion mining has been a prominent topic of research in Indonesia, however there are still many unanswered questions. The majority of past research has been on machine learning methods and models. A comparison of the effects of random splitting and cross-validation on processing performance is required. Text data is in Indonesian. The goal of this project is to use a machine learning model to conduct opinion mining on Indonesian text data using a random splitting and cross validation approach. This research consists of five stages: data collection, pre-processing, feature extraction, training & testing, and evaluation. Based on the experimental results, the TF-IDF feature is better than the Count-Vectorizer (CV) for Indonesian text. The best accuracy results are obtained by using TF-IDF as a feature and Support Vector Machine (SVM) as a classifier with cross validation implementation. The best accuracy reaches 81%. From the experimental results, it can also be seen that the implementation of cross validation can improve accuracy compared to the implementation of random splitting.

**Keywords**—Random splitting; cross validation; machine learning; Indonesian text

## I. INTRODUCTION

Opinion mining technology examines and interprets enormous amounts of text data automatically. Opinion mining is the technique of extracting useful information and knowledge from unstructured natural language texts automatically [1]–[5]. Opinion mining is a specific sub-field of text mining that seeks to automatically discover the polarity of opinions (positive, negative, and others) associated with natural language texts [6]–[11].

The language structure of the dataset determines the main challenge in opinion mining. Sentences can be ironic or have several meanings depending on the context. For example, someone can support school policies in the education sector

while also breaking school rules—another challenge in obtaining opinions in determining the difference between subjective and objective texts [12]–[14]. A subjective text is one person's point of view, bias, or opinion. News stories and neutral texts are examples of objective writing that deal with facts and are supposed to be fully unbiased [6], [15], [16].

A machine learning approach can be used for opinion mining. Machine learning refers to methods and systems that can learn from data automatically. The most common machine learning method is supervised learning. It entails creating a prediction model that can inductively learn from a training data collection [17]. The training data is a set of labelled instances, with each example consisting of a pair of input objects (specified in a feature set) and the desired output value, in the case of a classification model, a class label. After the model has been trained, it is ready to be applied to new data [6].

Opinion mining in Indonesia has been a popular topic of study, yet there are still many open challenges. Indonesia is morphologically diverse and ambiguous, with complicated morpho-syntactic rules and many irregular forms and a wide range of dialects with no written standards. Learning a robust general model from Indonesian text might be challenging without suitable processing and handling [18]. Furthermore, compared to English, Indonesian opinion mining has fewer freely available resources in terms of huge net sentiment lexicons and annotated opinion sets. These difficulties have piqued researchers' interest in Indonesian opinion mining [19].

Apart from increasing research on opinion mining on Indonesian text data, there are still some gaps. Most of the previous research has focused on machine learning models and algorithms. There is a need to compare the effect of random splitting and cross-validation on improving performance for processing Indonesian text data [19], [20].

Based on the above background, the purpose of this study is to conduct opinion mining on Indonesian text data using a machine learning model by implementing a random splitting and cross validation approach.

## II. RELATED WORK

The previous research of opinion mining on Indonesian text data using a machine learning model has been done by several scholars. Research by Fachrina & Widyanoro (2017) compares Support Vector Machine and Naïve Bayes Classifier to process 2960 Indonesian text data [21]. Research by Suciati & Budi (2019) compared the performance of Random Forest (RF), Multinomial Naïve Bayes (NB), Logistic Regression (LR), Decision Tree (DT), and Extra Tree classifier (ET) using ten folds cross-validation to process Indonesian text data.

The algorithm that achieved the highest score was obtained by Logistic Regression (LR) and Decision Tree (DT) [22]. Research by Miranda et al. (2019) used Bayes classification to process Indonesian text data. This study obtained an accuracy of 74.94% [23]. Research by Wisnu et al. (2020) uses the Naïve Bayes classifier and K-Nearest Neighbor or KNN to process Indonesian text data. This study obtained an accuracy of KNN (91.00%) and Naïve Bayes (83.50%) [24]. Research by Buntoro et al. (2021) uses the Naïve Bayes Classifier (NBC) and a Support Vector Machine (SVM) to process Indonesian text data. This study obtained an accuracy of SVM (79.02%) and NBC (44.94%) [25].

Most of the previous research has focused on machine learning models and algorithms. There is a need to compare the effect of random splitting and cross-validation on improving performance for processing Indonesian text data. This research is proposed to fill the gap by implementing random splitting and cross-validation for improving performance for processing Indonesian text data.

## III. RESEARCH METHODOLOGY

This study uses a public dataset to determine negative and positive comments on the Indonesian feedback dataset. The stages of the research can be seen in the following Fig. 1.

The first stage is the data collection stage. The dataset used for training and testing the model is sentiment data on Twitter obtained publicly provided by Sulistya in 2021 at Kaggle [26]. The dataset is a collection of feedback data in Indonesian by Twitter users on Covid-19. The dataset consists of 1000 records with 500 records each for the positive class and 500 tweets for the negative class. The following is an example of a dataset. The second stage is the preprocessing stage. This stage consists of six stages: data cleansing, case folding, tokenizing, stopword, normalization, and stemming. Details of these stages can be seen in the Fig. 2:

Based on Fig. 2 above, at the data cleansing stage, a cleaning process is carried out for words that are not needed in order to reduce the computational burden, such as text containing HTML, links, and scripts. In addition, this stage also removes punctuation marks such as periods (.), commas (,) and other punctuation marks. In this pre-processing process, the case folding method is also applied, namely the process of converting words into lower-case letters. The third stage is

tokenization. This method is implemented to transform the text's words into several sequences truncated by spaces or specific characters [23], [27], [28].

The stop word removal method is a method of deleting a word with a unique word from text data such as conjunctions and possessive words. In addition, types of words that are less meaningful will be removed, such as words: I, and, or by using this method. Stop word removal is meant to reduce the burden on system performance because the words taken are considered essential [29]–[31]. The last stage in the pre-processing process is the stemming stage. The method at this stage is done by transforming the words in the text to become essential words.

The third research stage is to perform feature extraction. We compare two text features at this stage, namely Count Vectorizer (CV) and TF-IDF. The Term Frequency-Inverse Document Frequency method, abbreviated as TF-IDF, is the most commonly used word weight calculation method in opinion mining. The method is known for its efficient computation time, ease of implementation, and good results or accuracy values. The method works by calculating the value of Term Frequency (TF) and Inverse Document Frequency (IDF) for each token (word) in the document in the corpus or dataset [32]–[34].

The fourth stage is the Training and Testing Model. Training and testing are done by comparing four classifiers, namely Random Forest (RF), Logistic Regression (LR), Naïve Bayes (NB), and Support Vector Machine (SVM)

Fig. 1. Main Research Methods.

<b>Stemming</b>	<ul style="list-style-type: none"> <li>• Convert prepositional words to base words</li> </ul>

Fig. 2. Pre-Processing Methods.

The Random Forest (RF) method is the development of the Classification and Regression Tree (CART) algorithm. This method applies bootstrap aggregating and random feature selection. This method can be used for classification that works by building a classification tree. Increasing the accuracy of the RF method is done by generating a child node on each node (the node above it) with random selection. Then, the classification results from each tree are accumulated and selected based on the classification results that appear the most [35]–[37]. The RF method has three main parts: the root node, internal node, and leaf node. The root node is the node at the very top, commonly referred to as the root of the decision tree. The internal node is the branch's node with one to two inputs. Finally, the leaf node or terminal node is the end node that has one input and no output. The calculation on the decision tree begins by calculating the entropy value as a determinant of the level of attribute impurity and the value of information gain [35]–[37]. The Logistic Regression (LR) method is used to express the relationship between categorical response variables (in the form of polychotomous or dichotomous) with either continuous or categorical predictor variables. Logistic regression aims to classify each event or observation into positive and negative classes [38] [39].

The Naïve Bayes (NB) method is a method that can be used in opinion mining. This method applies Bayes' theorem theory in classification based on attribute values that are conditionally independent if given an output value. In short, Bayes' theorem is a fundamental statistical approach to pattern recognition [40], [41]. The advantage of using the NB method is that the value or amount of training data required in data processing can be on a small scale and can still be used to determine parameter estimates in the data classification process [42].

The Support Vector Machine (SVM) method is a method with the concept of statistical learning theory, which has given better performance results than other classification methods in several research cases. This method does not study all the training data in the training process, but only a selected number of data is used to build a model in the classification process. The SVM method does not store all training data but only stores a small portion of training data for further processing. This has become an advantage in choosing the SVM method because not all training data is involved in each training iteration [43]. The SVM method works by maximizing the decision limit (hyperplane) or finding the best decision limit (hyperplane) as a separator of the two data classes depicted in the Fig. 3:

Fig. 3. Hyperplane [44].

In the picture above (a), there is a choice of possible decision limits (hyperplane) for the data set; then, in the picture above (b), there is a decision limit (hyperplane) with the maximum margin. The margin is the distance between the decision boundary (hyperplane) and the closest data from each class. This closest data is known as the support vector. The hyperplane component with the maximum margin will better generalize the classification process.

For example, in Fig 3 (b), the solid line component shows the best decision boundary (hyperplane) with a location in the middle of the two classes, while the dotted line component that passes through the circle and square data is a support vector. The central concept of training on the SVM method is finding the hyperplane's location [44], [45]. Experiments were carried out using the results of random splitting and cross-validation. The third and fourth stages are illustrated in the Fig. 4:

Fig. 4. Experiment Scenario.

The next stage is an evaluation to compare the best accuracy, precision, recall, f1-measure obtained. The performance evaluation measurement model is an approach that aims to measure the performance or performance of a system. This approach is widely used in the case of training or data training. Several formulas or equations in the performance evaluation measure are usually applied separately or in combination to get a better performance analysis perspective. Some of the calculations contained in the performance evaluation are as follows [46]. The precision method calculates the level of accuracy or accuracy of the results between user testing and system answers.

$$pre = \frac{TP}{TP+FP} \tag{1}$$

The recall is a measurement of the accuracy or accuracy of the same information with information that has existed before.

$$rec = \frac{TP}{TP+FN} \tag{2}$$

Accuration is a comparative calculation between the information the system answers correctly with the comprehensive information.

$$acc = \frac{TP+TN}{TP+TN+FP+FN} \tag{3}$$

IV. RESULT AND DISCUSSION

This study aims to determine negative and positive comments on the Indonesian feedback dataset publicly provided by Sulistya (2021) on the Kaggle web using a machine learning approach. This study also compares the performance of several machine learning methods to find out which method has the best performance.

The second stage carried out in the experiment is the pre-processing stage. The first stage of pre-processing is data cleansing. The cleansing of the dataset is: removing hashtags (#) and mentions (@), deleting URLs, deleting punctuation and deleting emoticons. The example result of data cleansing can be seen in the Table I:

TABLE I. RESULT OF DATA CLEANSING

Process	Data #1	Data #2
Data source	"Indonesia: APBN Sekarat, Covid-19 Meningkat,	#BREAKING:Pemerintah mengonfirmasi kasus posi
Text_remove_hastag_and mentions	"Indonesia:APBN Sekarat, Covid-19 Meningkat,	: Pemerintah mengonfirmasi kasus positif Covid
Text_remove_url	"Indonesia:APBN Sekarat, Covid-19 Meningkat,	: Pemerintah mengonfirmasi kasus positif Covid
Text_remove_punc	Indonesia:APBN Sekarat, Covid-19 Meningkat Rakyat	Pemerintah mengonfirmasi kasus positif Covid1
Text_remove_emojis	Indonesia:APBN Sekarat, Covid-19 Meningkat Rakyat	Pemerintah mengonfirmasi kasus positif Covid1
Text_remove_emoticons	Indonesia:APBN Sekarat, Covid-19 Meningkat Rakyat	Pemerintah mengonfirmasi kasus positif Covid1

The second preprocessing stage is case folding. This stage is done by converting text into lowercase ones. For example, "Pemerintah mengkonfirmasi kasus positif COVID19...", will be converted as "pemerintah mengkonfirmasi kasus covid19". The example results of case folding for our dataset can be seen in the Fig. 5:

```

0 bang gimna pemerintah mau peduli rrc urus abk ...
1 erinx tidak percaya data covid19 dari pemerin...
2 indonesia apbn sekarat covid19 meningkat rakya...

4 hingga Kamis 752020 pk 1200 Wibdata pemerint...
5 pemerintah mengonfirmasi kasus positif covid1...
```

Fig. 5. Example Result of Case Folding.

The next stage is tokenizing. This stage separates the text with white space and punctuation as token delimiters. For example, "pemerintah mengkonfirmasi kasus covid19", will be converted as "[pemerintah, mengkonformasi, kasus, positif, covid19]". The example result of tokenizing for our dataset can be seen in the Fig. 6:

```

0 [bang, gimna, pemerintah, mau, peduli, rrc, ur...
1 [erinx, tidak, percaya, data, covid, dari, pem...
2 [indonesia, apbn, sekarat, covid, meningkat, r...
3 [untuk, mengurangi, penyebaran, virus, covid, ...
4 [hingga, Kamis, pk, Wibdata, pemerintah, mempe...
5 [pemerintah, mengonfirmasi, kasus, positif, co...
```

Fig. 6. Example Results of Tokenizing.

The next step is stop-word removal. At this stage, the words included in the stop-word will be deleted. Stop-word deletion is done by matching the dataset with the Indonesian stop-word dictionary. For example, "[untuk, mengurangi, penyebaran virus, covid]", will be converted "[mengurangi, penyebaran virus, covid]". The word "untuk" stop-word so as it will be deleted. The example result of stop-word removal can be seen in the Fig. 7:

case_folding_tweets	tweet_tokens	tweet_stopword_removal

untuk mengurangi penyebaran virus covid menduk...	[untuk, mengurangi, penyebaran, virus, covid, ...	[mengurangi, penyebaran, virus, covid, menduku...

Fig. 7. Example Results of Stop-Removal.

The fifth preprocessing stage is normalization. Normalization changes non-standard words (slang words) and acronyms into familiar words by matching the dataset with the Indonesian normalization dictionary. The results of some normalization of words in Indonesian are shown in the Table II and Fig. 8:

TABLE II. RESULT OF NORMALIZATION

No.	Real Data	Normalization
1	&	Dan
2	l pun	Satupun
3	7an	Tujuan
4	@	Di
5	Jkt	Jakarta
6	Nasihat	Nasehat
7	SE	Surat edaran
8	Ababil	Abglabil
9	Abis	Habis
10	Ad	Ada

tweet_tokens	tweet_stopword_removal	tweet_normalized

[indonesia, apbn, sekarat, covid, meningkat, r...	[indonesia, apbn, sekarat, covid, meningkat, r...	[indonesia, apbn, sekarat, covid, meningkat, r...

Fig. 8. Example Results of Normalization.

The sixth preprocessing stage is stemming. At this stage, the affixed words are transformed into basic words using the literary method. The method at this stage is done by transforming the words in the text to become essential words. At this stage, the transformation of affixed words into basic words is carried out using the Sastrawi library. For example, “[mengurangi, penyebaran virus, covid]”, will be converted “[kurang, sebar virus, covid]. The basic words of “mengurangi” and “menyebarkan” are “kurang” and “sebar. The example result of stemming can be seen in the Fig. 9:

After completing six stages: data cleansing, case folding, tokenization, stopword, normalization, and stemming. The example of every step has been elaborated above. Attribute of Data#1 is text before method is applied and attribute of Data#2 is text after applied method. Moreover, an overview result of preprocessing stages can be seen in the Table III.

The third research stage is to perform feature extraction. At this stage, feature extraction is carried out on the dataset that has been processed in the previous stage. The feature extraction stage aims to obtain features used in model training and testing. We compare two text features at this stage, namely Count Vectorizer (CV) and TF-IDF.

The fourth stage is the training and testing model. Training and testing are done by comparing four classifiers, namely Random Forest (RF), Logistic Regression (LR), Naïve Bayes (NB), and Support Vector Machine (SVM). Experiments were carried out using the approach of random splitting and cross-validation.

The first experiment is training and evaluating machine learning models using random splitting. This experiment was carried out by randomly dividing the dataset into training and testing data with 80% of the training data and 20% of the testing data, respectively. Furthermore, an evaluation was carried out to compare the best accuracy, precision, recall, f1-measure obtained. The results of this experiment can be seen in the Table IV:

TABLE IV. PERFORMANCE EVALUATION

Process	Accuracy	Precision	Recall	F1
CV&RF	0.76	0.77	0.76	0.76
TF-IDF&RF	0.77	0.77	0.77	0.77
CV&LR	0.75	0.75	0.75	0.75
TF-IDF&LR	0.76	0.76	0.76	0.76
CV&NB	0.75	0.75	0.74	0.75
TF-IDF&NB	0.74	0.75	0.74	0.74
CV & SVM	0.76	0.77	0.76	0.76
TF-IDF&SVM	0.78	0.78	0.78	0.78

The second experiment is training and evaluation of machine learning models using cross-validation. This stage is carried out using 10-fold cross-validation. At this stage, cross-validation is implemented to find the maximum accuracy of the model. After cross-validation, training and model evaluation were carried out to measure the resulting accuracy, precision, recall, f1-measure results. The results of this experiment can be seen in the Table 5:

TABLE V. EXPERIMENT WITH CROSS VALIDATION

Process	Accuracy	Precision	Recall	F1
CV&RF	0.79	0.80	0.79	0.79
TF-IDF&RF	0.78	0.79	0.79	0.79
CV&LR	0.78	0.79	0.79	0.79
TF-IDF&LR	<b>0.81</b>	0.81	0.81	0.81
CV&NB	0.79	0.80	0.79	0.79
TF-IDF&NB	0.79	0.80	0.79	0.79
CV & SVM	0.79	0.79	0.79	0.79
TF-IDF&SVM	<b>0.81</b>	0.81	0.81	0.81

According to the Table above, utilizing TF-IDF as a feature and Support Vector Machine (SVM) as a classifier with cross validation implementation yields the best accuracy results. The highest level of accuracy is 81%. It can also be observed from the experimental results that cross validation can improve accuracy when compared to random splitting. Furthermore, for Indonesian language, the TF-IDF feature outperforms the Count-Vectorizer (CV).

## V. CONCLUSION

Based on the experimental results, the TF-IDF feature is better than the Count-Vectorizer (CV) for Indonesian text. The best accuracy results are obtained by using TF-IDF as a feature and Support Vector Machine (SVM) as a classifier with cross validation implementation. The best accuracy reaches 81%. From the experimental results, it can also be seen that the implementation of cross validation can improve accuracy compared to the implementation of random splitting.

This research has not discussed the problem of negation. In future research, issues that will be investigated further include the implementation of negation handling with the modified

syntactic rule method in the pre-processing process to increase the accuracy of opinion mining.

**Abstract**—Machine learning algorithms have aided health workers (including doctors) in the processing, analysis, and diagnosis of medical problems, as well as the detection of disease patterns and other patient data. Diabetes mellitus (DM), commonly referred to as diabetes, is a gathering of a syndrome issue that is portrayed by high glucose levels in the blood over a drawn-out period. It is a long-term illness that is a great threat to humanity and causes death. Most of the existing machine learning algorithms used for the classification and prediction of diabetes suffer from embodying redundant or inessential medical procedures that cause complications and wastage of time and resources. The absence of a correct diagnosis scheme, deficiency of economic means, and a general lack of awareness represent the main reasons for these negative effects. Hence, preventing the sickness altogether through early detection may doubtless cut back a considerable burden on the economy and aid the patient in diabetes management. This study developed diabetes classification using machine learning techniques that will minimize the aforementioned drawbacks in the prediction of diabetes systems. Decision tree classifiers, logistic regression, random forest, and support vector machines are all examples of predictive algorithms that were tested in this paper. 1009 records of data set were obtained from the Diabetes dataset of Abelvikas, Data World. We used a confusion matrix to visualize the performance evaluation of the classifiers. The experimental result shows that the four machine learning algorithms perform well. However, Random Forest outperforms the other three, with a prediction accuracy of 100% and has a better prediction level when compared with others and existing work.

**Keywords**—Machine learning; diabetes mellitus; predictive algorithm; correlation map; confusion matrix

## I. INTRODUCTION

Diabetes is one of the most common and speedily increasing diseases within the world [1] and a serious pathological state in the world. This polygenic disease is a condition in which the body is unable to produce the required amount of internal secretion to keep blood sugar levels in check (National Center for Biotechnology Information, NCBI). In general, a higher risk of diabetes infection is associated with female gender, age over 35, and individuals who are overweight.

The day demands to identify and diagnose this diabetes condition at an early stage cannot be over-emphasized. The diagnosis and analysis of diabetes disease is an important issue

in classification that is required and must be cost-effective, suitable, and valid to be built.

Diabetes mellitus, also known as diabetes, is a metabolic disorder that can result in elevated blood sugar levels (MSD Manual). It is a long-lasting disease that occurs when the pancreas fails to produce enough insulin or when the body fails to properly utilize the insulin that is produced. The insulin in the body system regulates the movement of sugar from the blood into the cells for energy use. Untreated high diabetes blood sugar can cause damage to the critical major organs such as the eyes, and kidneys, heart disease, sudden death which can lead to chronic damage to other organs, etc. [2, 3].

Therefore insulin is a catalyst in the regulation of blood sugar hormones. Hyperglycaemia (high blood sugar) is a common complication of uncontrolled diabetes that resulted in severe damage to nerves and blood vessels of the body's systems [4]. Diabetes is one of the most lethal diseases in the world, but with the introduction of machine learning, there is the potential to find a solution to this pandemic.

The crux of using a machine learning classifier and data mining is to derive knowledge from information stored in the dataset and produce a simple pattern description. A diabetes diagnostic tool using machine learning needs to be developed to predict patients with diabetes to detect the illness early before it is pathetic. Machine-learning algorithms (MLA) identify patterns from statistical quantities of data and feed them into the system to be digitally processed. Much has been achieved in the areas of using machine learning algorithms to solve many challenges in the health sector with the development of technology. Some of these are for the prognosis and/or diagnosis of diabetes for active and accurate decision-making [5]. Therefore, this paper focuses on the application of machine learning techniques to an online dataset to uncover hidden patterns in medical diagnosis and predict diabetes based on the data collected. To ensure that the information obtained from a system built using these techniques is reliable, a Support Vector Machine (SVM) and Random Forest (RF) are proposed for use in the prediction of diabetes in a patient.

It was discovered that there are three major kinds of Diabetes classified into three types: type 1, type 2, and gestational diabetes. Type 1 diabetes is distinguished by a lack of insulin production and necessitates daily insulin administration. Despite the fact that the exact cause of type 1

---

This work was financially supported by Yaba College of Technology in Lagos, Nigeria.

diabetes is unknown, it is unavoidable. The symptoms may appear unexpectedly and are caused by excessive urination (polyuria), fatigue (polydipsia), persistent hunger, loss of weight loss, and vision. Type 2 diabetes (non-insulin-dependent,) may be caused as a result of insufficient insulin in the body and is primarily caused by excess body weight and physical inactivity. The third type is gestational (hyperglycemia), which is defined as having blood glucose levels that are higher than normal but are lower than the conditions of diabetes that occur during pregnancy. This increases the likelihood of complications during pregnancy and childbirth and faces a greater chance of type 2 diabetes in the future too [6].

Patients with diabetes must undergo a series of tests and exams in order to properly diagnose the disease. These tests may include unnecessary or redundant medical procedures that result in complications and a waste of time and resources. Diabetes lowers the standard of living and reduces labor productivity, so the economic cost of the disease far outweighs the direct medical costs within the care sector. The main causes of these negative effects are a lack of a proper diagnosis scheme, a lack of financial resources, and a general lack of awareness. As a result, preventing the illness entirely through early detection will almost certainly reduce the economic burden and aid the patient in diabetes management. The following are the objectives of the study:

- Develop the Diabetes prediction system using a decision tree classifier, logistic regression, random forest, and support vector machine.
- Evaluate and compare the developed system and the performance of each algorithm in the ensemble of algorithms based on sensitivity, specificity, and accuracy.

The study is organized into five sections. Section I introduces the study by discussing the keywords briefly as well as the study's objectives Section II explains various related works in the field of diabetes type prediction Section III describes the study's methodology in detail. Section IV discusses the results of the algorithms. Section V concludes the study with recommendations for additional research.

## II. RELATED WORKS

Several researchers have made contributions to fields where diabetes was predicted. Diabetes has a significant economic impact on society, and it is the most expensive chronic disease. The author [7] addressed the fact that majority of diabetes patients are asymptomatic, which leads to delayed standard clinical laboratory examinations that create large health datasets over a lifetime. They looked at machine learning algorithms to help with diabetes screening via routine laboratory tests, using data from 62,496 patients' lab tests. The following classifications were used; artificial neural networks, Bayes naïve, K-nearest neighbor, random forest, regression models, and support vector machines. In detecting diabetes, the artificial neural network model outperformed the others. Based on clinical data processing, computer processing has been used to identify diseases [8]. Knowledge extraction from data to aid

decision-making by experts is a movement in the next generation of intelligent health systems [9].

The author [10] sought to develop effective models for predicting early gestational diabetes mellitus (GDM). The seven variables and 73 variables datasets were used to create models that predicted early GDM in different situations. In early pregnancy, ML models predicted GDM with high accuracy and were developed and tested in the Chinese population. The study [11] also employed ML and classification algorithms, with Logistic Regression providing the highest accuracy of 96 percent. Also, [12] carried out the use of random forest, KNN, Nave Bayes (NB), and J48 to develop diabetes analysis and prediction. The researchers used two datasets: PIDD (Pima Indian Diabetes Dataset) and 130 US hospital diabetes data sets. The developed system achieved 93.62 percent accuracy in the case of PIDD and 88.56 percent accuracy for a large dataset of 130-US hospitals. For large dataset analysis, the NB and J48 prediction algorithms were found to be superior. The author [13] reviewed diabetes types and treatments, as well as some emerging issues that may arise, and listed physical activities that will lead to healthy lifestyles.

Furthermore, [14] presented diabetes prediction based on big data from healthcare communities using various machine learning algorithms. Using SVM for classification and K-means for clustering, the developed system used an effective strategy for detecting diabetes disease earlier. The study [15] implemented a decision tree algorithm to predict diabetes. The experiments were carried out on the Pima Indians diabetes database, and the results achieved an accuracy of 87 percent. However, low sample sizes result in poor accuracy. The system that was developed can be used to predict or diagnose other diseases in the same family. In a similar vein, [16] used the most recent records of 13,309 Canadian patients aged 18 to 90 years, as well as their laboratory data. They developed predictive models using Logistic Regression and Gradient Boosting Machine (GBM) techniques and compared them to others such as Decision Tree and Random Forest. The GBM and LR models outperform the other two models. In this experiment, [17] proposed two machine learning classification algorithms, Fine Decision Tree and Support Vector Machine, which are used to detect diabetes at an early stage. When compared to the Fine Decision Tree algorithm, the SVM classification algorithm achieved a high percentage of accuracy.

The author [18] applied random forest, decision tree, and neural network in their study to predict diabetes mellitus with an accuracy of about 81 percent. The Pima Indians diabetes dataset from the UCI machine learning repository was used. The study [19] proposed using classification algorithms to predict diabetes. On a number of criteria, three machine learning classification algorithms were researched and assessed. According to the experimental findings, the Naive Bayes classification algorithm has an accuracy rate of 76.30 percent.

In [20] the author proposed the use of the Pima Indians diabetes dataset, using Decision Tree, K-Nearest Neighbors, Support Vector Machine, and Random Forest to predict diabetes at various stages and compare the performance of

different classification techniques. While [21] presented a Unified Framework for Diabetes Prediction Based on Machine Learning. Six machine learning classifications for predicting diabetes and various evaluation criteria were used to investigate the performance of these classification techniques. The analysis results show that Naïve Bayes achieved the highest performance than the other classifiers, obtaining the F1 measure of 0.74. According to [22] in the prediction of diabetes using the classification algorithms. Naive Bayes, Multilayer Perceptron, and IBK algorithms were used. The Naive Bayes algorithm shows 100% accuracy compared to IBK 88% and Multilayer perceptron 88%.

Research work made by [23] developed a machine learning-based framework for detecting type 2 diabetes in electronic health records. The system created a semi-automated framework based on machine learning. A data-informed framework for identifying subjects with and without T2DM from EHR was proposed using machine learning and feature engineering. The author in [24] created an Ontology-based Diabetes Management system, a computer-based system that assists physicians in correctly diagnosing diabetes mellitus disease in patients. They used the Bayesian Optimization technique to boost prediction accuracy. Similarly, [25] developed a medical expert system for diabetes diagnosis, a diabetes ontology with 9 sub-classes, and a web-based application with web service architecture. With test data from 65 patients, an overall consistency rate of 90.7 percent was achieved. The author [26] demonstrated diabetes detection at an early stage using a computational intelligence fuzzy hierarchical model capable of performing early detection and identifying someone's susceptibility to DM. The model's accuracy is 87.46 percent. A number of techniques have been proposed over the years for the prediction of diabetes types. The comparison of diabetes techniques in Table I shows their performance and limitation. Four different classifiers will be used, and because Random Forest excels at working with non-linear data, the prediction will be more accurate and stable, with improved performance.

TABLE I. COMPARISON ANALYSIS OF EXISTING TECHNIQUES

### III. METHODOLOGY

The importance of early diagnosis of diabetes mellitus to the life expectancy of the patient suffering from it cannot be over-emphasized. Early diagnosis will mean that, based on certain biological features found in the medical history of the patient, there is a predictive test. This section focuses on how predictive analysis of machine learning is used to predict the diabetes status of a patient accurately. Therefore, to develop and implement a diabetes recommendation prediction system, the proposed model employs machine learning techniques.

#### A. Predictive Analysis

This section illustrates the analysis of the proposed system and how the system that was designed works and is a feasible alternative to the existing one. The data used in this paper was collected from the dataset of Abelvikas, Data world. The data collected were subjected to different types of pre-processing, as will be addressed in subsequent sections to improve the system's performance. The proposed model implements the classification model with the highest accuracy level. These algorithms include Logistic Regression, Decision Tree, Random Forest, and Support Vector Machine Classifiers. Fig. 1 shows the block diagram for the proposed model.

1) *Data acquisition*: This research was carried out using the dataset of Abelvikas, Data world. The dataset has multi-class problems of diabetes which separate it into individuals who have tested either negatively or positively (type1, type2, and normal) to diabetes. The dataset consists of 1009 total instances with eight attributes to provide adequate data from training after pre-processing requiring the removal of certain entries. Entries included Age (years), BS Fast (mmol/L), BS pp (mmol/L), Plasma R mmol/L, Plasma F (mmol/L), and HbA1c (mmol/L). The data collected from the Abelvikas, Data World Database was shown in the Table II.

2) *The pre-processing stage*: This handles inconsistencies in data to improve accuracy and precise outcomes. This dataset has missing values for a few selected attributes like Glucose level, Blood Sugar, and HBA1C because these attributes cannot have values of zero. The dataset is then scaled to normalize all values. Correlation is an amount of context between characteristics. It is a real number value that denotes the degree of significance between 0 and 1 and a negative value indicates an inverse relationship, while a direct relationship is indicated by a positive value. Fig. 2 shows the correlation map of the proposed model.

3) *Training & classification*: ML algorithms require training data to achieve the objective. This training dataset will be analyzed by the algorithm, which will then classify the inputs and outputs before analyzing it again. A sufficiently trained algorithm will effectively memorize all of the inputs and outputs in a training dataset. The prediction model consists of the best machine learning model after implementing different models, and the best was taken and deployed for application. The output of each model is taken to the next stage for testing. In training the classification algorithms and constructing the model, the steps taken were to

import the modules and dataset as a data frame and get insights from the dataset. From the entire data set, a feature set containing the first seven attributes is extracted, and the output set is extracted, which is the product of the prediction and the whole set is split into a 7:3 ratio train set and test set.

4) *Testing*: After the model was built, testing data validate to make accurate predictions. This is to confirm that the ML algorithms were trained effectively to evaluate the prediction models created.

5) *Evaluation*: Assessing the performance of the model using different metrics is integral to this research work. Based on the result from the test stage, the model was evaluated based on classification accuracy and specificity. A classification metric was employed to evaluate the developed model. There are four types of outcomes that could occur when performing classification predictions.

a) True positives happen when you predict that an observation belongs to a certain class and it turns out to be correct.

b) True negatives occur when you predict that an observation will not belong to a class and it actually does not belong to that class.

c) False positives happen when you assume an observation belongs to a class when it doesn't.

d) False negatives occur when you incorrectly predict that observation does not belong to a class when it does.

The results are frequently plotted on a confusion matrix. After making predictions based on the test data and then classifying each prediction as one of the four possible outcomes described above, the matrix was generated.

Fig. 1. Proposed Model for the Research.

TABLE II. DATABASE FILE REPRESENTATION

S/N	Field	Type	Range
1.	Age	Integer	21 – 81
2.	Blood Sugar in fasting	Real	0 – 54
3.	Blood Sugar after a meal	Real	4.2 - 8.1
4.	Plasma Glucose in fasting	Real	3.9 - 9.1
5.	Plasma Glucose	Real	7.9 - 13.1
6.	Glycated hemoglobin (HBA1C)	Real	28 – 69
7.	Type	String	0 – 255
8.	Class	Boolean	1 - Diabetic, 0 - Non-Diabetic

Fig. 2. Correlation Map.

### B. Modelling Methods

In training the classification algorithms and constructing the model, the following steps were taken (see Fig. 3).

Step One: Import the modules and dataset as a data frame

```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns
import warnings
warnings.filterwarnings('ignore')
warnings.filterwarnings('ignore', category=DeprecationWarning)
df = pd.read_csv("../content/Diabetestype.csv")
```

Fig. 3. Code Snippet to Import Dataset.

Step Two: Get insights from data

The Insight derived from the dataset is shown in Table III

TABLE III. INSIGHTS GOTTEN FROM DATASET

	Age	BS Fast	BS pp	Plasma R	Plasma F	HbA1c	Type	Class
0	50	6.8	8.8	11.2	7.2	62	T1	1
1.	31	5.2	6.8	10.9	4.2	33	N	0
2.	32	6.8	8.8	11.2	7.2	62	T1	1
3.	21	5.7	5.8	10.7	4.8	49	N	0
4.	33	6.8	8.8	11.2	7.2	62	T1	1

Key: T1=Type1, N=Normal

Step Three: Specify features and test sets

A training set containing the first seven attributes of the data set is extracted and the test set which is the eighth attribute is also extracted, which is the product of the prediction and the entire dataset is split into a 7:3 ratio train set and test set.

Step Four: Train prediction model

The prediction model consists of the best machine learning model after implementing different models, and the best was taken and deployed for application. The output of each model is taken to the next stage for testing.

Step Five: Test model

The test set is used to assess the prediction models that have been created. This step is carried out four times to ascertain consistency.

Step Six: Evaluate

From the result of the test stage, the model is evaluated based on classification accuracy and specificity. The Table IV shows the accuracy of the four models based on these parameters.

1) *Prediction methods for diabetes*: The following machine learning strategies are used for comparative analysis of the diabetes predictive model. Classifiers include logistic regression, decision trees, random forests, and support vector machines.

a) *Logistic Regression (LR)*: It is another supervised learning classification algorithm that models the relationship between a categorical response variable and its covariates. It computes probabilities using a logistic function, which is the accumulative logistic distribution, to assess the association between a categorical dependent variable and more than one independent variable. It is another probabilistic-based statistical model used in machine learning to solve classification problems. The logistic regression model uses the sigmoid function to predict the probability of outcomes of positive and negative class and can be derived from a sigmoid function obtained below,

$$P = \frac{1}{1+e^{-a-bx}} \quad (1)$$

where P = probability, a and b = parameter of Model.

b) *Decision Tree Algorithm*: A DT is one of the supervised machine learning algorithms that employ the classification regression trees algorithm, which can handle both classification and regression. It aids decision-making by generating a decision-tree-like model in which data is continuously split according to a specific parameter. There are two types of units in the tree: decision nodes and leaves. The data is split at the decision nodes, and the final decisions or outcomes are at the leaves. To solve classification and regression problems, the algorithm generates decision trees from training data. The classification error rate is defined as the proportion of the training set that does not belong to the most common class:

$$\text{Entropy (S)} = \sum_{i=1}^n -P_i \text{Log}(P_i) \quad (2)$$

where  $P_i$  is the percentage of the training set from the  $i$ th class in the region.

c) *Random Forest (RF)*: It is one of the machine learning prediction algorithms. It lends itself better to the ensemble approach. It is capable of handling large datasets with ease. Random Forest is an ensemble classifier made up of many decision trees, with the ensemble implying that it employs multiple machine-learning algorithms to achieve predictive performance. It outperforms others in terms of diabetes mellitus prediction.

The following is the algorithm:

- 1 Create an N-Tree bootstrap sample using the input data.
- 2 Grow an unpruned regression for each bootstrap sample by splitting the node from all predictor nodes. Predictors select the best split from the input variables.
- 3 Predict new data by aggregating N-Tree predictions.

The random forest formulas are given below using Gini Index formulae for classification.

$$\text{Gini Index} = 1 - \sum_{i=1}^n (P_i)^2 \quad (3)$$

It measures total variance across  $i$ th classes that true positives and true negatives. It should be noted that the Gini index is a measure of node purity that has a small value if all of the  $P_i$  are close to zero or one.

#### Support Vector Machine

A Support Vector Machine (SVM) is a type of supervised classification algorithm that has been widely and successfully applied to text classification tasks. This helps with regression and classification tasks and can work with multiple variables. This algorithm effectively performs nonlinear classification and also maps the inputs into a high-dimensional feature space that is used for classification, detection, and regression.

Step 1: Identify the appropriate hyperplane.

Step 2: Following the first step, the second step is to maximize the distances between neighboring data points.

Step 3: Insert a feature  $z = x^2 + y^2$ . It implies that SVM can solve such a problem.

Step 4:-Use an SVM classifier to classify the binary class.

SVM formulae are derived from the equation of hyperplane function to obtain the below,

$$W^* = \arg_w \text{Max} \frac{1}{\|W\|_2} [\text{Min } Y_n | W^T (\phi(x) + b)] \quad (4)$$

Where  $\arg_w \text{Max}$  is an acronym for arguments of the maxima, which are simply the locations of a dynamic array domains where a function's particular value is maximized. The inner phrase  $[\text{Min } Y_n | W^T (\phi(x)+b)]$  essentially indicates the shortest distance between two points and the closest point to the decision boundary.

#### IV. RESULTS AND DISCUSSION

This section aims to get acquainted with results obtained after performing various activities on the dataset obtained from the dataset of Abelvikas, Data World. Fig. 4 shows the registration page for the patient.

##### A. Results

The implementation tools used in this research are Python programming language, google collaboratory, and libraries containing algorithms used for artificial intelligence development, and Anaconda houses a large amount of these libraries. Fig. 5 depicts the recent patient, daily added patient and diabetes rate charts. Fig. 6 shows the disease diagnosis and report.

Fig. 4. Landing Page and Registration Page.

Fig. 5. Dashboard Page.

Fig. 6. Diagnose Patient Page.

1) *Performance metrics*: The classifiers we used were then applied to the dataset individually and ran five iterations to ensure that the results obtained from the average of each implementation of a particular algorithm are accurate. Also, these tests were done on randomly selected samples of the dataset to avoid the problem of overfitting. Various parameters were used to evaluate the system, but for this research, three performance indexes were used: Sensitivity (SE), Specificity (SP), and accuracy, as shown in equations (5)–(7). True positives (TP) and true negatives (TN), as well as the false positives (FP) and false negatives (FN).

$$(SE) = \frac{\text{no\_of\_predicted\_true\_positive}}{\text{true\_positive} + \text{false\_negative}} \quad (5)$$

$$(SP) = \frac{\text{no\_of\_predicted\_true\_negative}}{\text{true\_negative} + \text{false\_positive}} \quad (6)$$

$$\text{Accuracy} = \frac{\text{number\_of\_correct\_predictions\_}}{\text{total\_number\_of\_prediction}} \quad (7)$$

The prepared model was integrated into a Python Web Framework, and Flask Framework and hosted on a server for testing. To test the solution, random records from the dataset were used, and an average of the following was calculated for each algorithm. From the above list, it is shown amongst our Ensemble of algorithms why the Random forest algorithm was chosen as the eventual algorithm used for the implementation of this work, as it has the highest average accuracy among the four algorithms.

2) *Confusion matrix evaluation*: A confusion matrix is also referred to as a contingency table or error matrix, used to visualize the performance of a classifier, it's a good way of evaluating a good effective classification model. This means that the high performance of any classification model can be visualized in its confusion matrix having a strong main diagonal shown in Fig. 7.

3) *Implementation of confusion matrix*: The confusion matrix was implemented for each algorithm in the ensemble of algorithms leading to the results are shown in Table IV, while Table V shows the confusion matrix for Classification Models using Logistic Regression (LR), Support Vector Machine (SVM), Random Forest (RF), and Decision Tree (DT).

The above shows the result of the confusion matrix for classification algorithms with 70% training data and 30% testing data of 1009 records. The result yielded the Table V below.

$$y = \frac{1}{N} \sum_{i=1}^5 Xi \quad (8)$$

where  $y$  is the mean,  $Xi$  is the result of the confusion matrix and the  $i$ -th attribute value of the no of iterations.

$$y = \frac{1}{N} \sum_{j=1}^3 yi \quad (9)$$

Fig. 7. Confusion Matrix for Classification Models using (i) LR (ii) SVM (iii) RF (iv) DT.

TABLE IV. PERFORMANCE OF THE STUDIES CLASSIFICATION MODEL USING NORMAL, TYPE 1 AND TYPE 2 DIABETES

Algorithm	Class	1 <sup>st</sup> Iteration	2 <sup>nd</sup> Iteration	3 <sup>rd</sup> Iteration	4 <sup>th</sup> Iteration	5 <sup>th</sup> Iteration	Mean Accuracy

Key: LR=Logistic Regression, RF= Random Forest, DT=Decision Tree, SVM = Support Vector Machine  
after the confusion matrix are similar to the classification model results. Examining the confusion matrix revealed the same similarity. Table VII shows the mean average score of the algorithms.

where  $y$  is the mean average,  $y_i$  is the mean of the result of the confusion matrix, and the  $i$ -th attribute value of the number of classes.

TABLE V. CONFUSION MATRIX DATA FOR CLASSIFICATION MODELS USING (I) LR (II) SVM (III) RF (IV) DT (%)

Classifier	Normal	Type1	Type2
LR	62.46	22.23	15.31
SVM	62.46	0.60	36.94
RF	62.46	17.12	20.42
DT	62.46	17.12	20.42

In Fig. 8 the use of an ensemble of algorithms aids data mining in determining the most effective algorithm that can be used to generate an effective model. The accuracy report obtained from multiple tests shows that the random forest and decision tree algorithms on our dataset proved to be better prediction algorithms than the other algorithms. The results were compared to the results of works of literature. The Table VIII demonstrated that the developed system's accuracy was higher than [28] accuracy of 91.32 percent because RF excels at working with non-linear data, constructing multiple decision trees, and merging them to produce a more accurate and stable prediction with improved performance.

### B. Discussion

Diabetes has recently become one of the leading causes of death in humans. Diabetes is becoming more common every year for a variety of reasons, including poor eating habits, and the prevalence of unhealthy foods. Diabetes detection early on can help with clinical management decision-making. We have employed numerous measures of evaluation throughout this research to determine and quantify the performance of each algorithm in our ensemble of algorithms, which comprises the Logistic Regression algorithm, Decision Tree, Random Forest, and Support Vector Machine Classifier algorithms, all these algorithms were tested on the diabetes dataset of Abelvikas in five iterations, and the result of the test gave a model that we eventually used for the implementation. However, with all these algorithms it was important to realize which was the most effective of all them, and this was achieved by getting an accurate reading of each and, including algorithm over five iterations. An average of the accuracy reading from each algorithm was used as a measure to determine the eventual algorithm that was used to form our model (Fig. 9), which turned out to be the Random forest and Decision tree Algorithms. From Table VI, the outcomes of the average of the accuracy tests on each algorithm are displayed, this also includes the specificity accuracy and sensitivity accuracy as well as the classification accuracy. When we compare the values in Tables V and VI, we see that the classification results

TABLE VI. COMPARISON OF RESULTS OF DIFFERENT CLASSIFIERS

Metrics Average	Logistic Regression	Decision tree Classifier	Random Forest	Support Vector Machine
Accuracy (%)	92	100	100	83

TABLE VII. THE MEAN AVERAGE SCORE OF THE ALGORITHMS

Metrics Average	Logistic Regression	Decision tree Classifier	Random Forest	Support Vector Machine
Sensitivity	0.921705	1.0	1.0	0.692391
Specificity	0.980548	1.0	1.0	0.933251
Accuracy	0.968964	1.0	1.0	0.893624

V. CONCLUSION

This study compares and evaluates the performance of four machine learning algorithms in the classification of diabetes. The Abelvikas datasets from the Data World repository are used to train and test the system. For diabetes classification, a host of machine learning models have been applied with 1009 instances and eight critical variable features were extracted and identified: age, blood sugar in fasting, blood sugar after a meal, plasma glucose in fasting, plasma glucose, glycated hemoglobin, type, and class. The results of the analysis revealed that the Random forest and Decision tree models were the most accurate in predicting diabetes. The system developed ensures a stable prediction. As a result, the models can be more effectively applied to other diseases. A combination of algorithms, rather than just the most performant algorithm in the ensemble, may be more beneficial in the future.

# Criteria and Guideline for Dyslexic Intervention Games

Noraziah ChePa<sup>1</sup>, Nur Azzah Abu Bakar<sup>2</sup>, Laura Lim Sie-Yi<sup>3</sup>

Human-Centred Computing, School of Computing  
Universiti Utara Malaysia, Sintok, Kedah  
Malaysia

**Abstract**—The utilization of game-based interventions is growing as a result of technological advancements, and it has shown to be effective in the treatment of dyslexia and other medical conditions. Games are typically viewed as activities having the essential components of challenge, incentive, and reward. Games were originally created for pleasure, and they can make dyslexic teaching and learning more enjoyable and exciting. Although there are numerous applications available for treating dyslexic children, the inclusion of games and their standards in those applications has not yet been established. Therefore, there is a need for a standard design guideline to be formulated in establishing a guideline for designing and developing games specifically for dyslexic children. This article proposes a design guideline for dyslexic intervention games. Two methods have been employed which are interviews and systematic literature reviews (SLR) to discover the characteristics of dyslexic games. The first set of the criteria was developed through interviews with the stakeholders who are directly associated with dyslexic children. Scopus, the ACM digital library, EBSCO-host, Wiley, and Web of Science (WOS) are the five primary databases used in SLR. 50 articles out of the 551 that were early screened from the five primary databases are qualified to be studied based on the criteria. Only 23 publications could be selected for the study after further screening, which led to the creation of a second set of criteria. These two sets of criteria are thoroughly analyzed, combined, and formulated as a guideline which comprises of four main categories; device and platform, interface, game features, and gameplay. The guideline consists of guidance to be used for designing and developing Dyslexic therapy games with the purpose of assisting Dyslexic children to read. The guideline is believed to be beneficial to many parties especially the educational game developers, therapists, and educationist who are dealing with intervention for Dyslexic children. This study is aligned and significant to Sustainable Development Goals (SDG) three and four, Good Health and Well-being and Quality Education respectively.

**Keywords**—*Dyslexic therapy games; game-based intervention; specific learning disorder; guideline for dyslexia games; dyslexia intervention*

## I. INTRODUCTION

Dyslexia refers to specific learning disorder (SLD) that involves difficulty in reading due to problems identifying speech sounds and learning how they relate to letters. It is listed as a mental disorder in the International Classification of Mental Disorders and the Diagnostic and Statistical Manual of Mental Disorders [1]. It resulted from an unexpected phonological deficit [2]. In other words, children with dyslexia

have low ability in decoding and spelling. Often a dyslexic child will have trouble connecting the sound made by a specific letter or deciphering the sounds of all the letters together that form a word. Dyslexia have increasingly been found to be the most common learning disability accounting up to 80% of the learning-disabled population in general [3].

As of 2020, it is reported that between 5 to 20% of the world population struggled to read due to dyslexia [4]. In 2017, the Dyslexia Association of Malaysia reported 10% of the school age children in Malaysia were affected by the disorder. The percentage shows an increase from 2014 in which 53,685 students with learning disabilities have been involved in formal education and from that total, 0.03% or 1,681 students have been involved in the dyslexia classroom programme [5]. Earlier study conducted by Socio-economic and Environmental Research Institute of Penang has identified 9.4% of children in Grade One elementary schools in Penang as having learning difficulties, and 92.3% of these children were found to have severe reading disabilities [6]. It is one dyslexic case in every 20 students, compared to one down-syndrome case in every 600 people or one spastic case in every 700 people [7].

Despite the emphasis on literacy difficulties, dyslexia would appear to include a wide range of symptoms including poor short-term memory, dyscalculia, visual impairment, speech disorders, and poor motor control as well as emotional difficulties such as poor self-esteem, clinical depression, chronic anxiety and conduct disorders. The deficits in these keystone academic skills lead to poor academic achievement and they tended to lag far behind in age and intellectual ability from their peers. The impact can change at different stages in a person's life. It can seriously affect a person's self-esteem [8]. Dyslexia students sometimes feel dumb, frustrated, lonely, humiliated, and academically less competent than they really are. They may get very frustrated and are at risk of developing mental health problems such as anxiety and depression. Despite all these, dyslexia are not related to intelligence or lack of desire to learn.

Although dyslexia are typically thought of as learning difficulty with educational consequences, there is increasing evidence that dyslexia are also associated with health difficulties. Auto immune disorders, allergies, autism and schizophrenia are common amongst families where there are learning disabilities [9]. Furthermore, [10] observed that dyslexic children with the most severe symptoms of fatty acid deficiency (rough skin, dry skin and hair) have the most severe reading, spelling and short-term memory difficulties.

There is lack of consensus on how dyslexia should be diagnosed or treated. One systematic review [11] revealed that traditional special educational methods have limited impact on dyslexic children. Improvements through intensive reading interventions yield small to moderate effects overtime, and there appears to be a subset of 25% of problem readers who do not respond to special education. In the absence of satisfactory remediation through traditional special educational methods, there have been several alternative treatments offered for dyslexia. These include biofeedback, hypnotherapy, music therapy, visual occlusion therapy, the neural organization chiropractic technique, primary reflex therapy and Dyslexia Dyspraxia Attention Treatment (DDAT) exercises.

Past studies on dyslexia[12]–[15] utilized games, either for identification or intervention purposes, as discussed further in Chapter 2. Games add more fun and excitement to teaching and learning. Quite a few games have been developed as an alternative treatment for dyslexia. These include the board games (e.g. Zingo Sight Words, Scrabble Junior, Brainbox ABC, Monopoly Junior and Alphabet Lotto) as well as the online or digital games that run either on IOS or Android or both platforms (e.g. Draw Something, Hanging with Friends, Anagram Scramble, ABCya, Chicktionary, Boogle Bash, Knoword and Word Whomp). Different strategies are used in these games such as draw out a given word, spell a complex word, create ambiguous word to puzzle others, make out words from a given set of letters, find word while beating the time allotted, and complete words by conjecture based on the word's definition and first letter.

Designing games for the dyslexic needs careful consideration on their special needs in order to maximize their learning experience and overcome their difficulties. Several criteria for designing and developing an effective game for dyslexia intervention have been discussed in the literature, however, they are yet to be formalized into a standard guideline. To date, very limited number of standard guidelines exists and none of these focus specifically on games [16]–[18].

The absence of systematic guideline in designing and developing therapy games for dyslexic children is key issue to be solved in this study. To date, very few systematic guidelines have been developed. The [17] guidelines focus on early detection of dyslexia and is not meant for therapy. Whereas the [18] guidelines focus on learning reading but their emphasis is on user interaction with the application, i.e., how to design interfaces that are affective for the dyslexics. The guideline excludes important game elements such as goals, rewards, challenge and feedback. The author [16] developed a guideline for dyslexic games; however, the coverage is limited to user interface aspects of the games. Many other criteria discussed in the literature are not yet formalized into a guideline and thus, the process of designing and developing therapy games for dyslexia is time consuming as the developers need to gather and analyse the criteria from various sources.

Considering the addressed issues, this article aims to identify the criteria and formalize the guideline to be used in the design of dyslexic games. This will serve as a reference that would be beneficial for the developers of games or tools for dyslexic children.

## II. DYSLEXIA AND INTERVENTION

The current state of dyslexia research can be characterized by the distinction of scientists in groups of protagonists of a visual versus a phonological/auditory deficit on the one hand and in groups of protagonists of a low, basic level versus a higher-level deficit on the other hand. A lot of contradictory results and theories posed the question about specificity and homogeneity of different deficits in dyslexic individuals. The model of [19] provides an integration of perceptive and cognitive deficits based on a common temporal processing deficit, which can be analyzed on a low, basic level and/or on a higher complex level of performance. Over the last 35 years, there has been a great deal of research focused on finding the most effective methods for treating dyslexia. This body of knowledge is complex, in part because although all individuals with dyslexia have a similar problem namely, difficulty in reading, they have heterogeneous characteristics, and depending on the child's developmental level, the demands of reading and the required skills are quite different [20].

The paper [21] suggests that difficulties in literacy acquisition for dyslexics are due to lack of phonological awareness, problems to recognize words and understand spelling rules, visual errors in spelling, letter and word confusion with similar-sounding words and omissions of words, parts of words and individual letters and sounds. In other words, their literacy skills are at word-level reading and spelling [22]. The dyslexics have difficulties in identifying phonemes and the exchanging of letters occurs very often during the spelling process; they also often mixed-up the letters of 'b-d', 'u-n', 'm-w', 'g-q', 'p-q', and 'b-p' [7], [23]. Evidence of their great difficulties in writing, poor skill of spelling, oral and written vocabulary and also weak in arranging the content of the compositions is also found in [24]. Besides, previous studies also found that children with dyslexia are significantly slower at naming colours, digits and letters, thus suggesting that children with dyslexia have persistent, and unexpectedly severe problems in naming speed for any stimuli [25].

The study [7] summarizes the difficulties in spelling, reading and writing faced by most dyslexic children as in Table I.

TABLE I. PROBLEMS FACED BY DYSLEXIC CHILDREN

Problem	Description
Spell	Confusion in identifying letters such as: <ul style="list-style-type: none"><li>• m – w; y – g – j; u – n; m – n; c – e; p – q; h – n; b – d</li></ul> Confusion in the letter sound such as: <ul style="list-style-type: none"><li>• t – h; f – v; s – h; r – l</li></ul>
Read	Reversal in the word such as: <ul style="list-style-type: none"><li>• Batu – tuba</li><li>• Gula – lagu</li></ul> Reversal in the sentence such as: <ul style="list-style-type: none"><li>• Pada masa yang sama – dapa masa yang masa</li></ul> Confusion between Malay and English word such as: <ul style="list-style-type: none"><li>• Jam – jem; cat – cat</li></ul>
Write	Difficulty holding a pencil; cannot write according to the line provided; tends to write words fads.

At a basic level of spelling, learning to represent sounds with letters requires a two-way mapping between phonology and written symbols, and it is here that difficulties will first be encountered by children with phonological deficits [26]. They need to acquire knowledge of the relationship between sounds and letters which requires them to be familiar with phonological representations and the correspondence between phoneme and grapheme. In the next step, they need to segment the target word into its salient sounds and then represent these sequentially with symbols [26]. What makes this exacerbated is the fact that spelling, unlike reading, is difficult to use context. In her study, [27] found a significant difference in the nature of the spelling errors in dyslexic children compared with a control group. They made 'phonetically unacceptable' errors that may not be recognized as the word because of a lack of phonetic similarity. This implies that the dyslexic children may have not developed phonological representation but use letter naming strategies to spell phonologically regular words.

Regarding reading, [28] suggests that for sight word reading to develop, learners must acquire and apply knowledge of the alphabetic system. According to [29], lexical processing, or the ability to recognize words quickly and accurately, is a symbol of skilled reading. In the context of Malay language, a study by [30] reveals both syllable awareness and phoneme blending are significant predictors of word recognition; when the readers have inefficient syllable segmentation, oversimplification of syllables, insufficient grapheme-phoneme knowledge and inefficient phonemic code assembly they will make errors in reading.

#### A. Dyslexia Interventions

Various intervention methods or treatments have been used to manage the literacy and cognitive abilities for children with dyslexia [31]. Most research used experimental designs [32]–[34]. There were a few studies that applied multimedia training in their intervention program. The researches [35] and [33] utilised computer-assisted training while [36] used video games in their remedial intervention. The study [37] adopted Magnocellular deficit theory in their treatment plan. A few studies employed multisensory approach [33], [38]–[42]. This approach uses graphics and strong colors to make associations between shape, letters, words and numbers that relate to the same topic, and involves techniques for linking eyes, ears, voice, and hand movements to symbolic learning. The approach taken is to try and engage as many sensory receptors in the learning process as possible, since it is argued that on many occasions, children with learning difficulties appear to have stronger sensory receptors over their non-dyslexic peers.

The majority of the studies targeted language or literacy components such as writing skills, reading skills, word and alphabet mastery as the outcome of the study [32], [33], [39], [40]. Many also carried out intervention or training based on specific impaired cognitive function such as visual-motor intervention and working memory training [35], [37], [38], [43], [44]. In other words, they have chosen a specific difficulty to be treated in their intervention.

To date, there are limited modules or intervention programmes being conducted in Malaysia for children with dyslexia. In fact, there is currently no standardized module for

dyslexia class in Malaysian public school [31]. Traditional methods in teaching these children to overcome their difficulties in the classrooms were found not to be encouraging and were not successful in overcoming their difficulties in reading [40]. Thus, traditional methods have a limited impact on dyslexic children [11], [45].

#### B. Digital Game-Based Interventions

Recent decades have witnessed the increasing use of digital interventions with game-like components. Initially developed for entertainment, a "game" is generally considered to be an activity with the key features of challenge, motivation, and reward. Digital game-based interventions have been found to have practical effects in addressing the main barriers of access and engagement in the healthcare domain, particularly for the young [46]. Evidence from neuropsychological research further suggests the therapeutic value of digital game-based interventions in depression therapy. Positive game-playing experiences are claimed to have triggered the release of hormones such as endorphins and striatal dopamine that are responsible for feelings of pleasure and well-being [47]. Interventions using games have also been used in therapy or rehabilitation sessions of various other illnesses such as brain injury [48], cerebral palsy [49] and upper limb injury [50].

Past studies utilized games for diagnosis or early detection of dyslexia [17], [51]–[53] as well as for intervention [12]–[14], [54]–[58]. Other studies [56], [59] use gamification approach by utilizing some game elements (such as scores or rewards) in non-game context or the so-called application which ranges from desktop, mobile and web-based applications.

As evidenced in [55] and [60], games for dyslexia often implement a collection of activities that are connected by a common visual theme and can be played independently of each other. On the other hand, a smaller number of games are built around a rich narrative in which the student progresses through a story by solving language-related activities. For example, iLearnRW [13] draws together these two alternatives and provides a common interface and metaphor for the visualization of learning progress. The game is built around characters rather than a fixed story; although there is no guarantee for infinite re-playability, this has improved player's engagement. Each character in the game represents a group of language difficulties that the student will practice every time he/she initiates an activity related to them. Following an initial interaction with a new character, the student earns that character as a friend, who is displayed on a social network-like interface. The design of iLearnRW also considered the need for personalized intervention as some students learn faster than the others or prefer playing sessions at different length.

#### C. Existing Guideline

The study [17] derived a set of guidelines to design an optimal tablet game for 5-year-old children. The guidelines, called DYSL-X, focus on early detection of dyslexia and was used to develop Diesel-X, a game about a robot dog character named Diesel, which must fight against a gang of criminal cats. Diesel-X contains three games, which require players to know letters. However, there is no further information about the validation DYSL-X. The author [18] proposed an affective

interaction design (IxD) model to facilitate reading for the dyslexics. Their study emphasized on the need to use proper interface when designing an application for the dyslexics, by taking into account the affective attributes of the dyslexic children. In [16] proposed a guideline for dyslexic game design which focused on user interface aspects, i.e., usage of font, colour, navigation, consistency, interaction and game type. Recent studies [16], [52], [53], [61]–[64] revealed multiple criteria which are further analysed and formalized into the guideline developed throughout this study. The detailed criteria from individual studies are presented in Section IV.

### III. METHODOLOGY

Due to its suitability and compatibility with the scope of study, a Design Science Research methodology [65] is adapted in designing the research framework. Research methodology is divided into four main phases; awareness of problems, identification of criteria, formulation of game guideline, and evaluation as illustrated in Fig. 1.

Fig. 1. Research Methodology.

#### A. Awareness of Problems

The first stage of conducting this study is about identifying issues and problems that lead to the formulation of solutions. Issues and problems are identified through content study and personal communications involving stakeholders in treating Dyslexic children. The absence of systematic guideline in designing and developing therapy games for Dyslexic children is key issue to be solved in this study.

#### B. Identification of Criteria

To identify the game criteria, combination of systematic interview and Systematic Literature Review (SLR) have been employed. Interview has been conducted involving eleven respondents among teachers and students at Dyslexia Incubator, School of Computing, UUM. Respondents involved are among the content experts, five teachers, and potential users who are the children diagnosed with Dyslexia.

SLR is conducted by adopting PRISMA approach in conducting SLR [66]. This study has focused on five main databases which are Scopus, ACM digital library, EBSCOhost, Wiley, and Web of Science (WOS). Four main processes that have been carried out in the searching process are identification, screening, eligibility, and data extraction and analysis as shown in Fig. 2.

Fig. 2. Four Main Stages of Reviewing Literatures.

1) *Identification*: The first phase is about determining the keywords to be used for searching. In this context, keywords related to reading disabilities and the affected group, which are the children are basically relied on. The use of game intervention in treating the affected age group are also used in the searching. All keywords that have been used specifically for the database involved are listed in Table II.

TABLE II. KEYWORDS AND SEARCHING INFORMATION STRATEGY

Databases	Keywords used
Scopus	TITLE-ABS-KEY ((dyslexia OR ("reading disabilities" AND (child* OR kid))) AND (game OR "game intervention"))
ACM	[[Publication Title: dyslexia] OR [[Publication Title: "reading disabilities"] AND [[Publication Title: child*] OR [Publication Title: kid]]] AND [[Publication Title: game] OR [Publication Title: "game intervention"]] OR [[Abstract: dyslexia] OR [[Abstract: "reading disabilities"] AND [[Abstract: child*] OR [Abstract: kid]]] AND [[Abstract: game] OR [Abstract: "game intervention"]] OR [[Keywords: dyslexia] OR [[Keywords: "reading disabilities"] AND [[Keywords: child*] OR [Keywords: kid]]] AND [[Keywords: game] OR [Keywords: "game intervention"]]
EBSCOhost	TI ((dyslexia OR ("reading disabilities" AND (child* OR kid))) AND (game OR "game intervention")) OR AB ((dyslexia OR ("reading disabilities" AND (child* OR kid))) AND (game OR "game intervention"))
Wiley	"(dyslexia OR ("reading disabilities" AND (child* or kid))) AND (game OR "game intervention")" in Title, Abstract and keyword
WOS	TS=((dyslexia OR ("reading disabilities" AND (child* OR kid))) AND (game OR "game intervention"))

2) *Screening*: For screening of the relevant articles, several conditions for inclusion and exclusion have been defined. Type of literature, language, and subject area are among the criteria that have been included. Criteria and its eligibility terms are defined in Table III.

TABLE III. THE INCLUSION AND EXCLUSION CRITERIA

Criterion	Eligibility	Exclusion
Literature type	Journal (research articles)	Journals (systematic review), book series, book, chapter in book, conference proceeding
Language	English	Non-English
Subject Area / Categories	Computer Science	Other than Computer Science

The searching also focused on literatures with empirical data such as journal articles, research articles, and review articles. To prevent difficulties of translation, only English articles are included. For relevance, articles with related to the focus are selected which are related to the use of intervention games that involve children with reading difficulties. For this phase, 10 articles have been removed.

3) *Eligibility*: The main focus of this phase is to identify the eligible articles to be included in the study based on the criteria explained earlier. To achieve this, the identified articles are reviewed and thoroughly analyzed. Focus is given on the targeted objectives. To identify the details, abstracts will be reviewed before the articles will be analyzed thoroughly. Fig. 3 illustrates the processes involved by adapting PRISMA method.

Fig. 3. Adaption of PRISMA Approach in Selecting the Articles.

From the process, there are 551 articles have been early screened from five main databases to be further reviewed. From this total article, there are 10 duplicate articles and have been removed for the next process. 541 articles were further screened based on the relevancy to the criteria. However, only

50 articles are eligible to be analyzed. After further screening, there are only 23 articles which are significant to be included in the study.

4) *Data extraction and analysis*: This phase is focusing on extracting and analyzing key details from the 23 articles that have been chosen. Various types of data are extracted from these articles. They are proponents of the criteria, year of study, game title, and the criteria of the game. The list of the extracted criteria is covered in findings section of Section IV. Deliverables of this phase are two sets of the criteria for Dyslexic game.

C. Formulation of Game Guideline

List of criteria gathered from SLR and interview are thoroughly analyzed and compared in formulating the guideline. Set one of the criteria is extracted from SLR, while set two of the criteria is gathered from interview. Processes involved in formulating the guideline are shown in Fig. 4.

Fig. 4. Processes Involved in Formulating the Guideline.

Second process involved the removal of duplicates of the criteria by analyzing similarities exist in both sets. Removal also involved for cases when some criteria are using different words but are referring to the same thing. The last step is classification, where all criteria are mapped into four main categories; device and platform, interface, game feature, and gameplay. The outcome of these processes is covered in Section IV.

D. Evaluation

To ensure that the proposed guideline is correctly formulated and meets its specification, both verification and validation are conducted in evaluating the proposed guideline. For verification, expert review has been conducted involving five experts from different areas; game development experts, educationist, and counsellors. For validating the guideline, a prototype of Dyslexic game, namely *DysRedia* is developed. The outcome of the evaluation and its detail discussions are covered in Section IV.

IV. THE PROPOSED GUIDELINE

The proposed guideline is formulated based on the two sets of criteria gathered and extracted from systematic interview and the existing studies through systematic literature review as

explained in Section III. The first set of criteria are extracted from 23 related articles from SLR. The extracted criteria are sorted based on its publication years. The listed criteria are carefully analyzed by focusing on similarity of the criteria proposed by its proponents. Duplicates are removed. The criteria are then classified into four main categories: device and platform, interface, features, and gameplay. There are five, eleven, thirteen, and sixteen criteria classified into four categories respectively.

Second set of the criteria are gathered from interview session involving teachers and students. Table IV depicts 30 criteria gathered from interview that have been categorized into four main categories.

TABLE IV. CLASSIFIED CRITERIA GATHERED FROM INTERVIEW

Category	Criteria	
<b>Device &amp; platform</b>	1. Mobile app 2. Tablet	3. Touch-based
<b>Interface</b>	1. Simple interface 2. Font & background: F8 (white font, red background)	3. Font type: comic 4. Font size: 16 5. Small caps
<b>Features</b>	1. Audio 2. Video 3. Still picture 4. Animation	5. Background music 6. Letter with phonic 7. Letter arrangement: keyboard design 8. Attractive images
<b>Gameplay</b>	1. Exercises 2. Different difficulty levels 3. Competition 4. Hints 5. Help 6. Tutorial 7. Rewards, more rewards at higher levels	8. Scoreboard 9. Replay 10. Auditory feedback 11. Different categories 12. Real images 13. More exercise in the same difficulty level 14. Levels arranged alphabetically

There are three, five, eight, and fourteen criteria have been classified into four categories respectively. Fig. 5 shows number of criteria and its category that have been successfully classified.

Fig. 5. Number of Criteria Acquired from Two Method and Classified into Four Categories.

These two sets of criteria are then combined based on its category. For Device and Platform, five criteria from SLR and three criteria from interview are combined producing only five criteria, as three of them are redundant and have been removed. The final five criteria are shown in Fig. 6.

Fig. 6. Criteria for Device and Platform Category.

For Game Features category, eleven and five criteria identified from SLR and interview respectively have been combined and produced a guideline of 13 criteria by removing three redundant criteria. The final thirteen criteria are shown in Fig. 7.

Fig. 7. Criteria for Game Features Category.

For Interface category, combination of 13 and eight criteria identified from SLR and interview respectively, have produced a final set of eleven criteria. Ten redundant criteria have been removed. Terms referring to the same criteria such as ‘small caps’ suggested by interview and ‘lower case’ suggested by SLR are combined. We decided to use ‘lower case’ in the criteria as suggested by most of the proponents. A final version of eleven criteria for Interface category is shown in Table V.

For Gameplay category, sixteen and fourteen criteria identified from SLR and interview are combined and produced a final set of 18 criteria. Twelve redundant criteria have been removed. Criteria using different terms but are referring to the same criteria are also removed. A proposed guideline for Dyslexic intervention games comprising of all final combined criteria are illustrated in Fig. 8.

TABLE V. CRITERIA FOR INTERFACE CATEGORY

Interface	
1. Simple interface	2. Font size: 16, 18, 18-26, minimum font size of 14 points
3. Font colour: grey scale in font (10%), text in black using a mono-spaced, dark colour on light background (Suggest cream color background, white font, red background)	4. Font type: lower case, Arial typeface, typeface Courier, font style Verdana, OpenDyslexic font, Helvetica, Comic san)
5. Background: grey scale in the bg (90%) crème/black color pairs, text in black on creme background, plain background, brilliant/bright colors	6. Layout: Fixed , Unobstructed views, playful, line spacing (1.4), paragraph spacing (2), column width (77 character/line), column width not wider than 60 characters per line, consistent, character spacing (+7%), Child friendly color (unique to induce positive emotion) and shape (round)
7. Figures: simple geometric	8. Icon: 3D
9. Graphic/visual: simple, consistent, appealing, easy to interpret, large and touchable, attractive, search-like, non-related linguistic, letter arrangement: keyboard design, real images	10. Character: cute, children friendly
11. Fantasy-themed setting	

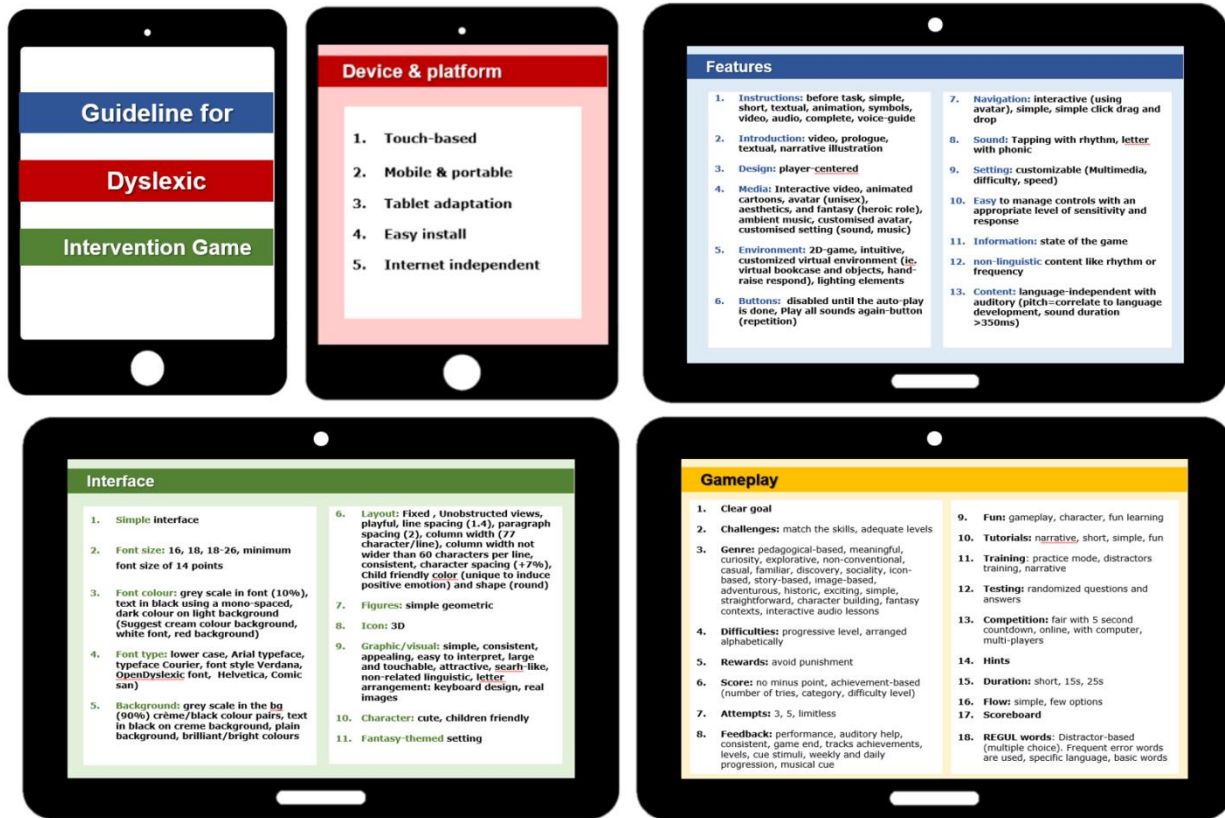

Fig. 8. The Proposed Guideline.

1) *Evaluation of the proposed guideline:* The proposed guideline has been evaluated through two methods; expert review and prototyping. Verification is conducted before validation. Five experts were involved in verifying the proposed models in ensuring that the proposed guideline confirms its specification. Table VI listed five experts involved in reviewing the proposed guideline.

TABLE VI. EXPERTS BACKGROUND

Expert	Field of expertise	Qualification & designation	Years of experience
Exp1	Special education	Dyslexia teacher	2 years
Exp2	Counselling	Trainee	4 years
Exp3	Computer system and network	PhD, Lecturer	More than 20 years
Exp4	Interaction design	PhD, Lecturer	20 years
Exp5	Counselling	Trainee	4 years

There are eight components that have been used in reviewing the proposed guidelines; clarity, visibility, comprehensive, evolutionary, flexibility, accuracy, understandability, and effectiveness. Clarity is meant to evaluate whether the guideline is clearly presented. There are four constructs used to measure the clarity of the guidelines; (C1)-the whole design guideline for Dyslexic game is clearly presented, (C2)-the categories in the design guideline for Dyslexic game are defined clearly, (C3)-the elements in the design guideline for Dyslexic game are defined clearly, and (C4)-all relations between the categories and elements are clearly presented. For measuring visibility, three constructs have been used; (V1)-the design guideline for Dyslexic game is visible to be followed, (V2)-the guides involved can be followed easily, and (V3)-the design guideline for Dyslexic game can be a guide by developers to solve related tasks of design and development. Fig. 9 shows the mean score for each construct for clarity, visibility, comprehensive, and evolutionary.

Fig. 9. Expert's Review on Clarity, Visibility, Comprehensive and Evolutionary.

To measure the completeness of the guideline, three constructs have been used; (CO1)-the whole design guideline for Dyslexic game is defined completely, (CO2)-the design guideline for Dyslexic game covers all related elements, and (CO3)-the relations between the categories and elements are sufficient. While for measuring the ability of the guideline to evolve, three constructs are used; (Ev1)-the design guideline for Dyslexic game is dynamic, (Ev2)-the design guideline for Dyslexic game allows additional factors in the future, and (Ev3)-the design guideline for Dyslexic game provides opportunity for improvements.

Mean score for all constructs in measuring clarity, visibility, comprehensive, and evolutionary are considered high (more than 2.5). It can be concluded that all experts agreed that the proposed guideline is clear, visible, complete, and able to evolve. Another four aspects used in measuring the guidelines are flexibility, accuracy, understandability, and effectiveness. There are three, four, two, and three constructs used for each aspect respectively. Constructs used to measure flexibility are; (F1)-the design guideline for Dyslexic game is flexible to be edited, (F2)-the design guideline for Dyslexic game is adaptive to changes, and (F3)-the design guideline for Dyslexic game is generalizable enough to be applied for other related tasks.

While for measuring how accurate the guideline is, two constructs are used; (A1)-the design guideline for Dyslexic game is presented correctly and (A2)-all categories and elements factors are labelled correctly. Four constructs are used to measure understandability; (U1)-the whole design guideline for Dyslexic game is easy to understand, (U2)-The label of each category is understandable, (U3)-the label of each factor is understandable, and (U4)-adhering to the design guideline for Dyslexic game is easy. The last aspect is the efficiency of the proposed guideline. There are three constructs used; (Ef1)-the design guideline for Dyslexic game can guide in the development of engaging Dyslexic games, (Ef2)-adhering to the design guideline for Dyslexic game will improve the engagement of Dyslexic games, and (Ef3)-adhering to the design guideline for Dyslexic game will improve usability in Dyslexic games. Fig. 10 shows the mean score for each construct for flexibility, accuracy, understandability, and effectiveness.

Fig. 10. Expert's Review on Flexibility, Accuracy, Understandability and Effectiveness.

Mean score for all constructs in measuring flexibility, accuracy, understandability, and effectiveness are considered high (more than 4.0). It can be concluded that all experts agreed that the proposed guideline is accurate, flexible, can be easily understood, and effective. Experts have also given their overall review of the guideline. They are particular on visual aspects of the guideline especially on interface elements as suggested by Expert 1, Expert 4, and Expert 2.

- E3 : Customizable font size
- E1 : Font style: = use the written letter 'a' not 'a'
- E2, E5 : Font style = choices between capital letter and small case

Font size is important element involving Dyslexic children. Three experts suggested font size to be customizable in the game. Expert 1 is consistent with what is proposed in the guideline on the font type, as San Serif font should be used. Expert 2 and 5 are also suggested that players should be given options to choose between capital letters or small letters to be used in the game. Other elements also attracted Expert's attention, for example background music (pleasant to children's ear) and hints (disclosing one letter). They prefer options to be given in turning on background music. While for hints, they suggested that hints only to be given when they win the game. Too many hints will discourage learning among players as suggested by Expert 1.

- E1 : Background music= on/off button
- E1 : Gain hint through winning, they will keep use hint if too many hint
- E4 : The guideline should be printed in bigger size.
- E1 : Application Icon = attractive

Experts are concerned about the look of the proposed guideline as well. They prefer the guideline to be printed in bigger size. However, the A4 size guideline is only printed for evaluation purpose. Since the guideline comprises of textual elements, Expert 1 also suggested the use of application icon which is more attractive.

Second phase of evaluation involved validation of the proposed guideline with the intention to check whether the proposed guideline meets the requirements and expectations. For validating purpose, prototyping method is used. A prototype of dyslexic game is developed, namely DysRedia by taking considerations the criteria listed in the proposed guideline. DysRedia is a proof of concept of the proposed guideline. Fig. 11 shows selected interfaces of DysRedia prototype.

Fig. 11. Selected Interfaces of DysRedia.

Version 1.0 of DysRedia has been demonstrated to two teachers and students at Dyslexia Incubator, School of Computing. 34 children had experienced playing and testing it. DysRedia has been improved by taking considerations of their responses and feedback. For example, letters were initially in upper case have been changed to lower case as shown in Fig. 12.

Fig. 12. The Improved Version of DysRedia.

## V. CONCLUSION

A design guideline for Dyslexic Intervention Games has been successfully designed and evaluated. A significant contribution of this study is the criteria and guidelines for Dyslexic game which will benefit game developers, practitioners, and educationist who are directly involved with Dyslexic children. The proposed guideline can serve in assisting them in designing and developing game applications for dyslexic children.

This study also presented DysRedia, a game which is designed and developed based on the proposed design guideline as a proof of concept to the proposed design guideline. With high acceptance of the game, it is supported that the proposed design guideline is an appropriate design that follow gamification concept, friendly to target audience, and Dyslexic acceptance. The proposed criteria and guidelines can be adapted to other similar domains, such as special needs education therapy, particularly involving with Dyslexic children.

This study is aligned and significant to Sustainable Development Goals (SDG) three and four, Good Health and Well-being and Quality Education respectively. The outcome of this study could contribute in improving the reading ability among dyslexic children. Future works might consider different type of evaluation of the proposed guideline involving bigger audience of testers.

## ACKNOWLEDGMENT

This research is funded by Universiti Utara Malaysia (UUM) through the University Grant [SO code: 14590]. The authors fully acknowledged UUM for the approved fund, which makes this important research viable and effective. Credit also goes to our game developer, Robin Chan.

# The Effectiveness of Gamification for Students' Engagement in Technical and Vocational Education and Training

Laily Abu Samah, Amirah Ismail, Mohammad Kamrul Hasan  
Faculty of Information Science and Technology  
Universiti Kebangsaan Malaysia (UKM)  
Bangi, Selangor, Malaysia

**Abstract**—The transformation of Technical and Vocational Education and Training (TVET) prioritizes by the national education convention to meet the needs of the industry through improving student skills and the quality of related systems. One of the transformations is practicing blended learning, such as a flipped classroom, to produce better quality student learning outcomes. However, based on previous studies, there are difficulties in maintaining student engagement during learning activities, even though blended learning offers some advantages. Therefore, this study suggests the development of a mobile application using gamification as a solution to enhance student participation. This paper proposes the design and development research (DDR) approach with the adaptation of the ADDIE model to build a learning content prototype. It involves five phases: analysis, design, development, implementation, and evaluation. The study participants consisted of two groups of students in the 1st semester of the Interactive Multimedia course from two different TVET institutions who were cleft into a control group and an experimental group. The experimental group is gamified, whereas the control group is not. The study evaluation uses two instruments: a test to compare students' understanding of both groups and an activity log to track the experimental group's use of the prototype. According to the findings, gamification during learning activities can increase student engagement by boosting performance through a more significant pre-and post-test mean score difference and creating a positive learning experience. Additionally, mobile applications with the gamification concept can be employed extensively in various TVET courses to encourage student learning performance.

**Keywords**—Technical and vocational education and training (TVET); flipped classroom; engagement; gamification; mobile application

## I. INTRODUCTION

UNESCO defines Technical and Vocational Education and Training (TVET) as a term that refers to aspects of education. It involves alternatives to academic education, the study of technology and related sciences, and an environment to acquire and apply knowledge, skills, and attitudes related to employment in various sectors of the economy and social life. The measurement of TVET students' competence refers to job analysis developed through the coordination of industry experts, skilled workers, and teaching experts by field to ensure

that the implementation of TVET meets and is in line with the needs of the industry [1].

Various approaches are used during learning activities to guarantee that students attain the essential competencies, one of which is blended learning. Blended learning is a blend of face-to-face or online learning activities that occur inside or outside of the classroom, such as conversations in group work, hands-on practice, presentations, and project-based solutions [2]. It was detected to be more successful at enhancing student engagement.

Although blended learning has a positive effect on student engagement, according to [3], there are difficulties in maintaining it. To sustain engagement potential and achieve learning objectives, students must be wise in how well they manage their attitude and autonomy during learning activities.

According to previous studies, gamification has been widely used in TVET, albeit it is unclear whether this manages to boost engagement [4]. Therefore, this study suggests developing a mobile application using gamification as a solution to assess student engagement by their achievement and learning experiences. Since students spend most of their time on their phones, mobile applications have emerged as the best way to motivate them to learn.

The implementation of this study is vital in contributing towards:

- Make students engage in learning activities through gamification to increase student performance and reduce the dropout rate.
- It adds to research on the wide use of gamification in the TVET environment but is less prominent.
- It can be extended to the entire TVET, whether public or private TVET institutions, in various areas of TVET.

## II. LITERATURE REVIEW

This section explains the synthesis of information obtained to assess student engagement in TVET blended learning through gamification. It is divided into several parts, starting with the introduction to TVET, the flipped classroom practiced in TVET institutions, the potential of student engagement in

learning activities, and the use of gamification elements to develop mobile application prototypes for self-learning.

#### A. Technical and Vocational Education and Training (TVET)

TVET plays a role in producing a skilled workforce in various fields through training that allows students to acquire knowledge and skills. It shapes students to have a lifelong learning mindset and be capable as employers who create jobs. TVET also provides individuals with expertise and skills appropriate to the job market to address the global unemployment problem that will produce competent and creative workers who function as agents of sustainability in the workplace [5].

Several aspects need to consider for effective TVET implementation listed as:

- The use and influence of technology in learning activities, like the importance of ICT to solve problems creatively and analytically through various applications, software, and devices [5].
- Instructors' preparation ensures that learning activities efficiently run where they need to master the knowledge and skills in the field by being able to explain and demonstrate correct and safe work steps and answer any questions from students [6].
- TVET-related systems are understood and implemented by all parties, for example, using job analysis correctly as a reference to carry out the learning process along with the right equipment, work steps, and technical information arranged according to the difficulty level [1].

Aspects mentioned, such as the influence of ICT, teacher preparation, and the system set, encourage the diversity of the implementation of learning activities in the TVET environment. One method that has gained attention is blended learning, which meets TVET learning activities by emphasizing specific jobs' theoretical and practical components. The following section will discuss blended learning.

#### B. Flipped Classroom

The learning environment needs to provide space for communication, collaboration, creativity, and critical thinking in making decisions, developing strategies, and solving problems with the help of technology [7]. This conducive condition is necessary to avoid boredom that limits the ability to perform tasks and creates a feeling of lack of interest, loss of motivation, and absence of student engagement [8].

Therefore, TVET practices blended learning to create a conducive learning environment. A famous example of blended learning is the flipped classroom. Students prepare beforehand using learning materials such as presentation slides or videos before undergoing face-to-face learning with instructor monitoring through various activities such as discussions, presentations, drills, group assignments, and assessments [8].

Comparison between flipped and traditional classrooms is the better way to understand it. Implementing a conventional

classroom is through the delivery of learning content by the instructor in the class at a set time and period. Then students must complete the tasks provided after the end of the study [9]. Meanwhile, flipped classroom implementation contradicts traditional classrooms, as shown in Fig. 1.

Fig. 1. Traditional Versus Flipped Classroom (Source: <https://edtechimpact.com/news/flipping-the-classroom-ultimate-guide>).

Although blended learning practices in the TVET environment positively impact students, engagement is challenging to maintain. This hardship pushes by several factors, such as the diversity of student characters, less effective learning materials, and constraints in the use of learning technology. The next section of the literature answers several points related to student engagement in learning activities.

#### C. Engagement

The foundation of high-quality learning is engagement, defined as the use of time and energy to carry out an action or task differently impacted by many circumstances [10]. Students' good attendance, commitment, interaction in learning activities [11], and valuable personalities, including satisfaction, success, belonging, enjoyment, liking, skills, competence, perseverance, motivation, and courage, are examples of engagement [4] [12].

Student engagement in learning activities is measured using numerous instruments related to various items. Some use the National Survey of Student Engagement (NSSE), K-12 classroom engagement scale, Student Engagement Questionnaire (SEQ), and a combination of positive and negative affect schedule and presence questionnaires [13]. However, most of the instruments employed focus on the three main measurement criteria' behavioral, cognitive, and emotional.

Behavioral criteria were discovered by looking at how engaged and diligent students are in their studies and how willing they are to ask for assistance when necessary [14]. These criteria also affect utilizing qualitative elements that require effort, attention, and persistence while being observed [4].

Cognitive criteria implicate the amount of effort and time required to comprehend the work, the drive to overcome shortcomings, the ease with which one can adjust to problem-

solving, and the achievement of learning success [14]. For easier understanding, this criterion requires efforts of academic knowledge's intellectual components [15].

Emotional criteria are determined by looking at positive emotions, such as excitement, joy, and confidence, as well as negative ones, such as boredom, frustration, and anxiety [13]. It also measures expression through feelings or reactions between a combination of physiological and psychomotor components positively or negatively, including pride and anger [4].

When implementing learning activities, it can be troublesome to keep students' attention because they come from different backgrounds and have different learning styles. Hence, it is necessary to set difficulty levels starting with easy, medium, and challenging levels throughout learning activities [16].

How can engagement be maintained to ensure learning activities achieve the set learning outcomes? This question is always floating around, and the implementation of various methods to address this issue. One way is using gamification in learning activities described in detail in the next section.

#### D. Gamification

Instructors are continually experimenting with a new pedagogical method to capture students' attention, motivate them, and engage them in learning activities. Thus, rather than traditional learning methods, digital computer games are customized to create an enjoyable and engaging learning environment for students [17]. The adaptation of a game into a non-game condition is key to gamification. As a result, the definition of gamification is the use of game elements or mechanics in non-game contexts [18].

Explicit knowledge is required when comparing gamification in learning activities to other methods that also use the basics of games, such as game-based learning (GBL), serious games, and simulations. GBL employs the power of games to engage students in learning activities [19]. On the other hand, serious games resemble gaming design worlds that solve problems unrelated to enjoyment [20]. While the simulation parallels a serious game, the main objective is training in the military, medicine, and aviation fields [17].

Gamification includes a variety of qualities that help it achieve its purpose. It provides rewards and develops motivation [21] to complete specific tasks. It makes learning material more dynamic, innovative, and appealing, encouraging participation and boosting understanding of the learning substances [22]. It promotes various active and successful learning strategies by maintaining attention and interest in all learning tasks [23]. It can also be an alternate strategy that adds value to normal learning activities by giving a more engaging experience through gamification elements [14]. Furthermore, gamification persuades students to complete assignments despite exhaustion [17].

Gamification aims to lower dropout rates by providing students with practical learning methods and creating a pleasant learning environment [22]. It can increase students' enjoyment and engagement to kindle their interest in studying

and obtain better results [21]. It can motivate and encourage student competitiveness by improving student happiness, effectiveness, and efficiency in learning activities [14]. When students face challenging topics and limited time, it eliminates challenges and solves problems during learning activities by integrating learning activities appropriately [18].

Application developers and instructors must work together to ensure that the gamification design delivers maximum benefits and effectively enhances student engagement [10]. One of the primary design criteria is incorporating relevant and purposeful gamification elements into the learning content via set objectives. By delivering clear, intuitive, and pleasant learning content, gamification elements should generate a good learning experience [21]. Table I depicts the use of gamification elements related to student engagement based on previous studies.

Besides that, gamification interface design must incorporate seamless navigation [21], an exciting narrative adjustment, and an acceptable combination of text, graphics, colors, and animations [17]. It is to ensure that students do not lose focus due to the excessive amount of gamification design so that they stray from the original learning goal [24]. The processing of learning content into gamification design needs to emphasize learning strategies so that students obtain quality learning results and experiences. Among the techniques practiced is segmentation, which breaks down learning material at a rate students can accept for knowledge retention [25]. The arrangement of learning content also needs to follow levels starting from low, medium, and high levels to meet the needs and abilities of students from various backgrounds [17].

The coming section explains the research methodology based on the problem statement and literature review. This section details the steps implemented to develop a mobile learning application prototype by including gamification elements identified to increase student engagement.

### III. METHODOLOGY

The study employs experiential learning theory, an essential theory based on cognitive results. This theory states that learning activities repeatedly occur through experience modification, observational reflection, abstract conceptualization, and active experimentation [26]. The repeating process is made feasible by learning exercises over a developed gamified mobile app prototype. The study occupies the design and development research (DDR) approach with the adaptation of the ADDIE model depicted in Fig. 2.

The selection of DDR as a research methodology is because DDR involves a systematic and organized process consisting of three stages: designing, developing, and evaluating the success of mobile learning application prototypes to obtain empirical evidence based on the collection and analysis of data from experiments conducted. The adapted ADDIE model into DDR consists of five phases: analysis, design, development, implementation, and evaluation, which are explained in more detail hereafter.

#### A. Analysis Phase

The analysis phase involves the analysis and setting of some criteria to launch the implementation of the study. It determines study participants, prototype users, learning content, and authoring tools with appropriate gamification elements.

The participants chosen were first-semester students' of Software Technology (Interactive Multimedia) from two different TVET institutions split into a control group and an experimental group. Both groups underwent face-to-face, blended learning activities, while only the experimental group had to use the gamified prototype as an addition to self-learning.

The module as the prototype's content is Image Editing from the five available modules. The topics involved are

shooting, selecting, editing, and saving photos. It is used with the instructor's help to optimize characteristics of knowledge, abilities, and attitudes in the prototype.

Furthermore, the selection of proper authoring tools ensures that the process of producing and testing the prototype achieves the study's goal. The research uses Buildbox software because it offers prototyping features with an excellent 2D graphic resolution display, appropriate gamification elements, and the drag-and-drop concept.

#### B. Design Phase

The prototype consists of four main parts according to sub-topics: notes, quizzes, assessments, and games. The prototype's content should comply with the TVET learning environment, including knowledge, skills, and attitude competencies. As in Table II, prototypes are developed by including eight gamification elements to trigger student engagement.

The prototype also applies Mayer's multimedia design principles to support learning activities to be more quality and effective. It also uses Jakob Nielsen's heuristic evaluation to ensure the display of the prototype works well.

Fig. 2. DDR Approach with the Adaption of the ADDIE Model.

TABLE II. GAMIFICATION ELEMENTS USED IN THE PROTOTYPE

Part	Gamification elements	Function
Notes	Leveling <sub>1</sub>	Before moving on to the subsequent sub-topic, be sure the sub-topic before has been finished.
	Progress bar <sub>2</sub>	Disclose the progress status of the reviewing notes.
	Badges <sub>3</sub>	The current sub-topic was reviewed and determined to be ready for a quiz or progression to the next sub-topic.
Quizzes	Points <sub>4</sub>	Answers earn points. If the answer is correct, points count; if incorrect, no points count.
	Feedback <sub>5</sub>	Feedback is provided based on answers. If the answer is correct, proceed to the next question. The necessary notes are displayed if the answer is incorrect and returned to the current question.
	Life <sub>6</sub>	Life is permitted to provide answers. If the answer is incorrect, life deducts, and students repeat the quiz if there is no more life.
	Leveling <sub>1</sub>	Students must earn all possible points to be qualified to respond to the assessment question or go on to the following subtopic.
Assessments	Time limit <sub>7</sub>	Allow time to respond to questions. No points if the timer ran out and skipped the question.
	Points <sub>4</sub>	Answers earn points. If the answer is correct, points count; if incorrect, no points count.
	Leveling <sub>1</sub>	Must complete specific parts (notes and quizzes) to be qualified to respond to the following assessment question.
Games	Challenges <sub>8</sub>	Make the game challenging by requiring players to collect and avoid specific things.
	Life <sub>6</sub>	Set up a gaming environment. Failure to dodge obstacles results in reduced life, and when life is gone, the game is over.
	Points <sub>4</sub>	Make a competition within the game to increase current points for the next round.

<sup>a</sup>. Total of gamification used: 1,2,3,4,5,6,7,8

Fig. 3. Some Prototype Interfaces that Incorporate Gamification Elements.

The quizzes and assessments structure meets the criteria of difficulty level and skill type formed through the Test Specification Table. The difficulty level refers to the value of the question hardship starting from low, medium, and high based on the student's ability to answer the question using the ratio 1 (low): 2 (medium): 1 (high). In contrast, the skill type refers to a category built on three aspects, consisting of theoretical, procedural, and attitude parts, using the ratio 6 (theory): 3 (procedure): 1 (attitude).

The game intends to give students a space to rest for a while from entirely focusing on learning activities through other parts of this prototype. However, the game produced revolves around graphics related to the learning material.

### C. Development Phase

This phase entails forming a prototype and continual testing to guarantee that it is functional. The prototype pre-use is a series of usability tests conducted with students, instructors, and developer experts utilizing the thinking-aloud method. Each examiner made a clear vocal comment while using the prototype, and the researcher recorded the statements.

Visual and functional characteristics that affect prototype performance, such as appropriateness and precision of navigation, clear writing, quality visuals, effective interface display, and efficient learning content, are reviewed. Fig. 3 depicts some prototype interfaces that incorporate gamification elements.

### D. Implementation Phase

The implementation phase includes a pre-test followed by the prototype usage within a specific time frame and ending with a post-test by 23 students in each group. The pre-and post-tests use the 40 same multiple choice questions (MCQ) in different positions to assess student comprehension.

The experimental groups (prototype users) must update the activity logs within two weeks of utilizing the prototype. This step intends to reduce the possibility of students becoming disinterested in self-learning. Meanwhile, the control group only underwent blended learning activities with the instructors.

The activity logs provided the student's prototype progress throughout the self-study session. Students only answer the items provided through yes or no options, record the date for each stage, and answer a few short questions. Intending to make it easier for students to provide the necessary information, gain initial exposure related to the prototype content, and allows students to focus while using this prototype.

### E. Evaluation Phase

The evaluation phase is the study's final stage to determine gamification's effectiveness on student engagement in TVET blended learning. Evaluation of the construction of a hypothesis is conducted based on pre-and post-test scores as follows:

- $h_0$  – no significant difference between the pre-test and post-test scores of the control group
- $h_1$  – no significant difference between the pre-test and post-test scores of the experimental group

In addition to the hypothesis findings, the study also analyzed the activity log updated by the experimental group.

## IV. RESULTS

### A. Pre-and Post-Test Scores

A quantitative analysis was conducted on the pre-and post-test scores by a total of 46 students from both control and experimental groups using SPSS software. Before the execution of the investigation on the constructed hypothesis, a normality test runs on the entire score obtained to determine the normal distribution of the scores. Table III shows the Shapiro-Wilk normality test results for the control and experimental groups' pre-and post-tests.

TABLE III. SHAPIRO-WILK NORMALITY TEST RESULTS

Group	Test	Statistic	df	Sig
Control	Pre	0.954	23	<b>0.545</b>
	Post	0.956	23	<b>0.389</b>
Experimental	Pre	0.923	23	<b>0.079</b>
	Post	0.953	23	<b>0.342</b>

Based on the table shown that the Shapiro-Wilk value for the entire score is determined as normally distributed with a significant rate of  $p > 0.05$ . As a result, parametric tests can be performed based on the overall score.

A paired sample t-test was conducted on pre-and post-test scores to prove the hypothesis built based on a significant value of  $p < 0.05$  as follows:

- " $h_0$  – no significant difference between the pre-test and post-test scores of the control group". Value  $p = 0.001$ , then  $h_0$  – rejected.
- " $h_1$  – no significant difference between the pre-test and post-test scores of the experimental group". Value  $p = 0.001$ , then  $h_1$  – rejected.

Depending on the paired sample t-test, hypotheses were all rejected because significant differences between the tested variables showed that student understanding increased between the pre-and post-test. However, the improvement achieved by students from the experimental group using gamified application prototypes is more remarkable through a mean difference of 17.52, referring to Table IV. This difference demonstrates that gamification affects student engagement in self-learning by leading to higher learning outcomes.

TABLE IV. THE PRE-AND POST-TEST MEAN DIFFERENCE

Group	Test	Mean Score	Mean score difference
Control	Pre	20.09	9.95
	Post	30.04	
Experimental	Pre	17.83	17.52
	Post	35.35	

### B. Gamified Activity Logs Analysis

An analysis enforced three criteria to analyze the activity logs amended by prototype users. It includes cognitive, behavioral, and emotional factors related to gamification elements influencing student engagement during learning activities. Table V summarizes the activity log's findings through gamification elements.

The gamification design is also vital in boosting the quality of learning activities. Table VI summarizes the engagement measurement of different gamification designs used in the prototype.

TABLE V. THE ACTIVITY LOG'S FINDINGS THROUGH GAMIFICATION ELEMENTS

Assessment criteria	Assessment item	Worksheet item	Finding	Result
Cognitive	Learning repetition	How many attempts to earn full marks when answering the quiz to be eligible to answer the assessment?	The mean of quiz repetitions is 3.32 times.	There is engagement through the retention of knowledge due to the repetition of learning activities.
		Do you read finished notes repeatedly?	100% answered Yes.	
		Did you repeat the completed assessment to improve the score obtained?	100% answered Yes.	
	Assessment score	The obtained score while answering the assessment.	The assessment mean of scores is 7.85 compared to 10 questions for each sub-topic.	There is engagement through good scores while undergoing assessment.
Behavioral	Duration	Duration to collect the badges (complete review of each sub-topic).	The duration mean is 5.47 days compared to 14 days to use the prototype.	There is engagement through attention and persistence due to using the prototype in a short period.
	Motivation	Did level openings by completed sub-topics motivate you to finish the study?	100% answered Yes.	There is engagement through motivation due to the completed sub-topic.
	Focus	Does the length of time to answer questions make you more focused on answering?	100% answered Yes.	There is engagement through the focus given when answering the assessment.
Emotional	Fun	Does earning badges give you joy?	100% answered Yes.	Engagement through emotions shows fun, stress, enthusiasm, and satisfaction during learning activities using certain gamification elements.
	Pressure	Does trying to get full marks would make you pressured?	100% answered Yes.	
	Enthusiastic	Does getting full marks and being eligible to answer the assessment make you enthusiastic?	100% answered Yes.	
	Satisfaction	Are you satisfied with the use of this prototype?	100% answered Yes.	

TABLE VI. ENGAGEMENT MEASUREMENT THROUGH GAMIFICATION DESIGN

Assessment item	Worksheet item	Finding	Result
Segmentation	Are the notes provided precise and easy to understand?	100% answered Yes.	The appropriateness of gamification design is critical. It ensures optimal gain of the positive effects of gamification.
Feedback	Does feedback on wrong answers help you?	100% answered Yes.	
Educational games	Did you learn something even while playing?	100% answered Yes.	A more flexible gamification design is needed so students can take a break from the relatively dense and heavy learning content.
	Do you play while studying?	100% answered Yes.	

## V. DISCUSSIONS

Based on the analysis enforced on two measurement instruments, gamification in TVET blended learning has proven to enhance student engagement during self-learning sessions. Student engagement during learning activities positively impacts students' learning experience, especially the emotions of fun that produce an effective learning environment. Subsequently, learning results increase through better student achievement than activities without gamification.

The main contribution of this study is to develop a mobile learning application prototype into TVET blended learning with gamification to increase the potential of involvement. The developed application prototype can be used as a reference and modified according to the suitability of learning in other TVET fields that emphasize competence from the aspects of knowledge, skills, and attitudes. Moreover, this prototype expects to help facilitate learning and provide additional reference resources for instructors and students.

Several previous studies also support the findings of this study. Gamification provides students a pleasant learning experience by encouraging comprehension, pleasure, and higher concentration. It promotes learning, lowers boredom, and enhances engagement, resulting in competitiveness and improved performance [27]. Students feel satisfied, have better interactions, stress and worry about the evaluation are lessened, and the generation's psychological requirements are met [28]. It boosts students' skills in discovering and solving complicated problems through simplified learning [8]. It increases student motivation as a stimulus for active participation in higher and continual learning performance. As a result, the dropout rate is reduced, particularly in the TVET context [29].

Even though gamification has a beneficial influence, several concerns must be addressed, particularly regarding long-term usage. For example, reducing students' motivation due to rules that prevent access to the next activity if they have not completed the previous one and notifications for completing incomplete activities or reaching a certain level [30].

## VI. CONCLUSIONS

This study successfully created a gamified mobile app prototype to assess the effectiveness of gamification on student engagement in TVET blended learning. Gamification assists students in improving their achievement and having a better learning experience. The prototype can be used in related domains and extended to additional TVET fields as gamified learning resources to ease the current learning process.

This study encountered several limits, including a lack of research on gamification in the context of TVET blended learning environments compared to academic-based education. The limitation slightly disrupts the study flow to gathering the best and most useful reference materials. Next, mobile devices impact the delivery of learning materials because of the limited display size, which causes misunderstanding of simple statements by students, low-quality graphics due to small size, and the difficulty in maintaining uniformity, such as the size of texts and answer selection buttons.

In addition, the application prototype is limited to Android device users only. Application prototype development for other platforms such as IOS devices and websites needs different software or system settings. This process requires allocating a lengthened period and appropriate expertise to enable the prototype on various platforms.

Gamified prototypes have the potential to be expanded as an alternate technique for executing learning activities to enhance student engagement in TVET and other educational domains. Collaboration among diverse stakeholders such as instructors, universities, industries, and application developers is vital in maximizing gamification's benefits. As a result, future study recommendations presents as follows:

- The sample size of the students from the control and experimental groups increased, and the more extended period of the application prototype use to determine a more accurate measurement of potential engagement.
- Further research on more specific gamification elements and designs is needed as a measurement item to identify the existence of student engagement in detail.
- The study is extended through blended learning using gamification for students with disabilities in the TVET environment.

Faculty of Science and Defence Technology, National Defence University of Malaysia, Kuala Lumpur, Malaysia<sup>3</sup>

**Abstract**—Wireless communication is very important in this generation where today's 5G internet connection is still unconfirmed and 4G communication is still needed. Network in Malaysia has been supported by many telecommunication companies and the Quality of Services is still poor supported especially in the campus area. This research presents a performance analysis of Quality of Services for 4G wireless Communication among Providers supported in a campus area in Malaysia. A 4G Nemo Outdoor wireless analyzer was used to collect the Reference Signal Received Power (RSRP) signal data based on the identified campus road maps. Digi and U-Mobile Network was identified and compared as two telecommunications providers in the testing. The identified road maps were analyzed along the routes while testing signals are collected while driving. It is identified that Digi supports better for the Mobile broadband network which shows an excellent of 1% and good connections of 29 % and 0% signal loss in the drive areas. RSRP signal for U-Mobile shows there is 8% signal loss and the connections provided only at the Mid-Cell for 43% and Cell Edge connections for 48%. This concludes that the 4G signal strength in the campus area having average signal strength, but some medium signal strength is also identified based on the road locations. This research is significant for QoS of supports mobile network in a campus area.

**Keywords**—Quality of services; 4G/LTE; mobile network; wireless communication; RSRP; campus network

## I. INTRODUCTION

Wireless communications have enabled the connection of billions of people to the Internet which they benefit from today's digital economy. A mobile phone is one of today's wireless communication devices where it allows people to use their devices and communicate everywhere in the world. It is identified that every sector of the economy now relies upon wireless technologies such as in banking, agriculture, transportation, healthcare, education, and many more [1]. Today's, the development of 4G to 6G services, mobile network, high-speed data, wireless sensor network and broadband services have become the most important sources of mobile communications operation services [2, 3]. Population changes using mobile phone data has been investigated and the social networking sites use and college students' academic performance on testing for an inverted U-shaped relationship using automated mobile app usage data

also has been analyzed[4]. 5G is a robust wireless communications networks but 5G is still in the stage of testing in Malaysia. Performance Analysis of Mobile Broadband Networks with 5G Trends and planning of antenna for future 5g energy harvesting in Malaysia has been done[5, 6]. Many applications and systems today like artificial intelligence and the Internet of Things need higher bandwidth to achieve QoS in communications either in wireless broadband or wireless sensor network [7, 8]. The advantage of using the wireless network is the costing is inexpensive compared to a wired network. A wireless network is using Radio Frequency (RF) for transmitting and receiving data by using the wave. The internet can be achieved on two platforms which are connections through coverage mobile data plan subscribed to the telecommunication by using the smartphone. Secondly are the broadband connections devices for the installation of mobile data for broadband providers needs updates checking for QoS. Some connections are identified as loss and slow. Thus, identify routes or areas of the supported broadband needs manually testing by using certain software to inspect all places without the reference map of routes. The other problems of data transmissions are noise.

This research described the performance analysis that has been done for QoS for 4G Wireless Communication among Providers which was tested in a campus area. A Nemo Outdoor tools and software has been used as the platform to analyze the transmission data 4G while driving test along the identified route maps in a campus network is identified for data collections. The Reference Signal Received Power (RSRP) performance of the 4G signal strength is presented to show the QoS for both providers in supporting coverage in the campus network.

## II. RELATED WORK

There are many types of performance analysis of the wireless network of 4G. Multiple-input and multiple-output (MIMO) is one technique for performance analysis for 4G Wireless. One research has presented that MIMO and orthogonal frequency division multiplexing (OFDM) were used for supported high data rate and high performance in different channel conditions [9]. Many methods have shown the use of different applications of voice and data connection

in the 4G wireless network. 4G analysis performance also used MADM algorithms which are integrated into three types of network situations. The network is WLAN, UMTS, and WiMAX [10]. Some references identified that the performance analysis for 4G wireless communication had three possible architecture types which are multimode devices, overlay networks, overlay networks, and common access protocol. The multimode device can access services in a different wireless network. The multimode device can improve call and expand effective coverage areas [11]. Conventional mobility management schemes tend to hit the core network with increased signaling load when the cell size is shrinking and the user mobility speed increases. A survey has been done for the idle mode mobility management and then proposes a new architecture, namely predictive mobility management (PrMM) to mitigate the identified challenges [12]. Malaysia has many telecommunications providers' services for wireless communication such as 4G/LTE. The famous providers in Malaysia are Celcom, Digi, Maxis, U-Mobile, and many more. These providers are much designated for the wireless network for the 4G services. 4G services are identified as the promise of a higher platform of a wireless network in the world although 5G has been implemented not all countries are ready and supported on the platform [13]. The fourth generation was upgraded from the three-generation 3G network. The different and the important of upgrading from the 3G to 4G network are the specifications on the coverage of speed and the costing to the consumers. The Table I shows the DIGI data features and Table II shows the U-Mobile data features on the download speed, upload speed, and latency between 3G and 4G of Digi and U-MOBILE network [14].

The keys of the 4G infrastructures are accessing information connected to a wide range of information and services, and receiving a large volume of information, data, pictures, voice, and video [15]. 4G is using the Orthogonal Frequency Division Multiplexing (OFDM) [16]. Besides, the advantages of using the 4G have advantages of supporting a higher speed that can reach up to 100Mbps. Using 4G with higher speed can do many things such as playing online games, watching high-definition video streaming, VOIP and can get interactive TV [17, 18]. The 4G there have 5 important ways and factors of making the 4G are Orthogonal Frequency Division Multiplexing (OFDM), Mobile WiMAX, Ultra Mobile Broadband (UMB), multiple-input multiple-output (MIMO), and Long-Term Evolution (LTE) [19]. It is mentioned that Mobile broadband (MBB) is one of the critical goals in fifth generation (5G) networks due to rising data demand. MBB provides very high-speed internet access with seamless connections. Existing MBB, including third-generation (3G) and fourth-generation (4G) networks, also requires monitoring to ensure good network performance [20]. Fig. 1 shows the Long-term Evolution or LTE are the norm for mobile device wireless broadband and Global Mobile

Communication System (GSM) information terminals. Using LTE can improve the information network's ability and speed focus applied in Malaysia[21]. Using LTE can enhance the capacity and speed of the data network. LTE characteristic are the bandwidths are can improve from 1.4 MHz until 20 MHz, LTE also supports the frequency division duplexing (FDD) and the time division duplexing (TDD)[18]. Additionally, the LTE can support the voice and data to the cell towers with older network technology such as CDMA2 2000 that are family of 3G mobile technology that can be sending voice, data, and signaling data besides mobile phone and cell sites [22].

TABLE I. DIGI DATA FEATURES

Feature	3G	4G
Download speed (Mb/s)	1.4	7.7
Upload speed (Mb/s)	0.3	3.4
Latency (ms)	657	45

### III. PROPOSED METHOD

#### A. Research Flow

Fig. 2 shows the research flowchart of the process. There are a few steps that need to follow in collecting the data by using the Nemo Outdoor

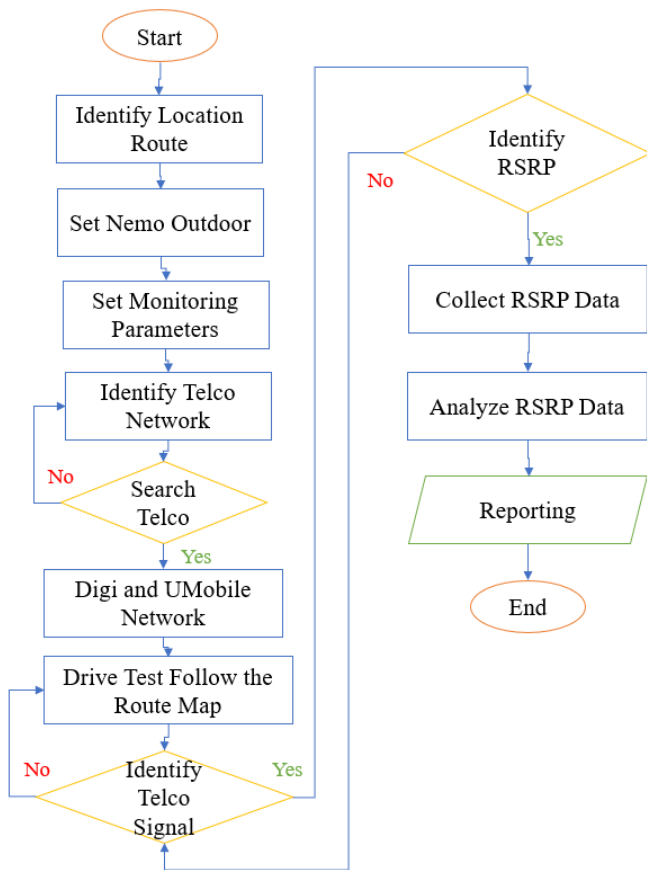

Fig. 2. Research Flowchart.

First, the task of checking or selecting the type of telecommunication network that can be identified around the campus area in Shah Alam is defined. Digi and U-Mobile were chosen based on the pre-trial where both signals gave the highest output in the communications signal. Next, the Nemo outdoor device and software is set for mapping signal is configured. After the configurations are justified and pretesting, the Nemo outdoor devices are to be ON while driving test followed by the route maps was tested. Data collections on the signal strength from Digi and U-Mobile have been set according to its frequencies on the Nemo Outdoor device. IF there are errors occurred then the driving test must be done again until the signal is collected successfully. During the drive test process, the data collection on the signal must be in real-time captured smoothly by time. Lastly, the result of the data collections is smoothly continued to be extracted from the Nemo software. Data is analyzed based on the defined wanted graph.

### B. Campus Route Map

The location of the route maps is defined to search for the RSRP Signal strength where setting is to be done on the Nemo outdoor. The Nemo Outdoor software then will open the maps to know the location of selected area for signal data collection. A Campus area has been selected which analysis on the data is important to present the reliability for students' connections in the campus who subscribed to the mobile data plan.

1) *Nemo monitoring tools*: The process of collecting the data is by drive testing which driver needs to ride the vehicle by following or marking the maps to get the data network signal and strength for RSRP. RSRP can be identified on the Long-Term Evolution (LTE) and 4G network. The admin for the data collector needs to insert a type of SIM card networks such as Digi or U-mobile into the smartphone of the Nemo Outdoor. This process is easier for data collection for each type of network, and it is read from the smartphone. Next, after the Handy Nemo software is activated from the admin or driver smartphone who drives the car according to routes of the campus map. The route of the campus maps also is mapping to the Nemo software. However, the route also can be created by the driver while driving the car. Table III shows the parameters for the used Nemo Outdoor analyzer.

TABLE III. DESCRIPTION OF NEMO OUTDOOR DEVICES

Type of Devices	Description
Laptop	<ul style="list-style-type: none"> <li>To open the software of the Nemo Outdoor</li> <li>To extract or transfer the data collect from the smartphone (Handy Nemo software)</li> </ul>
Smartphone	<ul style="list-style-type: none"> <li>Known as Handy Nemo devices in collecting the data network</li> </ul>
Dongle (Outdoor Measurement)	<ul style="list-style-type: none"> <li>The license to open the software of Nemo Outdoor</li> <li>To measure the measurement collection data</li> </ul>
Dongle (Outdoor Playback)	<ul style="list-style-type: none"> <li>The license to open the software of Nemo Outdoor</li> <li>To measure the data playback of the route</li> </ul>

Fig. 3 shows the handy Nemo Outdoor software with a specified setting and Fig. 4 shows the identified maps for data collections on the Digi network and U-mobile 4G network signals which have been linked to the laptop interface platform. Fig. 5 shows the Nemo Outdoor playback and measurement for the data signal collections.

Fig. 3. Handy Nemo Software.

Fig. 4. Interface of Maps to PC or Mobile.

Fig. 5. Outdoor Playback & Measurement.

2) *Digi and U-Mobile network*: The Digi and U-Mobile network has been identified for analysis based on the best pretesting signals achieved compared to the other providers. The references for checking the quality and strength of the 4G network have been established. The performance analysis has measured the RSRP for both Digi and U-Mobile network. RSRP is the average Resource Elements (RE) power that carries cell-specific Reference Signals (RS) across the whole bandwidth. Thus, RSRP is measured only in the RS symbols. RSRP is the average of one RS resource element received. Fig. 6 and Fig. 7 shows the driving test followed the route of maps of in the campus area for both networks.

Fig. 6. Digi 4G Network Map.

Fig. 7. U-Mobile 4G Network Map.

The Handy Nemo Outdoor has collected the data of each sector in the campus area in Shah Alam by following the routes map. The reading data on strength of the signal by the 4G network of Digi and U-Mobile are collected. The person in charge or driver needs to understand the condition of strength RSRP either it is Excellent, Good, Mid Cell, and Cell Edge while driving. Table IV shows the RF condition for the 4G signal strength. Additional quality can be measure by Reference Signal Received Quality (*RSRQ*), but it is not measured in this research.

TABLE IV. RADIO FREQUENCY (RF) CONDITION 4G SIGNAL STRENGTH

RF Condition	RSRP (dBm)	RSRQ (dB)
Excellent	$\geq -80$	$\geq -10$
Good	-80 to -90	-10 to -15
Mid Cell/ Medium	-90 to -100	-15 to -20
Cell Edge	$\leq -100$	$< -20$

3) *LTE signals strength*: RSRP is the average power received from a single Reference signal, and its typical range is around -44dbm (good) until -140dbm (bad) and the RSRQ is indicating the quality of the received signal, and its range is typical -19.5dB (bad) to -3dB (good).

- Identification of providers Signal

The identification of providers signal has been tested by using the Nemo Outdoor Software. This process needs to be done separately where the providers' signals will automatically be identified by the Nemo software. If the signals are undefined in the area the system will record as No Signal. Along the way while driving testing if the signal is changing the providers the system will record as Change Cells of network identification.

- RSRP Signal Strength

Nemo Outdoor Software is a multifunction for taking any data on wireless communication. The RSRP signal strength of the 4G network has been collected when the process identifies the provider's signal. The person in charge of the driving test needs to identify the signal strength of RSRP data collection. Some instructions must be followed to ensure the collection data signal strength of RSRP.

4) *Data Collection RSRP*: Two approaches can be done in collecting the data signals. First is the signal data can be request from the Research and Development team of each provider, but normally this approach is hard where data is confidential for outsiders. The second approach is where researchers must collect themselves the data based on the targetted area. Thus, Nemo Outdoor device and software is one of the most usable devices for data collections. Nemo outdoor provided data collections for RSRP strength of the 4G network. Few steps to be followed by the Nemo outdoor users for data collections in order the signal to be collected correctly without failed for data analyzing. The steps of setting up Nemo needs to be explored more where connections to the end devices like smartphone, laptop, and dongle of Nemo's license must be correct and properly running.

The research gaps have been identified such as the Performance, Speed, Frequency of 4G Network and RSRP Signal strength has been compared and identified in analyzing the performance of Campus Quality of Services Analysis of Mobile Wireless Communications Network Signal among Providers in Malaysia.

#### IV. RESULT AND ANALYSIS

##### A. RSRP Signal Strength

Fig. 8 and Fig. 9 show the data collection of Digi 4G Network and U-mobile 4G Network strength which is the RSRP signal for about an hour. The graph shows the condition strength of both networks was the same, but it has different

condition strength between each time in minutes. Result explained that most signals of LTE were greater than -100dbm, that means some of the area in the campus area have faced bad 4G/LTE signal of LTE.

##### B. Digi and U-Mobile RSRP Performance Analysis

The performance analysis for 4G/LTE signal strength is presented for both networks. The process of analyzing the collecting data which refers to the LTE signal strength is referred to Table IV. Result presents the 4G network signal strength based on the data referred to the reading of RSRP. The RF condition of the strongest signal was divided into four categories. First, Excellent that range is below and equal to -80dbm. Second, Good range from -80dbm until -90dbm. Third, Mid Cell range from -90dbm until -100dbm, and lastly cell edge was above -100dbm it shows that the signal strength was weak in those areas. Fig. 10 shows a five (5) hour data collection and Fig. 11 shows the best of RSRP signal strength that can be concluded that it has a few places that have a good 4G/LTE signal strength. The places that have the good signal strength of LTE were at the resident places which are the colleges, faculty, and cafeteria.

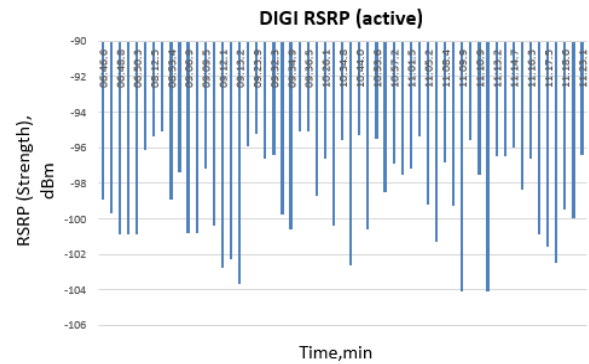

Fig. 8. RSRP Signal for Digi 4G Network.

Fig. 9. RSRP Signal for U-Mobile 4G Network.

Fig. 10. Digi 4G/LTE Signal Strength Network.

Fig. 13. Best U-Mobile 4G/LTE Signal Strength Network.

Fig. 11. Best Digi 4G/LTE Signal Strength Network.

Fig. 12 shows that some areas in the campus have a bad result of the signal strength of LTE or 4G network for U-mobile network. Some are having loss signal. Fig. 13 shows the best identified signal strength and most of the result from the signal strength in the campus area was only medium-range and cell edge signal strength. This is due to result shows the strength was mostly over and above from the -90dbm until -100dbm an above. Table V presents the comparison of Digi and U-Mobile RSRP identified form the research. It is identified that Digi supports better for the Mobile broadband network which shows an excellent of 1% and good connections of 29% and 0% signal loss in the drive areas. RSRP signal for U-Mobile shows there is 8% signal loss and the connections provided only at the Mid-Cell for 43% and Cell Edge connections for 48%.

Fig. 12. U-Mobile 4G/LTE Signal Strength Network.

TABLE V. DIGI AND U-MOBILE COMPARISON PERCENTAGE OF RSRP

RSRP Strength	Digi	U-Mobile
Excellent	1%	0%
Good	29%	0%
Mid-Cell	59%	43%
Cell Edge	10%	48%
No Signal	0%	8%

DiGi comes top for Download Speed Experience which presents DiGi users experienced the fastest overall mobile download speeds in Malaysia. This result has supported the Mobile Network Experience Report that presents 17.6 Mbps on average of 8% (1.3 Mbps) faster than Maxis’s users, 37.5%-40.4% faster than U Mobile and Unifi users, and almost 84% faster than those on Celcom broadband mobile network [23].

## V. CONCLUSION

This research has successfully analyzed the Quality of Services for 4G Wireless Network Communications among Providers in a campus network. Two main providers were analyzed which is Digi and U-Mobile which are most identified signal in the campus network. The transmission data of the LTE or 4G signal strength is identified which shows how the transmission data was done using the Nemo Outdoor. The transmission of signal strength of 4G has shown a different strength in each different place in the campus between the providers. Research also identified that data collection to analyse the problem of the quality and the performance of the signal strength that needs to improve. The used of NEMO Outdoor is a good platform for company telecommunication to get the signal and quality strength of the 4G network which is easy to detect and analyze the place that has the low 4G network signal strength. Future research recommendation is to try to make a network that can detect more different types of data analysed.

## ACKNOWLEDGMENT

The author would like to thank the Institute for Big Data Analytics and Artificial Intelligence (IBDAAI), Universiti Teknologi MARA, 40450 Shah Alam, Selangor, Malaysia for the support fund in publishing the paper.

# Exploring Alumni Data using Data Visualization Techniques

Nurhanani Izzati Ismail, Nur Atiqah Sia Abdullah\*, Nasiroh Omar

Faculty of Computer and Mathematical Sciences  
Universiti Teknologi MARA  
Shah Alam, Selangor, Malaysia

**Abstract**—Alumni data are mostly managed through paper-based and word file. With lots of alumni graduating each year, these massive data become difficult to handle. It is hard to look for past alumni data to know their current situation. Since the data is kept conventionally, there is no communication between the alumni and the faculty. Therefore, we proposed a solution that includes alumni information regarding their status in life where alumni themselves and individuals in the faculty can see. This study aims to visualize alumni data from a faculty in a public university through an exploratory dashboard using the identified data visualization techniques. This study adopts the dashboard development process consists of three major phases, which are conception, visualization, and finalization phase. The primary audience is identified and the theme for the dashboard is decided in the conceptual phase. The primary and support views are then designed together with the layout during the visualization phase. At the end of the study, the exploratory dashboard for alumni data using multidimensional and hierarchical data visualization is finalized with the interactive elements. The results are interpreted through descriptive and diagnostic analysis. The dashboard is then evaluated through convenience sampling technique to verify the representation of the dashboard. Majority respondents agreed on the simplicity of exploratory dashboard and the amount of data is also sufficient with the selection of the visualization types. The dashboard is beneficial to the university's administrator, alumni, and public.

**Keywords**—Alumni; descriptive analysis; diagnostic analysis; data visualization; exploratory dashboard

## I. INTRODUCTION

Alumni is classified as a significant secondary source of revenue [1]. Alumni are one of the important resources for the university. They are the individuals who symbolize the university within the world. Numerous alumni networks were at first began from regional groups of alumni united for university fundraising activities. These associations gradually obtained an added significance within the evolution of the university due to their tremendous advocacy capability that assists the university and prepares students in their future profession.

By connecting with alumni, a university can keep on profiting from their abilities and knowledge. Alumni management is straightforwardly related to the amplification impact of alumni resources in this technology era. The issue is that the conventional alumni data management system is hard to adjust to the large alumni groups and the massive amount of data [2]. The current method used by the university in

managing alumni data is through the traditional way where the alumni management staff is maintaining paper-based documents to store the information, for example, alumni and college details.

Thus, it is hard to sustain the past information and important data through a paper-based method. Staffs require more time to create required alumni reports. It is dreary to administer past information, which requires much room to store every one of the past year's records and documents paperwork. For example, Universiti Teknologi MARA is among the public university in Malaysia and has branches in every state in the country. Thus, they have a lot of alumni every year and without data visualization, it will be hard to trace the alumni current situation or where they are going after they finish their study.

There are several universities in Malaysia that embodied data visualization in their systems for alumni, but the visualization is limited to certain criteria. This paper proposes an alumni data visualization through an exploratory dashboard using identified data visualization techniques. This study uses the data from alumni of the Faculty of Computer and Mathematical Sciences, Universiti Teknologi MARA, Malaysia. The data are the alumni general academic program data and employment data, without containing any personal information. These alumni data are visualized using multidimensional and hierarchical data visualization.

The paper consists of five sections. It starts with Section I Introduction; continues with Section II Related Works. It follows by Section III Methodology to report on the methods used in this study. Then, Section IV includes the results and discussion, and the last section concludes the study.

## II. RELATED WORKS

### A. Data Visualization

Data visualization is the act of presenting data or information into a pictorial or graphical context, such as a chart, a map, or other visual formats, to make information uncomplicated for the human brain to comprehend and understand [3].

Data visualization is a sector that corporates data from numerous fields, for example, psychology which examines the data insight and the effect of certain components on data insight, next is the computer science and statistics field which expanded ideas in the new area like artificial intelligence and

data mining methods [4]. The visual and multimedia design field is also crucial to assembling infographic dashboards which involve a few elements including data, scales, lines, bars, and colored shaped sizes.

**B. Types of Data Visualization**

Some of most popular data visualization types are temporal, hierarchical, network, multidimensional, and geospatial data visualization. These data visualization types have different criteria and strengths in representing the alumni data.

1) *Temporal Data Visualization*: Data that have progressive values significant and recorded. Temporal visualizations usually include lines that either remains solitary or overlap with one another, with a beginning and end time [5]. Examples of temporal data visualization are scattered plots, line graphs, and polar area diagrams. This type of data visualization can represent the changes of data in timeline form. The parameters used in the alumni visualization are not suitable for temporal data visualization because there are no data on time-related. Thus, this study does not use the temporal data visualization.

2) *Hierarchical Data Visualization*: Information that can be organized as a tree [6]. The connection between the parent nodes and the child nodes forms a tree network. It shows how information was positioned and arranged together in a system [7]. Examples of hierarchical data visualization are treemap charts, tree diagrams, and sunburst diagrams. This type of data visualization can be used in data consisting of main categories and sub-categories. This study use a treemap chart to visualize alumni job category based on their domain.

3) *Network Data Visualization*: A set of nodes with links interfacing with the nodes [8]. Nodes stand for data points, and links represent the associations between them [9].

Examples of network data visualization are matrix charts, node-link diagrams, and word clouds. This data visualization is widely used on social media platforms such as Twitter and Instagram. Since the alumni data in this study has no relationship between parameters, network data visualization is not suitable to be used as the alumni data do not involve any associations among the dataset.

4) *Multidimensional Data Visualization*: It analyzes various data dimensions or qualities [10]. Multidimensional data visualization includes simply looking at distributions and possible connections, patterns, and relationships among these qualities. Examples of multidimensional data visualization are bar charts, Venn diagrams, and pie charts. Among all the five types of data visualization, multidimensional is commonly used for the dataset because the alumni data consists of many parameters that are suitable for multidimensional as it allows representation of multiple categories in the dataset.

5) *Geospatial Data Visualization*: It is the earliest type of data visualization [11]. Geospatial data visualization covers factors on a map using latitude and longitude to encourage understanding. Examples of geospatial data visualization are choropleth maps, cartograms, and heat maps. This data visualization is used for data that has locations and involve the use of the map. In alumni data visualization, choropleth is suitable to visualize alumni location because it uses values on a specific region on the map. However, we exclude this location information due to the privacy issue.

From Table I, two types of data visualization are more suitable to represent the relationship between alumni datasets in this study. Multidimensional data visualization and hierarchical data visualization can visualize multiple data variables such as alumni general data and alumni employment data, and it is easier to interpret the data and extract the information from the data.

TABLE I. COMPARISON OF DATA VISUALIZATION

Characteristic	Types of Data Visualization				
	<i>Temporal</i>	<i>Hierarchical</i>	<i>Network</i>	<i>Multidimensional</i>	<i>Geospatial</i>
<b>Type of data</b>	Time series, the event sequences	Data which have main category and sub-category	Relationship between nodes and links	Multiple data parameters and categories	Data involving geographical location
<b>Usage</b>	Use in climate data, and historical presentation	Use in politics, mathematics, or organizations	Use in social media platform	Use in medicine and social sciences	Use in Google maps, and weather maps
<b>Technique</b>	Scatter plot, Line graph, Polar Area, Time Series	Tree Diagram, Sunburst Diagram, Tree Map Chart, Circle Packing	Matrix Chart, Node-Link Diagram, WordCloud, Sankey Diagram	Stacked Bar Chart, Pie Chart, Venn Diagram, Histogram	Choropleth Map, Density Map, Cartogram, Heat Map
<b>Justification for the usage of data visualization in the proposed alumni data visualization</b>	The parameters use in the alumni visualization is not suitable for temporal data visualization because there are no time-related data.	Can be used in data consists of main category and sub-category. This study uses treemap chart to visualize alumni job category based on their domain	<i>The alumni data used in this study are simple data, network data visualization is not suitable to be used as the alumni data do not involve any associations among the datasets.</i>	Multidimensional is commonly used because the alumni data consists of parameters that allows representation of multiple categories in the dataset.	The alumni data used in this study is not suitable for geospatial data visualization because there are no data on alumni state of origin.

C. Alumni Data Visualization

This section focuses on analyzing five existing alumni data visualization models from foreign and Malaysia local universities.

1) *Graduate Alumni Salaries – University of Colorado Boulder*: It develops a data visualization for its alumni based on their salaries as shown in Fig. 1. This university used multidimensional, geospatial and hierarchical data visualizations [12]. The multidimensional data visualization is horizontal bar charts to visualize the alumni salaries, the job category and the employer category. The geospatial data visualization is a choropleth map to show the employer location by state. A treemap, which is a hierarchical data visualization, shows the top industries category where it displays categories similar to each other and any correlations between them. This data visualization has a filter feature to enable the user to search data based on specific keywords. This data visualization does not use temporal and network data visualization as it does not have any parameters that are suitable for that type of data visualization. This data visualization uses three colors, which are chocolate, grey and black. The use of three colors give a simpler and neat look. The visualization does not look crowded and messy.

2) *Mapping Institutes of Fine Arts (IFA), New York University Alumni*: It develops a data visualization for their alumni, which shows the current employment status of their active alumni as shown in Fig. 2 and Fig. 3 [13]. This institute uses network and multidimensional data visualizations. The network data visualization used is a network map that shows the current employment location of alumni where it shows how the different location is interconnected from one node to other nodes through link lines. The multidimensional data visualization used is a vertical bar chart to visualize the type of employment of the alumni. In this data visualization, several colors are used to represent the employment categories and display them in the bar graph. This data visualization does not use geospatial, temporal or hierarchical data visualization because the dataset involved is not related to this type of data visualization. This data visualization also uses a filter feature to enable the user to search alumni data based on institutes and people.

3) *Alumni of Universiti Malaysia Sarawak*: The university developed a data visualization for their alumni, which shows the number of alumni graduates from each faculty from 2006 to 2015 [14]. This data visualization used multidimensional data visualization and display data insight for the website visitor as shown in Fig. 4. The university used a stacked bar graph to show the trend of alumni graduates based on their level of study. This data visualization does not use an interactive dashboard. Thus, the visitor can only view the website for the alumni data and they cannot interact with the data. This data visualization only uses multidimensional. Thus, the presentation of data is not complete as it only visualizes the number of alumni who graduated. The alumni visualization developed in this research study can enhance this

issue by implementing the interactive dashboard for the alumni and incorporating other types of visualization to represent different types of alumni data.

Fig. 1. Data Visualization for Graduate Alumni Salaries.

Fig. 2. Network Data Visualization for Institutes of Fine Arts.

Fig. 3. Multidimensional Data Visualization for Institutes of Fine Arts.

Fig. 4. Data Visualization for Universiti Malaysia Sarawak Alumni.

4) Alumni of Universiti Islam Antarabangsa Malaysia:

The univeristy has developed a data visualization for its alumni, which shows the total numbers of local and international alumni [15]. This interactive data visualization used geospatial data visualization to display the number of alumni based on the country of origin as shown in Fig. 5. It used a choropleth map to visualize the geographical area where it will display the number of alumni based on the state. The university does not use an interactive dashboard for their data visualization as they only implement visualization for alumni state. The visitor can hover over the map and the number of alumni is displayed for the country chosen. Since this data visualization only uses geospatial, a lot of alumni data are not shown and the visualization looks simple. The visualization can be enhanced by including more types of data visualization so that more alumni data can be visualized to user.

two types of data visualization in order to visualize the alumni general data and alumni occupation data.

From Table II, the existing data visualization developed by the University of Colorado Boulder shows the best data visualization method and suitable to be adopted in this study. This is because the data visualization used by the university is multidimensional data visualization, hierarchical data visualization and geospatial data visualization. In this study, we adopt this technique to visualize alumni general data and alumni employment data.

Fig. 5. Data Visualization for Universiti Islam Antarabangsa Malaysia Alumni.

5) Alumni Data of Heritage College of Osteopathic Medicine, Ohio University:

The university developed a data visualization for their alumni, displaying the percentage of alumni practising area and specialization [16]. This interactive data visualization used multidimensional and hierarchical data visualization to visualize the alumni data as shown in Fig. 6 and Fig. 7. A multidimensional data visualization used in this system is the pie charts to show the percentage of alumni practicing and training areas in the primary and non-primary sectors. While the hierarchical data visualization used is a treemap chart to show the number of alumni based on their specialization. In the pie chart, several colors are used to represent the keyword for the alumni practicing sectors. The pie chart has also been divided into four sections with four different colors to enable the user to see the data explicitly and differentiate it. The treemap chart also been divided into four different categories for the alumni specialization. This research study will include these

Fig. 6. Multidimensional Data Visualization for Ohio University Alumni.

Fig. 7. Hierarchical Data Visualization for Ohio University Alumni.

TABLE II. COMPARISON OF EXISTING MODEL OF ALUMNI DATA VISUALIZATION

Characteristic	Existing Model of Alumni Data Visualization				
	<i>University of Colorado Boulder</i>	<i>Institutes of Fine Arts (IFA), New York University</i>	<i>Universiti Malaysia Sarawak (UNIMAS)</i>	<i>Universiti Islam Antarabangsa Malaysia (UIAM)</i>	<i>Heritage College of Osteopathic Medicine, Ohio University</i>
Category of data visualization	Multidimensional, Hierarchical and Geospatial data visualization	Network and Multidimensional data visualization	Multidimensional data visualization	Geospatial data visualization	Multidimensional and Hierarchical data visualization
Technique	Bar graph, treemap chart and Choropleth map	Network map and bar graph	Stacked bar graph	Choropleth map	Pie chart and Treemap
Strength	Search and filter function to enable user to search for specific data easily, Use of simple colors that make the dashboard look neat and not messy	Several colors are used to represent the employment categories and display in the bar graph and use of search and filter function	University used stacked bar graph to show the trend of alumni graduates based on their level of study	Used choropleth map to visualize the alumni state. Visitor can hover over the map and the number of alumni is displayed for the country chosen	The pie chart divided into four sections with different colors to enable user to see the data explicitly. The tree map chart divided into four different colors to indicate the different alumni specialization
Drawback	No use of network and temporal data visualization because no data related to time and association.	Do not use geospatial, temporal and hierarchical data visualization because the dataset involved is not related to this type of data visualization	Do not use an interactive dashboard. Thus, the visitor can only view the website for the alumni data, and they cannot interact with the data. This data visualization only uses multidimensional. Thus, the presentation of data is not completed	Do not use an interactive dashboard for their data visualization. Use geospatial data visualization to visualize alumni state, many alumni data are not shown, and the visualization looks simple	Do not use geospatial, temporal and network data visualization because the dataset involved is not related to this type of data visualization
Comparison to research topic	The use of the same type of data visualization to visualize the alumni data but with more parameters and categories	The use of the multidimensional data visualization for several data types in the alumni dataset	Alumni visualization developed in this research study can enhanced this issue by implementing the interactive dashboard for the alumni and incorporate other types of visualization to represent different types of alumni data	Inherit the geospatial data visualization from the university but including more type of data visualization so that more alumni data can be visualized to user	Include the same types of data visualization to visualize the alumni general data and alumni occupation data.

This study uses multidimensional data visualization the most because the dataset used has many parameters. This study uses the same technique to visualize alumni employment data based on their salary range. The study also uses hierarchical data visualization to show alumni job domain. The data visualization also enables the search and filtering function.

### III. METHODOLOGY

This study aims to develop an interactive dashboard with the visualization of alumni data for the alumni. It adopts the dashboard development process throughout the development phase [17]. The dashboard development process consists of three main phases, which are the conception phase, visualization phase and finalization. In this study, there are three types of alumni data that will be used to develop the dashboard for alumni visualization. The alumni data include alumni general data (gender, age range, and program name), and alumni employment data (job domain and salary range).

#### A. Conception Phase

There are three main activities during this phase. The first activity is to identify the primary audience for dashboard. The second activity is the main questions. The third activity is the theme.

- Identify primary audience: In this study, the primary end-user audience for the interactive dashboard is the alumni management staff of the university. The alumni of the university, parents, and public can also view the exploratory dashboard.
- Main questions: The questions focus on the purpose of the dashboard development and what the dashboard can do to answer the user's questions. Nine questions serve as the main ideas for the exploratory dashboard. The list of questions ensures that an exploratory dashboard can be developed and delivered based on these ideas. The list of questions is created based on several websites.
- Theme: this study aims to develop the exploratory dashboard, which uses the types of data visualization to answer the main questions. Alumni general data will be visualized by using hierarchical and multidimensional data visualization. Alumni employment data will be visualized using multidimensional data visualizations.

#### B. Visualization Phase

Three main elements need to be considered during this phase. The first element is the primary views. The second

element is the support views. The third element is the layout. During this phase, a prototype for the alumni data visualization is designed.

- Primary views: The primary views are views that visually address the main questions gathered for the specific users and align with the theme that has been selected.
- Support views: The support views are the contributory or helpful views that support, refine or add context to the primary views. For instance, the search or filtering function where the dashboard enables users to engage with the dashboard by enabling searching for alumni by state or filtering the alumni data by years of graduation or by salary range.
- Layout: It is a placement and alignment of views that focus users' attraction on the primary views and supporting views placed around them and visual indicators highlighting how the support views interact with primary views.

### C. Finalization Phase

In the finalization phase, there are two main activities taking place. The first main activity is the interactive elements. The second activity is perfect and feeling. At the end of this phase, evaluation is carried out through convenience sampling to evaluate the exploratory dashboard based on certain factors.

- Interactive elements: The interactions between the primary views and the supporting views are set up in a logical, progressively detailed sequence during this activity.
- Perfect and feel: The alignments, the fine-tune color, fonts, and fonts consistency will be finalized and ensure adherence to visual standards.

## IV. RESULTS AND DISCUSSION

This study developed an exploratory dashboard of alumni data visualization for Universiti Teknologi MARA. The alumni data visualization is illustrated in several diagrams of the preliminary design using Power BI.

### A. Pre-Processing in Power BI

The secondary data has approximately 714 alumni from three cohorts including graduate from March 2020, November 2020, and June 2021. The cleaning process filtered private and personal information. After that, we examine the dataset to discover any issues on the data that can lead to incorrect analysis and avoid from showing the irrelevant result.

In this study, there are two major tables for the alumni dashboard visualization. These two tables consist of alumni data for cohorts 2020 and 2021. The chosen columns are year of graduation, age, gender, program name, job domain, and salary range. From the columns, multidimensional data visualization is used to visualize alumni age range, gender, program name, and salary range. Meanwhile, hierarchical data visualization is used to visualize alumni job domains. This alumni data visualization embedded filtering function by using slicers.

The data columns in the slicers are year of graduation, gender, salary range and the job domain. Before creating the exploratory dashboard, a theme for the alumni data visualization has been decided and applied to ensure that all report items or panels are consistent. In this study, the alumni exploratory dashboard uses a blue and grey colour as an overall theme for the dashboard. The exploratory dashboard has two retrospective pages. The exploratory dashboard is specific to overview alumni data and their employment details.

### B. Descriptive Analysis

Fig. 8 shows the visualization of the alumni details based on the total number of alumni, the gender, the age range, the program name, and the job domain for the alumni.

The top of the dashboard displays the total number of alumni. About 500 of them are female alumni while 214 alumni are male. The data for the gender of alumni are represented using a pie chart that communicates a part-to-whole connection within the data. The age range is represented in the format of a horizontal bar graph. Alumni's ages ranged from 24 to 30 years old with 70.03% identified as female while another 29.97% identified as male alumni.

There are 10 programmes offered in this dashboard and represented using vertical bar graph. The program with highest number of alumni is Bachelor of Actuarial Science with 164 alumni and majority are female. The second highest number of alumni is Bachelor of Information Technology with 106 alumni.

Fig. 8. The Visualization of Alumni General Data.

In terms of job domain, the data is represented in the form of a tree map chart. Most of the alumni were successfully employed in their respective field of study which is computer science with 56.3% which is equivalent to 402 alumni. Most of the alumni who are working in the computer science domain work as system analysts, programmers, and web developers. However, some of the alumni are working in other sectors that are not related to their field of study.

Fig. 9 shows the visualization of alumni salary range in six categories based on the job domain. The data are visualized through multidimensional data visualization by using horizontal bar graph. For the job domain in computer science,

most of the alumni have a salary range from RM2501 to RM3000. Majority of the alumni are working as system analysts, web developers and programmers. The job domain with the highest number of alumni is in the administration field that a salary ranging from RM1001 to RM1500. It is a challenge to the university to ensure that the graduates can be employed in the related field to their studies.

Fig. 9. The Salary Range of Alumni based on their Program.

### C. Diagnostic Analysis

In this study, there are several anomalies and abnormal occurrences from the alumni data visualization. There are several alumni work in the job domain that are irrelevant to their field of study in the university. For example, aside from the computer science field, most of the alumni are working in the administration line of work as admin assistants, executive, salespeople, operator, and teachers.

Most occupations in computer science field require specific skills such as knowledge in multiple programming languages and proficiency in coding a software program. Some alumni may feel not confident to pursue their career in the computer science field. Thus, they change their interest to work in the field that they are comfortable with. The observation result is aligned with the finding from the study done by Salas-Velasco [18] on education-job mismatch in the labour market for graduates of universities.

Secondly, there is an anomaly in the alumni salary's visualization. Unfortunately, some alumni are working in computer science with a low salary of RM1500 and below. According to recruiting businesses and analysts from the article reported by Institute of Strategic and International Study (ISIS) Malaysia on their website, fresh graduates in computer science have low beginning salaries because they lack digital skills in an increasingly competitive market and an uncertain economy [19].

Some of the software businesses that hire these fresh graduates are usually start-up companies that unable to offer a high beginning salary for the fresh graduates. With the high competition for employment in gigantic computer science companies in Malaysia, some alumni have no choice but to accept the offer from the small company with the lowest salary paid.

### D. Evaluation

After developing the exploratory dashboard for the alumni data visualization, an evaluation is done by conducting a convenience sampling method using survey form.

The alumni data visualization is evaluated based on the simplicity, choice of visualization, layout, filtering features, and view of the exploratory dashboard in mobile phone. Majority respondents agreed on the simplicity of exploratory dashboard. They can interpret easily. The amount of data is also sufficient as there are no data overload that led to messy representation of the alumni data visualization. Most respondents also agreed on the selection of the visualization types. However, they suggested the change of color to a brighter tone. Most of the respondents agreed and were satisfied with the arrangement of the layout for the visualization.

The respondents suggested to enlarge the font size to ease the view the information from dashboard. Most respondents agreed that the filtering function is useful as it enables them to navigate throughout the data visualization and locate the specific data and information. The filtering function encourages the interactivity between the viewer and the data visualization. The respondents can navigate the data visualization by hovering over the chart and viewing the information of that specific chart. They also can select the data by filtering data from the slicers.

Most respondents agreed that the display in mobile view is quite inconvenience and difficult to navigate compared to the desktop view. Overall, the respondents were satisfied viewing the exploratory dashboard as they enjoy the navigation from one chart to another chart to visualize the alumni data.

### E. Challenges

The greatest concern in this study is the privacy issue related to alumni personal information such as home addresses, grade point, and working place. The original data set need to be pre-processed before it can be used to develop the exploratory dashboard to ensure that the private information of the alumni is eliminated from the study following the ethics of research. This can be seen as a limitation since the alumni data visualization dashboard are not able to display more variety of data visualization types such as temporal data visualization, network data visualization, and geospatial data visualization.

## V. CONCLUSION

The importance of this study is to use data visualization in presenting alumni data through an exploratory dashboard and visualization techniques. The dashboard development process consists of three main phases, which are the conception phase, visualization phase and finalization. The exploratory dashboard is developed to visualize the alumni data using multidimensional and hierarchical data visualization techniques. The multidimensional data visualization includes a pie chart to visualize the gender of the alumni and a horizontal and vertical bar chart to visualize the age range, program name, and salary range of the alumni. The hierarchical data visualization includes a tree map chart to visualize the job domain of the alumni.

This alumni data visualization included a filtering function by embedding slicers in the exploratory dashboard to enable visitors to interact with the alumni data. The evaluation uses a convenience sampling method. The majority of the respondents expressed their satisfaction in evaluating the dashboard as they enjoy the fun of navigating from one chart to another chart to observe the alumni data. This dashboard can be used by the university's administrator to identify the gap between the qualification and salary range, and the relativeness of the job domain.

For future study, it is recommended to include other data fields such as state and alumni working place to have geospatial data visualization, and alumni networking data to be able to visualize network data visualization. It is recommended to have other alumni data that can support the other chart of types of data visualization such as the scatter plot, sunburst diagram, node-link diagram, and cartogram so that the alumni data visualization exploratory dashboard can be more informative and insightful.

#### ACKNOWLEDGMENT

The authors express gratitude to Faculty of Computer and Mathematical Sciences, Universiti Teknologi MARA for supporting this publication. The authors acknowledge the Ministry of Higher Education (MOHE) for funding under the Fundamental Research Grant Scheme (FRGS) (FRGS/1/2018/ICT04/UITM/02/9) and 600-IRMS/FRGS 5/3 (209/2019).

**Abstract**—Early detection of the coronavirus (COVID-19) disease is essential in order to contain the spread of the virus and provide effective treatment. Chest X-rays could be used to detect COVID-19 at an early stage. However, the pathological features of COVID-19 on chest X-rays closely resemble those caused by other viruses. The visual geometry group-16 (VGG16) deep learning algorithm based on convolutional neural network (CNN) architecture is commonly used to detect various pathologies on medical images automatically and may have a role in the detection of COVID-19 on chest X-rays. Therefore, this research is aimed to determine the robustness of the VGG16 architecture on several chest X-ray databases that vary in terms of size and the number of class labels. Nine publicly available chest X-ray datasets were used to train and test the algorithm. Each dataset had a different number of images, class compositions, and interclass proportions. The performance of the architecture was tested using several scenarios, including datasets above and below 5,000 samples, label class variation, and interclass ratio. This study confirmed that the VGG16 delivers robust performance on various datasets, achieving an accuracy of up to 97.99%. However, our findings also suggest that the accuracy of the VGG16 algorithm drops drastically in highly imbalanced datasets.

**Keywords**—Covid-19; Chest X-Ray; CNN; transfer learning; VGG-16

## I. INTRODUCTION

X-ray images are often used to detect changes in the lungs, such as pneumonia caused by viral infections. Pneumonia is also one of the key indicators of an infection caused by coronavirus disease (COVID-19). However, the manual evaluation of X-ray images is time-consuming and often subjective. Artificial intelligence (AI) could be used to automatically distinguish infected and infection-free patients by extracting specific shapes and spatial features visible on chest X-ray images. Many studies have been carried out using X-ray images to detect Middle East Respiratory Syndrome Coronavirus (MERS CoV) since there are features on chest X-rays and CT that resemble pneumonia manifestations [1]. A convolutional neural network (CNN) model has been developed to identify the nature of the pulmonary modulus on CT images and diagnose pneumonia on chest X-ray images [2].

COVID-19 symptoms include cough, fever, dyspnea, and respiratory problems. In more severe cases, COVID-19 can cause pneumonia, acute respiratory distress, septic shock, failure of internal organs, or even death [4]. Reverse-transcription-polymerase chain reaction (RT-PCR) of samples obtained from either blood or the respiratory system is often used to diagnose COVID-19. Furthermore, due to the highly infectious rate of COVID there is a high demand for this service which leads to further delays to obtain the test results. Therefore, in the emergency department, the initial diagnosis of symptomatic patients is more likely to be done through a plain chest X-ray or CT scan. The early identification of COVID-19 on plain X-rays or CT images is essential to isolate patients and hence minimize the spread of the disease as well as to treat infected patients more effectively.

Bilateral pulmonary parenchymal ground-glass and consolidative pulmonary opacities, with a rounded shape and a peripheral lung distribution, are common chest X-rays in COVID-19 patients [3]–[5]. Pneumonia is also an important indicator of COVID-19. However, these pathological features may closely resemble those caused by other viral infections, which makes it difficult for the radiologist to identify the type of infection. Deep learning algorithms based on convolutional neural network (CNN) architecture could be used to identify specific COVID-19 features on X-ray images.

CNN algorithms are easy to model and reliable. As a result, they are currently the most widely used artificial intelligence (AI) model for the detection of COVID-19 on X-ray images [6]–[13]. We reviewed several studies that made use of the CNN architecture to diagnose COVID-19 on chest X-rays, as shown in Table I. Our findings indicate that the CNN model developed by the visual geometry group with 16 depth layers (VGG16) has been applied in about 50% of the COVID-19 studies [6], [8], [9], [13]–[15]. The VGG16 also performed very well when compared with other established models. However, although studies based on the VGG16 models reported high levels of accuracy, research on COVID-19 is still evolving. Furthermore, most of the studies were based on a single dataset, potentially limiting the generalizability of the model. Therefore, the efficacy of the VGG16 model needs to be tested further on new emerging datasets. Because of these facts, we assessed additionally; we aimed to identify more

\*Corresponding Author.

pathological features on chest X-rays indicative of COVID-19 and other infectious diseases. This research contributes by testing the performance of VGG-16 on large, popular datasets and determining its level of accuracy. The results of this study will help to detect indications of COVID-19 more accurately in x-ray images and obtain alternative diagnoses of symptoms similar to those of COVID-19.

## II. METHODS

The research framework was divided into four steps: identification of publicly available chest X-ray datasets, image preprocessing, training and finally testing of the VGG16 algorithm, as shown in Fig. 1.

### A. Data Collection

Several publicly available image data repositories were searched using the keywords "COVID-19 X-ray". The search yielded 28 datasets composed of chest X-ray images used to diagnose COVID-19. The files within these datasets were reviewed to ensure that they contained chest X-ray imaging files that could be read by the COVID-19 detection system. Only the data set including big data i.e. containing more than 1000 images were included in the study. A total of nine datasets met the inclusion criteria. The final total datasets consisted of a total of 38,181 X-ray images. The images were classified into four categories: normal, pneumonia, viral pneumonia, and COVID-19, as shown in Fig. 2. However, the number of classifiers varied between the different datasets. The dataset source, the total number of images, and the number of classifiers within each dataset are summarized in Table II. Table II shows sample images for each class and the percentage number of images per class.

### B. Image Preprocessing

The VGG16 architecture uses a kernel size of 3x3 with an input image of 224x224x3 for the width, height, and channel, respectively [29]. In the preprocessing stage, the VGG16 input

was scaled to 224x224 pixels. The images of the classes were randomly extracted, and finally 80% were used to train the algorithm, 20% were used for validation, and the final 10% were used for testing as shown in Fig. 3.

Fig. 1. Chest X-rays Illustrating the Four Different Classifiers used in the Datasets.

TABLE I. SUMMARY OF RESEARCH STUDIES COMPARING THE ROBUSTNESS OF SEVERAL CNN ARCHITECTURES FOR THE DETECTION OF COVID-19 ON CHEST X-RAYS

### C. Application of the Convolutional Neural Network

CNN architectures are commonly used in computer vision and involve a convolution operation between the input signal and the filter. An important step in the development of the CNN algorithm involves the use of data pooling and convolution operations. During data pooling, the datasets are downsampled by averaging the data (average pooling) or by obtaining the maximum value (max pooling). In this case, the input signal features were derived from the chest X-ray image, which is commonly represented as  $n*m*c$ , whereby  $n$  and  $m$  represent the image width and length, respectively, and  $c$  represents the color channels. For example, in a typical red-green-blue (RGB) image with a pixel matrix size of  $256 \times 100$ , the input matrix would be defined as  $256 \times 100 \times 3$ . Convolution and pooling operations reduce the complexity by extracting only the important features. For example, an input signal consisting of 75,000 features can easily be reduced into 512 features by applying several convolution layers.

Several CNN-based architectures have been proposed in the last decade. Lenet-5 architecture was the first to propose a CNN-based architecture to solve a simple handwritten digit recognition problem [30]. The work was based on the older concepts of neural networks and back-propagation. The big leap of CNN-based algorithms was enabled by the availability of a large, labeled image dataset called Imagenet [31]. The dataset currently contains around 14 million labeled images, and it was initiated in 2009 by an artificial intelligence lab at Stanford University. Alexnet is the second most well-known CNN architecture that had won the Imagenet Large Scale Visual Recognition Challenge in 2014 [32].

The VGG16 model was initially proposed by Simonyan et al. [29] and it secured first place for object localization and second place for object classification in the Imagenet Large-Scale Visual Recognition Challenge 2014 (ILSVRC 2014). Since then, numerous other CNN architectures have been proposed including Inception net [33], ResNet [34], Inception-v4 and Inception-ResNet [33], Mobilenet [35], MobileNet V2 [36], EfficientNet [37] and XceptionNet [38].

The building block of the CNN architecture consists of two fundamental components: a convolution layer and a pooling layer. The filter size, padding, stride, activation function, and connection between layers can be manipulated to improve the performance of the algorithm. In order to improve the performance of the algorithm, the raw image signal has to be converted into a more straightforward representation before applying the classification task. The large number of images available on the Imagenet database could be used to train and compare the performance of various algorithms. Once an architecture has been trained and tested on the Imagenet images, researchers can ascertain the performance of their architectures and determine the weight parameters.

Transfer learning is a commonly used method in computer vision that applies the knowledge gained from the training of a network to solve a specific problem to a new similar scenario. This eventually reduces the time required for the training process allowing for the development of accurate algorithms in a shorter amount of time [29]. For example, if a pre-trained network previously developed to classify 1000 classes is now used for binary classification, the top layer (last layer) is adjusted so that the output is changed from 1000 into two classes only. The weight parameters also have to be updated in all network layers or for some of the layers. However, the learning process does not begin from scratch; instead, it starts with the pre-trained weight that has been applied to solve the previous problem.

Most model architectures such as VGG16, InceptionNet, mobilenet, and XceptionNet were trained on a large dataset such as Imagenet. As a result of the high computational cost incurred during training, an improved model was developed. Canziani et al. [39] conducted a comprehensive analysis of the performance of pre-trained models on computer vision challenges using data from the Imagenet [31] database. In computer vision, the transfer approach is popular because it enables the generation of accurate models in a shorter amount of time [40].

A typical CNN classification task has a feature generator and a classifier. The feature map generator input are the raw images, followed by a stack convolution and pooling layers. The main goal of the feature generator is to produce an array representing the input image in a smaller amount of data. On the other hand, the classifier's task is to categorize the feature into certain target classes. This task can be performed by classic classifiers such as support vector machines and decision trees. Another option is to place the fully connected layers on top of the feature generator. A fully connected layer is one whose neurons fully connect to all activations in the previous layer. The number of layers in the fully connected layer is significant and could be optimized by the researcher manually. The depth of the fully connected layers should be taken into account as it relates to the overfitting problem of the entire network. The deep learning approach independently computes the important input features during the learning process. Unlike the classical AI algorithm whereby the features extracted by the algorithm are based on the objective of the classification task and the image input, deep learning models learn hierarchical features by adjusting weight parameters on the CNN-based feature generator. The pattern of the input is then captured by the network and is then used as the input of the classifier. The pattern for a specific problem domain is accurately recorded as the weight parameter value. In transfer learning, the set of values can be applied to another specific problem domain.

Transfer learning involves two key steps. The first step involves selecting a pre-trained model, such as VGG16 [29], InceptionV3 [41], and ResNet5 [34], to fit the target problem. The second step involves the identification of features based on the size of the dataset and the similarities between the pre-trained dataset and the dataset we used. The comparison between the pre-trained dataset and our characteristics dataset could result in one of the following four transfer learning problems whereby the new problem dataset are:

- 1) large but dissimilar from the pre-trained dataset
- 2) large and highly similar to the pre-trained dataset
- 3) small and highly similar to the pre-trained dataset
- 4) small and dissimilar from the pre-trained dataset

In deep learning, a dataset consisting of 1000 labeled images per class is considered to be small. Dataset similarity refers to the availability of the same problem subset in the pre-trained dataset. For example, if the task is to recognize dogs and birds using a pre-trained network that has been trained on an Imagenet dataset since the dataset contains dog and bird classes, we can consider that the dataset is highly similar. However, in this paper, we classified the visual pathological features of COVID-19 patients through visible X-ray images which were not available in the Imagenet dataset. Hence, our transfer learning problem was due to a small dataset dissimilar from the pre-trained dataset.

This study employed the VGG16 [41], a pre-trained CNN-based architecture that consists of 16 CNN layers. The VGG architecture has already been applied in many medical image classification tasks [42]. This research provides an evaluation and comparison of the performance of various architectures in detecting COVID-19 on various chest X-ray datasets.

The comprehensive evaluation was made based on the accuracy achieved by the VGG16 architecture when applied to different datasets. Since the number of classes within the dataset varied, the multiclass confusion matrix was used to determine the robustness of the VGG16. Table III illustrates a confusion matrix with  $n$  classes, including the experimental results obtained for each scenario.

TABLE III. MULTICLASS CONFUSION MATRIX

		Predicted Number			
		Class 1	Class 2	...	Class n
Actual Number	Class 1	$x_{11}$	$x_{12}$	...	$x_{1n}$
	Class 2	$x_{21}$	$x_{22}$	...	$x_{2n}$
	...	...	...	...	...
	Class n	$x_{n1}$	$x_{n2}$	...	$x_{nn}$

Furthermore, the performance of the VGG16 model was quantified by calculating the total numbers of false-negative (TFN), false positive (TFP), true negative (TTN), total true positive (TTP) for each class  $i$  based on the general equations 1 to 4.

$$TFN_i = \sum_{j=1, j \neq i}^n x_{ij} \quad (1)$$

$$TFP_i = \sum_{j=1, j \neq i}^n x_{ji} \quad (2)$$

$$TTN_i = \sum_{j=1, j \neq i}^n \sum_{k=1, k \neq i}^n x_{jk} \quad (3)$$

$$TTP_i = \sum_{j=1}^n x_{ij} \quad (4)$$

In addition, the precision (P), recall (R), and specificity (S) for each class  $i$  were also calculated as shown in equations 5, 6 and 7. The total accuracy and F1-Score were calculated as shown in equations 8 and 9, respectively.

$$P_i = \frac{TTP_{all}}{TTP_{all} + TFP_i} \quad (5)$$

$$R_i = \frac{TTP_{all}}{TTP_{all} + TFN_i} \quad (6)$$

$$S_i = \frac{TTN_{all}}{TTN_{all} + TFP_i} \quad (7)$$

$$Accuracy = \frac{TTP_{all}}{Total\ Number\ of\ Testing} \quad (8)$$

$$F1 - Score = \frac{TTP_{all}}{Total\ Number\ of\ Testing} \quad (9)$$

### III. RESULT AND DISCUSSION

In this study, we made use of nine open databases to measure the performance of the CCN transfer learning model, VGG16, to detect pneumonia and COVID-19 cases. Each database contained more than 1000 images and a total of 38,181 images were evaluated. The datasets were divided according to the number of images and classifiers. The robustness of the VGG16 model was then tested on datasets that were.

- 1) with more than 5000 images.
- 2) with less than 5000 images.

3) with a different number of classes.

Fig. 4. Relationship between the Number of Classes in the Dataset and the Accuracy of the Algorithm.

Fig. 4 shows the relationship between the number of classes in the dataset and the resulting performance of the algorithm in terms of accuracy. The accuracy of the algorithm ranged from 80.10% to 97.99%. The algorithm performed better in datasets with three classifiers when compared with datasets with two classifiers. The algorithm had the worst performance in datasets with four classifiers.

The performance of the VGG16 algorithm was validated by splitting the dataset into three categories; training (80%), validation (10%), and test (10%). Fig. 5 illustrates the results of the confusion matrix from data test, while Table IV compares the accuracy, precision, recall, and F1-score of the VGG16 model in all of the nine databases evaluated in this study.

The testing accuracy analysis of the VGG16 algorithm in datasets containing more than 5,000 images is illustrated in Fig. 6. For this evaluation, we compared the accuracy of the VGG16 algorithm in D1, D2, D4, D6, and D8 datasets, which contained 5,856, 5,910, 6,432, 6,533, and 6,515 images, respectively. Following testing, the VGG16 algorithm in datasets with more than 5,000 images ranged from 97.99% to 88.22%. The findings of this analysis indicate that for both the validation and testing the detection accuracy of the algorithm decreased as the number of images increased.

The accuracy of the VGG16 algorithm on datasets containing less than 5000 images is illustrated in Fig. 7. For this analysis, the D7, D9, D5, and D3 datasets were used, which consisted of 940, 1,088, 2,002, and 2,905 images, respectively. For the testing data, the mean accuracy of the VGG16 algorithm was 94.31% with a range of 80.10-93.84%. As shown in Fig. 7, the difference in accuracy within each dataset was relatively small except for the D5 dataset, which showed an accuracy of 80.10%. However, further analysis showed that the low level of accuracy in the D5 dataset was caused by the very high-class difference ratio within this dataset.

Fig. 8 illustrates the performance of the VGG16 algorithm on datasets with two, three, and four classes. As evident in Fig. 8, the datasets with two and three classes did not differ much in terms of accuracy, but when a dataset has four classes, the accuracy decreases by 9.57%.

Based on the results of this study, we can conclude that the performance of the VGG16 algorithm is affected by the number of images and the number of classes within the dataset: For datasets with more than 5000 images, the accuracy of the algorithm decreased as the number of images in the dataset increased. The VGG16 model achieved a mean accuracy of 93.7%. Compared with previous studies, the VGG16 algorithm performed well despite its relatively simple architecture.

For datasets containing less than 5000 images, the number of images did not impact the algorithm's accuracy except for the D5 dataset. However, the lower performance of the algorithm in D5 was attributed to the larger class ratio within this dataset. The number of classes within a dataset affected the accuracy of the algorithm, whereby the VGG16 model performed worse in datasets with four classes. However, further research is recommended to test the efficacy of the transfer learning VGG16 model on the detection accuracy of COVID-19.

Compared to other popular transfer learning, the advantage of the VGG16 architecture is that it has only six layers in depth. The small layer makes the identification process fast. This fast time allows it to be applied to devices that have low specifications and are mobile. In real conditions, the dataset is not ideal, with different numbers and ratios between different classes. Based on the experiment, VGG16 solved cases of COVID-19 data with the characteristics of having a small class due to imbalanced data conditions. The limitation of VGG16 occurs in the unbalanced condition dataset, which has a large gap ratio (database D5 in Table II), and the number of classes is greater than four this show in Fig. 8.

TABLE IV. PERFORMANCE OF THE VGG16 ALGORITHM FOR ALL THE NINE DATABASES EVALUATED IN THE STUDY

Data	Name	Acc.	Prec.	Rec.	F1-Score
D1	Chest X-ray Images (Pneumonia) [18]	94.87	94.92	94.72	94.82
D2	CoronaHack -Chest X-ray-Dataset [19], [20]	97.99	97.65	97.29	97.47
D3	COVID-19 Radiography Database [21], [22]	93.84	90.48	88.68	89.57
D4	Chest X-ray (COVID-19 & Pneumonia) [23]–[25]	94.73	95.17	89.81	92.41
D5	COVID-19 Detection X-ray Dataset [18]–[20]	80.10	80.78	79.91	80.34
D6	Covid-GAN and Covid-Net mini Chest X-ray [18]–[20], [26]	92.67	89.43	85.75	87.55
D7	COVID-19 X-ray Images [27]	88.30	85.98	66.03	74.7
D8	Curated Chest X-ray Image Dataset for COVID-19 [25]	88.22	88.68	86.45	87.55
D9	COVID-19 X-ray Dataset With Preprocessed Images [19], [28]	93.69	93.69	94.03	93.86

#### IV. CONCLUSION

The aim of this study was to assess the performance of the VGG16 algorithm on different datasets. The experimental results confirmed the high accuracy of the VGG16 algorithm in detecting COVID-19. The study also confirmed the robustness of the VGG16 architecture when applied to datasets with various image numbers, classes, and class ratios on chest X-rays. However, in this study, we did not evaluate the impact of high-class ratios on the performance of the VGG16 algorithm. However, the class imbalance problem can easily be resolved via the application of data augmentation and class balancing techniques.

#### ACKNOWLEDGMENT

We would like to thank TopEdit ([www.topeditsci.com](http://www.topeditsci.com)) for its linguistic assistance during the preparation of this manuscript.

Funding statement: This research was funded by the Deanship of Scientific Research at Imam Mohammad Ibn Saud Islamic University through Research Group no. RG-21-51-01.

Conflicts of interest: The authors declare that they have no conflicts of interest to report regarding the present study.

# A Comprehensive Review and Application of Interpretable Deep Learning Model for ADR Prediction

Shiksha Alok Dubey<sup>1</sup>, Anala A. Pandit<sup>2</sup>

Department of Computer Application  
Veermata Jijabai Technological Institute (V.J.T.I)  
Mumbai, India

**Abstract**—Drug safety is a pressing need in today's healthcare. Minimizing drug toxicity and improving the individual's health and society is the key objective of the healthcare domain. Drugs are clinically tested in laboratories before marketing as medicines. However, the unintended and harmful effects of drugs are called Adverse Drug Reactions (ADRs). The impact of ADRs can range from mild discomfort to more severe health hazards leading to hospitalization and in some cases death. Therefore, the objective of this research paper is to design a framework based on which research papers are collected from both ADR detection and prediction domain. Around 172 research articles are collected from the sites like ResearchGate, PubMed, etc. After applying the elimination criteria the author categorized them into ADR detection and prediction themes. Further, common data sources and algorithms as well as the evaluation metrics were analyzed and their contribution to their respective domains is stated in terms of percentages. A deep learning framework is also designed and implemented based on the research gaps identified in the existing ADR detection and prediction models. The performance of the deep learning model with two hidden layers was found to be optimum for ADR prediction and further, the non-interpretability part of the model is addressed using a global surrogate model. The proposed architecture has successfully addressed multiple limitations of existing models and also highlights the importance of early detection & prediction of adverse drug reactions in the healthcare industry.

**Keywords**—Drug safety; adverse drug reactions; early detection; deep learning; interpretable models

## I. INTRODUCTION

Drug safety is a pressing need of today's healthcare. Minimizing drug toxicity and improving the health of individuals and society is the key objective of the healthcare domain. The drug development process starting from discovery to market is long and costly. Rigorous efforts are involved in clinical trials to ensure the safety and efficacy of the developed drugs. Clinical trials are performed on any new drug substance to check its safety and effectiveness against the particular disease before marketing them as medicines to the general population [1]. Currently, all developed drugs have risks associated with them [2] and only those drugs whose curative impact is greater than the risk, are marketed as medicines. Any unwanted, undesired effects of drugs on human health are considered Adverse Drug Reactions

(ADRs). According to the definition provided by WHO (World Health Organization), an ADR can be unintended and occurs at doses normally used in man for the prophylaxis, diagnosis or therapy of disease, or modification of physiological function" [3]. Simply, it can be seen as an unpleasant or unexpected effect of drugs on patients. The impact of ADRs is considered to be one of the reasons behind mortality and morbidity in humans. The contribution of ADRs is about 5% of all hospital admission and it is considered the fifth most common reason for mortality during hospitalizations [4]. The severity and harmfulness of the reported ADRs have caused a ban on many developed drugs. In about 20 years around 40 drugs are withdrawn from the drug market due to the severe reactions caused due to them [5]. Around 50% are banned from the US market [6] then Germany [5] and finally from the Europe drugs market. The most common occurring toxicities due to drugs are cardiotoxicity (32%, [13]), hepatotoxicity (20%, [8]) then death risk (10%, [4]), and finally risk of overdose (7%, [3]). A recent example of a Sibutramine (Meridia) drug got initial permission from FDA to be sold as an appetite suppressant, but in 2010 it was banned from the market as it caused an increase in heart disease and heart stroke risk in patients. The severity of ADRs can also be measured in terms of the burden of healthcare cost and length of hospital stay [7]. A variety of factors are also responsible for the development of ADRs in humans. These factors can be classified as patient-related, drug-related, and social environment-related [8]. Gender and age are critical patient-related parameters that need to be considered while assessing the impact of ADRs on individuals while drug dosage and drug-drug interaction are important drug-related factors [8]. Confounding factors like smoking and alcoholism are crucial in the development of ADRs [8]. For better patient safety and improving healthcare, it is important to not only predict an ADR on time but also detect it at an early stage.

The following diagram Fig. 1, shown illustrates that ADRs are included as part of ADE (Adverse Drug Event) which is again a subset of adverse events. But the fact that separates ADRs from ADE is that they are caused due to drug intake even at normal dosage.

Fig. 1. Classification of Adverse Events. Adverse Events Include all Harmful Events Occurring during Treatment with a Drug without the Necessity of a Causal Link between the Drug and the Reaction. If the use of Medication is Causal to the Reaction, the Condition is called an Adverse Drug Event. A Subform of Adverse Drug Events is Adverse Drug Reactions that are Triggered by the Drug Itself Despite its Appropriate Dosage [9].

## II. FRAMEWORK FOR RESEARCH PAPER SELECTION

In the last two decades, a lot of research has been done in this field of ADR identification and improving drug safety. Researchers have published their research works highlighting the need for the detection and prediction of ADRs in the healthcare industry. Therefore the purpose is to first summarize these published research articles from multiple perspectives and then apply deep learning models for ADR prediction. The research papers are collected from both domains. Depending on the elimination criteria defined, only the relevant research works are selected for further analysis. Arksey and O'Malley's [10, 11] methodological framework is used for selecting research papers for literature review. This framework has helped researchers to concentrate on a single domain for a short duration and identify research gaps depending on the collected research works. The entire methodology can be summarized as follows:

### Stage 1: Identifying the research question

As previously discussed this review focuses mainly on the research studies done in the past related to the detection and accurate prediction of ADRs. Detecting an ADR from data is important before predicting it, therefore research papers are included from both domains.

#### Theme 1: ADR Detection

What makes ADR detection critical for drug safety? What is the different ADR signal detection techniques applied to datasets? How the different techniques are evaluated on a variety of datasets?

Detecting an ADR is an important step to improve healthcare and drug safety [12]. It is important to detect ADR and distinguish it from the symptoms of the disease. Different detection techniques are defined for different datasets.

#### Theme 2: ADR Prediction

Why accurate prediction of ADR is important for better patient safety and minimizing ADR occurrences? What is the different prediction models applied for ADR prediction? How computational models are useful in preventing severe ADRs in the future?

Predicting an ADR can prevent its occurrence and minimize healthcare costs [13]. Different models have been applied in the past, present, and future to predict and prevent such ADRs. The extent of this review study includes machine learning and deep learning models for ADR prediction [14].

### Stage 2: Collecting the research studies

As previously discussed, the author has collected research articles related to ADR detection and prediction domain published throughout 10yrs. The research studies are from both computer science and biomedical domain. Major search engines and databases from where these publications & databases used in those publications are:-

PubMed:-It is a search engine that provides easy access to the MEDLINE database [15] and is freely available. It also provides access to abstracts and references related to biomedical as well as life science domains [16].

ResearchGate:- It is a European social networking site [17] that provides a common platform for both researchers and scientists. The majority of research articles related to different domains are published on ResearchGate [18] for access to both researchers and academic professionals.

The indexing mechanism available in PubMed is Medical Subject Headings (MeSH) [19].

MeSH:- It is a controlled comprehensive vocabulary [19] used for indexing journals available on PubMed. This indexing is very helpful for searching research articles and journal papers. The research studies were searched using different keywords related to 'adverse drug reaction', 'prediction related ADR', and 'detection of ADR', and different datasets were openly accessible and acquired through ethical permission.

Query-based search: - The different query strings related to pharmacovigilance [20] are used for searching different articles on Google Scholar. The articles are searched based on heading, abstract and main content.

### Stage 3: Select only the relevant studies.

The author has defined some criteria based on which only the relevant research studies were selected. The elimination criteria are listed below:-

Duplicate research papers are eliminated.

Research studies not related to the review.

The research papers largely focused on the biomedical domain.

The research studies were more related to clinical research.

The research article more focused on drug-drug interaction and the genetic interaction of drugs.

Other unrelated research works.

After filtering, only relevant research works are selected for further analysis, and the results drawn are presented in this paper.

Stage 4: Charting the Data

The author has reviewed the research papers from multiple aspects. The various perspectives based on which the research studies are evaluated are described below:-

- Search Engine/Database
- Year of Publication
- Journal/Conference
- Name of the research paper
- Datasets used
- Models applied for ADR detection & prediction
- Drugs mentioned for a given ADR
- Evaluation metrics applied

Stage 5: Summarizing and reporting results

The research studies are summarized and segregated based on the approach used. In the initial phase, only the relevant studies are considered and the irrelevant ones are filtered out. Then the research works are grouped according to themes 1 and 2. Theme 1 is ADR detection whereas theme 2 is ADR prediction. The layout of the entire process is outlined in the flowchart shown in Fig. 2.

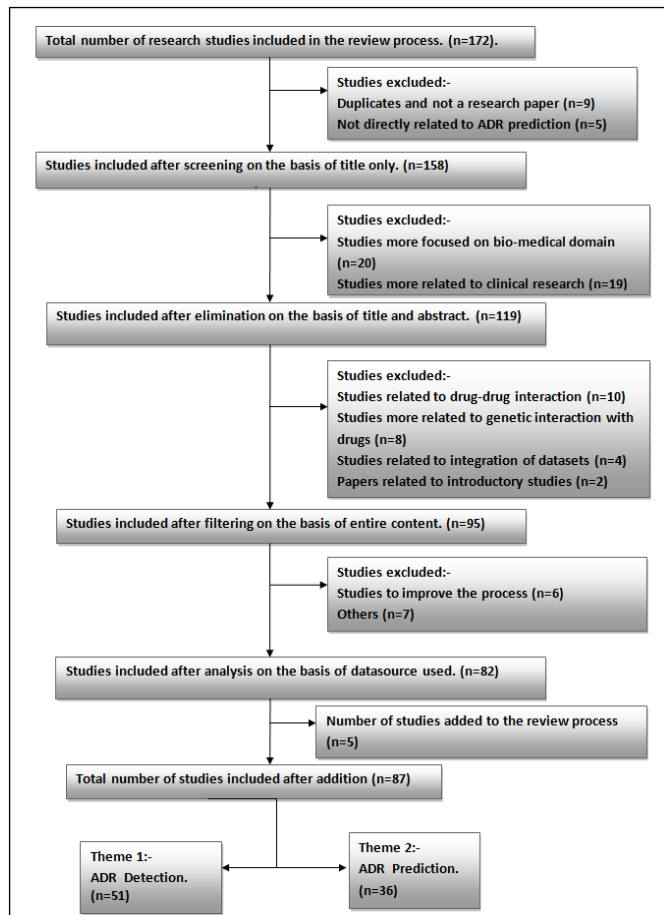

Fig. 2. Framework for Research Paper Selection.

The layout of the entire process is illustrated in the above diagram. Around 172 research works are collected showing the adverse effects and reactions of drugs on human health. The elimination criteria are used to eliminate irrelevant research papers. Repeated research works (n=9) and studies not related to ADR prediction (n=5) are filtered. Around 158 research works remained after elimination. About 19 research studies were eliminated in the screening process that belongs to the clinical research domain. Around 20 research works, more related to the biomedical domain were also eliminated. After filtering it only 119 research works remained. Research related to drug-drug interaction (n=10) and genetic interaction of drugs (n=8) were also screened out. Introductory studies (n=2) and research works related to the integration of datasets (n=4) are eliminated. A total of 95 research papers remained. Some research studies related to the improvement of ADR detection and prediction process (n=6) along with others (n=7) are also eliminated. In addition, five more research papers were made for the final review analysis. Finally, after filtering the research studies based on elimination criteria previously defined, the author identified about 87 research papers for further analysis.

Classifying them according to the two themes of ADR detection and prediction, there are about 51 papers associated with ADR detection and the remaining 36 are related to ADR prediction.

III. SUMMARY OF ADR DATASETS

Incidents of adverse reactions have been in existence for more than two decades. Over the period many countries have established pharmacovigilance centers [21] for collecting the reported occurrences of ADRs from medical practitioners and healthcare workers. These centers contribute to the postmarketing surveillance of ADRs. Many secondary data sources have been established by collecting both prescription data and ADR information. ADRs are also monitored actively through clinical trials and identified in different structured and unstructured data sources [22]. Different ADR-related data sources are listed and discussed in Table I.

TABLE I. SUMMARY OF ADR DATASETS

ADR related datasources	Description	Website
<b>Primary databases</b>		
<b>Spontaneous reporting Systems(SRS)</b>		
FAERS[23] EMA[24] UMC[25]	The incidents of ADRs are reported to the regulatory bodies of the country. They are analyzed and stored in databases for further action against the reported drug. These databases are also available for review and research process.	<a href="https://open.fda.gov/data/faers/">https://open.fda.gov/data/faers/</a> <a href="https://www.ema.europa.eu/en">https://www.ema.europa.eu/en</a> <a href="https://www.who-umc.org/">https://www.who-umc.org/</a>
Electronic Health Records[26]	This database contains records of patients admitted to the hospital. The datasource is very accurate as it records all information about the patient's condition the disease and its recovery phases.	This database can only be required through ethical permission from the required regulatory authority
Clinical narratives	The narratives and discharge summaries are written by experienced healthcare professionals. It contains	This data again requires ethical permission for

	data about a patient, disease, prescription information, and the treatment given. This information is very accurate and precise.	using it as part of the research.
<b>Major secondary ADR databases</b>		
SIDER 4.1[27] (Medical Literature)	This dataset includes data of 1430 marketed medicines and their recorded 5868 ADRs. It also includes around 139756 drug-SE association pairs.	<a href="http://sideeffects.embl.de/">http://sideeffects.embl.de/</a>
OFF-SIDES[28]	Offsides is a database of drug side effects that were found, but are not listed on the official FDA label.	<a href="http://tatonettlab.org/resources/nsides/">http://tatonettlab.org/resources/nsides/</a>
TWOSIDES [28]	An online available dataset containing information about drug-drug interaction and side-effects due to drug-drug interactions.	<a href="http://tatonettlab.org/resources/nsides/">http://tatonettlab.org/resources/nsides/</a>
ADReCS [29]	A comprehensive ADR ontology database.	<a href="http://bioinf.xmu.edu.cn/ADReCS">http://bioinf.xmu.edu.cn/ADReCS</a>
Medical Forums	These are public websites used for posting health-related inquiries.	<a href="https://www.dailystrength.org/">https://www.dailystrength.org/</a>
<b>Major API(Active Pharmaceutical Ingredients) interaction databases</b>		
DrugBank [30]	Comprehensive online database containing information on drugs & drug targets.	<a href="https://go.drugbank.com/">https://go.drugbank.com/</a>
PubChem [31]	A resource with information on chemical substances and their biological activities	<a href="https://pubchem.ncbi.nlm.nih.gov/">https://pubchem.ncbi.nlm.nih.gov/</a>
SuperDRUG 2[32]	SuperDRUG2 is a unique, one-stop resource for marketed and approved drugs containing 4,600 active pharmaceutical ingredients [32].	<a href="http://cheminfo.charite.de/superdrug2/">http://cheminfo.charite.de/superdrug2/</a>
SuperTarget	A resource that contains information about drug and target proteins and analyses their associations.	<a href="https://bioinformatics.charite.de/supertarget/">https://bioinformatics.charite.de/supertarget/</a>
STITCH[33]	A resource collecting known and predicted interactions between chemicals and proteins.	<a href="http://stitch.embl.de/">http://stitch.embl.de/</a>
PharmGKB [34]	The pharmacogenomic knowledgebase is a publicly available online knowledge base used for aggregation and integration of information on drugs and analyzing their impact on genetic variation.	<a href="https://www.pharmgkb.org/">https://www.pharmgkb.org/</a>
KEGG(Kyoto Encyclopedia of Genes & Genomes ) [35] & GO(Gene Ontology) [36]	It is a collection of databases dealing with genomes, biological pathways, diseases, drugs, and chemical substances. GO resource contains information about gene function.	<a href="https://www.genome.jp/kegg/">https://www.genome.jp/kegg/</a> <a href="http://geneontology.org/">http://geneontology.org/</a>

Different related data sources are grouped into separate categories. The basic categories defined are primary and secondary data sources. The table incorporates a variety of ADR-related data resources for both ADR detection and prediction.

#### A. ADR Detection

The research studies are majorly done in USA (n=33/51, 65%), Europe (n=6/51, 12%) and Korea (33/51, 8%). Apart from this research contributions from Australia (n=3/51,6%) and India (n=2/51,4%) are also considered.

Fig. 3. The Layout of the ADR Detection Process.

As shown in Fig. 3, the ADR detection data sources are categorized into two groups that are structured and unstructured datasets. The unstructured dataset is used in about 34% (n=17/51) of the research works while structured datasets are again categorized into primary and secondary data sources. The primary data sources are again divided into SRS and EHR. SRS is utilized in around 28% (n=14/51) of the research papers while EHR is in 46% (n=23/51) of the research. The secondary data source includes information about the drug-ADR association and is included in about 18% (n=9/51) of the research works. The different techniques are applied based on the data sources used.

DPA (Disproportionality analysis) is applied in around 28% of research papers where SRS is involved to validate the potential drug-ADR association.

Fuzzy Decision Making & Temporal Association Mining is applied equally in about 26% of the research studies for the early detection of ADRs.

Machine Learning (ML) & Deep Learning (DL) models are applied for secondary and primary data sources in around 28% of the research studies. The models are trained to detect unknown drug-ADR associations from datasets.

Finally, NLP (Natural Language Processing Tools & Techniques) are applied in about 24% of the research studies for extracting meaningful insights from unstructured text.

EHR and unstructured text has been used to early detect an ADR while SRS is helpful in the accurate detection of ADR.

#### B. ADR Prediction

The geographical research distribution for ADR prediction shows that the majority of research work is carried out in the USA at 44 % ( n=16/36) followed by China at 22 % ( n=8/36) and finally in Europe at 17 % ( n=6/36). Other countries like Croatia, Romania, India, Israel, Iran, Korea, and Japan have also contributed to the research in the ADR prediction domain. The major steps performed for ADR prediction are illustrated as follows:-

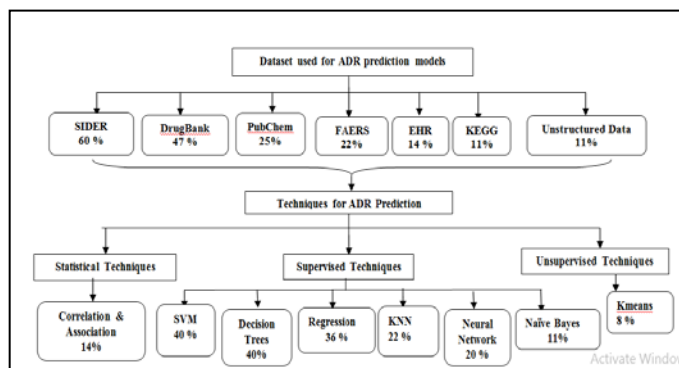

Fig. 4. The Layout of the ADR Prediction Process.

The Fig. 4, illustrates that the datasets mainly used for ADR prediction are SIDER 60% (n=21/36), Drugbank 47% (n=17/36), PubChem 25% (n=9/36) and FAERS 22% (n=8/36). Further, the techniques applied for ADR prediction are divided into three categories that are statistical, supervised, and unsupervised techniques. The statistical methods are further defined as correlation and association methods that contribute to 14% (n=5/36) of the research works while unsupervised techniques are further classified as Kmeans are applied in about 8% (n=3/36) of the research works. The common supervised techniques applied in the research works are SVM (Support Vector Machine) 40% (n=14/36), Decision Trees 40% (n=14/36), Regression techniques 36% (n=13/36), KNN (K-Nearest Neighbor) 22% (n=8/36) and Neural Network 20% (n=7/36).

The models are also analyzed based on evaluation metrics applied to the models for examining their performance.

The diagram in Fig. 5, depicts the percentage contribution of different evaluation metrics to ADR detection & prediction models. The precision & recall evaluation metric contributes to about 48% of ADR detection research papers while 60% of ADR prediction research works. The specificity, sensitivity & AUC are applied in about 30% of ADR detection research studies while only AUC is applied in about 70% of ADR prediction research papers. Lastly, the accuracy metric is used in around 40% of the research studies while the Ranking of drug-ADR association based on different metrics is involved in about 20% of the research works.

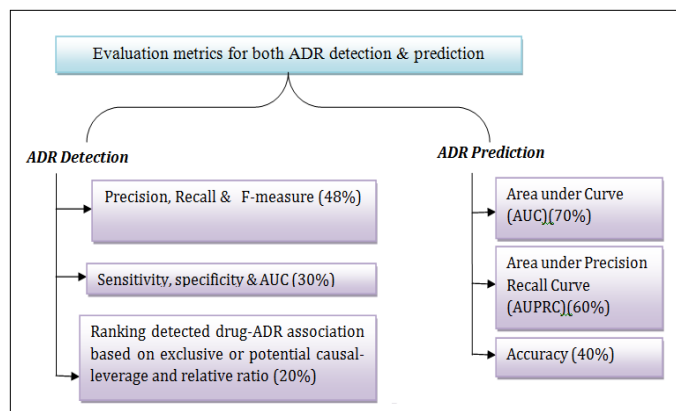

Fig. 5. Evaluation Metrics for ADR Detection and Prediction.

### C. Research Gaps Analysis

After reviewing the research studies, the author has identified some major dataset and technique-related limitations that are shown in the diagram:-

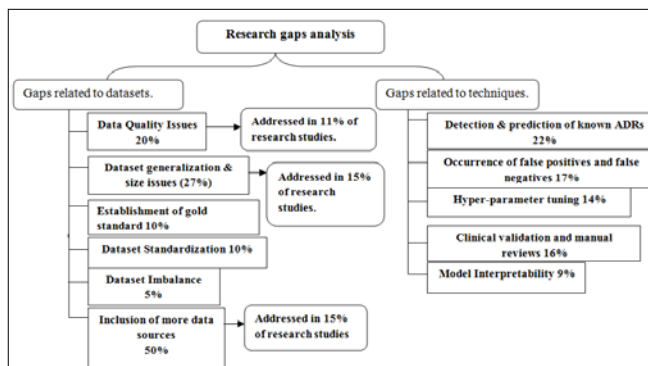

Fig. 6. Research Gap Analysis.

The Fig. 6, shows a thorough gap analysis depending on selected research papers. The significant research gaps related to ADR datasets are data quality, data generalization, and integration of more data sources which is specified in about 50% of the research papers. The research gaps are also analyzed based on the techniques applied for detecting and predicting an ADR. The major gaps discussed are the detection & prediction of known ADRs, the occurrence of false positives and false negatives, hyper-parameter tuning, and clinical validation. We have tried to address some research gaps in our research work but still many needs to be addressed for the future research study. These limitations form the basis to design our model for ADR prediction.

A framework is developed based on the gap analysis illustrated in Fig. 7.

Fig. 7. Framework of the Proposed Model.

The framework signifies the key steps performed for ADR prediction. It tries to address the above-stated research gaps namely inclusion of more data sources, dataset imbalance, dataset size issues, and detection & prediction of known ADRs. The steps shown in the framework are practically implemented and results are derived accordingly.

### IV. DATASET SELECTION AND APPROACHES FOR INTEGRATION

The FAERS [23] data source used as input is a primary data source. It is available and freely accessible online. The data is collected and stored through an authentic process and

validated. This dataset is presented both in ASCII and CSV format. Around three million records were collected from the FAERS dataset dated from 2019 to 2020 end in ASCII format. Once downloaded and extracted the overall dataset is visualized in Fig. 8.

Fig. 8. FAERS Dataset [23].

The data in the FAERS dataset is unreadable and segregated across multiple tables. Therefore it is required to convert the dataset into a readable format and then integrate it using primaryid and caseid. The size of the integrated dataset is huge therefore it is necessary to detect and identify significant drug-ADR associations. The disproportionality analysis technique is applied for extracting such associations from the dataset.

The drug-ADR association is calculated in terms of PRR (Proportionality Reporting Ratio) [37]. Only those associations which are greater than the threshold value i.e.  $PRR \geq 3$  are filtered for further processing.

The output of the ADR detection algorithm is illustrated in Table II:-

TABLE II. RESULTS OF ADR DETECTION

Product	Adverse Event	Count	p_value	PRR
cc-10004	lymph node tuberculosis	102	-6167.969382	1.04847E+13
rifampicin	skin papilloma	6	-6168.662469	5.24282E+12
rapamune	hemiplegia	8	-6168.662467	5.24279E+12
alpelisib	osteonecrosis of jaw	16	-6168.662472	5.24272E+12

Overall the result of the initial experiments provides us with a processed and filtered FAERS dataset which is used further for integration with other data sources. The final ADR prediction is performed using drug characteristics as well as patient characteristics.

SIDER contains information regarding the marketed medicines along with their recorded ADRs. This dataset is secondary and is easily available on the internet for research purposes. The data source also includes information about drug indications on patients which are extracted from

unstructured text using NLP tools and techniques [27]. These drug indications help to distinguish ADRs from symptoms of disease and thus reducing the number of false positives. It is one of the most popular datasets used in ADR detection & prediction-based research study. It has been used in almost 60% of the research work done.

DrugBank was created by the University of Alberta and The Metabolomics Innovation Centre in Alberta, Canada [30]. It is a comprehensive, easily available, online data source that includes data about drugs and the protein targets of drugs. It also includes the components of proteins in terms of enzymes, transporters, receptors, and ion channels. The biological effect of drugs in terms of drug toxicity is also included as part of this research dataset. This dataset was acquired after obtaining the required permission from the authorities and assuring them of its ethical use.

PubChem includes information about drug molecules along with their chemical composition and their effect in response to the biology of patients. This data source is developed by NCBI (National Center for Biotechnology Information) which is a part of NLM (National Library of Medicine). The NLM is also included as a part of NIH (National Institutes of Health) of the USA [31]. It is also easily available for research purposes online.

The selected datasets are integrated using two different techniques. Each technique is illustrated in the following Fig. 9 and 10.

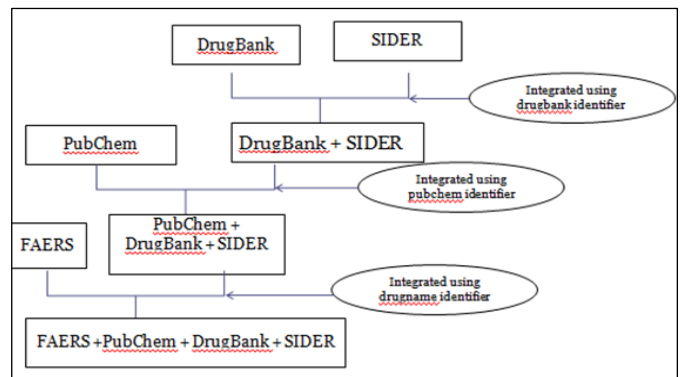

Fig. 9. Drug Identifier-based Integration.

Fig. 10. Knowledge Graph Integration [38].

In drug identifier-based integration the DrugBank and SIDER are integrated using the drugbank identifier. Further PubChem is integrated using the PubChem identifier and lastly, FAERS is included using drug names. Similarly, in the case of knowledge graph [38] based integration, knowledge graphs are constructed using nodes of different datasets like drugs, target proteins, enzymes, pathways, indications, and adverse drug reactions. In the above figure, knowledge-graph integration information is derived from knowledge graphs which are used for identifying side-effects as well as detecting probable ADR for the prescribed medicines.

Further, the features of the integrated datasets are reviewed by the domain expert, and useful feedback and inputs were obtained by the author accordingly. Some features were dropped from the dataset while some were added as per their recommendations. The feature variables included as part of the integrated dataset are the type of target and target sequence. The type of targets can be divided into four categories receptors, ion channels, enzymes, and carrier molecules. Target sequences are genetic variants targeted by a given drug molecule. Apart from target type and target sequence some other features were also added as part of this dataset which is described in Table III.

TABLE III. FEATURE VARIABLE DESCRIPTION

Feature Variable	Description
LogP	Lipophilicity is a valuable parameter of the drug which affects its activity in the human body. The Log P value of the compound indicates the permeability of the drugs to reach the target tissue in the body[39]
LogS	The aqueous solubility of a compound significantly affects its absorption and distribution characteristics. Typically, a low solubility goes along with a bad absorption, and therefore the general aim is to avoid poorly soluble compounds. Our estimated logS value is a unit stripped logarithm (base 10) of the solubility measured in mol/liter.[39]
CYP inhibitors	The inhibitors are responsible for delaying the action of target proteins and that lead to a large amount of drug disposition in the human body which is harmful and severe.
Toxicity	The toxic nature of the drug molecule on the human body.

A. Dataset Preprocessing

The integrated dataset contains several redundant columns, null values, and categorical feature variables that must be pre-processed before further analysis. The steps involved in the pre-processing of both identifiers integrated and knowledge graph integrated datasets are described in the following Fig. 11.

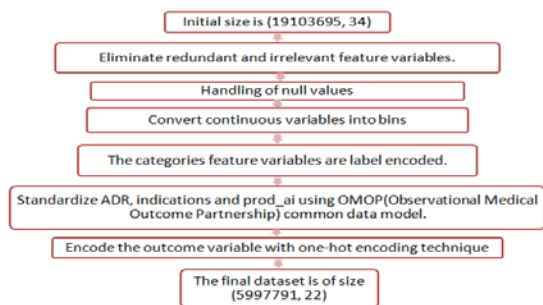

Fig. 11. Pre-processing Steps on Integrated Dataset.

The data distribution of the significant feature variables in the integrated dataset is visualized in the following bar charts shown in Table IV.

TABLE IV. DISTRIBUTION OF FEATURE VARIABLES

B. Kruskal Wallis Test

This test is used to determine whether or not there is a statistically significant difference between the medians of three or more independent groups [40]. The result of this test is shown in the output below.

```

H-statistic: 84253398.14222576
P-value: 0.0
Reject NULL hypothesis - Significant differences exist between groups.
    
```

The p-value is zero which is less than 0.05 which shows that a significant difference exists between groups and rejects the NULL hypothesis.

C. ADR Prediction Dataset

The current dataset includes only positive ADR samples. For any prediction problem, a balance of positive and negative data samples is required. Therefore the author applies GANs (Generative Adversarial Networks) [41] architectures to the original dataset and generates negative data samples based on the features of the original dataset. The output of the application of GANs is shown in Fig. 12.

Fig. 12. Generative Adversarial Network for Data Creation.

A combined dataset of 20 lakh records was generated for both presence and absence of ADRs. This dataset will be used for the implementation of ADR prediction algorithms. The target class distribution before and after the application of GANs is illustrated in Fig. 13.

Fig. 13. Target Class Distribution.

The target class distribution shows the balance of positive and negative samples in the ADR dataset after the application of the GAN model.

## V. RESULTS

Deep learning models are Deep Neural Networks (DNN) containing non-linear processing units that transform raw data into higher-level representative information [40]. In recent years these techniques are actively applied in the field of drug discovery, precision medicine, protein engineering, genetic expression data analysis, and pharmacodynamics modeling [42]. Given the significant contribution of deep learning techniques in the domain of drug discovery, its capability can be very well extended to predict adverse reactions to drugs in humans. As previously discussed the ADR data sources both structured and unstructured are huge, diverse, and heterogeneous. DNN can successfully be applied to these data sources without the need for manual tuning. The initial training using a deep neural network is very complex and time-consuming but the network improves its performance by learning from input data.

Therefore the author proposes to apply deep learning models to the integrated dataset and evaluate its performance in terms of different evaluation metrics like accuracy, precision, recall, and F1 score. The model training is performed based on drug-ADR associations and other associated information. Deep learning performs well on a huge dataset. It also eliminates the need for hyper-parameter tuning. The number of hidden layers is optimized to provide the best results on the given dataset. The results obtained are shown in Table V:-

TABLE V. DEEP NEURAL NETWORK RESULTS

	Accuracy	Precision	Recall	F1 Score
The model with one hidden layer	0.57	0.9	0.57	0.64
The model with two hidden layer	0.91	0.92	0.91	0.91
The model with three hidden layer	0.55	1	0.55	0.71

From the results obtained it can be observed that the performance of the model with two hidden layers provides is optimum for all evaluation metrics. The performance seems to be consistent for precision but it varies significantly for the other evaluation metrics. It gives poor performance for one and three hidden layers but the best performance for two hidden layers. The results can be visualized in below Fig. 14.

Fig. 14. Results Obtained by Models based on different Numbers of Hidden Layers.

Fig. 14 reflects the results obtained in the table and the performance of all evaluation metrics is consistent for the model with two hidden layers. It can be observed that the benefits of deep learning approaches are extensive but they suffer from the issue of non-interpretability. The 'black box' nature of deep learning techniques has restricted the interpretability of the model. The author has demonstrated the need for interpretable models for overall acceptability in the medical domain. Therefore to address this limitation the author has proposed the application of LIME (Local interpretable model-agnostic explanations) [43] for model explainability.

LIME is a technique that approximates any black-box learning model with a local, interpretable model to explain each prediction. From the definition it can be understood that LIME provides approximate explanations to individual prediction instances i.e. it is a local surrogate model. But to interpret the results based on the entire dataset SP-LIME [43] is applied. SP-LIME (Sub-modular Pick- Local Interpretable Model-Agnostic Explanation) tries to provide an answer to the question of developing trust for a given model for its acceptance. The trust is developed by dividing a given problem into several sub-problems for optimization. That means it identifies a series of instances along with their predictions that reflects the overall performance of the model based on the given data. The instances are selected in such a

manner that the features which are responsible for explaining different predictions are given higher importance value.

The results obtained by applying the SP-LIME algorithm to the given dataset are shown as follows:-

Fig. 15. SP-LIME Results.

Fig. 15 describes that the feature variable CYP2D6 inhibitor and sex contribute the highest to the target outcome prediction positively while hepatotoxicity, LOGP, and CYP3A4 are responsible for predicting the ADR outcome negatively. The proposed framework tries to address the research gaps stated in the existing research works. The inclusion of more data sources is identified in about 50% of the research studies, this issue is tackled by our proposed model. Other than this the model is trained on only validated drug-ADR association which is stated in about 16% of the research work. Lastly, the model's interpretability issue is also handled using a surrogate model. Therefore the proposed framework tries to address issues related to both data sources and techniques applied to these data sources.

## VI. DISCUSSION

Many reviews and surveys have been done in the past to address the issue of drug safety and healthcare. In 2015, Lardon et al. [11] in their research study tried to explore the breadth of evidence about the use of social media as a new source of knowledge for pharmacovigilance. They adopted a similar methodology of collecting research articles based on research questions and then analyzing them from multiple perspectives. The scope of their work is satisfactory but they have limited themselves to only unstructured datasources and NLP (Natural Language Processing) tools and techniques while in our research study the author has provided a comprehensive approach in terms of dataset selection and tools and techniques applied to them. Another research study was done by Ho et al. [44] in 2016 collected and analyzed research papers in terms of their problem statement, the dataset used and the methodology applied. The research summary provided in this paper is sufficient but it does not lead to any concrete solution to the existing research problem. Similarly, research studies conducted by Tan et al. [45] in 2016 have reviewed the interaction of different ADR datasets with biological and genetic datasets. Further, they discussed the benefits and limitations of these integrated datasets in the current scope. The drug-ADR associations are analyzed

statistically only on the basis datasource but no practical implementation is provided unlike in our research study. Although many other reviews and survey reports have discussed the major datasources related to ADR and their transition from a data-driven approach to machine learning models [42] for ADR prediction they do not provide an overall broad approach in terms of the datasources discussed, methodologies applied and a practical solution to the problem in the existing research works. Thus, our research study not only provides a comprehensive framework for both datasources and techniques applied to them but also implements the proposed model to obtain better results in terms of accuracy, F1 score, and interpretability.

## VII. CONCLUSION

In conclusion, this research study provides a bird's eye view of drugs, the importance of drug-ADR association, and the methodologies used to discover them. It also analyses its impact on human health. Although each step in this research study has been carried out in detail starting from research paper selection to proposed framework implementation and results in discussion, still some research gaps in the given study that should be considered for future research. First, the research papers are selected based on single drug-ADR association while research studies considering drug-drug interactions are ignored, so for future research work research studies considering drug-drug interaction should also be included. The proposed model has applied only a deep neural network for prediction and evaluated its performance based on the different number of hidden layers. Further, the author proposes to apply different deep learning models to this integrated dataset and then compare its performance with the existing results. The main aim of this research is to optimize the performance of the proposed model in terms of accuracy and other evaluation metrics.

## ACKNOWLEDGMENT

We would like to extend our sincere gratitude to Prof. Shreerang V. Joshi and Prof. Prashant S. Kharkar of the Institute of Chemical Technology (ICT), Mumbai as domain experts for their invaluable assistance and support in helping us to understand the pharmacological aspect of our research work. Their insights into our research have greatly improved the manuscript.

**Abstract**—Now-a-days, the hydroponic farming system with the Internet of Things (IoT) technology is increasingly becoming a trend for researchers to produce a more capable farming device or remote monitoring system. However, this intelligent system is not controlled securely and will be dangerous when system hacking occurs. Therefore, developing a secure indoor hydroponic monitoring device with multi-factor authentication (MFA) method is proposed. The research aims to develop a secure cloud-connected indoor hydroponic system via multi-factor authentication on the ThingsSentral IoT platform with an MFA technique. The developed system comprises an iPhone Operating System (iOS), an Arduino node microcontroller unit and a ThingsSentral web IoT platform. A security software application on iOS phones with MFA techniques is built to authenticate devices before communicating with ThingsSentral.io. Token authentication between ThingsSentral.io and the security software application must be done before the hydroponic monitoring device can send and receive data. An indoor hydroponic monitoring system device with MFA security technique has been successfully produced from the study. An MFA security technique for iOS apps has also been successfully developed. In conclusion, using the MFA technique, this research successfully develops a high-security control and communication system between the field device and the IoT platform. Although the MFA security system developed for this IoT platform has several steps that need to be done before data can be sent to the cloud database, the users themselves can allow or prohibit a device from operating. Besides, users can also control and monitor the security of the device and the IoT platform when they operate.

**Keywords**—Internet of things; intelligent system; remote monitoring; hydroponic; multi-factor authentication

## I. INTRODUCTION

Due to an increase in population and a country's development, a diverse alternative has dealt with the crisis of

adequate food provision. This is because land and farms must be reduced to make room for more excellent homes. The development of indoor hydroponics farming, a relatively successful means of producing a crop, is one of the most recent agricultural technologies established to mitigate this problem [1]–[4]. Hydroponics technology is used throughout the world. Numerous methods and techniques have developed. Most hydroponic surrounding areas are prepared with their temperature, humidity, electrical conductivity (EC) and pH manually measured by producers. Adjustments are then calculated to meet the needs of the plants [5]–[7].

With the advent of IoT technology, hydroponic farming systems can increasingly thrive. The combination of IoT technology in this hydroponic farming system can also monitor and control the condition of the crop environment in real-time. In addition, it can also reduce inefficiencies and improve agricultural performance [8], [9]. Combining the Internet of Things and the agriculture industry can minimize inefficiencies in food production and expand the food market [10], [11]. The potential of IoT systems can connect breakthrough technology like plants that deploy sensors.

IoT technologies that use the medium of internet connection can send data to a cloud server or receive instructions to operate [12]. Most IoT technologies use an open internet connection medium to perform these processes. When an IoT device uses an open internet connection, it will expose to dangers such as information theft or system hacking [13].

Hydroponic farming systems combined with IoT technology are increasingly becoming a trend for researchers to produce a more capable farming device or system. However, studies related to secure hydroponic monitoring systems with IoT integration are still lacking. If this IoT hydroponic farming system is not controlled securely, it will be a danger when system hacking occurs. Hence to solve the problem, the current novelty research proposes the development of a secure indoor

\*Corresponding Author

hydroponic monitoring device with multi-factor authentication (MFA) method.

This study has developed a security authentication application on mobile phones to control the connection between the gateway device and the ThingsSentral application. Next, a gateway device is developed to send the data obtained from the sensors to the ThingsSentral application using the Hypertext Transfer Protocol (HTTP) communication protocol. The security authentication application only needs to be done at the beginning of the gateway device requesting to send data only.

## II. HYDROPONIC MONITORING SYSTEM

A literature review has been made related to the hydroponic monitoring system. This section describes some research done by other researchers related to electronic technology used in producing hydroponic monitoring systems. This section also shows the results obtained by past researchers during this study.

In the era of technology centuries, human lives have become more accessible in all parts with the growth of wireless technology, the Internet of Things (IoT). Agricultural systems' decisions demonstrate the rapid rise in internet users over the previous decade. The IoT development guarantees that the surveillance system technique becomes more advanced on the 'user's terms and can be accessed anytime and anywhere within a distant place [14]–[16]. The development of a hydroponic farming system communication based on the IoT platform monitors the plant condition at a remote monitoring station. It allows the automatic system to turn on when necessary [17]–[19].

Melchizedek I. Alipio et al. [20] employed a Bayesian network to analyze the data and automate the hydroponics method as the human population expands to meet the food requirement. Using IoT technology in conjunction with hydroponics allows a high-quality farmer to produce more. The farm's hydroponics is linked to the light intensity, pH, EC, water temperature, and humidity sensors. Sensor data were gathered for analysis, and a Bayesian Network was built. The nutrient film method (NFT) was used with sensors and actuators attached to the plant. To use a remote location to monitor and gather data from the hydroponics farm and deliver it to the web interface.

Fuzzy logic was utilized to regulate the supply of nutrients to hydroponic plants, according to M. Fuangthong and P. Pramokchon [21]. Instead of employing soil, water solvent was used to supply nutrients to the crops. Farmers in soilless culture need extra attention from growing plants in hydroponics to analyze nutrient solvent's EC and pH levels. The pH value varies depending on the crop, and the automatic monitoring mechanism provides a nutrient solution. A farmer's practical abilities are required to prevent an excess delivery of nutrient solutions to plants. The Dynamic Root Floating Technique (DRFT) automatically controls the nutrient solvent flow to hydroponic plants using fuzzy logic.

In 2017, Ms.S.Charumathi et al. [22] proposed a novel cultivating crops in soilless culture. Hydroponics can enhance yields while taking up less space and producing high-quality

crops. Because of the less fertile soil, farmers utilize pesticides and fertilizers to produce crops that damage human health. In a closed location, the hydroponics arrangement can alleviate traditional framing issues. The Arduino Microcontroller was combined with the IoT concept to detect the situation around the plants automatically. The proposed method has a major flaw in that it requires a farmer's observation because the data is stored locally.

R.Rajkumar and R.Dharmaraj [23] proposed a hydroponics idea with the wireless sensor network. Planting in a contaminated climate is difficult in conventional farming. Improving the yield requires more fertile soil. It also necessitates a higher weed extraction cost and a large growing area. Then, seasonal food processing is only possible at that time. The hydroponics technique allows for year-round production of the crops. Instead of using artificial mineral nutrients, the author experimented with hydroponics using organic ash fertilizer. Moisture, temperature, and water level are all sensed by the microcontroller. The sensor data is sent to the cloud, allowing the farmer to track the progress of his plants from afar. The author uses Blynk, an open-source API that receives sensor data.

M.K.R.Effendi et al. [24] developed smart farms and agriculture. The Internet of Things (IoT) and data analytics are being used to improve farm and agriculture sector operational efficiency and productivity. They devised monitoring, control, or automation system to help the farmer and then gathered all data on rainfall, temperature, humidity, and light intensity. The development included hardware, software, programming, and sensors such as a water sensor, light-dependent resistor sensor, temperature and humidity sensor, and weight sensor for data collection. The project's outcome is that they were able to apply IoT concepts to aquaponics and goat stall monitoring, control, and automation systems.

With the Wireless Sensor Network, Jumras Pitakphongmetha et al. [25] suggested a hydroponics technique to transfer sensor data to the cloud. Compared to conventional farming, hydroponics lets farmers raise money with higher yields. With global warming, the natural climate is challenging to foresee. Hydroponics can solve this issue by introducing without disturbance from the atmosphere in a protected environment. The significant parameter was then calculated using a different sensor around the hydroponics plant.

From the literature review, we found that the study related to hydroponic agriculture monitoring systems is sustainable and somewhat advanced in terms of controlling the environmental conditions of crops. However, most hydroponic monitoring devices are lacking from the perspective related to the security and safety of the monitoring devices. Electronic devices are vulnerable to a cyber-security threat and can be misused by others to cause harm to the community or society. These security and safety aspects are very much lacking and should be given extra attention. Although numerous security techniques and devices are available, most IoT devices do not come with security-enabled capabilities. Amongst the available and often used security methods for the connected or IoT system is via the authentication approach [26] and [27].

Security technologies can be implemented by integrating electronic devices, computers, and wireless communication to provide further protection. The second-factor authentication strategy, often utilized in account defense, is the next degree of protection [28], [29]. Two-factor authentication is a type of authentication that determines its identity using two out of three variables. “Something the user knows,” “something the user has,” and “something in the user” are three regularly seen variables [2], [30], [31]. The use of this two-factor authentication approach improves network security. This is due to the use of technological devices with an internet connection.

This combination of IoT and urban agriculture will evaluate data automatically by uploading it to the cloud and allowing users to make decisions [32], [33]. Furthermore, this indoor farming system is self-contained and can work safely with this network security mechanism. The ability to produce could change the agriculture industry, helping to enhance the smart but inefficient rural sector in our economy.

### III. SECURE INDOOR HYDROPONIC MONITORING SYSTEM DEVELOPMENT

This section describes in detail the methodology implemented in this research. The study of how people utilize hydroponic systems was carried out to create a monitoring device for the farming system. Furthermore, the proposed approach makes the hydroponic system simple to maintain. Multiple security can be achieved by using the general design of the system with an MFA approach. This section has two parts: indoor hydroponic device monitoring system design and device security system design.

#### A. Device Monitoring System Design

Fig. 1 shows the main layout of an indoor vertical hydroponic farming system using the MFA method. Indoor hydroponic devices include three major components: input, controller, and output. On the input side, water electrical conductivity (EC), water parts per million (PPM), humidity sensors, temperature sensors, and keypad (users to enter their Wi-Fi information) were used. Using a Node microcontroller in the controller portion is critical for securing the input part to the output and the input to the cloud database. Because NodeMCU acts as a WI-FI chipset, it can send data to the internet. An OLED panel displays data straight from the sensor on the output side. Fig. 2 shows the sensor and module information connected to the NodeMCU ESP8266. While Fig. 3 shows the indoor hydroponic monitoring device that has been connected.

The system starts with the user configuring the service set identifier (SSID) and the password to connect to the internet using the keypad provided. Once the SSID and password of the nearest internet have been successfully entered, the user needs to enter the user and device id, which can be obtained on the ThingsSentral website. Once the user and device id have been entered, a notification will be sent to the security verification application on the user’s phone. Fig. 4 below shows the interface of the security authentication application.

Users can choose either to allow or not the hydroponic monitoring device to function and be able to send data to the ThingsSentral platform. The National University of Malaysia

developed ThingsSentral, a cloud based IoT platform (UKM). The ThingsSentral application’s UI is shown in Fig. 5. This platform allows users to develop their own cloud based IoT systems for data collection, storage, and retrieval. This system platform communicates over the internet using the HTTP protocol. Data can be sent to or from hardware microcontrollers like Arduino, Node MCU, and Raspberry Pi. ThingsSentral’s functioning is based on channels that comprise data fields, position fields, and status fields.

Fig. 1. System Design Framework of Hydroponics Farming System with an MFA Method.

Fig. 2. The Required Hardware for Monitoring Temperature, Humidity, EC and PPM with Component Description [34]–[37].

Fig. 3. The Hardware Set Up for the Indoor Hydroponic Monitoring System used in this Study.

Fig. 4. An MFA Security Interface for Mobile Application.

Fig. 5. ThingsSentral Application for Live Data Monitoring.

After the user confirms the indoor hydroponic monitoring device, it will read the temperature and humidity of the plant environment. The plant environment data can also be sent to the cloud database. Fig. 7 shows that the hydroponic model was built. While Fig. 6 shows the readings obtained by the ambient temperature and humidity monitoring device.

### B. Device Security System Design

This section describes the proposed multi-factor authentication that uses a credential token key. Fig. 8 shows the architecture of the proposed system. The system consists of an IoT device as a client, a ThingsSentral server as a web services platform, and an authentication application as a phone authentication application. All these systems need to perform registration with the ThingsSentral Server. ThingsSentral server generates unique registration IDs for all entities and certificates of credential token keys for IoT devices. In this system, the mutual authentication between IoT device and authentication services, authentication application and authentication services, token generator services, and IoT devices occur. The certificate of a credential token key

establishes between IoT devices and ThingsSentral primary services. The proposed security architecture system consists of five processes, which explain as follows.

Fig. 6. Indoor Vertical Hydroponic Model for a Data Monitoring System.

Fig. 7. Live Data Pickup by Sensor Shown in I2C OLED Display.

Fig. 8. The Proposed Architecture for the Security System.

IV. RESULTS AND DISCUSSION

The results obtained after applying the methods are described presently. The results relate to the indoor hydroponic farming monitoring module and hardware security system using the MFA authentication method.

In order to obtain this result, the study's implementation method and prototype model have been shown in Fig. 2, 3 and 7. Fig. 9 represents the screenshot of the authentication process performed from the start of the monitoring device until the data was retrieved from the water nutrient and DHT-11 sensor. In contrast, Fig. 10 and Fig. 11 show the screenshots of the dashboard display for the IoT-based hydroponic crop monitoring system on a PC/laptop and a mobile phone, respectively. As can be seen, the ThingsSentral platform has afforded an informative, real-time and excellent visualization approach to monitoring the hydroponic crop. The IoT-based

monitoring system has successfully implemented a secured system using multi-factor authentication.

The local OLED display module and the centralized cloud dashboard on ThingsSentral will display all data obtained at the hardware module. Then it is displayed on the I2C OLED. The I2C OLED provided the interface for user WI-FI SSID, WI-FI password, user id and device gateway. The water nutrient solution (EC and PPM), humidity and temperature of the surrounding hydroponic module were also displayed on the OLED. The data analysis was based on the data presented in the methodology and also the data obtained from the graph on ThingsSentral, as shown in Fig. 10 and Fig. 11. The real-time timestamps and data for the indoor hydroponic monitoring module on the water nutrient solution and surrounding humidity and temperature were recorded on the ThingsSentral platform. The result for the MFA validation application display is shown in Fig. 4.

Fig. 9. Dashboard for ThingsSentral Web-based Interface with MFA Method.

Fig. 10. The OLED Displays Wi-Fi and Device Monitoring Registration Process Flow.

Fig. 11. MFA Method used on a Dashboard for ThingsSentral Web-based Interface Viewed on Mobile Phones.

The hydroponic monitoring module was tested 100 times using proposed IoT platforms. Each time this monitoring device successfully displays the indoor hydroponic module system’s current data, this device will be turned off and on again to repeat the device verification process and data transmission to the cloud database. Fig. 12 shows the time graph for 100 times hydroponic monitoring devices to obtain the credential key and send data to the ThingsSentral server. From the data obtained, the average time taken for this system to start operating until the data received on the ThingsSentral server is 579ms (red line). The results for the average time required have been included in Table I and compared with other platforms.

Table I shows the names of the different IoT platforms, the average time taken and their respective security techniques. As result of the comparison that has been made shows that the time taken by the ThingsSentral IoT platform with the MFA technique takes a little longer compared to other IoT platforms. However, the ThingsSentral IoT platform uses the MFA technique that allows users to authenticate a device to operate. ThingsSentral also uses a dynamic credential key every time the device starts operating. Unlike other IoT platforms, they use API keys or token keys only. In addition, this other platform uses a static token key. If hackers or strangers can figure out this token key, they can do unexpected things.

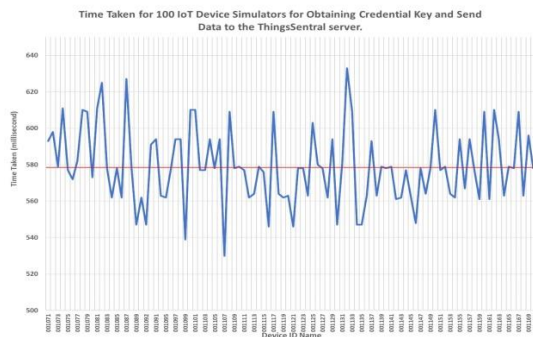

Fig. 12. Time Graph for 100 Times IoT monitoring Device Tested Request Credential Key and Send Data to ThingsSentral Server.

TABLE I. COMPARISON OF SYSTEM SECURITY FOR FIVE DIFFERENT IOT PLATFORMS

IoT Platform Name	Security Technique	Average Time Taken / Response Time (ms)
Kaa IoT [33]–[38], [40]–[42]	SSL security elements are combined with basic authentication through JSON web tokens.	150
ThingSpeak [43]–[47]	Secured MQTT broker and random static token on personal API Key	25.2
Thingier.io [39], [48]–[51]	SSL security elements are combined with basic authentication through JSON web tokens.	266.7
Thingsboard [39], [52]–[55]	Encryption algorithms on SSL and credential types certificates and access tokens.	217.5
ThingsSentral (proposed platform)	SSL security features on web API services with a multi-factor authentication method on the registered device.	579

## V. CONCLUSIONS

This paper describes developing a secure indoor hydroponic farming monitoring system based on a wireless system using the XOJO platform, ThingsSentral IoT, NodeMCU, and hydroponic sensors. The hydroponic monitoring system device was tested on an indoor vertical hydroponics module and the system’s functionality was assessed. The system can display temperature, humidity, and nutrient solution content in water. The developed system also uses the MFA method to increase further the level of communication between the monitoring device and the cloud database. This system is also compared with several other cloud database IoT platforms. One noteworthy finding is that this developed system takes a little longer than the use of cloud database IoT platforms. However, this system is safer because the ThingsSentral IoT platform uses authentication from humans or owners to the device itself. Unlike other IoT platforms, they only use the API Key or token that needs to be entered into the device. This study only used one indoor vertical hydroponic module to obtain data. Therefore, the data used is only to measure the security and usage of cloud based IoT platforms at a time. In the future, studies on several indoor vertical hydroponic modules can be used to obtain more data to produce more accurate and valuable results. The data obtained from the hydroponic monitoring module can be compared with the existing device. In addition, future research can be done by developing more hydroponic monitoring sensors to control plant environmental conditions and a phone application by integrating it with the data obtained from the device. The data obtained will be displayed on the user’s phone application. Users can also see their crops’ condition from time to time, even if they are far from the crops.

## ACKNOWLEDGMENT

The authors would like to thank the Ministry of Higher Education (MoHE) for supporting this research through the LRGS/1/2019/UKM-UKM/5/2 grant code and Faculty of Engineering and Built Environment, Universiti Kebangsaan Malaysia (UKM) for providing the research facilities.

**Abstract**—Brain disease prognosis is considered a hot research topic where the researchers intend to predict the clinical measures of individuals using MRI data to evaluate the pathological stage and identifies the progression of the disease. With the lack of incomplete clinical scores, various existing learning-based approaches simply eradicate the score without ground truth score computation. It helps restrict the training data samples with robust and reliable models during the learning process. The major disadvantage of the prior approaches is the adoption of hand-crafted features, as these features are not well-suited for the prediction process. This research concentrates on modelling a weakly supervised multi-tier dense neural network model (*ws - MTDNN*) for examining the progression of brain disease using the available MRI data. The model helps analyze the incomplete clinical scores. The preliminary ties of the network model initially haul out the distinctive patches from the MRI to extract the global and local structural features (information) and develop a superior multi-tier dense neural network model for task-based image feature extraction and perform prediction in the successive tiers for computing the clinical measures. The loss function is adopted while examining the available individuals even in the absence of ground-truth values. The experimentation is done with the available online Dataset like ADNI-1/2, and the model works effectually with this Dataset compared to other approaches.

**Keywords**—Brain disease; learning approaches; ground truth value; feature learning; global and local feature analysis

## I. INTRODUCTION

Magnetic resonance imaging (MRI) is a suitable imaging technique for the head (specifically the brain) used in everyday clinical practice. It enables doctors to assess the nervous system's health and identify the existence of specific disorders. The computer-aided Alzheimer's disease (AD) prediction and premonitory phase, moderate cognitive decline (MCI), has made extensive use of MRI in recent years [1]–[6]. Anatomical MRI may detect aberrant brain structure and find imaging biomarkers for Alzheimer's disease (AD) in medical settings without radiation or other invasive procedures. Lately, assessing the state of disease and forecasting outcomes of AD and MCI progress employing baseline (BL) MRI information has been a popular issue.

Although numerous machine-learning approaches have already been developed for risk ratings utilizing BL MRI [11], a frequent difficulty of current systems is inadequately labelled information; participants may ignore ground-truth

diagnostic marks at specific time, amongst 805 participants inside AD Neural correlates Initiative-1 (ADNI-1) database [7]–[10], only 622 & 631 individuals had full CDR-SB & MMSE ratings 24 months following BL time, correspondingly. Earlier research simply discarded patients with incomplete clinical ratings owing to the sensitivity of reinforcement methods. Coupe [11] evaluated improvements of two clinical indicators from MRI utilizing 186 participants with comprehensive ground-truth clinical ratings from ADNI-1. Removing individuals with incomplete scores reduces the training dataset, decreasing the efficiency and resilience of estimation techniques. Furthermore, earlier machine-learning approaches often fed predetermined interpretations [e.g., image strength and tissue volume inside regions-of-interest] to ensuing prediction models, even though these characteristics may not be optimum for estimation techniques decreasing prognosis effectiveness.

The performance of deep learning methods has inspired various researches to use convolutional neural networks (CNN) to identify MRI characteristics for identifying certain diseases. Moreover, these techniques often fall inside the supervised learning method, making it impossible to train networks using people whose diagnostic ground-truth scores aren't full. Using all relevant poorly classified models (training participants with inadequate ground-truth scores at key time-points) is critical in Magnetic resonance brain illness diagnosis.

This research proposes the weakly supervised deep neural network (*ws - MTDNN*) for cerebral illness prediction utilizing BL MRI and partial clinical ratings at several time points. We define the following MR images and then identify multi-resolution image patchwork which relies on AD-based features. Finally, the deep CNN for forecasting of different clinical ratings at several points in time is created. This CNN has a novel weighting nonlinear function that enables the systems to learn sparsely labelled training data. Unlike prior MRI-based investigations, our suggested *was - MTDNN* technique can train models using all accessible individuals, even if some lack medical ratings at key periods[12][13]. Also, our anatomy landmark-based multi-resolution patch extraction procedure may address the issue of limited data by employing texture features instead of whole 3-D MR images as training examples.

Fig. 1. Input MRI Image.

This section is used to summarise the paper's key contributions. First, unlike earlier researches [11], [17], we create a computational model with such a balanced gradient descent that can use all accessible weakly labelled patients (i.e., with partial ground-truth clinical ratings). It allows us to use all accessible labelled subjects. Integrating additional individuals in the training phase might aid in strengthening the resilience of the learnt system. Secondly, we suggest extracting variations in terms (as opposed to fixed-sized) input images if both small & large-scale patches centred at every location are retrieved. Our process is based on anatomic structures relevant to AD. This kind of approach assists in capturing the local/global analytical brain information [16]. Third, we create a combined prediction technique that simultaneously estimates many clinical scores at various times. The collaborative learning technique is anticipated to mimic the natural link between scores at/across various time points, aiding in the improvement of predictive performance. Using an MR image of a fresh experiment, the suggested technique can estimate four clinical ratings at four time-points in 12s, which is near to instant response. The research contributions are:

- 1) The input image is pre-processed for noise removal with Weiner filter and the contrast histogram equalization (CLAHE) is used for pixel block selection.
- 2) The weakly supervised multi-tier dense neural network model (  $ws - MTDNN$  ) is proposed to perform the classification process.
- 3) The performance is evaluated with indices like accuracy, specificity, sensitivity and error rate.

The work is provided as: Section II provides the comprehensive analysis of various prevailing approaches; Section III gives methodological analysis using pre-processing and IV is methodology explanation. The outcomes are discussed in Section 5 and summary in Section VI.

## II. RELATED WORK

In this part, we first discuss the standard interpretations of central nervous system MRIs before showcasing current MRI-based machine learning research to forecast and detect brain diseases. Many different features extracted from brain MRI have indeed been created in the research for automated AD/MCI prediction and diagnosis. These models may be loosely divided into three phases: voxel information, ROI recognition and patch recognition. More information on each type is provided as follows.

Voxel techniques [18] evaluate brain MRI by accurately measuring local tissues density (white and grey matter) following rigid normalization of actual brain images [19]-[20]. Sherubha et al. [21] suggested identifying volumetric information from specific brain parts from MR scans and then using them to categorize gender and AD. Moreover, voxel approaches are generally premised on the 1-1 anatomy mappings among participants and Gaussian dispersion of focal organ concentrations throughout statistical testing [23]. To suit the voxel description, tissue density is distorted with larger cones at the price of focused precision, which may lessen the voxel-based representation's racist and discriminatory potential for MRIs. Some downside of voxel-based modelling shows the amount of training data for individuals is typically quite small, resulting in the small-sample-size issue [24] and decreasing the effectiveness of learnt models. ROI-based depictions concentrate on assessing locally anatomical quantities in the mind's designated areas, in contrast to voxel-based characteristics. In example, earlier ROI-based studies often use tissue volume [11], [25]-[27], cortical thickness [28], hippocampal volume, and tissue densities in specific areas of the brain as feature extraction of MR data. This sort of representation, however, calls for an a priori hypothesis about aberrant areas from a structural standpoint to designate sections, even though these notions may not hold in actuality [22]. A defective brain area may cover numerous ROIs or only a tiny section of an ROI; therefore, employing a fixed brain division may reduce learning performance.

Patch-based analysis three was created to identify minute anatomical differences in brain MRIs using nonlinear analyses to represent the one-to-many mappings between brain structures. According to the author, the patch-based analysis may help diagnose AD and evaluate MCI development. Mohan et al. [28] used GM concentration within image regions as MRI for Disease prediction. The author suggested extracting morphometric information (local energy distribution) using AD-related anatomic structures. These carefully created MRI characteristics are often used to feed established models (such as SVMs and model structure [28]) for the diagnosis and prediction of diseases. However, given that the process of image retrieval and machine learning are carried out separately in these approaches, the pre-extracted MRI features in question may not be the most effective estimation techniques. Numerous supervised learning approaches have been developed to learn MRI characteristics that are task-oriented [14] [15]. An MR scan has millions of vertices, so many brain areas may not have been impacted by Alzheimer's. As a result, one of the main challenges in MRI-

based transfer learning is figuring out how to identify correctly (e.g., discriminatively across groups) in MRIs.

To overcome this trouble, Myronenko et al. [29] suggested concentrating on three ROIs (i.e., the hippocampus, ventricle, and neuroimaging surface) and created the deep CNN for risk that exists in measurements of participants using 2D texture features taken from the three ROIs. In brain scans (i.e., architectural MRI and mobility tensor image information), the CNN used the hippocampus ROI and adjacent areas. Similarly, the author published a deep ranking algorithm for classifying AD from the hippocampus ROI. These studies employ experimentally identified MRI areas without addressing other possibly essential brain regions. The author created a 2D CNN to distinguish AD patients using functional and structural MRI scans. However, they reduce 3D and 4D images to 2D slices and give inputs to the networks, neglecting the crucial spatial information. Recently, Risk et al. [30] developed an anatomic heritage site deep learning system for Clinical examination and MCI conversion prediction. To be more precise, they first identify 3-D image patches using brain regions with AD-related anatomic structures, and afterwards, they create a CNN for combined MRI extracting the features and disease categorization. However, set the size of texture features is employed in these investigations, disregarding the possibility that structural alterations brought on by dementia might differ significantly across various brain areas.

Additionally, most current deep learning techniques are completely regulated, with individuals lacking ground-truth ratings at certain intervals simply being eliminated. To properly engage all available patients (including those lacking ground-truth ratings) for training, a semi-supervised CNN is presented for prediction of MRI data. The suggested approach departs from the earlier research in [30]. In this research, we employ weakly labelled training items by designing a distinctive weighted nonlinear function in the suggested neural net, while earlier techniques [30] can only use completely labelled (whole ground-truth score) training cases. This article attempts to extract multi-resolution input images centred at each landmark site to simulate brain MRI multi-resolution spatial features, whereas only uses fixed-sized input images.

### III. DATA ACQUISITION

We conducted trials on 1469 individuals drawn from subsets of the accessible Dataset collected [10], namely ADNI-1/2. 805 participants have BL structured MRI data from ADNI-1, and 664 individuals from ADNI-2. Individuals are immediately deleted from ADNI-2 if they feature for both ADNI-1 and ADNI-2. In contrast to the participants in ADNI-1, who had 1.5 T T1-weighted MRI, ADNI-2 had 3.0 T T1-weighted MRI. In our investigations, ADNI-1/2 are two separate databases. These issues may be divided into three groups based on several criteria: AD, MCI, and HC.

Four clinical criteria are utilized: 1) CDR-SB; 2) ADAS-Cog11, a different form of the ADAS-Cog with 11 items; 3) ADAS-Cog13, a 13-item version of the ADAS-Cog; and 4) MMSE. The BL time following approval is the day individuals were supposed to conduct the screening. Additionally, the length beginning from the BL time indicates

the time points for obeying visits. Every participant under investigation has MRI data at baseline. However, many lack ground truth scores for certain clinical parameters at particular periods. Table I displays comprehensive details on the topics under study. For each subject's structural MR imaging, we first correct the anterior-posterior commissures, strip the skull and remove the cerebellar. Next, we align every image to a shared Colin27 template before resampling all MR images with a horizontal spatial resolution. Finally, we adjust brightness heterogeneities for each MR image using the N3 method.

#### A. Weiner Filter

It provides a substantial role in various applications like echo cancellation, linear prediction, signal restoration, system prediction and channel equalization. The Weiner coefficients are evaluated to reduce the average squared distance among the desired input and the filtered output. The proposed filter theory considers the inputs that are stationary process. When the filtering coefficients are re-evaluated at periodic intervals for every blocks of 'N' signal samples then the filter needs to adapt the average signal characteristics within the block and works block adaptively. It is determined to be stationary over the relatively small sample blocks. The target of Weiner filter is reducing the mean square error value and image restoration. It is expressed as in Eq. (1):

$$x(n) = d(n) + v(n) \quad (1)$$

Here,  $d(n)$  and  $v(n)$  represents stationary random process.

#### B. Contrast Limited Adaptive Histogram Equalization

The following are the CLAHE procedure:

1) Partition the image into number of equal sub-blocks (size) and every sub-block should be non-overlapping and continuous.

2) Measure the local histogram of every sub-block;

3) Evaluate the average number of pixels allocated to sub-block gray level ( $Avnum$ ). When  $GrayNum$  is utilized to specify the probable gray level to sub-blocks, the process is depicted in Eq. (2) where  $XP$  and  $YP$  represents the number of pixels in  $X$  and  $Y$  sub-block directions.

$$AvNum = \frac{XP.YP}{GrayNum} \quad (2)$$

4) The shear coefficient  $CV$  is fixed with a range of [0,1]. For various images, it can be adjusted to provide superior value via the simulation outcomes, and the actual shear limit value  $NV$  is expressed as in Eq. (3). Here, round specifies the rounding off function.

$$NV = Avnum + \text{round}(CV.(XP.YP - AvNum)) \quad (3)$$

5) With the shear limit, the pixels for every gray level of local histogram and the added number of pixels are re-distributed to every gray level of histogram. Consider, that  $Nclip$  specifies the total amount of pixels that are eliminated. Therefore, the number of pixels can be attained  $NA_{cp}$  that every gray level is allocated with Eq. (4) and Eq. (5):

$$Nclip = \sum(\max(H(i) - NV, 0)) \quad (4)$$

$$NA_{cp} = \frac{Nclip}{GrayNum} \quad (5)$$

Here,  $CH$  is the histogram after the re-distribution process and it is attained by Eq. (6):

$$CH(i) = \begin{cases} NV & H(i) > NV \\ NV & H(i) + NA_{cp} \geq NV \\ H(i) + NA_{cp} & else \end{cases} \quad (6)$$

6) Consider that the remaining amount of pixels after distribution is  $NumLeft$ , step distribution size is depicted as:

$$Step = \frac{GrayNum}{Numleft} \quad (7)$$

Initiate searching from minimal gray level by step size; therefore the pixels are allocated when the numbers of pixels are lesser than shear threshold. Then, finish the cycle from the minimal to maximal gray level till  $Numleft$  is set to zero. Therefore, the histogram allocated is fulfilled and some new histogram is acquired.

7) Histogram equalization is done on every sub-region after the shearing process.

8) The centre-point sub-blocks is considered after the reference point acquired from the gray value. Every image pixel is executed by bilinear interpolation and pixel mapping is provided using the related regions with adjacent reference points. Assume, the small rectangle  $(x, y)$  specifies target point and  $f(x, y)$  represents gray value to evaluate  $(x, y)$ . The adjacent regions' center point is provided as  $A(x-, y-), B(x+, y-), C(x-, y+)$  and  $D(x+, y+)$ . The gray level value  $f(x, y)$  is specified as linear gray value combination with four points. For every pixel over the boundary regions, gray level is evaluated using the linear interpolation adjacent sample points where the corner points are evaluated with the adjacent sample points as in Eq. (8):

$$f(x, y) = a[bf(x-, y-) + (1 - b)f(x+, y-)] + (1 - a)[bf(x-, y+) + (1 - b)f(x+, y+)] \quad (8)$$

$$a = \frac{y-(y-)}{(y+)-(y-)} \quad (9)$$

$$b = \frac{x-(x-)}{(x+)-(x-)} \quad (10)$$

#### IV. METHODOLOGY

In this study, we aim to address two difficult issues in MRI-based brain illness prediction: how to fully exploit poorly labelled training data (i.e., individuals with inadequate ground-truth medical ratings) and how to learn important characteristics of MR images structurally. A weakly supervised CNN is created to incorporate extraction of features and model learning into a cohesive framework, using all accessible weakly labelled subjects for the training phase. The suggested  $ws - MTDNN$  approach consists of two basic steps: extracting multi-scale image patches and classification. More information is provided below. There are thousands of voxels for each brain MR imaging, yet dementia's structural alterations may be minor. When the complete MR image is

provided to the deep learning model, the inputs contain much loud noise data, making network development challenging with just a few hundred training subjects. To train the classifier for accurate illness prediction, we want to find important brain areas in each MRI rather than utilizing the complete image.

We use anatomical markers to find AD-related areas. Here, landmark detection is used to derive 1741 anatomical structures from the Colin27 templates. Numerous landmarks are geographically adjacent to one another, as can be seen in the supplemental materials in Fig. 2. To avoid data duplication and computation time, we chose  $K = 40$  anatomical landmarks. We initially sorted those features in order of increase using the p-values that the landmark identification method obtained via a correlation among AD and HC individuals. The spatial Distance measure is provided to limit (i.e., 20) the separation among landmarks, and we use the top  $K = 40$  monuments. For example, we display the recognized features on three individuals and these landmarks in the templates region.

We generate multi-resolution texture features from an input MRI using these landmarks to obtain extra depth information. Specifically, we derive both small and large scale regions out of MRI. Those patches are all centred on the respective landmarks. So, provide  $K$  landmarks, we can get  $2K$  image patches of certain MRI. These multi-resolution image patching serve as the input information for suggested model.

We simultaneously conduct pattern recognition of MRIs and recovery of numerous clinical ratings at four consecutive using multi-scale image patches from each MRI using the suggested human brain. The proposed scheme receives  $2K$  image patches from each participant as inputs, and it outputs four different clinical measurements at 4 various time points.

Fig. 2. Proposed Model Network Architecture.

We initially concentrate on modelling the nearby spatial features seen in multi-scale image patchwork using  $K$  parallel subnets, each mapped to a particular landmark point. Within every sub-network, the investigators first decrease the effect of the major large-scale update. Therefore, it is a relatively similar diameter to the small-scale patch. These tiny patches are therefore individually sent into a sub-network consisting of three deep convolutional modules (DCMs) and two fully connected (FC) levels, treating them as the two-channel input. In each DCM, three convolutional neural networks are followed by a 222 max-pooling plane for output feature wavelet decomposition. In distinctive, for a precise convolution operation within every DCM, the feature maps (the images that come out of each convolution operation) of all the layers before they are being used as inputs, and the convolution layers of all the layers after they have been used as inputs. Batch standardization and linear transfer unit (ReLU) activation are used after each convolution operation. Such densely linked design strengthens feature propagation, encourages feature reuse, and reduces network parameter optimization. The  $K$  parallel subnetworks have identical designs but individually optimized characteristic weights. We want to discover landmark local characteristics from images using  $K$  sub-networks to preserve each landmark site's distinctive local analytical information. If sub-networks share properties, we can't extract historic site-local spatial features from brain MRIs.

It is important to note that the overall architecture of an MRI cannot be captured by utilizing merely the local patches alone. To do this, the feature maps knowledge gained since the last  $K$  FC layers in  $K$  sub-networks are added together, and then two more FC layers are added to learn the neighbourhood classification model of the information MR image. Four clinical-grade categories at four different time points are predicted using the last FC layer (containing 32 neurons). Based on [3], we created a weighted loss function for the network model so that all available loosely labelled training participants could be used to their fullest (missing ground-truth clinical scores). We will refer to the training set of  $N$  individuals as  $X = [x_1, \dots, x_n, \dots, x_N]$ , where  $W$  refers to the network coefficients. Its  $s$ th ( $s = 1, \dots, S$ ) ground-truth clinical value at the  $t$ -th ( $t = 1, \dots, T$ ) time-point is indicated as  $y_n^{s,t}$  for the  $n$ th ( $n = 1, \dots, N$ ) subject  $x_n$ . The suggested optimization problem aims to reduce the gap here between the following projected number  $f^{s,t}(x_n; W)$  and the actual number  $y_n^{s,t}$ :

$$\arg \min_W \frac{1}{N} \sum_{n=1}^N \frac{1}{\sum_{s=1}^S \sum_{t=1}^T \gamma_n^{s,t}} \sum_{t=1}^T \gamma_n^{s,t} * \left( y_n^{s,t} - f^{s,t}(x_n; W) \right)^2 \quad (11)$$

Where  $\gamma_n^{s,t}$  indicates whether or not  $x_n$  is given the  $s$ th medical value at the  $t$ -th time-point. In particular, if the ground-truth score  $y_n^{s,t}$  is accessible for  $x_n$ , then  $\gamma_n^{s,t} = 1$ . To be more particular, even if an instructional subject has omitted scores at some points in time and therefore does not start contributing to the loss of data processing (i.e.,  $\gamma_n^{s,t} = 0$ ), it still start contributing to the logistic regression during network training. Therefore, increased throughput is used at various time points. Furthermore, we may have used all accessible individuals (even if they lack ground reality diagnostic ratings

at various time intervals) for model training using Eq. (11). It seems possible because (1) allows us to build representations from MR scans informally automatically. The typical beginning of the module dismisses individuals with insufficient ground-truth scores, in contrast to this.

We randomly choose alternative patches centered at each landmark position with separations, and the phase margin is one. This one will increase the training set and lessen the detrimental effect of landmark identification mistakes. As a result, each MRI may also provide 125 patches, one for each point, at each scale. Given  $K$  landmarks, we may create 125K variations of patched at each size, each serving as a unique sampling for the neural framework. It technically allows us to create 125K examples for MRI, but these sampling are utilized as input information randomly for the suggested system.

At the training step, designers use the instructional subject matters' BL MRIs as inputs and their own ground-truth diagnostic and therapeutic goals scored at four points in time (with incomplete data) as outputs to train the network. In particular, we firstly collect variations in terms (i.e., 242424 and 484848) image regions from each train MRI and then input such patched to the networks  $k$  – Means and  $k$  anatomic structures. This method may discover a mapping function from every MRI source to the three clinical ratings at four different periods. During testing step, we first identify its related landmarks using deep learning for an unknown experiment with just a BL MR image and then create a multi-resolution patchwork. We next input these multi-resolution image patches to the trained network to forecast the clinical ratings at four different periods for this test patient.

Stochastic gradient descent (SGD) and the back-propagation technique for generating network concentrations and updating parameters are used to improve the objective function. The mobility parameter and the number of iterations for SGD were explicitly calibrated experimentally to 0.9 and 104. Fig. 3 displays the changing curves for the calibration and testing loss functions on the ADNI-1 database. Using a computer with a solitary GPU, our process utilizes about 12 seconds to forecast the four types of diagnostic tests of the MRI experiment. Inferring the suggested  $ws$  – *MTDNN* approach is anticipated to carry out real-time brain illness diagnosis in practical applications. The software and primarily targeted model are accessible online.

Fig. 3. Layer Description.

### V. NUMERICAL RESULTS AND ANALYSIS

We execute two sets of trials in twofold confidence intervals to test the suggested method's resilience. We explicitly train models on participants from ADNI-1 and evaluate them from the separate ADNI-2 Dataset in the first set of trials. The second category trains on ADNI-2 and tests on ADNI-1. Various performance metrics like accuracy, specificity, sensitivity and error rate are evaluated and compared with other approaches. The expressions for these metrics are given below:

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \quad (12)$$

$$Sensitivity = \frac{TP}{TP+FN} \quad (13)$$

$$Specificity = \frac{TN}{TN+FP} \quad (14)$$

$$Error\ rate = 1 - \frac{1}{2} (sensitivity + specificity) \quad (15)$$

Fig. 4. Input Image.

Fig. 5. Filtered Image.

Fig. 4 to Fig. 6 provides the outcome of the pre-processed image. Table 1 compares approaches like conventional ANN, SVM, BoVW-based SVM, conventional CNN and DNN. Here, metrics like accuracy, specificity, sensitivity and error rate are evaluated and compared with other approaches. The

accuracy of the anticipated model is 93.08% which is 58.08%, 2.08%, 1.08%, 20.08% and 25.08% higher than other approaches. The specificity of the anticipated model is 83.47% which is 48.47%, 7.47% and 15.47% higher than ANN, conventional CNN and DNN and 6.53% and 9.53% lesser than SVM and BoVW-based SVM model. The specificity of the anticipated model is 100% which is 65%, 9%, 7%, 31% and 35% higher than other methods. The error rate is 0.069 for the anticipated model, which is comparatively lesser than other approaches. Other approaches pose an error rate of 1.2568, 2.564, 3.548, 1.565 and 16.235, respectively. Based on the analysis, it is proven that the anticipated model works well compared to other approaches in the prediction process (See Fig. 7 to Fig. 10).

#### A. Constraint Analysis

The following is a summary of the restrictions this paper still has.

1) The suggested technique was only evaluated for predicting clinical values from MRI images, but ADNI-1 and ADNI-2 databases include transverse MRI scans. The issue with utilizing longitudinally MRI scans for therapeutic score prediction lack subsequent images.

2) The process largely functions for estimating various clinical scores while measuring the relationship among the clinical scores and subject classifications (such as AD or HC).

3) Local patch identification based on anatomic structures is autonomous of extracting the features and classification building, which may hinder prognosis performance.

4) We did not consider the differences in the subject distribution of data between ADNI-1 and ADNI-2. It might adversely impact the generalizability of our technique.

As a result:

1) Users will translational MRI scans to assess the clinical scores. For accurate prediction, missing MRI scans will be filled with learning algorithms (like generative adversarial). Also, full (after calculation) MRI images for evaluating clinical grades at all time points may indicate which time point would be most relevant in disease progression.

2) Given the strong correlation between clinical values and membership functions for a given patient, it seems sensible to create a single deep learning model that combines analysis and categorization.

3) Immediately detect patch/region-level racially discriminatory spots in the entire MRI so patch and region organization contains may be concurrently learnt and merged to build illness classification techniques.

4) We want to develop a better classification approach to address the issue of diverse data distributions. It is anticipated to better the suggested network's capacity to generalize.

#### VI. CONCLUSION

In this research, we suggested ws – MTDNN for predicting many clinical scores based on individuals having MRI data and partial clinical ratings. It was done using individuals as training data and individuals as validation data. Specifically, we pre-processed all MR images and then used feature detection algorithms to locate disease-related anatomical structures in the patients' bodies. Based on the position of each landmark, we selected multi-scale patchwork with the landmarks serving as their centres. We constructed a deep convolutional neural network to concurrently learn discriminant information from MRI and forecast several clinical grades at four different periods. The input data for this network were image patches. Our network model constructed a balanced loss function for all training patients, though many may not have full ground-truth clinical ratings. The suggested ws – MTDNN algorithm can identify clinical grades at future time points utilizing MRI data in science experiments from the available datasets.

**Abstract**—In our study, we propose a hybrid Convolutional Neural Network with Support Vector Machine (CNN-SVM) and Principal Component Analysis with support vector machine (PCA-SVM) methods for the classification of cocoa beans obtained by the fermentation of beans collected from cocoa pods after harvest. We also use a convolutional neural network (CNN) and support vector machine (SVM) for the classification operation. In the case of the hybrid model, we use a convolutional network as a feature extractor and the SVM is used to perform the classification operation. The use of PCA-SVM allowed for a reduction in image size while maintaining the main features still using the SVM classifier. Radial, linear and polynomial basis function kernels were used with various control parameters for the SVM, and optimizers such as the Stochastic Gradient Descent (SGD) algorithm, Adam, and RMSprop were used for the CNN softmax classifier. The results showed the robustness of the hybrid CNN-SVM model which obtained the best score with a value of 98.32% then the PCA-SVM based model had a score of 97.65% outperforming the standard CNN and SVM classification algorithms. Metrics such as accuracy, recall, F1 score, mean squared error (MSE), and MCC have allowed us to consolidate the results obtained from our different experiments.

**Keywords**—Support vector machine; convolutional neural network; cocoa beans; principal component analysis; hybrid method

## I. INTRODUCTION

Côte d'Ivoire is the world's largest producer of cocoa [1] and cocoa is an important cash crop in the world. The cocoa culture produces beans from the ripe pod seeds of the Theobroma plant [2]. Cocoa beans are the main raw material for chocolate [3] and the first step in this process is fermentation.

Fermentation is an essential step in cocoa processing, and it has an impact on the flavor, color, and aroma of cocoa products [4]. Unfermented cocoa beans do not have the full flavor of chocolate, but fermentation triggers chemical changes within the cocoa bean that contribute to the development of chocolate flavor [5]. Once harvested, farmers open the cocoa pods, extract the cocoa seeds with the pulp and fill wooden boxes or containers to begin fermentation [6]. Using quality dried cocoa beans from the fermentation process allows for obtaining better-finished products. The process of detecting the quality of dried cocoa beans is a tedious task and requires special attention, hence the need to use computer vision that will allow an image to specify its category of it. In recent years, computer vision has an important role in agricultural production with the

use of machine learning and more specifically deep learning convolutional neural networks [7]. We can note here the popular image analysis techniques in machine learning such as Support vector machine (SVM), Artificial Neural Network (ANN), Convolutional Neural Networks (CNN), Normalized Difference Vegetation Index (NDVI), and statistical tools such as correlation and regression analysis, etc [8]. In order to facilitate the classification of cocoa beans, we proposed the methods of CNN, SVM, hybrid CNN-SVM, and principal component analysis with support vector machine (PCA-SVM). The general principle of the hybrid model is to automatically extract features based on the CNN and do the classification using the SVM classifier, while the PCA-SVM reduces the image size while keeping the main features still using the SVM classifier. All these methods were used to detect the category of cocoa dried seeds and then we compared them to come out with the best method. Our technique can evolve into an industrial application with an appropriate integration framework, replacing the traditional method of quality control of cocoa beans. Thus, our study can be integrated into a computer vision system and implemented in the cocoa production and processing chain, resulting in a state-of-the-art automatic solution. The proposed approach could benefit the industry by enabling them to accurately determine the quality of cocoa beans.

This paper is organized as follows: Section II presents some previous work, and Section III details the methodology and the material we propose. Section IV presents the results obtained and discusses them, and we conclude in Section V.

## II. RELATED WORK

Several works focused in this area and we can cite some of them, namely, Oliviera et al. used handcrafted features calculated from the beans provided by image analysis tools, and then the random decision forest predictor was used to classify the samples. This experiment yielded an accuracy of 92% [9]; Kaghi et al. used a pre-trained AlexNet CNN as a generic feature extractor of a 2D image whose dimensions were reduced using PCA + TSNE and finally classified using a simple machine learning algorithm like KNN, and Naïve Bayes Classifier. These results could match a CNN Softmax classifier [10]; Barbon et al. used machine learning-based methods namely J48, Naïve Bayes, K-NN, Random Forest, SVM, MLP, and Fuzzy approaches to predict the storage time of pork, and these methods provided the accuracies which ranged from 78.26 to 94.41% [11]. A. and Renjith provide a special

architecture to identify the features of different classes of Durian fruit, the image processing model allows the classification to be divided into two parts: feature extraction and classification of the fruit used. The use of edge detection and color extraction provide correct feature extraction of durian, the performance is measured using non-destructive machine learning techniques such as SVM, GNB, and Random Forest. The results obtained provide the best accuracy of 89.3% using the SVM technique and 84.3% using Random Forest [12]; Harel et al. proposed maturity classification algorithms. Their algorithms were applied to the maturity classification of peppers. Maturity classification achieved 98.2% and 97.3% accuracy for two-class classification between mature and immature classes of red and yellow peppers, respectively, and 89.5% and 97.3% accuracy for four-class maturity classification. The random forest algorithm has been shown to be very robust [13]. Elleuch et al. explored a method focusing on the use of two classifiers in this case Convolutional Neural Network (CNN) and Support Vector Machine (SVM) for offline Arabic handwriting recognition, the performance of their methods was compared with the character recognition accuracies obtained from the state of the art of optical Arabic character recognition, producing favorable results [14].

### III. MATERIAL AND METHOD

#### A. Materials

The digital images of cocoa beans used for the study were obtained at YAKASSE 1 (longitude: -3.77374 latitude: 5.23841) village located near GRAND-BASSAM in Côte d'Ivoire. These cocoa bean samples were classified as follows:

- Category 1 beans: fermented and dried cocoa beans of superior quality.
- Category 2 beans: fermented and dried cocoa beans of intermediate quality.
- Category 3 beans: non-fermented and dried cocoa beans.

Once the data is obtained as shown in Fig. 1, we will proceed to the pre-processing that will extract the seeds from each image.

Fig. 1. Cocoa Beans Sample Images from the Three Classes: (A) Category 1 Beans; (B) Category 2 Beans; (C) Category 3 Beans.

Fig. 2. General Schema of the Dataset.

We describe the preprocessing stage now

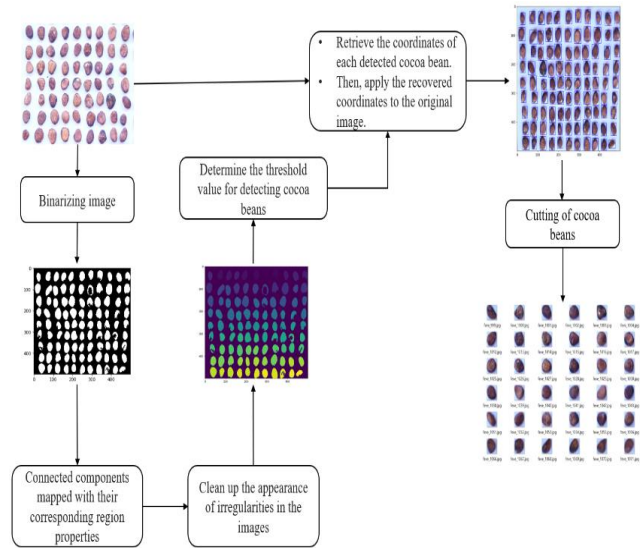

Fig. 3. Preprocessing Cocoa Beans Extraction.

After the preprocessing step as shown in Fig. 2 and Fig. 3, we obtained a dataset of 3470 images of cocoa beans, including 917 images of beans of category 1, 1675 images of beans of category 2, and 878 images of beans of category 3. We split the dataset into 60% for training, 20% for testing, and 20% for validation.

The table I presents the data split description-

TABLE I. DESCRIPTION OF THE DATA SPLIT

Dataset	Training set	Validation set	Test set
100%	60%	20%	20%
3470	2082	694	694

We trained the models on a Windows 10 system with an Intel(R) Core™ i7-8650U processor, 16 GB of random-access memory (RAM), and an NVIDIA GeForce MX150 graphics processing unit (GPU). The models are configured in Python using the Keras version 2.4 API with the TensorFlow version 2.4 backend and CUDA/CuDNN dependencies for GPU acceleration.

#### B. Methods

Our method is segmented into three main parts as shown in Fig. 4, namely preprocessing as seen in the materials section, feature extraction, and classification.

Fig. 4. Architecture of the Model for the Classification of Cocoa Beans.

1) *Feature extraction*: We proposed two feature extractors namely the CNN and the PCA.

a) *CNN*: The CNN we used in our study consists of two convolutional layers with 32 filters each and a 3x3 size kernel with a Relu activation function. The convolutional layer allows for the generation of a particular feature map by applying a filter that examines the whole image. Each of the convolutional layers has a max-pooling layer of 2x2 core, it is a subsampling layer. The subsampling of the pooling layer consists of extracting the most important value of each pattern from the feature map. This layer reduces the parameters and computations in the network, this layer improves the performance of the network and avoids overlearning [15]. Finally, a Flatten layer that flattens the feature map and reduces its size. The Table II gives the description of CNN.

b) *PCA*: Principal component analysis (PCA) is a technique that is applied in applications such as dimensionality reduction, data compression, feature extraction, and data visualization. PCA allows a set of correlated variables X to be transformed into a smaller number y with  $y < X$  of uncorrelated variables called principal components while retaining as much variability of the original data. One of the features of PCA is image compression a technique that reduces the size of an image while retaining as much of the image quality as possible [16].

2) *Classification*: Classification is a task that uses machine learning algorithms that learn to assign a class label to examples in a domain for a given problem. There are many types of classification tasks in machine learning and specialized modeling approaches that can be used for each [17]. In our study, we used the Softmax and SVM classifiers.

a) *Classifier Softmax*: The Softmax classifier is a generalization of the binary form of logistic regression, It has been used in deep learning more precisely in the field of computer vision to classify the vectors obtained after feature extraction [18]. In its operation, the mapping function F is defined such that it takes a set of input data x and maps to output class labels from a simple dot product of the data x and the weight matrix W.

$$F(x_i, W) = W * x_i \quad (1)$$

The Softmax score function gives a probability based on the final score. The sum of the probability of all categories is equal to one [18]. The equation is as follows:

$$f_j(z) = \frac{e^{z_j}}{\sum_k e^{z_k}} \quad (2)$$

The Softmax loss function can be viewed as the entropy of two probabilities, as shown in the following equation:

$$H(p, q) = -\sum_x p(x) \log q(x) \quad (3)$$

We will use optimizers which are algorithms used to minimize the loss function. These functions are:

- SGD which stands for Stochastic Gradient Descent, is a gradient descent optimizer that is used in machine learning and deep learning. Stochastic means a system that is connected or linked with a random probability [19].
- Adam is the extended version of stochastic gradient descent that could be implemented in various deep learning applications such as computer vision and natural language processing [19].
- RMSprop which stands for Root Mean Squared Propagation is an extension of gradient descent and the AdaGrad version of gradient descent that uses a decreasing average of partial gradients to tailor the size of each parameter step. The use of a decreasing moving average allows the algorithm to forget about bad gradients and focus on the best gradients observed during the search progress, overcoming the limitations of AdaGrad [19].

TABLE II. CNN ARCHITECTURE

Layer	Output Shape	Parameter Size
Convolutional 1	(58, 58, 32)	896
Pooling	(29, 29, 32)	0
Convolutional 2	(27, 27, 32)	9248
Pooling	(13, 13, 32)	0
Flattening	5408	0
Total parameter	703 012	
Trainable parameter	703 012	
Non-Trainable parameter	0	

b) *Classifier SVM*: The support vector machine (SVM) is a supervised algorithm used in machine learning. It tries to find a hyperplane that best separates the different data. The SVM is based on statistical approaches, it allows the classification of the data and assigns to each data a specific score as a basis for evaluation. SVM can be used for both regression and classification tasks. However, it is more commonly used for classification objectives [20]. The SVM constructs a hyperplane or a set of hyperplanes in a high or infinite dimensional space, which can be used for classification, regression, or other tasks. Intuitively, a good separation is achieved by the hyper-plane that has the largest distance to the nearest training data points of any class, because in general the larger the margin, the smaller the generalization error of the classifier [21]. The SVM solves the following equation:

$$\min_{\omega, b, \zeta} \frac{1}{2} \omega^T \omega + C \sum_{i=1}^m \zeta_i$$

$$\text{Subject to } y_i(\omega^T \Phi(x_i) + b) \geq 1 - \zeta_i,$$

$$\zeta_i \geq 0, i = 1, \dots, n \quad (4)$$

The loss function is represented by the false predictions of the score function. In SVM, Multiclass SVM Loss is used. The main idea of Multiclass SVM Loss is to determine the scores given by Score Function, requiring the final score to be at least one unit higher than the incorrect score [22]. The loss function is defined by the following equation:

$$L_i = \sum_{j \neq y_i} \max(0, w_j^T x_i - w_{y_i}^T x_i + \Delta) \quad (5)$$

We use the following SVM kernels in our study:

- The linear kernel and its equation is:

$$K(x, y) = x * y \quad (6)$$

- The polynomial kernel and its equation is :

$$K(x, y) = [(x \times y) + 1] d \quad (7)$$

- The RBF (Radial Basis Function) kernel and its equation is:

$$K(x, y) = \exp(-\gamma \|x - y\|^2). \quad (8)$$

Also, we have used the values 1 and 100 for the parameter C which is common to all SVM kernels, it allows us to correct the errors in the classification of the training examples by the simplicity of the decision surface.

### C. Evaluation Metrics

To validate the performance of the pre-trained models in our study we will use the following metrics:

- Accuracy is a performance measure that shows how well the system has classified the data into the correct class.

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+TN+FN} \quad (9)$$

- Precision is the ratio of correctly classified positive images to the total number of true positive images.

$$\text{Precision} = \frac{TP}{TP+FP} \quad (10)$$

- Recall is the ability of a classifier to determine actual positive outcomes

$$\text{Recall} = \frac{TP}{TP+FN} \quad (11)$$

- The F1 score is the weighted average of precision and recall

$$F1 \text{ score} = 2 * \frac{\text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}} \quad (12)$$

- The Matthews correlation coefficient (MCC) is used in machine learning as a measure of the quality of classifications

$$MCC = \frac{TP * TN - FP * FN}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \quad (13)$$

- The mean square error of an estimator measures the average of the squared errors, i.e. the mean square difference between the estimated values and the true value.

$$MSE = \frac{1}{n} \sum_{i=1}^n (Y_i - \hat{Y}_i)^2 \quad (14)$$

With TP: True positive, TN: True negative, FP: False positive, and FN: False negative.

## IV. RESULTS

### A. CNN with Softmax

In the case of the CNN with Softmax, we can record the results presented in the Table III which takes into account the different optimizers mentioned above.

TABLE III. THE GENERAL PERFORMANCE OF THE SOFTMAX CLASSIFIER

	Accuracy	Loss	Precision	F1 score	Recall	MCC	MSE
SGD	92,95	17,93	93,37	92,95	92,95	89,2	3,41
Adam	<b>95,64</b>	<b>17,18</b>	<b>95,65</b>	<b>95,64</b>	<b>95,63</b>	<b>93,18</b>	<b>2,37</b>
RMSprop	94,63	36,99	94,83	94,62	94,63	91,73	3,18

The results presented in Table III show that the Adam optimizer obtains the best performance with a score of 95.64%, followed by the RMSprop and finally the SGD. We see in this experiment that the softmax classifier using the Adam optimizer is more optimal.

Fig. 5 presents the confusion matrix of each softmax experiment case; also, a histogram of the metrics has been created.

### B. SVM

In the case of SVM we can record the results presented by the Table IV which takes into account the different kernels and parameters.

The results presented in Table IV show that the SVM with the RBF kernel; and the C parameter at 100 obtained the best performance with a score of 97.32%.

We now present the confusion matrices and histograms of the metrics in Fig. 6.

Fig. 5. (A) Confusion Matrix of Adam ; (B) Confusion Matrix of SGD ; (C) Confusion Matrix of RMSprop ; (D) Graphical Representation of Optimizer Metrics.

TABLE IV. GENERAL PERFORMANCE OF THE SVM CLASSIFIER

	Accuracy	Precision	F1 score	Recall	MCC	MSE
<i>SVM (rbf ; C=1)</i>	93,96	94,08	93,94	93,95	90,65	6,37
<i>SVM (rbf ; C=100)</i>	<b>97,32</b>	<b>97,33</b>	<b>97,31</b>	<b>97,31</b>	<b>95,82</b>	<b>3,35</b>

(A) Confusion Matrix of SVM (RBF ; C=1) ; (B) Confusion Matrix of SVM (RBF ; C=100) ; (C) Confusion Matrix of SVM (Linear ; C=1) ; (D) Confusion Matrix of SVM (Linear ; C=100) ; (E) Confusion Matrix of SVM (Poly ; C=1) ; (F) Confusion Matrix of SVM (Poly ; C=100) ; (G) Graphical Representation of Optimizer Metrics.

### C. CNN with SVM

For the hybrid CNN-SVM method, we can record the results presented in Table V which takes into account the different kernels and SVM parameters.

TABLE V. GENERAL PERFORMANCE OF THE CNN WITH SVM

	Accuracy	Precision	F1 score	Recall	MCC	MSE
<i>CNN - SVM (rbf ; C=1)</i>	95,08	95,29	95,06	95,07	92,44	4,92
<i>CNN - SVM (rbf ; C=100)</i>	<b>98,32</b>	<b>98,34</b>	<b>98,32</b>	<b>98,32</b>	<b>97,39</b>	<b>1,67</b>
<i>CNN - SVM (linear ; C=1)</i>	95,86	95,95	95,85	95,86	93,59	4,47
<i>CNN - SVM (linear ; C=100)</i>	95,86	95,95	95,85	95,86	93,59	4,47
<i>CNN - SVM (poly ; C=1)</i>	95,41	95,61	95,4	95,41	92,96	5,25
<i>CNN - SVM (poly ; C=100)</i>	98,10	98,11	98,09	98,09	97,04	1,90

The results presented in Table V show that the CNN-SVM with the RBF kernel; and the C parameter at 100 obtained the best performance with a score of 98.32%.

We now present the confusion matrices and histograms of the metrics in Fig. 7.

Fig. 7. (A) Confusion Matrix of CNN - SVM (rbf ; C=1); (B) Confusion Matrix of CNN - SVM (rbf ; C=100); (C) Confusion Matrix of CNN - SVM (Linear ; C=1); (D) Confusion Matrix of CNN - SVM (Linear ; C=100); (E) Confusion Matrix of CNN - SVM (Poly ; C=1).

D. PCA with SVM

For the PCA-SVM method, we can record the results presented in Table VI which takes into account the different kernels and parameters of the SVM.

The results presented in Table VI show that the SVM with the RBF kernel; and the C parameter at 100 obtained the best performance with a score of 97.65%.

We now present the confusion matrices and histograms of the metrics in Fig. 8.

E. Comparison of the Results of the Different Methods

We will compare the results of the different methods used in our study, namely: CNN, CNN-SVM, SVM, and PCA-SVM. The results will be represented in Table VII.

Table VII compares the best results obtained in our different experiments. It appears that the hybrid CNN-SVM method obtained the best score followed by the PCA-SVM. Fig. 9 shows the histogram of the comparison

TABLE VI. GENERAL PERFORMANCE OF THE PCA WITH SVM

	Accuracy	Precision	F1 score	Recall	MCC	MSE
PCA - SVM (rbf ; C=1)	95,41	95,49	95,4	95,41	92,89	5,21
PCA - SVM (RBF; C=100)	97,65	97,67	97,64	97,65	96,34	3,02
PCA - SVM (linear; C=1)	93,40	93,55	93,38	93,4	89,79	7,94
PCA - SVM (linear; C=100)	91,39	91,52	91,36	91,38	86,64	9,95
PCA - SVM (poly; C=1)	92,73	93,13	92,74	92,72	88,81	10,96

TABLE VII. COMPARATIVE TABLE OF THE BEST RESULTS OF OUR EXPERIMENTS

Models	Accuracy
CNN - SVM (RBF; C=100)	98,32
PCA - SVM (RBF; C=100)	97,65
SVM (RBF; C=100)	97,32
Softmax with Adam optimizer	95,64

Fig. 9. Histogram of Best Scores of Experiments.

#### F. State-of-the-art Comparison

The results of our experiments have given better results than the state of the art and Table VIII presents the results. These results are also represented by the histogram as shown in Fig. 10.

TABLE VIII. COMPARISON OF THE RESULTS OF OUR EXPERIMENTS WITH THE STATE-OF-THE-ART

Models	Accuracy
Oliviera et al. [9]	92
CNN - SVM (rbf ; C=100)	98,32
PCA - SVM (rbf ; C=100)	97,65
SVM (rbf ; C=100)	97,32
Softmax with Adam optimizer	95,64

Fig. 10. Histogram of the Results of our Experiments with the State-of-the-Art.

#### V. DISCUSSION

The analysis of digital images of a cocoa bean using CNN and PCA-based feature extractors were used to then perform the classification of cocoa beans from softmax and SVM classifier. The work resulted in the following:

First, we used the CNN coupled with the softmax classifier using several optimizers in this case Adam, RMSprop, and

SGD. The Adam optimizer obtains the best performance with a score of 95.64%, followed by RMSprop and SGD. These results are presented in Table III. In the second step, we used the SVM classifier using several kernels such as rbf, linear, and poly with the parameters C with a value of 1 and 100. We thus obtained a score of 97.32% which represents the best accuracy coming from the rbf kernel with C = 100, these results are presented in Table IV. In a third step, we used the hybrid CNN-SVM method with the same parameters used by the SVM, again we have a score of 98.32% achieved with the rbf kernel and C=100, these results are presented in Table V. Finally in a fourth time we have the PCA-SVM method which also uses the same parameters of the SVM and obtained a score 97.65% with the kernel rbf and C=100, these results are presented in Table VI. At the end of our work, we realize that the hybrid CNN-SVM method obtained the best accuracy of all the methods used as shown in Table VII of the comparative study, and also of the methods of previous studies in the literature review as shown in Table VIII.

#### VI. CONCLUSION

Cocoa production is an area of research that needs the use of automated methods for product quality assessment. The results obtained showed that feature extractions based on CNN coupled with an SVM classifier are promising systems to classify cocoa beans according to quality. Also, we used principal component analysis to reduce the size of our data while designing the main features and this allowed us to have a satisfactory result, which results in showing that we can minimize the computational time of the classifiers proceeding to a reduction of the dimensions. The result of the hybrid CNN-SVM method obtained the best score of all the methods used including the one in the literature. We achieved our goal because the hybrid method gives us a better score. In future work, we will be able to use texture extraction methods and pre-trained CNN sets for more accuracy. Also, a study of the quality of cocoa beans based on the approach of the maturity of cocoa pods will initially distinguish the best pods. The harvest of unripe pods gives beans of poor quality, while a pod too ripe has beans that begin to germinate or alter inside the pod. The classification of cocoa beans according to their shape or morphological parameters will also help to obtain quality beans.

#### ACKNOWLEDGMENT

Our gratitude goes to the village community of YAKASSE, located in the town of GRAND-BASSAM in CÔTE D'IVOIRE, who kindly put their plantations at our disposal for our studies.

# SQrum: An Improved Method of Scrum

## Proposed Metamodel for SQrum Method

Najihi Soukaina, Merzouk Soukaina, Marzak Abdelaziz

Department of Mathematics and Computer Sciences, Hassan II University- Casablanca  
Faculty of Sciences Ben M'sik, Casablanca, Morocco

**Abstract**—Software systems are having a major impact on many aspects of personal and professional life. Safety-critical applications, such as production line controls, automotive operations, and process industry controls, rely significantly on software systems. In these applications, software failure may result in bodily damage or death. The proper operation of software is essential to the safety and well-being of individuals and businesses. Therefore, software quality assurance is of paramount relevance in the software business today. In recent years, Agile Project Management and particularly Scrum, have gained popularity as a method of dealing with "vuca" business environments, which are characterized by rising Volatility, Uncertainty, Complexity, and Ambiguity. This paper contributes to the software development body of knowledge by proposing a metamodel of Scrum quality assurance, named SQrum ('SQ' of Software Quality and 'rum' of Scrum). Our objective is to make Scrum more efficient and reliable and to assist enterprises in undertaking quality assurance activities while considering agile practices and values.

**Keywords**—Agile project management; IT; OMG; meta-object facility; MOF; metamodel; scrum; SQrum; quality assurance; QA; quality management; QM; software development project

### I. INTRODUCTION

The capacity to successfully execute Information Technology (IT) projects has become a crucial and strategic need for modern organizations. When expenses for field updates, recalls, repairs, downtime, etc. are included, the release of a product with problems may be extremely costly. Damage to a company's reputation is less measurable but equally significant. In addition, a failed software project might damage the competitive position of an organization. Value and quality delivery are essential variables for determining the success of a software development project; they are crucial assets for any firm seeking to remain competitive in the marketplace. Despite extensive efforts to find methods for maintaining software quality, software projects continue to fail [1].

There is a growing demand for the deployment of software development methods that are both flexible enough to keep up with the rapid rate of change and the competitive market and rigorous enough to prevent defects and assure product quality. However, humans are fallible. Even with the most advanced and conscientious design processes, erroneous outcomes cannot be avoided beforehand. As a result, software products, like the outcomes of any engineering effort, must be validated against their requirements throughout their development. Agile software development has arisen as an alternative to planning

and managing complicated projects by offering methods to accommodate frequent project changes.

Agile is a method characterized by continuous iterations and testing throughout a product's Software Development Life Cycle. Scrum is the most popular agile approach [2]. Scrum is a lightweight, agile framework that provides processes for managing and controlling the software and product development process. Although Scrum offers a number of benefits, such as incremental deliverables at the end of each iteration, stakeholders and product owners can modify requirements throughout the process, and Scrum can swiftly adapt to these modifications. Process and product quality remain Scrum's principal problems.

One of the most significant contrasts between agile and traditional development is the agile "whole-team" approach [3], in which quality is the responsibility of the entire team and quality assurance is incorporated into the process itself, without an explicit Quality Manager (QM) role. Quality Assurance (QA) activities are integrated into the team's day-to-day operations in order to improve product quality through a smooth process. Large organizations frequently face the issue of combining the Agile requirements of adaptability, transparency, and collaboration while also assuring product quality and adhering to required QA processes. With these changing issues in this area, businesses struggle to identify the best method to integrate QA into Agile environments, particularly Scrum.

Within an Agile team, each team member is responsible for testing and product quality and participates in test-related activities. Each member of the team may see quality from a unique perspective and mindset. All of them are acceptable contributions to quality, but Scrum projects are still facing quality challenges due to the lack of defined rules in Scrum. This necessitates an explicit QM position to incorporate non-functional requirements (NFR), assure process improvement, and provide shared ownership of quality. Just as the Product Owner is responsible for maximizing the value, the QM is responsible for increasing the quality.

Every member of an agile team is a tester, but a QM is more than just a tester. A QM on the Agile team is able to give an overview perspective on all team contributions in order to establish the product quality strategy. Instead of criticizing, QM provides proactive ways to improve productivity, promote software quality within the team, and give software testing and quality coaching.

Quality assurance is like a ship; everyone participates in making it move forward, but only one person can steer it in the right direction. A QM is the one who gives the "course" to follow for the whole team to reach a satisfactory quality level. He is the one who carries the global vision of the product and process quality.

The aim of this paper is to propose a new agile approach called "SQrum", whose central concept is the addition of a new quality role and all of the artifacts it will require. We will build a metamodel using the OMG Meta-Object Facility (MOF) that provides an abstract view of the new agile development process. The Meta Object Facility (MOF [4]) standard was created by the Object Management Group (OMG) to facilitate the development of modeling formalisms in the form of metamodels. This consists of a set of meta-classes connected by meta-association [11]. The rest of this paper is organized as follows: Section II details the related work of this study. Section III provides an overview of Scrum. Section IV describes the disadvantages of Scrum. SQrum is presented in Section V. Finally, Section VI concludes the study.

## II. RELATED WORK

Hanssen et al. [5] found that Quality Assurance processes in Scrum are becoming inadequate. Consequently, they suggested a new method called SafeScrum, which is a Scrum variant with some supplementary XP methods that can be used to develop safety-critical software and IEC 61508 certified software. They evaluated the standard, sought out an impartial evaluator, and collaborated with the Scrum team to identify the required additional tasks to be included in the Safe Scrum process for an internal quality assurance component. They did not cover all aspects of quality in a scrum project with the proposed role.

Jeon et al. [6] explain that Scrum does not place enough focus on non-functional requirements, whereas the key success factor of software projects is not only the satisfaction of functionalities, but also of quality attributes; therefore, they propose the ACRUM method for the analysis and incorporation of quality attributes into software projects. Jan Bosch concurs with Jeon et al. and suggests an approach that explicitly takes nonfunctional criteria into account during design.

Timperi [7] explains the weakness of scrum is the lack of concrete guidance and instructions about quality assurance activities and that the focus has been on the development activities while quality assurance practices of different agile methodologies have received less attention and an overall picture is missing. The author recommends combining quality assurance practices of different methodologies, like Scrum and XP, in order to get good enough software delivered to the customer.

Aamir et al. [8] assert that due to the rapid delivery process of sprints, quality is not considered in the scrum framework, and the majority of Quality Control (QC) operations are overlooked. To address this issue, the authors offer an enhanced scrum model for implementing QC activities and evaluating the product's quality. They also provide a new

concept of "test backlog" for documenting test cases within the scrum.

Bajnaid et al. [9] addressed the limitations of agile practices that do not include quality assurance in their process to guarantee that the quality assurance procedure has been followed and quality assurance criteria have been satisfied. To overcome the drawbacks, they suggested a process-driven e-learning system that senses developers' activities and guides them through necessary software quality assurance methods during software development.

## III. SCRUM OVERVIEW

Scrum is a management process that was initially mentioned in 1986 by Takeuchi and Nonaka in their paper "The New New Product Development Game," in which they describe a flexible, fast, and self-organizing product development process. Sutherland and Schwaber [10] used these discoveries and the word "Scrum" to create the currently known framework, which was initially introduced in 1995.

Scrum is a lightweight development methodology that allows IT organizations to handle complicated adaptive challenges while delivering solutions of the highest possible quality. Scrum was developed based on the premise that software development is too complicated and unpredictable to be meticulously planned at the start of a project [11]. Therefore, a progressive, iterative method is used to maximize predictability and limit risk. Given that change cannot be avoided, it must be managed. Scrum handles change by developing software in iterations as opposed to a one-shot method.

Scrum is based around three roles (Product Owner, Scrum Master, and Development Team), four meetings (Sprint Planning, Daily Scrum, Sprint Review and Sprint Retrospective) and three artifacts (Product Backlog, Sprint Backlog, Product Increment) [10] (see Fig. 1.)

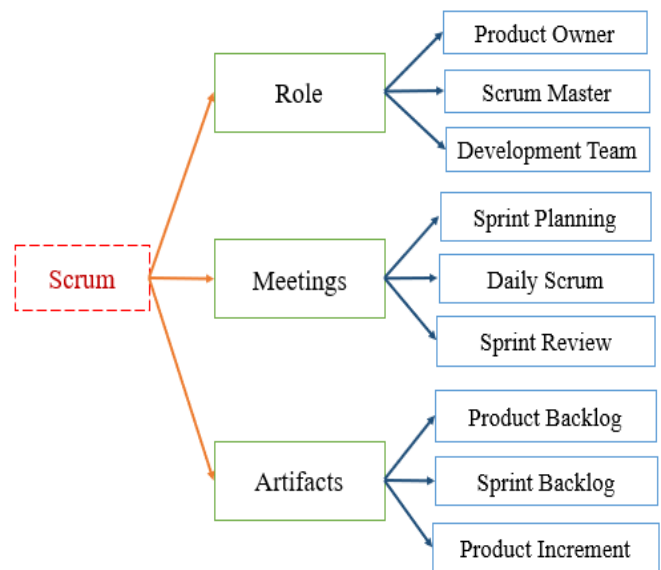

Fig. 1. Roles, Artifacts, and Activities in Scrum [12].

Each project has a Product Backlog, which is a list of a product's requirements ordered by business value. It is a constantly evolving document based on changing requirements, changing problem understanding, and changing contexts. Each Product Backlog Item (PBI) is estimated using an abstract effort measure based on "Story Points" and has a set of acceptance criteria.

Scrum teams are self-organized, multi-skilled, and capable of producing products iteratively and incrementally, thus increasing opportunities for ongoing feedback. A Scrum team consists of a product owner, who acts on behalf of the client and is charged with maximizing the value of the developed product, and a development team, which is responsible for creating the product. The development team is made up of developers and a Scrum master. The Scrum master is a facilitator who ensures that the development team is supplied with an appropriate environment to finish the project effectively, removes impediments for the team, and guarantees adherence to Scrum practices.

The Scrum development process is carried out by cross-functional teams of individuals with diverse skill sets[10]. The teams often possess a variety of specializations, including programming, testing, analysis, database administration, user experience, and infrastructure. All of these skills are required to provide the product, and Agile projects employ a whole-team approach to execute it. Advantages of employing a whole-team approach include the fact that quality is everyone's responsibility. Scrum focuses on developing high-quality software within a timeframe that optimizes its business value. This is everyone's responsibility, not just the testers. Every member of a scrum team is a tester. Tests, from the unit level on up, drive the code, teach the team how the program should function, and indicate when a task or story is "done." A Scrum team must have all the competences necessary to generate high-quality code that provides the organization's requested features. This means that the team is responsible for all testing activities, including test automation and manual exploratory testing. It also implies that the entire team continuously considers testability while creating code.

Scrum divides a project into iterations known as "Sprints". A Sprint is a time-boxed, often 30-day iteration in which the

Scrum team adds new features to the product. The sprint begins with a "Sprint Planning Meeting" where the team picks from the product backlog the items to be handled in the sprint and plans the work to be performed. The team will estimate the selected items based on their velocity (e.g., the number of "story points" they can execute within a predetermined time limit). The result of planning is turned into an objective known as the "Sprint Goal" The Scrum Team then has an internal meeting and utilizes the Sprint Goal to generate a list of the necessary requirements to achieve the target. These requirements are decomposed into "tasks" that become entries in the "Sprint Backlog." The success of the sprint is based on the achievement of the sprint goal [2].

During the sprint, the team holds daily 15-minute stand-up meetings called "Daily Scrum" with the purpose of assessing progress and maximizing the chance that the development team will accomplish the sprint goal. Each team member responds to three questions [13]:

- What progress has been made since the last meeting?
- What will be accomplished by the next meeting?
- What impediments stand in the way?

The Sprint yields a deliverable product increment as its final output. During a 4-hour Sprint Review, the Scrum Team inspects the product increment, evaluates what they were able to accomplish during the sprint, and modifies the product backlog as needed prior to the next Sprint Planning meeting [17]. The "Product Owner" will approve the needs for the live system based on the requirements and their preset acceptance criteria.

The last meeting of a "sprint" is the "retrospective," at which time the team examines and comments on itself and the project in terms of people, relationships, processes, and tools. As a consequence, an improvement strategy may be developed.

Merzouk et al. [12] proposed, in their paper titled "Towards a New Metamodel Approach of Scrum, XP, and Ignite Methods," a metamodel of Scrum (see Fig. 2).

Fig. 2. Proposed Metamodel for Scrum Method [12]

#### IV. CRITICAL ANALYSIS OF SCRUM

Scrum is the most popular and effective Agile methodology due to its many advantages, including quick delivery and flexibility to change. It emphasizes customer satisfaction, continuous feedback, and process transparency. In spite of its many advantages, it has three disadvantages. First, Scrum backlogs focus only on functional requirements (FR) and tend to neglect non-functional requirements (aka Quality Attributes; see Fig. 3) [6] [14]. Second, the majority of quality assurance activities are skipped in scrum due to the sprint's short period and the lack of a dedicated quality management role [8]. Finally, in Scrum, the requirements are typically managed by a person with a business-oriented profile. Thus, the focus is on the development activities that produce business value, while

quality assurance practices receive less attention and an overall picture is missing [7].

This study proposes the SQRum as the solution to the aforementioned problems. SQRum is built on the traditional scrum to present a more effective method.

Our new approach will improve classic Scrum in three ways.

- The quality attributes will be considered and included in the product backlog.
- Quality assurance activities will be effectively handled.
- The tester's responsibilities will be precisely outlined.

Fig. 3. ISO 9126 Model for Quality Attribute [15].

## V. PROPOSED METHOD

### A. SQRum Quality Artifacts

SQRum intends to incorporate the DoD as an artifact into its new model and proposes four new artifacts: QA strategy, test plan, defect backlog, and test library.

1) *Definition of done*: DoD is a significant part of the test plan. It is used by the QM as a check list of items, each one used to validate a story or a PBI for completeness. Unlike the acceptance criteria, the DoD is applicable to all items in the Product Backlog, not just a single user story. It is applied to the product increment as a whole [16]. The QM collaborates with the PO and the dev team to identify all the conditions that make an increment shippable or not at the end of the sprint. This proposal's DoD should emphasize quality attributes.

2) *QA strategy*: A QA strategy is a long-term plan of action, the key word being "long-term" about the overall test approach to projects. It defines the project's testing guidelines on how to test the target system.

Using the ship analogy once more, the QA strategy symbolizes the "course" to follow in order to reach the final destination.

QA strategy is a static high-level document that can be used as a reference that doesn't change much over time and needs to be updated only if processes change. It generally includes decisions made in terms of sprint timelines, test types required, infrastructure such as test management tools, defects management tool, test environments, test monitoring and reporting.

3) *Test plan*: A test plan is a concise and lightweight document used to organize the test activities. Each sprint has its own test plan, which is a living document that changes and evolves based on sprint requirements. A test plan outlines the scope, approach, resources, and schedule of planned testing activities. It identifies, among other things, the items and features to be tested, the assignment of tasks, the DoD and the test types to be performed, the test environment, the test design techniques, test data requirements and test measurement techniques to be used, the risk and dependencies assessment carried out, automation tests programmed, and time budget allocated. Continuing with the ship metaphor, the sprint is the trip, and the test plan is all that is required to ensure its success.

An Agile Test Plan is a crucial document since it collects all the answers to test-related questions in one place.

4) *Defect backlog*: A defect backlog is an ordered list of all the known defects in the project that haven't been fixed yet.

Defects may be functional, describing misbehavior or technical related to quality attributes such as performance, security, or other. The remaining bugs can be calculated by subtracting the fixed bugs from the total bugs:

$$\text{Remaining bugs} = \text{number of total bugs} - \text{fixed bugs}$$

There are three types of defects that we can find in the defect backlog:

- **Defects within the current iteration**: These are defects that can't be fixed immediately and do not impact the increment date of release. Ideally, defects should be corrected as soon as they are discovered, before they become massive, tangled defects.
- **From the Legacy System**: These are inherited defects of the old system that have remained hidden until now. When found, they are logged to the defect backlog and the QM with the team can choose to fix them or not. If so, they will be prioritized as part of the product backlog.
- **Found in Production**: These are bugs found by the customer in production. Depending on their severity, these bugs may be fixed immediately, at the time of the next release, or they'll be estimated, prioritized, and put in your product backlog.

5) *Test library*: Scrum uses an iterative approach for product development; the same approach can also be applied to testing. As a product is produced, the test library expands progressively. It includes test cases, test scenarios, and test campaigns. User stories are the basis for the creation of test cases. The relationship between test cases and user stories in the sprint backlog is one-to-many, as a single user story may have numerous test cases. The test cases are similar to puzzle pieces that compose the test scenario (see Fig. 4), and test scenarios are the main components of test campaigns. Each campaign is designed to evaluate an increment. Utilizing the library enables testers to save time since for each new script, there are reusable components that can be used to develop a new test campaign. Also, all they have to do is make test cases and scenarios for the new features. For example, a first sprint is conducted to develop a command-launching feature. The test campaign is then utilized to check that this increment functions properly. Sprint 2: This sprint's objective is to develop functionality that allows for the management of billing for placed orders. Testers won't have to start from scratch to test this new feature. Instead, they can use the first tests they ran to launch the order and finish this test campaign with tests that make sure billing is handled correctly.

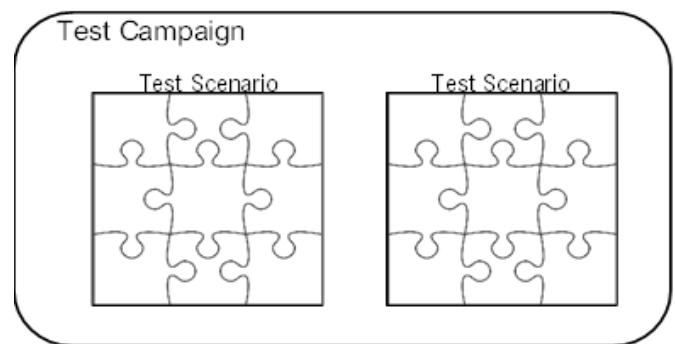

Fig. 4. The Components of a Test Campaign.

## B. SQRum Events

1) *Refactoring iteration*: it is a dedicated sprint for continuously enhancing the design of an existing solution without modifying its core behavior. Agile teams incrementally maintain and enhance their code from Sprint to Sprint. If code is not refactored, the resulting product will be of poor quality, with unhealthy dependencies between building blocks and improper allocation of component responsibilities [17].

2) *Product backlog grooming*: is a meeting that helps the Product Owner maintain his Product Backlog. He can ask for the aid of the team in creating and refining Product Backlog Items, estimating the amount of work required to complete a PBI, and prioritizing PBIs in the Product Backlog to ensure that the Product Backlog is ready according to the Definition of Ready [18].

## C. Quality Manager Responsibilities

1) *Manage quality attributes*: Quality Manager is responsible for NFR. Also known as quality attributes (see Fig. 3), QM works with the scrum team to analyze the quality attributes based on the functional requirements. With the agreement of the product owner, he completes the product backlog by mapping out the functional requirements and the quality attributes. QM can use three ways to elicit NFR: 1) Acceptance criteria 2) User story 3) Definition of done.

QM plays an important role in every stage of the sprint:

- During the Product Grooming meeting, the QM begins gathering NFR by asking the PO and the development team several questions, such as: the system's scalability when more resources are added; the likelihood of the system performing without failure; and how long data should be retained in the system for reference (this might be a government/national regulation); What are the consequences if the user cannot access the system?
- Prior to Sprint planning: QM works with the PO to complete the product backlog.

QM incorporates NFR testing into the test plan.

- Sprint planning: QM presents and explains to the development team the identified NFRs for each user story.
- Daily meeting: QM tracks NFR work progress and assists the team in overcoming difficulties.

QM assists the team in remembering the importance of the quality attributes.

- Review meeting: While the PO focuses on the FR, the QM examines the NFR.
- Retrospective: QM recommends enhancements to increase product quality. For instance, devote more time to quality attributes such as security.

2) *Manage testing activities*: The SQRum method enhances the classic scrum "whole team" approach, in which

every team member is responsible for quality and every team member is a tester [19]. SQRum proposes to give the responsibility for managing testing tasks to a single member who is the Quality Manager. QM's mission is not to pilot and supervise the SQRum team, but to accompany and coach them to ensure that they have all they need to execute QA activities. His role is to:

- Break down testing activities into several tasks.
- Ensure that the appropriate testing tasks are scheduled during release and iteration planning sessions.
- Assign testing responsibilities to team members so that everyone is aware of what to accomplish.
- Ensure that all testers meet their deadlines for work completion.
- Take notice of test-related challenges and attempt to address them.
- Ensure that each tester has the skills and knowledge necessary to develop and perform the tests required for each user story.
- Employ pair testing to address the skills gaps of the tester.
- Help to estimate the overall test effort and the technical resources needed.

3) *Define QA strategy*: In Sprint Zero (also known as the pre-planning phase of a sprint project), the QM collaborates with the scrum team to develop the QA strategy. However, his responsibilities do not end there because he is also responsible for keeping the QA strategy updated. The QA strategy is used by the quality manager to provide a new tester with an overview of the test process.

4) *Establish the test plan*: Before the sprint planning, the QM asks the PO about what stories will be in the next sprint, so he takes time to understand functionally and technically the requirements, and he starts working on his sprint plan. When the sprint planning comes, he already has an idea about quality attributes, possible issues and dependencies, data creation estimation, and test effort. This raises awareness of potential resource, time, and scope of work constraints confronting testers, as well as risks that must be discussed and addressed. This also allows the PO to reevaluate the level of quality he requires, and how much work should fit within the actual, achievable velocity of the sprint.

The Quality Manager may delegate the preparation of the test plan to a member of the team, but he remains responsible for the veracity of the information included within.

5) *Help the team in expressing its DoD*: The Quality Manager assists the team in creating a common understanding of quality to ensure that each user story makes sense within the context of the product's bigger story. The QM helps the team in formulating its DoD by asking the appropriate questions, such as:

Are functional tests passed?

Is acceptance testing finished?

Are quality attributes considered?

6) *Tracking test tasks and status*: At any point in the sprint, the Quality Manager must be able to quickly determine how much testing work remains on each story and which stories are "done." He must also ensure that no story is "done" until it has been tested at all appropriate levels. This helps him to check if the team is on schedule and to anticipate if there is a story that cannot be completed and he must remove it or ask programmers to help with the testing tasks.

Tracking the number of tests produced, executed, and passed at the story level helps indicate the status of a story. The number of tests written shows the progress of tests to drive development. Knowing how many tests aren't passing yet gives you an idea of how much code still needs to be written. The burndown chart is an example of a method used for measuring team progress.

Story or task boards are a helpful visual way to determine the state of an iteration, particularly if color coding is utilized; there are different colored index cards for the various types of tasks, such as green for testing, white for coding, and yellow and red for defects. Progress tracking can be achieved by any method and with both virtual and physical storyboards, as long as it enables the QM to see at a glance how many stories are "done," with all coding, database, and testing completed, and whatever the team's DoD is.

7) *Identify risks and threats to sprint*: Every user story in the product backlog is a potential risk. A story risk is the level that a user story will fail (the impact of the failure multiplied by the probability of failure). The key purpose of the risk prediction is to accurately anticipate the testing work so that all user stories can be tested in accordance with the risk level defined by the entire team. A simple test is sufficient for stories with a low likelihood of failure. Unlike stories with a high failure risk, which require a very careful test plan containing a variety of test techniques. Stories with a high failure risk require a very careful test plan containing a variety of test techniques. The QM assists the team in achieving the ideal balance between sufficient quality and acceptable risk, on the one hand, and time and resource limits, on the other.

The QM can initiate the identification and assessment of risk for both functional and non-functional requirements prior to sprint planning, and the team can finish the risk analysis during sprint planning. If there is not enough time to address the relevant risks at this meeting, the QM can ask the Scrum Master to organize a risk poker session. Once the risks have been identified, the team classifies and evaluates them based on likelihood and impact. This assessment is recorded in the test plan and taken into account during the design, implementation, and execution of tests for this iteration.

8) *Track defect*: Since quality is the concern of the entire team, everyone works collaboratively throughout. The Quality Manager's responsibility is to assist the SQRum team in setting

targets relating to defects and using the right metrics to assess progress toward these goals. Gathering metrics on defects helps reflect the trend, which means the growing attitude in the number of defects in the defect backlog over a period of time. Another QM's responsibility is to communicate the trend in the defect backlog to the SQRum team. If the defect backlog is decreasing, there are no concerns. If it is increasing, the SQRum team must invest time in analyzing the underlying cause. In order to address the root cause, the QM must tell the SQRum team about the nature of the defects. If the defects could not have been detected using unit tests, then perhaps the programmers need additional training in unit test writing. If defects are missed or functional requirements are misinterpreted, then perhaps not enough effort is spent on sprint planning or acceptance tests are insufficiently thorough.

The QM can use a visual technique such as "Defect Trend chart." As shown in Fig. 5, the "Defect Trend chart" is a graphical representation of reported defects over time. The x-axis represents a period of time, while the y-axis represents the number of defects.

9) *Manage defects backlog*: The Quality Manager is in charge of the Defect Backlog, which includes what's in it, when it's available, and how it's organized. Before sprint planning, the quality manager makes an initial selection of defects based on their severity. Product backlog grooming is an excellent opportunity to discuss this selection with the product owner in order to determine which defects to fix first. The selected defects are presented to the team during the sprint planning and are scheduled for the next sprint.

The QM must ensure that the team does not accumulate technical debt, particularly when working with legacy code. The longer a defect remains in the system, the greater its impact. Defects in a code base have negative effects on code quality, system security and flexibility, team effectiveness, and velocity.

Fig. 5. Defect Trend Chart.

Early detection and correction of defects is more cost-effective. In iSixSigma Magazine, Mukesh Soni [20] cites an IBM report stating that a defect discovered after product release costs four to five times as much as one discovered during product design and up to 100 times as much as one discovered during product maintenance.

The QM must constantly evaluate the amount of technical debt dragging it down and work on reducing and preventing it. The QM needs to persuade the product owner of the benefits of addressing technical debt by demonstrating that technical debt may be costing the business money due to decreasing velocity. The team's velocity is sometimes consumed by bug fixes and trying to make sense of the code.

The QM can request that the PO reduce the scope of his desired features to allow sufficient time for good practices such as continuous small refactoring, which results in improved test coverage, a solid foundation for future development, decreased technical debt, and higher overall team velocity.

If it is insufficient and the PO cannot budget time in each iteration, the QM may suggest to the PO that a "refactoring iteration" be planned as a last resort to upgrade or add necessary tools, reduce technical debt, automate more tests, and perform major refactoring efforts. Planning refactoring iterations at regular intervals improves quality, maintains the system and its infrastructure, and preserves the team's velocity, allowing the team to move faster.

*10) Help the team stay focused on the big picture:* he Quality Manager tries to put each story in the context of the whole system by looking at possible risks, dependencies, and unplanned effects on other parts. The QM assumed the perspectives of the user, product owner, programmer, and tester, as well as everyone engaged in building and using the features. He can consider the effects of FR and NFR on the larger system and bring this to the attention of the team. Everyone on the team may easily focus their attention on the work or story at hand. This is a disadvantage of working on small feature portions at a time. The goal of the QM is to help

the team take a step back and evaluate how their current stories fit into the big picture. QM keeps challenging the team to do a better job of delivering real value.

*11) Keep testing environment updated:* Testers cannot test effectively in the absence of a test-controlled environment. The QM must continuously inspect test environments and collect information regarding the deployed build, database schema, whether or not somebody is altering the schema, and other processes operating on the system. This information enables him to sustain the test environment with the most recent or updated version and eliminate the obsolete test environment, its tools, and techniques. This is also true for databases. Sometimes other teams can modify fields, add columns, or remove obsolete ones. The QM must be aware of all these changes in order to keep his database updated.

#### *D. SQRum Process*

We have identified eleven quality manager responsibilities. This list of eleven responsibilities indicates the tasks for which the QM is accountable; the remaining QA activities can be performed by the rest of the team, since quality is still owned by the entire team (everyone is a tester), but managed by just one person.

SQRum method follows eight phases, which are: Project Initiation, Sprint 0, Product Grooming, Sprint Planning, Sprint Execution, Sprint Demo, Sprint Retrospective, and Release. These phases are described in Table I with the artifacts of each phase.

#### *E. SQRum Metamodel*

This section presents the proposal of the new SQRum method as a metamodel. As shown in Fig. 6, the SQRum Metamodel is based on the transformation of the method's concepts into metaclasses linked by meta-associations, which define the kinds of relationships between these concepts. The green metaclasses represent the new concepts added to the Scrum method related to QA viz, Test Library, Defect Backlog, Definition of Done, QA Strategy, Refactoring Iteration, Test Plan, Product Grooming, and Quality Manager.

TABLE I. SQRUM PROCESS

	Project Initiation	Sprint 0	Grooming	Sprint Planning	Sprint Execution	Sprint Demo	Sprint Restro	Release

## VI. CASE STUDY AND EVALUATON

### A. Project Description

To validate our model, we conducted a four-month case study on a software development project in a multinational telecommunications and IT services company, which is a large

mobile network operator that serves European and worldwide companies. When we began the case study, the project had been underway for more than a year, and the team was using the agile scrum methodology. The main goal of this project is to rebuild a legacy system used by the project managers to plan and manage the deployment of internet solutions for enterprise

customers (btob business model). By rebuilding the system, the company wants to establish a new technological system, standardize further development and maintenance procedures, improve the system's quality and facilitate project managers' work. The team has agreed to test our method to determine if it will help them achieve this goal. Before starting the use trial, the team received SQRum training. The case study was distributed into four increments. Three are development sprints, and one is a refactoring sprint. Sprints were 4 weeks long. One quality manager, one product owner, seven developers, and one scrum master made up the team that worked on the project.

The company required a 10-month trial period, and if the deployment is successful, it will adopt SQRum as a standard methodology for two of its projects.

### B. First Results

This section presents results after only four months of using SQRum. It is a classification of the team's feedback about which aspects they think have been improved using SQRum.

1) *Awareness about quality*: All the team members reported that SQRum made them more aware of software quality during the sprint. Developers paid more attention to quality and were more focused.

2) *Better organization and more communication*: Communication and organization were also cited by the team as SQRum improved aspects. Since the QM took over the management of everything related to quality, the Scrum Master was able to focus on monitoring development activities and assisting the team in overcoming obstacles.

The team was also able to communicate more effectively as a result of the new SQRum events, since each event provided an opportunity for sharing and interacting.

3) *Efficiency improvement*: The team members reported improved efficiency. By mapping out the functional requirements and quality attributes, the QM helps the PO define clearer user stories from a technical perspective. Due to the clarity of the user stories, the team was more efficient and had a better knowledge of what to do and how to do it, as well as a better understanding of potential risks, which has improved not only the efficiency of the team but also the quality.

4) *Better use of team velocity*: Analysis and verification of quality attributes on a periodic basis, as well as the implementation of a refactoring sprint, led to a reduction in defect counts and defect-fixing time, resulting in a 21% increase in development productivity. The team spent more time in providing value rather than fixing issues.

5) *Testing properly*: The team found that the tests had been enhanced; they were better documented and structured as a result of the use of the test library. That helped them keep the balance between communication and documentation. Developers also reported that with the help of the test plan, they were able to test more thoroughly and were aware of the

aspects to be taken into account when testing in order to improve quality.

6) *Improving quality*: Initiating the refactoring iteration, checking the quality attribute, and using the newly proposed artifacts decreased the defect density and time required to fix defects. The prevention and control of bugs contributed to a 36% decrease in the defect density of the project, and the time necessary to remedy defects was decreased by 41% by easily locating the spot of change and estimating side-effects.

### C. Aspects to be Improved

Despite the positive results of SQRum, months is not enough time to test all its aspects. Also, for a better assessment of quality, the method needs to be used on large-scale projects with SAFe.

The members suggested detailed guidance on analyzing the quality attributes and enhancing the traceability, they also suggest a burn-down chart to assess the current state of the QC activities in SQRum.

## VII. DISCUSSION AND CONCLUSION

Scrum is the most used method because it is adaptable to all project types. It is an iterative and incremental method that helps teams to deliver a high-quality project. Scrum's primary issues continue to be process and product quality.

This study introduces SQRum which is an adaptation of Scrum that includes and promotes the existence of a quality owner role.

SQRum provides a quality enhancement by adapting the traditional Scrum to emphasize non-functional requirements, establishing a new role and new artifacts to focus on control assurance activities, and ensuring that the quality assurance process has been adhered to.

In an ideal world, the goal would be to have zero defects, but due to the sprint's short lifecycle, this goal is almost impossible to achieve. Quality should not be seen as a constraint, but rather as a tool for maximizing business value. The QM's responsibility is to assist the PO in finding the ideal.

**Abstract**—Malaysia is focused on the development and use of technologies among consumers. Thus, technological innovations are used in the adaptation of online learning to educate students, as well as to enhance the teaching and learning process in Technical and Vocational Education and Training (TVET) institutions. There is a need to expose students to the online learning revolution, which conceptualises using computerised systems to facilitate the learning process. However, the COVID-19 outbreak has disrupted the academic year across the country. Due to the unusual circumstances related to the pandemic, the Malaysian government has urged all academic institutions to conduct online teaching and learning. Thus, an e-Learning system, known as SpmiILP, has been designed and developed accordingly for an interactive multimedia course to encourage online interaction among students and lecturers, as well as to enhance human learning and cognitive development. In fact, these essential elements such as learning style of the students and user experience are focused on to engage them in learning effectively as well. An e-Learning System for Interactive Multimedia Course was used to develop the e-Learning system (SpmiILP). The usability test showed that the developed e-Learning system has a positive influence that provided potential contributions to (TVET) students in their learning processes.

**Keywords**—e-Learning; interactive multimedia; learning style; user experience

## I. INTRODUCTION

The evolution of information technology has spread worldwide in conjunction with the rapid growth of various technologies. Multimedia technology has demonstrated the great potential of evolution in learning, accessing, and manipulating information. Multimedia contributions have an enormous opportunity for educators to expand numerous learning techniques, especially e-learning. e-Learning shows the potential of digital transformation in the education system that would allow the development of new teaching and learning ecosystems. e-Learning growth was facilitated using digital tools involving interactivities that encourage online interaction between students and lecturers. e-Learning concepts encompass many multimedia technologies and the Internet that enable access to virtual learning environments. The use of information and digital technology empowers the diverse learning process by combining traditional classroom and online learning environments. Therefore, e-Learning has been massively implemented in higher education institutions based on pivotal success factors categorised as system quality,

service quality, information quality, usefulness, and engagement.

The advancement of teaching and learning technologies has helped improve students' critical thinking skills. e-Learning's enormous growth, alongside technological advancement, has promoted high-quality learning techniques that fit students' preferences. The term "digitally literate" indicates the ability to perform and handle digital technologies humans use daily [1],[2]. Indeed, the quality of learning has been enhanced by advancing educational tools. Nowadays, younger generations are immersed and surrounded by technologies, with easy access to information.

The e-Learning approach supports collaborative communication that allows users to control and customise their learning environment. Satisfaction in e-Learning has enabled users to experience learning that fits their preferences and styles [3]. Multimedia elements also play a significant role in education by allowing users to experience interactive learning. Multimedia elements consisting of text, audio, animation, image, and video can trigger users to be more entertained and keener to continue learning [4]. The intensive penetration of multimedia has fuelled the demand for visualising educational materials to be more engaging and effective.

Hence, this next section of the paper will further provide detail on the related works; methodology will emphasize the five phases of analysis, design, development, implementation, and evaluation, then will summarize the results, discussion and conclusion.

## II. RELATED WORKS

The massive spread of coronavirus disease or COVID-19 has become a global pandemic that forces social distancing policy. Progressive steps are taken to limit the spread of this policy in the community and influence various sectors, including education. Therefore, there is a sudden transition of learning where the institutions are required to implement online learning. Human motion restrictions force changes in our education in new aspects such as learning styles, learning platforms, accessibility, and the deliverance of information [5]. Thus, the pandemic of COVID-19 leads educators to provide learning materials through online learning. The transition from face-to-face learning to remote learning as an alternative shows the potential of e-Learning that uses an online platform. To that end, face-to-face learning has become vulnerable in most

institutions due to the COVID-19 pandemic, which results in another alternative of providing online learning for the students.

In a world with ever-evolving computing technology, e-learning has been pushing the advanced technology boundaries. e-Learning is recognised as an important part of learning in higher education institutions. The expansion of e-learning has initiated several changes in education delivery, as shown in Fig. 1 [6].

This e-learning model shows the different e-learning techniques in education that learners can employ. First, adjunct e-learning can be used in a traditional classroom that provides relative independence to learners. Second, the blended e-Learning technique can explain the delivery of course materials using traditional learning and e-Learning methods. The third technique is conducted online, devoid of traditional learning or classroom participation, because it features individualised and collaborative learning. The development of the proposed e-learning system in this research paper was focused on blended e-Learning.

Therefore, Industrial Training Institutes, or Institut Latihan Perindustrian (ILP), provide formal training for school leavers and industrial workers that would enable them to acquire skills for specific work fields. By upgrading their skills, they would be more focused on their work and contribute effectively to this country's development. Interactive Multimedia has been introduced to ILP students as one of the main subjects in the Information Technology (IT) course. ILP students have been using the conventional way of learning instead of focusing on the rapid growth of digital technology for teaching and learning [7]. The lack of motivation and engagement has caused them to lose interest in learning.

Fig. 1. e-Learning Model.

Nonetheless, the ongoing technological changes have enhanced the education system in this country with the use of digital technologies. The e-Learning system for the Interactive Multimedia subject can drive ILP students to use technology and learn effectively. e-Learning has become a learning platform with various benefits, such as being easy to use, user-friendly, interactive, and efficient for students [8].

Online learning has been introduced in ILP to expose students to different teaching and learning methods that would suit their learning styles. Some students prefer to study in groups, while some prefer to study alone. Additionally, some of the students' performances showed that they understand better through verbally explained lessons, while some might have difficulties in this environment. They might prefer learning using visual and graphical forms of the lesson to understand and improve their motivation and engagement [9],[10]. These different learning styles show that students have different capabilities in adapting to knowledge. Thus, the e-Learning system for the Interactive Multimedia subject has been developed with several functionalities, such as interactive notes, videos, and quizzes. These functionalities enable the students to complete the tasks involving problem solving and assignments. The students can improve their cognitive abilities by adopting an online platform during the pandemic COVID-19. The user interface is obtained based on the user requirements specified on the usage of multimedia elements such as animation, text, videos, and audio. Using multimedia elements helps them stay focused and have fun while learning.

The students involved in this study could complete their assessments and were evaluated right after they completed the e-Learning. It should be aligned with the users' performance and learning styles to make the e-Learning system more effective. The constantly growing research on interactive multimedia e-Learning systems has helped foster new approaches to learning. Therefore, this study has aimed to design and develop an e-Learning system for the Interactive Multimedia subject (SpmiILP) for ILP students that could improve their learning outcomes.

In the meantime, students can utilise other currently available systems, such as Moodle, as a learning management system. Moodle offers various features, such as reading materials, papers and projects, forums relating to the course, conduction of quizzes, the distribution, collection, and evaluation of assignments, keeping track of class attendance, and recording grades. Some of these features have been used to develop the e-Learning system (SpmiILP) based on the user requirements of ILP students enrolled in the Interactive Multimedia subject.

The SpmiILP was adapted to fit the needs of individual learners. For example, it offers students the flexibility of time and place to access the huge amount of information in the system, eliminates the barriers that could potentially hinder student participation in the classroom, and it enables the students to study at their own pace and speed [6], [7],[11]. As a result, they can be satisfied with their performance and decrease their stress level. Since every student's learning style must be taken into consideration, this paper presents the design

and development of an e-Learning system that is focused on the user requirements of ILP students.

### III. METHOD

This study was conducted in five phases: analysis, design, development, implementation, and evaluation. Each phase is explained in detail in the following sections.

#### A. Analysis Phase

This phase involved analysing user requirements obtained from the users, as shown in Table I. Previous studies have highlighted the learning styles of undergraduate students, multimedia elements, user interaction, user experience, usability, and types of technology used [7], [8], [9], [11], [12], [13]. Identifying user requirements of a system has helped strengthen their understanding of the learning process.

The user requirements listed in Table I have been acquired to develop an e-Learning system for the Interactive Multimedia subject. Instead of focusing on interface designs, this e-learning system was developed to meet students' requirements with functional features that could engage and motivate them in their learning process. ILP students mostly prefer learning using different forms of visual and graphic learning tools, including animation, text, video, and audio. The tasks given to the students were in the form of online learning by providing quizzes and assessments. The implementation of online learning has enhanced the use of technologies among these students that they can use to obtain unlimited access to information.

#### B. Design Phase

This phase involved utilising the outputs obtained from the analysis of user requirements. The selection of activities must be suitable for ILP students to improve their learning performance. This system has adapted multimedia elements that showed greater potential and have gained popularity among the students. Fig. 2 shows a model of the e-Learning system for Interactive Multimedia subject (SpmiILP). This model consists of user specifications and software content.

TABLE I. USER REQUIREMENTS OF ILP STUDENTS

User Requirements	
1.	Device Used: Computer/Laptop
2.	User Interaction
3.	Learning Styles: Visual & Graphics
4.	Multimedia Elements: Animation, Text, Video, Audio
5.	Usability: Effectiveness
6.	User Experience: Engagement, motivation
7.	Activities: Quizzes & Assessments

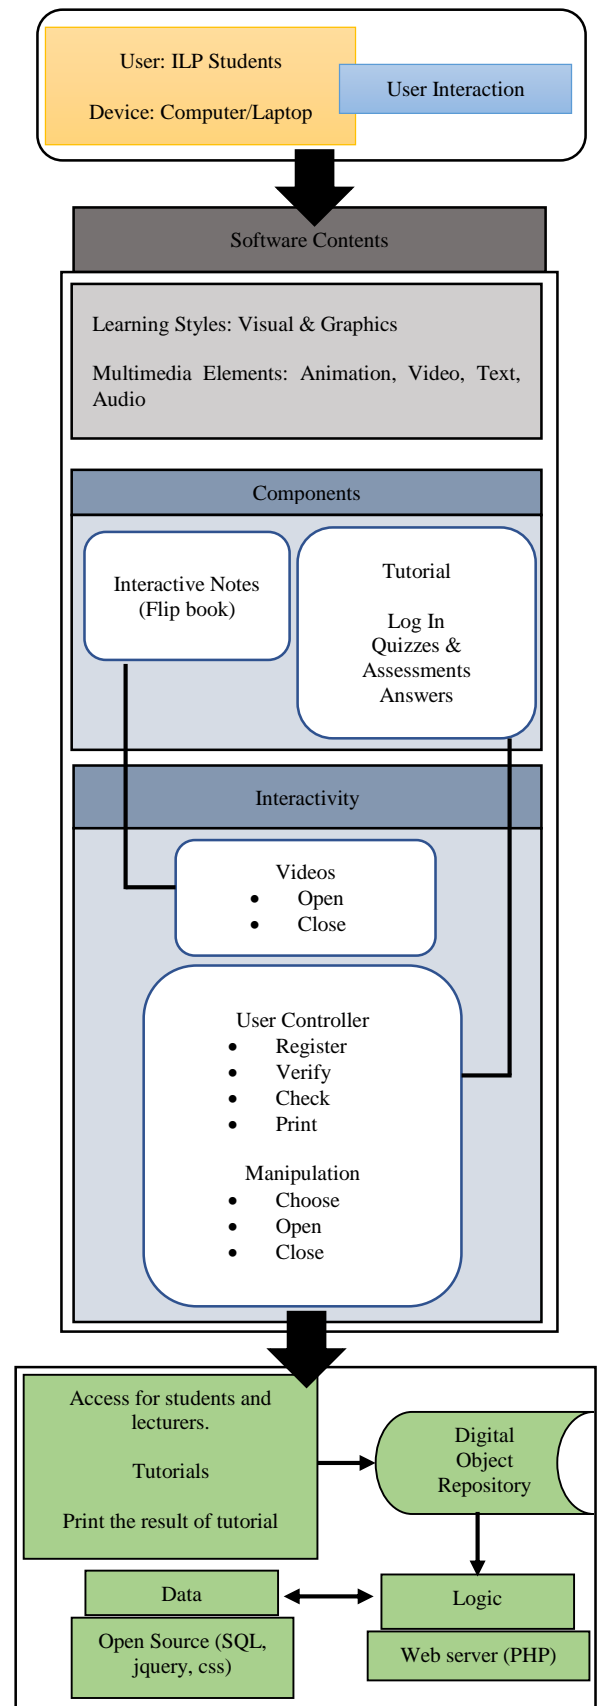

Fig. 2. Model of the e-Learning System for Interactive Multimedia Course (SpmiILP).

The target users of this system were the ILP students, who interactively used current technology, such as computers or laptops. The software contents of this system consisted of different learning styles: visual and graphical learning tools; multimedia elements, such as animation, video, text, and audio; and other components, such as interactive notes (Flipbook) and tutorials. This flipbook consisted of several learning materials, such as notes, videos, and animation that can enhance the learning experience using technology. The interaction between the users and the system occurred through buttons; for example, videos were provided with open and close buttons. Meanwhile, accessing the tutorials with functionalities that consisted of login, quizzes, assessments, and answers has enabled the users to choose, open, close, register, verify, check, and print the results using these buttons. PHP MySQL was the database system for SpmiILP, and HTML was used for the interface design template to develop this e-learning system.

Fig. 3 depicts the hierarchy of the e-learning system's interface design, which includes login, user ID, password, notes, upload notes, list of notes, students, registration, list of students, and quizzes.

C. Development Phase

Fig. 4 shows the interface design for the SpmiILP that ILP students use to access and study the Interactive Multimedia subject. This is the main page for student registration, and this interface consists of the main page, student registration, upload notes, interactive notes, quizzes, and results. Before logging in, the students need to obtain their user ID and password by filling in their details, such as matric number (NDP), name, gender, session, and phone number. These details are compulsory for registration, where the ID and password are set up the same as the NDP for the students. The main page of this e-Learning system consists of the main menu, notes, students' names, lists of quiz categories, quiz sections, and results.

Fig. 5 shows the feature for uploading notes in the e-learning system. This page can be accessed by both the lecturers and the students. The lecturers can upload their visual and graphical notes for teaching and learning. Instead of learning by reading notes consisting only of texts, this method could help students engage more in the learning process.

Fig. 3. Hierarchy of the e-Learning System Interface Design.

Fig. 4. Students' Registration.

Fig. 5. Features in the e-Learning System (Uploading Notes and Interactive Notes).

Fig. 6 shows the interface for the quizzes section. In this section, the lecturers can update the students' quizzes list. The quizzes section aimed to evaluate students' understanding of the subject they were learning. It can also provide lecturers with insights into students' progress. After the lecturers have finalised the quizzes, the students can answer them within the estimated time.

Fig. 7 shows the interface for quiz results. The students can check their marks after completing their quiz sessions. They would be evaluated based on their performance in answering the quizzes. The lecturers can access this page, and the students can view their grades. This feature showed the user interaction among the students through this platform. Therefore, the lecturers could use this platform to impart to their students a great deal of knowledge.

D. Implementation and Evaluation Phase

The usability of the SpmiILP was evaluated among ILP students using questionnaires. There were 24 respondents from the Interactive Multimedia class in this usability evaluation. Data are obtained from a questionnaire after respondents use the application. The questionnaires consisted of Section A and Section B, where Section A was focused on the respondents' background, as shown in Table II. Meanwhile, Section B focused on three dimensions of the usability evaluation: efficiency, functionalities, and effectiveness. Respondents' responses were based on agreement on all items based on a 5-point Likert scale; namely, 1 = strongly disagree, 2 = disagree, 3 = slightly agree, 4 = agree, and 5 = strongly agree. The usability of this system was analysed using answers scales of 4 and 5 points to get the percentage using Microsoft Excel.

Fig. 6. Features in the e-Learning System (Quizzes Section).

Fig. 7. Features in the e-Learning System (Results).

Table II shows the respondents' background in gender, age, race, education, and application usage in teaching and learning. Based on the collected data, 91% of the respondents had not used the system or other applications during the learning process. This result was troublesome because the development of technologies in Malaysia is growing rapidly, whereby the evolvement of technological innovation can enhance the teaching and learning process. Yet, these respondents have failed to take this opportunity. Therefore, there is a need to develop online learning systems or applications that could enhance the effectiveness of e-Learning and increase students' motivations. By providing the online learning platform to TVET students, they can use it to improve their communication with their educators instead of only focusing on conventional learning.

Fig. 8 shows the percentage of all items in the efficiency dimension. More than 70% of respondents answered using scales 4 and scale 5. The highest percentage was 91% of respondents who agreed with using text, graphics, audio, and videos in the system, which would engage them to learn more. This agrees with another study that reported that multimedia elements attracted the respondents to explore more of the e-Learning system (Nauman et al., 2020). Meanwhile, the lowest percentage was 77% of respondents who agreed with the notes provided. Based on the questionnaire, several problems were found, such as the bland design of the interactive notes and the size of letters that have caused difficulties in reading the notes.

TABLE II. SECTION OF QUESTIONNAIRES (BACKGROUND OF RESPONDENTS)

Details of Respondents	Backgrounds	Total Percentage of Respondents (%)
Gender	Man	77.3
	Woman	22.7
Age	18 – 20 years	100
Race	Malay	95.5
	Indian	4.5
Education	Certificate	100
Have/Have not used system/application in the process of teaching and learning	Yes	9
	No	91

Fig. 8. Efficiency Data Distribution for the e-Learning System.

#### IV. DISCUSSION

Fig. 9 shows that the percentage of all items in the functionality dimension is more than 60%. The highest percentage was 91% (the system was useful for the respondents), and the lowest was 68% (the system was functional, as expected). Therefore, system functionality is the primary determinant supporting students' learning satisfaction. The ability of the system to meet users' requirements has contributed to the overall satisfaction with the system's usefulness [3].

Fig. 10 shows that the percentage of all items in the effectiveness dimension is more than 50%. The highest percentage was 91% (this system is easy to use), and the lowest percentage was 55% (I do not notice any inconsistencies when using this system). Feedback from the respondents showed that inconsistencies occur because of the unstable LAN internet network provided at ILP Kuala Langat.

Overall, the newly developed e-Learning system has helped improve students' performances in the learning process using technology. This system can be used for teaching, whereby the lecturers can upload interactive notes and evaluate the student's performance online. Using multimedia elements and interactive notes have engaged the ILP students in learning.

Developing technologies as essential skills development and learning tools have proved that e-Learning is an effective learning method. The demand for adopting technology-based education, such as e-Learning, has shown an increase in a similar usage, enabling communication with the educators [14], [15]. Instead of only focusing on teaching, combining conventional and technology-based education could improve students' interests. This is because some students could face difficulties articulating their thoughts and would keep the problems to themselves. Through online learning, the educators could help these students figure out their problems [16].

The e-Learning system is an alternative learning system that the students can access online. Due to the advancement of technology, students would easily access the learning materials. The e-Learning system was developed and presented on the platform of mobile devices. Based on the preliminary study, 91% of respondents had not used the online learning system for their teaching and learning process. This has led to several problems, such as the one-way communication between the lecturer and students. The students could also lose their focus during a learning session, and the learning styles can affect their performances [7], [17]. There is a small number of studies conducted on TVET students. Students from the Z generation, or digital native generation, must change their interaction with high technology devices. The e-Learning system emphasises learning activities, social communication, activity control, notifications, file storage, and data security to help the students experience engagement and learnability from the teaching and learning process.

The intensive penetration of digital technology into everyday life has fuelled a new demand in teaching and learning. The educational materials were transformed from conventional learning's functional capabilities into online learning. Adopting online learning, in line with digital technology, can affect the student's learning styles. Their capabilities to learn through online learning have improved their motivation, whereby they could stop being worried or anxious to talk freely with the lecturers. Online learning has helped them learn effectively, whereby the combination of students' learning styles, such as active, visual, and audio, has caused them to be more engaged in the learning process [18].

Consequently, online learning has provided flexibility and mobility because the learning process does not remain at a fixed location and is accessible everywhere. Therefore, the growing outbreak of COVID-19 has forced all academic institutions to adopt online learning. All classes and examinations were cancelled; thus, the sudden shift away from learning has affected the students and lecturers [19]. In response to the significant demand for online learning, institutions of higher learning across Malaysia have provided online platforms to conduct classes and examinations. This shift showed that digital technology would help the users improve their learning motivation. In terms of teaching and learning, the Malaysian education system has changed with the remarkable rise of e-Learning undertaken remotely via digital platforms.

Fig. 9. Functionality Data Distribution for the e-Learning System.

Fig. 10. Effectiveness Data Distribution for the e-Learning System.

In conclusion, the e-learning system for the Interactive Multimedia subject for ILP students has enhanced their performances, motivation, and learning engagement. Different learning styles have caused them to explore various learning methods and improve communication between the lecturers and students. The developed e-learning system has shown the effectiveness and efficiency of this platform and provided functionalities that have enabled the students to access the system easily. The adaptation of the e-learning system has allowed the students to access information at anytime and anywhere. Therefore, e-learning has enhanced the abilities of students to foster the development of digital technology skills. However, the challenges faced in implementing teaching and learning still require the support of educational institutions. Embedding technologies in the classroom help in enhancing teaching and facilitating learning. Broadly, the potential to widen the access and the advancement quality of education need the adoption of technologies that will remain as challenges not only for students but educators as well.

## V. CONCLUSION

The use of technology for teaching and learning has helped improve the quality of the student's performances. The rapid growth of digital technology has allowed educators to utilise various teaching techniques based on the different learning styles among students. Hence, developing the e-learning system for the Interactive Multimedia subject has improved ILP students' engagement in the learning process. The students have adapted well to the functionality and interface design of the system. Several learning techniques have encouraged the students to explore the usage of technology and improve their skills. The developed e-learning system can display teaching and learning materials through computerised digital technology. The system's main features included uploading notes, interactive notes, and quizzes for students and lecturers.

This study has found that the e-learning system has benefited the users in learning interactive multimedia subjects. The rapid growth of online learning methods was due to the advancement of learning technologies and students' needs. With the advancement of the teaching and learning method, the students showed their skills and great potential in mastering other learning methods instead of focusing on conventional learning.

## ACKNOWLEDGMENT

**Abstract**—Dropping out of depression treatment commonly occurs in the current psychotherapy treatment. Adolescents often find it difficult to express their thoughts and feelings clearly due to their developmental constraints. They also have trouble realising their behaviours as unhealthy or problematic. The use of therapeutic games in depression treatment among adolescents can enhance the engagement level. Indirectly, the issue of dropping out can be reduced among the adolescents. Therefore, this study aimed to improve engagement levels and reduce depression level among adolescents with depression by designing a therapeutic game. A prototype named CBT4Depression was developed in this study. A quasi experimental study was conducted to evaluate the developed therapeutic game and 115 adolescents were recruited to measure their depression level using CBT4Depression. Based on the findings from the evaluation process, it can be concluded that the CBT4Depression considered success to engage and reduce the depression level among adolescents.

**Keywords**—Therapeutic; game; depression; adolescents; cognitive behavior therapy

## I. INTRODUCTION

In recent years, a markedly increased number of adolescents diagnosed with depression each year throughout the world. According to the World Health Organization (WHO), depression is one of the leading causes of illness and disability among adolescents aged 10-19 years [1]. This is, perhaps, not surprising that the statistics of suicide and homicide also increased in line with the numbers of depression, and have become the third-leading cause of death in 15-19-year-olds as reported by WHO. According to Hink et al., [2], this age group is 4 times more likely to die by committing suicide compared to other older adolescents.

As for the treatment, disturbed adolescents need to undergo a number of sessions in psychotherapy but the limitations in the current talk-based treatment may lead to negative experiences among the adolescents [3]. They also face difficulty expressing their feeling verbally and may also deny that they are suffering from depression [2]. Adolescents with depression also may have limited knowledge regarding depression, such as the differences between normal sadness

and depression, early symptoms and impacts that could affect their daily life. In addition, adolescents also have several barriers to seeking professional help or appropriate services such as financial problems, lack of knowledge in the help-seeking process, and their attitudes towards the psychological treatment [3], [4].

Afterwards, this problem could contribute to the higher possibility of dropping out of the treatment [5]. Being aware of the flaws in conventional psychotherapy, researchers and therapists started utilising the popularity of game technology as an assistive tool, also called therapeutic games. The rapid innovations and advances in information and communication technologies have brought a great positive impact on the gaming industry, especially among the young generation. They become very attached to digital games [6]. Psychotherapists have realised the advantages of using games as assistive tools in psychotherapy among young patients. The use of serious games is already being applied to various types of mental illnesses, such as anxiety, depression, phobia, panic disorder and eating disorder [7].

With the arrival of recent game technologies in this area, it can be seen a rapid proliferation of therapeutic games in psychotherapy practices. The advent of game technology has facilitated psychotherapists to have a better understanding of their patients, particularly adolescences. Furthermore, the level of relationship, or rather, engagement, between therapist and adolescent could be enhanced. One of the most intriguing aspects of therapeutic games is that they could promote patients' engagement and motivation during the treatment, and indirectly enhance the success rate of the therapeutic process.

In the earlier version of digital games, it is only used as entertainment tools. To date, digital or serious games are not only utilised in training but also in education, medical and military simulation. The popularity of serious games has grown extensively and is broadly accepted by various age groups, ranging from children to adults. Given the wide popularity and benefits that can be obtained from using serious games, this has increased the interest of researchers and health professionals in using serious games in treatments as assistive tools [8].

---

This study was funded by the Universiti Utara Malaysia through Journal Publication Fee Funding Scheme (SPYPJ).

Due to this growing demand, new alternative technologies for treatment and therapeutic support of various mental illnesses are being developed and implemented [9], [10]. Despite the broad range of effective treatments available for depression, there is still a need for more research to support their use in clinical treatments [11].

The use of games in healthcare settings has increased these past few years. The present studies also display the effectiveness of therapeutic games as an assistive aid in mental health interventions [12]. Moreover, recent research has shown that using games in psychotherapy can help establish the therapeutic relationship between two parties: therapist and patient. Successful psychotherapy depends on the positive progress of the correlation between these parties. This is because, most of the patients, usually involving children and adolescents, face problems with traditional psychotherapy [13]. It is difficult for young patients to develop an emotional connection with their therapist. Thus, it increases their resistance to sharing with the therapist. In turn, this difficulty could lead to unsuccessful treatment [14].

Utilising therapeutic games could provide rich experiences and is also capable of stimulating the motivation and engagement of patients, which are important during the psychotherapy session [15]. As an interactive medium, therapeutic games promise a viable, engaging and cost-effective approach that may benefit in reducing the stigma of mental illness [16]. Several therapeutic games have been purposely designed to enhance patients' motivation in order to support changes in their daily behaviour towards improving their quality of life. Therefore, a therapeutic game that is designed accordingly might increase one's intrinsic motivation and reduce reactance [17].

Several researchers have also proven that therapeutic game has a good prospect of supporting a higher level of cognition, for example, self-esteem, problem-solving, decision-making, cognitive and emotional skills [8]. Utilising therapeutic games in psychotherapy has already been proven as an efficient tool in supporting young patients during a psychotherapy session, capable of bringing positive changes to their mental health [18]. Hence, therapeutic games have high potential for improving health outcomes [13]. Playing games is synonymous with young patients, in which they can easily get immersed in the game. Hence, a strong relationship between therapist and patient can be built through this valuable tool.

A new style of communication between therapists and their patients can also be designed through therapeutic games, which can decrease face-to-face therapist contact [19]. This could very well contribute to a successful psychotherapy session. Activities involved in the session must be able to capture the attention of young patients. Thus, while they play and immerse in the game, they would give full attention to the game and forget that they are, in fact, in a psychotherapy session [20], [21]. At a certain point, they might even begin to feel comfortable with the psychotherapy environment and have no fear to express their feelings indirectly. Therefore, it is important for therapists to provide a convenient and safe environment during the therapeutic process [14].

## II. RELATED WORK

In this section, the most related work in therapeutic games for mental illness and targeted to young people from year 2021 to 2022 were discussed and compared. Based on the reviewed previous studies, it have clearly shown that the use of gaming intervention for mental illness in young people can improve their quality of life and reduce the depression symptoms. A comparative analysis that involved the 10 recent works related to therapeutic games in depression was conducted as shown in Table I.

Based on the comparative study, it was found that the most therapeutic approach utilized in the therapeutic games is Cognitive Behavior Therapy (CBT). This approach already known as an effective treatment to treat various mental health problems [25]. Thus, this is the main reason why most of the studies are using the therapeutic approach. This approach is very suitable to use for various game genres or platform such as video games, mobile games, online games, and role playing games. In addition, CBT is an action-oriented therapy that makes it very suitable for therapeutic games.

TABLE I. COMPARATIVE ANALYSIS

Game	Type	Therapeutic Approach	Focus	Source
I- SPARX	Video Game	CBT	Psychoeducation	[22]
SPARX	RPG	CBT	Behaviour change and engagement	[23]
Pesky gNATs (Depression & Anxiety)	Computer Game	CBT	Emotional problems	[24]
REThink (Depression)	Online Game	CBT REBT	Increase resilience	[8]
Grow It! (Depression)	Mobile Game	CBT	Emotional dynamics	[25]
Horizon: Resilience	Mobile Game	CBT Positive Psychotherapy	Increase motivation, cognitive flexibility activation and positivity	[26]
Moving Stories	Mobile 3D Video Game	NA	Mental health literacy and stigma reduction	[27]
EmoTIC	Mobile Game	NA	Social-emotional programme	[28]
Merlynne	Role Playing Game	CBT	Peer-to-peer support	[29]
MT-Phoenix i	Mobile Game	CBT	Reducing depressive symptoms	[30]

Legend:

CBT: Cognitive Behaviour Therapy

REBT: Rational Emotive Behavioral Therapy framework

Although all the studies as tabled in Table I focus on various elements, it clearly can be seen that most of them focus on the reducing the depressive symptoms by providing skills and knowledge to the young people. This is because young people have lack of skills and knowledge to handle depression. They also have a negative stigma toward depression as mentioned by [27]. Therefore, it is important to provide relevant skills and essential information to the young people to help them handle the depressive symptoms.

Other than that, gamification elements in the therapeutic game is vital to enhance engagement among the adolescents. Although the number of therapeutic games are increasing but the use of gamification in therapeutic games still limited. This is supported by a study conducted by [29]. The use of gamification elements will be able to sustain engagement among the adolescents to complete therapeutic activities in the game. The most common problem in the current treatment is inability to engage young people to the treatment and this leads to the dropping out from the treatment. Thus, the gamification elements should be fully utilized to increase their engagement.

### III. COGNITIVE BEHAVIOUR THERAPY

A broad range of therapeutic approaches is available for depression, but Cognitive Behaviour Therapy (CBT) has been the most widely used and extensively researched among young patients [25]. Fig. 1 describes the main components of this model.

This therapeutic approach is an effective intervention for improving coping strategies among adolescents. The effectiveness of CBT in treating depression among young patients is well-known and has been acknowledged by most therapists and researchers. To date, CBT has emerged as the 'gold standard' therapy approach for depression or even most mental illnesses [31]. In recent years, there is growing evidence for the efficacy of CBT on depression [32]. As depicted in Fig. 1, the components in CBT consist of: i) thoughts (how one thinks); ii) emotions (how one feels); and iii) behaviour (how one acts), combined to modify how adolescents think and react so as to eliminate negative thoughts.

The main aim of CBT is to assist patients in recognising their pattern of negative thinking, evaluating their validity, and replacing these faulty patterns with a more positive thinking style [33]. In the procedure of CBT with adolescents, therapists will observe and start analysing the patterns of thoughts, feelings and behaviour exerted by adolescents during particular events. This is done because therapists in CBT attempt to modify the ways adolescents think and feel in a more positive manner, which will be reflected in the behaviour exhibited by the patients in certain situations. Most importantly, CBT therapists would try to eliminate automatic negative thoughts that always influence the adolescents in their reactions.

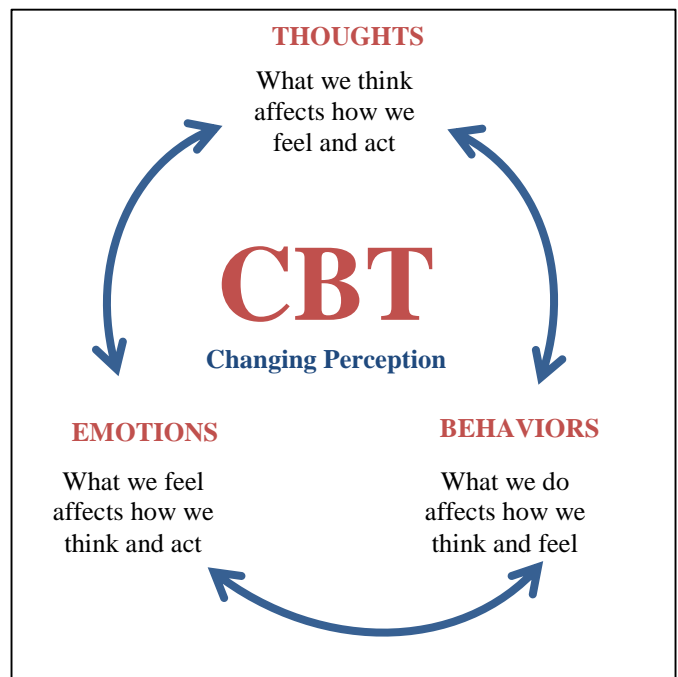

Fig. 1. Cognitive Behavior Therapy.

Now-a-days, CBT is widely utilised in therapeutic games that are designed for various mental illnesses, including depression [7]. This shows that the combination of CBT and therapeutic games can promote positive outcomes for people with depression, especially adolescents as tabled in Table I. To date, several therapeutic games were developed as an assistive aid to overcome the mental health illnesses. In this section, the study of the related works to therapeutic game discussed that focused on the reviewing the existing therapeutic game for mental illness.

### IV. CBT4DEPRESSION

The findings from the comparative analysis that was discussed in Section II lead to the design and development decision of CBT4Depression. CBT4Depression is an interactive therapeutic game application designed to deliver CBT to depressed adolescents. The target users for CBT4Depression were defined as ranging from 13 to 16 years old, who could play and are usually interested in computer games. It is also the most common age group among adolescents that is always experiencing depression. This therapeutic game application was meant to be a therapeutic material that serves as a kit for therapists or tutorials for the targeted users.

As found in the comparative analysis, gamification elements embed in the therapeutic game. Thus, the concept of CBT4Depression was designed to be fairly simple in a 2D game environment with a single character game control. The aim of CBT4Depression was to serve as an assistive aid to target users in identifying and reducing their depression levels. This is because vast evidence portrays that many adolescents, especially at present times, have failed to realise that they are suffering from depression [34].

Through this prototype application, users can learn techniques to strengthen their basic life skills that are critical to hinder their depression from getting worse. The CBT4Depression was designed and developed in the Malay language to suit the target users, as recommended by mental health experts during the preliminary investigation. So far, most therapeutic games have been developed in the English language, such as SPARX [19] and Pesky gNATS [24]. Table II summarises the detailed description of CBT4Depression.

### A. Therapeutic Elements

The CBT4Depression was designed based on a well-known therapeutic model named CBT, as described in Fig. 2. This model was chosen in this study because of its proven effectiveness in various mental health treatments. This model is also highly suitable for adolescents suffering from depression. CBT therapeutic strategies were applied to strengthen the elements of therapeutic game in CBT4Depression. The game highly focused on how to handle automatic negative thoughts and reactions.

TABLE II. DETAILED DESCRIPTION OF CBT4DEPRESSION

<b>Main topic</b>	Depression
<b>Target users</b>	Adolescents
<b>Type</b>	Single Player Role Playing Game (RPG)
<b>Game graphics</b>	2D Graphics
<b>Concept</b>	Therapeutic
<b>Language</b>	Malay
<b>Depression Inventory</b>	Beck Depression Malay
<b>Objective</b>	Beat Nega, collect points and escape from the jungle
<b>Therapy Content</b>	CBT, psychoeducation, and basic life skills

Fig. 2. CBT in CBT4Depression.

CBT4Depression helped the player recognise negative thoughts and poor reactions due to those thoughts. Thus, the therapeutic game embedded cognitive and behavioural techniques that are in line with CBT. Both techniques were implemented as part of the game elements and therapy content. Fig. 3 shows one of the cognitive techniques used in CBT4Depression, which is known as Socratic questioning.

Socratic questioning is an important component of CBT interventions that facilitates patients in assessing their automatic thoughts. It works by asking the player questions that encourage active participation in seeking answers and indirectly stimulating their critical thinking. Through this technique, the therapist can help patients become aware of and modify the process involved in their difficulties, and also learn how they can re-evaluate their thoughts.

Meanwhile, Fig. 4 describes one of the behaviour techniques called behaviour experiment, which was embedded in the therapeutic game. This technique was conducted after the player had learnt about negative thoughts and was used to evaluate underlying beliefs and assumptions.

The experiments were executed through questions and answers, writing notes on a certain given situation as an example and making predictions. Through these experiments, the player was encouraged to enhance the memory of the positive experience and avoid negative thoughts. Most of the existing therapeutic games for mental health apply these techniques in their games because such techniques are essential in psychotherapy [19], [35].

Besides, the use of a depression inventory was essential to measure the therapeutic outcome. A depression inventory is a set of self-rated questions used for assessing an individual's overall health condition related to depression symptoms [36]. In this study, the Beck Depression Inventory in Malay version (BDI-Malay) was utilized in the CBT4Depression. The BDI-Malay is suitable for adolescents because it is easy to understand. One example of the questions in the BDI-Malay is indicated in Fig. 5.

Fig. 3. Socratic Questioning.

Fig. 4. Behaviour Experiment.

Fig. 5. BDI-Malay.

Other than that, psychoeducation was also embedded in the CBT4Depression to raise awareness among the target users. Concurrently, teaching critical basic life support skills in the therapeutic game application is also important in order to help target users cope with depression in certain situations. The life skills embedded in the CBT4Depression were problem-solving skill, decision-making skill, coping skill, relaxation skill, as well as communication and social skills. Similarly, existing therapeutic games that are designed for depressed adolescents also focus on comparable skills that cover cognitive, social and emotional skills for life and the school environment. The skills range from relaxation skills and literacy skills to emotion regulation skills [37].

### B. Game Elements

The storyline embedded in CBT4Depression was about a teenager (player) who was lost while exploring the jungle. The player needed to find a small village far inside the jungle to seek help from the villagers to escape from the jungle. However, at the same time, the player needed to fight with some enemies, called Nega. Nega(s) were incarnations from

the player's own negative thoughts that appeared in various forms, such as a friend, stepmother or black shadow. Hence, the player had to defeat Nega by fighting negative thoughts and modifying them into positive thoughts.

Various elements of mixed fantasy and curiosity were used in the game story to ensure that CBT4Depression was capable of capturing the interest and attention of the player as depicted in Fig. 6. The story involved the elements of exploration or fantasy, which then lead to surprise, wonder, and awe, all of these supporting the fun elements.

In addition, the rules in CBT4Depression were clear and specific, thus, allowing a player to receive feedback discrepancies, which then can trigger greater focused attention and enhance player engagement. The linking activities provided in the prototype also contributed to engaging competitive and cooperative motivations. All these elements can help in enhancing the engagement level among adolescents.

Fig. 6. Game Elements.

The difficulty levels in CBT4Depression were designed to increase gradually from the first level onwards. The difficulty at each level was matched with the player's skills so that the player can complete all the challenges in the game. The challenges in the therapeutic game were also tested by the health experts during evaluation to ensure that the moderate challenges were suitable for the target players [38]. As the therapeutic game was targeted at adolescents with depression, the challenges were not too difficult and yet not too easy.

Besides, since CBT4Depression was purposely designed for people with depression, time challenge was not utilised in the game based on the advice of the experts. After all, failing to meet the challenge may cause the player to feel more depressed. The challenges at each level required the player to master different skills. The relevant skills used by the player can be practised outside the game context, facilitating an effective skill transfer in the player's daily life [39]. Once the player mastered the skills at a level, the difficulty of the challenge will be increased at the next level, and the player will then need to master a new skill to complete the challenge. The challenges at each level are listed in Table III.

TABLE III. GAME CHALLENGES IN CBT4DEPRESSION

<b>Level 1</b>	Exploration, survival, and accuracy
<b>Level 2</b>	Exploration, memorisation, defeating the enemies, and finding a key to open an exit door.
<b>Level 3</b>	Defeating the enemy and helping a friend
<b>Level 4</b>	Answering questions correctly, finding essential information, and defeating the enemies.

Meanwhile, Fig. 7 shows one of the game challenges that was designed in the therapeutic game. In this game challenge, the player will learn that negative thinking will lower their confidence level and indirectly lead them in making poor decisions. Therefore, this game challenge could help to increase their awareness of the importance to hinder negative thinking.

Fig. 7. Game Challenges in Level 1.

### V. RESULTS AND DISCUSSION

In order to evaluate the effectiveness of CBT4Depression, a quasi-experimental study was conducted. The evaluation was adopted in this study to measure player experience in terms of engagement, as well as to test the effectiveness of CBT4Depression. The study was conducted in a lab environment with each PC installed with the CBT4Depression. Each participant in this study was assigned one PC.

A total of 115 adolescents aged between 13 and 16 were recruited in this study to measure their engagement level using CBT4Depression. The scores of BDI-Malay in the CBT4Depression were recorded and compared against the score classification, as indicated in Table III. The results demonstrated that the depression level of the respondents decreased from the pre to post-sessions. Then, the mean of the BDI score before and after using CBT4Depression was compared. Descriptive statistics for the two related samples were analysed, as presented in Table IV. The results showed that the mean for the BDI score after using the CBT4Depression was lower than the pre-score.

Nevertheless, the Paired Samples Test table was examined to ascertain whether the obtained result was significant or due to chance. Thus, the differences between the BDI score in both samples were examined for significance. As shown in Table V, the p-value was less than .05 (significance [2-tailed]). Referring to the results of the tests as shown in Table V and Table VI, it was found that the BDI scores reduced significantly after using CBT4Depression. Hence, this study has proven that therapeutic games support treatment for young people suffering from mental health, which is congruent to the findings of the study conducted by [13]. Therapeutic games can act as an alternative tools for psychotherapist in treating young patients such as children and adolescents. The information can be effectively delivered to them by using the therapeutic game as the medium of delivery.

TABLE IV. BDI SCORES CLASSIFICATIONS

Classification	Total Score	Pre-score	Post-score
Minimal Depression	0 - 9	-	79
Mild Depression	10 – 16	80	18
Borderline Clinical Depression	17 – 29	20	11
Moderate Depression	21 – 30	12	6
Severe Depression	31 – 39	3	1
Extremely Severe Depression	Over 40	-	-
<b>Total</b>		<b>115</b>	<b>115</b>

TABLE V. DESCRIPTIVE STATISTICS OF THE PAIRED SAMPLE (BDI SCORES)

		Mean	N	Std. Deviation	Std. Error Mean
Pair 1	Pre score	12.9739	115	8.22647	.76712
	Post score	8.0783	115	8.41901	.78508

TABLE VI. PAIRED SAMPLES TEST RESULT USING CBT4DEPRESSION

		Paired Differences				t	df	Sig. (2-tailed)	
		Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference				
					Lower				Upper
Pair 1	Pre score – Post score	4.89565	6.84717	.63850	3.63078	6.16052	7.667	114	.000

In addition, it is evident that the therapeutic elements and game elements in CBT4Depression is effective in reducing depression level among adolescents. In other words, CBT4Depression can be used as an assistive tool in mental health treatment among young patients.

## VI. CONCLUSION

This study has presented the effectiveness of CBT4Depression as a game-based digital intervention in reducing depression levels among adolescents. CBT4Depression comprises therapeutic elements that are adopted from a well-known therapeutic approach known as Cognitive Behaviour Therapy (CBT). In order to engage the adolescents in the game world, several game elements are applied in the game, such as challenge, curiosity, fantasy and fun. A quasi-experimental study has been conducted to measure the effectiveness of CBT4Depression. It has been found that CBT4Depression is effective in helping adolescents reduce their depression. Future work will involve expanding the CBT4Depression to cater more mental illness such as anxiety disorder, eating disorder and intermittent explosive disorders. The target groups will also expand to the adult as well.

## ACKNOWLEDGMENT

**Abstract**—The overwhelming number of video uploads and downloads has made it incredibly difficult to find, gather, and archive videos. A static video summarization technique highlights an original video's significant points through a set of static keyframes as a video visual storyboard. The video visual storyboards are created as static video summaries that solve video processing-related issues like storage and retrieval. In this paper, a strategy for effectively summarizing static videos using the feature vectors, which are fractional coefficients of the transformed video frames, is proposed and evaluated. Four popular orthogonal transforms are deployed for generating feature vectors of video frames. The fractional coefficients of transformed video frames taken as 25 percent, 6.25 percent, and 1.5625 percent of full 100 percent transformed coefficients are considered to form video visual storyboards. The proposed method uses the benchmark video datasets Open Video Project (OVP) and SumMe to validate the performance, containing user summaries (storyboards). These video summaries created using the proposed method are evaluated using percentage accuracy and matching rate.

**Keywords**—Keyframe; orthogonal transform; VSUMM; video visual storyboard; video summarization

## I. INTRODUCTION

Due to the significant increase in the cases of pushing promotional videos in online drop boxes, Emails, and social network accounts of users, the users are forced to get these videos downloaded to understand the contents of the video. After seeing the video, the user often finds that he is not interested in the whole content. With the easy accessibility of Internet Services and handheld image/video capturing devices, there is a lot increase in the photos and videos in online/offline databases. But it has introduced new challenges in computer vision research, such as storage, search, and navigation, due to the huge volume of video data. There is a critical need to address these problems because of the abundance and accessibility of video data. A video content summarization aims to summarize the full video content in this situation into short video clips or groups of frames that are crucial for understanding video content. This summary is known as a visual video storyboard.

Video content summarization through storyboards enables quick browsing of a collection of sizable video datasets. Additionally, it supports associated video-related tasks like

video indexing and retrieval. Nowadays, video summarization has evolved in various applications as a problem of keyframe extraction [1]. But the key frame extraction is very challenging due to the complex nature of the video. Key frame extraction, which substitutes for the most crucial elements of the movie, is one method for producing video summaries/storyboards.

The video storyboard is a quick and meaningful way of giving an abstract perspective on an entire video by creating a video summary[2]. The viewer might not have enough time to see the complete movie. At that time, the storyboards may help users to watch only the important content using these keyframes to narrate the full story of a video. These storyboards can be static [3] or dynamic [4].

Over the past two to three decades, videos have increased. Still, there isn't an ideal system that can handle the time-consuming process of creating a visual video storyboard. So, the indexing, retrieval, and storage of video are affected. All of these video-related concerns can be addressed by video storyboards. The number of approaches proposed for creating video summaries mainly focuses on feature selection techniques used for keyframe selection and evaluation with the ground truth.

The existing video summarization methods divide the whole video into shots and segments. Then it applies the feature selection process as defined in VSUMM [5][6][7], the DT triangulation method for clustering the video frames [8], Local descriptor based and temporal features based [9], diverse color space-based key frame extraction [10].

In VSUMM and DT methods, the video frames are considered in a batch of the first 25-30 frames or by interleaving sequence, thereby not including all the features in video frames. In VSUMM and DT methods, the keyframes are selected only by grouping and distance between the video frames. This leads to the loss of a few important frames in a sequence. This limitation can be overcome by using all the video frames in a video, as stated in the proposed method.

In state-of-art summarization of video, video summaries are dependent on the key frame extraction, and feature selection plays an essential role in this keyframe extraction step. Therefore many researchers have demonstrated different techniques for selecting these features for key frame extraction

[11][12]. Based on the input and output features, video summarization has two different ways: dynamic and static. A dynamic summary of the video is the abstraction of the lengthy video into a compact reel in which the scene is recreated using only keyframes, and a motion is applied [13]. A static summary of the video includes a series of static keyframes that shows the entire story of the video without motion. The choice of static and dynamic is user dependent.

The use of orthogonal transforms assures the full feature in the input frames. Orthogonal transforms are applied with fractional energy coefficients for the various applications of content-based video retrieval with performance measure as precision and recall[14]. The use of transformed features assures high energy compaction; therefore, transformed features are used in video processing. The research work presented here addresses the issue of feature selection in key frame extraction by using the transformed features and proposes a novel video summarization technique with the creation of visual video storyboards. The proposed method first segments the video into video frames, spreading all video content over multiple frames.

In most of the existing static video summarization approaches, the observed limitations are the huge size of feature vectors of video frames, unequal size of feature vectors, suitability of the features for a particular type of video dataset only, and experimental validation is done with a single dataset. Hence there is a need to have the optimal minimum size of a more robust feature vector with the ability to show analogous performance across multiple video datasets.

Depending upon the discussion above, the key contributory significance of the proposed static video summarization method is as follows:

- 1) The use of fractional energy of transformed video frames to produce a video summary (video visual storyboard).
- 2) The use of orthogonal transforms to obtain the fractional coefficients of transformed video frames.
- 3) Performance validation using Open Video Project (OVP) and SumMe benchmark video datasets.

The remaining part of this paper is structured as follows: Section 2 illustrates the current work. The proposed static video summarization method using fractional energy coefficients of transformed video frames is put forth in Section 3, and Section 4 describes the results with the OVP and SumMe dataset and the test bed used for experimentation. The conclusion obtained by thorough investigation and demonstration is summarised in Section 5.

## II. RELATED WORK ON STATIC VIDEO SUMMARIZATION

Lengthy videos have a large sequence of short segments (shots) in video frames; these shots are made up of only the most essential frames (keyframes) that can be used to search and retrieve the original videos. Through these keyframes (storyboards), the videos can be understood easily. According to the literature, transformed features ensure retrieval effectiveness and reduce the calculations required for time-consuming video processing [14]. But these transformed features are extracted for content-based image retrieval, not video retrieval. It does not include a sequence of images in a

query. In [15], adaptive threshold-based key frame extraction uses the MPEG -7 color layout descriptors combined with adaptive thresholding. In [16], annotation-based keyframe identification is defined with interest as a key frame identification concept. Both static video frame extraction methods use the actions in a video as a base for the shot selection. This will not apply to all videos; a few videos may be just informative or storytelling. In [17], a review presents different video summarization categories based on features, clusters, shots, and trajectories. But this study concludes with a video summarization of the region of interest problem. Every time human intervention is needed while summarizing the video. So there is a need for an automatic summary generator with minimum computations. The specific feature should be selected with automatic computations for the keyframe selection.

Orthogonal transforms, including Discrete Cosine, Kekre, Walsh, Slant, Discrete Sine, and Discrete Hartley, have been explored for content-based image retrieval (CBIR)[18]. Mean Square Error (MSE) is the similarity metric considered. This method creates an efficient image signature for each image and ensures full input feature selection. But this operation is performed on each distinct image in a dataset. In a video, many similar images, known as near duplicates, will increase the computational overhead; in such cases, using transformed features may reduce the computational complexity. Therefore in the proposed work, different orthogonal transforms are used for storyboard creation in static video content summarization.

But in [18], the transformed features are used for image retrieval; no recreation is performed here with the retrieved image. The proposed video visual storyboard creation method is explained in detail in the following section and generated video storyboards are validated using the novel performance metrics. A brief review of the techniques that support the video summarization is given in Table I.

TABLE I. RELATED WORK COMPARISON OF VIDEO SUMMARIZATION TECHNIQUES

Author List	Type of Features used	Dataset	Performance
Xiang et al. [16] 2020	ConvNet	VSUMM	F-score (72.1%)
Rukiye et al. [19] 2021	CNN & RNN	UCF 101	Accuracy (67.39%)
Vijay Kumar et al. [20] 2014	Discrete Wavelet Transform, Haar Wavelet based	Sports Video	Precision (0.83)
Naveed et.al. [21] 2013	Discrete Cosine Transform	Open Video Project	F-Measure (82%)
Kavitha et al. [22] 2015	Discrete Wavelet Transform	Open Video Project	F1-Score (87%)
Ajay Narvekar et al. [23] 2013	Discrete Cosine Transform	Online videos	Precision (0.78)

The work presented in [19][20][21][22], briefly compared in Table I, clearly indicates that the transformed feature gives more precision and recall than the cluster-based approach,

along with the reduction in computational costs since kernel size varies. It provides a quick review of existing methods where the orthogonal transforms are used in video summarization, and CNN performance is also compared with recent work. This has given the motivation for selecting the orthogonal transforms to prove the efficiency for static video content summarization, i.e., creating the video visual storyboards.

### III. PROPOSED METHOD OF STATIC VIDEO SUMMARIZATION USING ORTHOGONAL TRANSFORMS

The proposed method of creating feature vectors for static video summarization uses fractional energy coefficients of transformed features to make a video visual storyboard. The proposed framework is shown in Fig. 1.

The Proposed framework has three steps: first, to form a transformed feature vector of all video frames using the 'T' transform; the second step is to prepare a feature vector using fractional energy coefficients; the third step is to select the number of keyframes. All these three steps are pictorially represented in Fig. 1. The above steps are elaborated in the following subsections.

#### A. Orthogonal Transform

Different orthogonal transforms used in this proposed method are discussed here. The 'T' transforms used in this system are defined in the form of their matrix equations.

##### 1) Discrete Cosine Transform (DCT)

The Discrete Cosine Transform is the most widely used orthogonal transform in image processing. The  $N \times N$  cosine transform matrix is defined as below in equation (1),

$$c(p,n) = \begin{cases} \frac{1}{\sqrt{N}} & p = 0, 0 \leq n \leq N-1 \\ \sqrt{\frac{2}{N}} \cos \frac{\pi(2n+1)p}{2N} & 1 \leq p \leq N-1, 0 \leq n \leq N-1 \end{cases} \quad (1)$$

##### 2) Slant Transform

The Slant transform is a constant function with a one-row function and the second row is a linear function of the column index. It includes sparse matrices, reducing the computations and leading to a fast process.

The matrix equation of the Slant transform is given by equation (2),

$$S_2 = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \quad (2)$$

##### 3) Walsh Transform

The set of  $N$  rows denoted as  $W_k$ , for  $k=0, 1, \dots, N-1$ , is defined in Walsh Matrix that has distinct properties.

$W_k$  takes on the values +1 or -1.

$W_k [0] = 1$  for all  $k$ .

$W_k \times W_l = 0$ ,  $k \neq l$  and  $W_k \times W_l$  has exactly  $k$  zero crossings, for  $k=0, 1, \dots, N-1$ .

Each  $W_k$  is either even or Odd.

##### 4) Kekre Transform

This transform matrix is an  $N \times N$  matrix, where the upper diagonal values are one, and the diagonal values of Kekre's transform matrix are also one, except other values below the diagonal is zero.

This matrix equation is defined using the Hadamard matrix of order  $N$  in equation (3),

$$K_{xy} = \begin{cases} 1 & , x \leq y \\ -N + (x+1) & , x = y+1 \\ 0 & , x > y+1 \end{cases} \quad (3)$$

#### B. Feature Vector Extraction

Each video frame is resized to  $256 \times 256$ . On each color plane video frame of size  $N \times N$ , the 'T' Transform (alias DCT, Walsh, Slant, and Kekre Transform) is applied to extract the visual feature vector of size  $N \times N$  as a full or 100% energy content scenario as shown in Fig. 1.

The fractional energy coefficients are computed by dividing the full features of the video frame into block sizes of  $32 \times 32$ ,  $64 \times 64$ , and  $128 \times 128$  and are taken as top left-hand side coefficients of transformed color planes of video frames, as shown in Fig. 2.

In this proposed method, the transformed coefficients are used to form the feature vector. In [24], transformed coefficients as features have shown better accuracy in the keyframe extraction. The proposed method uses these transformed video frame coefficients with a reduced number of feature vector elements.

#### C. Feature Vector Database using Fractional Coefficients

The proposed video visual storyboard generation method for static video summarization uses fractional energy coefficients. The diagrammatic representation of extracting fractional energy coefficients to generate feature vectors from a transformed video frame is shown in Fig. 2.

Fig. 1. The Proposed Method of KeyFrame Extraction with Fractional Energy Coefficients of Transformed Video Frames for Visual Storyboard Creation.

If the video frame is of size 256x256, the fractional energy coefficient proportions are taken as 25%, 6.125%, and 1.5625%, respectively, with sizes 128x128, 64x64, and 32x32. Considering high energy coefficients as feature vectors reduces feature vector size, time, and computational complexity.

Fig. 2. Proposed Feature Vector Extraction with Fractional Energy Coefficient.

#### D. The Decision of Keyframe for Video Visual Storyboard

The keyframes are the significant frames that contain the maximum information in a video frame. These keyframes are selected based on the consecutive differences between two transformed video frames. These consecutive differences are then compared with the certain constant threshold calculated with standard deviation and mean. Each transformed video frame in the sequence is associated with the difference; if this difference is above the threshold, then that particular frame is selected as a keyframe; otherwise, it is discarded. In this process of keyframe selection, there might be a possibility of selecting near duplicates along with essential frames. These

near duplicates are eliminated by interleaving manually or statistically.

TABLE II. VIDEO DATASET DETAILS CATEGORY WISE

Open Video Project Video Dataset			
Category	Documentary	Educational	Lecture
*No. of videos	15	20	20
Category	Historical	Public Service	Ephemeral
*No. of videos	20	20	15
Total 110 videos			
SumMe Video dataset			
Total 25 videos			

#### IV. RESULTS AND DISCUSSION

The implementation details and results are discussed in this section.

##### A. Experimental Video Testbed

Two video datasets, the Open Video Project (110 videos) and SumMe (25 videos) of various categories, are used for proposed experimentation. The videos are provided in both compatible file types (MPEG-2, MPEG-4). These video datasets are openly accessible. The OVP contains the categories of Lectures, Television, Demonstrations, and Documentary videos. The SumMe dataset includes videos of categories like Cooking, Bike polo, Base jumping, etc.

These two benchmark datasets provide video user summaries as visual storyboards for respective videos [21]. These user summaries are further used for performance comparison to evaluate the proposed static video summarization technique for creating video visual storyboards. A few video frames are shown in the following Fig. 3, with a few sample frames from the OVP and SumMe datasets. Each video length varies from less than 1 minute to 2 minutes.

a) OVP- Family TV Spots around the World

b) SumMe – AirForce, Base jumping, fire Demo

Fig. 3. Few Video Frames from a) OVP Dataset and b) SumMe Dataset.

Table II shows the number of videos considered from the OVP and SumMe datasets for the experimentation of the proposed method with respective categories. The type of video in the Lecture category has slow transitions in the scene, leading to fewer keyframes in the final output of the video visual storyboard. The sudden changes in the scene will affect the number of keyframes extracted. The proposed experimentation testbed includes all types of videos with such variations.

### B. Results and Discussion

The experimentation is performed using the above videos shown in Fig. 3. The proposed method extracts the keyframes from each video from the dataset. The obtained keyframes are compared with the already existing given ground truth in the OVP and SumMe datasets. The performance metrics matching rate and percentage accuracy are calculated to identify the exact matching frame from the given set of keyframes in the OVP and SumMe video dataset storyboard.

The number of keyframes extracted using the fractional energy coefficients of transformed video frames is evaluated using the given ground truth of videos from the OVP and SumMe datasets.

#### 1) Performance Metric

The percentage accuracy is calculated as the ratio of the number of correctly extracted keyframes by the proposed method and the total number of keyframes given in the standard user storyboard.

In the matching rate, the matching from the given summaries with frame numbers given in ground truth is done with the keyframes obtained using the proposed method. The matching rate is calculated as the number of identical matching video frames similar to the keyframes given in the OVP video user summary. Here it is assumed that keyframes in the user summary are provided with the frame numbers from the original video frame sequence.

The performance metrics used in the proposed system are explained in equations (4) and equation (5).

The keyframes in the given OVP summary are downloaded from <https://openvideo.project.com>. The user summary from OVP and SumMe datasets are compared with a set of keyframes obtained through the proposed system.

The keyframes obtained are used to create a visual video storyboard. The results are summarized in Tables III and IV for the orthogonal transform using fractional energies with OVP and SumMe videos.

The percentage accuracy and matching rate are given in Tables III and IV with the detailed analysis of the proposed fractional energy-based keyframe extraction method using orthogonal transform alias DCT, Walsh, Slant, and Kekre transform.

The results show that the performance improves in the case of the proposed use of fractional energy coefficients compared to the consideration of 100% coefficients. This reduction in the sizes of the different feature vectors in the proposed method improves the accuracy of video visual storyboard creation by finding more accurate keyframes.

TABLE III. PERCENTAGE ACCURACY AND MATCHING RATE OF PROPOSED FRACTIONAL ENERGY COEFFICIENTS BASED ON KEYFRAME EXTRACTION METHOD FOR RESPECTIVE ORTHOGONAL TRANSFORMS EXPERIMENTED ON OVP DATASET

Performance using OVP dataset				
Fractional energy coefficients	10 0%	25 %	6.25 %	1.526 %
Discrete Cosine Transform (DCT)				
% Accuracy	76. 23	75. 31	75.0 6	76.28
Matching Rate	19. 2	20	20.2	20.2
Walsh Transform				
% Accuracy	73. 45	73. 49	72.2 5	73.63
Matching Rate	16. 63	17. 24	17.4 8	16.78
Slant Transform				
% Accuracy	70. 19	71. 59	70.3 6	71.45
Matching Rate	15. 82	15. 24	15.6 3	15.89
Kekre Transform				
% Accuracy	69. 38	70. 39	70.7 2	70.49
Matching Rate	14. 92	15. 24	15.7 8	15.58

The above performance comparison, as shown in Table III and Fig. 4 indicates that the results of DCT based proposed keyframe extraction method outperform when compared to the other Walsh, Slant, and Kekre orthogonal transform-based keyframe extraction.

$$\text{Percentage Accuracy} = \frac{\text{Number of correctly extracted keyframes}}{\text{Expected number of keyframes}} \quad (4)$$

$$\text{Matching Rate} = \frac{\text{Exact matching extracted keyframes}}{\text{Total number of keyframes}} \quad (5)$$

Fig. 4. Performance Comparison of the Proposed Fractional Energy Coefficients based Video Keyframe Extraction Method for Respective Orthogonal Transforms Experimented on OVP Dataset.

A similar method applies to other "T" orthogonal transforms with fractional energy coefficients. The reduction in the feature vector is not affecting the percentage accuracy but increases the selection of keyframe matching to the given keyframe from OVP visual storyboards. Table IV and Fig. 5 show the analysis of the performance obtained by the proposed method using SumMe videos.

TABLE IV. PERCENTAGE ACCURACY AND MATCHING RATE OF PROPOSED FRACTIONAL ENERGY COEFFICIENTS BASED ON KEYFRAME EXTRACTION METHOD FOR RESPECTIVE ORTHOGONAL TRANSFORMS EXPERIMENTED ON SUMME DATASET

Performance using SumMe dataset				
Fractional energy coefficients →	10	25	6.25	1.526
	0%	%	%	%
<b>Discrete Cosine Transform (DCT)</b>				
% Accuracy	.75	.74	.743	.7359
Matching Rate	.18	.17	.179	.175
<b>Walsh Transform</b>				
% Accuracy	.73	.73	.722	.7363
Matching Rate	.16	.17	.174	.1678
<b>Slant Transform</b>				
% Accuracy	.72	.72	.731	.7324
Matching Rate	.16	.15	.162	.1649
<b>Kekre Transform</b>				
% Accuracy	.73	.73	.742	.7347
Matching Rate	.16	.16	.154	.1638

Fig. 5. Performance Comparison of the Proposed Fractional Energy Coefficients based Video Keyframe Extraction Method for Respective Orthogonal Transforms Experimented on SumMe Dataset.

### 2) Significance of the Proposed Method

The proposed method generates video summaries with a few keyframes displayed below in Fig. 6(a) and 6(b) to support the performance metrics discussed in this paper. The similarity can be compared with the frame numbers similar to the OVP and SumMe storyboards.

Fig. 6. Video Frames of a Video – a) A NEW Horizon Segment 5 of 13 b) The Voyage of Lee (Highlighted Keyframes Match with OVP Storyboard).

The highlighted frames, as shown in Fig. 6 above, are the ones that are used to calculate the matching rate. The keyframes whose frame numbers match the given keyframes in the OVP storyboard are highlighted.

The relationship between the feature vector computation and the energy reduction coefficients utilized in this implementation is shown in Table V. The 6.25% feature vector space reduces the whole feature vector by 93.75% and gives similar percentage accuracy.

TABLE V. COMPARISON OF PROPOSED % FRACTIONAL ENERGY COEFFICIENTS AND REDUCTION IN % FEATURE VECTOR SIZES

Feature Vector Size	% fractional Energy Coefficients	% reduction in Feature Vector Size
$N \times N \times 3$	100	0
$\frac{N}{2} \times \frac{N}{2} \times 3$	25	75
$\frac{N}{4} \times \frac{N}{4} \times 3$	6.25	93.75
$\frac{N}{8} \times \frac{N}{8} \times 3$	1.5625	98.4375

The proposed method here is effective for storyboard generation as compared to other techniques DT [8] and VSUMM [7] in terms of computations required to process video frames. Here the dimensionality of each feature vector is reduced due to the use of fractional energy coefficients.

1) Comparison with other Techniques

This section compares the proposed system with existing techniques like DT [8] and OVP summary. The experiments were performed on videos downloaded from OVP and SumMe. These summaries are evaluated in percentage accuracy and compared with existing VSUMM and DT Summary ground truth. The same comparison of the proposed method performance is made with VSUMM and DT summaries using the performance metric as percentage accuracy. Tables VI and VII show this comparison.

Fig. 7 below shows the visual static storyboard comparison between OVP ground truth, VSUMM, and DT summary with the static summary obtained through the proposed method of static video summarization in the form of a set of keyframes extraction for storyboard creation. Fig. 7 shows the highlighted keyframes that match the ground truth and user summary.

Fig. 7. Comparison of Video Storyboard Created by the Proposed Method Versus DT, VSUMM, and OVP Storyboards.

Table VI shows that the proposed system's performance is better than the DT summary using OVP videos and closer to the VSUMM summary.

TABLE VI. PERFORMANCE COMPARISON OF THE PROPOSED FRACTIONAL ENERGY COEFFICIENTS BASED VIDEO KEYFRAME EXTRACTION METHOD WITH DT[8] AND OVP VIDEO SUMMARIES EXPERIMENTED ON THE OVP DATASET

Name of the Video from (OVP)	Video length in Seconds	Percentage Accuracy (%)		
		VSUMM [7]	DT [8]	Proposed
A New Horizon Segment 5	1.59	78.57	42.86	<b>78.57</b>
A New Horizon Segment 6	1.05	80.00	60.00	60.00
A New Horizon Segment 7	0.47	87.50	75.00	<b>75.00</b>
The Voyage of Lee 15 of 21	1.15	75.00	50.00	<b>83.33</b>
The Voyage of Lee 16 of 21	1.27	71.43	42.86	42.86

Average		78.24	55.38	64.32

Comparatively, the VSUMM summaries are closer to the OVP summary, and second next better accuracy is provided by our proposed method of creating a visual storyboard. The proposed storyboard generation method performs better than the Delaunay triangulation method. The same comparison of the proposed method performance is made with VSUMM and DT summaries using SumMe videos.

Table VII shows that the proposed system's performance is better than the DT summary using SumMe input videos.

TABLE VII. PERFORMANCE COMPARISON OF THE PROPOSED FRACTIONAL ENERGY COEFFICIENTS BASED ON VIDEO KEYFRAME EXTRACTION METHOD WITH DT [8] AND SUMME VIDEO SUMMARIES EXPERIMENTED ON SUMME DATASET

Name of the Video (SumMe)	Video length in Seconds	Percentage Accuracy (%)		
		VSUMM [7]	DT [8]	Proposed
Air_Force_One	2.59	68.42	68.42	47.37
Base Jumping	2.38	78.26	47.83	52.17
Bike Polo	1.43	83.33	50.00	55.56
Cooking	1.26	84.62	61.54	<b>76.92</b>
Scuba	1.14	55.56	55.56	<b>77.78</b>
Fire Demo	0.54	66.67	66.67	66.67
Average		72.81	58.33	62.74

So the major contribution of the proposed system is that it overcomes the problem of inclusion of near duplicates due to Delaunay triangulation of clustering. Instead of that proposed system, select the keyframes from all video frames using fractional energy coefficients. In the DT method, summaries are produced for a batch of videos, whereas the proposed system processes each video one by one to include all features giving significance.

## V. CONCLUSION

Video summarization faces the challenge of reducing computational complexity and retrieval accuracy due to its complex nature. This work focuses on reducing visual video frame features for static video summarization, and a new method is proposed for creating a video visual storyboard using transformed visual features with fractional energy coefficients. The transformed coefficients of color planes of the video frames are considered for finding the final feature vector as the set of fractional energy coefficients 25%, 6.25%, and 1.5625% of total coefficients using transforms alias DCT, Slant, Walsh, and Kekre. These features are used for keyframe extraction, and a set of extracted keyframes forms a video visual storyboard.

The average percentage accuracy obtained by the proposed system is 72.51 with the OVP dataset and 73.55 with the SumMe dataset. The keyframes obtained through the proposed system match with the given set of keyframes in the OVP and SumMe dataset videos. The percentage accuracy and matching rate using fractional energy coefficients are higher than using complete 100% energy coefficients used in the existing DT and VSUMM Summary. The keyframe selection done with the proposed use of fractional energy coefficients of transformed video frames for creating a video visual storyboard is better than the use of full energy content, proving the worth of the proposed method. This same method can be further extended for creating the video logs for video storage and indexing as future scope.

## ACKNOWLEDGMENT

I sincerely thank my Ph.D. Guide and mentor Dr. Sudeep D. Thepade (Professor, Computer Engineering, PCCOE Pune and BOS Computer Engineering, Member SPPU Pune) for his valuable guidance in computer vision.

**Abstract**—The impulse noise often damages the human dental X-Ray images, leading to improper dental diagnosis. Hence, impulse noise removal in dental images is essential for a better subjective evaluation of human teeth. The existing denoising methods suffer from less restoration performance and less capacity to handle massive noise levels. This method suggests a novel denoising scheme called "Noise removal using Partition supported Median, Interpolation, and Discrete Wavelet Transform (NRPMID)" to address these issues. To effectively reduce the salt and pepper noise up to a range of 98.3 percent noise corruption, this method is applied over the surface of dental X-ray images based on techniques like mean filter, median filter, Bi-linear interpolation, Bi-Cubic interpolation, Lanczos interpolation, and Discrete Wavelet Transform (DWT). In terms of PSNR, IEF, and other metrics, the proposed noise removal algorithm greatly enhances the quality of dental X-ray images.

**Keywords**—Salt and pepper noise; impulse noise; X-ray noise removal; X-ray teeth image quality enhancement; dental X-ray noise reduction

## I. INTRODUCTION

X-ray, CT, and MRI-like medical devices generate many medical images to help doctors. The impulse noise contaminates the medical image pixels, damaging the real data [1]. Currently, X-Ray images are the primary sources for diagnosing dental diseases [2]. The dental diagnosis via dental-X-ray images is a trustful field that provides the exact outcome in dentistry, and it faces the real test of the contingency of impulse noise. The impulse noise is also known as salt and pepper noise. As stated in [3], identifying Dental-images in X-ray is crucial for any intuitive assessment of the denoising of impulse. Impulse noise causes a complete loss of image information, which lowers the quality of X-RAY images [4] [5]. Therefore, impulse noise in dental X-ray images must be addressed. An essential step in any process of enhancing and diagnosing Dental-X-ray images is noise removal [6]. Transmission, acquisition, image processing, and storage are the main causes of impulsive noise. The salt noise has an intensity of 255, whereas the pepper noise has a value of zero [7] [8]. Hence, impulse noise reduction is a crucial part of human dental X-Ray image diagnosis.

A noise removal approach that fixes the corrupted images using either the median or the adjacent pixel value was proposed by Srinivasan et al. [14]. The problem is that they are

unsuitable for low-range noises. Pitas et al. [10] presented a Nonlinear mean filter that works based on the nonlinear-means concept to eliminate impulse noises. The short range of noise reduction is the flaw. Zhang and Li [22] describe an adaptive weighted mean filter (AWMF) to remove impulse noise, especially in images containing high-level noises. The limitation is that the computational time of the work increases in high noise-contaminated images. To sharpen or enlarge the digital image bicubic interpolation is used [31].

Tracey et al. [17] described an enhanced non-local means (NLM) based noise removal technique for X-ray scatter (XBS) images. The edges are not appropriately preserved in this work which is a drawback of this model. Kundu [18] proposes a noise removal method using the PND-NLM technique in X-ray images. The method employs enhancement of X-ray images of bones using Gaussian higher-order derivative operation. X-ray teeth images are not considered in this model, which is a limitation of this work. Shi et al. [16] describe a noise removal technique in real-time X-ray images as it encounters high noise and low contrast. After computing the relationship between noise variance and grayscale value, a modified adaptive noise reduction filter is used to filter the image. Some optimization in work is essential to address the low contrast issue. Shanida et al. [19] suggest a wavelet-based noise removal and enhancement method to address the high noise and low contrast issue in X-Ray teeth images. This work cannot process huge-noise-density teeth X-ray images. Naouel et al. [23] suggest a noise removal and localization method using discrete wavelet transform and thresholding methods. This model extracts seven Regions of Interest from the images, which consumes more time which is a drawback of this work.

Khan et al. [20] developed a Poisson noise and impulse noise removal method based on an improved layer discrimination approach in X-Ray images. The edges are not preserved correctly in this model which is a disadvantage of this work. Markarian et al. [21] propose a denoising method in a compressive sensing framework using high-order total variation method in SAR images. It adopts method based on MAP estimation for denoising and recovering large-size complex SAR images. The thickness of objects in images becomes bulky unnaturally. A noise suppression technique for X-ray images was created by Mandic et al. [24] by altering the intersection of confidence intervals. The relative Intersection of the Confidence Intervals rule is the name of this set of rules.

The teeth X-ray has not been used to examine this work. The existing noise reduction methods suffer from mitigated Peak signal-to-noise ratio, blurred edges, and incapable to resolve a massive range of noises. The proposed NRPMID filter resolves the above issues. It reduces the impulse noise in dental X-ray images. The NRPMID filter is constructed using partition-based Median filter, Interpolation, and DWT techniques. To achieve high denoising accuracy, a new rule set is developed. The partition-based methods are employed according to this new rule set. The biggest drawback that they experience is the noise that is added as a result of the wave's transmitted coherent nature. The image is distorted by these sounds, which might also lead to misidentification. There is a variety of noise in every one of those medical imaging systems. The x-ray images, for instance, are frequently distorted by Poisson noise, salt and pepper noise, and speckle noise. Before continuing with subsequent image processing operations, it is imperative to remove salt-and-pepper noise since this type of noise greatly contaminates images and does severe harm to any knowledge or data that may have been contained in the original image. To overcome certain drawbacks the proposed method is used. The primary contributions of this work are the partition-based methodology and the efficient rule construction.

Section I includes the introduction section. Section II explains the literature review. Section III explains the proposed work, section IV assesses the performance of the NRPMID filter. Section V notifies the conclusion statements about the NRPMID method.

## II. LITERATURE REVIEW

Hawang et al. [9] focused on two algorithms, namely Ranked-order based Adaptive Median Filter (RAMF) and Size based Adaptive Median Filter (SAMF), for denoising the impulse noise. Herein, multiple-size window kernels are used. The surrounding noisy pixels badly impact the denoising quality.

Tao et al. [11] introduced an image enhancement technique to denoise impulse noise based on Tri-state Median Filter (TSMF). Herein, two concepts are used: Standard Median (SM) filter and the Centre Weighted Median (CWM) filter.

Chen and Lien [13] proposed a novel algorithm for removing impulse noise from corrupted images. It employs an efficient impulse noise detector to detect the noisy pixels and an edge-preserving filter to reconstruct the intensity values of noisy pixels.

Gouchol et al. [12] designed a denoising algorithm for impulse noise by performing the Selective removal of impulse noise. This approach works based on homogeneity level information of an image. This work has used the fixed window kernels, which is the disqualification.

Toh et al. [15] described a two-stage noise adaptive technique for eliminating salt-and-pepper noise. The method is based on a fuzzy switching median filter for noise detection and removal. Herein, noisy pixels are determined based on the histogram concept. The artifact generated by the filtering process is found using fuzzy reasoning. The drawback is substantial cost consumption, which has negative effects when used in complicated systems.

## III. METHODOLOGY

The proposed denoising method NRPMID removes impulse noise from Dental X-RAY images using the eight concepts such as Mean filter, Median filter, Bi-linear interpolation-based filter, Partition based Median filter, Bi-cubic interpolation-based filter, Partition based Bi-cubic interpolation-based filter, Partition based Lanczos interpolation-based filter, and Partition based HAAR wavelet transform based filter. This technique makes use of the multi-size window and trimming concepts. This method involves the Trimming concept and multi-size window concept.

Fig. 1 reveals the overall block diagram of the NRPMID filter. The 512x512 size dental grayscale  $I_N$  is fed as input and the final noise-free output is noted as  $I_{NF}$ . The noise-added image is quoted as  $I_N$ . The assignment of  $\alpha = 5$  is made, and  $\alpha$  refers to the maximum permitted iterations. The minimum value of the noisy image is set in  $\beta^1$ . The maximum value of the noisy image is stored in  $\beta^2$ . In this work maximum of five iterations (itr) are used to resolve the noises. If itr=0 then Procedure\_Iteration\_0 is called. If itr=1 then Procedure\_Iteration\_1 is called, and so on. The window size  $\gamma$  is computed as  $\gamma = itr + 1$ . The noisy pixels which meet the condition  $I_N^{ij} \leq \beta^1 \parallel I_N^{ij} \geq \beta^2$ , are stored in  $I_{NI}^{ij} = 0$ , otherwise stored as non-noisy pixels by assigning  $I_{NI}^{ij} = 1$ . Then, the particular iteration is called based on the value of itr-number. Finally the objective function checks for the next progress, by verifying any modification in the current and previous noise-free images.

### A. Itr\_0 Process

The three components Mean computation, Median computation, and Bi-linear interpolation are used in the design of the itr\_0 process. A 3x3 size window is extracted from the noisy locations, and the non-noisy information/intensity is stored in the linear vector  $\delta$ . This scenario is noted as the trimming process. The trimming process yields a maximum of eight elements for a 3x3 window. The non-noise element count is stored in  $TNC$ . If the  $TNC$  is in between one and four, then the mean-oriented denoising is progressed. Otherwise, the standard deviation of  $\delta$  is computed, and if it is less than or equal to 3.2 then the median oriented denoising is progressed, otherwise Bi-linear interpolation [30] oriented denoising is progressed. The denoised outputs are assigned in  $I_{NF}^{ij}$ . Suppose the  $TNC$  is equal to zero then the original intensity is stored in  $I_{NF}^{ij}$ . This process is employed for the entire noisy pixels of the noisy image.

### B. Itr\_1 Process

The Itr\_1 procedure is designed using a new set of rules and four computations viz. Mean, Median, Partition oriented median, and Bi-cubic interpolation. The Itr-0 output is fed as input and quoted as  $I_N$ . A 5x5 window size window is extracted from a noisy pixel, and the trimmed elements are stored in the linear array  $\delta$ . Herein, the maximum numbers of non-noisy elements are 16. The term  $TNC$  is also computed. If  $TNC > 0$  &  $TNC \leq 4$  then Mean oriented denoising is approached. If  $TNC > 4$  &  $TNC \leq 8$  then Median oriented

denoising is approached. If  $TNC > 8$  &  $TNC \leq 12$  then Partition oriented median-based denoising is approached, and it can be calculated by a range of equations from (1) to (4).

$$M_i = FindMedian(\delta) \quad (1)$$

$$M_{P1} = FindMedian(\delta^{0 \text{ to } (\frac{TNC}{2})-1}) \quad (2)$$

$$M_{P2} = FindMedian(\delta^{(\frac{TNC}{2}) \text{ to } TNC-1}) \quad (3)$$

$$M_P = \begin{cases} M_{P1}, & \text{if } abs(M_{P1} - M_i) \leq abs(M_{P2} - M_i) \\ M_{P2}, & \text{otherwise} \end{cases} \quad (4)$$

Fig. 1. Working of the Proposed NRPMID Filter.

Where

$M_I$  - Integrated-median,  $M_{P1}$ - Partition\_1 oriented median,  $M_{P2}$ - Partition\_2 oriented median, and  $M_P$  - Final partition-oriented median.

The  $M_I$  is computed from the whole data of  $\delta$ . Herein,  $\delta$  is divided into a couple of divisions, and they are partition\_left and partition\_right. The Partition\_left is used to compute  $M_{P1}$ , and partition\_right is used to calculate  $M_{P2}$ .

The closest part of  $M_I$  is determined via Equation (4) to find the  $M_P$ . If  $TNC > 12$  &  $TNC \leq 16$  then Bi-cubic interpolation-oriented noise removal is approached. The denoised outputs are assigned in  $I_{NF}^{i,j}$ . Suppose the TNC is equal to zero then the original intensity is stored in  $I_{NF}^{i,j}$ . The noisy pixels in the entire noisy image are processed using this method.

### C. Itr\_2 Process

The Itr\_2 procedure is incorporated by a  $7 \times 7$  size neighbor window, new rules, and 4 computations such as Mean, Median, Partition oriented median, and Partition oriented Bi-cubic interpolation. Herein, a maximum of 24 non-noisy neighbors can be extracted. If  $TNC > 0$  &  $TNC \leq 4$ , then mean-oriented noise removal is progressed. If  $TNC > 4$  &  $TNC \leq 8$ , then median value is used for noise cancellation. If  $TNC > 8$  &  $TNC \leq 16$  then Partition oriented median is the source for noise suppression. If  $TNC > 16$  &  $TNC \leq 24$  then Partition oriented Bi-cubic based noise removal is progressed using the range of equations (5) to (8).

$$BC_I = FindBCubicValue(\delta) \quad (5)$$

$$BC_{P1} = FindBCubicValue(\delta^{0 \text{ to } (\frac{TNC}{2})-1}) \quad (6)$$

$$BC_{P2} = FindBCubicValue(\delta^{(\frac{TNC}{2}) \text{ to } TNC-1}) \quad (7)$$

$$BC_P = \begin{cases} BC_{P1}, & \text{if } abs(BC_{P1} - BC_I) \leq abs(BC_{P2} - BC_I) \\ BC_{P2}, & \text{otherwise} \end{cases} \quad (8)$$

where

$BC_I$  - Integrated-BiCubic data

$BC_{P1}$  - Partition\_1 oriented Bi-cubic data.

$BC_{P2}$  - Partition\_2 oriented Bi-cubic data.

$BC_P$  - Final partition oriented Bi-cubic data.

This process is repeated for the whole noisy pixels of the noisy image.

### D. Itr\_3 Process

The Itr\_3 procedure is carried out via a  $9 \times 9$  side window, and the five techniques like i) Mean ii) Median, iii) Partition oriented median, iv) Partition oriented Lanczos interpolation and v) Partition oriented Haar-Wavelet transform. Herein, a maximum of 32 non\_noisy neighbours are collected. The noise reduction is performed based on Fig. 1 corresponding to

iteration\_3. If  $TNC > 16$  &  $TNC \leq 24$  then Partition oriented Lanczos interpolation-based denoising is progressed. Haar\_wavelet transform [32] which is a discrete wavelet transform, is utilized to characterize the image. If  $TNC > 24$  &  $TNC \leq 32$  then Partition-oriented Haar\_wavelet transform-based noise removal is progressed, and it can be done via the range of equations (9) to (12).

$$HW_I = FindHaarWTValue(\delta) \quad (9)$$

$$HW_{P1} = FindHaarWTValue(\delta^{0 \text{ to } (\frac{TNC}{2})-1}) \quad (10)$$

$$HW_{P2} = FindHaarWTValue(\delta^{(\frac{TNC}{2}) \text{ to } TNC-1}) \quad (11)$$

$$HW_P = \begin{cases} HW_{P1}, & \text{if } abs(HW_{P1} - HW_I) \leq abs(HW_{P2} - HW_I) \\ HW_{P2}, & \text{otherwise} \end{cases} \quad (12)$$

where

$HW_I$  - Integrated-HaarWT data.

$HW_{P1}$  - Partition\_1 oriented HaarWT data.

$HW_{P2}$  - Partition\_2 oriented HaarWT data.

$HW_P$  - Final partition-oriented HaarWT data.

This process is continued for the whole noisy pixels of the noisy image.

### E. Itr\_4 Process

The Itr\_4 procedure is designed based on  $11 \times 11$  size window and the Mean computation. The  $\delta$  and TNC are found. If  $TNC > 0$  then mean of  $\delta$  is assigned in the location of noisy data. If  $TNC = 0$  then mean of the whole  $11 \times 11$  size neighbors is assigned as the noise-free data in the corresponding noise location.

In this model, the proposed NRPMID filter reduces the salt and pepper noise or impulse noise in the X-ray dental images.

## IV. DISCUSSION AND ANALYSIS

The MATLAB 15 version was used to build this novel technique. The NMIC Dental X-Ray image dataset [26] and the VAHAB Dental X-Ray image dataset [25] are the databases that were used in this study. 150 dental teeth X-Ray images from each dataset are used in this study as test images. On dental X-ray images, the proposed NRPMID approach is compared to the following three denoising techniques.

- Image denoising using Newton Thiele filter (ID-NTHF)[27].
- Image noise removal based on adaptive fuzzy switching median filter (ID-FSMF) [28].
- Image denoising based on Adaptive Sequentially Weighted Median Filter (ID-AWMF) [29].

The denoising of the proposed technique for 98.32 percent noise corruption is shown in Fig. 2. The input image used in this instance was obtained from the VAHAB database. Fig.

2(a) points out the original image, Fig. 2(b) focuses on the noisy image, and Fig. 2(c) shows the final noise-free image.

1) *Accuracy*: Accuracy is metric used to evaluate how precisely the measured value or findings reflect the real or the original values. The Table I represents the accuracy analysis obtained by the proposed and the other denoising models.

From Fig. 3, it can be observed that the proposed NRPMID filter achieves the highest accuracy value of 0.96% when compared to other models, which indicates that it efficiently reduces the noises from the input image.

2) *Mean Square Error (MSE)*: Mean Square Error is a metric used to measure the amount of error in statistical models. It assesses the average squared difference between the observed and predicted values. When a model has no error, the MSE equals zero. As model error increases, its value increases. The mean squared error is also known as the mean squared deviation (MSD).

In this analysis, the MSE of the proposed NRPMID filter and the other denoising models are analyzed. It is evident from the results demonstrated in Table II and Fig. 4 that the proposed NRPMID filter achieves the lowest MSE value of 0.037.

Fig. 2. Noise Removal NRPMID for 98.32% Noise Corruption, (a) Original Input Image (b) Noise Added Image (c) Noise Free Image.

TABLE I. ACCURACY ANALYSIS

Denoising method	Accuracy (%)	
	NMIC database	VAHAB database
ID-NTHF	0.74	0.76
ID-FSMF	0.77	0.79
ID-AWMF	0.89	0.90
NRPMID	0.95	0.96

Fig. 3. Accuracy Analysis on Four Methods and Two Datasets.

TABLE II. MSE ANALYSIS

Denoising method	MSE	
	NMIC database	VAHAB database
ID-NTHF	0.256	0.236
ID-FSMF	0.225	0.207
ID-AWMF	0.101	0.098
NRPMID	0.041	0.037

Fig. 4. MSE Analysis for Four Methods and Two Datasets.

3) *Average MSE analysis*: The average MSE analysis is also computed in this analysis and results are represented in Table III.

TABLE III. AVG. MSE ANALYSIS FOR 90% NOISE CORRUPTION

Denoising method	Avg. MSE	
	NMIC database	VAHAB database
ID-NTHF	656.276	629.623
ID-FSMF	591.679	533.435
ID-AWMF	427.640	391.810
NRPMID	131.555	124.198

The proposed NRPMID filter's effectiveness in the average MSE analysis case with noise corruption of 90% is shown in Table III. When compared to other approaches, the NRPMID method produces low MSE values.

4) *PSNR Analysis*: The Peak Signal to Noise Ratio (PSNR) analysis is computed and the High PSNR means better denoising.

The average PSNR values with noise corruption of 90% can be seen in Fig. 5. Each database's 150 images are used to compute it. It demonstrates that the NRPMID filter can be used to restore more successfully than the conventional filters.

5) *Root Mean Square Error (RMSE)*: The mathematical derivation for computing RMSE is provided in Equations (13).

$$Error_{RMSE} = \sqrt{\frac{\sum_{i=1}^N (p_i - r_i)^2}{T}} \quad (13)$$

Fig. 5. Average PSNR Analysis for Noise Corruption of 90%.

TABLE IV. RMSE ANALYSIS

Denoising method	MSE	
	NMIC database	VAHAB database
ID-NTHF	0.506	0.486
ID-FSMF	0.474	0.455
ID-AWMF	0.319	0.314
NRPMID	0.203	0.194

Fig. 6. RMSE Analysis.

The RMSE analysis of the proposed NRPMID filter and other denoising models are expressed in Table IV and Fig 6. From the results, it is evident that the proposed work achieves the lowest RMSE value of 0.194 which indicates the accuracy of the NRPMID filter is high.

6) *Structural Similarity Index (SSIM)*: A perceptual metric called the Structural Similarity Index (SSIM) measures the loss of image quality put on by denoising [33]. The denoising Quality is better if the MSSIM value is high.

The average SSIM results in 60% noise corruption, as shown in Fig. 7. It illustrates that the proposed NRPMID approach obtains higher SSIM values than the traditional methods.

7) *Average IEF analysis*: The IEF analysis is used to assess the effectiveness of salt and pepper noise denoising in dental X-ray images. Better denoising quality is correlated with higher IEF and vice versa [34].

Fig. 7. Avg. SSIM Analysis for 60% Noise Corruption.

Fig. 8. Avg. IEF Analysis for 90% Noise Corruption.

The average IEF analysis values for noise corruption of 90% are shown in Fig. 8. The proposed NRPMID filter outperforms existing techniques in terms of high IEF values. The VAHAB database is the finest database to support the proposed work, according to the analysis.

## V. CONCLUSION

This research proposes the NRPMID filter to reduce the impulse noise in teeth X-ray medical images. The NRPMID filter can resolve salt and pepper noise from the dental X-Ray images, which are even corrupted by 98.32%. The proposed filter improves the visual quality of dental X-ray images. It assists dental pathologists in having an accurate diagnosis. The time complexity of this approach is significantly less. The analysis section proves the noticeable results of the NRPMID filter than the existing denoising methods. The advantage of the method is simple and less costly. The drawback of the proposed system is the high computational time. In the future, this research can be extended to solve the Poisson noise in dental X-Ray images. Also, image enhancement techniques will be used to enhance the image quality.

**Abstract**—While big data benefits are numerous, most of the collected data is of poor quality and, therefore, cannot be effectively used as it is. One pre-processing the leading big data quality challenges is data duplication. Indeed, the gathered big data are usually messy and may contain duplicated records. The process of detecting and eliminating duplicated records is known as Deduplication, or Entity Resolution or also Record Linkage. Data deduplication has been widely discussed in the literature, and multiple deduplication approaches were suggested. However, few efforts have been made to address deduplication issues in Big Data Context. Also, the existing big data deduplication approaches are not handling the case of the decreasing performance of the deduplication model during the serving. In addition, most current methods are limited to duplicate detection, which is part of the deduplication process. Therefore, we aim through this paper to propose an End-to-End Big Data Deduplication Framework based on a semi-supervised learning approach that outperforms the existing big data deduplication approaches with an F-score of 98,21%, a Precision of 98,24% and a Recall of 96,48%. Moreover, the suggested framework encompasses all data deduplication phases, including data pre-processing and preparation, automated data labeling, duplicate detection, data cleaning, and an auditing and monitoring phase. This last phase is based on an online continual learning strategy for big data deduplication that allows addressing the decreasing performance of the deduplication model during the serving. The obtained results have shown that the suggested continual learning strategy has increased the model accuracy by 1,16%. Furthermore, we apply the proposed framework to three different datasets and compare its performance against the existing deduplication models. Finally, the results are discussed, conclusions are made, and future work directions are highlighted.

**Keywords**—Big data deduplication; online continual learning; big data; entity resolution; record linkage; duplicates detection

## I. INTRODUCTION

Nowadays, data quality is gaining wide attention from both academics and professionals. Indeed, data quality dramatically impacts the business as executives rely mainly on data to manage their business and make informed decisions

[1]. Indeed, better data quality translates directly into better business value. Data quality could be defined in terms of different dimensions such as completeness, accuracy, timeliness and consistency [2] [3].

This article addresses one of data quality's main aspects: uniqueness. Uniqueness ensures that there is only one instance of each information in the dataset and thus points out that there should be no data duplicates [4]. Indeed, data duplication issues are not only related to storage. Duplicate data also lead to inaccurate analysis, which may cause significant problems and costly mistakes. There are many sources of data redundancy, including users providing erroneous information, typing errors, data integration, etc. With the emergence of Big Data, data duplication has become more common and challenging. This is related to big data Volume, Variety, Velocity, and other characteristics of big data known as Big Data V's [5] [6]. Thus, because of the particular characteristics of big data, new data deduplication issues were raised related to the huge data volume, variety of data sources, inconsistency of data types and schemas, and so on.

Therefore, duplicate detection approaches have been widely discussed in the literature under different names, such as entity resolution, deduplication, or record linkage. All these terms refer to the same meaning: identifying records referring to the same real-world entity. The deduplication process is usually followed by an entity consolidation or fusion process defining the unified representation of duplicated values that best represents the real-world entity. Even if data deduplication was widely discussed in the literature, more efforts are needed to address the challenges related to Big Data Deduplication. Indeed, most existing big data deduplication approaches focus only on data volume. Also, most existing methods are limited to the duplicate detection phase, which is only a part of the deduplication process. Moreover, the current deduplication approaches are not ensuring a maintained accuracy score during the serving, so the model's performance usually decreases over time [7].

Believing that Big Data Deduplication should be addressed more comprehensively, we aim through this paper to enhance big data quality measurement with three main contributions:

- We suggest an End-to-End Big Data Deduplication Framework encompassing five phases: data pre-processing, data labeling, duplicate detection, data cleaning, and finally, model monitoring using continual retraining.
- We address the issue of the decreasing performance of the deduplication model by setting an online learning strategy for big data deduplication to maintain a high accuracy level during the serving.
- We design a framework that outperforms the existing big data deduplication methods and provides the best results based on a Semi-Supervised learning approach.

The rest of this paper is organized as follows: Section 2 describes the research methodology followed for the literature review. Section 3 reviews the most recent and relevant studies that have tackled data deduplication. Section 4 highlights the importance of deduplication for big data. Section 5 presents our suggested end-to-end big data deduplication framework. Section 6 offers the implementation of the suggested framework and discusses the obtained results. Finally, we highlight the primary outcomes as well as some research outlooks.

## II. RESEARCH METHODOLOGY

A systematic literature review was conducted to capture and synthesize the relevant and available studies addressing data quality measurement. This literature review was performed following the guidelines stated in [8], where the authors have proposed a review methodology that consists of planning the review by preparing a review proposal. A second step consists of searching and selecting studies. Finally, the main findings of the review are reported. The goal of this study was to choose two main kinds of contributions:

- Studies suggesting deduplication frameworks in a big and non-big data context.
- Studies addressing Uniqueness as a quality metric

For this, primary research was conducted first using generic keywords such as “Data Deduplication”, “Entity Resolution” and “Data Uniqueness”. Then, to capture studies about big data, specific keywords such as “Big data Deduplication”, “Big Data Entity Resolution”, and “Big Data Redundancy” were used. Then, abstracts were reviewed, and irrelevant papers were excluded. This primary search yielded 60 articles. The research was limited to recent articles published in journals and conference proceedings and was performed on: IEEE Xplore, Springer, Google Scholar, Science Direct, Research Gate, and ACM digital libraries. After a literature search, the next step consists of narrowing down the papers based on their relevancy, freshness, and availability. For this, a diagonal reading was performed on the selected papers filtered out based on multiple criteria: we included studies that were addressing data deduplication, recent, available, in English, and published in digital libraries.

A total of 23 articles were selected, followed by a more in-depth analysis.

Further, we reviewed the references of the selected studies and added two more articles to the selected papers. Then, the chosen studies were thoroughly read and carefully examined, and 17 studies were deemed relevant to the scope of our research. Finally, the articles' descriptive details were checked and filed in a Zotero database. This literature review has shown a significant lack of deduplication frameworks that fit big data requirements, which motivates us to perform an in-depth analysis of the current state of the art to frame the need and make a significant contribution. The following section reviews the papers selected for our study and highlights the main findings of this literature review.

## III. RELATED WORK

Data deduplication is a trending topic that many researchers have long addressed in the literature. Thus, many approaches for data deduplication have been suggested in the literature, such as [9], where the authors have proposed a six-step deduplication framework that detects duplicated records using record linkage. The framework includes preparing data, matching attributes using sorted neighborhood, building a decision mode, and clustering. In this paper, the authors have raised the current issue of the lack of labeled data for big data deduplication, which hinders the evaluation of the model performance. This issue was also mentioned in [10], where the authors have raised the lack of labeled data for deduplication and suggest using active learning as an alternative. The authors have achieved the highest results with an F-score of 98,4% for structured datasets. However, for dirty datasets, a lower score of 52% was achieved. Deep learning was also used to address data duplication, such as in [11], where the authors define a binary classification approach for safety engineering based on fuzzy string-matching algorithms. The proposed approach is based on Convolutional Neural Networks (CNN) binary classifier and string similarity-based classifier. All the research mentioned above has significantly contributed to duplicate detection and entity resolution. However, these approaches are not appropriate for large-scale datasets in terms of accuracy and execution time. Also, in addition to the dataset volume concern, the above approaches did not address the particular issues raised in a big data context. Indeed, with the emergence of big data, new challenges have been raised, such as the diversity of data sources, the variety of data types, and the high velocity and veracity of data [12] [13]. These particular issues were discussed in recent studies, such as in [14], where the authors have performed a survey of the indexing techniques for big data deduplication. The experiments have shown that sorted neighborhood is the best indexing technique for large datasets in terms of complexity. Also, in [7], Christophides et al. have performed a comprehensive survey of all the existing methods for entity resolution. They provided an overview of the different steps of entity resolution for big data, including blocking, block processing, matching, and clustering. The authors have also raised the challenge of the decreasing performance of the deduplication methods over time. Likewise, in [15], the authors have discussed big data's challenges to entity resolution and proposed a hybrid

similarity measurement approach based on traditional syntactic and word-embedding approaches. In [16], Abd El-Ghafar et al. have suggested an entity resolution approach for big data based on hashing TF and Jaccard similarity. The approach was applied to seven scenarios where different Natural Language Processing (NLP) techniques were used to show the impact of these techniques on entity resolution. This approach reaches an accuracy of 91% for a dataset of 1M records. To address data duplication in the web of data, Efthymiou et al. have proposed in [17] a deduplication that allows reducing the required number of pairwise comparisons. The suggested process blocks data when comparing entity descriptions within the same blocks. The results show a high performance of the suggested method; however, it is only appropriate for the web of data as it is based on entity descriptions. Using deep learning, the authors in [18] have introduced a new Stacked Dedupe Learning entity resolution approach based on Bidirectional Recurrent Neural Networks (RNNs) with Long Short-Term Memory (LSTM). However, the study does not show the impact of big data on the performance and accuracy of the model. Moreover, recent studies have addressed the data blocking for big data, such as in [19], where the authors have defined a progressive blocking (PB), detecting 93% of duplicates during the first third of the execution time. Likewise, a multi-phase blocking strategy detecting big data duplicates has been suggested in [20].

Even if data deduplication has been widely discussed in the literature, there have been few efforts to address deduplication issues in the big data context. In addition, most of the existing approaches are only limited to the duplicate detection phase and are not comprehensively managing data deduplication. Furthermore, the model's predictive performance usually degrades over time as the data keep changing. To the best of our knowledge, no deduplication approaches have been set to address the decreasing accuracy during the model serving. Therefore, we aim through this paper to propose an end-to-end Big Data Deduplication framework with three main contributions:

- Ensuring increased performance and accuracy of the deduplication by setting an online learning strategy for deduplication.
- Setting a more comprehensive Big Data deduplication Framework that addresses all the big data deduplication processes and consists of five steps: data preprocessing, data labeling, duplicate detection, data cleaning, and model monitoring using continual retraining.
- Suggesting a novel framework that outperforms the existing big data deduplication methods based on a Semi-Supervised learning approach.

In the next section, we highlight the importance of deduplication for big data.

#### IV. BIG DATA DEDUPLICATION

In a Big Data context, ensuring data quality has always been a critical concern for data managers. Data quality could be defined in terms of multiple dimensions, also called “Data

Quality Dimensions” such as completeness, accuracy, readability, consistency, etc. In this paper, we are addressing one of the primary data quality dimensions: uniqueness. It refers to the unicity of the information provided by the dataset and ensures that there are no duplicated records. To improve data uniqueness, data should be cleaned from duplicated data. This process is known as Data Deduplication. Data duplication can occur for different reasons, such as data integration, where data are gathered from multiple data sources so the same information can be recorded more than once in another format [21] [22]. Also, data duplication could be related to human errors, so the same person, for example, could provide data with slightly different information intentionally or by mistake multiple times. Indeed, Experian [23] found that human input error is the leading cause of data inaccuracy and duplication. Data duplication heavily impacts data analysis and can negatively affect the business. Data duplication can bias data analytics. For example, companies lack a single customer view with duplicated customer dataset. They could not have a clear idea about the real number of their customers and their behavior which may hinder activities like targeted marketing. Also, data duplication incurs a high cost as it leads to wasteful marketing activities, such as targeting the same customer multiple times. Data duplication could also be costly in terms of storage, as redundant records can take up a lot of space, which increases storage costs. A recent study [24], about the impact of data duplication has shown that companies that store big data and apply a backup policy can see that 80% of their corporate data are duplicated. Also, according to another study [25], reducing the transmitted data can save money in terms of storage costs and backup speed up to 50%. Thus, data deduplication helps optimize marketing spending in terms of time and cost. In short, data duplication can result in significant damage and cost for businesses and, therefore, should be addressed effectively for accurate and successful data management. In the next section, we present the suggested end-to-end big data deduplication framework and describe each step of the framework straightforwardly.

#### V. A SMART END-TO-END BIG DATA DEDUPLICATION FRAMEWORK

In this section, we present an end-to-end Big Data deduplication Framework, shown in Fig. 1 to 6 that consists of five steps: The first step is a preprocessing phase where data is cleaned and prepared for deduplication due to the low quality of the extracted data in big data environments. The next step consists of building a training dataset using an automated data labeling process. Then, fuzzy matching is performed on the dataset to detect duplicates. The detected duplicates are then cleaned using the appropriate strategies. Finally, the model is deployed using a real-time continual learning strategy for continuous accuracy improvement during the serving. The framework is designed to address the different issues linked to big data environments. In the following, we provide a detailed description of each stage of the framework.

##### A. Pre-processing

Because of the Big Data V's, the extracted data in big data environments are usually unstructured, noisy, and poorly formatted. Therefore, going through a pre-processing phase is

highly required before using data [26]. In this first phase, raw data is prepared and converted into a more appropriate format making it understandable and suitable for use by Machine Learning (ML) algorithms. This process significantly impacts the efficiency and accuracy of the model and can ruin the subsequent phases if it is not done correctly. In the following, we present the transformations required to prepare big data for deduplication, as shown in Fig. 2.

1) *Feature Selection and Extraction*: Feature Selection and Extraction are crucial in dealing with a high-dimensional dataset as not all the extracted data in Big Data environments are relevant for the intended use. The goal is to keep relevant information by selecting only the most informative variables (Feature Selection) or creating new useful ones (Feature Extraction). This process is required for data deduplication as it allows determining the most significant features on which the model will be based to detect duplicates.

2) *Imputing*: Big data is usually messy, skewing data analysis and leading to biased results. Imputing data is required for deduplication, especially when there is a large number of missing values, as, with low information, duplicates cannot be detected effectively. There are various ways to address the missing values depending on the ratio of the missing values. The missing values can either be ignored, deleted, or replaced by an estimate based on the existing part of the data. The estimated value could be the mean value, the most frequent value, the min or max value, etc. Data could also be attributed using ML algorithms such as K-Nearest Neighbour and Multivariate Imputation or deep learning such as DataWig.

3) *Encoding*: Encoding is the process of converting categorical variables into numeric types. Most ML algorithms cannot handle absolute values and work better with numerical

inputs. There are multiple techniques for encoding, such as Label Encoding, One Hot Encoder, Vector Indexer, etc. Moreover, encoding ensures data consistency, a crucial factor for data deduplication. Indeed, as big data are gathered from multiple sources, categorical values may be represented differently, such inconsistency issues impede duplicate detection.

4) *Upper casing/Lower casing*: This transformation consists of standardizing text data to all Lowercase or Uppercase. For the sake of simplicity, it is more common to convert all data to lowercase, especially for NLP applications. This process is also essential for deduplication as the same word (Good/ good) may be taken as different words (in the vector space model) if we ignore this transformation.

5) *Stop Words and Symbols Removal*: This process consists of removing irrelevant words- the most common words- from the text data. The idea behind eliminating stop words is to provide more importance to the information contained within data, as ignoring them doesn't drastically impact the meaning. Also, the dataset should be cleaned from special symbols and punctuations as they will not help identify similarities. According to the context, other text elements could be removed, such as URLs, HTML tags, etc.

6) *Normalization*: Due to the variety of data sources, some variables in the data may have different scales. This inconsistency at the scale level will bias duplicate detection as records should be compared based on a unified scale. To overcome this, data should be normalized so that the range of all the variables is similar (usually between 0 and 1).

We consider these transformations the most important ones to prepare data for deduplication. However, according to the dataset context, more text cleaning may be needed, such as Spell Corrections and Stemming.

Fig. 5. Online Continual Learning Process.

Fig. 6. Data Deduplication Pipeline.

### B. Data Labeling

Once the dataset is pre-processed, and in a ready-to-use state, the next step consists of building a labeled dataset that will be used to train the deduplication model. Labeling data is one of the most challenging tasks that could be faced in AI projects. According to a study [27], labeling data takes up to 80% of AI project time. If most labeling approaches use human labelers, this solution becomes unsuitable when dealing with big data, not only for quantity reasons but also for quality reasons. To overcome this, we are using an automated approach to produce labeled data for deduplication based on Record Linkage techniques. This approach, shown in Fig. 3, consists first of indexing records into pairs. Then, a weighted similarity score is computed to determine if the couples are duplicates, and finally, pairs are labeled based on their similarity score.

1) *Indexing*: Indexing consists of generating pairs of candidate records. The idea behind this step is not to create all

possible combinations of record pairs in the data set, as it will lead to quadratic time complexity, but to select only the likely duplicated pairs. Several indexing techniques are available for record linkage, such as Blocking, Sorted Neighbourhood, TF-IDF, etc. In this paper, we use Sorted Neighbourhood for pairs indexing as it is the most suitable indexing technique for big data [14]. More details are provided in the implementation section.

2) *Comparison and Similarity*: After generating the record pairs, a comparison of the candidate records is performed, and a similarity score is then attributed to each pair. Depending on the field type (string, numerical value, date...), multiple comparison measures, such as Jarowinkler, Levenshtein, Cosine, Jaccard, etc., could be used. For more accurate measurements, weights could also be assigned to data fields, as some areas may be more significant than others to determine duplicate records.

3) *Labeling*: Once similarity scores are measured, pairs are classified using supervised or unsupervised methods such as Optimal Threshold, SVM, K-Means, Farthest First, etc. Pairs are then classified into two classes (matches/non-matches). As a record can have more than one duplicate, we are suggesting in this approach to gather duplicates into clusters instead of pairs so that each cluster can contain more than two records. Non duplicate records are removed, and only matching records are kept as a training dataset.

### C. Duplicates Detection

With a set of labeled data, we can thus train the deduplication model. Then, use the trained model to identify matches and find the correct parameters to get optimal results. It is worth noting that in this approach duplicate detection is not based on a text comparison but on deduplication predicates and indexing rules generated by the model after the training. More details about the generated indexing rules are provided in the implementation section.

1) *Training*: This first step consists of training the model to classify records as duplicates and non-duplicates based on the training dataset. At the end of the training, the model comes up with indexing rules that will be used to identify potential matches. Thus, records will be blocked by matching the deduced indexing rules (also called Predicates) during the learning.

2) *Testing and Parameter Tuning*: The next step consists of assessing the model's accuracy and maximizing its performance by finding the best-suited clustering threshold for the model to give optimal results. The parameter tuning can be done either manually or automatically using methods such as Bayesian Optimization, Random Search, and Tree-structured Parzen Estimator (TPE). Also, the parameter tuning remains relative to how precise we want to be on finding or dropping matches while clustering, as there is always this trade-off between precision and recall.

3) *Serving*: This last step uses the trained and optimized model to identify matches and classify the records as "duplicate" or "not duplicate". Finally, the model returns clusters of partners. As duplication is transitive, clustering is performed on the matching pairs, so the same cluster's records are considered duplicates.

### D. Duplicates Cleaning

Once matches are gathered into clusters, data should be consolidated from many records into one. Many data fusion strategies could be used at this stage according to the strategic priorities of the data team (see Fig. 4). For example, if the process is more oriented towards data accuracy, the record of the most reliable source will likely be kept. Otherwise, the complete record will be held if the goal is to gather as much data as possible. Another data fusion strategy is to create a new record by merging the existing ones. In this case, a conflict resolution approach should be implemented to integrate duplicated columns. Multiple data fusion strategies were discussed in [28] [29].

### E. Continual Learning (Model Retraining)

Because of big data variability, data keeps changing constantly. Data could be changed regarding schema, statistical distribution, data quality, etc. This kind of change is known as data drift. In addition, data could also be exposed to a concept drift when the statistical properties of the target variable change over time [30]. Thus, the model's predictive performance may degrade over time because of data drift and concept drift. Therefore, it is crucial to adapt the model to data changes to ensure that the model accuracy is always maintained. For this, the model should be retrained after deployment according to an ML strategy called Continual Learning. Continual Learning is a process that automatically and continuously retrains a ML model with new data, which makes the model auto-adaptive and improves its performance. A critical use case of continual learning is recommendation systems that should always be updated with new data as user behavior changes over time. There are two approaches to performing continual learning:

- *Offline Mode (Batch learning)*: In this approach, the model is retrained from time to time with the new accumulated data.
- *Online Mode (Incremental Learning)*: the model is retrained sequentially with a live data stream.

With Online Continual Learning, the model does not decay following a data or concept drift as it is dynamically updated with new data patterns. The online mode is also a time effective solution as there is no need to store and manage large batches of accumulated data. On the other hand, the input data should constantly be monitored if the model is fed with insufficient data, the performance will be impacted instantly. The online mode remains suitable, especially in big data environments and real-time applications. Research has recently been conducted on Online Continual Learning, especially in a deep learning community. In [31], the authors have shown that algorithms and the architecture of neural networks impact continual learning performance. In [32], the authors have suggested a supervised training method for continual learning. The method's effectiveness was proven in three systems for continual online learning. In [33], the authors have introduced a new memory population approach (CBRS) for continual online learning that deals with imbalanced and temporally correlated data. Other pertinent methods for enhancing Online Continual Learning were suggested in [34] [35] [36]. For data deduplication, even if the deduplication model is trained with high-quality pairs, features defining duplications may change over time, especially when data is human input. Thus, new duplication features may come into play. Also, the used parts may become misleading, so they must be excluded or reweighted. Deduplication models are susceptible to duplication features, so a small features drift may drastically impact the model performance. In this regard, we suggest an Online Continual Learning approach for deduplication that consists of the following steps:

1) Building a dataset composed of new data and the found pairs during the serving.

- 2) Comparing and computing a similarity score of the built dataset.
- 3) Selecting the most similar pairs using a Threshold
- 4) Labeling the selected pairs as duplicates
- 5) Retraining the model with the new labeled pairs
- 6) Evaluating the model performance

This approach (Fig. 5) is executed in online mode, which makes it memory and time efficient, and hence, suitable for large datasets. This approach has also shown remarkable results in improving the model's accuracy. The model is continuously trained with new pairs, which allows updating the indexing rules with more pertinent ones. More details about the obtained results are provided in the next section.

In this section, we have presented the different steps of an end-to-end deduplication framework, including the data pre-processing, the labeling, the training, the serving phase, and finally, the retraining phase according to an online continual learning approach. For each phase, we have presented the different implementing techniques that could be used. Thus, the suggested framework is comprehensive and may be implemented differently depending on the intended use. Fig. 6 shows the machine learning pipeline of the whole framework. In the next section, we present how each step of the framework is implemented and the dataset and tools used for the implementation. Also, the suggested framework is compared against the existing approaches in terms of accuracy and scalability as the framework is designed to work in big data environments. Finally, a discussion is conducted about the possible evolutions.

## VI. IMPLEMENTATION

### A. Datasets Description

This section presents the implementation of the deduplication framework described in the previous section. The suggested framework was applied to 3 datasets:

**Dataset 1:** This first dataset is a built dataset with synthetic duplicated records. Indeed, to assess and evaluate the performance of the proposed strategy, the framework should be used for an extensive dataset with labeled duplicated records. Thus, we conducted research for datasets with two main criteria:

- A labeled dataset with a pre-defined state of true and false duplicates.
- Large Scale dataset with over 1M records.

Unfortunately, among the found datasets, no dataset matches the above criteria and, thus, was not appropriate for our use case. Indeed, previous research has also faced the same challenge as labeling big data sets manually are a very tedious and effortful task. To overcome this challenge, we built a labeled dataset with synthetic duplicated records using the Duplicate Generator tool DupGen [20] which allows for generating a synthetic dataset according to multiple criteria, such as the percentage of generated records and the changes made to data values. The built dataset contains over 1M records. It matches the Big Data characteristics not only in terms of Volume but also in terms of Variety, as the dataset

was gathered from multiple restaurant data sources with different formats and schemas. To ensure consistency, we have only kept standard fields: name, address, city, and type that refer to the restaurant's specialty. To stress our deduplication Framework, distinguishing features such as phone number and email were not considered even if they were available in all the datasets. The data sources used were clean of duplicates and were chosen from different countries so to avoid having common records between the datasets. After integrating and pre-processing source datasets, we have gathered a dataset with over 500 000 unique restaurants. The next step consists of creating duplicated records. For an accurate assessment, this process should not be done randomly. For this, we have reviewed restaurant datasets with real duplicates (these datasets were not suitable for our use due to their small volume) and tried to simulate duplicated data using the DupGen tool. Thus, we have noticed that most duplicated restaurants have either:

- Identical name, similar address and similar city and type
- Identical address, similar name, and similar city and type
- Similar name, similar address, and similar city and type

Also, we measured the average number of different characters between two duplicates for each column and applied the same distribution to our built dataset. Finally, we have created a dataset with over 1 M records with the following duplicates distribution: 80%: no duplication, 10%:1 duplication, 4%: 2 duplications, 2%: 3 duplications, 2%:4 duplications, 1%:5 duplications, and 1%: 6 to 10 duplications.

The number of duplicates was around 122 000, so the goal was to reduce over 1M records to about 878 000.

**Dataset 2:** The second dataset is a real companies name dataset containing 663000 records with 58700 duplicated records [37]. The dataset is prelabelled and intended for deduplication frameworks. This dataset was chosen to test our framework performance with a dataset of real-world values.

**Dataset 3:** The third dataset is a small dataset of 864 records with 112 duplicated records [38]. This dataset is prelabelled and was used by previous research to evaluate the deduplication methods. This dataset was chosen to compare our framework performance against the existing models.

Table I presents the characteristics of the three datasets used for our experiments. Before submitting the simulation results, we will first review the implementing tools and techniques in the next section.

TABLE I. DATASETS CHARACTERISTICS

Dataset	Records	Matchings	Threshold
Restaurant	864	112	0.76
Company	663000	58700	0.83
Built Dataset	1001300	122 000	0.75

### B. Adopted Tools and Techniques

The deduplication framework was developed on Apache Spark, suitable for Big Data. It was implemented in Python using Pyspark libraries such as Scikit-Learn for NLP and Fuzzy matching, Pandas, Scipy, and Numpy. For data pre-

processing, string functions were used as well as some Python's preprocessing packages such as NLTK, Stopwords, Unicode, Geocoder, LabelEncoder, RE (regular expressions) and Text blob. Then, data were first indexed using **Sorted neighborhood to build the training dataset**. The sorted neighborhood is an indexing technique that consists of sorting data values using the blocking key value and then moving a window of a fixed number of records over the sorted values. The sorted neighborhood index method is great when there is a relatively large amount of unstructured data. A recent study [14] has compared the indexing techniques for scalable linkage. It has shown that a sorted neighborhood is the most appropriate indexing method for big data in terms of execution time and accuracy. For more precision, we have applied weighted indexing to the restaurant dataset using the weights presented in Table II. With this parametrization, we suppose that the name and address are the most important columns to consider for restaurant's deduplication. These weights have allowed detecting accurately most of the pairs. No weights were applied to the company datasets with only one column (Company Name). Then, a similarity score is measured using **Cosine Similarity**. As mentioned before, various methods, such as Euclidean distance, and the Jaccard coefficient, can be used. However, Cosine Similarity is the most suited to measure text similarity, according to several studies [39] [40]. For more accuracy, the pairs are filtered out based on a min and max threshold range to keep only the most similar records. The selected records are then gathered into clusters to be used as a training dataset for the deduplication process. As mentioned before, the next step consists of dedupling the dataset using a ML algorithm. As mentioned before, in this approach duplicate detection is not based on a text comparison but on deduplication predicates and indexing rules generated by the model after the training. For this, we have used **Dedupe**. Dedupe is a Python library for accurate and scalable data deduplication and fuzzy matching based on ML [41] [42]. The first step consists of creating a dedupe instance for the dataset. Then, the dedupe instance is trained using the dataset built in the previous step. After the training phases, the model generates the indexing rules that will be used to detect similar records. In our case, one of the generated predicates was: (CommonTwoTokens, name), (SameSevenCharStart, name), (CommonThreeTokens, address). This means that the records with Names with the same two tokens AND Addresses with the same three tokens are considered duplicates. Once trained, the model can be used for deduplication using a semi-supervised clustering method, so similar records are clustered based on the provided labeled dataset. Then, the clustering threshold is tuned to get an optimized accuracy. Finally, duplicates are cleaned.

The Continual learning is performed in an online mode as it is carried out sequentially after each deduplication and is executed in real-time according to an automated machine learning pipeline. For this, a new dataset is built based on the

found pairs and additional 100 000 records. Then, the similarity of the detected pairs is evaluated using Cosine Similarity. A similarity threshold is set to select only the most matching pairs which are then labeled appropriately. The deduper is then retrained with the selected pairs to enhance the model's performance. An accuracy assessment is performed to evaluate the impact of continual learning on the model.

TABLE II. RESTAURANT DATASET INDEXING WEIGHTS

Name	Address	City	Type
0.55	0.35	0.05	0.05

### C. Results

#### a) Accuracy:

The framework was first applied to an extensive dataset of over 1M records with 122 000 duplicated records. 70% of the dataset was set to build the training dataset. Thus, the dataset was first indexed into pairs. Only 420 000 records were indexed as pairs. Then a similarity score was computed for the indexed pairs and a threshold of 0.75 was set to filter out only the most similar pairs. This first process resulted in 165000 pairs considered duplicates. The selected pairs were then gathered into clusters to detect records with more than one duplicate and were exported to a .csv file as a training dataset. Then, for each dataset, a dedupe model was trained using the built training dataset, tested, and optimized using the appropriate threshold. The performance of the framework was evaluated using the confusion matrix defined by the following metrics:

$$Precision = \frac{TP}{TP+FP} \quad (1)$$

$$Recall = \frac{TP}{TP+FN} \quad (2)$$

$$F - score = 2 * \frac{Precision*Recall}{Precision+Recall} \quad (3)$$

TP, FP, and FN are True Positive, False Positive, and False Negative, respectively.

The metrics above were measured for three different datasets: Restaurants, Companies, and our Built Big Dataset coming out with the results presented in Table III.

TABLE III. DEDUPLICATION FRAMEWORK EVALUATION

Dataset	Precision (%)	Recall (%)	F-s (%)
Restaurant	98,25%	100,00%	99,12%
Company	94,17%	98,13%	96,11%
Built Dataset	98,24%	96,48%	98,21%

It is worth noting that the framework accuracy has evolved considerably after applying online continual learning. For our built dataset, the framework detected 117700 out of 122 000 duplicated records with an F-score of 98,21%. Indeed, the resulting F-score was initially 97,05% and has increased by 1,16% after applying the continual learning process to the model with an additional dataset of 100 000 records.

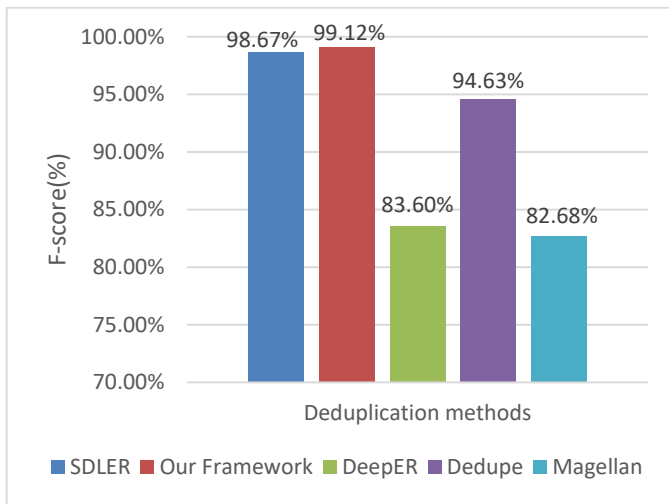

Fig. 7. F-Score Comparison.

As mentioned previously, we chose the third dataset to compare our framework’s performance against the existing models that have used the same dataset (restaurant dataset), such as SDLER [18], DeepER [43], Magellan [44], and Dedupe [42]. Fig. 7 compares the F-score achieved by each model when applied to the Restaurant dataset. The obtained results show that the proposed framework provides the best results in terms of accuracy. When dealing with big data, the execution time is yet another factor that should be considered besides accuracy. We present in the next part the time complexity of the proposed framework.

#### b) Scalability

As the framework is intended to be used in a big data environment, the framework scalability also needs to be ensured. Table IV shows the processing time and the corresponding dataset size. Thus, the framework has shown acceptable results in terms of processing time with a linear complexity  $O(n)$ . Indeed, the framework is based on scalable methods such as Sorted Neighborhood, Cosine Similarity, and Dedupe having a linear complexity and hence, are suitable for Big Data [45] [41].

TABLE IV. PROCESSING TIME

Dataset	Records	Processing Time
Restaurant	864	~3 m
Company	663000	~ 1h
Built Dataset	1001300	~ 3h30

#### c) Framework Limitations

A second phase of the implementation consists of scrambling the built dataset intentionally by feeding the datasets with more challenging duplicates. The goal is to uncover the framework limitations and discover how the accuracy is impacted by the inferior and very poor data quality and to what extent the framework remains suitable for use. For this, we have unfiltered in the dataset extreme cases of non-duplicates where for example the name and the address are similar, but the records are not duplicates. The framework was applied to a very poor big data quality to uncover the limitations of the framework. The dataset was then scrambled

progressively with a very poor-quality dataset, and the accuracy was assessed in each round. The F-score has decreased in each round, as shown in Table V. Thus, it turns out that the framework resists and remains functional in a half-scrambled dataset with an F-score of 88,2%. Therefore, the accuracy is acceptably impacted by a very-poor biasing dataset.

TABLE V. F-SCORE EVOLUTION IN A VERY POOR-QUALITY DATASET

Percentage of scrambled data	F-s (%)
20 % of the very poor-quality dataset	97,9%
35 % of the very poor-quality dataset	94,8%
50 % of the very poor-quality dataset	88,2%
60 % of the very poor-quality dataset	83,4%

#### D. Discussion

Although significant efforts have been made in recent years for data deduplication, there are still challenges to be addressed, especially for big data. Indeed, data uniqueness as a quality metric depends highly on other quality metrics such as completeness, accuracy, validity, etc. For example, even if we have imputed data during the pre-processing phase, most imputation methods are not accurate, which can impact the deduplication accuracy as data is credited with inaccurate values. Meanwhile, ignoring missing values will negatively affect the model accuracy, especially in a big data environment where most of the data are incomplete. On the other hand, deduplication can also impact the other metrics, as the cleaning phase consists of keeping the most accurate, complete, or recent record. In some cases, records can even be merged. All these changes have a high impact on the other metrics. Thus, data deduplication could not be improved separately and, therefore, should be addressed in a more comprehensive approach that considers this strong relationship between the quality metrics. Continual Learning is yet another research area that needs more focus. Even if Continual Learning has been around for more than 20 years, there are challenges that still need to be addressed, such as catastrophic forgetting, auditing, mentoring, evaluating continual learning techniques, etc. In addition to these challenges, new issues have been raised with big data, such as handling memories, learning for streaming multimodal data, model saturation, etc. Thus, continual learning is not already in its explosion, and further research is needed. However, it is safe to say that Continual Learning will become increasingly crucial as ML models could not be effectively performed without accumulating the learned knowledge.

#### VII. CONCLUSION

While data deduplication has been the subject of several studies in the last decade, some challenges remain, especially in the Big Data Era. In this article, we have reviewed the most recent big data deduplication frameworks suggested in the literature. We also proposed a novel end-to-end big data deduplication framework based on a Semi-supervised clustering approach. The experiments have shown that the framework outperforms the existing big data deduplication approaches with an F-score of 98,21%. The suggested framework is also extended with an online continual learning phase that continuously improves the deduplication model

performance and increases the model accuracy by 1,16%. In future work, we aim to enhance our framework by reducing the error rate when used on a very-poor quality dataset. Also, we aim to extend our framework to address more quality dimensions.

# Student's Performance Prediction based on Personality Traits and Intelligence Quotient using Machine Learning

Samar El-Keiey<sup>1</sup>, Dina ElMenshawy<sup>2</sup>, Ehab Hassanein<sup>3</sup>  
Information Systems Department  
Faculty of Computers and Artificial Intelligence  
Cairo University  
Egypt

**Abstract**—Apparently, most life activities that people perform depend on their unique characteristics. Personal characteristics vary across people, so they perform tasks in different ways based on their skills. People have different mental, psychological, and behavioral features that affect most life activities. This is the same case with students at various educational levels. Students have different features that affect their academic performance. The academic score is the main indicator of the student's performance. However, other factors such as personality features, intelligence level, and basic personal data can have a great influence on the student's performance. This means that the academic score is not the only indicator that can be used in predicting students' performance. Consequently, an approach based on personal data, personality features, and intelligence quotient is proposed to predict the performance of university undergraduates. Five machine learning techniques were used in the proposed approach. In order to evaluate the performance of the proposed approach, a real student's dataset was used, and various performance measures were computed. Several experiments were performed to determine the impact of various features on the student's performance. The proposed approach gave promising results when tested on the dataset.

**Keywords**—Prediction; student performance; machine learning; personality; intelligence quotient

## I. INTRODUCTION

People have a wide range of cognitive abilities, including intelligence, memory, attention, and so on. People can carry out brain-based operations or activities in a variety of ways and for varying lengths of time. Two people can perform the same operation in two different ways. This is because people's personal characteristics differ, and most life activities are dependent on these personal characteristics.

Each person has certain abilities which he/she uses to deal with various real-life activities. Also, people have different ways to process and memorize information. Actually, all operations or activities a person performs are based on his/her features either the behavioral features or the psychological ones.

For example, the tasks that need some sort of intelligence, people who have higher intelligence quotients usually finish their assigned tasks in fewer steps and in less time than others who have lower intelligence quotients. Moreover, people who

have higher memory skills usually remember things better and more quickly than other people who have lower memory skills.

Apparently, most life operations or actions which people perform are done based on their various skills. The same idea goes for students at all educational levels. Students have different characteristics either psychologically or mentally which affect their academic performance.

Some students perform better in theoretical questions that need remembering skills while other students perform better in practical questions which need brain-based skills. Mainly the academic score of a student depends on his/her unique characteristics.

The main purpose of this research is to measure the impact of the personality traits and the intelligence of students on their academic performance. In addition to these features, some personal data and the academic score have been used to predict the academic performance of undergraduate students.

To the best of our knowledge, no work exists answering the question of the impact of personal data, personality traits, intelligence quotient, and academic score on the student's performance.

The research questions of this research are:

- 1) What effect does the Intelligence Quotient (IQ) have on the undergraduate student's performance?
- 2) What effect do personality traits have on the undergraduate student's performance?
- 3) What effect does the combination of IQ, personality traits, personal data, and academic score have on the undergraduate student's performance?
- 4) What are the most significant features in the student's performance prediction?

## II. STUDENT PERFORMANCE PREDICTION

Student performance prediction has played a significant role in educational systems. Predicting student performance helps students to select appropriate courses which match their skills as the student's performance can vary across different courses. Prediction helps students choose courses that match

their abilities. Also, student performance prediction can assist in designing appropriate future study plans for students. Beyond predicting student performance, it helps teachers and managers to monitor and support the students, and to offer training programs to achieve the best results. Other benefits of student performance prediction are reducing official warning signs and discarding students for inefficiency.

Machine learning techniques have played a significant role in the creation of effective educational systems over the past two decades. These techniques helped in offering better learning techniques and in enhancing the academic performance of students [1].

Applying machine learning techniques in educational systems has played a crucial role in discovering concealed and unexpected methods to impart knowledge across all educational levels. As a result, some prediction models have been proposed by numerous researchers to enhance the student's performance and learning quality as in [2], [3].

### III. MOTIVATION

Student performance mainly can be predicted through historical records of quizzes and exams, and Grade Point Average (GPA). This is usually common in various educational levels and ages. However, sometimes there are other factors that may influence a student's performance such as mentality skills, behavioral characteristics, cognitive skills, personality traits, and psychological factors.

Also, some of these factors may affect the performance of students at certain ages but may have no effect at other ages or at other educational levels. For example, personality traits may have a great influence on older students like university students but may not have a noticeable effect on younger students at primary or high school levels.

Moreover, the factors that are considered important for student performance prediction for preschool students may not have the same importance as for older students like undergraduates in universities. Also, gender can play a role in student performance prediction. For example, sometimes male students have better scores in different courses or specialties than female students and vice versa.

The importance of a certain factor or a feature in student performance prediction usually depends on the age or the educational level in which the student is enrolled. Consequently, in this research, we focus on a certain educational level which is undergraduates in universities.

As a result, in this paper, an approach based on personal data, personality traits, and intelligence quotient is proposed to predict the student's performance of university undergraduate students.

The main contributions of this paper are as follows:

1) Proposed an approach that utilized academic score, gender, region/city, number of brothers/sisters, Intelligence Quotient (IQ), and personality features to predict student's performance.

2) Applied five machine learning techniques in the proposed approach to predict student's performance.

3) Applied the proposed approach on real students' datasets.

4) Compared the performance of different features across the five machine learning techniques.

5) Predicted the best indicators that assist in student performance prediction.

The rest of the paper is organized as follows: Section 4 presents the literature work on students' performance prediction. Section 5 presents the proposed approach. Section 6 presents the results. Section 7 presents the analysis and discussion of the results. Section 8 presents the conclusion and future work.

### IV. RELATED WORK

In the following paragraphs, related work on students' performance prediction using different techniques is presented.

In recent decades, many attempts have been made to predict students' academic performance before students start the learning process to make their outcomes predictable. This is also necessary for instructors to know the areas where students have defects so that students' skills in these areas can be improved. By predicting future results in a timely manner, instructors can know the areas that need improvement while teaching students.

Educational institutions and governments also want to know the performance of the current educational system in order to perform improvements in the long term. In [4], the authors showed that students' performance depends on various factors such as demographics, behavior, previous outcomes, and habits. Unexpected factors, such as the address of students, had a great impact on the student's performance.

Many studies have been conducted to discover the effect of various variables on student academic performance. These factors are not the same all over the world and may vary from university to university, from university to school, and also from individual to individual.

In today's world, data has become very powerful, and machine learning can be very helpful in harnessing the power of this data. Machine learning techniques, along with deep learning techniques, have played a very important role in predicting student academic performance.

Various machine learning and deep learning techniques, such as Support Vector Machine (SVM), Neural Networks (NN), and clustering have been studied on different datasets in different institutions to find hidden and unexpected patterns. Several machine learning techniques were applied in [5].

In [6], various models for academic performance prediction have been developed using Decision Tree (DT), Naïve Bayes (NB), and Rule-Based (RB) for the Bachelor of Computer Science students at the University Sultan Zainal Abidin. The results showed that DT and RB provided better accuracies than NB.

In [7], the authors applied SVM, NN, DT, and NB models on two independent datasets. The results showed that SVM performed better than the other methods in terms of statistical significance.

Predicting student performance is a key challenge in the educational process that uses technology to help students towards success [8]. Previous research has detected several factors that influence the student's performance. Some of these factors are student demographics such as gender [9], previous academic grades [10], and interaction with the learning environment [11], [12].

In [13], DT, NB, logistic regression, SVM, K-nearest neighbors, iterative minimum optimization, and NN were utilized to study the student's performance in final undergraduate exams. Logistic regression performed the best compared to other models used in this study, with an accuracy of 66%.

In [14], the proposed model applied NN, logistic regression, and SVM algorithms in a virtual school learning environment.

In [15], recurrent neural networks (RNNs) for detailed knowledge and engagement studies were used. In this study, the authors achieved an accuracy value of 88.3%. SVM, linear discriminant analysis, random forests, K-nearest neighbors, and classification regression trees (CART) were used in this study. Random forests performed the best, with an accuracy of 90%.

In [16], the research applied a logistic regression prediction model on some variables which are level of involvement, level of prestige, level of visibility, number of student visits, and management system by subject, experience, age, and gender. The predictive models used in the analysis were NN, DT, and NB using bagging, boosting, and ensemble techniques. The DT classifier gave the highest accuracy value of 82%.

In [17], the authors provided the most comprehensive assessment to ensure the strength of the relationship between the big five personality traits and academic performance through the synthesis of 267 independent samples (N = 413,074) in 228 original studies. Also, the progressive validity of personality traits beyond cognitive ability in predicting academic performance was examined.

In [18], the research introduced a Contextual Cognitive Skill Scores (CCSS) approach to predict the student's performance. To determine the CCSS score, the cognitive skills required to solve the exam questions were combined with the exam scores. In doing so, the authors focused on generalizing the student's performance to understand its utility in predicting student risk profiles.

Exam questions and their scores vary by course and by exam. Such data heterogeneity is very important when generalizing the model. This is because feature variation affects the results. Therefore, the authors built the CCSS so that the feature space is the same for all courses so that students' performance can be visualized in the same dimension.

In [19], the proposed model predicted the success of students based on their behavioral patterns/activities in the learning process. Six machine learning prediction models were presented. Then, accuracy measures were computed to evaluate the proposed model.

In [20], data was collected from different students with different parameters, then these parameters were analyzed using techniques similar to those used in [21]. After that, decision trees for all considered attributes were built. Next, "if-then" rules for the relationship between various attributes and the student's performance were generated.

In [22], some machine learning algorithms were utilized to predict and classify different types of educational data. Three machine learning algorithms, namely, backpropagation (BP), support vector regression (SVR), and long short-term memory (LSTM) were used to predict the student's performance. In addition to these algorithms, a Gradient Boosting Classifier (GBC) is implemented in the classification phase.

## V. PROPOSED APPROACH

In this section, the proposed approach is presented along with the features used, the techniques applied, and the dataset used.

The main idea of our proposed approach is to discover the impact of the big five personality traits and the intelligence quotient on the performance of students when these features are integrated with the academic score feature and some personal data namely, gender, number of brothers/sisters and the region/city where each student lives in. The proposed approach was implemented in Python.

### A. Features Used and Data Collection

For the proposed approach, the data was collected from students in the Faculty of Computers and Artificial Intelligence, Cairo University. The data was collected from students from various levels, namely, 1<sup>st</sup>, 2<sup>nd</sup>, and 3<sup>rd</sup> year undergraduate students. Approximately 300 students shared their data and their grades in different courses which are an introduction to database systems, fundamentals of computer science, and Web-based information systems.

The features collected are:

- Gender
- Number of brothers/sisters
- Region/city
- GPA
- IQ
- Five personality traits, namely,
  1. Openness (O)
  2. Conscientiousness (C)
  3. Extraversion (E)
  4. Agreeableness (A)
  5. Neuroticism (N)

The 300 students who shared their data were divided into 117 females and 183 males. The average GPA is 2.9 and the average IQ is 3.7.

A snapshot of the dataset is shown in Fig. 1.

GPA	Gender	brothers/sisters	O	C	E	A	N	IQ	city/region
2.32	Male	3	4	2	3	3	3	5	Helwan / Cairo
2.9	Male	1	2	5	1	4	1	4	Cairo
3.6	Male	2	3	5	5	1	1	4	Giza
2.1	Male	2	3	4	4	3	4	2	Helwan/Egypt
3.65	Female	2	2	5	2	5	2	5	Ciario
2.99	Male	2	2	5	4	5	2	4	Giza
2.9	Male	2	2	3	4	4	4	3	Maadi , Cairo
2.67	Male	3	1	4	3	3	1	4	Nasr city
3.4	Male	3	2	5	3	3	1	5	fisal-guza
3	Female	2	4	3	3	3	5	4	giza
3.45	Female	2	4	4	4	4	3	5	New cairo
3.67	Female	2	4	5	4	4	4	5	Maadi-Cairo
3.95	Male	2	3	5	1	4	1	5	Giza/Haram
2.93	Male	3	2	3	3	4	3	4	giza
3.7	Female	2	3	5	4	3	1	4	Cairo
2.96	Male	2	3	4	3	4	1	4	Giza
3.01	Female	2	4	3	4	3	4	4	Giza
1.91	Male	2	2	1	4	1	5	2	Cairo
2.7	Female	3	3	3	3	1	4	4	Giza
2.87	Male	2	2	3	2	3	3	4	Cairo
3.43	Female	2	3	4	3	3	2	5	cairo

Fig. 1. Snapshot of the Dataset.

### B. Data Preprocessing

The data was collected from a questionnaire via Google form so some preprocessing steps were performed so that the data can be used in the proposed prediction approach. The preprocessing steps focused mainly on removing noise and minimizing redundancy. Also, some features whose values were text were converted to numeric so that they can be used in the prediction model.

Moreover, the numeric scores were converted to categorical classes which are low, medium, and high so that the class label to which each student belongs can be predicted. Each categorical class included a range of values, as follows:

- Low (0 - <40)
- Medium (40 - <80)
- High (>= 80)

### C. Techniques Used

Mainly, five machine learning techniques were used in our proposed approach in predicting the student's performance. The used techniques are:

1) **k-nearest neighbor (KNN)**: KNN is a non-parametric supervised machine learning classifier algorithm, which is used for regression and classification [23]. After performing various experiments to determine the best value of k, a value of 6 gave the best accuracy, as presented in Fig. 2.

Fig. 2. The Best K Value.

2) **Support Vector Machine (SVM)** is a supervised learning model used for regression as well as for classification [24].

3) **Decision Tree (DT)** is a non-parametric supervised machine learning classifier algorithm, which is used for regression and classification. It has a hierarchical tree structure [25].

4) **Random Forest (RF)** is a classification algorithm used for classification and regression. It consists of several decision trees [26].

5) **Naive Bayes (NB)** is a probabilistic classifier that applies Bayes' theorem [27].

### D. Features Importance

To know the most influential features in the prediction, the Scikit-learn (Sklearn) python library and the feature importance python function [28] were used to determine the most important features as presented in Fig. 3.

Fig. 3. The Most Important Features.

As shown in Fig. 3, the features are abbreviated as follows:

- GPA: Grade Point Average
- F: Female
- M: Male
- BS: Number of Brothers/Sisters
- O: Openness
- C: Conscientiousness
- E: Extraversion
- A: Agreeableness

- N: Neuroticism
- IQ: Intelligence Quotient

After performing several experiments, it was deduced that the most important features that have the highest significance on the student’s performance are Conscientiousness, GPA, and IQ.

Also, it was noticed that gender and location have the least significant on the student’s performance. The location feature is not of great importance, so our proposed approach can be applied easily in online learning.

E. Correlation Matrix

To know the correlation and the dependencies between the features, the correlation matrix was constructed, and it is shown in Fig. 4.

Fig. 4. Correlation Matrix.

The correlation between the features is the indicator of the extent of the effect of one feature on another one. The higher the value (either positively or negatively) between a pair of features, the higher is the correlation between them.

On the other hand, the less correlated features gave values closer to zero. When a value becomes closer to zero, this means that the features are less correlated.

When a value of a certain feature increases and the value of the other correlated feature increases, this denotes a positive correlation. On the other hand, when a value of a certain feature increases and the value of the other correlated feature decreases, and vice versa, this denotes a negative correlation.

After performing several experiments on the various features, the most correlated features were GPA, Conscientiousness, and IQ.

VI. RESULTS

The collected dataset was used to evaluate the performance of the proposed approach. The prediction accuracy, precision, recall, F1 measure, and the confusion matrix (true positive, true negative, false positive, and false negative) were computed for all techniques. Also, the results are compared across the five techniques. The results are presented in Table I.

TABLE I. PREDICTION RESULTS OF THE FIVE TECHNIQUES

Technique	Accuracy	Precision	Recall	F1 measure
KNN	0.85	0.84	0.85	0.84
NB	0.86	0.86	0.86	0.86
RF	0.83	0.82	0.83	0.83
DT	0.90	0.89	0.90	0.89
SVM	0.88	0.87	0.88	0.88

As shown in Table I, the decision tree technique gave the best performance among the other techniques with accuracy = 0.90%, precision = 0.89%, recall = 0.90% and F1 measure = 0.89%.

A. Confusion Matrix for All Techniques

The confusion matrix is used to analyze the performance of the classification techniques by computing the True positive (TP), the True Negative (TN), the False Positive (FP), and the False Negative (FN) for the testing data which are described as follows.

- TP: The true positive value is the case in which the actual value and expected value are identical [29].
- TN: A class’s True Negative value is the sum of all columns and rows, except those for the class for which we are computing the values [29].
- FP: A class’s False-positive value is the sum of all the values in the relevant column, except for the TP value [29].
- FN: A class’s False-negative value is the sum of the values in the relevant rows, except for the TP value [29].

Using the confusion matrix, we can assess the model’s performance in terms of recall, precision, and accuracy.

The confusion matrices for the prediction classification techniques are shown below in Tables II to VI.

1) K-Nearest Neighbor

TABLE II. KNN CONFUSION MATRIX

	High	Medium	Low
High	31	0	0
Medium	1	11	4
Low	2	2	9

Predicted values

Actual values

2) Naïve Bayes

TABLE III. NAIVE BAYES CONFUSION MATRIX

	<b>High</b>	<b>Medium</b>	<b>Low</b>
<b>High</b>	31	0	0
<b>Medium</b>	1	13	2
<b>Low</b>	3	2	8

Predicted values

3) Random Forest

TABLE IV. RANDOM FORESTS CONFUSION MATRIX

	<b>High</b>	<b>Medium</b>	<b>Low</b>
<b>High</b>	31	0	0
<b>Medium</b>	1	12	3
<b>Low</b>	3	2	8

<b>Medium</b>	0	13	3
<b>Low</b>	2	2	9

Predicted values

VII. RESULT ANALYSIS AND DISCUSSION

The proposed approach proved that the big five personality traits, especially the “conscientiousness” feature, are the most significant features in predicting student’s performance for undergraduate students in the Faculty of Computers and Artificial Intelligence, Cairo University in Egypt.

The intelligence quotient score also has a significant role in our prediction approach.

In order to test the efficiency of our proposed approach in integrating several features, personality traits and IQ features were removed from the dataset and the results were compared before and after removing these features as will be described in the following paragraphs.

A. The Impact of Removing the Big Five Personality Traits

Another experiment has been conducted to evaluate the performance of all techniques after removing all big five personality traits features from the dataset. This experiment was performed to monitor the impact of the big five personality traits on the academic performance of Egyptian students. The results are presented in Table VII.

TABLE VII. PREDICTION RESULTS WITHOUT BIG FIVE PERSONALITY FEATURES

Technique	Accuracy	Precision	Recall	F1 measure
<b>KNN</b>	0.66	0.68	0.66	0.67
<b>NB</b>	0.75	0.77	0.75	0.75
<b>RF</b>	0.76	0.77	0.76	0.76
<b>DT</b>	0.71	0.71	0.71	0.71
<b>SVM</b>	0.76	0.77	0.76	0.77

Table VII shows that accuracy, precision, recall, and F1 measure had decreased after removing the big five personality traits from the dataset, compared to the results in Table I.

Also, Table VII shows that the SVM provides the best performance in terms of accuracy, precision, recall, and F1 measure.

On the other hand, Table I shows that the decision tree technique provides the best performance in terms of accuracy, precision, recall, and F1 measure.

This emphasizes that the existence of the big five personality traits has a very significant role in predicting a student’s academic performance.

B. The Impact of Removing the IQ Feature

Another experiment has been conducted to evaluate the performance of all techniques after removing the IQ feature from the dataset. This experiment was performed to discover the extent of the impact of the IQ feature on the academic performance of students. The results are presented in Table VIII.

Table VIII shows that the decision tree technique provides the best performance in terms of accuracy, precision, recall, and F1 measure; this corresponds to the results in Table I.

Table VIII shows that accuracy, precision, recall, and F1 measure had a little decrease after removing the IQ feature from the dataset, compared to the results in Table I.

This means that the existence of the IQ feature has an important role in the prediction of student academic performance in the proposed prediction approach.

TABLE VIII. PREDICTION RESULTS WITHOUT IQ FEATURE

Technique	Accuracy	Precision	Recall	F1 measure
KNN	0.76	0.76	0.76	0.76
NB	0.84	0.83	0.84	0.83
RF	0.82	0.81	0.82	0.82
DT	0.89	0.88	0.89	0.88
SVM	0.86	0.86	0.87	0.86

After conducting several experiments, the results have proved that “conscientiousness” is the most significant predictor when it is integrated with IQ.

To conclude, it was found that merging the big five personality traits with IQ and the academic feature besides the other moderator features namely, gender, region/city, and the number of brothers/sisters provided better results in all performance measures (accuracy, precision, recall, and F1 measure) compared to each one of them separately.

A comparison of accuracy with adding and removing the important features for all applied machine learning techniques is shown in Fig. 5.

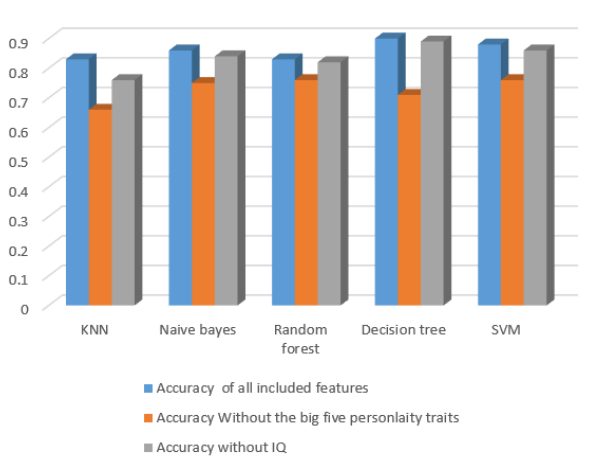

Fig. 5. Accuracy Comparison of All Techniques with and without Important Features.

### VIII. CONCLUSION AND FUTURE WORK

Predicting student academic performance is very helpful for educators and learners to improve the teaching and learning processes. In this paper, student academic performance was predicted by applying various machine learning techniques with different features.

The main idea of this research is to discover the impact of the student’s personality and the IQ along with other moderator features namely, gender, region/city, and the number of brothers/sisters integrated with the student’s GPA on the student’s academic performance.

Classification algorithms are widely used in education. K-nearest neighbor, decision trees, support vector machine,

random forests, and Naive Bayes techniques were used to predict the student’s academic performance. The decision tree technique performed the best in predicting the student’s academic performance.

To enhance the effectiveness of the proposed approach, the personality traits and the IQ features were removed. After that, the proposed approach was re-implemented after removing these features then the performance measures were re-computed. The results showed a decrease in accuracy, precision, recall, and F1 measure which emphasizes the significant role of personality traits and IQ in predicting student academic performance.

To conclude, a lot of work can be done in predicting student academic performance so further research can be conducted as future work. This helps the educational systems to track the student’s academic performance in a structured way. Furthermore, further research can use deep learning techniques and neural networks besides machine learning techniques to enhance the results.

### ACKNOWLEDGMENT

We would like to express our appreciation to the students in the Faculty of Computers and Artificial Intelligence, Cairo University for their valuable role in helping us to collect the data needed for this research work.

**Abstract**—The forest is an outdoor environment not touched by the surrounding community, so it is not immediately handled when a fire occurs. Therefore, surveillance using cameras is needed to see the presence of fire hotspots in the forest. This study aims to detect hotspots through video data. As is known, fire has a variety of colors, ranging from yellow to reddish. The segmentation process requires a method that can recognize various fire colors to get a candidate fire object area in the video frame. The methods used for the color segmentation process are Gaussian Mixture Model (GMM) and Expectation–maximization (EM). The segmentation results are candidates for fire areas, which in the experiment used the value of  $K=4$ . This fire object candidate needs to be ascertained whether the segmented object is a fire object or another object. In the feature extraction stage, this research uses the DenseNet-169 or DenseNet-201 models. In this study, various color tests were carried out, namely RGB, HSV, and YCbCr. The test results show that RGB color produces the most optimal training accuracy. This RGB color configuration is used to test using video data. The test results show that the true positive and false negative values are quite good, 98.69% and 1.305%. This video data processing produces fps with an average of 14.43. So, it can be said that this combination of methods can be used to process real time data in case studies of fire detection.

**Keywords**—Fire detection; color segmentation; GMM-EM; DenseNet; real time

## I. INTRODUCTION

Human daily life cannot be separated from the heat energy produced by a fire. The heat energy from this fire is often used for cooking, lighting candles as a light source, and burning garbage. However, fires can be catastrophic if they are not controlled and burn a large area. Fires can occur in indoor and outdoor environments such as forests. In Indonesia, forest fires often occur in Sumatra and Kalimantan because forest areas are still common [1]. Natural factors and human error can cause the emergence of fire hotspots. Some natural factors are hot weather, wind, and chemical reactions [2]. Then human error can occur due to forgetfulness in activities with fire, especially in rural areas that still use firewood for daily life [3]. Currently, the government has made efforts to mitigate fire disaster management [4], but the efforts made have not used Artificial Intelligence technology for automation. Therefore, the need for prevention efforts by detecting hotspots as early as possible before the fire spreads. This hotspot detection process can be done by installing an intelligent camera programmed using Artificial Intelligence to identify hotspots.

Several researchers have developed early detection of hotspots, including fire detection using video [5] and sensors [6]. Limitations in using sensors, especially gas sensors, can occur when there is other smoke, for example, people smoking. Then the heat sensor can also go wrong when the weather is hot. Using fire detectors through sensors also costs a lot when used in an outdoor environment because they must replicate the tool at many points. So, the proposed research focuses on using video to detect hotspots. Video data can be obtained by installing a Closed-Circuit Television (CCTV) camera. CCTV camera can detect fires using digital image processing and computer vision technologies, known as image-based fire detection. The advantages of image-based fire detection compared to conventional fire detectors can be installed in a large, open area to reduce expenses. The use of video data requires a method that can run in real-time [7]. Besides, the video resolution also affects the detection accuracy results. In a previous study [2], the fire detection system produced a reasonably accurate accuracy, but the processing time of each frame could not be done in real time. It is also a limitation of previous research. The main steps that affect the speed and accuracy are image segmentation, feature extraction and classification.

The segmentation process is carried out to take the fire area in the video frame. The segmentation stage of searching candidate fire object is very important to separate the fire candidate object from the background, which should not enter the feature extraction stage. The color of fire is a combination of various colors, ranging from reddish to yellow [8]. Previous studies conducted experiments using fire color segmentation, including RGB, HSV, and YCbCr color features, have not produced optimal accuracy [9]. The lack of this feature is because the color of the fire changes due to the wind. Therefore, this research uses a segmentation method that can overcome the quick color change of the fire using probability. This probability makes several color combinations of fire. The proposed research uses color probabilities to perform segmentation. In other case study research, the segmentation process was carried out on the image using a combination of the Gaussian Mixture Model (GMM) and Expectation–maximization (EM) methods [10][11]. The segmentation results show that combining these methods can detect multi-colored objects. Therefore, the proposed research uses of GMM-EM for the segmentation of candidate fire objects contained in video frames.

After the candidate fire object is obtained, the fire object must be sure that the segmented one is a fire object. Several studies of feature extraction and classification use the transfer learning method. The transfer learning of DenseNet201 model is used for image classification [12]. The results showed good accuracy for the feature extraction of corn disease. In another research, the DenseNet model was also used for feature extraction of the lungs affected by Covid-19 [13]. The results showed good accuracy using the DenseNet model. This research will also use the DenseNet model at the feature extraction and classification stage. The result of this research is a real-time fire early detection system using video data.

This research aims to build a real-time fire point detection system using video data for early warning of fires. Speed is an important thing in this study to be evaluated. The color of fire that is not only yellow requires a precise segmentation process, so the proposed method uses a combination of various colors of fire. The segmentation results are then extracted and classified to ensure that the object is a fire. Overall, the contributions of this research are:

- The use of various color combinations of fire to perform the segmentation process for searching fire object candidates.
- Evaluation of the segmentation process on each video frame to minimize non-fire object detection errors.
- The use of transfer learning as feature extraction and classification to achieve optimal accuracy and real-time processing.

## II. RELATED WORK

The development of fire detection applications often uses sensors [14]. The downside of using this sensor depends on the surrounding weather. When using a heat sensor during the dry season, the sensor may experience error detection. Then the gas sensor can also experience an error when there is other smoke, for example, cigarette smoke, smoke from burning garbage, etc. Even detecting hotspots in open areas, such as forests, is very difficult. Therefore, the fire detection uses video data.

Several researchers who process fire video data, including Khan et al. [15], used a fire's color, perimeter, area, and roundness for an indoor fire case study. The method used does not consider small fires, so it cannot carry out early detection of hotspots. Then, research by Thepade et al. [9] used a color combination of HSV and YCbCr to detect hotspots. The method used is still static, so the use of dynamic video data cannot be done. The segmentation process can also use the deep feature [16]. This deep feature is suitable for high-resolution images such as satellite images. Several segmented objects produce relatively good accuracy. However, the disadvantage of using deep features is that the processing time is quite long, so it is unsuitable for real-time processing. The color component of fire is not only red, but a combination of various colors, including yellow, orange, red, white, and blue. Previous research by Dong Keun Kim [10] used Gaussian Mixture Model (GMM) and Expectation-maximization (EM) to detect color combinations on objects. The proposed research will segment fire objects with fire color data training using the

GMM-EM method. Video resolution also affects the detection accuracy results. In a previous study [2], the fire detection system produced a fairly accurate accuracy of 99.7%, but the processing time of each frame took 0.23 seconds or four fps. Therefore, this research proposes a new approach to obtain optimal accuracy and can run in real-time.

Currently, deep learning is a method that researchers often use for classification case studies. Deep learning, frequently used to handle picture data, is called Convolutional Neural Network. Deep learning is a technique used by artificial neural networks to manage input data utilizing multiple hidden layers. The output of this process is a non-linear modification of the input data used to determine the output value [17]. Deep learning is typically used for vast amounts of data. However, the data is relatively small in some instances, such as in this fire detection scenario. Transfer learning is a strategy for processing small amounts of data in which the model has been trained using other data [18]. DenseNet is an example of a transfer learning model. In this research, an evaluation of the DenseNet-169 and DenseNet201 models will be carried out.

## III. PROPOSED METHOD

Fig. 1. Proposed System of Fire Detection.

The hotspot detection system starts from the training stage. There are two training processes: training for the segmentation process and feature extraction on fire objects. The training process uses a combination of GMM and EM methods. The fire segmentation process uses image data of fire colors. Then, the feature extraction process uses fire and non-fire image data. Before the training process, the image is converted to HSV or YCbCr color. The training process uses the transfer learning

method. The best model is used for matching video data. Then the testing phase begins with real-time video data input. Video data is extracted in the form of frames. Detection of fire candidates in video frames is done by matching the color model. Flame object candidates are converted to HSV or YCbCr color. The conversion results are matched with the feature extraction model. The feature extraction and classification stage use DenseNet model. The results of the classification are fire and non-fire objects. Fig. 1 shows the flowchart of this research's fire point detection.

### A. Acquisition Data

This research used two datasets: a dataset for segmentation of fire object candidates and a dataset for fire object classification. The dataset for segmentation uses 30 images of fire color images. This dataset uses three color channels: Red, Green, and Blue (RGB), measuring 100 x 100. The features of this dataset were taken from it based on the RGB color model, which was used to show the different colors of fire in the color probability model. The fire color varies so that it can detect various colors of fire when testing using video data. Fig. 2 shows an example of a fire color dataset used for the segmentation process.

Fig. 2. Fire Color Data for Segmentation Stage.

Then at the feature extraction stage, the data uses from Kaggle created by Jadon et al. [19]. This dataset consists of two classes, namely the fire class in various places and the non-fire class like other objects. The number of fire data is 1123 images, while the non-fire data is 1301. It was made by taking images of fire and things that don't fire under challenging situations, like the fire image in the forest and the non-fire image with things that look like fire in the background. At the training stage, the percentage of training data used is 80%, while the testing data is 20%. Fig. 3 shows an example of training data for the feature extraction stage.

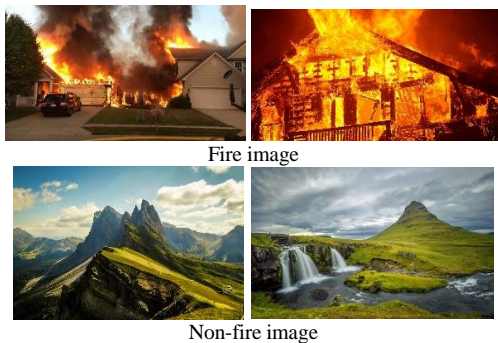

Fig. 3. Fire and Non-Fire Image for Feature Extraction Stage.

### B. Fire Object Segmentation

Multiple clusters can describe a dataset's distribution. Modelling a dataset with a single mean (one Gaussian) and estimated parameters is not optimal. For example, if a dataset contains two means of 218 and 250, the average may be close

to 221. It is not a precise estimate. Multiple Gaussians with means of 218 and 250 provide a more accurate representation of the distribution of the data set.

In situations where multiple data sets with varying numbers of clusters describe the same feature, it is preferable to model the data across the three sets using a multivariate Gaussian [20]. Equation (1) represents the multivariate Gaussian equation. It allows for a more precise evaluation of the distribution of clusters across the provided data.

$$N(x|\mu, \Sigma) = \frac{1}{(2\pi|\Sigma|)^{\frac{1}{2}}} \exp \left\{ -\frac{1}{2} (x - \mu)^T \Sigma^{-1} (x - \mu) \right\} \quad (1)$$

This research employs a multivariate Gaussian with three color channels: Red, Green, and Blue. It has detected fire-based objects, so the number of clusters in each color channel will be examined. This research uses the Expectation-Maximization algorithm to estimate the means and covariances and determine the probability of a pixel belonging to a cluster. The total image is then modelled with a three-dimensional Gaussian.

The following sections outline the stages involved in performing the EM algorithm:

1) *Using some random numbers:* initialize the means and covariances. The covariance matrix must have the shape (dim, dim), where dim is the Gaussian's dimension number. These values are stored in a dictionary data structure called 'parameters.'

2) *E Stage:* Gaussians are combined in (2).  

$$p(x) = \sum_{k=1}^K \pi_k N(x|\mu_k, \Sigma_k) \quad (2)$$

These are the probabilities associated with a given value x. It can accomplish this by applying the Bayes rule as (3).

$$= \frac{\pi_k N(x|\mu_k, \Sigma_k)}{\sum_{j=1}^K \pi_j N(x|\mu_j, \Sigma_j)} \quad \text{where, } \pi_k = \frac{N_k}{N} \quad (3)$$

These are saved in an array named 'cluster prob' with the dimensions (n\_feat, K). n\_feat is the number of rows in the dataset in this case.

3) *M Stage:* Then, update the means and covariances. This can be accomplished using the following (4).

$$\mu_j = \frac{\sum_{n=1}^N \gamma_j(x_n) x_n}{\sum_{n=1}^N \gamma_j(x_n)}$$

$$\Sigma_j = \frac{\sum_{n=1}^N \gamma_j(x_n) (x_n - \mu_j)(x_n - \mu_j)^T}{\sum_{n=1}^N \gamma_j(x_n)}$$

$$\pi_j = \frac{1}{N} \sum_{n=1}^N \gamma_j(x_n) \quad (4)$$

4) *Calculate the Log Likelihood:* The objective is to increase the log likelihood function until the change in likelihood is equal to or less than a specified number. The following (5) is used to get the log likelihood.

$$\ln p(X|\mu, \Sigma, \pi) = \sum_{n=1}^N \ln \left\{ \sum_{k=1}^K \pi_k N(x_n|\mu_k, \Sigma_k) \right\} \quad (5)$$

The log likelihood is appended to the log likelihoods array. The log probability difference is calculated by subtracting the most recent value from the most recently stored value. This technique is continued iteratively until the difference in log likelihood reaches a predefined value or the maximum number

of iterations is reached. The final values produced are the dataset's estimated means and covariances. Fig. 4 shows an example of segmentation results.

Fig. 4. Fire and Non-Fire Image for Feature Extraction Stage.

### C. Feature Extraction and Classification on Fire Object Candidate

In this study, the feature extraction phase uses HSV or YCbCr colors. The image of the flame candidate is converted to HSV or YCbCr color space. The results of this conversion are utilized in the process of feature extraction. The process of feature extraction employs the DenseNet transfer learning model [21]. A DenseNet is a convolutional neural network with dense connections between layers using Dense Blocks, where all layers (with matching feature-map sizes) are directly connected. Maintain the feed-forward nature; each layer receives additional inputs from all preceding levels and sends its feature maps to all subsequent levels.

Model: "sequential"

Layer (type)	Output Shape	Param #

Trainable params:	492,033	
Non-trainable params:	18,321,984	

Fig. 5. Architecture for Training Stage on Fire and Non-Fire Image.

At the training stage, the preprocessing process such as resizing to 224x224 pixels and normalizing the data after resizing the data. The training data image uses a method with the DenseNet model, which includes feature extraction and classification processes. The DenseNet model has general operations for batch normalization, ReLU activation, and convolution. DenseNet model with 201 layers has dense block 1, transition layer 1, dense block 2, transition layer 2, dense block 3, transition layer 3, dense block four, and classification layer processes that produce the output model with .h5 format. In this research, feature extraction will be carried out using the

DenseNet-169 and DenseNet-201 models. Fig. 5 shows the architectural configuration used for the training process.

### D. System Evaluation

Using video data in a fire detection system requires evaluation, especially regarding the accuracy and speed of processing video frames. The first test is carried out at the segmentation stage. The segmentation process is used to find the fire object candidate area in the video frame. This research evaluates the value of  $K$  used in the GMM method against the segmentation results and the resulting fps. Then at the feature extraction stage, this research assesses the use of RGB, HSV, and YCbCr colors to see the results of training accuracy. The last configuration is used for evaluation using video data to see the true positive and false negative values of the video data matching results. The last is an evaluation of the video data processing speed to see the fps value.

## IV. RESULT AND DISCUSSION

This section conducts some experiments at the segmentation stage, feature extraction and classification of fire or non-fire objects. The last is matching using video data. In this experiment, this research used a computer with Core i5 specifications with 8GB of RAM and VGA GTX 1650. Then, the computer program uses Python programming language.

### A. Fire Object Segmentation

At the segmentation stage using the GMM and EM methods, the most influential parameter is  $K$  value, which functions as a clustering dataset of fire colors. Table I shows the results of the variation of the  $K$  value on the segmentation results.

TABLE I. THE EFFECT OF K VALUE ON SEGMENTATION RESULTS

K Value of GMM	Ground Truth Image	Segmentation on Frame	Fps
2			31.28
3			29.22
4			20.66
5			17.65
6			15.13

Based on the experiment using the  $K$  value in the GMM method, there are no segmented fire objects when the value of  $K = 2$ . Whereas in the ground truth image, there are two fire objects contained in the image. Then at the value of  $K = 3$  to

6, the segmentation results show two fire objects with the same ground truth. However, if it looks closely, the more  $K$  values are added, the closer the segmentation results get to the ground truth shape. In processing video data also need to pay attention to the resulting speed. In this experiment, it was tested with the resulting fps value. As the value of  $K$  increases, the resulting fps also decreases. Because the number of clusters is increasing, it takes time to match each cluster. Therefore, this research choses a value of  $K = 4$ , which still produces an average of 20 fps. This configuration will be used to test using multiple videos containing fire objects.

### B. Feature Extraction and Classification on Candidate Fire Object

This transfer learning model uses to process features into the feature extraction layer before the classification layer. The feature extraction used in this study is the DenseNet-169 or DenseNet201 model. The difference between DenseNet-169 and DenseNet-201 is the number of parameters. In DenseNet-169 it is 14.3M, while in DenseNet-201, it is 20.2M [22]. This study's training process configuration uses an image input size of 50 x 50. Then the distribution of training data and testing data is 80% training data and 20% testing data. Then the optimizer used is Adam with a loss configuration using binary\_crossentropy because the number of classes used is two, namely fire and non-fire. Table II shows training results using two DenseNet models by monitoring validation accuracy. This research experimented with three colors, namely RGB, HSV, and YCbCr.

TABLE II. THE TRAINING RESULT FOR FEATURE EXTRACTION STAGE

Epoch	Transfer Learning Model					
	DenseNet-169			DenseNet-201		
	RGB	HSV	YCbCr	RGB	HSV	YCbCr
1	0.8438	0.6484	0.6562	0.8672	0.6484	0.6406
2	0.9766	0.8750	0.8906	0.9531	0.8984	0.8047
3	0.9844	0.9453	0.9531	0.9766	0.8984	0.8750
4	0.9844	0.9531	0.9375	0.9844	0.9375	0.9219
5	1.0000	0.9688	0.9609	0.9922	0.9375	0.9453
6	1.0000	0.9844	0.9609	1.0000	0.9688	0.9531
7	1.0000	-	0.9766	1.0000	0.9844	0.9766
8	1.0000	-	0.9844	1.0000	0.9922	0.9766

Based on the experimental results in Table II, the best results are obtained using RGB colors. It is because the pre-trained model uses images with RGB colors in the transfer learning model. So, when tested using other colors such as HSV and YCbCr, the accuracy results obtained have not reached 100% in epoch 8. This training process uses an early stop with a maximum of no change of 5 epochs. In this experiment, all models stopped at the eighth epoch. Therefore, this research used RGB color as the color configuration in the video data experiment. From the DenseNet-169 and DenseNet-201 models, the best results are obtained using the DenseNet-169 model because in the fourth epoch, the accuracy is 100%, and the DenseNet-169 model is lighter, which affects faster data processing. Therefore, in the experiment using video data, this research used the DenseNet-169 model.

### C. Matching with Video Data

The segmentation and feature extraction models were obtained for video data testing. In this test, the data used is a

fire video obtained from the VisiFire fire detection software [23]. All video datasets have a resolution of 400 x 256 at 15 fps. The number of video frames varies, Controlled1 260 frames video, Controlled2 246 frames, Controlled3 208 frames, Forest1 200 frames, Forest2 245 frames, and Forest3 255 frames. It will check whether a fire object is detected in the video frame. It will evaluate true positive (TP), and false negative (FN) results in each video experiment. Table III shows the results of the evaluation of video data processing.

TABLE III. RESULT OF MATCHING WITH VIDEO DATA

Video	Proposed Method		Color + SVM [24]		Tempo-spatial + SVM [25]	
	TP	FN	TP	FN	TP	FN
Controlled1	100	0	55.2	44.8	94.98	5.02
Controlled2	100	0	77.7	22.3	-	-
Controlled3	100	0	97.9	2.1	95	5
Forest1	100	0	-	-	-	-
Forest2	100	0	-	-	-	-
Forest3	92.17	7.83	-	-	-	-
<b>Average</b>	<b>98.69</b>	<b>1.305</b>	<b>76.93</b>	<b>23.067</b>	<b>94.99</b>	<b>5.01</b>

The experimental results show that the combination of segmentation and feature extraction models produces a reasonably good true positive, 98.69%. In previous studies, 95% true positive results did not exist in the model using supervised learning. Likewise, with false negative results, in this study, the value was below 2 percent, which means that only a few fire objects were not detected. Previous research also used the handcrafted method, which means that the features obtained are based on the components contained in the fire object. The classification process is also carried out using machine learning. Quantitatively, the average true positive of the proposed method is better than the previous research. The amount of video data tested is also more, so this method passes more test data with various fire object conditions. In this case, it makes qualitative testing of the proposed method better. In addition to testing true positive and false negative values, we also evaluate the resulting fps results for video data processing. Table IV shows the fps results obtained from the tested videos.

TABLE IV. RESULT OF COMPUTATION TIME

Video	Fps
Controlled1	16.63
Controlled2	14.75
Controlled3	11.42
Forest1	14.84
Forest2	12.6
Forest3	16.36
<b>Average</b>	<b>14.43</b>

The video used to test the fps is 400x 256 resolutions. The fps results obtained based on Table IV are not the same because the fire objects detected in the video are different. The more fire objects there are in a frame, the fps result also decreases. The average fps produced is quite good, namely 14.43 fps, meaning that for 1 second, it can process around 14 frames. An example of the results of the segmentation and detection processes in this system is shown in Fig. 6. This study has limitations related to the resulting fps that are not optimal. There are still about 12 fps in testing, while CCTV cameras usually produce 15 fps recordings. The challenge in further research is to increase the resulting fps value so that the

use of CCTV cameras with high fps can be applied. However, video data processing must also consider the detection results in addition to the resulting fps value. In this study, the number of true positives produced was quite good, 98.69%.

Fig. 6. Example Fire Detection on Video Frame.

## V. CONCLUSION

Fire is a disaster that must be handled immediately so that it does not spread to a broader area. Early hotspot detection is needed, so a fire is directly identified to extinguish the fire. This research proposes a framework for fire detection using video data. The detection process starts with the fire object candidate segmentation. The fire object candidate area was performed by feature extraction and classification using the DenseNet model. It matches results using video data, resulting in true positive values of 98.69% and 14.43 fps. Future research can modify the combination of segmentation and feature extraction methods to produce higher fps. It is because with the development of technology, of course, CCTV cameras will also produce clearer videos with more fps. Therefore, future research is still very open to improving the resulting fps for real-time processing. In addition, if the method produces a high enough fps, it can be applied for implementation with configurations through embedded system devices with CCTV cameras.

## ACKNOWLEDGMENT

We would like to thank the Kementerian Pendidikan, Kebudayaan, Riset, dan Teknologi Indonesia through the Penelitian Dosen Pemula (PDP) grant at the number of IT Tel3701/LPPM-000/Ka.LPPM/VI/2022.

**Abstract**—The field of Digital Pathology (DP) has become more interested in automated tissue phenotyping in recent years. Tissue phenotyping may be used to identify colorectal cancer (CRC) and distinguish various cancer types. The information needed to construct automated tissue phenotyping systems has been made available by the introduction of Whole Slide Images (WSIs). One of the typical pathological diagnosis duties for pathologists is the histopathological categorization of epithelial tumors. Artificial intelligence (AI) based computational pathology approaches would be extremely helpful in reducing the pathologists ever-increasing workloads, particularly in areas where access to pathological diagnosis services is limited. Investigating several deep learning models for categorizing the images of tumor epithelium from histology is the initial goal. The varying accuracy ratings that were achieved for the deep learning models on the same database demonstrated that additional elements like pre-processing, data augmentation, and transfer learning techniques might affect the models' capacity to attain better accuracy. The second goal of this publication is to reduce the time taken to classify the tissue and tumor Epithelium. The final goal is to examine and fine-tune the most recent models that have received little to no attention in earlier research. These models were checked by the histology Kather CRC image database's nine classifications (CRC-VAL-HE-7K, NCT-CRC-HE-100K). To identify and recommend the most cutting-edge models for each categorization, these models were contrasted with those from earlier research. The performance and the achievements of the proposed preprocessing workflow and fine-tuned Deep CNN models (Alexnet, GoogLeNet and Inceptionv3) are greater compared to the prevalent methods.

**Keywords**—Colorectal cancer; deep learning; CNN; tumor epithelium; Alexnet; GoogLeNet; Inceptionv3

## I. INTRODUCTION

Historically, pathologists have examined the micro-anatomy of cells and tissues under a microscope. The development of Digital Pathology (DP) imaging in recent years has given pathologists an alternative method to perform the same analysis on a computer screen [1]. The current inquiry methodologies for breast cancer include mammography, magnetic resonance imaging (MRI), and pathology examinations. The histopathological scans are recognized as a golden standard to improve the diagnostic accuracy for patients who also had other investigations, such as mammography [2]. Additionally, a histopathological examination can offer more thorough and trustworthy information to detect cancer and to evaluate, how it affects the tissues around it [3]–[5]. The new

modality, digital pathology imaging, now makes WSI (Whole Slide Imaging) a reality. Through WSI, the images may be shared, viewed on a digital display, and can be controlled/ examined on a screen [6]. Tumor architecture in Colorectal Cancer (CRC) evolves as the disease progresses [7] and is associated with patient prognosis [8]. Therefore, it is important for histopathologists to quantify the tissue composition in CRC. Inter-tumor heterogeneity and intra-tumor heterogeneity are both forms of tumor heterogeneity. By the different signals that cells pick up from their microenvironment, the tumor microenvironment (TME) really plays a significant role in the establishment of intra-tumor heterogeneity (ITH) [9]. The third most common cancer type to cause mortality is colorectal cancer (CRC), which is ranked as the fourth most common cancer [10]. In fact, treating patients and saving their lives depends on early-stage CRC diagnosis [11]. For the classification and prognostication of cancer, the study of tumor heterogeneity is crucial [12]. In-tumor heterogeneity can help to clarify, how TME affects patient prognosis and can also be used to spot new aggressive phenotypes that may be potential targets for future therapies [13]. Although most present histological analysis relies on the pathologists' subjective assessments, a critical need for automating the various processing techniques arises, that can provide good quantitative analysis and throughput of the digital pathology images for precise identification and assessment of various tumor epitheliums.

Deep convolutional neural networks (CNNs) algorithms automatically analyse images for handling classification and detection tasks, reducing the amount of manual labour necessary for the feature-extraction operations [14]. The lack of a suitably sizable annotated data set for training is a significant barrier to applying deep learning to many biological domains. Transfer learning, which makes use of deep CNNs that have already been trained on a significant amount of natural scene data, may be used to circumvent the need for sample size, nevertheless. This approach is based on the notion that the characteristics discovered by deep CNNs to identify classes in a dataset may also be useful for clinical data sets with marginally worse performance.

In medical domain there are currently three approaches in deep learning: (i). Acquiring features learned in the training phase of deep CNN with numerous natural images, then the features acquired are used for classifier training [15], [16], and [17], (ii) fine-tuning a small number of network layers are fine tuned in the pre-trained CNN on a desired data set [18], (iii)

training directly the deep CNN with real-world data. The author in [19] suggests categorizing brain tumor based on multiphase MRI scans and compares the outcomes to several deep learning structure configurations and baseline neural networks.

Based on the findings of this work, the effectiveness of identifying tumor epithelial tissues using transfer learning approaches in the area: In what ways, would fine-tuning the models in the Validation Frequency, Dropout Layer, and Classification Layer improve the classification performance, were investigated.

## II. RELATED WORKS

The classification of the different tissue types in histological images is frequently done under supervision [20]. Modern approaches for phenotyping CRC tissues under supervision can be divided into two groups: learnt methods [23,24] and methods based on texture [21]. Additionally, other efforts, like [24], integrated shallow and deep characteristics. In order to extract certain structures from image areas, hand-crafted techniques known as "texture approaches" were developed [25]. Deep learning techniques, on the other hand, have the capacity to directly learn more pertinent and sophisticated image characteristics across layers, particularly, when the relationship between both the source data as well as the expected outcomes is not known in advance. As pathological imaging activities are incredibly complex and there is little knowledge on which quantitative image properties predict the outcomes, deep learning approaches are suitable for these activities [26, 27]. In [20], Kather et al. did the primary researches to handle CRC multi-class tissue types where 5000 histological pictures were used to create a database that included eight different CRC types of tissues. Modern texture descriptors and classifiers were put to the test by J. N. Kather and colleagues. Their suggested strategy is based on a promising mix of global lower-order texture metrics along with local descriptors from GLCM and LBP. The General Purpose (GenP) approach, which Nanni et al. proposed in [24], is based on the collection of learned features, hand-crafted, and dense sampling. In their proposed method, all features were trained using SVM, and the integration were achieved using the sum rule. To differentiate between the various CRC tissue types, [28] evaluated shallow and deep characteristics. In their research, they looked at how dimensionality reduction techniques affected accuracy and computing expense. Their findings demonstrated that CNN-based features may achieve the best accuracy/dimensionality trade-off. In [29], J. N. Kather et al. created a dataset consisting of one lakh images which categorized eight tissue types using eighty-six H&E slides of CRC tissues. They evaluated the AlexNet [31,38], ResNet-50 [34], GoogLeNet [33], VGG19 [30], and SqueezeNet version-1.1 [32] pretrained CNN models. They came to the conclusion that among the five CNN models, VGG19 was the best. A novel CRC-TP database with 280K patches taken from 20 WSIs of CRC and divided into seven different tissue phenotype was proposed by Javed et al. [22]. They employed 27 cutting-edge techniques, including texture, CNN, and Graph CNN-based approaches (GCN), to categorize different tissue types. According to their test findings, the GCN performed

better than the texturing and CNN approaches. Although hand-crafted feature-based and deep learning approaches have been employed to classify many CRC tissue types, their performance still needs to be enhanced. In order to do this, deep CNN methods have been enhanced that significantly outperformed baseline results on two well-known databases.

## III. MATERIALS AND METHODS

### A. Kather-CRC-Data set

This dataset contains non-overlapping 100,000 image patches, which include histological images of healthy tissue and CRC in humans (H&E). Each image is 224x224 pixels (px), with a pixel size of 0.5 microns (MPP). Adipose tissue, background (no tissue), detritus, lymphocytes, normal mucosa, mucus, stroma, muscle, and tumor epithelium were the nine types of tissues that were chosen from their database. The NCT Biobank and the UMM Pathology Archive provided the 86 formalin-fixed paraffin-embedded (FFPE) samples from which these images were manually retrieved. The tissue samples included CRC original tumor slides and tumor tissue from CRC liver metastases. To improve variety, non-tumorous gastrectomy specimen sections were included to the normal tissue classes.

Five samples of each CRC tissue type are shown in Fig. 2 from the Kather-CRC-NCT-CRC-HE-100K database. Tenfold cross validation was performed by J. N. Kather et al. [12] (<http://dx.doi.org/10.5281/zenodo.1214456>) to assess texturing approaches. The image composition of the databases NCT-CRC-HE-100K and CRC-VAL-HE-7K is shown in Table I.

TABLE I. DATABASE COMPOSITION

Class	Number of Images in NCT-CRC-HE-100K Database	Number of Images in CRC-VAL-HE-7K Database
adipose tissue	10,407	1,338
background (no tissue)	10,566	847
debris	10,512	339
lymphocytes	11,557	634
mucus	8,896	1,035
muscle	13,536	592
normal mucosa	8,763	741
stroma	10,446	421
tumor epithelium	14,317	1,233

Fig. 1. Empty Patches in Database (b) Proposed Preprocessing Workflow.

Fig. 2. Samples from the Kather-CRC- Database [12].

### B. Preprocessing of Dataset

By removing the empty tissue patch from the dataset, extra computations have been avoided on the non-tissue regions of the slide. There are many different techniques to evaluate an image's contrast. In deep learning, the standard deviation of an image's pixels or a region of an image is commonly referred to as contrast in equation (1) and (2).

$$\sqrt{\frac{1}{3rc} \sum_{i=1}^r \sum_{j=1}^c \sum_{k=1}^3 (X_{i,j,k} - \bar{X})^2} \quad (1)$$

where  $\bar{X}$  is the mean intensity of the entire image:

$$\bar{X} = \frac{1}{3rc} \sum_{i=1}^r \sum_{j=1}^c \sum_{k=1}^3 X_{i,j,k} \quad (2)$$

compute the LCN as proposed in [18] which is given in equation (3)

$$V_{i,j,k} = X_{i,j,k} - \sum_{i,p,q} w_{pq} X_{i,j+p,k+q} \quad (3)$$

Where  $w_{pq}$  is the Gaussian waiting window.

The RGB colour scheme of the low-resolution image was changed to LAB colour space before applying OTSU's threshold. After thresholding, binary morphological techniques were carried out to assist in the accurate patch extraction at small tissue regions and tissue borders. Fig. 1(a) shows few

samples of empty patches available in the database and Fig. 1(b) shows the proposed preprocessing flow for preprocessing the database. Even after separating the tissue region there is a chance of extracting patches with no information. So, one more step of patch optimization has been added to discard empty patches as shown in Fig. 1(b).

### C. CNN Architectures

Three of the most powerful fine-tuned CNN architectures, Alexnet, GoogLeNet, and Inception-v3 have been tested. Pre-trained models have been employed in this instance that was developed using the Kather-CRC-database [12].

#### D. Alexnet

The architecture is made up of eight layers: five convolutional layers and three fully connected layers. However, this is not what distinguishes AlexNet from other convolutional neural networks; rather, they are some of the characteristics that are employed. AlexNet uses Rectified Linear Units (ReLU) in place of the tanh function, which was referred as the industry standard. ReLU outperforms Tanh in terms of training velocity. A CNN utilizing ReLU was able to achieve a 25% error on the CIFAR-10 dataset six times quicker. CNNs frequently "pool" the outputs of neighboring neural groups without any overlap. However, after adding the overlapping, the error was reduced by roughly 0.5%, and it was shown that models with overlapping pooling are often more difficult to overfit. Overfitting was a serious concern for AlexNet.

#### E. GoogLeNet

The primary design of GoogLeNet [25] enhances computational capabilities inside the network model to encompass inception layers with the goal of minimizing complexity. By adding 1x1 convolutional layers to the network and using a different kernel, it not only enhances the depth but also the width of the architectural approach. In order to capture sparse correlation patterns, this lowers the number of computing levels

#### F. Inception-v3

The third iteration of the Inception networks family, which was initially introduced in [27], is known as Inception-v3 [34]. Inception block uses stacked 1x1 convolutions to reduce dimensionality, enabling fast computing and deeper networks. Unlike previous CNNs, which stacked kernel filter sizes sequentially, Inception architectures run several kernel filters with varying size on the same level. Making the networks larger rather than deeper is meant by this. The authors in [22,23] depicts the architecture of Inception-v3, which differs from the original Inception versions in a number of ways. These enhancements include propagating label information further down the network via an auxiliary classifier, factorized 7x7 convolutions, and label smoothing.

#### G. Fine-Tuning of Selected Models

Fine-tuning is a transfer learning concept in which information gained via training with one kind of difficulty is applied to training with another similar task or area [35]. The initial layers of deep learning algorithms are instructed to identify task-specific traits. The transfer learning phase is used

to remove few final layers of learnt network which can then be retrained with better task specified layers. Even if fine-tuned learning trials involve some learning, they nonetheless proceed far more quickly than learning from beginning [36]. Additionally, compared to models created from scratch, they are more accurate.

Data augmentation was used to fine-tune CNN Alexnet, Inceptionv3, GoogLeNet, and architecture using the Nct-Crc-He-100k and CRC-VAL-HE-7K datasets. The pretrained model has undergone the following adjustment.

1) The overfitting is greater if the size of the target data set is smaller and more comparable to the size of the training data set. The amount of overfitting that necessitates fine-tuning the data set for the pre-trained model is minimal if the target data set is bigger and comparable in size to the training data [37]. Therefore, a dropout layer has been added with probability 0.6 to the network to replace the final dropout layer, "pool5-drop 7x7 s1," which will randomly set certain features to zero.

2) Frequency can be modified based on the number of images allocated for training as follows.

$$\text{Validation Frequency} = \left\lfloor \frac{\text{Number of Images}}{\text{Batch Size}} \right\rfloor$$

3) The models were developed and then loaded with ImageNet pre-trained weights. As a result, a new fully-connected layer was developed in order to conduct the classification layer.

#### IV. EXPERIMENTAL RESULTS

##### A. Experimental Setup

The main components of the hardware environment are an Radeon RX 550X video card and an Intel Core i7-85650 CPU with 16 GB of RAM. Matlab R2020a is the software environment for language programming on a Windows 10 computer.

##### B. Dataset

To evaluate the fine-tuned pretrained model, two databases have been used: CRC-VAL-HE-7K and NCT-CRC-HE-100K. The bigger dataset of 100,000 non-overlapping image patches, NCT-CRC-HE-100K, and the smaller dataset of 7180, CRC-VAL-HE-7K, were chosen for testing. The comparison criteria used are displayed in Tables II and III. A total of 40% of the images in each dataset were used as the training set, 20% as the validation set, and 40% as the testing set.

##### C. Discussion

In the area of machine learning for image processing, deep learning models have prevailed. The possibility to extend the study and application to the identification and categorization of tumor epithelium in high resolution images is presented by

advancements in deep learning and image processing. However, the main problem with high quality images is training time.

TABLE II. PARAMETER VALUES TAKEN FOR COMPARISON (NCT-CRC-HE-100K DATABASE)

Fields	Size
Number of Classes	9
Dropout Probability	0.8 Vs pretrained models
Batch size	64
Epoch	15
Iterations	9360
Learning rate	1e <sup>-05</sup>

TABLE III. PARAMETER VALUES TAKEN FOR COMPARISON (CRC-VAL-HE-7K DATABASE)

Fields	Size
Number of Classes	9
Dropout Probability	0.4 Vs pretrained models
Batch size	64
Epoch	15
Iterations	660
Learning rate	1e <sup>-05</sup>

TABLE IV. TRAINING, VALIDATION AND TESTING ACCURACY OF NCT-CRC-HE-100K DATABASE

(Batch size = 64, Iterations = 9360, Learning rate = 1e<sup>-05</sup>, Epoch = 15)

Model	Training Acc. (%)	Validation Acc. (%)	Training Loss	Testing Acc. (%)	Testing Loss
Alexnet	95	95.03	0.42	94.5	0.39
GoogLeNet	95	94.08	0.38	94.3	0.29
InceptionV3	98	97.79	0.21	97.42	0.25

TABLE V. TRAINING, VALIDATION AND TESTING ACCURACY OF CRC-VAL-HE-7K DATABASE

(Batch size = 64, Iterations = 660, Learning rate = 1e<sup>-05</sup>, Epoch = 15)

Model	Training Acc. (%)	Validation Acc. (%)	Training Loss	Testing Acc. (%)	Testing Loss
Alexnet	93	93.18	0.51	93.2	0.43
GoogLeNet	92	91.36	0.59	91.4	0.7
InceptionV3	89.4	89.57	0.71	89	0.73

The deep learning architectures are adjusted in accordance with Section 3.G's instructions. Fig. 3 to 7 displays the experiment's findings. The accuracy and dropout probability of deep learning models (Alexnet, GoogLeNet and Inceptionv3) are shown in Fig. 3 and 4. For the pretrained model the default dropout parameter is 0.5 and it has been adjusted to 0.4 (for small dataset) and 0.8 (for large dataset) which is shown in Fig. 3 and 4. Therefore over fitting issue is properly handled using the dropout parameter which results good in both training set and the validation set. As the validation frequency has been generalized based on the size of the database, the batch loss and validation loss are very less which is shown in the Fig. 5, 6 and 7. Based on the above adjustments, all the models' accuracy increased after 15 epochs.

TABLE X. TRAINING TIME FOR FINE-TUNED MODELS

Models	Training Time CRC-VAL-HE-7K Database in Seconds		Training Time CRC-VAL-HE-7K Database in Seconds	
	No preprocessing	Proposed preprocessing	No preprocessing	Proposed preprocessing
Alexnet	3060	2564	307380	256897
GoogLeNet	8520	6295	83880	51520
Inception V3	41520	11265	110735	92545

The validation accuracy of the proposed finetuned Alexnet is better when compared to the validation accuracy proposed in [38]. The later achieved 91.8% accuracy with 25 epoch whereas this work achieved 93.18 % (Table V) and 95.03 (Table IV) in 15 epochs using the same database. The author in [39] claimed, that the network they developed, SCDNet, achieved an accuracy of 96.91% which is 4% more than the pretrained inception v3 model. The proposed fine-tuned inceptionv3 model achieves 97.79% accuracy which is better when compared to SCDNet. Additionally, as shown in Fig. 5 to 7, good accuracy results were obtained for all the chosen models even after the 30th training iteration with much reduced batch and validation loss.

GoogLeNet and Inceptionv3 models regularly outperform Alexnet among the three models chosen. Tables VI, VII, VIII, and IX shows the accuracy of nine tissue classes mentioned in Table I. As shown in Tables VI, VII, VIII, and IX, the accuracy of the tumor epithelium classification is higher in inceptionv3. Table X shows the training time required to execute the finetuned models based on the experimental setup. As indicated in Table X, training time has been reduced by at least 30% using the suggested preprocessing workflow. Overall, Alexnet fared badly, having the least accuracy and having the largest batch and validation loss, whereas finetuned inceptionv3 performed well, having the highest accuracy and the lowest batch and validation loss.

## V. CONCLUSION

A workflow has been suggested to preprocess the dataset in this article. Additionally, the most advanced deep convolutional neural network for classifying tissues and tumor epithelium is being tuned and evaluated. The architectures under consideration are Inceptionv3, GoogLeNet, and Alexnet. According to the experiment, Inceptionv3 tends to provide a cogent accuracy increase with increasing epochs, without showing any signs of overfitting or performance degradation. Additionally, Inceptionv3 performs better in classification exhibitions with few parameters and fair processing time. Inceptionv3 outperforms the other architectures with a test accuracy score of 97.42% for the 15 epoch. Thus, Inceptionv3

is a promising design for the goal of identifying tumor epithelium. The proposed parameters can be extended with other pretrained models and the performance can be compared with the parameters F1-score, AUC, Recall and Precision. Also, a new generalized Deep CNN model can be designed which satisfies the proposed adjustment parameters.

**Abstract**—Based on the advancement in the field of Artificial Intelligence, there is still a room for enhancement of student university retention. The main objective of this study is to assess the probability of using Artificial Intelligence techniques such as deep and machine learning procedures to predict university student retention. In this study a variable assessment is carried out on the dataset which was collected from Kaggle repository. The performance of twenty supervised algorithms of machine learning and one algorithm of deep learning is assessed. All algorithms were trained using 10 variables from 1100 records of former university student registrations that have been registered in the University. The top performing algorithm after hyper-parameters tuning was NuSVC Classifier. Therefore, we were able to use the current dataset to create supervised Machine Learning (ML) and Deep Learning (DL) models for predicting student retention with F1-score (90.32 percent) for ML and the proposed DL algorithm with F1-score (93.05 percent).

**Keywords**—Artificial intelligence; machine learning; deep learning; retention; student; prediction

## I. INTRODUCTION

To begin with, Neural Networks remained extensively recognized as Artificial Neural Networks. A construction similar to the biological neurons implementation, with a learning configuration grounded on probability that gets input data to make a decision on an output. Texts, images and audio files are examples of input data. Deep Learning (DL) employs artificial neurons to work on high dimensional data. DL can accomplish tasks including information processing and communication patterns [1, 2, 3].

Fig. 1 exemplifies the rudimentary structure of Neural Networks, beginning with the first layer called the input and the last one is the output with the middle layers as the hidden layers therefore the name “deep”. With additional research, and with the implementation of backpropagation, the structure was enhanced. The algorithm of backpropagation has two

phases, the first one is for the input to forward the data in the direction of the output, the second one is to assess and approximate the error and back-propagating error values to the neural networks for correcting the error.

Fig. 1. Structure of Neural Networks

Every node in is an attribute pulled out from the portion beforehand. The count of neurons in a layer differs for every system, as c of the neuron in every layer should be capable of capturing the vital layer. The first layer of the model is usually high in terms of the count of neurons [4, 5].

DL defines an entirely new area of research with the architecture that has solved many of the problems that existed in the traditional systems in which the model was used for definite usage or exact commands [6].

DL was capable of a more unified model that could be useful on many applications in addition to diverse users. The structure of DL can be applied on numerous applications, like Google Assistant which can be implemented in mobile devices (Android), moreover can be implemented in search engines (Google) in addition to being applied on home devices (Google Home), and likewise employed in video captioning like video captioning on the YouTube [7, 8].

In this paper, some data classification techniques are applied to the evaluation of the dataset to predict whether students will continue to attend university or not by finding

the best classification technique in accordance with these measures: F1-score, Accuracy, Precision, Recall, and time performance.

We used 20 machine learning algorithms to predict whether students will continue to attend university or not. Furthermore, a deep learning model was proposed for the same purpose.

The aim of this study is to answer the following questions:

- Can we use the dataset at hand to create a supervised machine learning classifier to predict reliably whether a student will go to university or not?
- Can we use the dataset at hand to create a supervised Deep learning classifier to predict reliably whether a student will go to university or not?
- Would the performance of Deep Learning techniques be better than the machine learning techniques in this case?

## II. MACHINE LEARNING ALGORITHMS

Machine learning algorithms can be applied to solve multiple problems. Classification can be used to assign a category to items or answer “yes” or “no” questions. An example of a classifier is a program that categorizes news articles or a spam filter that answers the question “spam” or “not spam”. Regression algorithms can be used to predict values for items such as housing prices. Ranking can be used to order items according to a criterion and clustering can be used to partition items into homogeneous regions [9, 10, 11, 12, 13].

A decision tree is an example of a machine learning algorithm. Decision trees contain a root with a question. The root has branches to more nodes with questions and each path of nodes and branches ends with a leaf containing a label. The tree is traversed by taking decisions at each node based on the question until a leaf is found and the label for the leaf is returned as the answer to the root question [14, 15, 16].

Ensemble learning methods are boosting algorithms that combine several weak learners into a single strong learner. One example of a boosting algorithm, AdaBoost [17], builds this strong learner from several weak learners by making the

next learner focus on improving the mistakes of the previous learner. The learners are assigned weights by the algorithm after each iteration and the weights are used to merge the weak learners into a strong learner [18, 19].

Linear models predict values by seeking a hypothesis of a hyperplane that has the smallest outcome of an error function. The linear model has to predict the value of  $y$  for the input value  $x$ . Using a set of known inputs  $x$  and labeled output values  $y$  a model is evaluated which has the smallest error, in this case distance of the line from the points in the graph. The model with the smallest error is represented as a line passing through the points. New input values  $x$  can then have their output values  $y$  predicted using the model by inspecting where the line meets the input value  $x$  on the  $y$  axis. Linear models such as Logistic Regression can also be used to solve classification problems [20, 21, 22, 23, 24].

Support Vector Machines (SVM) can be applied to both regression and classification problems. SVMs seek to find a hyperplane which has the maximum margin from all inputs in the training set. SVMs differentiate and improve upon Linear Models with a better error or loss function. SVMs can be even more improved upon with the use of kernels to define non-linear decision boundaries [25, 26, 27, 28].

In addition to the aforementioned algorithms, a great deal of other algorithms exist. K-Nearest-Neighbor considers neighboring objects in the dataset to train a better model [29]. Naive Bayes (NB) algorithms use Bayes’ theorem to compute conditional probabilities [30]. Discriminant Analysis classifies objects in a dataset by identifying the best feature to discriminate between classes [31, 32].

## III. METHODOLOGY

In this section we will give details of the data collection, preparation, feature analysis, data splitting, modeling the proposed deep learning algorithm, training, validating and testing all the algorithms used in this study(as shown in Fig. 22).

### A. Dataset

The dataset was collected from Kaggle depository. The dataset consists of 11 features and contains 1000 records. Table I lists all the features available from the dataset.

TABLE I. A LIST OF AVAILABLE FEATURES

Feature	Type	Description
Type-school	object	Academic or Vocational
School-accreditation	object	A or B
Interest	object	Very Interested, Uncertain, Less Interested, Quiet Interested, Not Interested
Average-grades	numeric	75% to 98%
Gender	object	Male or Female
Residence	object	Urban, Rural
Parent-age	numeric	40 to 65 years
Parent-salary	numeric	1,000,000 to 10,000,000
House-area	numeric	20..120
Parent-was-in-university	Boolean	True or False
In-university	Boolean	True or False

B. Feature Analysis

1) *Correlation matrix*: The highest in negative correlation will be parents-was-in-university – parent-age, and with positive is parent-salary – in-university, house-area – in-university and average-grades – in-university as illustrated in Fig. 2.

2) *Histogram for distribution*: Fig. 3 shows the distribution of the features: parent-age, parent-salary, house-area, and average-grades.

3) *Density plot for distribution*: Fig. 4 illustrates the density plot distribution for parent-age, parent-salary, house-area, and average-grades. The overall distribution looks a little bit normal.

4) *Outliers*: Fig. 5 does not show so many outliers, so my decision is to keep it without further cleaning.

5) *Residence count based on university status*: Overall the Urban is more likely to go to university and the opposite happens in Rural as shown in Fig. 6.

Fig. 2. Correlation Matrix.

Fig. 3. Histogram for Distribution.

Fig. 4. Density Plot for Distribution.

Fig. 5. Outliers of the Parent-Age, Parent-Salary, Average Grades, and House-Area.

Fig. 6. Residence Count based on University Status.

Fig. 7. Residence with Parent Salary based on University Status.

6) *Residence with parent salary based on university status*: Fig. 7 illustrates that the higher the salary the more likely to go to university for both Urban and Rural.

7) *Interest count based on university status*: From Fig. 8, Very Interested and Uncertain Interest are the two most categories attending the university, and Less Interested is the most in the category who does not attend the university.

Fig. 8. Interest Count based on University Status.

8) *School type count based on university status:* Fig. 9 show that the Academic is the most in the category who attended the university.

Fig. 9. School Type Count based on University Status.

9) *Gender count based on university status:* From Fig. 10, females are slightly higher to attend the university than Males.

Fig. 10. Gender Count based on University Status.

10) *Parent age, residence and parent-was-in-university:* Fig. 11 illustrates that urban parents was slightly higher to attend the university than rural parents.

Fig. 11. Parent Age, Residence and Parent-was-in-University Relation.

11) *Parent salary, residence and parent-was-in-university:* Fig. 12 show that rural parents were higher salary and not attended to university and the opposite for urban parents.

Fig. 12. Parent Salary, Residence and Parent-was-in-University.

12) *Parent salary, residence and in-university:* The more salary in both Rural and Urban parents the more likely for their child to attend the university as can be seen in Fig. 13.

Fig. 13. Parent Salary, Residence and in-University.

13) *House-area, residence and in-university:* The more house area in both Rural and Urban the more likely for a child to attend the university, that's means by logic the family has more salary overall as can be seen in Fig. 14.

Fig. 14. House-Area, Residence and in-University.

14) *Average-grades, gender and in-university*: The more average grades in both males and females the more likely to attend university as shown in Fig. 15.

Fig. 15. Average-Grades, Gender and in-University.

15) *Average-grades and in-university*: The higher on average grades the more likely to attend the university as in Fig. 16.

Fig. 16. Average-Grades and in-University.

16) *Parent-age and in-university*: Not so much effect by the age of parents for a child to attend the university as in Fig. 17.

Fig. 17. Parent-Age and in-University.

17) *Parent- salary and in-university*: From Fig. 18, the higher on a parent's salary the more likely for the child to attend university.

Fig. 18. Parent- Salary and in-University.

18) *House-area and in-university*: From Fig. 19, it can be seen that the higher the house area the more likely for the child to attend university.

Fig. 19. House-Area and in-University.

19) *Converting categorical column to numeric ones*: We have converted the categorical type features (type-school, school-accreditation, gender, interest, residence, parent-was-in-university, and in-university) to numeric values.

20) *Class (in-university) Distributions*: We checked whether the class (in-university) is balanced or not. It turned out to be balanced as shown in Fig. 20.

C. Dataset Splitting

We have split the current dataset into three datasets: Training, validating, and testing datasets. The ratio of splitting was (80%, 10%, 10%).

Fig. 20. Class (in-University) Distribution.

D. Description of the Algorithms used in this Study

There are many algorithms of Machine Learning that can be applied for the prediction of whether the student continues to attend university or not. We have trained, validated and tested 20 various ML algorithms on our current dataset. The algorithms that were used for prediction and analysis are from different categories of machine learning algorithms to predict whether students will continue to attend university or not.

Furthermore, a deep learning model was proposed to predict whether students will continue to attend university or not. The proposed DL model consists of 6 Dense layers: one input layer (10 features), 4 hidden layers (128, 64, 32, and 16 neurons), and one output layer with 2 classes and softmax function as shown in Fig. 21.

IV. RESULTS AND DISCUSSION

A. Performance Evaluation

We used the most popular performance measures for machine and deep learning algorithms such as: precision, recall, accuracy, and F1-score as outlined in eq. 1, 2, 3, and 4.

$$\text{Accuracy} = (\text{TP} + \text{TN}) / (\text{TP} + \text{TN} + \text{FP} + \text{FN}) \quad (1)$$

$$\text{Precision} = (\text{TP} / (\text{TP} + \text{FP})) \quad (2)$$

$$\text{Recall} = (\text{TP} / (\text{TP} + \text{FN})) \quad (3)$$

$$\text{F1-score} = 2 \times (\text{Precision} \times \text{Recall}) / (\text{Precision} + \text{Recall}) \quad (4)$$

Where TP = True Positive, TN = True Negative

FP = False Positive, FN = False Negative

B. Performance of used Algorithms

We used a group of machine learning and one proposed deep learning algorithm for the prediction of whether a student will continue to attend university or not.

The machine learning algorithms belong to different categories of machine learning like Naïve based, SVM, KNN, trees, analysis, and others [28-30]. The proposed deep learning algorithm is custom made for the prediction if a student will continue to attend university or not.

We have split the dataset into Training, Validating, and Testing. We have trained every algorithm individually using our training dataset, tested it and we made a record of its

accuracy, recall, F1-score, precision, and time needed for training and testing.

Furthermore, we have trained the proposed deep learning algorithm using the same training dataset and cross-validated it using the validating dataset. We kept training the proposed DL algorithm until there was no room for improvement. We made a record of the DL algorithm accuracy, recall, F1-score, precision, and time needed for training, validating and testing. Part of the DL algorithm training, validating accuracies and losses are shown in Fig. 23.

It turned out that the best Machine Learning algorithm was NuSVC for predicting whether students will continue to attend university or not.

NuSVC (Nu-Support Vector Classification) belongs to the family of Support vector machines (SVM). SVM can be used in classification problems as well as regression problems. SVC (C-Support Vector Classification): Support vector classification, based on libsvm, the time complexity of data fitting is the second power of the data sample, which makes it difficult to expand to 10,000 dataset, when the input is multi-category (SVM was originally to deal with two classification problems), through a one-to-one solution, of course there are other solutions.

NuSVC core support vector classification, similar to SVC, is also implemented based on libsvm, but the difference is the number of support vectors through a parameter null value.

Fig. 23. Training vs Validation Losses and Accuracies.

NuSVC model achieved F1\_score (90.32%), Accuracy (91.00%), Recall (92.31%), Precision (88.42%), time required for training and testing (0.05 second) as can be seen in Table II.

Additionally, the proposed DL algorithm scored: Accuracy (93.23 percent), F1-score (93.05 percent), Recall (93.22 percent), Precision (92.55 percent), and time necessary for testing (0.67 second) for predicting whether student will continue to attend university or not as can be seen in Table III.

The first aim of this study was to answer the following question: Can we use the dataset at hand to create a supervised

machine learning classifier to predict reliably whether a student will go to university or not? The answer for this question is yes, we were able to create a supervised machine learning algorithm and F1-score accuracy was 90.32%.

The second aim of this study was: Can we use the dataset at hand to create a supervised Deep learning classifier to predict reliably whether a student will go to university or not?

The answer to this question was also yes and achieved an F1-score of 93.05%.

TABLE II. PERFORMANCE OF THE MACHINE LEARNING ALGORITHMS

Machine Learning Model-Name	Accuracy	Precision	Recall	F1_score	Time-in-Sec
NuSVC	91.00%	88.42%	92.31%	90.32%	0.05
RandomForestClassifier	90.00%	90.00%	90.00%	90.00%	0.19
GradientBoostingClassifier	89.50%	87.23%	90.11%	88.65%	0.14
LogisticRegressionCV	88.00%	83.84%	91.21%	87.37%	0.31
QuadraticDiscriminantAnalysis	87.50%	83.00%	91.21%	86.91%	0.01
MLPClassifier	87.50%	84.38%	89.01%	86.63%	0.68
LogisticRegression	87.00%	82.18%	91.21%	86.46%	0.01
LGBMClassifier	87.50%	85.87%	86.81%	86.34%	0.08
LinearSVC	86.50%	81.37%	91.21%	86.01%	0.01
CalibratedClassifierCV	86.50%	81.37%	91.21%	86.01%	0.06
LinearDiscriminantAnalysis	86.50%	82.65%	89.01%	85.71%	0.01
AdaBoostClassifier	86.00%	80.58%	91.21%	85.57%	0.10
GaussianNB	86.50%	84.04%	86.81%	85.41%	0.00
BaggingClassifier	86.50%	84.04%	86.81%	85.41%	0.05
Perceptron	85.00%	79.05%	91.21%	84.69%	0.01
SGDClassifier	84.50%	81.25%	85.71%	83.42%	0.01
KNeighborsClassifier	84.00%	84.71%	79.12%	81.82%	0.01
LabelPropagation	83.50%	82.22%	81.32%	81.77%	0.03
ExtraTreeClassifier	81.50%	78.12%	82.42%	80.21%	0.01
DecisionTreeClassifier	80.50%	74.53%	86.81%	80.20%	0.01

TABLE III. PERFORMANCE OF THE PROPOSED DEEP LEARNING ALGORITHM

Deep Learning Model-Name	Accuracy	Precision	Recall	F1_score	Time-in-Sec
Proposed DL Model	93.23%	92.55%	93.22%	93.05%	0.67

The last aim of the study was: Would the performance of Deep Learning techniques be better than the machine learning techniques in this case?

The answer is yes, because the deep learning algorithm scored 93.05% in F1-score while the machine learning algorithm achieved 90.32%.

#### V. LIMITATION OF THE STUDY

The current study is limited in terms of the dataset collected where it consists of 11 features (10 input features and one output feature) and 1100 records only. Furthermore, the current study is limited in terms of ML algorithms used, where we used only 20 ML algorithms among many as indicated in Table II.

#### VI. CONCLUSION AND FUTURE WORKS

In this study, we used twenty Machine Learning algorithms and a deep learning algorithm for predicting whether students will continue to attend university or not. The dataset was collected from Kaggle Repository. In order to predict whether students will continue to attend university or not, a group of 20 machine learning and one deep learning algorithm were used. Among the machine learning models used, the best machine-learning algorithm was NuSVC for predicting whether students will continue to attend university or not. NuSVC model achieved F1-score (90.32 percent), Accuracy (91.00 percent), Recall (92.31 percent), Precision (88.42 percent), time required for training and testing (0.05 second). Furthermore, the proposed DL algorithm attained: F1-score (93.05 percent), Accuracy (93.23 percent), Recall (93.22 percent), Precision (92.55 percent), time required for training and testing (0.67 seconds) for predicting whether student will continue to attend university or not.

In future work, other methods of ML algorithms may be utilized and the deep learning model should be tuned further to get better performance.

**Abstract**—This study aims to provide a comprehensive source of knowledge regarding aviation accidents in Indonesia caused by human factors, which are the most significant among other causative elements, requiring a detailed assessment of the accident as a result of pilot and co-pilot faults while operating the aircraft. The KNKT website database is still in the form of accident reports. To this end, the retrieved information based on historical data for 23 years of accidents caused by humans by analyzing the data using the clustering approach to gain data insight in the relationship between total flying hours and pilot licenses. The data analysis revealed that, in general, the aircraft operator complied with the CASR standards.

**Keywords**—Aviation accidents data; pilot's licenses; flying hours; human factor

## I. INTRODUCTION

The advancement of technology, particularly in the transportation industry, is usually swift; and one mode of transportation is nearly numbered one in aviation. Due to the relatively rapid time efficiency, security, and safety, aircraft make it easier for individuals to travel between provinces and across nations [1]. However, using this mode of transportation has been associated with a great risk of accidents [2][3]. Several studies on aviation risk have been conducted, especially those related to flight crews [4] [5].

Human casualties, environmental damage, property loss, and psychological impacts are all losses caused by plane crashes. According to Article 3 paragraph (1) of The Minister of Transportation (Indonesia) Regulation No. 77 of 2011, compensation for passengers who perished in aviation accidents amounted to Rp. 1,250,000,000 (one billion two hundred and fifty million rupiahs) per passenger, which is paid to the heirs of the deceased [6]. According to study [3] [7], four elements are found responsible for plane accidents: human factors, environmental factors, facility issues, and engineering considerations. Human factors affecting pilots and co-pilots, aviation security officials, and poor aircraft maintenance staff are among the four. This is followed by environmental conditions such as dense clouds, heavy rain, high winds, and mountains. The properties of the runway and the potential risk of animals being found on it contribute to the facility issues mentioned. Finally, engineering factors are associated with the

type of engine utilized as well as aircraft and engine maintenance.

According to study [7], statistics on aviation accidents and incidents in Indonesia gathered from the National Transportation Safety Committee (KNKT) show 26 significant incidents and 15 accidents between 2010 and 2016. There has been a 20% distribution of all events in the last seven years, and several factors were found responsible for such events. The percentage calculation of various causal elements, such as human factors (67.12 percent), technical factors (15.75 percent), environmental factors (12.33 percent), and facilities (4.79 percent) was obtained from the research. Given this context, investigators looked into whether human factors were still relevant after 2016, where to analyze data from the same sources between 2017 and 2020, which revealed that human factors were still the dominant factor in accidents and incidents, accounting for 52.6 percent of all accidents and incidents. This percentage represents a decrease of approximately 14.52 percent from the previous data.

Furthermore, a preliminary experiment was conducted using the same data provided by the KNKT (1997-2020), and using the same approach it was found that the human component still played a role in accidents 23 years ago with a percentage of 46.5 percent [7] [8]. Consequently, if the pilot's performance does not meet the criteria, does not correspond to a standard operating procedure (SOP), or does not correspond to the flying hours, the passenger will be at risk. As a result, the requirements to become a pilot must be understood, of which their license is the most important.

According to [8], the terms of the pilot's license are based on total flight hours under the provisions of the Civil Aviation Safety Regulation (CASR). There are four main licenses in aviation. For a prospective pilot to fly while they are learning, one must receive a Student Pilot License (SPL). When the pilot's flight hours increase, the pilot gets a Private Pilot License (PPL) with a minimum standard flight duration of 50 hours. To earn a Commercial Pilot License (CPL), a minimum standard flight duration of 150 hours must be met, and to obtain an Airline Transport Pilot License (ATPL), a minimum total flight duration requirement of 1500 hours must be met.

\*Corresponding Author.

An airline must determine the pilot in charge of flying a commercial aircraft far before the day of departure. What concerns us here is whether accident data from 1997 to 2020 contains improper pilot assignments due to licenses that were inappropriate for flying commercial aircraft flown, which may have led to the accidents. This issue is investigated to uncover the same. To this end, the retrieved information based on historical data for 23 years of accidents caused by human factors by analyzing the KNKT data using the clustering approach to gain data insight based on the variables' total flying hours and pilot licenses. Based on the description above, it is important to categorize total flight hours and pilot licenses such that they may be considered objects with characteristics to analyze.

A structural and hierarchical approach is required to address the research question, categorizing data based on pilot licenses who have encountered accidents or incidents. The agglomerative hierarchical clustering (AHC) method helps generate output in the form of a hierarchical structure that can provide an overview of data comprehensively. AHC is a bottom-up method wherein each data point is initially its own cluster, and as one ascends the hierarchy, additional clusters are amalgamated. In this method, the two neighboring clusters are merged into a single cluster. With this advantage, it allows for the researcher to identify hidden data from clusters so that they may view the distribution of the data and identify whether there are pilots in the KNKT data who have total flight hours.

This research only focuses on archival data of official aircraft accident reports issued by the KNKT Institute and finds out whether the human factor (pilot) shows a correlation with the cause of the accident. While factors outside the discussion are the limitations of this paper.

The structure of the presentation of this research is as follows: Section II describes the materials and methods used; Section III presents the results and discussion; and the conclusions are presented in Section IV.

## II. MATERIALS AND METHOD

### A. Materials

Researchers used credible and public data sources to obtain information on aviation accidents in Indonesia via the KNKT website database, which is still in the form of accident reports. This collection of accident reports is available on the website, organized by the year of the accident. The report data for each accident includes information on the event's timeline, the pilot's identity, and detailed information regarding the aircraft involved. However, as the data have not been integrated into a unified tabular format, researchers must consolidate accident data into a single database to simplify the analysis.

The researchers only used 341 data points from Indonesian aircraft accidents that occurred between December 19, 1997, and September 15, 2020, accounting for the completeness of each data point. The collected data is then analyzed to produce cluster results and conclusions regarding the link between two factors in an aircraft disaster.

### B. Method

The methodology carried out in this research process is described within a research framework, which is illustrated in Fig. 1.

Fig. 1. Research Framework.

The first step of conducting any work of research is to develop a research topic. In making this research inquiry, the goal is to construct a question that is clear, focused, and free of prejudice. This is followed by providing a literature review to comprehend the context of the topic sufficiently. A literature review allows the researcher to construct questions that express the concepts and problems to be explored, also informing the public of the relevance of the outlined issues, which are beneficial to society once addressed, furthering scientific development.

In the second phase of the research, the data used in this study is explained in the previous sub-chapter; data from KNKT about aviation accidents in Indonesia have been used. Data collection of accidents is carried out and then put together into a spreadsheet. Researchers collect essential and relevant information and arrange them in the chronology of accidents. The data collected from accident reports have 16 variables, which include the date, year, province, location, aircraft type, aircraft operator, crew, passengers (PAX), injured, fatalities, type of accident (A/I), flight phase (POA), cause of the accident (PCOA), total pilot's flight hours, type of pilot's license and remarks, altogether culminating in 341 lines of data. After data collection, information is saved with the file extension .csv and imported into the Jupyter notebook program for data analysis.

The third stage is data preparation, which includes multiple processes such as data cleaning, data integration, data transformation, and data reduction. This step involves loading the data into the Jupyter notebook. Data processing is performed, followed by a data cleaning process, which includes the selection of the required variables. Following identification of the required variables, data that includes null or empty values will be cleaned up and outliers in the data will be verified and removed in case they impact the data balance.

The next stage in this study is data transformation. The encoder label is applied in the pilot license variable column to change the data from category to numeric. Furthermore, data reduction will complete the standard scaler procedure at this step, which is required to normalize the value of the variable column of total flight hours and pilot license. Data will be visualized using EDA after completing the data pretreatment stage as part of the pre-modeling phase to display variable data such as total flying hours and pilot licenses, following which, the clustering method is employed for analysis.

The researchers adopted the AHC approach at this stage. This clustering method is divided into several sub-methods for the calculation of proximity between clusters. Researchers only use three methods, which are single-linkage (Closest distance), complete linkage (Farthest distance), and average linkage (Average distance). It then uses Euclidean calculations to compute distance and the silhouette index to estimate the ideal number of clusters. Two variables are employed in this grouping: total flight hours and pilot's license, which will be clustered to determine the link between the two and the frequency of accidents that occur as a result.

Following the above mentioned procedure, a validation test on the number of each cluster found is required to select the best approach. This selection will be based on the value of the validation test index that has a satisfactory performance by analyzing the distribution of the data for each cluster. This is followed by an analysis of research questions based on the relationship between the two variables used, namely total flight hours and pilot license. The method is then evaluated for selection.

The final stage is the conclusion, which will include the results of the AHC method, which involves a validation test value that meets the criteria with the number of clusters used. The results are bound to demonstrate whether or not a relationship relevant to the research question can be established. Furthermore, significant insights will be discovered in the form of information due to the preceding stage's clustering and data distribution.

### III. RESULT AND DISCUSSION

#### A. Data Preparation

Researchers execute variable filters on this preparation data used in this investigation. It is known that there are 16 variables from raw data; however, in this study procedure, only two variables are employed, while the remaining variables are not used. Both variables, total flight hours and pilot's license are utilized.

#### B. Data Preprocessing

The data on aviation accidents in Indonesia from 1997 to 2020 were collected using the date of the accident reports on KNKT websites. The first step is to erase the missing data values in the variable column used, particularly the total flight hours and pilot's license. After deletion, the total data collected was 177 out of 341 reports. The second procedure is to remove outliers - data with distinctive features that appear different from other data. After removing missing data values, outliers acquired 156 data points from a total of 177 data points.

TABLE I. DATA BASED ON PILOT'S LICENSE

No.	Pilot Licenses	Numbers of Data
1	ATPL	99
2	CPL	45
3	SPL	8
4	PPL	4

Data that has already been cleaned will be transformed into a suitable form for processing. The first step is to examine the various types of pilot licenses including ATPL, CPL, SPL, and PPL. The results are shown in Table I, with data from four pilot licenses.

This step is followed by the creation of an encoder label for the type of pilot license. ATPL (0), CPL (1), PPL (2), and SPL (3) are the designations for each type of license. In this study, data reduction is used to reduce dimensions in data so that later on, data will be comprehensive; this would also retain the integrity of the data as much as possible. This reduction data strategy is a standard scaler that seeks to normalize the data so that massive variations may be avoided. It is used in this study to standardize the variables - total flight hours and pilot's license value.

#### C. Descriptive Statistics

Following the completion of the data preparation stage, descriptive statistics of the data were used as an additional tool within the data processing stage before proceeding to the data visualization stage. This study employs two types of variables: quantitative and qualitative data variables. The quantitative data variables in this study are variables with numerical numbers - the total flight hours of pilots. Qualitative data variables are categorical variables - pilot licenses. The results are produced using descriptive statistics based on the quantitative and qualitative data factors, as shown in Table II.

According to Table II, the mean or average value of the accurate data for the quantitative data variable (total pilot flight hours) acquired is 7,024.58 hours. Furthermore, for the dispersion value (data spread to the average value) acquired by 0.69, this variable's median value was found to be 5,935 hours. This signifies that the variable corresponds with homogenous data with a tiny dispersion value - a minimum value of 20 hours and a maximum value of 17,547 hours. It also implies that the missing value for this variable is already worth 0, which means that there is no lost or empty data. While the type of qualitative data variable (pilot license) is categorical, it is converted to numerical using the encoder label. The pilot license data has a mean value of 0.50.

Furthermore, the median value of this variable is 0, indicating that ATPL is the midpoint value of the pilot license variable. Aside from the dispersion value, the average value was found to be 1.59, indicating that this variable corresponds to heterogeneous data with a high dispersion value, a minimum value of 0, and a maximum value of 3. For this variable, a missing value is already worth 0, indicating that no data was lost or is empty.

TABLE II. DESCRIPTIVE STATISTICS OF DATA

Variable Types	Mean	Median	Dispersion	Min	Max	Missing Value
Quantitative	7024.58	5935	0.69	20	17547	0(0%)
Qualitative	0.50	0	1.59	0	3	0(0%)

D. Data Visualization (EDA)

Following the data preprocessing and descriptive statistics phases, the EDA step is used to comprehend the contents and components of the data. The EDA approach employed in this study is univariate and bivariate; univariate analysis is used to distribute data from a single variable while bivariate analysis demonstrates the link between two variables [9]. To comprehend data trends, both analyses are used to examine the distribution of data for varying total flight hours and pilot licenses in detail. As follows, pie charts are used for univariate analysis and scatter plots are used for bivariate analysis.

The Pie Chart is used to determine how much category distributes on a pilot's license. According to Fig. 2, the most significant proportion of ATPL (0) license types was 63.2 percent, followed by 29.0 percent for the CPL (1) category, 2.6 percent for the PPL (2) category, and 5.2 percent for the SPL (3) type. The scatter plot is used to illustrate data distribution, to examine how data spread links between the variable total flight hours and the pilot's license.

According to Fig. 3, it may be noted that the patterns across the two variables do not have a link as no tendency of specific values can be observed in common. Each pilot's license has its unique pattern that appears to be completely unrelated to the value of each pilot's license in the crash data.

Fig. 2. Pilot License Data Visualization.

Fig. 3. Visualization of Total Flight Hours based on Pilot's License.

E. Cluster Test

At this juncture, it is important to mention that the test used three predefined agglomerative strategies. First, the distance is calculated using the Euclidean formula, then the ideal number of clusters is estimated using the silhouette index technique, the amount of data spread for each cluster is examined, and finally, the dendrogram of each approach is visualized.

The following are the findings of the validation test of the number of clusters using the silhouette index technique with a range of cluster values 2-4. Using two clusters yielded an average value of 0.5156, three clusters yielded an average value of 0.5004, and four clusters yielded an average value of 0.5500. Based on the computation of the silhouette index, if the average value is close to the value of one, the data grouping is considered better [10].

F. Hierarchical Agglomerative Method Test

The grouping approach employs the three techniques selected to acquire the data dispersed across clusters and provide dendrogram visualizations based on the number of clusters formed from each AHC method.

1) *Single linkage*: The single linkage approach is used to group two variables with a distance between cluster pairs determined by the two nearest objects between separate clusters [11]. According to Table III, each cluster contains a varied quantity of data, and the data in each cluster is far apart and unbalanced. Cluster 3 has the least data with 4 data points, while Cluster 2 has the most data with 99 data points. The dendrogram construction employs a single linking approach with four clusters connected by a pair of points with the closest distance between each other, as depicted in Fig. 4. (a).

TABLE III. NUMBER OF EACH SINGLE LINKAGE CLUSTER

Cluster	Numbers of Data
1	45
2	99
3	4
4	8

2) *Complete linkage*: The distance between clusters has been computed on the furthest distance between a pair of items [12] [13]; the quantity of data per cluster and visualization results (using a dendrogram) was determined with the Euclidean formulae for four clusters. The data of each cluster corresponded with a ratio that was less balanced than the single linkage technique due to the quantity of data used in the complete linkage method (See Table IV). Cluster 4 has the least quantity of data (12) while Cluster 1 has the most data (72).

TABLE IV. NUMBER OF EACH COMPLETE LINKAGE CLUSTER

Cluster	Numbers of Data
1	72
2	42
3	30
4	12

The output of the dendrogram implementation employs the entire linkage approach, with four clusters connected from the longest distance from a pair of objects seen in Fig. 4. (b).

3) *Average linkage*: The average linkage computes the average distance between all pairs of data points from various clusters [14]. The amount of data per cluster and the visualization results used for four clusters were determined using Euclidean equations. The number of clusters in this technique is not found to be highly significant, as seen in Table V. In comparison to the whole linkage and single linkage approaches, the amount of data in each cluster is more evenly distributed. Cluster 1 has the smallest amount of data, whereas Cluster 2 has the largest. The average linkage approach is used to achieve the results of the dendrogram implementation, as shown in Fig.4(c).

TABLE V. NUMBER OF EACH AVERAGE LINKAGE CLUSTER

Cluster	Numbers of Data
1	30
2	53

4	31

Fig. 4. Visualization Dendrogram Method: (a) Single-linkage (b) Complete Linkage (c) and Average Linkage.

### G. Index Validation Test

The validation test of the score value in clustering is used to determine the optimal AHC approach. The silhouette index matrix was used in the first measuring procedure, the Davies Bouldin index in the second, and the Calinski Harabasz index in the third.

The data grouping is considered better in silhouette index calculations if the index value is close to one [15]. The results of calculations using the silhouette index based on Table VI show that the index values for the three grouping techniques differ. Compared to the single and complete linkage, the average linkage technique yields the highest index value with 0.5623 or 56% being calculated. The silhouette index method was then used to obtain the best method on the validation test, namely average linkage.

The Davies Bouldin index is used for the second measurement. According to [16], the index value approaches zero, implying that the data grouping in one cluster is better. The Davies Bouldin index calculations in Table VI show that the three techniques have varying index values. The average linkage technique has the lowest index value of 0.5644 or 56%. As a result of the validation test using the Davies Bouldin index, the best technique obtained is average linkage.

The Calinski Harabasz index is used in the third measurement, wherein the index value is not limited. The higher the index value, the better the data grouping in one cluster [17]. Table VI shows the results of the Calinski Harabasz index calculation. It is well known that the index values of the three techniques differ. The average linkage technique produces the highest index value of 284.68, while the single linkage technique produces the lowest index value of 93.37. Using the Calinski Harabasz index, the best technique is determined using the validation test, which was found to be average linkage. For the three validation test methods, all the measurements showed elicited 100 percent, indicating that average linkage is the best method for viewing data insights into licenses and total flight hours.

TABLE VI. INDEX VALIDATION TEST RESULTS

Methods	Single	Complete	Average
Silhouette	0.4838	0.4045	0.5623
Davies Bouldin	0.6238	0.7421	0.5644
Calinski Harabasz	93.37	159.09	284.68

### H. Analysis of Cluster Average Linkage Results

This study shows the results of each cluster in relation to the total flight hours and pilot licenses based on the type of the pilot license used - ATPL, CPL, SPL, and PPL, which were mapped based on the number of clusters. The average value has also been based on the number of clusters. Table VII displays the number of pilot license categories in each cluster and the total number of pilots' flight hours.

After selecting the agglomerative method approach with average linkage, the researcher noticed two accidents in the fourth cluster involving pilot licenses under the ATPL category (Table VII). While the pilot involved in the fourth cluster had

an average flight time of 1071.67 hours, which when combined should have been more than 1071.67 hours, the ATPL standard is at least 1500 hours. Such anomalies must be investigated as the total rata-average of these four licensing classes is 1071.67 hours, while certain anomalies may be assumed to have a duration of over 1071.67 hours. Thus, a deeper delve into Cluster 4 was necessary. Based on the established statistics, researchers found two ATPL-type permits with a total flight hour of fewer than 1500 hours. Despite CASR standards requiring ATPL type pilots to have a minimum flight hour requirement of 1500 hours, two pilots in Cluster 4 did not meet the minimum flying hours required by their pilot's license, with total flight hours of 1200 hours and 1339 hours, for each pilot. The Cluster 4 results are shown in Fig. 5, illustrating the ATPL (0) licenses that were found to be different from the rest of the data.

TABLE VII. NUMBER OF PILOT'S LICENSES AND AVERAGE TOTAL PILOT HOURS

Cluster	Pilot Licenses				Average of Total Data Pilot's Flight (Hours)
	ATPL (0)	CPL (1)	PPL (2)	SPL (3)	
1	27	3	0	0	14625,23
2	33	20	0	0	4634,84
3	37	5	0	0	9060,54
4	2	17	4	8	1071,67

Fig. 5. Visualized Data Cluster 4 Average Linkage.

#### IV. CONCLUSION

This study was carried out to provide a comprehensive source of knowledge regarding aviation accidents in Indonesia caused by human factors, which are the most significant among other causative elements, requiring a detailed assessment of the accident as a result of pilot and co-pilot faults while operating the aircraft. The approach used to analyze KNKT data was clustering algorithms to identify insightful data in the relationship between total flying hours and pilot's license, based on the historical data of accidents caused by human factors over 23 years.

The data analysis revealed that, in general, the aircraft operator complied with the CASR standards. However, using clustering, it was discovered that the pilot had a license that did not match with the flown aircraft in 1.3 percent of the 156 accidents. Another finding revealed that, in comparison with other causes, human-caused accidents (pilots) had the highest proportion - with 46.5 percent from 1997 to 2020. Meanwhile, the level of representation of the analyzed data was only 46 percent as only 156 out of 341 accidents over 23 years were processed due to the relevant observation values on license data variables and flight hours.

#### ACKNOWLEDGMENT

We thank those who have helped us complete this study.

**Abstract**—Cyber-attacks have become one of the world's most serious issues. Every day, they wreak serious financial harm to governments and people. As cyber-attacks become more common, so does cyber-crime. Identifying cyber-crime perpetrators and understanding attack tactics are critical in the battle against crime and criminals. Cyber-attack detection and prevention are difficult undertakings. Researchers have lately developed security models and made forecasts using artificial intelligence technologies to solve these concerns. In the literature, the authors explained numerous ways of predicting crime. They, on the other hand, have a problem forecasting cyber-crime and cyber-attack strategies. Here, in this paper author proposed a digital forensic investigation procedure that deals with cyber-crime. In this investigation, the process author explains digital forensics techniques for ensuring that digital evidence is located, collected, preserved, evaluated, and reported in such a way that the evidence's integrity is preserved. These sequential digital forensic stages affect a standard and accepted digital forensic investigation procedure, and each phase is influenced by sequential occurrences, with each event relying on tasks. Digital forensics investigation is a technique for ensuring that digital evidence is handled in such a way that the evidence's integrity is preserved. Sequential digital forensic stages affect a standard and accepted digital forensic investigation procedure, and each phase is influenced by sequential occurrences, with each event relying on tasks.

**Keywords**—Cyber-crime; digital forensics; digital evidence; data analysis; security and privacy; cyber-attack

## I. INTRODUCTION

Information security has given users complete control over data by specifying who has access to it, who can govern it, and who may receive it [1]. People's lifestyles are changing as a result of technological advancements. For example, nowadays most people prefer online payment to traditional payment, access to social media, medical consultation through phone or video chat, online schooling, and so on. As technology advances and new services become available, the number of internet users grows, and an exponential increase in information causes its use, as well as misuse, resulting in cyber-attacks and cyber-crime. Cyber-attacks have an impact on the economic systems of our countries. According to research by Mahindra SSG and ASSOCHAM, cybercrime costs India around 24,630 crores per year [2]. Attacks have become more complex as a result of technological advancements, and defending oneself is no longer as simple as installing anti-virus software.

The general concept of evidence preservation in the chain of custody has remained the same but the original process of investigation may vary. The preparation, examination, identification, collection, analysis, validation, acquisition, documentation, and forensic reporting of digital evidence in a court of law, is known as the digital forensics investigation process. The process of interpreting and imaging digital evidence from various electronic devices using scientifically sound and validated methodologies is an indestructible part of digital forensic investigation. Digital forensics is a rapidly growing field that uses a variety of analysis tools and computer investigative approaches to locate relevant legal evidence and hints [3]. In general, digital forensics is a process that involves not only retrieving information about a reported incident but also properly processing that information so that experts can obtain all relevant clues and evidence, which can then be used to pursue your legal interests against someone or in any other situation. Finding evidence, keeping it, accurately documenting it, and presenting it in a court of law are all part of the digital forensic process. Although, because this is not a simple process, it might often take years to solve the issue. Furthermore, complex systems are making it harder to hit these days. We now have a complex methodology and enhanced technologies and techniques to determine if any pieces of evidence are present or not. We now have a complicated methodology, as well as new technologies and techniques, to determine whether a criminal case has occurred and a huge amount of money is spent to solve the case [2].

Cyber-attacks and cyber-crimes are a serious worry for large countries such as the US and the UK, which have developed a number of security solutions to combat them [4]. All countries are seeking to secure and adapt to cyberspace security [5]. The security of critical infrastructure must be a top priority for countries [6]. In the year 2020, information taken from the Airbus Company's information system was sold on the dark web. Millions of people's medical information has been stolen, and several communities have declared a state of emergency as a result [7]. With each passing day, the workforce grows insufficient in combating cyber-attacks, necessitating the search for new alternatives. Machine-learning approaches are being used by researchers to detect power outages caused by cyber-attacks [8] and to prevent the Internet of Things vulnerabilities [9]. Other applications include detecting spam and network attacks [10], detecting phishing attempts against banks [11], and increasing sexual crimes on social media [12] Stock prediction [13], risk mapping [14], and

cyber profiling [15] are some of the sectors where these technologies have been used. Implementation areas include predicting crime trends and patterns [16], criminal identity detection [17], and crime prevention [18].

The authors suggest a framework called "Crime Detection and Diminution in Digital Forensics (CD3F)" in this study. The goal of this research article is to create a framework that connects the stable and sequential aspects of the digital forensic investigation process. With the many operations of the investigation workflow comprising physical and investigative duties and judgments. The Digital forensic framework's intended role is to enable effective, focused, and fast risk identification and management. This CD3F framework contains and outlines eight major workflow stages, as well as the procedures and duties that each stage entails. The article is organized as follows: some of the current digital forensic investigation process models proposed by the researchers are elaborated on and discussed, followed by an explanation of why the digital forensic workflow should be mapped. The following section is about "Phases involved in proposed framework and explanation" and gives an overview of the framework, including all eight stages that the author proposes. "The suggested digital forensic guiding framework specifics" is the topic of the study's next session which focused on the CD3F framework workflow stages: forensic request, preparation, examination, identification, collection, analysis, acquisition, and forensic reporting. The discussion and critical evaluation of the proposed framework are covered in greater depth in the paper. The text is then concluded with some notes about the study's significance and the last half of this research article.

## II. LITERATURE REVIEW

A description of all previously developed cyber forensics investigation frameworks that the authors investigated before developing the proposed framework is not possible due to space limits. Although some of the reviewed frameworks are described in this work, it should not be considered that the suggested model is based on them. In 2001 [19] authors proposed a framework where they have covered preparation, identification, permission, and communication were the four phases of the initial introduction model DFRWS. This paradigm was expanded into the SRDFIM framework, which includes additional steps such as scene securing, screening, scene documenting, evidence gathering, communication shielding, screening, preservation, analysis, and presentation [20]. The FaaS Framework 2014 is based on the IDFPM framework [21], which begins with the collecting and authentication stages. Evidence acquired throughout the investigation will be stored in central storage, followed by the inspection phase in this suggested architecture. The analysis phase will be conducted with current analysis tools, with the results being kept in a centralized database.

The DFRWS Investigation Model is used by the FBI. A fog IoT forensic framework (FOBI) is a network model that performs important operations such as data filtering and aggregation [22, 23]. Storage and processing resources are located at the network edge in this paradigm [24]. Fog protects data sent to IoT devices while also filtering traffic data. As a

result, this architecture provides a number of benefits to IoT devices, including reduced network latency, faster and smarter responsiveness, more scalability, and greater security and privacy. Early detection of a cyber-threat or cyber-attack. It can be used to discover problematic IoT devices by including a fog layer in the framework [22] [25]. Frameworks for research must also be adjusted as a result of technological advancements. As the author mentioned above, some frameworks are presented to combat crime using the most up-to-date technologies and techniques. With some rising issues, law agencies is required for a framework that can combat crime and track down criminals' tracks. Cloud computing is a new level of networking since it offers limitless processing capacity and storage, which poses security concerns [20]. Cyber-attacks such as distributed denial of service (DDoS) attacks that deliver harmful packets [26] and phishing attempts that trick users on banking and shopping sites have increased dramatically. Furthermore, attackers are increasingly deploying malicious attack software (viruses, worms, trojans, spyware, and ransomware) that is installed on a user's computer without their knowledge or agreement [28]. Social engineering attacks are, once again, the most widespread of these attacks and one of the most difficult to counter. They are based on technical expertise, ingenuity, and persuasion, and are carried out by exploiting the victim's weakness. Kevin Mitnick, a well-known hacker who specializes in social engineering attacks, was able to break into most of the computers he targeted using this method [29].

This attack is mentioned as one of the main security vulnerabilities in the system by Breda, Barbosa, and Morais [30], regardless of how secure a technical system is. Similarly, assaults on IoT devices, which have expanded dramatically in recent years, have a significant impact on society. For security reasons, assaults and threats to the IoT structure should be understood [31]. As described in this paper, studies performed to analyze and combat cyber-attacks highlight the importance of crime prediction. Many jurisdictions' legal frameworks characterize the attacks listed above as banned criminal offenses. The task of combating crime and criminals is delegated to law enforcement agencies. Researchers provide numerous analysis and prediction approaches to the institutions undertaking the research. Many studies, for example, have used big data [32] and machine-learning [18] methods to analyze crimes. With artificial intelligence models, they have contributed to crime and crime-fighting institutions. Identifying the regions where crime can be perpetrated and the story behind it [33], predicting crime using spatial, temporal, and demographic data [34], and assessing crime using literacy, unemployment, and development index data [35] are just a few examples. A time series of crime data from San Francisco, Chicago, and Philadelphia was utilized to forecast crimes in the year's ahead. K-nearest neighbors (KNN) and Naive Bayes (NB) classification models performed worse than Decision Trees (DT) [36]. Using the KNN and DTs, a crime prediction was made with an accuracy of 39 to 44 percent [38]. The location, kind, date, time, latitude, and longitude of crimes committed in the United States were used as input. The results of crime predictions using KNN Classification, Logistic Regression (LR), DTs, Random Forest (RF), Support Vector Machine (SVM), and Bayesian approaches showed that the

KNN classification was the most accurate at 78.9% [37]. Thirty-nine distinct categories of crime statistics from San Francisco were used in the study. A model splitting crimes into two types, blue/white-collar crime and violent/non-violent crime, was built using Gradient Boosted Trees and SVMs. The categorization of blue-white collar offenses was done with great precision.

The study, however, did not produce significant results in terms of classifying violent and non-violent crimes [39]. The data was taken from a ten-year murder in Brazil. The RF approach was used to make 97 percent accurate predictions in order to examine the effect of non-Gaussian residuals and urban metrics on murders. Unemployment and ignorance were found to be significant factors in homicide in this study. The relevance of each factor in predicting the crime was also assessed [40]. Another study employed the type, timing, and location of crime data to predict crime in certain Indian regions. It was decided to employ the KNN prediction algorithm. Robbery, gambling, accidents, violence, murder, and kidnapping crimes were predicted using this strategy. It was shown to be more successful than a previous study of a similar nature [41]. Using crime data obtained from social media networks, big data and machine-learning frameworks were created. Volunteered Geographic Information, web, and mobile crime reporting applications were used to collect the information. The NB algorithm was used to generate crime predictions from the collected data. The goal of these forecasts is to pinpoint the site of potential crimes so that they can be avoided [42].

The demographic and geographic data from past years' events were utilized to forecast terrorist attacks in India. Using artificial intelligence algorithms, this model predicted terrorist occurrences with a high degree of accuracy [43]. The data used to analyze cyber-crime was publicly available information from social media platforms such as Facebook and Twitter. The F-measure value, which is the degree of accuracy and precision, was used to compare the algorithms. The RF algorithm was shown to be the best fit in the circumstance, with an accuracy of 80%. Threats were identified automatically using a model that analyses cyber-crime [44]. Through the screening program, real-time crime data from the internet news was employed. The classification algorithms employed were SVM, Multinomial NB, and RF. The data was divided into two categories: criminal and non-criminal. The most essential aspect is that it now includes news analysis [45]. Machine-learning algorithms were used to classify data from cyber-crime incidents in India. The program, which was 99 percent accurate in predicting crimes, cut down on time spent on analysis and manual reporting [46]. Kaggle was utilized to obtain a universally compared intrusion detection dataset.

On the bases of the literature review, the authors observed and analyzed that cyber-attacks and crimes are vital to investigate since they inflict significant harm to persons and governments. The studies contributed significantly to the literature and, in particular, to the criminal investigation units. General crimes, cyber-crimes, and attacks are commonly employed as a dataset in these studies. The real dataset based on personal qualities is looked at to a lesser extent, and a framework for digital forensic inquiry is proposed as a result.

Because of the importance of the fields investigated, the cyber-attack and perpetrator estimating approach is addressed.

### III. PHASES INVOLVED IN PROPOSED FRAMEWORK AND EXPLANATION

Almost all major transactions are adopted by web applications. Their web environment is deployed by different purpose applications like we have different applications for social surfing, cloud storage, emails, online marketing, etc. With all these bundles of online applications, online frauds and online crimes are increasing swiftly [21]. Many online actions are punishable by a court of law. To justify any case or prove any complaint experts fetch data present in digital devices known as digital evidence. While the process of investigation, experts have to collect and analyze many devices and their data, which makes this process difficult. The process of investigation may vary from device to device and case to case. One process used for investigation in one case for one device may completely be different from other cases and another device. Hence it is really hard to find a compatible investigation process for digital devices. Cloud storage and online disk, where users can store their data are generation problems during the investigation. Forensic devices are getting advanced day by day, but anti-forensics development has obstructed the path of digital forensic investigation [22].

The proposed framework is about crime detection and control. The primary goal of crime detection and diminution in digital forensics (CD3F) is to help the investigator explain how specific digital evidence is discovered on a device. Despite the existence of numerous frameworks in the current literature, the CD3F methods and nomenclature have yet to be properly standardized. Attempts to standardize computer investigative process frameworks in the past appear to have not been fully successful for a variety of reasons. The authors' main reason for failing is that they used their own vocabulary instead of seeking to discover the most common language that can be accepted universally by digital forensic investigators. Fig. 1 is block representation of the proposed digital forensic guidance model (CD3F) and the detailed process flow of the same is explained further. The suggested model's first phase, "Forensic analysis," examines case reporting and determines whether a digital forensic investigation is required for the same. The "preparation" phase follows, which focuses on the initial preparation for the case by examining the required set of acts and getting a search warrant or other necessary authority. The "examination" phase follows, which focuses on searching for evidence at the crime scene or in a location where evidence might be found. The "identification" and "collection" phases were devoted to locating and gathering prospective evidence shards. The "analysis" phase focuses on reviewing and analyzing the acquired material in order to collect evidence that can aid in the "analysis" phase. The final phase is "forensic reporting," in which the investigator reports the evidence discovered throughout the investigation. The proposed digital forensic model has the following phases.

#### A. Forensic Request

This is the first stage of the digital forensic process when incidence is reported and higher authorities hand over the case to digital forensic experts. The forensic request phase of a

digital investigation begins when an incident is detected by either internal events such as an intrusion detection system or external events such as a crime reported to the police. The occurrence must be confirmed or denied after it has been discovered and reported. However, once the incident is confirmed, the investigators must be notified so that the first response can begin. The digital forensic investigation may be of these two kinds.

a) *Public Digital Forensic Investigation:* In the Public digital forensic investigation method, government body is responsible for the investigation of the registered case request. During this investigation of a criminal case, the investigator must have a sound knowledge of local city/town, state, country, and country laws related to the criminal case and all cyber-crime laws and all standard legal processes of investigation [23].

b) *Private Or Corporate Digital Forensic Investigation:* Whereas private investigation deals with private lawyers and companies who look after legal issues and that particular company policy violation. In such an investigation, the investigation must take care of business and should not let it suffer and the investigator should interrupt company employees to the minimal during the investigation. Investigators cannot seize the evidence, rather than seize it, they acquire memory images and allow the system to go back to work [23].

### B. Preparation

The next phase is to get prepared with the tools and methods which will be used further for the process and if required, train and build the forensic expert team for the investment. It is also suggested in this phase that if a search warrant or other documents are required then try to obtain in the initial level of this model. These documents will help in the further investigation process. Basically, in this phase investigator identifies the incidence and calculates possible risk assessment. Investigators determine which software and what kind of hardware will be required for investigation. He/ she will also try to define if any specific tool will be required for the investigation process to fetch information that will be further used as 'evidence'.

### C. Examination

In this phase of the investigation, the investigator will lock the crime scene's physical environment. The digital forensic expert will try to secure all correlated logs, data, and volatile evidence like laptops, mobile phones, and hardware and he/she will also ensure that condition of electronic devices won't get altered by any means. Investigators aim to examine and identify similar past investigations in this phase. If they find one, they study it and follow the footprint of that investigation, which can help them during the investigation from a secure physical location. Investigators also verify the extent of the damage/impact of the incident and ensure that non-digital evidence such as fingerprints are protected. Observe and document the physical scene, device positions, device locations relative to one another, and device conditions, including power status.

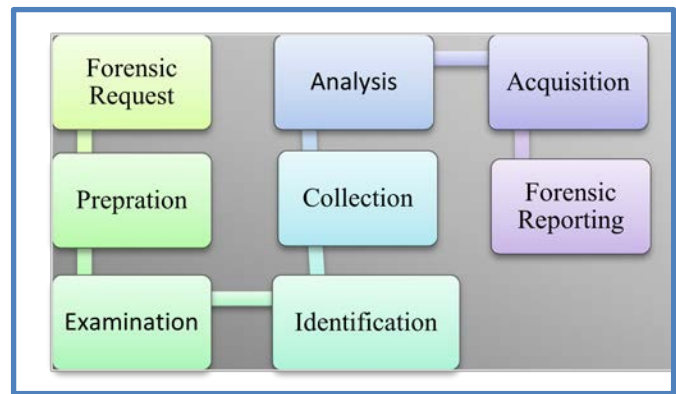

Fig. 1. The Proposed Digital Forensic Guidance Model.

### D. Identification & Collection

The next phase in this model explains about identification and collection of digital evidence after performing examination of evidence around the crime scene. After the collection of evidence from the crime scene, an important and necessary step is to preserve all evidence so that they can utilize it further for examination (if required) and their integrity will remain constant. Detailed information regarding the evidence will be included into the evidence gathering form during this step. If electronic evidence is being used, a deeper inquiry into the device's volatile data will be required. If volatile data is needed, execute a live acquisition of volatile data first, then verify if non-volatile data is needed, and then perform a live acquisition of non-volatile data. Make a duplicate copy of the data you just got and double-check it. This phase will involve labelling the evidence discovered, as well as packing and transporting the evidence. The evidence is then placed in a legal custody room with labels and security measurements. Maintaining and preserving the chain of custody is essential.

### E. Analysis

This phase focuses on the process of examining digital evidence that has been discovered. During the analysis, the examiner assembled the evidence to gather information, and after reviewing the information, the examiner may develop certain conclusions for final reporting. During this phase, the investigator gathers unprocessed data and devices from the linked investigation and compares them to the condition of the device obtained through the related investigation. Investigator Extracts data from gathered devices using physical, logical, and dead acquisition methods.

### F. Acquisition

This is a critical stage in the digital forensic investigation process. In this case, digital forensic professionals will attempt to gather all unprocessed data and devices from the investigation. After successfully collecting physical and logical data, he will make duplicate copies of all collected data so that the original data is not affected, and only the investigator will execute all operations and analyses on the copied data. During this phase, the investigator compares duplicate data to the original in terms of timestamp and reconstructs the data taken from devices. Only the investigator selects an analysis approach from a list of options, such as data hiding analysis, log analysis, timeframe analysis, application and file analysis,

and so on. Finally, reconstructs the chronology of crimes in order to provide a clear picture and discover missing links in order to locate relevant evidence.

#### G. Forensic Reporting

This is the final phase of the digital forensic investigation framework, and it entails reporting and drawing conclusions from all previous phases, as well as all essential material. The conclusion will be drawn and reported to the court of law. This is the final phase of the CD3F architecture; investigators prepare a detailed report that can be understood by laypeople, choose the target audience, gather evidence, and maintain the chain of custody throughout this phase. Closer documents will be provided by the investigator, along with the time and date of release, as well as to whom and by whom they were released. This evidence will be presented in a court of law to assist in the resolution of the case.

There are primarily eight steps in the proposed digital forensic guiding model that describe the investigative process. This digital forensic investigation technique entails obtaining digital data for inspection in order to use the information discovered as evidence in reopened cases. The type and format of this digital record can vary. Smartphone data, a list of all phone calls made, desktop files, recorded video and audio files, a bit of signal strength from a mobile SIM station's base station, all electronic mail chats, installed and attacked virus, and so on [24]. Once investigators have obtained these records, the most important next step is to create copies of all evidence, which will then be examined and analyzed so that the integrity of the original evidence is not compromised and no issues are raised about its integrity.

#### IV. THE PROPOSED DIGITAL FORENSIC GUIDANCE FRAMEWORK DETAILS

This model is influenced by previous existing models as well as some physical forensic models so that model can encounter the challenges from the electronic evidence to make them admissible in a court of law. This framework has two major contributions. First, it describes a framework that is trying to cover previous events and the state of electronic devices at the primitive and abstract level of investigation. Second, it provides detailed steps for each phase, so that it can use as a reference investigation framework. The following goals were used to define the model:

- The framework is designed based on the theoretical foundations of digital forensic investigation so that current and future work in digital forensics science can be used.
- The framework must be general with high opinion based on the technology being investigated so that this theory could be applied to upcoming as well as existing technologies.
- The framework must be adept at events, supporting systems, and storage locations at arbitrary levels of abstraction so that complex systems can be represented.

- The framework designed as per it is capable of describing past events and states so that all electronic evidence can be represented.

After obtaining a forensic request for a registered or reported case digital forensic investigation progress gets triggered. Here is the description of the phases of the proposed investigation model in brief.

#### A. Preparation Phase

The initial understanding of the problem, as well as the appropriate tools, are all part of the preparation phase. This step is used to get authorization and approval, as well as a search warrant and legal notification to people who have expressed concern, before developing a suitable plan. Detailed explanation is given in Fig. 2. Here's a rundown of the steps involved in the planning phase.

- 1) Identify or detect incidence and possible risk assessment of the reported case.
- 2) Actuate Computer Emergency Response Team (CERT) divide preliminary assignment and maintain legal activity coordinated plan before arriving at the crime scene.
- 3) If required obtain a search warrant and permission from concerned authorities.
- 4) Formulate paperwork according to the requirement of the case and gather all needed requirements and identify requirements.
- 5) Develop an onsite plan which includes policies and individual responsibilities.
- 6) Select approach and strategy for collection, preservation, examination, and analysis of evidence.
- 7) Have any information about the suspected operation system.
- 8) Determine the kind of software and hardware for investigation. Specific tool, accumulate evidence collection, and packaging equipment and materials.
- 9) If more information does not require further processing. Then move to the next step of digital forensic investigation.

#### B. Examination Phase

The second phase focuses on protecting the crime scene from illegal entry and preventing contamination of the evidence. An early investigation by the investigators to assess the crime scene, identify potential sources of evidence, and devise a search strategy. This phase entails photography, sketching, and crime-scene mapping, as well as the adequate recording of both physical and digital crime scenes. Detailed explanation is given in Fig. 3. The brief of the examination phase is as follows -

- 1) The most first step is to secure the crime scene's physical environment & secure all correlated logs, data, and volatile evidence. Laptops, hardware, and secure narrative description. Don't alter the condition of electronic devices.

Fig. 2. Dataflow Diagram for Preparation Phase Digital Forensic Investigation Model.

2) Try to analyze and find similar previous investigations; if find one then study similar investigation & follow the footprint of that investigation that can help during the investigation from the secure physical environment in step 1.

3) Place labels over all the drive slots and power connections and take preliminary photographs of the crime scene.

4) Select narration technique (written, audio or video) to delineate the search area and detect unauthorized activity and report it.

5) Validate the damage/ impact of incidence and ensure the protection of non-digital evidence like fingerprints.

6) Evaluate whether any movement appears in evidence, determine devices on the network and make a complete evolution sheet.

7) Observe & document the physical scene, the position of devices, the location of devices relative to each other, and the condition of devices including power status.

8) Take written notes on what appears on the screen, take snapshots of the screen, and the active program should be videotaped.

9) Take photographs before and after examination of evidence. Label properly each evidence.

10) Maintain and seize evidence log that includes a brief description and photographic log. Prepare a chain of evidence.

11) Start Identification & collection.

### C. Start Identification & Collection Phase

In the identification phase investigator needs to disable all other possible communication methods for the devices. Some communication technologies, such as WiFi or Bluetooth, may be enabled even if the device appears to be turned off. This may result in the overwriting of existing data, so such scenarios should be avoided. In evidence, both volatile and non-volatile evidence could be present. To preserve its integrity, the required precautions must be performed. Detailed explanation is given in Fig. 4. A brief of the identification and collection is given below-

1) Firstly, check whether evidence to be collected are physical or electronic?

2) If evidence is physical then apply the tag on an identified object as evidence like removable media, cables, publications, and all computers. Or if the evidence is electronic then check whether the device is running or not.

3) Fill evidence collection form with detailed information about the evidence.

4) If electronic evidence is running, then checking for volatile data of the device will require further investigation.

5) If volatile data is required, then perform live acquisition of volatile data then check non-volatile data is required then perform live acquisition of non-volatile data.

6) Check whether found device data is stable. If yes, then remove the power source whether battery or main switch. If no, then perform a normal system shutdown.

7) Decide the most appropriate way to acquire data and then acquire data from the device.

8) Make a duplicate copy of the acquired data and verify.

9) Check whether all required data has been acquired. If yes, then seize found device.

10) Record and return the connection of the device. Label the evidence found then pack and transport the evidence.

11) Store the evidence in a legal custody room with labels and security measurements. Maintain and preserve the chain of custody.

### D. Analysis and Acquisition

Examining the content of the acquired evidence and extracting information for presentation in court is what a forensics specialist does. This consists of both volatile and non-volatile data. The acquisition is more of a technical evaluation undertaken by the investigation team based on the findings of the digital evidence inspection and the reconstruction of event data. Detailed explanation is given in Fig. 5. The brief of this phase is given below-

1) Collect unprocessed data and devices from the related investigation.

2) Identify operating systems used in incidence & choose data extraction techniques for examination & analysis of evidence.

3) Check documents obtained by related investigation of the condition of the device.

4) Perform physical, logical extraction, and dead acquisition on data from collected devices.

5) Make duplicate copies of all acquired data from electronic devices.

6) Authenticate duplicate data with the original one in their timestamp.

7) Reconstruct the extracted data from devices.

8) Choose the analysis technique - Data hiding analysis, log analysis, Timeframe analysis, Application & file analysis, etc.

9) Reconstruct the sequence of crimes to produce a clear picture & try identifying missing links.

10) Compare acquired evidence with proven facts and with physical forensic results.

11) Documentation & Preserve chain of custody in storage.

12) Store evidence in a secure custody room.

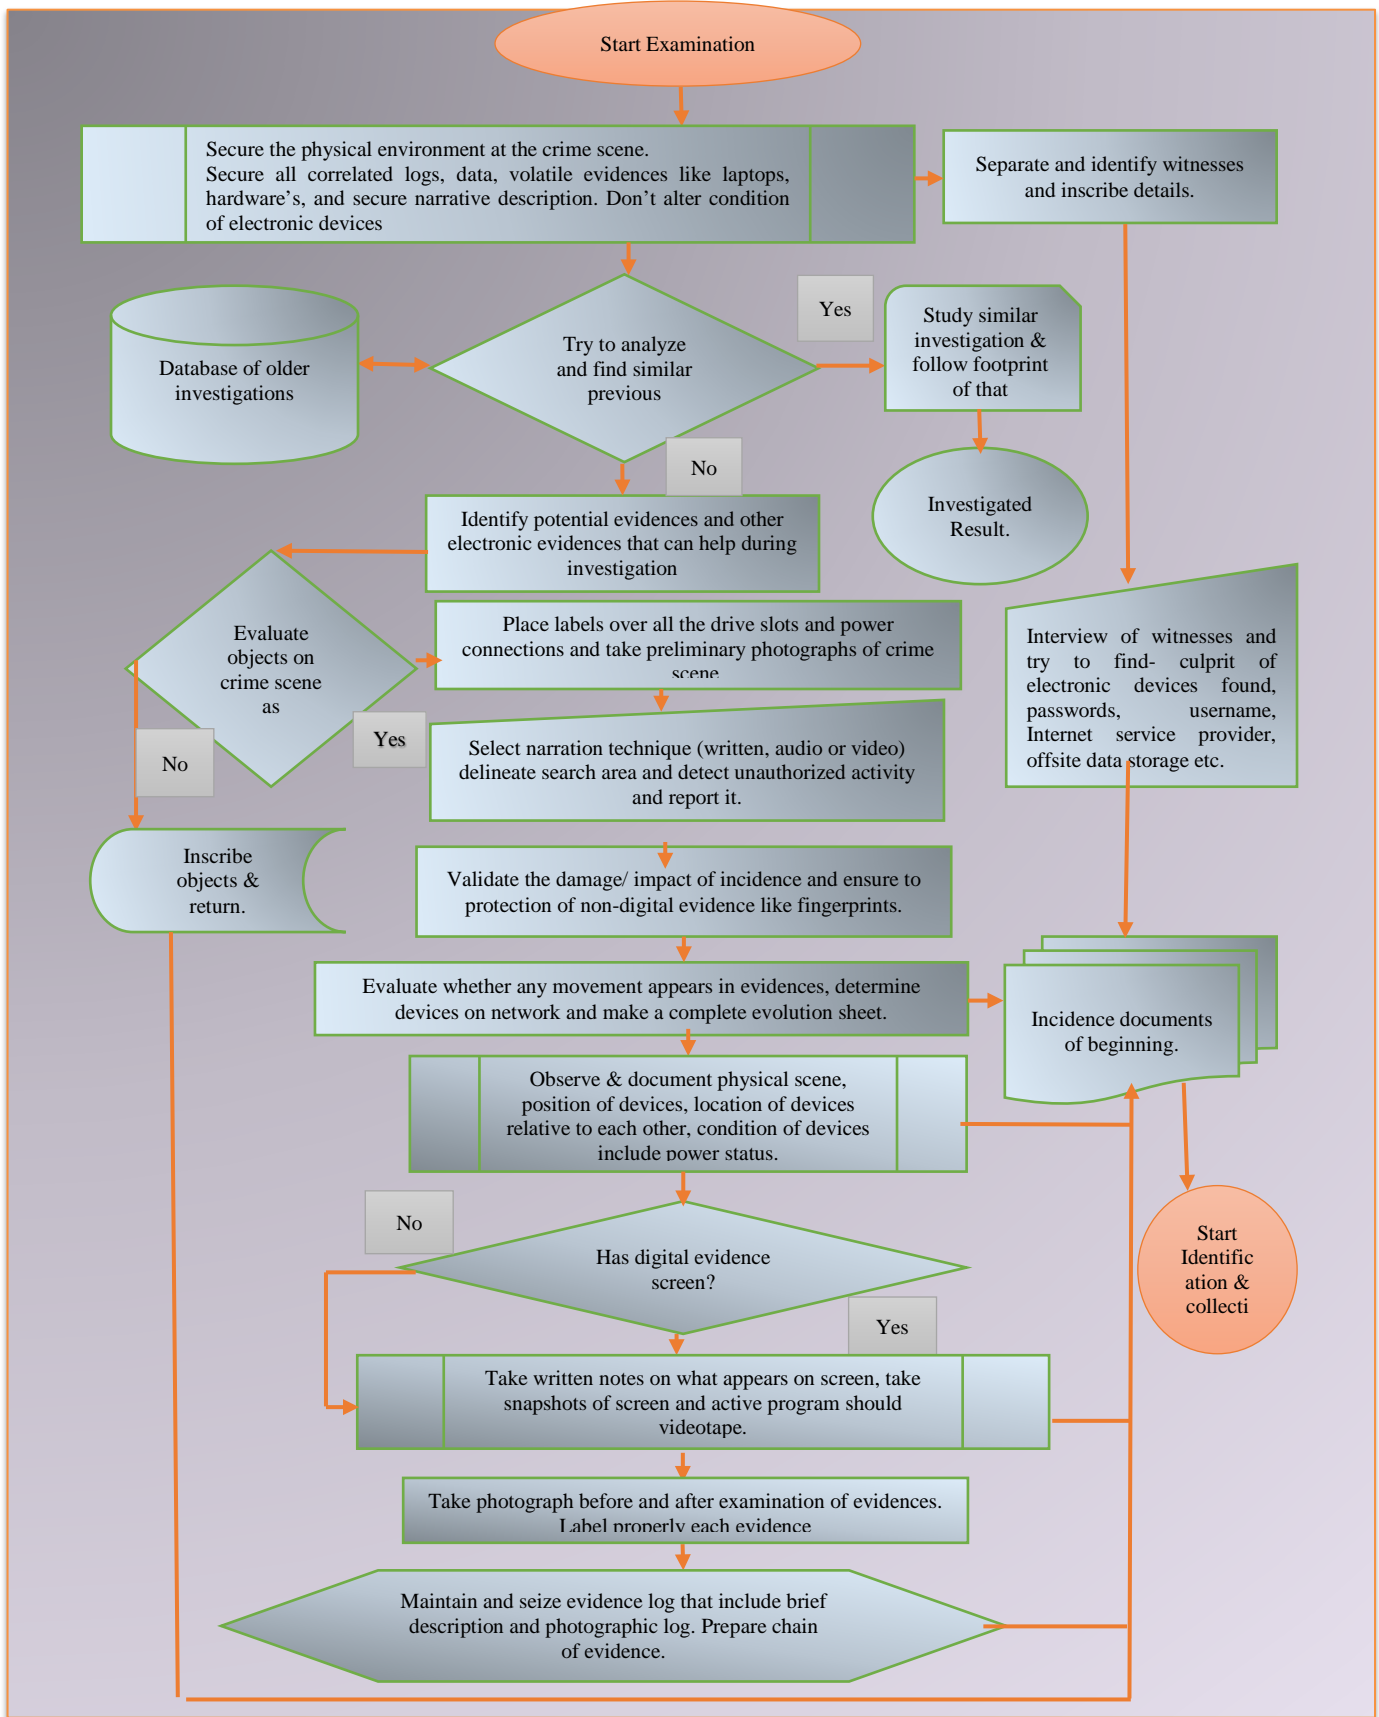

Fig. 3. Dataflow Diagram for Examination Phase of Digital Forensic Investigation Model.

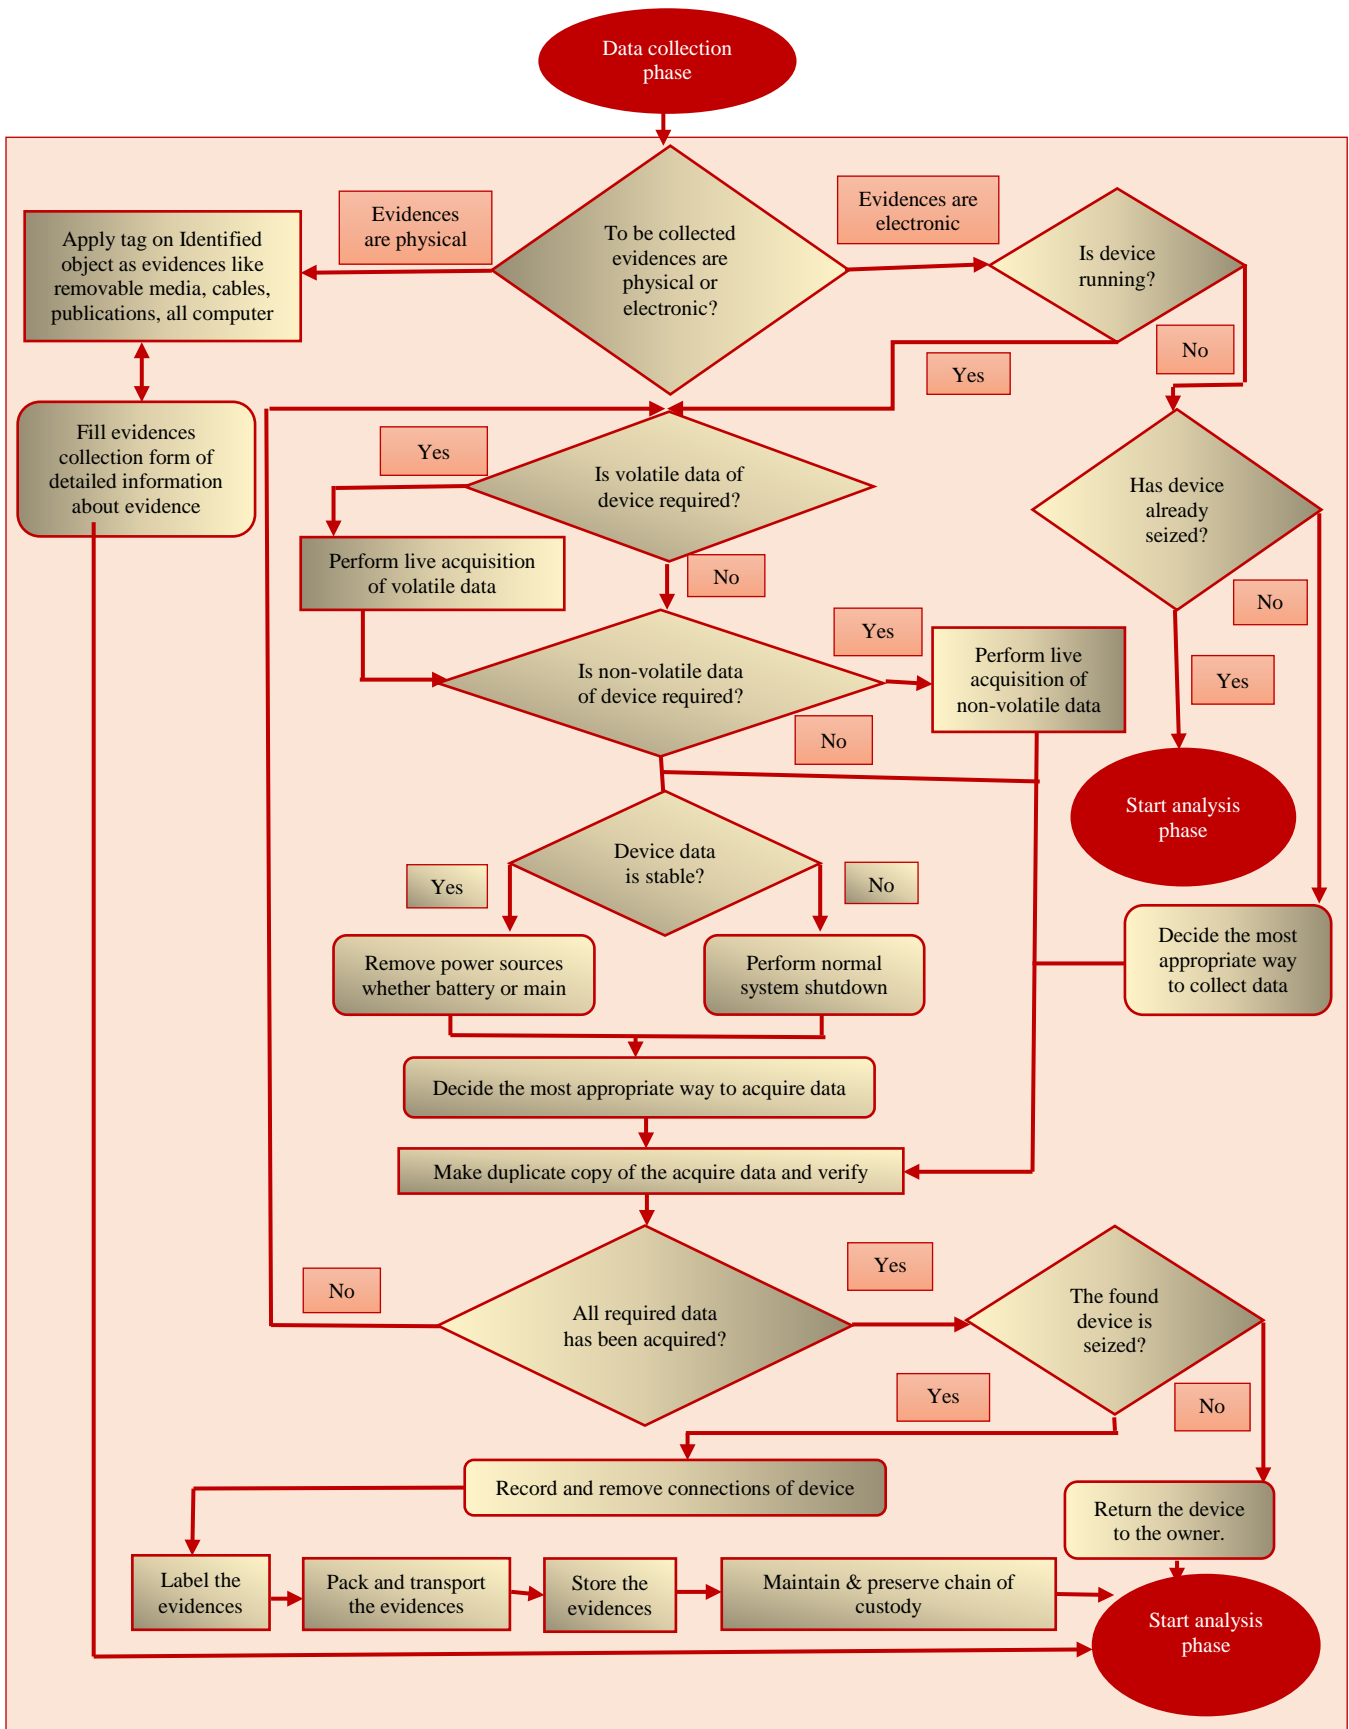

Fig. 4. Dataflow Diagram for Collection Phase of Digital Forensic Investigation Model.

### *E. Reporting & Presentation*

A report containing a full overview of the various procedures done during the investigation of evidence and System (Organization of potential evidence) and the conclusion reached is presented to the proper authorities [48]. This model was a basic workflow without any validation and verification. The model was designed to help individual investigators in organizing, but this was a very complex puzzled workflow. Presentation phase: When a crime is committed, it is presented to a court of law, and when an event occurs, it is presented in court. At the conclusion of the investigation, an evaluation is conducted, and the results are utilized to update or repair any shortcomings discovered during the inquiry Detailed

explanation is given in Fig. 5. A brief of this phase is given below-

- 1) Write a comprehensive report which can be understood by the layman as well.
- 2) Determine the target audience and put together evidence and preserve the chain of custody.
- 3) Present evidence according to rules of the law enforcement.
- 4) Preserve evidence for further requirements.
- 5) Handover closer Documents, with time & date of release, to whom & by whom released.

Fig. 5. Dataflow Diagram for Analysis, Acquisition, Reporting, and Presentation Phase of Digital Forensic Investigation Model.

## V. DISCUSSION

Dimpe and Kogeda [47] examined the earlier proposed models and found the integrity of evidence can be preserved by documentation of each action performed during the investigation. To serve this purpose they proposed a generic investigation framework. This framework is focused on the integrity of evidence, while collecting evidence in the collection phase this phase will be divided into sub-phases –

acquisition, transport, and storage. The author claimed that they explained requirements during the digital forensic investigation to make investigation work easy and explained standers. But setting investigation standards cannot solve all problems and challenges faced by investigation officers. Dimpe and Kogeda analyze the need for documentation for the integrity of evidence, but their main focus was on standardizing phases of investigation and developing skills for

the investigator. But even we have national and international courses and training systems for professionals. If through documentation only the investigator can save the integrity of evidence, then we will not be facing any of such problems yet. Hence, we proposed standards and an easy framework by analyzing the earlier proposed one that accommodates everything which could be considered and followed in the investigation process.

Bulbul, Yavuzcan, and Ozel suggested a model named “Digital forensics: An Analytical Crime Scene Procedure Model (ACSPM)” which focused on procedures of crime scenes [48]. This multi-stage model tries to offer a series of evidence collection procedures and multiple tasks for the crime scene to support the investigation process. This proposed model is having some new suggested tasks like Crime scene examination, Evidence search, Potential evidence acquisition, System assurance and management. This model was incapable to focus on all electronic devices and all electronic pieces of evidence which needed to be collected during the investigation.

Ohaeri and Esiefarienhe proposed a digital forensic model for network security management and information system. In this model digital forensic investigation stages were implemented as a security mechanism. The basic thought behind this model was to provide a detailed knowledge of the digital forensic technology practices in institutions, organizations, or companies [49]. The model is claimed to ensure uniqueness and effectiveness while succeeding to provide adequate, reliable, and effective security. But this model is not successfully achieving its goal of real-time dealing with the investigation. It is just like a traditional search method for investigation. According to the author, data integrity is justified while keeping the laws and rules of digital evidence but the model seems to fail in proper documentation of evidence. This can be raised finger on the integrity of evidence.

Graeme Horsman proposed DERDS framework to support the digital forensic investigation. This model serves with

logical decisions and the investigator those are experienced but lack confidence. This guidance model is a process flow for making the right judgment with the help of found digital evidence. The DERDS framework delivers three corridors-inferences, assumptions, or conclusions, for an investigator to test and search for the consistency of digital investigative [50]. But this model capacity is depending on the ability of the investigator or researcher. DERDS framework always needs a doorkeeper for proceeding further in the investigation and for key decisions during the investigation process.

Author suggested a digital forensic investigation framework in our proposal, hoping to provide an optimistic method to researching cyber-attacks. This structure is mostly made up of four-fold. First, it aids in the digital forensic investigation model's preparation phase. Second, is the digital forensic inquiry model's examination step. The digital forensic investigation model's third phase, is collection. The fourth phase of the digital forensic investigation process is the examination, acquisition, reporting, and presentation. We proposed a simple and standard methodology that includes accurate documentation at each stage and attempts to cover all parts of the investigation.

## VI. CRITICAL EVALUATION OF THE PROPOSED FRAMEWORK

The proposed framework is based on a holistic approach which is able to focus and combine all aspects of digital forensic investigation. The processes provided in the proposed framework is vital in investigation and provide more advantages. The proposed framework tries to cover all aspects of the investigation process and all predefined framework processes which show that this framework is enough comprehensive to cover whole aspects of the investigation. One of the important benefits of the proposed framework is fetching out potential evidence forensically to improve admissibility in a court of law. Table I is showing a comparison of the CD3F framework with some pre-existing frameworks.

TABLE I. COMPARISON OF THE PROPOSED FRAMEWORK FROM PRE-EXISTING FRAMEWORKS

	Framework	Year	Contribution	Loophole	Comparison from the proposed framework
[1]	Systematic Digital forensic Investigation Model [29]	2011	Model work for dynamic evidence & reconstruct events.	The process is similar to old process like only the terms used are different.	Proposed framework provide a less complex investigation path way to the investigator as well as compatible with the advance technology.
[2]	Integrated Digital Investigation Process Model[30]	2011	Identifies the need for interaction with resources in right way.	Proposed Interaction tool needs proper training & patience.	Proposed framework can be used in any digital forensic investigation with only basic training of investigator.
[3]	Generic Digital forensic Framework[25]	2013	Set standard requirement for digital forensic investigation.	Explained standard does not satisfy promise.	Framework explains set of slandered required in each phase.
[4]	An analytical crime scene Proceeding Model (ACSPM)[26]	2018	Talk about management of digital evidence & crime scene investigation	Only focused on crime scene procedure.	Proposed framework is focused on every aspect of investigation like crime scene investigation, evidence collection, analysis, lab examination etc.
[5]	Digital Evidence Reporting and Decision Support (DERDS) framework[27]	2019	Guidance model for the investigator, when to report findings to minimize unsafe disclosure of evidence	Not 100% error-free & may not agree to report all evidence so that evidence may get lost.	Clearly report all evidence so that it requires reinvestigation, evidence recall is unbiased.

## VII. SIGNIFICANCE OF STUDY

The framework highlighted certain phase commonalities that may be regrouped to make the framework more logical. For example, Survey and Recognition could be part of Preparation, Documenting the Crime Scene could be part of Securing the Crime Scene, and Communication Shielding could be part of Securing the Crime Scene because these two independent phases in this model are actually part of Securing the Crime Scene. It's also possible to mix examination with analysis. These phrases were employed as different activities in the model, although their definitions are not just comparable, they also complement one other, which can lead to confusion if they are separated. The following are some advantages of the proposed framework.

- In the proposed framework, a standardized process is used. This makes higher chances of extracting the potential evidence during the investigation.
- The proposed framework is based on a holistic approach and the framework is also able to incorporate the existing frameworks, and thereby this framework could be used as a harmonized model during IoT environment investigation.
- Throughout the whole process of the proposed framework integrity of collected potential evidence is preserved.
- The proposed framework provides a less complex investigation pathway to the investigator as well as is compatible with advanced technology.
- From a reinvestigation point of view, all useful information and all extracted evidence are preserved digitally.

In the proposed framework, all processes can be executed continuously and also insuring the evidence admissibility in a court of law. The authors have involved the concurrent processes in the proposed framework as per guided in ISO/IEC 27043: 2015 standards. A comparison with existing models by the table is also been done in this paper which will further bring out the efficiency of the proposed framework.

## VIII. CONCLUSION AND FUTURE WORK

The author provided a framework for digital forensics in this study. As technology advances, so does the number of incidents of cybercrime. Over previous models, the suggested framework's level of comprehensive processes for each phase independently offers unique benefits. This is a framework that consists of steps that the investigator must follow during the investigation. It is a generic/universal framework that is not dependent on technology or limited to a set of tools. As a result, it will not be constrained by current technologies. The suggested framework is technology-neutral, it may be used in a variety of research platforms and scenarios. This framework could also be utilized in a variety of digital forensics cases. This study will help the different stake holders to detect the crime at a very early stage (as explained in the examination phase, step 2) by following the old recorder investigation footprint. This detection at an early stage can reduce the

detection time of the crime and hence can reduce the further process time in the digital forensics investigation.

Since CD3F only includes activities for on-site plane and lab work, the study described in this paper is clearly lacking. In order to maximize the process of its continued development, the proposed CD3F would need to be applied to a number of case studies with a methodical approach. It is acknowledged that the work still has some limitations in terms of future work. Despite the fact that the CD3F has previously been reviewed by a few knowledgeable experts in the area. As a result, as part of a bigger study, future work should involve a more thorough investigation by digital forensic investigators. The forensic laboratory's typical examination and analysis might also be covered by the CD3F in the upcoming work, which would help to ensure the work in more controlled environment.

**Abstract**—The imaging modalities of chest X-rays and computed tomography (CT) are commonly utilized to quickly and accurately diagnose COVID-19. Due to time and human error, it is exceedingly difficult to manually identify the infection using radio imaging. COVID-19 identification is being mechanized and improved with the use of artificial intelligence (AI) tools that have already showed promise. This study employs the following methodology: The chest footage was pre-processed by setting equalizing the histogram, sharpening it, and so on. The transformed chest images are then retrieved through shallow and high-level feature mapping over the backbone network. To further improve the classification performance of the convolutional neural network, the model uses self-attained mechanism through feature maps. Numerous simulations show that CT image classification and augmentation may be accomplished with higher efficiency and flexibility using the Inception-Resnet convolutional neural network than with traditional segmentation methods. The experiment illustrates the association between model accuracy, model loss, and epoch. Inception-statistical Resnet's measurement results are 98%, 91%, 91%.

**Keywords**—Deep Learning; COVID-19; classification; artificial intelligence

## I. INTRODUCTION

COVID-19, a new strain of the Coronavirus, was initially discovered in Wuhan, China in December of this year and has since spread rapidly over the globe [1, 2]. SARS-CoV-2, the virus that causes the disease, has infected millions of individuals throughout the globe. After infecting throat mucosa, COVID-19 may move to lungs through respiratory tract. In order to stop the spread of COVID-19 and expedite treatment, it is critical to quickly screen, identify, and isolate people who have the illness. Medical imaging, such as CXR and CT scans, have been shown to accurately diagnose COVID-19 infection and are now frequently utilized in disease screening [3–5]. However, owing to the disease's recent origins and resemblances to other respiratory conditions such as pneumonia, proper interpretation of findings via pictures presents various difficulties. Achieving a reliable diagnosis of COVID-19 is difficult and time consuming because of its complexity [6-10]. Only radiologists are qualified to conduct this work. Healthcare personnel all throughout the globe have a

difficult task as a result of this epidemic. Many patients' test findings must be analyzed over a period of time. In recent years, there has been a growth in the need for clinical assistance for COVID-19 patients' treatment [11,12]. In order to meet the needs of a large number of patients, image analysis on medical pictures combined with decision support systems may give an accurate and speedy diagnosis of illness. While radiologists can spend up to 10 minutes reviewing CT scans manually, decision support systems can do the same in less than a minute. Although COVID-19 may induce major organ malfunction, such as pneumonia and renal failure, it can also lead to mortality (Fleuren, Tonutti et al., 2021). As a result, early detection of COVID-19 patients is critical. The illness continues to spread since the patient is not isolated after the PCR test, which was used to diagnose COVID-19.

The rest of the paper is organized as follows; Section II describes about the related work; Section III describes proposed model; Section IV describes about the deep residual networks; Section V describes about results and discussions; Section VI describes about conclusions.

## II. RELATED WORK

Deep learning may be classified into unsupervised, supervised, and semi-supervised learning depending on the training dataset's labels. Images are all tagged via supervised learning, and the model is tuned using these image-label pairings. A probability score will be generated for each testing picture based on the model's optimum parameters [15]. It's possible to use unsupervised learning to discover patterns or hidden data structures without providing any labels to the model beforehand. In this case, the model learns input-output relationships from the labelled data and is enhanced by the unlabeled data, which contains more semantic and fine-grained information. Semi-supervised learning is a term for this sort of learning method [13]. We'll cover the most popular frameworks for each of these learning paradigms. The three broad methodologies mentioned here may be integrated with other learning standards for enhanced medical image processing performance. The general classification of the radiography image is represented in Fig. 1. The chest X-Ray images of various formats are represented in Fig. 2.

Fig. 1. General Classification of Radiography Images.

Fig. 2. Chest X ray Images (a) Covid 19, (b) Bacterial Pneumonia (c) Viral Pneumonia (d) Normal.

### III. PROPOSED MODEL

Presently, the most popular machine learning method is the convolution neural network (CNN), a kind of deep artificial neural network with superior feature extraction and identification capabilities [14, 15]. One of its most distinguishing characteristics is weight sharing, which drastically decreases the network complexity and total weights [16]. With numerous convolution layer, followed by pooling layer, activation functions like softmax, ReLu, and fully connected layers reduce the loss function to a minimum.

The ultimate result of a typical CNN network structure is often one or more fully-connected layers [17, 18, 19], however the network itself is typically composed of convolutional and pooling layers. The final output of the layer is obtained by applying a bias to fully connected layer and activation function.

$$D_j^l = f\left(\sum_{D \in M_j} D_j^{l-1} \cdot h_{ij}^l + v_i^l\right) \quad (1)$$

The Eq. 1 illustrates this process. feature map is represented as  $D_j^l$ , excitation function is shown as  $f$ , input feature maps is shown as  $M$ , convolution operation is mentioned as  $\cdot$ , and bias term is represented as  $h$ .

### IV. DEEP RESIDUAL NETWORKS

ResNet is built on top of deeper networks, the theoretical foundation of which is described in [20, 21]. There are 50, 101, and 152 nodes in a traditional ResNet network. The 2015-ILSVRC competition was won by a CNN with 152 layers. In addition, ResNet improves by 28% on the well-known cOco132 example dataset for image recognition [22, 23]. For the most part, ResNet takes use of the concept of bypass channels in the "road network," as seen in the mathematical Eq. 2 and Eq. 3.

$$g(y_i) = f(y_i) + y_i \quad (2)$$

$$f(y_i) = g(y_i) - y_i \quad (3)$$

The transformed signal, denoted by  $f$  in Eq. 2 and Eq. 3, is defined in relation to the input signal,  $y_i$ . A side-channel adds the first input to  $f(y_i)$ . When computing the residual in Eq. 4,  $g(y_i)$  is employed. In order to facilitate communication across layers, ResNet deploys "shortcut channels" inside those levels; in contrast to the gates used in traditional highway networks, however, these gates are both data-agnostic and parameter-free. They stand for the non-residual functions of a highway system after the bypass route has been closed. A linear direct mapping

$y \rightarrow y_i$  and a nonlinear mapping  $F$  are both possible components of the submodule  $f(y_i)$ . Once the learning algorithm determines that the direct mapping,  $y \rightarrow y_i$ , is best, it may simply zero out the weight parameters of the nonlinear mapping  $f(y_i)$ . When there is no one-to-one mapping, it might be challenging to learn a linear mapping from a nonlinear function  $f(y_i)$  [24, 25]. On the other hand, with ResNet, residual information is continuously sent and the shortcut channel is never closed. In order for ResNet to circumvent the gradient reduction issue, it makes use of residual links, which are rapid channel connections that speed up the fusing of deep networks. The architecture of ResNet50 is shown in Fig. 3.

Fig. 3. ResNet Network Architecture.

**Algorithm:**

Input: Feature vector from CNN model( $F$ ), Size of  $F(S)$ ,  $F$  average (Avg),  $F$  Standard Deviation (SD), Threshold ( $T$ ), Parameter Tuning ( $F(X)$ )

Output: Reduced Feature ( $OF$ )

Step 1: *Feature Reduction* ( $F, SD, Avg, T$ )

Step 2: Begin

Step 3:  $OF = F$

Step 4: *For*  $i = 1$  to  $S$  *do*

Step 5:  $X = SD/OF[i]$

Step 6:  $Y = Avg/OF[i]$

Step 7: *if*  $X > T$  and  $Y > T$

Step 8: Parameter Tuning

$$F(X) = F(X) \pm X \text{ and } F(Y) = F(Y) \pm Y$$

---

Step 9:	$OF[i] = []$
Step 10: end if	
Step 11: end for	
Step 12: end	

---

V. RESULTS AND DISCUSSIONS

We started by analysing X-ray and CT scans of the lungs taken from a wide range of patients and healthy individuals (<https://www.kaggle.com/datasets/tawsifurrahman/covid19-radiography-database>). We gathered X-ray and CT scans of the lungs from 2045 healthy controls, 785 mild cases, and 130 severe cases of COVID-19. Data sets were obtained and manually annotated by expert imaging specialists, and pictures were utilised with patient and hospital permission. Ethical clearance is given by the institution's review board. A total of 2960 samples were obtained. All pictures were exactly 299 pixels in width and height. Table II displays the experimental data distribution. We combine COVID-19 features with clinical knowledge to segment the lesion area, to train a neural network to predict COVID-19 diagnoses, ultimately narrowing down the features to 20 that have the highest diagnostic value. This offers a non-invasive technique for detecting COVID-19 in advance.

Chest X-Ray images from Kaggle: 6110 pre-processed images are used for training and testing. If model can train in a shorter time, this means that model will be more efficient at more training iterations. As it can be seen on the Table I below DenseNet-121 model is more in the aspect of time. It is common knowledge that classification algorithms are evaluated based on parameters like specificity, sensitivity, and accuracy as shown in Eq. (4), Eq. (5), and Eq. (6). And proposed model attain values are mentioned in Table II. Accuracy is defined as the ratio of correctly categorized instances to the total number of examples. The output images are represented in Table III. Proposed method compared with the existing method are shown in Table IV.

Accuracy is compared with number epoch as shown in Fig. 3.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{4}$$

$$Sensitivity = \frac{TP}{TP+FN} \tag{5}$$

$$Specificity = \frac{TN}{TN+FP} \tag{6}$$

## VI. CONCLUSION

The approach described in this work has been developed primarily for the purpose of making early and definitive diagnoses for patients, although it has broad use in pathological categorization and prognosis prediction. When compared to the riskier and slower nasal swab, CNN is a preferable approach for identifying people infected with COVID-19. Importantly, the proposed approach allows for a multiclass diagnosis with other pulmonary disorders, which is important since many of these diseases may have startling similarities in their symptoms and consequences on the lungs. The superiority of CNN models like COVDC-Net in real-world applications may soon become apparent, rendering other testing obsolete. Another advantage of AI-assisted diagnosis is that it may be quickly scaled to existing hospitals and clinics using X-ray machines, without the need for specialised infrastructure and testing equipment. We want to improve the suggested model's robustness in the future by testing it on a more comprehensive range of pulmonary disorders.

**Abstract**—This study examines the consumer's visual attention toward gamification options while watching the OTT (Over-the-top) online content. Also, the impact of gamification on user engagement (UE) on the OTT platform was studied using data collected by conducting an eye-tracking experiment and subsequently using a user engagement scale (UES). The study was carried out at the marketing and behavioural lab of a management institute in India using the OTT platform website and Tobii eye-tracker. Empirical data was collected from 52 respondents within the age group between 23 to 35 years. The relation between Attention to Gamification (AG), Reward Satisfaction (RS), and User Engagement (UE) were studied by running a mediating linear regression analysis. From the results, it was found that respondents were equally interested in watching the online content as well as ready to explore the gamification options. The research findings demonstrate that Reward Satisfaction (RS) acted as a mediating factor in the relation between Attention to Gamification (AG) and User Engagement (UE). This study adds to the literature on consumer engagement towards gamification on the OTT platform, where the literature is still limited. Future research could consider mobile apps as a platform to undertake the study. This study aimed to empirically test the effect of AG on UE with the involvement of RS as a mediator. The study is the first of its type to use eye-tracking data to understand the impact of gamification on the OTT platform.

## I. INTRODUCTION

Technology is proliferating, and the internet offers a new way of entertainment, which has augmented the adoption of Over-the-top (OTT) media. The OTT platforms are a significant by-product of the expansion and exploration of digital media. The OTT market is anticipated to grow at a compounded annual growth rate (CAGR) of 14.3 % to reach US \$86.80 billion by 2026 [1]. This growth is due to easily accessible and inexpensive internet connections and low-cost subscription-based OTT platforms. With technological advancements in handheld devices, viewers can see content, including videos, movies, series, etc., anytime and anywhere. OTT service platforms like Netflix, Disney Hotstar, Amazon Prime, Discovery Plus, YouTube, EPIC ON, ZEE5, and others enable viewing movies, series, TV shows, and other content at a click. The OTT market has steadily and slowly shaken the

linear, complex, and vertically unified television distribution industry, which has been dominated for years by traditional pay television channels [2]. The stagnancy of the conventional television market created a vacuum in the media market. OTT platforms have seized this chance to strategize about how to engage with their customers more effectively, micro-target them, customize their products, and take advantage of the impending media collapse. This has eventually created an inspiring and level-playing scenario for OTT content providers [3]. Thus, to stay in the competition, many OTT platforms have implemented gamification to provide value-added engagement to customers [4]. Gamification is implemented to increase awareness about the gamified platform, achieve a prominent presence in the market, develop its user base, strengthen the bonds with the viewers, and improve consumer engagement.

With multiple players in the OTT market, operators aim to understand and offer services that cater to the viewer's demand by analysing the subscriber's preferences, thereby transforming how consumers consume online media content. The streaming platforms provide viewers with the freedom to select and access the content of their choice. Many platform providers have adopted operational changes concerning content creation, representation, and delivery to attract customers and gain their loyalty, as well as the introduction of gamification to encourage customers to participate actively. Games are essential to motivation and engagement when applied to interactive platforms [5]. Gamification refers to playing games on the platform to achieve rewards that can be redeemed in return and generate consumer engagement [6]. It is a concept of improving services with value addition to gaming experiences [7]. With gamification, consumers play games and enjoy the experience, irrespective of the result, thus increasing their involvement with the gamified platform [8] [9]. With gamification tools, consumers participate in interactive games, puzzles, questions, fantasy points, leader boards, bids, auctions, badges, feedback challenges, performance or game progress bars, lotteries, countdowns, and other options alongside viewing content. Affordances (points, badges, and leader boards) in gamification are the elements that form game structure and induce gameful experiences. The user interfaces with gamification and rewards (incentive to play games) shape consumer behaviour [8]. Gamification has attracted many retailers and e-commerce giants to include it for engaging customers with loyalty programs, impacting consumers' buying decisions and incremental sales [10]. The point-of-purchase

marketing was improved for offline and online stores that included gamification in the purchase process [11]. Gamification impacts viewers' behavioral outcomes, increasing platform involvement, and engagement [7]. Gamification in the marketing campaign comprises four levels: "attract, engage, retain, and reward" [12], with the ultimate goal of enhancing participation. Investigating gamification implementation in the context of the OTT platform is of significant importance as the OTT platforms are featured with online content viewing, which leads to involvement, interaction, and playful machination of the everyday world. Gamification enhances motivation [13]; therefore, the impact of gamification on customers' intention to engage on the OTT platform deserves investigation.

Concerning the OTT platforms, studies have mainly concentrated on examining the factors impacting the adaption and adoption of OTT platforms by the viewers [14]. Other studies include the OTT business models and approaches for business extension [15]. Even though OTT platforms have become part of everyday media, the studies related to the adoption and effect of gamification on OTT platforms are limited. ZEE5 (OTT platform) started ZEE5 Super Family (ZSF), a gaming experience for fictional content viewers [4]. EPIC ON has incorporated games that let the viewers redeem the rewards with coupons and discounts. Thus, this study tries to understand if implementing gamification on the OTT platforms improves customer engagement with the following research questions-

RQ1: Does the customer pay equal attention to the gamification option while watching the online content on the OTT platform?

RQ2: Does the option to earn rewards on playing the game act as a mediator between attention to gamification and customer engagement on the OTT platform?

To address the above research questions, this study considered the EPIC ON OTT website platform and collected users' visual attention data from an eye-tracking device to investigate the effectiveness of gamification on OTT. Indian OTT market is set to arise as the next biggest OTT market to reach the value of ₹ 138 billion by the end of the financial year 2023 with an estimated growth of 45%, following the USA [3]. OTT platforms have therefore been forced to implement structural changes to improve user engagement and retention. Many OTT service providers have embedded gamification into their platforms. This technological and structural update provides an important context that answers the research questions.

The objective of this study is two-fold. Firstly, a lab experiment was conducted using eye-tracking software to investigate customers' visual attention towards the option to watch and play the game on the OTT platform. Secondly, the study examined the impact of reward as a mediator for attention to gamification and user engagement. With the growing competitive environment in the local and international media marketplaces produced by global OTT services, it is vital to develop a new strategy for each OTT service through research that considers the viability of novel techniques like gamification. As of yet, the OTT platform is used to view content, but playing games on the OTT platform while

watching content is a new concept. The results from this study contribute to the body of literature on OTT-based gamification and provide developers an insight into whether the implementation of gamification on OTT is feasible.

The remainder of this research paper is comprised as follows. First, the report starts with the literature review and formulates the hypotheses. Then, the paper presents the methods and outcome of the analysis. Thirdly, arguments on the findings and implications are mentioned. Lastly, the report provides limitations and directions for future research.

## II. LITERATURE REVIEW

### A. Gamification Research

Extensive use of the term *gamification* started an era ago [16]. Since its commencement, it has been implemented in diverse fields, including computer sciences, educational scenarios, the health care sector, tourism, governance, research, and marketing [17][18][19], to name a few. Gamification means utilizing game elements and collaborating with various platforms to improve engagement. It is an approach to implementing game design components in the non-gaming environment [16]. Gamification has been defined as "the process of using game mechanics with other forms of technology to increase engagement" [20]. Most of the description of gamification that has been published state that it adopts game-like strategies in non-game contexts and can engage users and produce value that users perceive [21]. When implementing gamification, the creation of customer engagement is necessary. If the users do not experience participation, the whole gamification process fails [7][6][16].

A few quantitative research studies have shown the causal relationship between gamification, purchasing decisions, and customer engagement. In human-computer interaction, "user engagement" describes how people interrelate with the technology that fascinates them. A study by [22] stated that gamification improves adoption via playfulness, making consumers curious about the innovative features and their relative advantage. With gamification, consumers comment on products or services, give reviews, and share the content, increasing active users and repeated visits [23]. Gamification consists of stages like- appeal, involve, hold, and monetize [12], with the final goal to engage customers on the platform [24]. Involvement in technology results in engagement from the interaction between an emotional, cognitive, and behavioural relationship [25]. Gamification has been successfully applied across the learning management system for the students, motivating and generating interest in the subjects [26]. Employee engagement and job interest have been seen to be improved with gamification [9]. Thus, much of the research in the past has focused on understanding the role of gamification in encouraging customer participation and enhancing engagement in areas including social media, e-commerce, fitness apps, etc. Previous researchers have considered engagement and its effect on users; these ideas involve studies related to loyalty [27][28], pleasure [27], conviction [29], commitment and emotional connection [30]. However, gamification has been implemented recently in the case of OTT platforms, so the research conducted to understand the influence on viewer engagement is limited [31].

Providing options to play games on the OTT platform offers gameful experiences for the users regardless of the outcomes [7]. The present work attempts to study the gap using an experimental design in a lab setting with an eye-tracking tool.

### B. OTT Platform

The increased internet penetration and availability of multiple media platforms have stimulated video consumption via digital platforms. OTT service platforms, adopted from the TV set-top box, distribute video content using internet protocol. Reference [32] indicated that there had been a growing tendency toward the consumption of OTT platform content compared to traditional TV. Bypassing cable and satellite transmission, OTT video streaming services are defined as digital platforms providing consumers with handpicked content worldwide. A study by [33] stated that the pattern of complete streaming seasons for instant consumption has acted as a seed for the change from the television viewing culture to OTT content viewing. With the rapid growth in the media market, research studies have focused on user acceptance behaviour towards OTT platforms. Studies show that the content streamed over the platform and the involvement of consumers with it has played an essential role in consumers' reception and loyalty to the forum. This has led to unique content on the OTT platform that ensures enhanced experiences and consumer engagement [1]. Previous studies on consumer behaviour towards OTT platforms adopted expectation confirmation theory (ECT) [34] to understand the continued use intention of the consumers. The technology acceptance model (TAM) [35] was used to understand the motivation systems theory [36] regarding the consumer's choice of OTT platforms. With the increase in the number of OTT services and the number of viewers, [37] carried out user-centric research to study the user experience on the OTT platform (Netflix) based on uses and gratification theory

(UGT) and TAM. Reference [38] used niche analysis and the Uses and Gratification Theory (UGT) to inspect the viewers' interest in the OTT platforms. As OTT platforms are in their innovative stage, the service providers are experimenting with different tools to increase engagement. Reference [39] conducted a literature review study on 262 articles based on the OTT phenomenon, adopting experimental analysis, descriptive analysis, case study method, survey, content analysis, and theoretical analysis. However, in India, the majority of the studies on the OTT have used survey techniques. Thus, this study fills a research gap by adopting a novel methodology like experimental design using eye tracking in the Indian context.

### C. Customer Engagement (CE) Research

Customer engagement (CE) research has gained momentum. Gamification analysis primarily displays platform engagement [40]. Attention has been defined differently across various academic disciplines [41], and numerous definitions have been used to describe diverse engagement objects and subjects (e.g., brand engagement, customer engagement, student engagement, user engagement, employee engagement). In recent years, multiple studies have researched the relationship between gamification and various forms of engagement. Gamification implementation to motivate and engage students in academics has received the most attention, with education being the most fertile research field [42]. Nevertheless, research concerning engagement and gamification in contexts apart from education is getting attention rapidly. As mentioned in Table I, research studies have investigated the link between gamification and brand engagement [40],[60],[49]; customer engagement (e.g., [24], [9], [47], [48]); employee engagement (e.g., [61]) and user engagement (e.g. [55], [57]). The current study focuses on user engagement, which is driven by gamification and related reward.

TABLE I. STUDIES INVESTIGATING THE RELATIONSHIP BETWEEN ENGAGEMENT AND GAMIFICATION

Reference	Independent variables	Mediator/Moderator	Dependent variables	Research design	Key findings
<b>Customer engagement</b>					
Reference [24]	Game elements (challenge, tasks, rewards, badges, leader boards and win condition)	Customer engagement behaviours and customer engagement emotions	Reward, relationship, loyalty and Subversion	Geographic approach	The study identifies essential behaviours and processes of online customer interaction.
Reference [43]	Gamification mechanics for player types		Customer and employee Engagement	Case Study	Gamification may increase employee and customer engagement, enhancing how people interact with brands and businesses and boosting workplace efficiency.
Reference [44]	Gamification mechanics	Challenge, entertainment, social dynamics and escapism/ Medical predispositions and age	Patient engagement (cognitive, emotional and behavioural)	Case study	Patient engagement is increased due to the four experiential outcomes that gamification mechanisms generate in patients: challenge, amusement, social dynamics, and escape.
Reference [45]	Perceived usefulness, ease of use, social influence and	Customers' engagement intention	Brand attitude	Focus group and survey	Perceived enjoyment and usefulness forecast brand attitude and engagement intentions. These characteristics are not influenced by perceived ease of use. Only brand attitude is influenced by

	enjoyment				perceived social impact.
Reference [46]	Game elements		Brand awareness, tourist experiences, tourist engagement, customer loyalty, entertainment and employee management	Case study	Gamification can be used in tourism marketing
Reference [47]	Gamified customer benefits (epistemic, social integrative and personal integrative)	Age and experience	Customer engagement behaviour and purchase	Longitudinal design	Personal and social consolidative reimbursements are the best drivers of engagement and purchase
Reference [44]	Game elements (competition and cooperation)	Customer experience, losing a contest/Prior level of customer engagement	Customer engagement toward the co-creation activity (conscious attention, enthused participation and social connection) and community	Experiment	Win/lose choices fall apart the benefits of gamification. Losing a competition incorporates an adverse effect on client encounters and engagement.
Reference [48]	Gamification principles (social interaction, sense of control, goals, progress tracking, rewards and prompts)	Hope, compulsion, customer engagement	Purchases	Interviews and survey	Trust emphatically intercedes the relationship between gamification standards and client engagement. Compulsion decreases the plausibility of client engagement.
<b>Brand Engagement</b>					
Reference [49]	High interactivity; optimal challenge	Emotional brand engagement; cognitive brand engagement	Self-brand connection	Experiment	Gamified communications that are highly collaborating and optimally challenging enable self-brand connections.
Reference [24]	Challenge, tasks, rewards, badges, leader board, and win condition	Customer engagement behaviours, fun/enjoyment (flow), dissatisfaction	Reward, relationship, loyalty, subversion	Geographic approach	The findings distinguish primary forms and results of C and CEB inside virtual gamified stages.
Reference [50] [51]	Perceived mobility, utilitarian and hedonic features	User experience; perceived benefits; perceived values	Brand equity (perceived quality, loyalty, associations, trust)	Web-based survey	Mobility has a significant effect on functional & hedonic features, while mobility and utilitarian and hedonic features influence consumer experience, which affects brand fairness.
Reference [18]	Gamification mechanisms		Brand engagement, brand loyalty, and brand awareness	Case study and interviews	Marketing executives see increased engagement as one of the most vital benefits of gamification.
Reference [40]	Gamification		Consumer brand engagement and consumer benefits (functional, hedonic, social, and educational)	Interviews	Gamified packaging generates: hedonic, functional, social, and academic edges for the client that are coupled to consumer whole engagement dimensions (cognitive, emotional, and behavioural)
Reference [52]	Immersion-, achievement- and social-related gamification features	Brand engagement (cognitive, emotional and behavioural)	Brand awareness and brand loyalty	Survey	Achievement and social interplay-related gamification feature positively impact the three varieties of company engagement. Immersion-related gamification aspects are solely positively associated with social brand engagement. Brand engagement will increase company consciousness and brand loyalty.
<b>User Engagement</b>					
Reference [53]	Game Design Mechanisms		Engagement with online platforms (Objective metrics)	Experiment	Gamified thematic activities, graphical incentives, and discussion boards influence member retention and engagement.
Reference [54]	Game elements (points, rankings, achievement and		Engagement toward a computation system, acceptance (attitude, intention to use, and intention to	Experiment	Respondents experience added engagement and show higher behavioural intents toward the gamified system. Perceived output

	social elements)		recommend), perceived usability and perceived output quality		quality and perceived engagement influence the reception of the gamified system
Reference [55]	Game dynamics (rewards, competition, self-expression, altruism)	Competence, autonomy, relatedness and enjoyment	User engagement with a gamified information system (vigor, dedication, and absorption)	Survey	Gamification improves user engagement by mediating psychological needs, satisfaction (autonomy, competence, and relatedness), and fun.
Reference [56]	Game elements (score system, a progress bar and levels, leader board, feedback)		TAM (perceived utility, ease of use, external factors, attitude towards and demonstrated results) and user engagement with a health mobile app (focus and attention, usability perception, aesthetic aspects, supportability, originality, and involvement)	Experiment	Gamification impacts engagement positively, inspiring intrinsic motivation in the respondents.
Reference [57]	Game elements (competition and leader boards)		Engagement with an app (objective metric)	Experiment	Gamification intensifies engagement with the app
Reference [58]	Commensurate game elements (e.g., points) and incommensurate elements (e.g., likes)		Autonomy, competence, relatedness, engagement behaviour (objective metrics), intrinsic motivation, loyalty	Experiment	Users who engage with equivalent game features exhibit greater internal motivation, are more involved in physical activity, and are more devoted to the fitness app than users who do not.
Reference [59]	Perceived usefulness, perceived ease of use, convenience and enjoyment	Engagement with mobile apps	Intention to use	Survey	Perceived ease of use, perceived usefulness, and enjoyment influence engagement, leading to users' intention
Reference [13]	Gamification Design (Badges)	Disparity in professional seniority	Engagement with online platforms (objective metrics) and inequality economic of returns	Experiment	Gamification design boosts doctors' participation in online health communities.

The User Engagement Scale (UES), developed by [62], is the most popular measure for user engagement. The original UES included 31 components across six user engagement dimensions (i.e., aesthetic appeal, felt involvement, novelty, perceived usability, focused attention, and durability). The factors included the following- Focused Involvement (FI) (if the experience is enjoyable or intriguing); Focused Attention (FA) (focused concentration, absorption, and the loss of the sense of time); Endurability "EN" (holistic response to the experience and overall success of the interaction); Novelty "NO" (interest or curiosity generated by the system throughout the buying task); Perceived Usability ("PU") and Aesthetic Appeal ("AE") are two terms for the visual look of an interface, which includes the visuals, graphics, and other items that appeal to the user's senses (affective and cognitive aspects derived from the use of the system).

Understanding individuals' communicative patterns with digital platforms (e.g., eHealth, eLearning, digital games, social media, online search) is essential in studying their effects on user behaviour [63]. With a wide variety of digital platforms (e.g., social networking sites, mobile apps, web search engines, and others), the association between gamification and user engagement has been investigated in various contexts like online platforms, mobile apps, learning management systems, human computation and others (Table I). These studies

established a positive relationship between gamification and users' engagement.

### III. PROPOSED MODEL AND HYPOTHESES: GAMIFICATION AND ENGAGEMENT

#### A. Study 1

For the first part of the study, the data from the eye-tracking device was used to examine the users' visual attention towards the option to watch online content and the opportunity to play games. Eye-tracking data analysis helps to find patterns in the respondent's visual data. However, finding those patterns and analyzing the eye-tracking data require more than one visualization metric. Using multiple metrics to analyze the eye-tracking data can improve the result [64]. Fixation count (location), fixation length, and saccades (movement) are the essential pieces of eye-tracking data that form important parameters [65]. When the eye is reasonably still, it is called a fixation. Fixations determine where participants fixate their eye vision when viewing the platform. Visualization data regarding fixation duration and the count was used for the present study. Fixation Duration determines how long people spend staring at a specific spot. Each interval is a few milliseconds long. Processing is linked to increased duration, indicating complexity, interest, or engagement. Fixation counts determine which portion of the page receives more or less attention. Fixation counts are numbered in sequence to see how people

process survey pieces. Studies based on advertisements [66] included visual attention data to analyze the impact on viewers. Therefore, based on the above statements, the following hypotheses are proposed.

H1: Duration of visual attention (fixation duration) towards watching online content and gamification is the same.

H2: Visual attention, using fixation counts across watching online content, and gamification are the same.

### B. Study 2

For the second part of the study, a model in Fig. 1 is proposed to understand if the viewer's attention to gamification impacts engagement with reward as a mediator. The data based on the user's visual attention on a platform displays the depth of user involvement on the platform and is an aspect of the user experience [67]. Reference [23] and [68] analyzed the visual attention data to understand user engagement. Gamification elements impact the perceived ease of use of shopping and e-banking websites [69]. Many gamified services introduce challenges as one of the prime game elements [70]. Previous research studies have shown that challenges in gamified shopping impact buying behaviour [71]. A reward gained by completing a task increases the likelihood of acting on that reward [11]. This effect has been explored in situations other than gamification and intrigues the effort necessary to overcome the challenge. Earning a reward improves the likeliness of the tip compared to receiving a prize by luck [72]. Benefits such as coupons, discounts, cashback offers, or free subscriptions motivate and engage users. A reward is considered an essential aspect of engaging customers in gamification, and thus, the following conceptual model is proposed, as given in Fig. 1.

Fig. 1. Attention to Gamification and its Impact on user Engagement with Reward Satisfaction Acting as a Mediator.

1) *Attention to gamification and user engagement:* In their study, [73] stated that the adoption of gamification significantly leads to customer engagement. Reference [9] cited gamification as a game design scheme to achieve customer engagement and retention. Similarly, organizations use gamification to motivate and engage employees and customers [74]. Reference [48] suggested that gamification helps firms achieve customer engagement via social interactions. Reference [51] supported using gamification in marketing activities to strengthen customer engagement. Reference [75] stated that gamification's adoption boosted stakeholder engagement and is the primary driver of customer engagement. Tourist destinations employ gamified journeys to

engage visitors through various elements such as interactive maps, challenges, rewards gain, plot, and other aspects [76]. Thus, to test the impact of gamification on user engagement when implemented on OTT, the following hypothesis is formulated:

H3: There is a positive relationship between Attention to Gamification on the OTT platform and User Engagement.

2) *Reward satisfaction and user engagement:* Gamification on a gamified platform involves dealing with obstacles or being challenged [77], and dealing with such contests takes a certain amount of engagement. Continued engagement intent is driven by reward fulfillment. An extrinsic motivator, such as a reward, is a particular outcome of an activity that seeks to influence a person toward a specific action (like playing games). A reward represents a distinct outcome from the act itself, making it an extrinsic incentive and a motivator [78]. In the gamification literature, rewards are frequently used to incentivize activity. Users feel their connections with the gamified system are valuable and meaningful if they achieve rewards via participation [11]. In our study, on playing games, users were rewarded in the form of coupons, discounts, and redemption in monetary or non-monetary conditions. As rewards act as an extrinsic motivator to improve user engagement, the following hypotheses is proposed:

H4: There is a positive relationship between Attention to Gamification (AG) and Reward Satisfaction (RS).

H5: There is a positive relationship between Reward Satisfaction (RS) and User Engagement (UE).

H6: Reward Satisfaction (RS) mediates the effects of Attention to Gamification (AG) and User Engagement (UE).

## IV. METHOD

### A. Data Collection and Procedure

The experimental study was conducted in a marketing and behavioural studies lab within the college campus premises in November and December 2021. In the experimental setup, the respondents were assigned to a gamified situation. Data was collected from the eye-tracking device and administered through a quantitative questionnaire. The respondents were instructed to browse through the OTT platform website, but nothing was informed about the gamification option. The participants were briefed about the various navigation choices available on the website and were allowed to browse at their leisure. In the lab, the respondents were made to sit in front of a laptop with a Tobii Eye tracker installed. After the calibration procedure, the participants explored the OTT platform website. The method of calibration involves estimating a subject's eyes' geometrical properties to create a fully-tailored and precise estimation of their gaze point location. The user is instructed to focus on specific points on the screen during calibration, also referred to as calibration dots.

In the gamified condition, the respondents were free to play games while browsing the website. The website hosted

numerous games, which included fun games, puzzles, logic games, candy games, train the brain games, and others. These games offered coins which were declared at the end. One currency was rewarded for every 10 points earned by players while playing the game. On earning coins, respondents could redeem those coins in the form of discounts or cash back. After the respondents had finished navigating through the website, they were instructed to complete the questionnaire.

### B. Participants

As the study was conducted in the institute's laboratory and respondents were approached from within the campus; thus, convenience sampling was adopted. Initially, the total number of respondents was 60. Out of these, 8 participants failed the calibration process or had an incomplete recording. Finally, 52 participants' data was used during the analysis, as given in Table II, out of which 50 percent were females, and 50 percent were males in the age group between 20 years to 35 years. The participants were presented with a memento on task completion.

TABLE II. DEMOGRAPHICS OF RESPONDENT

Items	Types	N	%
Gender	Male	26	50
	Female	26	50
Age	20-30	47	91
	30-35	5	9
Occupation	Students	52	100
Education	Post-Graduate	45	87
	Ph. D. Scholar	7	13
Time spent on the OTT platform	Less than 1 hour	7	14
	1-2 hours	20	38
	2-3 hours	25	48

Note(s): N represents the number, % represents the percentage

### C. Measures

The study variables were measured using a five-point Likert scale (Strongly Agree to Disagree Strongly) based on previous literature (see Appendix A). Individuals' interactions with the website were measured using the visualization data from eye-tracking. User engagement was measured using the user engagement scale (UES) by adopting dimensions-aesthetic appeal (AE), focused attention (FA), perceived usability (PU), and reward satisfaction (RS). It felt involvement and novelty (FN). Lastly, the study includes four control variables: age, gender, and how much time the users spend on the OTT platform daily.

### D. Attention to Watching Online Content and Gamification

Several eye-tracking statistical metrics are frequently used to translate simple eye gazing into insightful data. These metrics give a quantitative assessment and can be determined as a count, a mean, a maximum value, a minimum value, or a summation value [79]. A commonly used metric is the fixation duration and fixation count. Fixation count is used in understanding which stimuli a viewer viewed more than other

stimuli content. Another measurement, fixation duration, gives a similar meaning but with a time measurement of a stationary position of the gaze point. Reference [80] measured the visual attention of the respondent using the metrics like fixation duration, fixation counts, mouse clicks, click-through rates, and page sights. In the present study, fixation duration and fixation count are used to measure visual attention toward watching online content and gamification for analysis. For the current study based on gamification, these forms of participant-action metrics can understand the experience and awareness of the viewers.

### E. Apparatus and Material

An OTT platform service provider with a game-playing option was considered for the experiment. Tobii eye-tracking devices and software were used to quantify visual attention. The eye tracker used in the study is a hardware device clamped to the laptop screen. It is a technology that accurately records the participants' gaze behaviours. The output from the equipment is in the form of a video that shows where on the screen the participant has looked during the whole experiment. It presents visual data through gaze plots, heat maps, and clusters. The gaze points were filtered using Tobii I-VT (Attention) fixation filter [79]. The fixations duration and fixation count on the targeted options of the website were considered. Peer researchers visually reviewed a random set of coded data for quality faults.

## V. DATA ANALYSIS AND RESULTS

The data from the study were analyzed in two stages. In the first stage, visualization data for the watch (content) and play (gamification) options in the form of fixation duration and fixation count were analyzed. In the second stage, the mediation model was tested using regression analysis.

### A. First Part of the Analysis

For analysis, visualization data was collected using gaze plots and heat maps. Gaze plot data collate data for fixation duration and fixation count. The primary purpose of the gaze plot is to show the time sequence of where and when the respondent is looking at. Along with gaze plots, heatmaps are an effective tool for analyzing user behaviour on website pages, which includes user clicks, how far they scroll, and what they pay attention to or ignore. Using a heat map, researchers can identify the portion of a stimulus where participants spent the maximum time. The heatmap's color palette makes it possible to distinguish between places with longer dwell durations and shorter dwell times [81]. The heatmaps show how the total number of fixations is spread across the screen. The deeper red areas indicate which parts of the screen involved the maximum number of desires, and the green areas show the least attended function.

Fig. 2 and Fig. 3 represent aggregated heat map data images with the red color denoting maximum concentration and green indicating the least amount. At a glance, attention is more dispersed during the website navigation task, more concentrated on the play option (Fig. 2) and the watch option (Fig. 3) area on the website. Thus, stating that the visual attention towards both options was almost similar. The initial part of the quantitative finding answers the first part of the

research question- whether the viewer’s attention toward the opportunity to watch online content and the gamification option is the same. As the data under consideration (visualization data from gaze plots) has non-normal distribution, a non-parametric Mann–Whitney test was performed. The proposed hypotheses H1 and H2 were tested using the Mann-Whitney U test. This test's dependent variable is continuous or ordinal and compares variances between two independent groups.

Fig. 2. A Heat Map with Maximum Concentration on the Play Option on the OTT Platform. Source: Tobii Eye Tracker (Visualisation Data).

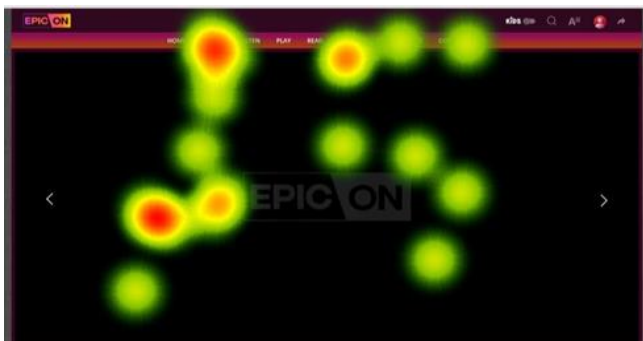

Fig. 3. A Heat Map with Maximum Concentration on the Watch Option on the OTT Platform. Source: Tobii Eye Tracker (Visualisation Data).

From Table III and Table IV, N=52, the mean rank for the option to play is more than the watch option, with U=1053.5 and p=0.052(the significance level, p<0.05) for the fixation duration and U=1056.5 and p=0.54(the significance level, p<0.05) for the fixation count, suggests that the difference between the fixation data for watch option and play option is insignificant. This states that both options' visualization data (fixation data) are not significantly different. Thus, hypotheses H1 and H2 are accepted.

TABLE III. RANKS STATISTICS FOR FIXATION DURATION (FD) AND FIXATION COUNT (FC)

Tabs	N	Fixation Duration (FD)		Fixation Count (FC)	
		Mean Rank	Sum of Ranks	Mean Rank	Sum of Ranks
Watch	52	46.76	2431.50	46.82	2434.50
Gamification	52	58.24	3028.50	58.18	3025.50
Total	104				

TABLE IV. MANN-WHITNEY TEST STATISTICS FOR FIXATION DURATION (FD) AND FIXATION COUNT (FC)

	FD	FC
Mann-Whitney U	1053.50	1056.50
Wilcoxon W	2431.50	2434.50
Z	-1.941	-1.930
Asymp. Sig. (2-tailed)	.052	.054
a. Grouping Variable: Tabs Note: p<0.05		

OTT platforms are primarily considered for viewing online content in the forms of web series, movies, and others. The above results inferred that the viewers paid equal attention to the watch option and the option to play games while browsing the website. Thus, a potential strategy for OTT platform developers to work on adopting gamification to enhance user engagement can be considered.

B. Second Part of the Analysis

In the second part of the study, the proposed hypotheses based on the mediation model were tested using regression analysis presented by [82]. The research was conducted using SPSS 22.0 software to test the mediating effect. It was examined that Reward Satisfaction (RS) acted as a mediator between attention to gamification (AG) and user engagement (UE). AG was measured using the fixation duration data from the eye-tracker. For RS and UE, data was collected using a questionnaire that had 16 items based on the User Engagement Scale (UES) [62].

1) Hypothesis testing: Previous research on gamification has incorporated regression analysis using structural equation modeling (SEM) [69]. The present study attempted to predict user engagement (dependent variable) based on attention towards gamification (independent variable) with reward satisfaction as a mediator. As recommended by [70], multiple regression analysis was used to test the model. Multiple regression analysis is an extended form of linear regression analysis. It predicts the value of a variable based on the value of two or more other variables. It determines the overall fit of the model and the contribution of each of the predictors to the total variance.

TABLE V. REGRESSION ANALYSIS

Hypothesis	R	R <sup>2</sup>	Adj.R <sup>2</sup>	F	β	P	Durbin-Watson	VI F
AG-RS	0.401	0.161	0.152	24.1	0.382	0.000	1.928	1.000
AG-UE	0.251	0.063	0.055	9.9	0.261	0.005	1.906	1.000
RS-UE	0.334	0.112	0.102	15.3	0.371	0.000	1.813	1.000

The regression analysis states that all the hypotheses have been supported as per Table V. Durbin-Watson statistics is between 1.5 and 2.5; hence there is no autocorrelation [83]. By analyzing the path connecting AG to RS (H4), it can be stated that AG substantially impacts RS for the viewers. It explains

nearly 15.2% of the total RS variance. The  $\beta$  coefficient of this path is 0.382 and was found to be statistically significant at  $p < 0.000$ .

The mediating regression analysis output is presented in Table VI. The statistics propose that AG under the mediating effect of RS (H6) is an essential predictor of UE. Sobel statistics suggested by [84], with a  $p$ -value  $< 0.05$ , was used to signify the mediating regression. The study revealed that the direct effect ( $c' = 0.15$ ) of AG on UE is insignificant, whereas the indirect effect ( $a \times b = 0.124$ ,  $p < 0.05$ ) is significant, indicating that RS plays a mediating role between AG and UE. Complete mediation occurs in a condition where the independent variable has no effect when the mediator is controlled [82]. AG accounted for 5% variability in UE. However, when RS was introduced as a mediating variable between AG and UE, the variability increased to 12%, which is more than double compared to the AG- UE model. Thus, the model improved with the mediating effect of RS.

Our study highlights that gamification adoption improves user engagement with rewards as one of the key contributors. Therefore, the developers need to pay attention to innovating and improving the adoption of gamification across OTT platforms. This seems logical because when the user is provided with an option to play and earn, they feel motivated and engage on the platform. Although the application of gamification on the OTT service providers' platform is in its primary stage, our study highlights a positive future. Considering that the satisfaction of the reward is a mediator, it will be a practical step to improvise the quality of the reward to improve user engagement. This improvement seems reasonable as the users will have options to earn good quality rewards while playing short and easy games on the OTT platform [11], [85]. It will enhance their interest in playing and watching online content.

TABLE VI. MEDIATING REGRESSION ANALYSIS

IV	MV	DV	Effects of IV on MV (a)	Effects of MV on DV (b)	Direct effect (c')	Indirect effect (a × b)	Total effects c'+(a × b)	Mediation	Sobel p-value
AG	RS	UE	0.382 (0.087)*	0.371 (0.092)*	0.15 (0.09)	0.124	0.261 (0.091)	Complete mediation	0.002

Notes: IV, independent variable; MV, mediating variable; DV, dependent variable; AG, Attention to gamification; RS, reward satisfaction; UE, User Engagement.  
\* $p < 0.05$

## VI. DISCUSSION AND IMPLICATIONS OF RESEARCH

Many companies are driving their focus toward implementation gamification in their business processes to improve employee-customer engagement. Businesses employ game features to increase repeat purchasing behaviour. This study aims to understand if the adoption of gamification with reward enhances user engagement. While previous studies [69], [86] have attempted to link gamification to customer engagement, the current study mediation process was used to understand how rewards motivate viewers on the OTT platform. This part of the paper suggests theoretical and practical applications of the study conducted, thereby adding to the body of knowledge by advancing the theoretical and practical discussion related to gamification adoption and behavioural studies.

This study makes several significant theoretical contributions. Firstly, the study is one of its kind to demonstrate the relation between gamification, reward, and user engagement. An experiment was designed to test how gamification and rewards influenced viewer engagement. Earlier studies have used the gamification concept across platforms like tourism websites, mobile apps, crowdfunding platforms, and others. In contrast, the current study considered an OTT platform to test the impact of gamification on viewer engagement. Since its inception, users have been using OTT platforms to watch online content in web series, movies, and others. This study brings a new perspective toward understanding the role of gamification on the OTT platform, which is in its booming stage. Previous studies concerning OTT platforms have focused on understanding the users' adoption behaviour. With the adoption of gamification on the

OTT platform, OTT service providers are reshaping their basic structures of providing online content. Thus, this study provides insight into the practicality of the OTT platform's new approach, like gamification. A survey by [87] stated that reward was a mediator in the relationship between gamification and motivation (hedonic and utilitarian). Similarly, the current study successfully analyses the mediating role of rewards in the relationship between gamification and user engagement. This study is a first-hand approach to conducting eye-tracking analysis on the OTT platform, thereby adding to the literature on the methods used across OTT platforms.

In addition to the theoretical contributions, several managerial implications derive from the study's empirical results. Integrating gamification components into marketing, social media, community, and other digital brand experiences is a potent user engagement tactic for increasing engagement. Though not a one-size-fits-all solution, gamification can assist in increasing brand and content awareness in the OTT video market in various ways when used carefully and tailored to the content [88]. Earlier research demonstrated that gamification positively impacts buying behaviour and engagement [54], [61]. The results from the present study support the inclusion of gamification for increasing engagement. The findings state several practical suggestions to help OTT platform developers and marketers make better decisions regarding the implementation of gamification. With gamification getting a similar amount of visual attention compared to watching content options, marketers and developers must work hard towards the appropriate implementation of gamification to increase user engagement on OTT platforms.

Game components like rewards (received upon playing games) make it desirable for consumers to interact with

gamification options and influence user engagement. Game designers can think about including challenges and real-time feedback in their games so that users can keep track of their improvement and outcomes. Players can receive points for their efforts and, based on the points earned, progress to advanced levels with more challenging activities, giving them the impression that their abilities are growing and that spending time on such platforms is valuable. Gamification on the OTT platform is in the nascent stage, so game developers should pay attention to the game's aesthetic appeal as it is the first thing the user views. Games that are visually attractive with high-quality graphics have a high chance of getting spotted.

The present study used an eye-tracking device to map the OTT viewers' visual attention and platform activities. Eye-tracking (Eye movement analysis) is a valuable source for investigating the visual attention process (which is directed by the sub-conscious behaviour) while involved in an activity. It displays how visual attention is allocated to the objects (e.g., words and graphic portions), how long, and in what direction [68]. The eye-tracking approach has been used widely in library science and information search [89]. This study has used eye-tracking software to analyze user engagement through visual attention data towards gamification on the OTT platform and is one of a kind.

#### VII. LIMITATIONS AND FUTURE RESEARCH

The study provides possibilities for further research. The study adopted a unique approach to understanding the impact of gamification on OTT with a preference for user engagement. Although this study makes several contributions, it also has several limitations. The information was gathered all at once; longitudinal data could be used in future studies to determine the long-term impact of gamification. Second, the data was collected via a single OTT platform; thus, future studies might be conducted on different OTT. Thirdly, future research could carry out a comparative study between the two or more OTT platforms with or without gamification.

In the current study, the sample size was limited to only 52. The respondent was college campus students with an average age between 20 to 30 years; future research could use an improved sample size and age range above 35 years. With respondents from the Millennials category, the interest, involvement, and engagement could give mixed results. The present study was purely quantitative; in the future, mixed-method or qualitative research might generate different insights. Also, the future progress in this study could be to understand the continued usage intention [90] driven by user engagement towards the OTT platform. With the OTT content becoming part of everyday life, it has become a topic of conversation among viewers. Finding, watching, and discussing content has become a social experience amongst online communities. OTT providers must comprehend how potential viewers find specific and exciting content and apply this knowledge to their marketing strategies, generating a requirement for future research to explore social interaction and engagement on the OTT platform.

#### VIII. CONCLUSION

The result of this study showcases how gamification affects users while watching online content on the OTT platform. With the intrinsically motivating aspect of the gamified services [91], usage of gamification on the OTT platforms could increase due to its appealing approach towards the users. The present study does not engage with the general inclination to use the app; it only shows how the implementation of gamification can improve the viewer's engagement on the OTT platform and can be used as an efficient marketing tool for promoting the OTT apps.

	RW.3	The experience of playing a game on the OTT platform did not work out the way I had planned.
	RW.4	My experience while playing games on the OTT platform was rewarding.
RW.5	I recommend playing a game on the OTT platform to my family and friends.	

# Optimally Allocating Ambulances in Delhi using Mutation based Shuffled Frog Leaping Algorithm

Zaheeruddin<sup>1</sup>, Hina Gupta<sup>2\*</sup>

Department of Electrical Engineering  
Jamia Millia Islamia University, New Delhi, India

**Abstract**—This paper presents a reliable and competent evolutionary-based approach for improving the response time of Emergency Medical Service (EMS) by efficiently allocating ambulances at the base stations. As the prime objective of EMS is to save people's lives by providing them with timely assistance, thus increasing the chances of a person's survivability, this paper has undertaken the problem of ambulance allocation. The work has been implemented using the proposed mutation-based Shuffled Frog Leaping Algorithm (mSFLA) to provide an optimal allocation plan. The authors have altered the basic SFLA using the concept of mutation to improve the quality of the solution obtained and avoid being trapped in local optima. Considering a set of assumptions, the new algorithm has been applied for allocating 50 ambulances among 11 base stations in Southern Delhi. The working environment of EMS, which includes stochastic requests, travel time, and dynamic traffic conditions, has been considered to attain accurate results. The work has been implemented in the MATLAB simulation environment to find an optimized allocation plan with a minimum average response time. The authors have reduced the average response time by 12.23% with the proposed algorithm. The paper also compares mSFLA, Genetic Algorithm (GA), and Particle Swarm Optimization (PSO) for the stated problem. The algorithms are compared in terms of objective value (average response time), convergence rate, and constancy repeatability to conclude that mSFLA performs better than the other two algorithms.

**Keywords**—Ambulance allocation; ambulance service; emergency medical service; shuffled frog leaping algorithm; mutation based shuffled frog leaping algorithm

## I. INTRODUCTION

Emergency Medical Service (EMS) control centers are vital in modern health systems and act as a pre-hospital component. EMSs provide out-of-hospital medical care and transport activities for the victims of accidents or illnesses. It plays a significant role in the public health system, and its ability to respond to emergency calls can significantly impact a patient's health and recovery [1]. Therefore, EMS control centers need to strategize and work towards handling a significant concern of allocating an appropriate count of ambulances to the base stations in an area [2]. Having a suitable count of ambulances available at the base stations will help the EMS provide a timely response to the persons in need. This motive has attracted many researchers to suggest solutions that prove viable in the working environment of EMS. As per the working procedure, an ambulance is selected and dispatched to the demand site when the EMS control center receives a request call. The rules set by the EMS authority help select and

dispatch the ambulance from one of the base stations (with ambulance availability) to serve the request. The rule may select the nearest ambulance to the requested location or the ambulance that will take less time to reach the location [3]–[5]. When the ambulance reaches the requested location, it may provide first aid to the patient or resuscitation. It then takes the patient to the hospital as per the requirement.

Research carried out to date has emphasized many issues related to planning, working, and management activities related to EMS using static models, dynamic models, hypercube models, covering models, etc. To attain optimum service performance, EMS facilities must be positioned strategically in a specific locality. Decisions here are taken from two aspects: selecting appropriate sites at which ambulances should be stationed and the number of ambulances stationed at each site [6]. However, considering densely populated cities and countries, deciding on allotting and constructing new places for base stations is challenging for the government. Therefore, the authors have undertaken the problem of optimizing the performance of EMSs by finding an optimal allocation solution for distributing ambulances among the existing base stations using the details regarding (1) the number of ambulances in the fleet, (2) the location of base stations, (3) frequency of request calls, and (4) tentative demand sites.

The remaining paper is organized as follows: Section II covers the literature review; Section III focuses on the problem background; followed by problem formulation in Section IV. Simulation modeling has been explained in Section V. Section VI covers the details related to simulation, results obtained, and discussions related to the same. Finally, the paper is concluded in Section VII.

## II. LITERATURE REVIEW

Out of all the literature available on this domain, the authors have cited works primarily focusing on optimizing ambulance allocation. Ambulance allocation is the distribution of ambulances to the base stations based on specific criteria [7]. The base station is an area where the ambulances are in standby mode. They are dispatched from the base station when they have to serve any request. However, deciding the locations for positioning the base station is out of the scope of this work. Our work primarily focuses on finding the allocation plan for ambulances at the existing base stations. Many researchers have extensively explored the EMS field to improve the service level provided to society. The research in the field of EMS needs the answer to the following two queries: (1) the optimization criterion that can be used as the

\*Corresponding Author.

best proxy for health outcomes, and (2) the model that is apt to be used for designing EMS systems handling a mixed territory comprising urban and rural areas. The work of many authors has covered the answer to the first query. In work put forward by [8]–[10], the authors have tried to determine the attribute that should be measured to assess the performance of EMS.

Many models exist in literature like Location Set Covering Problem (LSCP), Maximal Covering Location Problem (MCLP), Maximum Expected Covering Location Problem (MEXCLP), and Double Standard Model (DSM) for solving the facility location problem that has considered area covered by EMS as a significant attribute for proposing allocation plans. Similarly, some papers in the literature have considered service distance as an attribute for evaluating the performance of EMSs. In addition, the background of many articles has validated response time as a significant factor for gaining better insight into the operational performance of EMS. Some works have demonstrated that the patient's mortality and recovery rates are highly influenced by the response time [11]–[14]. Using the same objective in this paper, the authors have considered response time as the prime attribute for estimating and improving the medical service provided by EMS.

EMS operates in an uncertain environment in terms of demand rate, travel time, and response time. The effect of such an uncertain environment on the working of EMS was studied using a simulation-based evaluation method by Ünlüyurt and Tunçer [15]. Different authors have used various algorithms to attain optimized ambulance allocation plans. A data-driven approach was used to allocate and dynamically relocate the complete fleet of ambulances, using a mixed-integer linear formulation to solve the problem of ambulance allocation [16]. Firooze et al. proposed an optimizing model for allocating the ambulances to the base stations, considering the capacity of every base station, travel time, and service time of ambulances [17]. The authors [10], [18] proposed a new model by integrating survival functions with a motive to capture different categories of patients. The conditions faced by the EMS organization are dynamic in terms of variation in travel time, frequency of requests, speed of ambulances, and coverage of areas while fulfilling the requests. The critical issue of the impact of spatial randomness of demand has been considered in very few studies failing to obtain appropriate solutions. The covering models may not be suitable because the spatial distribution of demands may or may not be covered entirely, violating the assumption of the all-or-nothing binary coverage [19]. In 2018, an adjusted queuing solution for ambulance allocation was proposed by considering a heterogeneous spatial distribution of demands in urban and rural areas [20]. Although this solution helped overcome the overstaffing problem, it ignored the definite spatial distribution of demand in each area. In another solution by Chen et al., the authors used various shapes and sizes of grid systems to overcome the problem of the spatial distribution of demand [21]. However, obtaining a probability density function for request calls in a specific grid is challenging [22]. Moreover, a grid area holds no importance until it is classified as an area with a high frequency of request calls, a hospital, or a community resulting in an unstable demand distribution in the grid.

Considering these factors, Degel et al. proposed a time-dependent ambulance allocation model to improve the quality of emergency services [23]. In another work, the authors used a robust optimization approach to improve the functioning of EMS, considering the spatial demand characteristics and uncertain travel time to the requested site [24]. Geroliminis et al. presented a model and a heuristic solution for the optimal deployment of ambulances. They integrated a location model, Genetic Algorithm (GA), and hypercube model for their work [25]. The work by [26] used GA to propose an optimized solution for ambulance deployment. Later, a simulation model incorporating a Gaussian-process-based search algorithm was proposed to attain an optimal allocation plan for ambulances [27]. The authors in [28] handled the emergency department's overcrowding problem by using game theory-based optimization to propose a new optimized allocation plan for ambulances to reduce patient waiting and treatment time. Similarly, many authors [29]–[31] have used Particle Swarm Optimization (PSO) algorithm to achieve an optimized ambulance allocation plan for ambulances. Work was proposed by the authors [32], where a solution for optimally allocating the ambulances was proposed using Jumping PSO. Ant Colony Optimization (ACO) was also used for deploying and redeploying ambulances by [33], [34]. Another algorithm called Shuffled Frog Leaping Algorithm (SFLA) has been used in some works to explore the field of EMS. The authors [35], [36] used SFLA to optimize the working of EMS. SFLA has also been used in different domains for optimally allocating resources [37], [38]. However, there is a dearth of research papers where SFLA is used in the context of EMS.

Research by Elbeltagi et al. [38] indicated that SFLA is a better optimization technique than other evolutionary algorithms such as PSO, ACO, GA, and memetic algorithms. SFLA is a memetic metaheuristic algorithm proposed by Eusuff and Lansey in 2003. This algorithm combines the benefit of the social behavior-based PSO algorithm and genetic-based memetic algorithm. It performs similarly to PSO and surpasses GA in terms of quality of solution, consistency, and processing time. It is considered an efficient and fast algorithm as it can quickly converge to global optima with small population size. However, in some cases, traditional SFLA traps in local optima. To avoid this issue, the authors have proposed mutation-based SFLA (mSFLA) by incorporating the concept of mutation into the working of SFLA.

Considering the previous studies focusing on improvising EMS, most works have used simplified assumptions to come up with a result, while others fail to provide a mutual comparison of models. Computer simulation has proved to be the best way to assess the validation of different processes. Due to the lack of operational data or to avoid ample computation time, many simulation models oversimplify the actual operation. However, the simulation model should consider all the processes, sub-processes, and real-time conditions to find accurate results. The actual operation of the system should be considered while deriving the parameters for the simulation model. Therefore, in this work, the authors have proposed and used a simulation-optimization framework with mSFLA as the optimization component for ambulance allocation. The work

considers the spatial distribution of demands and other uncertainty factors associated with the environment of EMS. To verify and validate the suitability of mSFLA, the algorithm is executed in the MATLAB environment to compare the results with PSO and GA.

### III. PROBLEM BACKGROUND

In India, EMS refers to the ambulance service provided for on-the-spot treatment by paramedics or transporting sick or accident victims to the hospital. Despite being an essential component of society, a fully encompassing definition of EMS is impossible as it does not have a strong representation at the federal level owing to numerous local agencies providing EMS to the public. EMS agencies are classified into three categories based on the tasks they perform.

- 1) EMS that handles scheduled medical transport,
- 2) EMS that handles emergent inter-facility transport, and
- 3) EMS agencies that primarily handle 102-based emergency calls with or without transport.

In this study, the authors have focused on the third category that deals mainly with the optimized use of ambulances. In terms of population and vehicle density across any country, extensive growth is visible. With an increase in vehicle density, accidents (fatal and non-fatal) have also increased, thus, raising the concern of providing medical facilities at the location of the accident. Therefore, when an accident occurs at any location, an ambulance or hospital should be within reach in the shortest duration possible. Since setting up hospitals in every area is impossible, ambulances can be strategically deployed so that on-the-spot treatment and transportation can be provided to accident victims at the earliest. Centralized Accident and Trauma Services (CATS) is an autonomous body of government in Delhi, India, that provides EMS to the victims of accidents and trauma with an ART of approximately 13 minutes. CATS has deployed 50 ambulances at 11 base stations covering the southern portion of Delhi. The area of Southern Delhi is approximately 857 square kilometers and comprises four districts South West Delhi, South East Delhi, New Delhi, and South Delhi. The high frequency of request calls from Southern Delhi motivated the authors to select and work upon the data of this region to allocate and dispatch ambulances for handling accidents and reducing the casualty rate.

### IV. PROBLEM FORMULATION

The problem of allocating ambulances involves distributing a specific count of ambulances ( $A$ ) in the fleet among the base stations ( $B$ ) in such a way that the performance of EMS in terms of response time is improved while serving the requests generated from numerous demand points ( $D$ ). The solution for the distribution of ambulances among the base stations is represented by an integer variable  $a_i$ , where  $i \in B$  specifies the exact count of ambulances placed at different base stations. Thus,

$$A = \{a_1, a_2, a_3, \dots, a_B\}$$

Considering the real-world scenario, the authors have assumed that at an instant, only ' $p$ ' ambulances are available out of ' $A$ ' ambulances to handle the requests as the other

ambulances are busy handling the patients or are on their way back to the base station. The number of ambulances available at each base station ' $i$ ' is denoted as  $a_i(p)$ . To indicate the availability or non-availability of an ambulance at the base station ' $i$ ', a binary variable  $x_i(p)$  is used. Values 1 and 0 for  $x_i(p)$  indicate availability or non-availability at a particular base station. The mathematical formulation for minimizing ART is as follows.

$$\min RT = \sum_{i \in D} v_i * t_{ij} \quad (1)$$

subject to the constraints.

$$\sum_{i \in D} a_i(p) = p \quad (2)$$

$$\sum a_i = A \quad (3)$$

$$x_i(p) \leq a_i(p) \quad (4)$$

$$a_i(p) \geq 0 \quad (5) \quad x_i(p) \geq 0 \quad (6)$$

$$x_i(p) \in (0,1) \quad (7)$$

In the objective function shown in Equation 1,  $v_i$  indicates the arrival rate of request calls per hour and  $t_{ij}$  denotes the travel time from location  $i$  (base station) to location  $j$  (demand spot). As stated if ' $p$ ' ambulances are available out of  $A$  ambulances, Constraint (2) checks that the total ambulances available at each base station are equal to the total number of ambulances present in the system at the same instant. Constraint (3) restricts the total count of ambulances to  $A$ . The fulfillment of requests is constrained by the presence of a certain number of ambulances at the base station by Constraints (4)-(6). Constraint (7) restricts the value of the variable.

### V. SIMULATION MODELLING

The essential processes of an EMS system are structured in a simulation model, as shown in Fig. 1. As soon as the EMS center receives a call after an emergency occurs, the dispatcher selects the nearest ambulance available to serve at the accident site. The ambulance commutes from the base station to the requested site to locate the victim and provides on-the-spot treatment. After assessing the victim's situation, an ambulance transports the victim to the hospital if needed. The ambulance crew transfers the victim to the emergency room at the hospital. After completing the call, either at the requested site or the hospital, the ambulance returns to the base station and waits until assigned a new task.

An EMS system's complicated structure and process dynamics can be effectively represented with the help of an operational model. Fig. 2 shows the operational model designed using the workflow of EMS to achieve the objective of the proposed work. The emergency calls exhibit strong randomness in dimensions of time and space as they can occur at any time and place. Therefore, the spatiotemporal randomness of such calls should be described quantitatively for the correct working of the simulation model. Hence, all the data used in the simulation should be defined accurately to attain relevant results. A random two-dimensional variable ' $r$ ' represents the latitude and longitude coordinates of the point from where the request initiates. The EMS system uses these coordinates to know the exact request location to respond to

emergency calls. The optimization algorithm used in work determines the state values for base stations and ambulances. These state values act as input for the simulation model. The state values refer to the data on the location (coordinates) of the base station, the id of the base station, and the number of ambulances available at that base station. Whenever a request call arrives, the travel time between the request location 'r' and each base station 'bs<sub>i</sub>' can be calculated using the coordinate

data of 'r', base stations, and Google distance matrix application programming interface. This way, a list of base stations ranked by travel time from the requested location is obtained. Then an ambulance with the status 'available' is selected from the base station with the least travel time to request location and dispatched to serve the patient. The status of the selected ambulance is changed from 'available' to 'busy.'

Fig. 1. Simulation Model of EMS System.

Fig. 2. Operational Model for the Proposed Work.

After the ambulance dispatches, the system calculates response and delay time values. Response time is the time an ambulance takes to reach the patient's location after the request is initiated. As soon as the ambulance arrives at the requested site, the simulation model records the time for on-the-spot treatment. If the patient does not require transportation to a hospital, the ambulance returns to the base station, and its state changes from busy to available. Otherwise, travel and waiting time values are calculated if the patient is transported to a hospital. If no ambulance is available, the patient has to wait in a queue and is served as soon as an ambulance is available. The response time, in this case, is calculated as the sum of travel time and waiting time. After all the requests are served in a day, the total time taken by ambulances to reach the requested locations (response time) is divided by the total number of request calls received at the EMS centre to find the value of ART. The algorithm of mSFLA has been used as an optimizing component and works on the result of the simulation component to find the best allocation plan for ambulances.

#### A. Shuffled Frog Leaping Algorithm

The shuffled frog leaping algorithm helps in finding an optimal solution. It is a memetic meta-heuristic population-based cooperative search approach that imitates the group behavior (jumping strategy) used by frogs to find a location with the maximum amount of food. The algorithm incorporates techniques for performing local searches and exchanging global information. The frogs are randomly assigned a location in the search space. Several groups are formed by dividing the population of frogs, thus generating memeplexes. The memeplexes then evolve separately in different directions

within the search space. Individual frogs can use the information of the population's best frog (global best) or best frog in the memeplex (local best) and change their direction. Each frog experiences memetic evolution because they influence each other and improve their performance to achieve the goal. After a specific number of memetic evolutions, the memeplexes are shuffled to generate new memeplexes, enhancing frogs' ability to attain the best solution in search space. Thus, PSO and Shuffled complex evolution [39] are used for local search and integrating information from parallel local searches in SFLA. The various steps in SFLA are explained below.

Step 1: Population initialization and parameter setting: Various parameters need to be set up for SFLA, such as the size of the population, number of memeplexes and sub memeplexes, and number of memetic evolutions. A random population of 'N' frogs is generated to form the population. For all the frogs in the population, the fitness value is calculated.

Step 2: Grouping: The fitness value obtained above is used to sort the frogs in descending order of their fitness value. These frogs are then divided into 'm' subgroups, with n frogs in each subgroup.

Step 3: Intra-group search: From each subgroup, the frog with the best fitness value 'X<sub>b</sub>' and worst fitness value 'X<sub>w</sub>' are found. The worst solution in the subgroup is updated by using Equation 8 and 9, and only one solution which is the worst in the subgroup is updated at a sub iteration. For updating the position of the worst frog the following equations are used

$$S_i = rand * (X_b - X_w) \quad (8)$$

$$X'_w = X_w + S_i \quad (9)$$

so that

$$S_{imin} < S_i < S_{imax}$$

where  $S_i$  is the variation in the location of frog attained in a single jump. 'rand' is a uniformly distributed random number ranging between 0 and 1. The minimum and maximum step sizes for frogs are represented by  $S_{imin}$  and  $S_{imax}$ . The new position of the worst frog is represented by  $X'_w$ . If the value of  $X'_w$  is better than  $X_w$  then the value of  $X'_w$  replaces the value of  $X_w$  else the new value for  $X'_w$  is calculated by Equation 10 and 11.

$$S_i = rand * (X_{bg} - X_w) \quad (10)$$

$$X'_w = X_w + S_i \quad (11)$$

$X_{bg}$  is the best frog in the current population. In case if the value of  $X'_w$  is still not better than  $X_w$ , then the value of  $X'_w$  can be calculated using

$$X'_w = g + rand(1, D) \otimes (h - g) \quad (12)$$

In the above equation  $D$  represents the dimension of the optimization problem.  $rand(1, D)$  is a random vector of  $D$  components with each component between 0 and 1. 'g' and 'h' represent the upper and lower boundary vectors of the decisive variables.  $\otimes$  means an entry wise multiplication.

The worst frog and best frog is determined from the subgroups attained. Repeated subgroup search is carried out for predefined number of sub iterations. The intra group search stops when the search has been finished by all the subgroups.

Step 4: Exchange of global information: The exchange of global information considers reorganizing all the subgroups into a population of N frogs. Steps 2 and 3 are used again to sort and divide the population into subgroups. Alternate executions of these steps are carried out until either the termination criterion is reached or the best solution is obtained. However, in some cases, a low diversity in the population traps the SFLA into local optima or premature convergence. Therefore, the concept of strong mutation is proposed in this paper to increase the diversity in the population. This concept works upon generating a trial mutated vector using the values of the best solution ( $X_b$ ) in each memplex and the value of the globally best solution ( $X_{bg}$ ). It is crucial to ensure that the dimension of the mutation vector and the number of memplexes is the same.

$$X_{mut}^i = X_{rand}^i + ra(X_b^i - X_{rand}^i) + ra(X_{bg}^i - X_{rand}^i) \quad (13)$$

$i = 1, 2, 3, \dots$  number of memplexes.

Here  $X_{rand}^i$  represents a randomly generated vector and  $ra$  is random number between 0 and 1. Now, the generation cost of trial vector  $f(X_{mut}^i)$  and target vector  $f(X_{bg}^i)$  are compared. If the value of the former is better than the latter, then the target vector is replaced by the trial vector in the next generation. Thus using this step, the algorithm can be prevented from being stuck into a local optimum, and convergence of the algorithm to a global value can be assured.

## B. Application of mSFLA to the Problem of Ambulance Allocation

The application of mSFLA to ambulance allocation problem is explained in this section. The steps used in the work are as follows:

- 1) The coordinate data about the base stations, count of ambulances at the base stations, total number of ambulances in the fleet, coordinate data of demand points are defined.
- 2) Initial population is generated as

$$\text{Population} = \begin{bmatrix} A_1 \\ A_2 \\ A_3 \\ \dots \\ A_{100} \end{bmatrix}$$

$$A_i = a_{i,1}, a_{i,2}, \dots, a_{i,N}$$

- 3) The objective function is defined stating the constraints and values.
- 4) Compute the fitness value for the objective function.
- 5) Sort and divide the population into memplexes on the basis of the value of the fitness function. The local best solution ( $X_b$ ) and the global best solution ( $X_{bg}$ ) is defined.
- 6) The frog with worst solution ( $X_w$ ) is amended using Equation (8) and (9) or Equation (10) and (11) depending on the situation explained in previous section.
- 7) The process of mutation is applied and the result obtained is compared with the value of  $X_{bg}$ .
- 8) The values are updated and the amended and steps through 4 to 8 are repeated until the termination criteria is met.
- 9) The best solution is obtained.

## VI. SIMULATION RESULTS AND DISCUSSION

### A. Area of Concern

The authors have undertaken the southern portion of Delhi to obtain an optimal allocation plan for a fleet of 50 ambulances at 11 base stations in the area. Fig. 3 and Fig. 4 show the southern portion of Delhi and base stations (BS1-BS11) of that area. The traffic police department of Delhi maintains records and releases a report every year stating the details like count of accidents, locations of accidents, time at which the accident took place, information regarding vehicles involved in accidents, etc. To get an insight into the situation, the authors used the report for the year 2019-2020. The report mentions different locations in Delhi which are accident-prone and must be taken into consideration by EMS organizations while devising and designing any policy or strategy. However, since an accident can occur at any location and at any point of time, the authors invented a robust framework that can handle any request initiated from any point in a short time. Considering each point (latitude and longitude) as a tentative spot for the occurrence of an accident, the authors divided southern Delhi into 230 blocks. Each block covered an area of approximately four kilometers square shown in Fig. 5. In every run of the framework, random requests are generated ensuring at least one request is initiated from each block.

Fig. 4. Base Stations of Southern Delhi.

Fig. 5. Tessellations of Southern Delhi.

**B. Results and Discussion**

MATLAB environment is used to execute the work for 15000 requests and a population size of 100. To exemplify the robustness and efficiency of mSFLA, the algorithm is executed as the optimization component in the operational model of the work. For implementing the mSFLA, the authors conducted many experiments to find appropriate values for various parameters. From the result of the experiments, the authors set values for the parameters: number of memplexes, number of frogs in each memplex, iteration count for global exploration,

and iteration count for local exploration, as shown in Table I. The parameter values used for GA and PSO are shown in Table II and Table III respectively.

For comparison, similar simulations are performed using PSO and GA as optimization components in the operational model stated in Section V. 20 runs of simulations are performed with each algorithm to compare the performance of the algorithms using the metrics such as the value of the objective function, convergence rate, and constancy repeatability.

TABLE I. PARAMETERS FOR M SFLA OPTIMIZATION

Parameter Name	Value
Number of frogs in each memplex	10
Number of memplexes	10
Iteration max <sub>1</sub>	70
Iteration max <sub>2</sub>	100
Iteration of mutation	10

TABLE II. PARAMETERS FOR GA

Parameter Name	Value
Population size	100
Number of iterations	1000
Crossover fraction	0.1
Mutation fraction	0.8

TABLE III. PARAMETERS FOR PSO

Parameter Name	Value
Population size	100
Number of iterations	1000
Cognitive coefficient (c <sub>1</sub> )	2
Social coefficient (c <sub>2</sub> )	2
Inertia coefficient (w)	0.8

1) *Convergence rate*: The suitability of an algorithm for an optimization problem can be evaluated using convergence rate [36]. The convergence graph can also estimate an algorithm's best, average, worst results, and standard deviation. The convergence graph for PSO, GA, and mSFLA is shown in Fig. 6(a), 6(b), and 6(c). As stated, 20 different runs were carried out for all three algorithms to attain the global fitness value for the objective function. The global fitness value is the best fitness value obtained in each iteration within the defined population size of the algorithm. The graph illustrates that the value of global fitness (in the best iteration/generation of every algorithm) changed from 13.58172 to 11.9733 in the case of PSO, 19.52089 to 11.72735 in the case of GA, and 12.93752 to 11.4127 in the case of mSFLA in 1000 iterations of each. The graph also indicates that the PSO algorithm converged in 94, the GA in 358, and the mSFLA in 41 iterations. The quick convergence of mSFLA indicates that the convergence rate and computational time of mSFLA are better than GA and PSO.

Another comparison result is shown in Fig. 7 and Fig. 8, where the values of standard deviation, best, average, and worst solutions are plotted for each algorithm. The result in Fig. 7 indicates that the even worst solution (maximum ART) provided by mSFLA is better than the other two algorithms' average solutions. In addition, the average result of mSFLA is also better, making it more efficient. The value of Standard Deviation (stdev) for all the algorithms shown in Fig. 8 reveals that the value of stdev i.e. 0.045331 is almost negligible in the case of mSFLA; therefore, it can provide the best solution in each run.

(a)

(b)

(c)

Fig. 6. (a). Convergence Graph of PSO, (b). Convergence Graph of GA, (c). Convergence Graph of mSFLA.

Fig. 7. Comparison of Worst, Best, and Average Result.

Fig. 8. Comparison of Standard Deviation.

2) *Objective function value:* In this work, the objective function minimizes the value of ART of EMS to provide a prompt service to the people in need. The evolution graph in Fig. 9 depicts the global fitness values of ART for PSO, GA, and mSFLA are 11.9733 minutes, 11.72735 minutes, and 11.4127 minutes respectively.

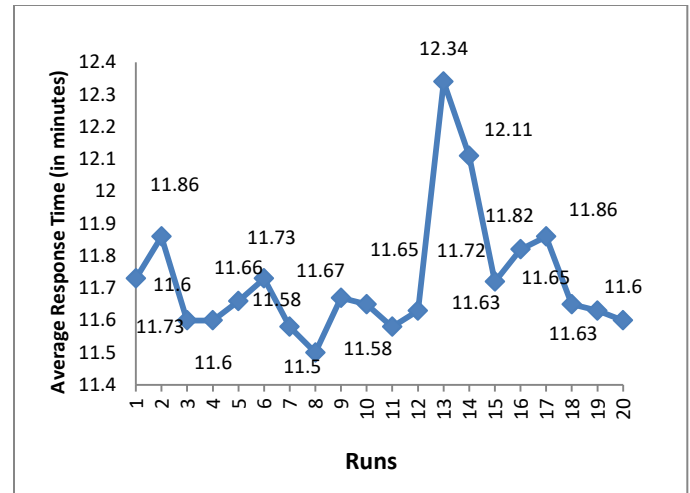

Fig. 9. Evolution Graph of Algorithms.

The convergence of mSFLA to the least value demonstrates that the result and performance of mSFLA is better than PSO and GA for the problem of ambulance allocation.

(a)

(b)

(c)

Fig. 10. (a). Constancy Graph of GA, (b). Constancy Graph of PSO, (c). Constancy Graph of mSFLA.

Fig. 11. Ambulance Allocation Plan Attained by Each Algorithm.

3) Constancy repeatability: The performance of any algorithm can also be measured using the concept of constancy repeatability. Constancy repeatability of an algorithm is the similarity rate of the results obtained by the algorithm in different executions with the same input values [40]. To infer the constancy and repeatability of the algorithm, the authors plotted the fitness values obtained by all three algorithms in twenty runs of the operational model. Fig. 10(a), 10(b), and 10(c) show that the changes in the fitness value of GA, PSO, and mSFLA. The changes in the value of GA are from 12.34 to 11.50 minutes, in PSO are from 12.34 to 11.68 minutes, and in mSFLA are from 11.55 to 11.41 minutes. To be more exact, the variance of the results is calculated. The variance values are 0.043178 for PSO, 0.038826 for GA, and 0.00205 for mSFLA. The consistency of any algorithm can be highlighted with the value of variance ranging between 0 and 1. In the proposed work, the variance value is between 0 and 1 for all three algorithms stating that all the algorithms are stable and consistent. However, the global optima results obtained by mSFLA are close to the average value in most runs, so it characterizes mSFLA as the most stable algorithm among the three algorithms. In other words, it can be said that in most cases, mSFLA will converge to global optima or near global optima. The ambulance allocation plan for the area of Southern Delhi provided by each algorithm is shown in Fig. 11.

## VII. CONCLUSION

The performance of EMS significantly affects a country's healthcare system as it is considered responsible for saving people's lives. Response time is considered a key indicator to measure the performance of EMS by evaluating the time an ambulance takes to report at the spot from where the request was generated. To reduce the response time of EMS, the ambulances should be strategically allocated at the base stations so that the commuting time of the ambulance from the base station to the demanded spot is reduced. Considering this motive, the authors undertook the problem of finding an optimal allocation plan for a fleet of 50 ambulances among the

11 base stations in the southern portion of Delhi. The authors used an operational model that showed the flow of data between the simulation component and optimization component. For the optimization component, the authors proposed mSFLA that used the concept of mutation in SFLA to avoid being trapped in local optima. mSFLA was compared with GA and PSO using different metrics. The results shown in Section VI help analyze the performance of mSFLA with PSO and GA. The objective of the work to attain an allocation plan with minimum response time is attained by mSFLA. It is able to reduce the value of ART from 13 minutes to 11.41 minutes, i.e., by 12.23%.

A comparison of standard deviation, best and worst solutions of the proposed algorithm proves that mSFLA is more effective than the other two algorithms. The small value of 0.045331 for standard deviation signifies that mSFLA is consistent and reliable. Quick convergence and short execution time of mSFLA imply that it can be efficiently utilized in optimization problems similar to ambulance allocation problems. Moreover, mSFLA converges to a global optima value of 11.4127 minutes at lower iterations i.e. 41<sup>st</sup> iteration number taking less execution time than PSO and GA, which converge to a global optima value of 11.9733 and 11.72735 in 94<sup>th</sup> and 358<sup>th</sup> iteration number at much higher iterations. Therefore, mSFLA appears superior to the other two algorithms regarding the quality of solution and convergence rapidity. This work also validates the competency of mSFLA to other algorithms in handling problems similar to allocation problems.

As it is impossible to consider all the possible scenarios, the authors would like to extend the work by changing the single objective function to a multiobjective function. In addition, the authors will also focus on proposing an efficient strategy and solution for dynamically allocating and relocating ambulances.

STIE Team, CRMEF Casablanca-Settat, Provincial Section of El Jadida, El Jadida, 24000, Morocco<sup>4</sup>

**Abstract**—Digital Transformation has become one of the most discussed debates; many sectors have adopted digital transformation to gain a competitive advantage and to ensure their continuity. Moroccan universities, in their turn, are facing strategic and managerial challenges due to emerging practices related to digital transformation. To address this issue, the proposed work sets out to define the factors that lead us to adopt a digital transformation using SWOT analysis and to apply total quality management techniques to contribute to our research laboratory's digital transformation, by digitalizing and managing knowledge and processes. KMS-TQM digital platform has been used to capitalize knowledge and profile the different existing functions, positions, tasks, and referential competencies. Then, we analyzed all the actual processes to propose a business process re-engineering using Bizagi Modeler. The study's contribution is to standardize all the current processes in the laboratory to help the Doctoral Studies Center successfully carry out the digital transformation. Moreover, the aim is to make all functions and tasks for each position explicit.

**Keywords**—Business process re-engineering; digital transformation; knowledge management system; Moroccan research laboratory; total quality management

## I. INTRODUCTION

Digital Transformation (DT) has recently increasingly driven organizations to change [1]. It has become one of the most discussed debates in business and organizational contexts [2]. The DT has involved sustainable management in coping with these changes; this is a vital and essential process for organizations that pretend to be leaders of change and be competitive in their sector [3], [4].

COVID-19 pandemic has mobilized research community for developing early diagnosis systems [5]–[11]. In addition, this pandemic has confirmed the need to digitalize public and private organizations (companies and educational institutions, etc.). The pandemic was an opportunity to innovate and accelerate the digital transformation to ensure the continuity and sustainability of the company [12].

In the education sector, the digital transformation has implicated sustainable management in dealing with these transformations [13]–[15]. The DT has been significant as a primary focus for higher education institutions (HEIs) [16].

Many studies have introduced the digital transformation in public administrations and the public sector [17], [18], that are

focusing on redefining their processes to create new forms of public administration and interactions with users of their services.

In the current research, we will focus on the Moroccan research structures, taking as a case study our scientific research laboratory LaROSERI, which unfortunately requires additional efforts to ensure good productivity and sustainability. Through digital transformation, it will be able to manage efficiently and effectively the whole research laboratory from different axes: performance, knowledge management, and business process re-engineering.

In our previous work [19], we considered the research laboratory as a non-profit organization, and then we defined an indicator called “Global Laboratory Performance Indicator GLPI” to measure the laboratory's global performance. As a result, it has been shown a suitable approach should be adopted.

For this purpose, we suggest the following rankings, which show the necessity to rethink our managerial and strategic organization. To define the gaps that lead us to this study, we refer to the Ranking Web of World Research Centers as an initiative of the Cybermetrics Lab, a research group belonging to the Consejo Superior de Investigaciones Científicas (CSIC)<sup>1</sup>. CSIC is one of the leading essential research organizations in Europe. In 2006, CSIC comprised 126 centers and institutes throughout Spain. CSIC is attached to the Ministry of Education, and its primary goal is to promote scientific research to enhance scientific and technological progress.

The following Table I ranks the top ten research centers/labs, according to the 2019 CSIC ranking.

The Table II describes the global and African ranking of Moroccan research centers. As presented, the Moroccan Institute of Scientific and Technical Information - IMIST is ranked 65<sup>th</sup> in Africa and 4094<sup>th</sup> worldwide.

These rankings highlight the importance and the need for a set of actions to reposition the scientific research structures that are facing strategical and managerial challenges. Furthermore, Morocco upholds digital transformation through many initiatives to accelerate its development; we can cite some of them as described in the Table III.

<sup>1</sup> <https://research.webometrics.info/en/>

TABLE I. CSIC RANKING – 2019

Ranking	Institution	Country
1	National Institutes of Health	USA
2	National Aeronautics and Space Administration	USA
3	Centre National de la Recherche Scientifique CNRS	France
4	Max Planck Gesellschaft	Germany
5	Chinese Academy of Science CAS / 中国科学院	China
6	Centers for Disease Control and Prevention	USA
7	US Department of Veterans Affairs	USA
8	Consejo Superior de Investigaciones Cientificas CSIC	Spain
9	National Oceanic and Atmospheric Administration	USA
10	Consiglio Nazionale delle Ricerche CNR	Italy

TABLE II. CSIC MOROCCAN RESEARCH CENTERS/LABS - AFRICAN RANKING - 2019

Global ranking	African ranking	Research Center/Lab
4094 <sup>th</sup>	65 <sup>th</sup>	Moroccan Institute of Scientific and Technical Information - IMIST
4198 <sup>th</sup>	69 <sup>th</sup>	National Center for Scientific and Technical Research - CNRST
4263 <sup>rd</sup>	70 <sup>th</sup>	Royal Institute of Amazigh Culture - IRCA
4529 <sup>th</sup>	77 <sup>th</sup>	Pasteur Institute of Morocco
5139 <sup>th</sup>	90 <sup>th</sup>	Scientific Institute of Rabat

TABLE III. MOROCCAN INITIATIVES

Moroccan Initiative	Description
“Horizon 2020”	In Morocco, the digital transformation has been accelerated, mainly due to the major government initiatives, "Horizon 2020", launched in 2017, and then "Horizon 2025", which have set ambitious goals in terms of e-government and training of young people in innovative technologies.
The National Plan to reform administration (2018-2021)	It is considered a crucial demand to upgrade the administration and the public Service through its restructuring and the reinforcement of its managerial and technical capacities to be qualified to offer good governance, ensure services of the general interest, and provide users with quality services.
The Framework Law 51-17	The Moroccan parliament approved the framework law 51-17 in August 2019, which concerns the government's strategic plan "2015-2030" to strengthen the national education system. The framework law 51-17 will mandate the creation of a national commission to supervise its execution and the overall education system reform in Morocco.

To properly define the factors that led us to this study, we propose a SWOT analysis as described in Table IV.

As shown in the SWOT analysis, it describes what the research laboratory excels, identifies in which it needs to undertake improvements to remain competitive. In addition, the analysis mentions factors that have the potential to harm the research laboratory or that could provide a strategic advantage to it.

TABLE IV. SWOT ANALYSIS

SWOT analysis	
Internal	
Strengths	Weaknesses
<ul style="list-style-type: none"> <li>- The diversification of the theses topics, which emerge from several fields</li> <li>- Developing scientific and technical research in the computer sciences field</li> <li>- Offering different doctoral training and part-time teaching opportunities for PhDs</li> <li>- Collaborations between research teams, such as thesis co-supervision, and co-authors.</li> <li>- A good work atmosphere</li> </ul>	<ul style="list-style-type: none"> <li>- Insufficient dynamics of doctoral studies (doctoral theses duration are too often exceeding the regulatory period, which is three years)</li> <li>- Lack of a Digital workspace that can promote collaborative work</li> <li>- Insufficient resources (offices and materials) for the expected increase in the number of doctoral students enrolled.</li> <li>- Percentage of funded theses</li> <li>- Lack of using monitoring and steering tools (skills management, performance management, process management)</li> <li>- The absence of an internal structure specialized in setting up and monitoring theses, research projects, and research activities.</li> <li>- Lack of training to prepare PhD students for the job market actions (soft skills, coaching, personal development)</li> <li>- The need for a digital strategy</li> <li>- Lack of a quality management system</li> <li>- Lack of a digital tool to communicate research outcomes within the laboratory members</li> <li>- Lack of positions and skills repository</li> <li>- Integration of new information and communication technologies is relatively modest.</li> <li>- Lack of a digital system for monitoring and evaluating research activity</li> <li>- Lack of using efficient governance tools such as the BSC</li> <li>- Need for a management training, people in positions of responsibility</li> </ul>
External	
Opportunities	Threats
<ul style="list-style-type: none"> <li>- Research in collaboration with external laboratories, universities, or institutions.</li> <li>- Research projects in collaboration with CNRST, OCP, UM6P</li> <li>- Communicating research outcomes in different scientific events</li> <li>- Publishing scientific papers in indexed journals</li> </ul>	<ul style="list-style-type: none"> <li>- Absence of a digital platform</li> <li>- Concurrence with other national institutions</li> <li>- The absence of an alumni network</li> <li>- The gap between ambition and resources allocated to research</li> <li>- Weak private R&amp;D and insufficient business/university interactions</li> <li>- Lack of sufficient anticipation of investments in IT/digital infrastructure</li> </ul>

According to the points above, we have decided that adopting a digital transformation could solve this issue, thus digitizing, managing, and eventually repositioning the research laboratory within the university.

This work emphasizes using a knowledge management system (KMS) capable of filling all the gaps mentioned.

To successfully conduct this research, we focused on the following three research questions:

- How can the laboratory develop the digital transformation strategy?
- How clear does the management in the Lab understand the needs for a digital transformation of its organization?
- How does the laboratory apply digital technologies and managerial practices in its processes?

To answer the research questions, the main contributions of this work are the following:

- Defining the factors and limits that have forced us to adopt a digital transformation using the SWOT analysis.
- Using a Knowledge Management System that combines all the TQM aspects to manage the whole structure.
- Standardize all the research structure processes to be expressed explicitly.

The rest of this paper is structured as follows: Section II presents the related works and the problematic. Section III describes the proposed approach. Section IV shows the implementation using KMS-TQM digital platform and Bizagi Modeler. Finally, section V concludes the current work and proposes the perspectives.

## II. RELATED WORKS

Due to new needs and requirements, several sectors have used digitalization to obtain a competitive advantage and ensure continuity [20], [21]. To discuss the state of the art, we propose the following subsections that determine each aspect of our work: Digitalization and Digital transformation, Knowledge Management, Business process Re-engineering, and their applications in the context of HEIs.

### A. Digitalization and Digital Transformation

According to [12], the COVID-19 pandemic has confirmed the need and importance of digitalization in public and private organizations. It was an opportunity to innovate and accelerate the digital transformation to ensure the continuity and sustainability of organizations. To define the term 'Digitalization' and 'Digital Transformation', the following Table V illustrates some definitions proposed in the literature.

As pointed out in [25], digital competence is considered as a set of skills, knowledge, and attitudes necessary to use ICT and digital devices for responsibilities such as information management, and collaboration in an effective, efficient and ethical way. Digital transformation is considered a well-

known topic at the moment, and ideas for digital products, facilities, and media were already widely understood in the 1990s and 2000s [26].

TABLE V. DIGITALIZATION AND DIGITAL TRANSFORMATION DEFINITIONS

Ref	Definition
[22]	Digitalization is a "sustainable company-level transformation via revised or newly created business operations and business models achieved through value-added digitalization initiatives, ultimately resulting in improved profitability."
[23]	The digitalization is "the application of any digital technologies to all human activities, such as personal life, social, economic and political activities."
[24]	Digital transformation is "a process that aims to improve an entity by triggering significant changes to its properties through combinations of information, computing, communication, and connectivity technologies."

"Each organizational transformation implies a cultural transformation", the introduction of new technologies and digitalization has strongly contributed to the organizational and cultural transformation of companies [27]. Digital transformation has caused a significant change in the business, both in its activities, its organization and even in its culture [28]. Digital transformation is the integration of new processes within the company, such as adopting new technologies, tools, and work methods [29]. It impacts the global functioning of companies and transforms working methods and processes, requiring managerial approaches for a long-term vision to remain competitive, efficient, and modern [30].

### B. Total Quality Management

Total quality management is a managerial approach that began in Japanese industry and has received increased attention in the West since the early 1980s[31], [32]. Total quality refers to a company's culture, attitude, and organization that attempts to consistently offer its customers products and services that fulfill their expectations [33].

TQM is a quality management approach whose target is to achieve ideal quality, the entire company should be mobilized and involved, by reducing waste as much as possible and by continuously improving the output elements [28]. Many agree that the TQM movement began in Japan, the term TQM comes from TQC, it was coined by A.V. Freignbaum, 1983 [34], [35]. Organizations that have successfully used the principles of TQM, have integrated the customer and quality into their business strategy [36]. It is the result of the efforts made to develop Quality Management.

Important aspects of TQM encompass quality management leadership and commitment, continuous improvement, rapid response, evidence-based actions, employee involvement, and a TQM culture [37].

In the context of higher education, several quality management models developed for use in industry have been involved in HEIs around the world [43], such as TQM, EFQM, Balanced scorecard, Malcolm Baldrige award, ISO 9000, Business process re-engineering and SERVQUAL. One of the most well-known quality management models that have

been implemented in higher education is Total Quality Management (TQM) as described in Table VI [44].

The study [45] defines the seven TQM factors as follows: Leadership, Strategic planning, Human resource management, Customer orientation, Process management, Information analysis, and Continuous process improvement. Through the implication of TQM concepts, assists organizations in learning strategies to increase productivity. The dimensions of TQM indicate the broad range of features in organizational cultures that promote innovation. Yet, the success of TQM demands an organizational culture based on trust and knowledge sharing [46].

TABLE VI. TQM APPLICATIONS IN HEIS

Ref	Year	Overview
[38]	2018	Through a review of the literature, this research aims to examine the impact of TQM on the organizational performance of Portuguese universities and polytechnic higher education institutions. The purpose of this study is to point out the importance of quality in education, specifically in HEIs, as indicated by the recent studies, the existing literature has highlighted the fact that educational institutions are lagging behind other organizations in terms of total quality culture.
[39]	2019	This research represents a survey done at two Swedish universities, and it attempts to determine teacher educators' use of digitalization technologies and the resulting demand for digital competence in higher education. Digital competence involves, among other factors, acquiring and familiarizing with various digital tools and apps to utilize Internet and digital technology is a critical and educative approach.
[40]	2019	The digital transformation strategy seeks to create the capacity to fully use the potential of new technologies in a fast and innovative manner in the future. The study proves that planning and implementing infrastructure allow all students and staff to effectively communicate, share information, and collaborate in research skills, thus improving teaching and learning and supporting administrative functions, students, and staff to use computer systems to boost their digital skills.
[41]	2020	This work represents a bibliometric of 1590 papers from the Scopus database. In the education sector, the Digital transformation has necessitated the implementation of a long-term management strategy. The authors conclude that HEIs are progressing in managing their economic, environmental, and social sustainability, concerning digital transformation to reach the model of an open, digital, innovative, and connected institution.
[42]	2022	Higher education institutions around the world have used numerous quality management strategies. As mentioned in this work, with the growing interest of the quality measures for sustained growth in education, the potential of developing a paradigm that reflects the challenges of higher education while including comprehensive quality and social responsibility ought to be considered. Therefore, the authors proposed an approach that connects the TQM and social responsibility of organizations and higher education institutions.

Recently, knowledge management by the company has constituted a sustainable competitive advantage, forming a common point with the objectives of the quality approach: obtaining a competitive advantage [47]. Not only knowledge

management, but the implementation of business process management also helps organizations enhance their capacities through individual knowledge resources and greater collective knowledge of the organization.

The decision to manage the laboratory knowledge needs to set a standardized process by redesigning the actual processes. The following subsections define knowledge management and business process re-engineering.

### C. Knowledge Management

Knowledge is a valuable, scarce and non-substitutable resource that enables an organization to gain a sustainable competitive advantage [38]. It is a set of experiences, values, information and ideas to assess and integrate new knowledge and experiences. Knowledge is an intangible attribute that is practically impossible to simulate and is considered a strategic asset that has to be effectively managed by every organization [48]. It can be explicit or tacit.

Knowledge management is the process of getting the right knowledge to the right person at the right time. Moreover, knowledge management aims to explicit the tacit knowledge by systematizing large sets of knowledge and gathering individual knowledge [49], [50]. The purpose is to produce valuable knowledge, fulfill the knowledge demands of customers, perform knowledge and innovations and strengthen the basic competitiveness of an organization [51]. The KM approach is the integration of individuals, methods and technologies implied in planning and implementing the infrastructure of the educational institutions [52].

Therefore, the process of knowledge implies four steps: creation, retrieval/storage, transfer and application [53]. The different components of KM as cited in these works [53] in Table VII include five elements:

TABLE VII. ELEMENTS OF KM

<b>Knowledge Creation</b>	The organization's ability to create and communicate knowledge in its services, and systems. The process of knowledge creation consists in capturing a part of tacit knowledge and transforming it into explicit knowledge.
<b>Knowledge Application</b>	The most important step in knowledge management is to ensure that knowledge is productively applicable for the organization's benefit, aiming to maximize performance.
<b>Knowledge Sharing</b>	Knowledge sharing is a range of behaviors that include sharing information or helping others to inspire innovative behavior.
<b>Knowledge Capitalization (Storage)</b>	It consists in identifying its crucial knowledge, preserving it and making it sustainable while ensuring that it is shared and used by the greatest number of people. Without this capitalization effort, collective knowledge does not exist.
<b>Knowledge Transfer</b>	It is the process of transferring knowledge between individuals, groups or organizations using various means or channels of communication.

D. Business Process Re-engineering – BPR

Today, quality is identified by the process approach of the activities. The management of processes is a strategy adopted by organizations that want to become more efficient; it would make them more efficient in executing their processes and ultimately more competitive [54]. The term of ‘process approach’ first appeared in its 2000 version: "the application of the process system within an organization, as well as the identification, interactions and management of these processes". This definition summarizes the requirements of a management system of quality, and treats the customer satisfaction by adding value to each process.

The process approach has been described and established as the quality management basis in organizations through the ISO 9001 version 2015 standard. It allows to identify, map the processes, and understand their interactions in an organization [55]. In addition, according to FD X50-176 standard, “Process management can be applied to all types of organizations regardless of their size, activity, and to the various management systems implemented (quality, safety, environment, etc.)”[56].

E. Use case: Research Laboratory LAROSERI

1) *Description:* The LAROSERI research laboratory was created in 2014. It belongs to the Computer Science Department in the Faculty of Science in El Jadida, Morocco. LAROSERI includes four research teams as described in Table VIII.

2) *Challenges:* The main objective of this study is to reposition the Chouaib Doukkali University in scientific research, by applying the Total Quality Management and using a Knowledge Management System. The SWOT analysis described in Table IV has determined the factors that led us to adopt a digital transformation. The Fig. 1 shows some Laboratory challenges.

Aiming to address these issues, we propose an approach based on Total Quality Management techniques that can provide adequate solutions to digitalize manage and steer the entire laboratory. The following section presents the proposed approach.

TABLE VIII. RESEARCH LABORATORY DESCRIPTION

Department	Name of the laboratory	Research Teams
Computer sciences	Research Laboratory in Optimization, Emerging Systems, Networks and Imaging (LROSERI)	Optimization, Intelligent System and Imaging
		intelligent transportation systems
		Business Intelligence, Network and Imaging
		Decision and Information Systems

Fig. 1. Research Laboratory Challenges.

III. PROPOSED APPROACH

Related works have highlighted the potential that the TQM application in the research structure context offers. Our case study consists of proposing an innovative approach to properly digitalize and manage the research laboratory.

The proposed approach can be divided in the workflow as shown in Fig. 2. This digital transition impacts the overall functioning of companies and disrupts working methods and processes, which requires the use of managerial approaches for a long-term vision to remain competitive, efficient, and modern[57]–[59].

Fig. 2 and Fig. 3 describe the steps and tools that we used to adopt a digital transformation in our research laboratory.

A. Knowledge Management using KMS-TQM Platform

The knowledge management concerns the way knowledge is stocked and arranged. From a managerial perspective, the capitalization of knowledge is a major element in the improvement of performance via the establishing of a trustworthy resource base completed by appropriate software, and able to offer appropriate decision support. The objective of this function is to store relevant knowledge that assists actors in their operations [50].

In this work, we propose to use a KMS (Knowledge Management System) to capitalize and store knowledge in a repository, which is specifically designed for a scientific research laboratory, in order to provide relevant decision support to the different research laboratory’s actors.

Fig. 2. Used Tools.

Fig. 3. Approach Workflow.

1) *KMS-TQM digital platform*: We are going to use KMS-TQM Digital platform<sup>2,3</sup> as described in the Table IX:

**B. Business Process Re-engineering using Bizagi Modeler**

Unfortunately, for Quality module, the platform offers only process mapping. Therefore, we chose the Bizagi Modeler tool for process modeling in order to make explicit all the existing processes within the laboratory. The choice of this robust process management tool aims to redesign the research laboratory process, thus integrating all actors, functions, tasks, etc.

Bizagi<sup>4</sup> is a free BPM tool (for a single user) to create, optimize and publish a process. It also provides a cloud-based collaboration environment, offering powerful and fast drag-and-drop design tools. In addition, it allows users to review process models from any location and on any device and to provide real-time feedback.

The KMS-TQM digital platform allows us the features shown in Fig. 4.

TABLE IX. KMS-TQM DIGITAL PLATFORM

<b>KMS-Digital Platform</b>	A facilitator and accelerator of digital transformation and CSR transition, thanks to its transversal approach focused on the company's business processes.
	A data collector and organizer, which prepares organizations for the next Artificial Intelligence revolution.
	A powerful and adaptable tool for steering (Balanced ScoreCard, dynamic dashboards) and monitoring (risk management, project coordination, etc.) all of the operational activities, and which has the capacity to integrate those of the stakeholders (via the integrated ISO 26000 and BCorp certification reference systems).
	With a strong digital component (digitalizing procedures, workflows, data collection), it will also support organizations in their technological transformation.

<sup>2</sup> <http://37.187.48.129:9191/062021ic-canada-certified-trainings/>

<sup>4</sup> <https://www.bizagi.com/en/products/bpm-suite/modeler>

Fig. 4. Research Laboratory Digitalization and Management using KMS-TQM Digital Platform.

In this work, we intend to digitalize all the actual processes and make them as a standard in our Laboratory.

#### IV. RESULTS AND DISCUSSION

In this section, we will apply the proposed approach, first by using KMS-TQM digital platform to digitalize and manage knowledge, then by using the Bizagi Modeler to manage the laboratory processes.

The purpose of capitalizing knowledge in our case—is to make explicit functions, tasks, and competencies. It answers the question: who did what and how?

By using the KMS-TQM platform, we generate the function sheets of each position in the research laboratory. We have assigned to each position a function(s) that is linked to numerous tasks and competencies.

The first step is to create the organizational entities and assign each to a parent entity. For instance, in our case, a doctoral studies center depends on the doctoral college as mentioned in Fig. 5.

The next step is to create competencies referential to tasks. Then, assigning each task to an appropriate function becomes possible, and defining the function first manager and assignments. Fig. 6-8 below illustrate the entity's management, tasks, and function management.

After preparing functions with their owners, the platform proposes to generate a functional or organizational sheet. It summarizes all the functions depending on their relationship. Fig. 9 describes an example of the functional sheet.

Fig. 5. Entities Management.

Fig. 6. Functions Management.

Fig. 7. Tasks Management.

Fig. 8. Affecting Tasks to Function.

To set standardized processes within the Laboratory, each actor should elaborate a draft of the different activities; it concerns the laboratory chief, the research supervisors, research teams' chiefs, PhD students. After these tasks, the Director of the CeDoc (Center for Doctoral Studies) collects information concerning each process, capitalizes knowledge, redesigns the actual processes, and finally, validates, and standardizes these processes.

Fig. 9. An Example of a Functional Sheet.

Fig. 10 and Fig. 11 depict this activity and the different interactions.

Fig. 10. Research Laboratory Processes Re-engineering.

Fig. 11. Research Laboratory Knowledge Capitalization.

## V. CONCLUSION

In summary, the TQM applications aiming to digitalize and manage research structures are still very weak. This paper analyzes the factors to adopt a digital transformation in the research laboratory by applying the SWOT analysis and gives an overview of some available recent studies that apply this approach in the same context. The main objective of our research is to integrate a Knowledge Management System and apply TQM aspects, which can apply to any research laboratory that desires to adopt a digital transformation. The proposed approach briefly describes the steps to be followed to digitalize and manage knowledge and redesign the current processes.

Despite the advantages of the research approach, some limitations can be addressed through future research; the platform used in the implementation does not link process modeling with other modules, which means integration issues. Therefore, to propose a suitable and adaptable solution, it will be more practical to think of an open-source solution with huge possibilities.

In future work, as mentioned, we intend to conduct a comparative study between laboratory management information systems (LIMS) by selecting specific criteria to propose an adequate digital framework. The framework will combine the quality management system (QMS) aspects and integrate innovative solutions to digitalize and manage research structures.

## ACKNOWLEDGMENT

This work was funded by the National Center for Scientific and Technical Research (CNRST-Rabat).

**Abstract**—There is no doubt that the use of drugs has significant consequences for society, it introduces risk into the human life and causing earlier mortality and morbidity. Being a conscientious member of society, we must go ahead to prevent these young minds from life-threatening addiction. Owing to the computational complexity of wrapper approaches, the poor performance of filtering techniques, and the classifier dependency of embedded approaches, artificial intelligence and machine learning systems can provide useful tools for raising the prediction rate of drug users. Recently, the psychologists approved the recent personality traits Five Factor Model (FFM) for understanding human individual differences. The aim of this work is to propose a rough sets theory based method to investigate the relationship between drug user/non-user (month-based user definition) and the personality traits. The data of five factor personality profiles, impulsivity, sensation-seeking and biographical information of users of 21 different types of legal and illegal drugs are used to fetch all reducts and finally a set of classification rules are created to predict the drug user/non-user(month-based user definition). The outcomes demonstrate the novelty of the current work which can be summarized as The set of generalized classification rules which pronounced with logic functions build a knowledge base with excellent accuracy to analyze drug misuse successfully and may be worthy in many applications.

**Keywords**—Classification; personality traits; five factor model; rules extraction; drug abuse detection; rough sets theory; feature selection

## I. INTRODUCTION

One of the extreme serious matters taking into account the mental health in these days is drug addiction, where it has the ability to devastate life and a nation readily for their toxic and addictive effects. Drug intemperance means" the picking of diverse drugs illegally and being addicted to those drugs". Drug intemperance has turned into a severe truth for which the young descents from all lifestyles are influenced silently. Dissatisfaction is the cause for this intemperance, unemployed matters, political outburst, non-attendance of homely relationships, and non-attendance of ardent love fellowship which offers rise to disappointments [1]. Drug is having been thought to be one of the extreme used psychoactive substances. as stated by world health organization, drug consuming leads to the death of three million as well as 5.1% of several universal diseases all over the world yearly [2]. The practical

importance of the issue of estimating individual's risk of intemperance drugs is very high [3]. The connection of personality traits to risk of intemperance drugs is a continuous problem [4]. Many studies had been done to find the answer of the following Questions -"How do personality, gender, education, nationality, age, and other attributes affect this risk? Is this dependence different for different drugs? Which personality traits are the most important for evaluation of the risk of consumption of a particular drug, and are these traits different for different drugs? Is the prediction of drugs usage by a person helpful to prevent the persons from getting addicted to drugs?" Also, some related works had been done by researchers on drugs and addiction predictions to improve the methods which are used. Bergh [5] proposed a way to Predicting Alcohol Consumption in Adolescents from Historical Text Messaging Data. Belcher et al. [6] studied the personality traits and sensitivity or resilience to drug intemperance. Weissman, et al. [7] studied the effects of the drug intemperance adolescent and it is found that there is a strong connection between reward and cognitive control brain networks. Andreassen et al. [8] studied the relevance between behavioral addictions and the FFM of personality. Kumar, et. al. [9] proposed efficient prediction of drug-drug interaction using deep learning models. In this work all the questions which posed above have been reformulated as classification problem and an effective data mining technique dependent on rough set theory was employed to address these issues and extracting classification rules to predict the Drug User/Non-User (month-based user definition).

## II. RESEARCH PROBLEM

Psychologists tried many times to identify the connections between personality traits and drug user/non-user. Many studies are done and data mining techniques and methodologies had been used to manage these issues such as decision trees, linear discriminant analysis, and statistics estimation techniques [10]. The main aim of this work is to find answers to these questions: Which personality traits have the great importance for estimation of the risk of abusing drugs, and are these traits different for different drugs? What are the effects of personality, gender, education, nationality, age, and other factors on abusing drugs? What about this dependence for several drugs?

\* Corresponding Author

### A. Personality Traits

In recent years and due to the development in scientific research, the psychologists approved the recent personality traits Five Factor Model (FFM) for realization of human individual variances [11]. It consists of Neuroticism (N), Extraversion (E), Openness to Experience (O), Agreeableness (A), and Conscientiousness (C). These traits can be defined as follow:

- N : "Neuroticism is a long-term tendency to experience negative emotions such as nervousness, tension, anxiety and depression (associated adjectives [10]: anxious, self-pitying, tense, touchy, unstable, and worrying)"
- E: " Extraversion manifested in characters who are outgoing, warm, active, assertive, talkative, and cheerful; these persons are often in search of stimulation (associated adjectives: active, assertive, energetic, enthusiastic, outgoing, and talkative)".
- O: "Openness to experience is associated with a general appreciation for art, unusual ideas, and imaginative, creative, unconventional, and wide interests (associated adjectives: artistic, curious, imaginative, insightful, original, and wide interest)".
- A: "Agreeableness is a dimension of interpersonal relations, characterized by altruism, trust, modesty, kindness, compassion and cooperativeness (associated adjectives: appreciative, forgiving, generous, kind, sympathetic, and trusting)".
- C: "Conscientiousness is a tendency to be organized and dependable, strong-willed, persistent, reliable, and efficient (associated adjectives: efficient, organised, reliable, responsible, and thorough)".

The values of the five factors (N, E, O, A, C) are utilized as inputs in various statistical methodologies for prediction, diagnosis, and risk estimation. These methodologies and techniques are used a wide range of fields where personality has a great importance such as medicine, psychology, psychiatry, education, sociology, and many others areas. Other two additional feature of personality confirmed to be leading for analysis of matter use, Impulsivity (Imp) and Sensation-Seeking (SS) [12].

- Imp: "Impulsivity is defined as a tendency to act without adequate forethought "
- SS: "Sensation-Seeking is defined by the search for experiences and feelings, that are varied, novel, complex and intense, and by the readiness to take risks for the sake of such experiences"

### B. Rough Sets Theory

Rough sets theories (RST) is the core of most recent approximations based mathematical model to investigate the imprecision and uncertainty present in knowledge [13-17], as well as extract decision rules which act as classification scheme for prediction. We can say that it is a tool for data mining or knowledge discovery in relational databases. It is a formal approximation of a crisp set defined by its two

approximations namely, Upper and Lower approximation [18] as shown in Fig. 1.

Fig. 1. Represent Tation of a Set Approximation of an Arbitrarily Set X in U.

The definition of the indiscernible relation IND(B) is:

$$IND(B) = \{ (x, y) \in U \mid \forall a \in B, a(x) = a(y) \} \quad (1)$$

Also, in decision system  $(U, A)$  let  $B \subseteq A$  and  $X \subseteq U$ , the lower approximate  $\underline{B}(x)$ , upper approximate  $\overline{B}(x)$  and the boundary of X denoted by BND(X) are written as:

$$\underline{B}(x) = \{x \in U \mid [x]_B \subseteq X\} \quad (2)$$

$$\overline{B}(x) = \{x \in U \mid [x]_B \cap X \neq \emptyset\} \quad (3)$$

$$BND(X) = \overline{B}(x) - \underline{B}(x) \quad (4)$$

The B-positive region of X and The B-negative region of X, denoted as  $POS_B(X)$ ,  $NEG_B(X)$  respectively are written as:

$$POS_B(X) = \underline{B}X \quad (5)$$

$$NEG_B(X) = U - \underline{B}X \quad (6)$$

The accuracy of approximation can be written as:

$$\alpha_B(X) = \frac{|BX|}{|BX|} \quad (7)$$

Where  $|x|$  is the cardinality of X. Obviously  $0 \leq \alpha_B(X) \leq 1$ . The rough membership function can be written as

$$\mu_X^B(x) = \frac{|X \cap [x_i]_{Ind(B)}|}{|[x_i]_{Ind(B)}|} \quad (8)$$

Obviously,

$$\mu_x^B(x) \in [0,1] \tag{9}$$

### III. ANALYSIS

In the life of the any human there are various factors (attributes) for addiction that lead to increase the probability of drug consumption. Some of these attributes correlated with psychological, social, environmental, and economic characteristics [19, 20]. The most important risk factors are likewise associated with personality traits [21]. So this study proposes a methodology based on rough set theory to extract decision rules for predicting drug user/non-user (month-based user definition). We defined different categories (classifications) of “drug users” based on the regency of use as follows: class of “non-users”, “year-based”, “month-based” and “week-based” user/non-user.

Linear discriminates for user/non-user separation is evaluated by several methods, here we will consider the following Relations:

For users:

$$Th + \sum k_i CT > 0 \tag{10}$$

For non users:

$$Th + \sum k_i CT \leq 0 \tag{11}$$

Where

*Th* : is the thresholds.

*CT* : is the conditional attributes.

*k<sub>i</sub>* : are the coefficients of the conditional attributes.

Data had been taken from the database which was collected by Elaine Fehrman [22] for 21 different types of legal and illegal drugs separately, where the values of the five factors (N, E, O, A, C) in addition to Impulsivity (Imp) and Sensation-Seeking (SS) as well as biographical data: age, gender, and education are used as the conditional attributes in the decision table shown in Table I.

Now, we will use rough sets methodology to find structural connections within the given data to obtain all reducts and

finally a set of generalized classification rules are extracted to predict the drug user/non-user. The overall steps of the suggested rough sets methodology are shown in Fig. 2.

By using RST analysis toolkit software called ROSETTA where Semi-Naïve algorithm were used to discretize the data in Table I to be as shown in Table II where “ \* means do not care condition” . After that reduction techniques based rough sets is used to determine the minimal reducts of (factors) attributes that can characterize all the knowledge in the decision tables as presented in Table III. Finally, the knowledge gained from all extracted reducts can be outlined by rough sets dependency rules as shown in Table IV.

Fig. 2. The Overall Steps of the Suggested Rough Sets Methodology.

TABLE V. DRUG GROUPS ACCORDING TO THE VALUES WHICH DIFFER FROM THE SAMPLE MEAN FOR GROUPS OF USERS FOR THE MONTH-BASED USER/NON-USER

Group No.		N	E	O	A	C
1	Alcohol, Chocolate, Caffeine	Neutral value (i.e. all factors for these legal drug consumers does not significantly differ from the sample mean)				
2	Nicotine	high	Neutral	high	Neutral	low
3	Amphetamines, Ketamine, and Legal highs	high	Neutral	high	low	low
4	Ecstasy and LSD	Neutral	high	high	low	low
5	Amyl nitrite	Neutral	Neutral	Neutral	low	low
6	Cannabis and Magic Mushrooms	Neutral	Neutral	high	low	low
7	Benzodiazepines, Heroin, and Methadone	high	low	high	low	low
8	Crack	high	low	Neutral	low	low
9	Cocaine and VSA	high	high	high	low	low

As shown in Table IV, the extracted decision rules represent the influence of the personality traits on the risk of drug consumption. For drug users, it is found that the N and O values of are moderately high or neutral, while the value of A and C are moderately low or neutral. In general we can call that, the risk of drug consumption increases as the values of “N” and “O” increase, while the risk decreases as there is an increase in the values of “A” and “C”. So we can conclude that drug users (month-based user definition) have higher values of on N and O, and lower on A and C when compared to drug non-users (month-based user definition). The impact of the values of “E” is cannot be generalized i.e. specific. Also, all drugs can be separated into nine groups according to the values which differ from the sample mean for groups of users for the month-based user/non-user as shown in Table V.

#### IV. CONCLUSION

This work used the principles of rough set theory to find and explain the relationship between drug use and personality traits, impulsivity, and sensation seeking, by generating a set of decision rules to investigate and predict the impact of the personality traits on drug user/Non-user (month-based user definition). It is concluded that for drug users, the N and O values of are moderately high or neutral, while the value of A

and C are moderately low or neutral. These results demonstrate the novelty of the current work which can be summarized as the suggested methodology has simplified logic-based rules required to effectively analyse drug abuse, construct a knowledge base with high accuracy to analyze drug misuse successfully and may be valuable in many applications. The future work will be extended by using other intelligent systems like neural networks, genetic algorithms, fuzzy approaches, and so forth.

# Wavelet Multi Resolution Analysis based Data Hiding with Scanned Secrete Images

Kohei Arai

Faculty of Science and Engineering  
Saga University, Saga City, Japan

**Abstract**—Wavelet Multi Resolution Analysis (MRA) based data hiding with scanned secrete images is proposed for improvement of invisibility of the secrete images. Daubechies (biorthogonal basis was adopted as the wavelet, but it was demonstrated that the key image (or secret image data) information can be restored with the biorthogonal wavelet. Also, the information of what to adopt as the biorthogonal wavelet is hidden. Key image information can also be protected by doing so, that the horizontal biorthogonal wavelet of the image does not have to be the same as the vertical biorthogonal wavelet, and the insertion position of the secret image data can be freely selected. It is also possible to divide the bit string of the secret image data and insert it into an arbitrary high frequency component, that the information hiding capability changes depending on the number of bit strings (information amount) of the secret image data, and the secret image in the public image data. Random scanning is effective for improving the visibility of data, selection of scanning method type, random number initial value. It was shown that sharing only among parties is useful for improving confidentiality, resistance to noise, resistance to data compression, and resistance to tampering with data.

**Keywords**—Multi-Dimensional wavelet transformation; multi resolution analysis: MRA; image data hiding; scanned secrete image; Daubechies basis function; invisibility

## I. INTRODUCTION

Although personal works are often represented by digital format files, etc., the current situation is that the method of claiming the copyright of the digital contents works is unbearable. In other words, copyright cannot be protected even if it is plagiarized without knowing how to claim the copyright. The importance of digital forensics is being emphasized. That is, evidence is getting more important. How should the proof of copyright infringement be left behind? That is the question of the research. For this purpose, the digital content itself is hidden and hidden only between the recipient and the third party.

There is a method to send and receive so that it does not exist. Data hiding technology. Data hiding is a general term for steganography and digital watermarking. When the information to be embedded is important and its existence is not known, steganography, and when the content itself in which the secret information is embedded is important, it is generally referred to as a digital watermark [1].

In steganography, there is a trade-off between the quality of multimedia content and the amount of information that can be embedded. In digital watermarking, there is a trade-off

between resistance to attacks and the amount of information that can be embedded [2]. To efficiently perform a cryptographic protocol, such as a digital fingerprint system, a method that suppresses the amount of calculation and communication may be an excellent method. In addition, it is important to have a digital watermark technology that is resistant to attacks such as falsification and deletion of embedded digital fingerprints [3].

The data hiding introduced in this paper allows digital contents to keep secret keys of authors in circulation so that copyright can be claimed. This makes it possible for an author who can know the secret key to claim the copyright by taking out the distribution content from the distribution content.

The secret key must not be visible to the distributed contents, and this invisibility is important. It is also important to improve the confidentiality by devising a method to keep the secret key in the distribution contents. One of the methods is to hide the secret key in the decomposition factor in wavelet multiresolution analysis. Especially, if it is hidden in high wavelet frequency components, the visibility is generally high [4], [5], [6], [7]. The wavelet-based data hiding method includes reversible data hiding by the histogram gap method based on the integer wavelet, in addition to the method based on this multiresolution analysis [8].

Wavelets allows time-frequency analysis. Wavelet Multi Resolution Analysis: MRA based on biorthogonal basis function of Daubechies is applicable for a variety of application fields [9], [10], [11]. One of the application fields is data hiding.

If the frequency component in which the secret key is embedded is searched by the brute force method or the like, the secret key may be stolen or tampered with. Therefore, it is extremely dangerous to simply perform data hiding using multi-resolution analysis. Therefore, in this paper, data hiding by multi-resolution analysis is preprocessed, and the parameters of the preprocessing that only authors who can do it also need to know together with the information about the frequency component to be embedded. The author devised it so that the author could not find the key. To improve the invisibility of the secret key image in the distribution image, the secret key image is rescanned in accordance with the Hilbert scan algorithm or random scanning algorithm as a preprocessing of the MRA-based data hiding.

Section II outlines data hiding based on multi-resolution analysis, and Section III proposes a method for performing

sequence order conversion and permutation conversion processing by random scanning on the bit array of the secret key. The data hiding process in which the image data in the database is selected as the original image is exemplified, and the confidentiality and the visibility difficulty of the secret content in the distribution content are evaluated in Section 4. Sections 5 and 6 gives conclusions and future work, respectively.

## II. OUTLINE OF DATA HIDING BASED ON MULTI-RESOLUTION ANALYSIS

Method for data hiding based on Legall 5/2 (Cohen-Daubechies-Feauveau: CDF 5/3) wavelet with data compression and random scanning of secret imagery data is proposed [12]. Improvement of secret image invisibility in circulation image with Dyadic wavelet-based data hiding with run-length coding is also proposed [13]. Meanwhile, noble method for data hiding using Steganography Discrete Wavelet Transformation: DWT and Cryptography Triple Data Encryption Standard: DES is proposed and well reported [14].

In this paper, MRA based data hiding method with random scanning of the insert secrete image is proposed.

### A. Wavelet Multi-Resolution Analysis

The wavelet transforms of a given discrete scalar signal  $f = (f_1, f_2, \dots, f_n)^T$  is described as  $C_n f$  by a square matrix  $C_n$  composed of a sequence  $\{p_k\}$  and a sequence  $\{q_k\}$ .  $p_i$  is for low-frequency components, coefficient  $q_i$  is for high-frequency components,  $C_n$  divides  $f$  into low-frequency components and high-frequency components, and is composed of sequences  $\{a_k\}$  and sequences  $\{b_k\}$  The square matrix  $H_n$  is expressed as follows,

$$H_n C_n = I_n \quad (1)$$

where  $I_n$  is an identity matrix. And then, the following equation is defined.

$$H_n = C_n^T \quad (2)$$

When Eq. (2), the biorthogonal wavelet transform is an orthogonal wavelet transform, that is, the orthogonal wavelet transform is a kind of biorthogonal wavelet transform.

### B. 2D(Two Dimensional) Discrete Wavelet Transformation

For 2D image signals, this process is performed horizontally and vertically one level at a time. Fig. 1 shows the band components when two-dimensional DWT is performed twice. In the figure, L indicates a low frequency component, and H indicates a high frequency component. The image is decomposed into four bands (LL, LH, HL, HH) by the first two-dimensional DWT, and the lowest band component (LL) is further divided into four bands (LLLL, LLLH, LLHL, LLHH).

Following are the related research works: Data hiding method replacing LSB of hidden portion for secrete image with Run-Length coded image is proposed [15]. Meanwhile, Data hiding method with Principal Component Analysis: PCA and image coordinate conversion is proposed for improvement of invisibility of the secret key image [16].

Fig. 1. Band Components after the 2D DWT.

## III. PROPOSED METHOD

When the DWT is applied to  $n$  time series data in one stage, it can be decomposed into  $n / 2$  high frequency components and  $n / 2$  low frequency components. By further subjecting the  $n / 2$  low frequency components to a one-stage DWT, the  $n / 4$  low frequency components and the  $n / 4$  high frequency components can be decomposed. By repeating this, the number of data becomes 1 or 2. This is shown in Fig. 2. This is called the Laplacian Pyramid.

In this case, the size of the image in each stage is halved both vertically and horizontally by the DWT. A Dyadic Wavelet that does not downsize is also proposed. Also, in this case, a certain low-frequency component image is decomposed into four, but a Multi Wavelet that decomposes this into 16 images is also proposed. It is reported that they are effective for noise removal and data compression, respectively. These Wavelets and many others are published in the Special Issue on Visualization Information Society of Reference [9], so please refer to them.

The original time series data can be completely restored by applying the inverse wavelet transform (Inverse DWT: IDWT) for the number of transform stages using the high frequency components and the low frequency components of each stage generated by this decomposition. Of the decomposed frequency component data, the fact that "the human eye has a low resolution of high frequency components" is used to embed the secret data into one of the high frequency components and reconstruct it with the secret data embedded. When attempting to restore to the original image level, the secret data is embedded in the high frequency component, so that data like the original image is reconstructed in a state where it is difficult to see.

The data generated in this way is called distribution data (content). The distribution contents are contents that are open to the public and can be obtained by anyone. Therefore, they are exposed to the risk of plagiarism. This distributed content is almost the same as the original content but differs from the original content in that the secret data is embedded in the high frequency component. Even if the distributed content is stolen, the copyright holder can claim the copyright by extracting and showing the secret content (e.g., copyright) embedded in the high frequency component. Fig. 3 shows a series of processing flow from embedding secret data for asserting copyright in such copyrighted content, generating a distribution image, and restoring the secret data and the original content from the distribution image.

Fig. 2. Laplacian Pyramid.

Fig. 3. Process Flow of Data Hiding based on Multi Resolution Analysis (MRA).

The visibility of the secret content in the distributed content is greatly influenced by the confidential data to be embedded (frequency component of the content) and the place to be embedded (frequency component). Therefore, as shown in Fig. 4, the location where the secret content is embedded is a very important factor in considering the visibility of the secret image content in the distribution image content. In this case, LH1 of MRA (Fig. 4 (c)) of the original image (Fig. 4 (a)) is replaced to the secrete image of “CRAMPS” (Fig. 4 (b)). Then the reconstructed image is derived by Inverse DWT.

Fig. 4. LH1 of MRA is replaced to the Hiding Image Content of “CRAMPS”.

The scanning method of the secret image data can be changed from the normal line sequential scanning to the random scanning to improve the visibility of the secret image in the distribution image. The author proposes a method to obtain a distribution image in random scan (rand) by using the support length (dbn) of Daubechies basis function used in MRA and the initial value (rand50 / 5000) of uniform random numbers used in random scan as parameters.

#### IV. EXPERIMENT

##### A. Preliminary Results

A method has also been proposed to improve the visibility of the secret data in the distribution image by scanning it again before embedding the secret data. It is premised that the rules are shared. In contrast to normal image data that is line-sequential scanning, a secret image is converted to random scanning that determines the scanning order by, for example, generating a random number. It converts and stores 2D spatial data into a dictionary array (1D data).

The conversion of this scanning method can be performed by a permutation conversion matrix. At this time, if the random number generation rule information is shared between the sending and receiving parties, the inverse matrix of the permutation conversion matrix is applied after extracting secret data in random scanning. By doing so, the reverse conversion of the scanning method becomes possible and the secret data in the line sequential scanning can be reproduced. Since it is difficult for a third party to obtain the information of the scanning method when embedding the secret data, it is difficult to obtain the secret data. The confidentiality of information is also improved.

The experimental results are as follows: The used data is the original image shown in Fig. 5 (a) (The band 3 red area in which the Thematic Mapper: TM sensor mounted on the Landsat satellite observed near the Yamato interchange of Nagasaki Highway near Saga city) The original image is composed of 128x128 pixels, the secret data is composed of 64x64 pixels, and the quantized bits are 8 in each case. Landsat / TM is a 30m spatial resolution multi-spectral scanner with spectral bands of five bands from blue to near infrared and one band in thermal infrared.

The wavelet division was applied to the original image by one stage, and the secret data was embedded in HH1. At that time, the secret data was embedded in HH1 with line sequential scanning and the random number generation method of Merthenne Twister was used. Compared with the method of generating uniform random numbers, scanning again based on that, and embedding in HH1, the distribution image obtained by reconstructing using the embedded image is almost the same as the original image.

When the author tries to reconstruct the HH1 using this method, the secret data can be restored as shown in Fig. 7 (a), (b) and (c) for line sequential scanning (raster scan), random scanning and Hilbert scan, respectively. An example of Hilbert scan is shown,

Fig. 5. Original Image of Landsat-5/TM Band 3 Data of Saga City and Hiding Data.

Fig. 6. Hilbert Scan.

The Hilbert curve is one of the simplest curves which pass through all points in a space (Fig. 6). Many researchers have worked on this curve from the engineering point of view, such as for an expression of two-dimensional patterns, for data compression in an image or in color space, for pseudo color image displays, etc.

If the secret data is embedded in the original image as it is, the secret data itself can be restored in HH1, but in the case of random scanning, the secret data cannot be restored without knowing the control parameters for random number generation.

On the other hand, Fig. 8 (a) shows the secret image of “CRAMPS” derived from the Hilbert scanning. Also, Fig. 8 (b) and (c) are the randomly scanned secret image and the raster scanned secret image, respectively. Not only random scan, but also Hilbert scan can be used for improvement of invisibility of the hidden secret image from the reconstructed image. Fig. 8 (d) shows the reconstructed image derived from the decomposed image embedding the secret image with Hilbert scanning. Also, Figs. 8 (e) and (f) show the reconstructed

images derived from the decomposed image embedding the secret image with raster scanning and random scanning, respectively.

These are images obtained by scanning the key image by raster, Hilbert, and random scanning, replacing the original image with HH1 after MRA, and performing wavelet transform on the reconstructed image. As is apparent from these, in the case of raster scanning, the key image itself appears and there is no confidentiality. On the other hand, in Hilbert scanning, only horizontal stripe noise appears, and in random scanning, only random noise appears, so it is difficult to visually recognize the key image.

(d) Reconstructed Image (Random Scan).

Fig. 8. Secrete Image of “CRAMPS” Derived from the Hilbert Scanning and the Reconstructed Image Extracted from the Decomposed Image Derived from the Decomposed Image Embedding the Secrete Image with Hilbert, Random and Raster Scanning.

Furthermore, by understanding the parameters related to the scanning order generation method in random scanning and Hilbert scanning only between the sending and receiving parties, only the parties can know the key image, and the confidentiality and confidentiality can be improved.

### B. Experimental Results

Fig. 9(a) is an example of a secret image. Fig. 9(b), (c), and (d) show the distribution images when this is inserted into each of HH1, HL1, and LH1 of the above-mentioned original image (Lena).

As is clear from Fig. 9, the secret image data can be visually recognized on the distribution image. As shown in Fig. 10, this secret image data is changed from line sequential scanning to random scanning to improve visibility.

Fig. 11(a), (b), and (c) show the results of improving the visibility of the secret image data on the distribution image due to the change of the scanning method. Fig. 10(a), (b), and (c) show the circulation images when they are inserted into HH1, HL1, and LH1 of the original image (Lena).

(c) LH1.

Fig. 11. Hidden Image and Publicly Available Reconstructed Images through Embedding the Hiding Image at HH1, HL1 and LH1 Components after the Scanning Scheme Conversion for Hidden Image from Line-by-line to Random.

Distribution image and original image in line sequential scanning (Normal) and random scanning (rand) using the support length (dbn) of the Daubechies basis function used for MRA and the initial value of uniform random numbers (rand50 / 5000) used for random scanning as parameters Table I shows a comparison of the Root Mean Square Difference (RMSD) between the original and the publicly available reconstructed images and the results show that random scanning is better than line-sequential scanning, and that longer support length is better than short support length. It can be seen that the initial value of the random number is not so affected.

Since the visibility of the secret image data on the distribution image does not depend on the initial value of the random number used, if this initial value is hidden by steganography between the sending and receiving parties, only the party who knows this initial value will have the secret value. Image data can then be restored.

TABLE I. COMPARISONS OF ROOT MEAN SQUARE DIFFERENCE (RMSD) BETWEEN THE ORIGINAL AND THE PUBLICLY AVAILABLE RECONSTRUCTED IMAGES THROUGH DATA HIDING BASED ON MRA WITH EMBEDDING THE HIDING IMAGE TO HL1, HH1 AND LH1 AND WITH SCANNING SCHEME CONVERSION FROM LINE-BY-LINE TO RANDOM

Scanning Method	HL1	HH1	LH1
Normal(db2)	69.594	69.137	69.183

rand5000(db4)	68.665	68.291	68.316
rand5000(db8)	68.633	68.182	68.202

## V. CONCLUSION

The author has introduced a method that improves the confidentiality by applying principal component transformation and oblique coordinate transformation as preprocessing for data hiding based on wavelet multiresolution analysis. The author investigated the confidentiality when a third party attempts to extract secret data from only the data for distribution.

The method introduced in this paper allows only the author who knows the characteristics of the original multispectral image to recover the secret data, i.e., when the information of the original image needs to be protected. The author also showed how to convert the scanning method of the secret data from line-sequential to random scanning, which leads to the improvement of the confidentiality of the secret data and the visibility difficulty in the distribution image. By sharing the equation parameters only between the sending and receiving parties, more confidential data hiding can be realized.

In this paper, the Daubechies basis function is adopted as the wavelet, but the secret data can be restored by using the biorthogonal wavelet, and the secret data can be protected by hiding what is adopted as the biorthogonal wavelet.

## VI. FUTURE RESEARCH WORKS

In the future, the author will compare the proposed method with conventional data hiding methods such as steganography method.

## ACKNOWLEDGMENT

The author would like to thank Dr. Kaname Seto of former student of Saga University and Dr. Leland M. Jameson of Naval Research Laboratory for their contribution in this study. The author, also, would like to thank Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

AUTHORS' PROFILE

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was

a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 55 books and published 620 journal papers as well as 450 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. <http://teagis.ip.is.saga-u.ac.jp/index.html>.

# Multiple Eye Disease Detection using Hybrid Adaptive Mutation Swarm Optimization and RNN

**Abstract**—The major cause of visual impairment in aged people is due to age related eye diseases such as cataract, diabetic retinopathy, and glaucoma. Early detection of eye diseases is necessary for better diagnosis. This paper concentrates on the early identification of various eye disorders such as cataract, diabetic retinopathy, and glaucoma from retinal fundus images. The proposed method focuses on the automated early detection of multiple diseases using hybrid adaptive mutation swarm optimization and regression neural networks (AED-HSR). In the proposed work, the input images are preprocessed and then multiple features such as entropy, mean, color, intensity, standard deviation, and statistics are extracted from the collected data. The extracted features are segmented by using an adaptive mutation swarm optimization (AMSO) algorithm to segment the disease sector from the fundus image. Finally, the features collected are fed to a regression neural network (RNN) classifier to classify each fundus image as normal or abnormal. If the classifier output is abnormal, then it is classified by the corresponding diseases in terms of cataract, glaucoma, and diabetic retinopathy, which improves the accuracy of detection and classification. Ultimately, the results of the classifiers are evaluated by several performance analyses and the viability of structural and functional features is considered. The proposed system predicts the type of the disease with an accuracy of 0.9808, specificity of 0.9934, sensitivity of 0.9803 and F1 score of 0.9861 respectively.

**Keywords**—Adaptive mutation swarm optimization; fundus image; feature extraction; RNN classifier; standard deviation

## I. INTRODUCTION

Nowadays, aged people are mostly affected by chronic diseases such as cataract, glaucoma and diabetic retinopathy, which lead to visual impairment. The optic nerve is damaged due to glaucoma, which results in loss of vision. Glaucoma occurs due to a slow rise in the normal fluid pressure inside the eyes. Cataract occurs due to the clouding of the eye's lens. The progressive damage in the retina's blood vessels, which are essential for good vision of the eye, leads to Diabetic Retinopathy [1]. Based on the supervised learning method, blood vessels are segmented from the fundus image that can be done using Zernike moment-based Shape descriptors and training can be performed using an ANN-based binary classifier to predict cardio vascular diseases [2]. Multiple instances A learning technique is used to classify the diseased image and healthy image, in which the classification can be done by binary classification [3]. Microaneurysms can be recognized using principal component analysis, morphological

processing, averaging filter, and support vector machine classifier. Diabetic Retinopathy disease can also be identified [4]. The early signs of diabetic retinopathy can be identified by applying nineteen features extracted from the fundus image to an artificial neural network, which is trained by Levenberg-Marquardt, and the disease is classified by using Bayesian Regularization [5]. Red lesions can be detected in the blood vessels by using a Gaussian filter and the disease can be predicted using an SVM classifier [6]. Based on the singular value decomposition algorithm, dictionary learning methods can be used to classify healthy people from diabetic patients based on singular Value Decomposition Algorithm [7]. The fundus image is segmented by using a Deep Convolution Neural Network and it increases the accuracy and efficiency in predicting non-proliferated diabetic retinopathy [8]. The blood vessels can be segmented by using dilated convolution, which leads to more accurate detection of ophthalmologic diseases [9]. The two filtering methods, namely median filtering and Gaussian derivative filtering, are used to define the bifurcation point of a blood vessel image segment [10]. DR (Diabetic Retinopathy) can be recognized using the ANN classifier and region growing segmentation to extract exudates, optic plate and veins from the fundus images [11]. DR can be detected by using a reformed capsule network, which attains an accuracy of 97.98% [12]. A hierarchical severe grading system model was developed to detect and classify the different grades of DR. The classifier accuracy is 94% [13]. The optic disc and optic cup boundary of the fundus images are segmented and by using Weighted Least Square fit, holistic features and disc ratio are extracted, and then they are fed to a Convolutional Multi-Layer Neural Network Classifier to classify the glaucoma [14]. A classification method of multi feature analysis along with a Discrete Wavelet transform is used to detect glaucoma. This model classifies glaucoma with an accuracy of 95% [15]. The input fundus image is validated using Le-Net architecture and the optic disc and optic cup are segmented using U-Net Architecture. Glaucoma can be detected with the use of SVM Classifier, Neural Network Classifier, and Adaboost Classifiers [16]. The eyeball area is extracted from the fundus image using an object detection network and multi task learning is applied to detect the cataract [17]. A Deep Convolution Neural Network with Resnet for classification can be used to identify cataract. The systems show an accuracy of 95.77% [18]. Gray Level Co-occurrence Matrix is utilized for feature extraction, and the classification of different levels of cataract can be done by Back Propagation Neural Network Classifier. This system

provides an accuracy of 82.4% [19]. The above-mentioned techniques are utilized to anticipate a single disease from the fundus image of the retina. The proposed paper uses hybrid adaptive mutation swarm optimization and regression neural network (AED-HSR) to provide automated early detection of multiple diseases.

The contributions of the proposed work are:

- Multiple features are extracted from the collected data and standard deviation, smoothness, entropy, shape, color, intensity and statistics are included for feature extraction.
- An adaptive mutation swarm optimization (AMSO) algorithm is used to segment the disease sector from fundus image.
- The collected features are fed to the regression neural network-based classifier to classify each fundus image as normal or abnormal.

The rest of this paper provides the recent related works under Section II, Problem methodology and System model in Section III, the proposed AED-HSR technique using AMSO algorithm and RNN algorithm experimental setup and results are explained in Section IV, and Section V describes the conclusion of AED-HSR.

## II. RELATED WORKS

Kangrok et al., proposed a strategy to detect DR by utilizing automatic segmentation of the ETDRS 7SF in order to expel the undesirable components in the fundus image, and then it was fed to a ResNet – 34 model for the classification of the disease, which provided an accuracy of 83.38% [20]. Saeid et al., proposed a combinational approach of fuzzy C-means and genetic algorithms for the prediction of DR from the angiographic images of diabetic patients, which provided a sensitivity of 78% [21]. Zhuang et al., introduced a weighted voting algorithm to categorize the DR disease and the trained network model was applied to the hospital data, which provided 92% accuracy [22]. Rego et al., worked on a Convolutional Neural Network (CNN) model with Inception-V3 for DR screening of fundus images. In this approach, the model analyzed 295 images and the results were compared with a team of ophthalmologists. This model predicted DR with an accuracy of 95% [23]. Mohammed Hasan et al., suggested a combined method of Convolution Neural Network and Principal Component Analysis for the diagnosis of DR with an accuracy of 98.44% [24]. Hemelings et al., suggested a method based on a deep learning approach to identify glaucoma in which the fundus image was cropped with radius as image size percentage, optic nerve head (ONH) centered with spacing of 10–60%. This model resulted in an AUC of 0.94 [25]. Salam et al., developed an algorithm for glaucoma diagnosis based on combined structural and non-structural features. This method was evaluated with 100 patients' fundus images, which provided a 100% sensitivity and an 87% specificity [26]. Nataraj et al., suggested a machine learning based classification technique to identify glaucoma from fundus images. This method used a unique template approach for segmentation, the Gray Level Coherence Matrix approach

for feature extraction, and wavelet transform for texture and structure-based features to improve the efficiency of the system [27]. Latif et al., proposed a model for detecting glaucoma that had two parts: one to find the optic discs and the other to use transfer learning to find glaucoma. This method provided 95.75% accuracy, 94.75% sensitivity, and 94.90% specificity [28]. Xu et al., proposed a method based on the transfer induced attention network for glaucoma diagnosis that extracted the deep patterns related to disease with limited supervision. The model was evaluated on clinical datasets, which provided an accuracy of 85.7% [29]. A novel method was developed by Raja et al., to identify glaucoma at an earlier stage by using a deep learning approach for segmenting the optic cup and optic disc and an SVM classifier to predict the disease with 92% accuracy [30]. Hasan et al., suggested a convolution neural network to diagnose the cataract disease from the fundus image. This model predicted the cataract disease with an accuracy of 98.17% [31]. Azhar et al., employed CNN for extracting the features and Support Vector Machine (SVM) for the prediction of cataracts. The system model provided an accuracy of 95.65% [32]. Pratap et al., suggested a technique for automatic cataract detection by utilizing singular value decomposition as a feature extractor and SVM as a classifier. The accuracy of the method was 97.78% [33]. Imran et al., developed a strategy for the identification of cataracts. The fundus images were preprocessed and then, by using the combination of Self Organizing Maps and Radial Basis Function (RBF) Neural Network, the model predicted the cataract with an accuracy of 95.3% [34]. Behera et al., [35] used an RBF-based SVM Classifier to predict cataract diseases from fundus images.

## III. METHODOLOGY

The proposed automated early detection of multiple eye diseases by means of hybrid adaptive mutation swarm optimization and regression neural network (AED-HSR) techniques has been used to improve the accuracy of eye disease diagnosis. The proposed system consists of two phases. In the first phase, AMSO is used to segment the blood vessels, optic distance, exudates, and hemorrhage from the extracted features of the preprocessed fundus image. In the second phase, an RNN classifier is utilized to identify multiple eye diseases, namely cataract, diabetic retinopathy, and glaucoma. The flow diagram for the proposed system model for multiple disease detection is shown in Fig. 1.

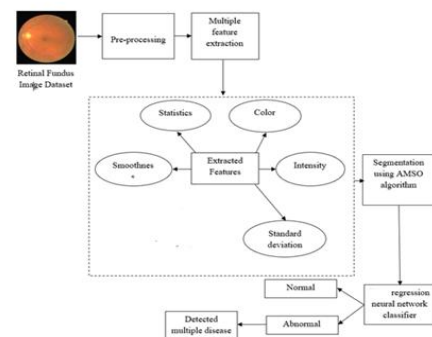

Fig. 1. System Model of Proposed AED-HSR Technique.

### A. Preprocessing

The creation of a binary mask is the initial step in image preprocessing, which is used to recognize that the pixels belong to the Region of Interest. Creating a binary mask avoids unwanted processing of pixels outside the ROI, which will reduce the processing time of an image. Masking can be done by convoluting the red color channel with a Gaussian low pass filter. Then the image undergoes thresholding by using Otsu's global thresholding [36]. The image is then converted to a grayscale image, which has better contrast than the other color channels, such as the red color channel and blue color channel. Since various eye diseases can be identified in the blood vessels of the fundus image, and the contrast between the blood vessels can be easily identified in the green channel of the color image. After the conversion of the grayscale image, the image is resized to standard form because of the wider size of the input image. The resized image is then denoised using a gray level morphological operation to remove the brightness strip located at the center of the blood vessels.

### B. Feature Extraction

Feature extraction is a method of mapping the primary feature into a low dimensional feature space for better classification. Each feature should have a larger variance to distinguish the features from the image. To detect the diseased image, the features such as blood vessels, optic disc, hemorrhage, and retinal exudates should be extracted from the fundus image of the retina. Glaucoma can be identified by the variation in the optic cup, which is a portion of the optic disc. In order to accomplish the automatic diagnosis of glaucoma, the location of the optic disc, which contains more information for glaucoma detection, must be extracted from the fundus image [37]. Optic disc feature extraction can be done by the entropy method. Blood vessels are extracted by using Gabor filters [38].

1) *Entropy*: The average quantity of information owing to the variance of pixel values in an image is defined as entropy in image processing. The image entropy of a distinct brightness values can be calculated by "1"

$$H(I) = \sum_{k=1}^{B_g} P(I_k) \log_2 \left( \frac{1}{P(I_k)} \right) \quad (1)$$

where  $P(I_k)$  denotes the  $k$  brightness value distribution of image  $I$  and  $B_g$  represents the number of brightness levels in an image.

Based on the values of entropy, texture analysis of an image can be done. Lower values of entropy result in the smoothening of texture, whereas higher values of entropy give texture with more details. In the proposed model, higher values of entropy in the fundus image are taken as the optic disc location as it has more details such as nerves and blood vessels.

2) *Gabor filters*: Gabor filters are mostly used to enhance the blood vessels from the fundus image. The product of Gaussian envelope function and complex trigonometric function results in complex Gabor function. To enhance the blood vessels in the fundus image, real portion of the complex Gabor function is utilized and is given by "2"

$$S(u,v,\lambda,\phi,\sigma,\tau) = \exp\left(\frac{-u^2 - v^2 - \tau^2}{2\sigma^2}\right) \cdot \cos(2\pi u' / \lambda + \phi) \quad (2)$$

where  $s$  represents the two-dimensional Gabor kernel function with variables  $u$  and  $v$  and  $u' = u \cos \phi + v \sin \phi$  and  $v' = -u \sin \phi + v \cos \phi$ . Scale ( $\sigma$ ), Wavelength ( $\lambda$ ), orientation ( $\phi$ ) and aspect ratio ( $\tau$ ) are the four parameters to control the shape. The Gabor kernel is rotated at an angle of 15 degree so that 12 different kernels are obtained; it is convolved with the preprocessed image and it selects the utmost response for each pixel. Subsequently, the pixels having blood vessels are more prevailing than the other pixels.

The statistical features, namely mean and standard deviation can be calculated using the following equations "3" and "4"

$$\mu = \sum_{k=0}^{L-1} k p(k) \quad (3)$$

$$\sigma^2 = \sum_{k=0}^{L-1} (k - \mu)^2 p(k) \quad (4)$$

### C. Proposed AED-HSR Technique using AMSO and RNN Algorithm

In this section, AMSO is described in Section.4.1 and Regression neural network classifier to identify the diseased image is explained briefly in Section.4.2.

1) *Segmentation using AMSO algorithm*: The features retrieved from the fundus image are segmented using the Adaptive Mutation Swarm Optimization (AMSO) technique. Basically, Swarm will be initiated by the Particle Swarm Optimization. The solution of each search space is determined based on the position and the velocity of the particle in the swarm. The position and the velocity of the particle are changed for each iteration and the global best position  $p_g$  and personal best position  $p_i$  are found out. To reach the ideal PSO state, a larger interference amplitude is needed in the early iteration phase to ensure better global search capabilities and a smaller interference amplitude is required in the late iteration phase to ensure convergence.

a) *Chase-Swarming Behavior*: where  $x_i$  represents the position of cockroach, step denotes a fixed value, 'rand' represents a random number lying between 0 and 1,  $p_i$  is the personal best position, and  $p_g$  is the global best position. The personal best position of cockroach of size  $N$  is given by "5" and "6"

$$X_i = x_i + \text{step} \cdot \text{rand} \cdot (p_i - x_i), x_i \neq p_i \quad (5)$$

$$X_i = x_i + \text{step} \cdot \text{rand} \cdot (p_g - x_i), x_i = p_i \quad (6)$$

where visual is a constant,  $j = 1, 2, \dots, N$ ,  $i = 1, 2, \dots, N$ . The global best position of the cockroach is given by "7" and "8"

$$p_i = \text{opt}_j \{x_j | |x_i - x_j| \leq \text{Visual}\} \quad (7)$$

$$p_g = \text{opt} \{x_i\} \quad (8)$$

The inertial weight to chase swarming component of original AMSO is given by "9" and "10"

$$X_i = \omega \cdot x_i + \text{step} \cdot \text{rand} \cdot (p_i - x_i), x_i \neq p_i \quad (9)$$

$$X_i = \omega \cdot x_i + \text{step.rand.}(p_g - x_i), x_i = p_i \quad (10)$$

where  $\omega$  is an inertial weight of the particle.

*b) Hunger Behavior:* In this paper, an enhanced cockroach swarm optimization is prolonged with an extra feature called hunger behavior. For a particular period of time, when the cockroach is hungry, it migrates from its original position and searches for food source  $x_{\text{food}}$  within the search space. Partial differential equation (PDE) migration technique is used for hunger behaviour modelling. Hunger behaviour impedes local optimization and increases population diversity.

Kerckhove defines the PDE migration equation as

$$\partial p / \partial t = -s \partial p / \partial x \quad (11)$$

with initial population distribution  $p(0, x) = p_0(x)$ .

where the parameter  $s$  controls the migration speed.  $p$  represents population size,  $t$  denotes the time, and  $x$  represents the location or position.  $(t, x)$  is the population size at time  $t$  in location  $x$

Equation (9) can be expressed as

$$\partial p / \partial t + s \partial p / \partial x = 0 \quad (12)$$

By integration, we have

$$x - st = \sigma, p = p(\beta), p = p(x - st)$$

$$p[t, x] = p_0[x - st]$$

Since displacement is the product of speed and time, in  $p_0(x - st)$ ,  $p_0(x)$  is replaced by  $st$ .

$p_0(x - st)$ , satisfies PDE at any initial population distribution  $p_0(x)$ . Hunger behavior is defined as follows: If hunger is equal to threshold hunger  $t_{\text{hunger}}$ , then the new position of cockroach is

$$X_i = x_i + (x_i - st) + x_{\text{food}} \quad (13)$$

where  $x_i$  denotes the position of the cockroach,  $(x_i - st)$  represents the migrated position of the cockroach from its current position, and hunger is a random number which lies in the range of 0 to 1.

#### D. Classifying Feature Models using RNN

The segmented portions of the fundus images are fed into the Regression Neural Network Classifier for the prediction of diseases in the form of a regression task. The architecture of the RNN is shown in Fig. 2. The segmented features are given as input to the RNN, which contains a fully connected layer and batch normalization with a Leaky Rectified Linear Unit (FC-BN-LReLU), pursued by a dropout layer with a dropping probability of 0.2 to avoid the overfitting problems, and two layers of FC-BN-LReLU, followed by a drop out layer. The following layer is a fully connected layer with LReLU, which does not contain batch normalization. The last layer is a fully connected layer without any activation function that will classify the type of disease.

Fig. 2. Test Image Samples.

#### IV. EXPERIMENTAL SET-UP AND RESULTS

In the proposed AED-HSR, Cataract, glaucoma, DR and normal images are classified from the fundus images and the performance analysis is calculated based on distinct algorithms. The proposed method was implemented in the online datasets using MatlabR2022a.

##### A. Dataset

The proposed AED-HSR method was implemented on the dataset that comprised of 800 normal images, 800 cataract images, 800 diabetic retinopathy images, and 800 glaucoma images, taken from the Ocular Disease Intelligent Recognition (ODIR) database, which contains the ophthalmic database of 5000 patients, including their ages, right and left eye fundus images, and the doctor's diagnostic keywords. The images are collected by the Shanggong Medical Technology Co., Ltd. from numerous hospitals in China.

##### B. Results

In the experimental set-up, 30% of images are utilized for testing and 70% of images are utilized for training. The test image samples are shown in Fig. 2. A learning rate of 0.01 with a maximum of 39 epochs was used in the training phase of the proposed system. The proposed method utilizes 5 distinct features such as smoothness, statistics, color, intensity, and standard deviation to train the RNN. The training performance of the AED-HSR in terms of training, validation and test data is shown in Fig. 3. From the training progress of AED-HSR, the mean square error (MSE) drops rapidly in the first 10 epochs and the best validation performance is 0.074662 at epoch 33. The training MSE gradually drops a bit and the stability is more in the final epochs. In the training model, more attributes are used to aid in prediction which may be useful to prevent overfitting.

The training state of the proposed AED-HSR shown in Fig. 4 will provide the gradient of 0.16819 at epoch 39 and the maximum mu value of 0.001 is reached at epoch 39 which controls the neurons weight updating process during training. By applying the test images as an input to the model, AED-HSR classifies the image as a diseased image or normal image.

A regression analysis was performed in order to determine the relationship between the network output and the corresponding targets. The Regression plot of the AED -HSR model is shown in Fig. 5 which shows a correlation between the two sets of data. It demonstrates that there is a good fit between the values that were predicted by AED-HSR and the actual measured data with higher values of R. The regression plot indicates that the outputs closely match the targets with an R-Value. The Confusion matrix for the four different models is shown in Fig. 6. From the values of Confusion Matrix (VCM), True Positive (TP), True Negative, False Positive and False Negative values are calculated in order to analyze the performance of the system model. Table I shows the prototype of VCM. Table II shows the characteristics of VCM.

Fig. 3. Training Progress of the AED-HSR Model.

Fig. 4. Training State of the Proposed AED-HSR Model.

TABLE I. VCM PROTOTYPE

		PREDICTED			
		X	Y	Z	R
ACTUAL	X	$L_{XX}$	$L_{XY}$	$L_{XZ}$	$L_{XR}$
	Y	$L_{YX}$	$L_{YY}$	$L_{YZ}$	$L_{YR}$
	Z	$L_{ZX}$	$L_{ZY}$	$L_{ZZ}$	$L_{ZR}$
	R	$L_{RX}$	$L_{RY}$	$L_{RZ}$	$L_{RR}$

TABLE II. CHARACTERISTICS OF VCM

<b>TRUE POSITIVE</b>	$TP_X = L_{XX}$
	$TP_Y = L_{YY}$
	$TP_Z = L_{ZZ}$
	$TP_R = L_{RR}$
<b>FALSE POSITIVE</b>	$FP_X = L_{YX} + L_{ZX} + L_{RX}$
	$FP_Y = L_{XY} + L_{ZY} + L_{RY}$
	$FP_Z = L_{XZ} + L_{YZ} + L_{RZ}$
	$FP_R = L_{XR} + L_{YR} + L_{ZR}$
<b>TRUE NEGATIVE</b>	$TN_X = L_{YZ} + L_{YY} + L_{ZY} + L_{YR} + L_{ZZ} + L_{RY} + L_{RZ} + L_{YR} + L_{RR}$
	$TN_Y = L_{XX} + L_{ZZ} + L_{XZ} + L_{XR} + L_{ZX} + L_{RR} + L_{RX} + L_{RZ} + L_{ZR}$
	$TN_Z = L_{RY} + L_{RR} + L_{XX} + L_{XY} + L_{XR} + L_{YX} + L_{YY} + L_{YR} + L_{RX}$
	$TN_R = L_{ZY} + L_{ZZ} + L_{XX} + L_{XY} + L_{XR} + L_{YX} + L_{YY} + L_{YZ} + L_{ZX}$
<b>FALSE NEGATIVE</b>	$FN_X = L_{XY} + L_{XZ} + L_{XR}$
	$FN_Y = L_{YX} + L_{YZ} + L_{YR}$
	$FN_Z = L_{ZX} + L_{XY} + L_{ZR}$
	$FN_R = L_{RX} + L_{RY} + L_{RZ}$

The proposed AED- HSR model detects the eye disease with an accuracy of 98.08%. DR detection from the proposed model is shown in Fig. 7. The classification of glaucoma using the proposed system model is shown in Fig. 8. Cataract image detection by utilizing the proposed AED-HSR model is shown in Fig. 9.

Fig. 7. Detection of DR.

Fig. 8. Detection of Glaucoma.

Fig. 9. Detection of Cataract.

C. Performance Analysis

The proposed model performance can be analyzed in terms of accuracy, sensitivity, specificity, negative predictive value (NPV), positive predictive value (PPV), false negative rate (FNR), false positive rate (FPR), and false discovery rate (FDR) from VCM. Table III shows the parameters of the performance metrics. Sensitivity alludes to a test’s capacity to assign a diseased image as positive. Specificity characterizes the capacity of the test to assign the non-diseased image as negative.

Accuracy is defined as the ratio of correctly predicted images to the total images. PPV refers to the probability that the individual has the disease when confined to those individuals who test positive. NPV measures the proportion of genuine negative expectations considering all negative forecasts. FNR is calculated by the ratio of false negative to total positive. The FDR measures the extent of the alerts that are irrelevant. Fig. 10 shows the performance metrics for each class of eye diseases based on RNN.

Fig. 10 shows that RNN has 94.1% accuracy rate for identifying the normal eyes. The maximum specificity for glaucoma affected eye is 98.5%. F1 score for DR is 95.41%.

TABLE III. PERFORMANCE METRICS PARAMETERS

Parameters	Formula
Sensitivity	$Sen = TP / (TP + FN)$
Specificity	$Spec = TN / (TN + FP)$ ;
Accuracy	$Acc = (TP+TN) / (TP+TN+FP+FN)$
False positive rate	$FPR = 1 - Spec$
False negative rate	$FNR = FN / (TP + FN)$
Positive predictive value	$PPV = TP / (TP + FP)$
Negative predictive value	$NPV = TN / (TN + FN)$ $NPV = TN / (TN + FN)$
False discovery rate	$FDR = 1 - PPV$
F1_Score	$F1\_Score = (2*TP) / ((2*TP) + FP + FN)$

Fig. 10. Performance Metrics of each Class using RNN.

Fig. 11 indicates the performance metrics for each class of eye diseases based on GA-RNN. Fig.11 shows that GA-RNN has 97.4% accuracy rate for identifying the normal eyes. The maximum specificity for cataract affected eye is 99.04%. F1 score for Normal eye is 97.99%.

Fig. 12 indicates the performance metrics for each class of eye diseases based on PSO-RNN. Fig.13 shows that PSO-RNN has 97.7% accuracy rate for identifying the normal eyes. The maximum specificity for Normal eye is 98.87%. F1 score for Normal eye is 98.30%.

Fig. 12. Performance Metrics of each Class using PSO-RNN.

Fig. 13 indicates the performance metrics for each class of eye diseases based on the proposed AMSO-RNN. Fig. 13 shows that AMSO-RNN has 98.5 % accuracy rate for identifying the normal eyes. The maximum specificity of Glaucoma diseased eye is 99.5% F1 score for Normal eye is 98.83%.

Overall, the system automatically detects the eye disease with 98.08 % accuracy, 99.34% specificity, 98.03% sensitivity, 98.03% PPV, 99.34% NPV, 0.62% FPR, 1.93% FNR, 98.67% F1 Score and 1.96% FDR.

Fig. 11. Performance Metrics of each Class using GA- RNN.

Fig. 13. Performance Metrics of each Class using AMSO-RNN.

The performance Matrix of AMSO-RNN is compared with that of the other strategies, namely RNN-PSO, RNN-GA, and RNN, as shown in the Fig. 14. From the comparison measures of four different methods, the proposed method has an improvement of 2.23% in accuracy, 2.18% in sensitivity, 0.71% in specificity, 2.19% increase in PPV, 1.45% increase in F1 Score, 53.38% decrease in FPR, 51.99% decrease in FNR, 0.72% increase in NPV and 54.2% decrease in FDR when compared with RNN-PSO. Also, the proposed AMSO-RNN provides an improvement of 3.16 % in accuracy, 3.14% in sensitivity, 1.01% in specificity, 3.08 % increase in PPV, 2.09% increase in F1 Score, 61.73% decrease in FPR, 60.61% decrease in FNR, 1.01% increase in NPV and 58.69% decrease in FDR when compared with RNN-GA and an improvement of 5.75% in accuracy, 5.72% in sensitivity, 1.88% in specificity, 5.68% increase in PPV, 3.79% increase in F1 Score, 74.05% decrease in FPR, 73.27% decrease in FNR, 1.83% increase in NPV and 70.61% decrease in FDR when compared with RNN.

**D. Comparison of Proposed Method with Previous Studies**

This subsection details the performance analysis comparison of the proposed method with other state of art methods. Table IV shows the performance comparison of the proposed method with previous strategies.

TABLE IV. COMPARISON OF PROPOSED METHOD WITH PREVIOUS STUDIES

Author	Task	Method	Accuracy (%)	Sensitivity (%)	Specificity (%)	F-1 Score (%)
Oh et al. [20]	DR	ETDRS&SF	83.38	80.6	83.41	-
Latif et al. [28]	Glaucoma	ODG-NET	95.75	94.90	94.75	-
AZhar et al. [32]	Cataract	CNN - SVM	95.6	-	-	-

Proposed method	Glaucoma DR, Cataract, Normal	AMSO-RNN	98.08	98.03	99.34	98.67

Fig. 14. Overall Performance Metrics.

**V. CONCLUSION**

From retinal fundus images, the proposed AED-HSR technique automatically detects the types of different eye diseases such as DR, glaucoma, and cataract from the retinal fundus images. In this approach, the input images are preprocessed by masking, thresholding, and resizing. The resized image is denoised by using gray level morphological transformation. The preprocessed image is then subjected to feature extraction in order to retrieve the image's statistical features. The collected features are then segmented using AMSO and given to the RNN Classifier. The proposed algorithm has been tested on an ODIR database from the Kaggle datasets. The proposed system predicts the type of the disease with 98.08% accuracy, 99.34% specificity, 98.03% sensitivity, 98.03% PPV, 99.34% NPV, 0.62% FPR, 1.93% FNR, 98.67% F1 Score and 1.96% FDR. The proposed methods provide better results in contrast with the other techniques such as RNN-PSO, RNN-GA, and RNN. The model that has been proposed provides better performance metrics when compared with the other networks in terms of accuracy, specificity, sensitivity, PPV, NPV, FPR, FNR, FNR, F1Score and FDR. The outcome of this study points to the enhancement of the suggested network architecture as work that should be done in order to achieve future improvements in terms of performance.

**Abstract**—Farmers' primary concern is to reduce crop loss because of pests and diseases, which occur irrespective of the cultivation process used. Worldwide more than 40% of the agricultural output is lost due to plant pathogens, insects, and weed pests. Earlier farmers relied on agricultural experts to detect pests. Recently Deep learning methods have been utilized for insect pest detection to increase agricultural productivity. This paper presents two deep learning models based on Faster R-CNN Efficient Net B4 and Faster R-CNN Efficient Net B7 for accurate insect pest detection and classification. We validated our approach for 5, 10, and 15 class insect pests of the IP102 dataset. The findings illustrate that our proposed Faster R-CNN Efficient Net B7 model achieved an average classification accuracy of 99.00 %, 96.00 %, and 93.00 % for 5, 10, and 15 class insect pests outperforming other existing models. To detect insect pests less computation time is required for our proposed Faster R-CNN method. The investigation reveals that our proposed Faster R-CNN model can be used to identify crop pests resulting in higher agricultural yield and crop protection.

**Keywords**—Deep learning; faster RCNN; insect pest detection; IP102 dataset; efficient net

## I. INTRODUCTION

Agricultural production from field crops has advanced quickly in both quantity and quality, but the prevalence of pests and diseases on crops has limited the quality of agrarian output. If pests on crops are not thoroughly inspected and a sufficient, long-lasting treatment is not offered, the quality and amount of food production will be lowered, causing an increase in poverty and food shortages. Any country's economy might be negatively impacted by this, but it would be most harmful in places where 60-70% of the populace relies completely on income from the agricultural sector to support itself. Getting rid of pests that are growing and reducing crop production is a significant issue for agricultural producers. According to our research, a pest is any species that disperses disease and induces damage to the plants. Aphids, flax budworm, flea beetle, cabbage butterfly, peachtree borer, prodenia litura, thrips and mole cricket are the most frequent pests that attack plants. In order to prevent a large amount of loss and boost crop yields, it is necessary to identify these pests at all phases of their life cycles, whether they are nascent or advanced. Understanding and classifying insects is the initial step in preventing crop damage caused by insect pests. This will allow us to distinguish between harmless insects and dangerous ones. In recent times, there has been a rise in

awareness of automated pests' classification because this activity necessitates ongoing, intensive monitoring [1]. It is commonly known that distinct insect species may have phenotypes that are similar to one another and that due to various habitats and growth cycles, insects can have intricate morphologies [2] [3]. An outstanding method for recognizing insect images has been made possible by the development of machine learning techniques. Vehicle recognition and motion detection have seen considerable success utilizing computer vision as well as machine learning techniques [4] [5]. A sizable pest dataset of 40 high-grade pest categories was labeled using a multi-level classification framework of alignment-pooling method [6]. A dataset with 563 pest images partitioned into 10 categories was used. To classify the dataset, training was done on a Support Vector Machine for custom features [7]. Various image processing techniques to detect and retrieve insect pests by developing a machine-driven detection and removal system for evaluating pest concentration in paddy crops [8]. To identify the pest from a dataset of pest images K mean segmentation technique was implemented. In order to classify the pests, the discrete cosine transform method was implemented and the pest images were classified using an artificial neural network. Images were validated for five pests and obtained an accuracy of 94.00 % [9]. Deep learning techniques like convolutional neural networks have lately been used in agricultural production as a viable approach for fully automated pest classification [10]. The convolutional neural networks exert a significant influence on image elements and has their own feature extractor, which makes them superior to conventional image processing techniques and machine learning. Additionally, in several applications of medical image analysis, convolutional neural networks demonstrated their ability to manage picture noise and illumination change [11]. In this study, a Faster R-CNN framework to detect and classify insect pests is investigated.

The main contributions of this work are as follows:

- 1) To detect and classify crop pests, a Faster R-CNN framework with Efficient Net is used. In order to improve the performance of the model the network drop connects is used to prevent over fitting and to increase regularization effect a swish function is utilized for Efficient Net.
- 2) The Region Proposal Network module and the bounding box regression can accurately predict the classes and

locations of various crop pests. The computational time required for detecting the insect pests is less.

3) Compared to other methods, the evaluation results of insect pest classification using the proposed Faster R-CNN framework demonstrated superior performance.

## II. RELATED WORK

Several deep learning techniques have been used recently to categorize pests and develop cutting-edge outcomes in several applications for pest identification. Convolutional neural network and saliency techniques were used for classifying insect pests. Image processing algorithms known as saliency approaches emphasize the most important areas of an image. These techniques are based on the realization that the observer accurately distinguishes between the portions of its field of vision that are important and those that are not useful, rather than focusing on the entire range of vision. They obtained an accuracy of 92.43 % for the smaller dataset [12]. To classify the defected wheat granules for a dataset of 300 images, an artificial bee colony, performance tuning artificial neural network, and extreme learning machine techniques are used [40]. A deep learning framework for multi-class fruit detection which includes fruits images along with data augmentation based on Faster RCNN was proposed and the performance was evaluated [41]. For identifying pests and plant diseases in video content, a deep learning-based Faster RCNN was investigated along with video based performance metrics [42]. A survey paper of current innovations in image processing methods for automated leaf pest and disease recognition [43]. Adao et al. collected a dataset of cotton field images and implemented a deep residual design and classified the pests. F1-score of 0.98 was achieved by using Resnet 34 model [44]. A metric for accuracy degradation was utilized to analyze machine learning algorithms by enhancing benign samples [24]. The natural statistics model was applied to create saliency maps and identify regions of interest in an insect pest image. Further work was done on the bio-inspired Hierarchical model and X (HMAX) method in the accompanying areas to retrieve invariant features for representing pest appearance [13]. Convolutional neural network-based frameworks, such as attention, feature pyramid, and fine-grained modeling techniques for the IP102 dataset were implemented and obtained an accuracy of 74.00 % [14]. Chen. H. C et al. implemented the AlexNet-modified architecture-based convolutional neural network model on the mobile application in order to identify tomato diseases utilizing leaf images. For a 9-class disease, the Alexnet model had a precision of 80.3% [15]. Pest detection for 10 pest classes using an efficient system for deep learning achieved an average accuracy of 70.5 %. Yolov5-S model was used for the detection of pests and the dataset used was IP102 [16]. A comparison of KNN, SVM, Multilayer Perceptron, Faster R-CNN, and Single Shot Detector classifiers in distinguishing Bemisia Tabacii embryo and Trialeurodes Vaporariorum embryo tomato pest classes was implemented [17]. K. Thenmozhi used three types of the dataset which include NBAIR, Xie1, and Xie2 for insect classification for 40 classes and 24 classes. Pre-trained deep learning techniques like AlexNet, ResNet, and VGGNet were used for insect classification and fine-tuned with pre-trained

models by utilizing transfer learning and obtained an accuracy of 96.75, 97.47, and 95.97% [18].

Wang et al. implemented a Multi-scale convolution capsule network for crop insect pest detection. The advantages of MSCCN are that it is able to extract the multi-scale discriminative features, encode the hierarchical structure of size-variant pests and for pest identification, softmax function was used to determine the probability. They obtained an accuracy of 89.6% for 9 classes of insect species [19]. Nour et al. worked on the AlexNet model to recognize the pests for an IP102 dataset. The model accuracy was fine-tuned by data augmentation to obtain an accuracy of 89.6 % for an eight-class insect pest [20]. Balakrishnan et al. implemented a real-time IOT-based environment to detect pests using a faster RCNN ResNet50 model for object detection framework. The model used 150 test images for each class of insects, 8 classes of the IP102 dataset. The model average accuracy achieved for eight-class insects is around 94.00 % [21]. Kasinathan et al. implemented machine learning techniques such as ANN, SVM, KNN, Naïve Bayes, and the CNN model for pest detection and classification. The model achieved an accuracy of 91.5 % and 93.9 % for nine class and five class pests. The drawback of this model they have used 50 images for each class even though more images of the pests were available in the dataset of IP102 [22].

Mohamed et al. developed a mobile application that uses deep learning to automatically classify pests and for the identification of insect pests, they used a Faster R-CNN model. The model achieved an average accuracy of 98 % for five pests. The drawback of this work, in training the image pests they have used a total of 500 image pests which results in poor approximation, and few test data will result in an optimistic and high variance estimation of prediction accuracy [23]. In order to overcome the above approach, the proposed work was implemented by using a Faster R-CNN for detection and classification of pests for around 1449 pest images for testing of five pest classes, similarly for 10 classes is 2921 images and 15 classes are 4321 pest images of IP102 dataset.

### A. Insect Pests

The proposed work, includes 15 classes of crop insect pests namely aphids, cicadellidae, flax budworm, flea beetle, cabbage butterfly, peachtree borer, prodenia litura, thrips, bird cherry-oat aphid, mole cricket, grub, wireworm, ampelophaga, lycoma delicatula and xylotrachus. Each class in the IP102 dataset is highly unbalanced, each class pest that contains more images in the dataset is taken into consideration for the study. The following insect pests framework cause considerable damage to the crops leading to a loss in crop productivity.

### B. Faster R-CNN

Faster R-CNN requires an image to be scaled to a certain length and width so that noise can be avoided and with the introduction of a region proposal network the detection speed of insect pests is vastly improved [37]. The feature map is generated by the convolution neural network layers for processing the images and the identified object undergoes location regression and classification. We evaluate the three important steps which are involved in Faster R-CNN. Feature

maps were obtained from a pre-trained convolutional neural networks framework in particular Efficient Net [25], Resnet 50 [21], and Dense convolutional neural networks [38]. Next, the Region Proposal network generates the region proposals to detect the pest's locations in the image. The regression box provides the exact location of the insect pests. The insect pest image processed by the region generative proposal is sent to the region of interest pooling to identify and predict the accurate location of the insect pest image. Fig. 3 depicts the proposed Faster R-CNN framework for detection and classification.

### III. MATERIALS AND METHODS

Efficient Net is a unique scaling method that uniformly scales all depth/width/resolution dimensions using a compound coefficient. Neural architecture search is used to generate a brand-new baseline network and scale it up to create the Efficient Nets family of modeling techniques, which outperform prior convolutional networks in both efficiency and accuracy, reducing parameter size and FLOPS [39]. Width scaling is the process of changing the width of an input image. The larger the image, the more feature maps/channels are possible, and thus the more information is available to process [36]. Resolution scaling is the process of changing the resolution of an image. The higher an image's Dots per inch, the higher its resolution. Better resolution is simply an augmentation in the number of pixels in an image. To scale the three dimensions, a baseline model called Efficient Net B0 was introduced. There are seven Efficient Net models ranging from B0-B7, where B0 is the baseline model. The size of the incoming image varies between models. As the model level increases, so does the image's input size. This flexible scaling strategy can be utilized to effectively scale Convolutional Neural Networks and enhance the accuracy with a variety of frameworks.

The input image is processed by MBConv bottlenecks in which direct connections are used because between bottlenecks with significantly fewer channels than expansion layers in inverted residual blocks as shown in Fig. 1. MB Conv has an attention blocks and are made up of a layer that expands and then compresses the channels, mechanism that allows it to optimize channel features that contain the highest information while restricting less significant channel features. The gradient of MBConv does not quickly vanish when the network depth is more thereby improving the model performance. The regularization effect can be increased by using a swish function with no upper limit wherein gradient saturation will not occur [25]. In order to improve the performance, the network drop connect is used to prevent over-fitting. The Efficient Net B4 and Efficient Net B7 model consists of nine phases with respect to Blocks. Blocks provide effective layers and their feature map is connected to the Region Proposal network and Region of Interest pooling as shown in Fig. 3.

Fig. 1. Efficient B7 Architecture.

#### A. Dataset

Capturing pest images is a difficult task although all insect pests go through several phases during their entire life, based on the species and category of pest. IP102 dataset is commonly used to test the insect pest for classification and detection based on deep learning methods [22]. As a result, we utilized pest images from the public IP102 dataset. The dataset has around 75000 images pertaining to 102 insect pest species. For detection and classification, we have chosen 5, 10, and 15 classes of insect pests. Dataset of 14490 pest images for the training of five pest classes, 29210 images for 10 pest classes, and 43210 images for 15 pest classes. The pest images were split in the ratio of 80 % training, 10 % validation, and 10 % for testing. Sample images of insect pests are shown in Fig. 2.

#### B. Proposed Framework for Detection and Classification

The pest images of the IP102 dataset are passed to Efficient Net network and are pre-trained on ImageNet to generate feature map. In order to improve the performance, network Drop connect and Swish function is utilised in Efficient Net. The feature map is passed to the RPN network to generate the bounding box and proposal score for the pest images. The output of RPN network and feature map obtained from the Efficient Net algorithm is passed to ROI pooling for detection and classification of pest images. Further the flow of the Proposed Faster R-CNN framework for Pest detection and Classification is explained in detail in the below following Section 3C and 3D.

Fig. 2. Samples of Pests Images from the IP102 Dataset.

Fig. 3. Proposed Faster R-CNN Framework for Pest Detection and Classification.

### C. Image Preprocessing and Augmentation

Images are transformed to (600,600) in the pre-processing stage phase to retain the same aspect ratio, and images are normalized to maintain the standardized data distribution [25]. The importance of data augmentation for image classification analysis has previously been proven due to insufficient datasets. The categories of each insect pest in the IP102 dataset are highly unbalanced. To increase the data while avoiding the over-fitting problem, various data augmentation techniques such as rescaling, zooming, and horizontal flipping have been used. Gaussian filter is first used to smooth the image. The images were rescaled, created a mask for every image, and then applied segmentation to each sample. Each image in the dataset is subjected to the processing pipelining by a function.

### D. Insect Pest Detection & Classification

The above-proposed learning architecture is used for image processing and to detect and classify pests using the Efficient Net and Faster R-CNN approach as shown in Fig. 3. The convolutional neural network layers of Efficient Net B4 and Efficient Net B7 has been used as feature extractor in this research and for Faster R-CNN because of their added advantage of lightweight and its processing speed which is critical for our end application. The pre-trained weights of Efficient Net were trained on the Image Net dataset. The size of the input image for this methodology is fixed at 224 x 224. Hence using the EfficientNet model we generate feature maps for an input image and pass it to the RPN.

The RPN takes these feature maps as an input to it and provides a set of rectangular proposals (bounding box) identifying the object i.e, a pest in the convolutional neural network feature map as an output along with the objectness score. Grid-anchor having aspect ratio [0.25, 0.5, 1.0, 2.0] is started with a 16x16 pixel size during this stage. These anchors point to available objects of different sizes and aspect ratios at the corresponding location. Intersection over Union determines how well the bounding box matches with the ground truth of the insect pest image, where A and B are two

sections of region proposals as given in (1). To improve the performance of the model and to reduce the noise, non-maximum suppression is utilized for identifying the bounding boxes with the highest confidence so that the small overlaps are ignored. The thresholds were kept at 0.7.

$$IoU = \frac{A \cap B}{A \cup B} \quad (1)$$

To create the proposals for the object, the Faster R-CNN architecture is utilized. It has a specialized and unique architecture that has got classifier and regressor. The Faster R-CNN is robust against translations, it's one of the important properties that it is translational invariant.

When multi-scale anchors are present, Faster R-CNN creates a "Pyramid of Anchors" rather than a "Pyramid of Filters," which consumes less time and is more cost efficient compared to various other architecture. The next step is to pass the proposals to Region of Interest pooling layers. To create a single feature map for each of the proposals provided by RPN in a single pass, Region of Interest pooling is utilized. It is implemented to address the issue of fixed image size difficulties with object detection. ROI pooling is utilized to create fixed-size feature maps against non-uniform inputs by applying max-pooling across the inputs. This layer needs two inputs: (i) A feature map obtained from a backbone of EfficientNet B4 or EfficientNet B7 used in our research methodology after multiple convolutions and pooling layers. (ii) 'N' proposals or Region of Interests from region proposal network (RPN).

The benefit of Region of Interest pooling is that we can utilize the corresponding feature map across all proposals, allowing us to pass the whole image to the convolutional neural networks rather than passing each proposal separately. The sub-windows have a size of (N, 7, 7, 512) which has been created by the Region of Interest pooling layer by applying max pooling over the next stage, where N represents the number of region proposals obtained by the RPN network. The features are moved into the classifier and regression sections after moving via two fully connected

layers. Using the softmax function, the classification division evaluates the probability of a region proposal comprising an insect pest. Additionally, Intersection over Union values are used to evaluate the accuracy of the bounding box generated surrounding the insect pest. The anchor box coordinates are provided by the bounding box regression.

*E. Classification Performance Metrics*

The performance for identifying the insects is measured by using rotation estimation for validating the insect pests of tested images with predicted classification results of the Faster R-CNN technique [26]. The Confusion Metrics are evaluated by True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). The TP indicates the current predicted insect pest class category that is correctly classified. The TN pertains to other groups that do not belong to the existing insect pest class category. The FP pertains to other insect pest class category incorrectly classified as the current insect pest class type. The FN relates to the current insect pest class category that was incorrectly classified and did not belong to the existing class. Precision metric indicates out of all points that are predicted to be positive, how many are actually Positive. The recall metric indicates out of all positive points, how many are actually positive. The classification metrics is given below.

$$accuracy = \frac{tp+tn}{tp+fp+tn+fn} \tag{2}$$

$$precision = \frac{tp}{tp+fp} \tag{3}$$

$$recall = \frac{tp}{tp+fn} \tag{4}$$

$$f1score = \frac{2*precision*recall}{precision+recall} \tag{5}$$

IV. RESULTS AND DISCUSSIONS

For this experiment, we have used an i7 processor with GPU (Nvidia RTX 3080 Ti) along with other supporting tools such as Keras and Tensor flow for the detection and classification analysis of insect pest images of the IP102 dataset. The performance of the insect detection and classification method was implemented on 5, 10 and 15 classes of insects. The insect pest images were split into the ratio of 80% training, 10% validation, and 10 % for testing. The proposed Faster R-CNN model is trained using Stochastic Gradient Descent as an optimizer with 0.9 momentum value, region proposal network weights, and the last fully connected layer weights. The learning rate tells about the learning progress and updates with weight parameters to reduce the loss. The learning rate is varied from 0.0005, 0.0001, 0.001. The maximum no of epochs trained to 40 steps. The detection and classification results are shown in Fig. 4 based on Faster RCNN. The proposed Faster R-CNN technique can correctly detect insect pests in the image and identify the categories. For all test datasets of pest species, classification accuracy ranged from 97.0 to 100.00%.

Fig. 4. Sample of Pest Detection Results for the IP102 Dataset.

The performance indicator for Pest detection is shown in Fig. 5, such as the two methods' average inferential speed. As shown in Fig. 5, Faster R-CNN Efficient Net B7 speed along with accuracy takes around 19.5 frames per second compared to the other model which takes 20.7 frames per second.

Fig. 5. Speed for Insect Pest Detection based on Faster-RCNN.

The model performance for five pest classes based on Faster R-CNN Efficient Net B7 and Faster R-CNN Efficient Net B4 model is shown in Fig. 6 and Fig. 7. The learning rate was reduced by a factor of 0.5 when the improvement during training went negative. The model continued to be trained with a stop patience of seven, i.e, if for seven continuous epochs there was a negative improvement, the training was halted automatically. The Validation accuracy of around 99.00 % was achieved during training, and the validation loss decreased progressively up to 0.4 % for the Faster R-CNN Efficient Net B7 model. Similarly, the Validation accuracy of 98.00 % and loss of 0.6 % are obtained for the Faster R-CNN Efficient Net B4 model.

Fig. 6. Model Performance for 5 Pest Classes based on Faster R-CNN Efficient Net B7.

Fig. 7. Model Performance for 5 Pest Classes based on Faster R-CNN Efficient Net B4.

The model performance for 10 pest classes based on Faster R-CNN Efficient Net B7 and Faster R-CNN Efficient Net B4 model is shown in Fig. 8 and Fig. 9. The Validation accuracy of around 96.00 % was achieved during training and the validation loss decreased progressively up to 0.6 % for the Faster R-CNN Efficient Net B7 model. Similarly, the validation accuracy of 95.00 % and loss of 0.7 % are obtained for the Faster R-CNN Efficient Net B4 model.

Fig. 8. Model Performance for 10 Pest Classes based on Faster R-CNN Efficient Net B7.

Fig. 9. Model Performance for 10 Pest Classes based on Faster R-CNN Efficient Net B4.

Similarly, we investigated the model performance for 15 pest classes based on Faster R-CNN Efficient Net B7 and the Faster R-CNN Efficient Net B4 models as shown in Fig. 10 and Fig. 11. The Validation accuracy of around 93.00 % was achieved during training and the validation loss decreased progressively up to 0.67 % for the Faster R-CNN Efficient Net B7 model. The validation accuracy of 86.00 % and loss of 0.72 % are obtained for the Faster RCNN Efficient Net B4 model.

Fig. 12, Fig. 13, and Fig. 14 shows the confusion matrix for 5, 10, and 15 Pest classes of the IP102 dataset during testing for the Faster R-CNN Efficient Net B7 model. For insect pests, aphids 0.006 %, cabbage butterfly 0.019 %, cicadellidae 0.006 % and flea beetle 0.042 % of images is incorrectly classified for five pest class. Flax budworm is correctly classified with a ratio of one for a five pest insect classification.

Fig. 10. Model Performance for 15 Pest Classes based on Faster R-CNN Efficient Net B7.

Fig. 11. Model Performance for 15 Pest Classes based on Faster R-CNN Efficient Net B4.

Fig. 12. Confusion Matrix for 5 Pest Classes for Faster R-CNN Efficient Net B7 Model.

Fig. 13. Confusion Matrix for 10 Pest Classes for Faster R-CNN Efficient Net B7 Model.

Fig. 14. Confusion Matrix for 15 Pest Classes for Faster R-CNN Efficient Net B7 Model.

Fig. 15 to 17, show the confusion matrix for 5, 10, and 15 Pest classes during testing for the Faster R-CNN Efficient Net B4 model. For insect pest aphids 0.016 %, cabbage butterfly 0.027 %, cicadellidae 0.006 % and flea beetle 0.084 % of images is incorrectly classified for a five pest class. Flax budworm is correctly classified with a ratio of 1 for a 5 pest insect classification.

Fig. 18, illustrates the classification report for the test dataset for 5, 10 and 15 pest classes using Faster R-CNN Efficient Net B7 for IP102 dataset. Classification Accuracy of 99.00 %, 96.00 %, and 93.00 % is achieved for 5, 10, and 15

pest classes based on Faster R-CNN Efficient Net B7. For the five pest classes, the accuracy ranges from 98 % to 100 %. The Precision, recall, the F1 score is 99.00 % for 5 classes and of 10 class pests test data it is around 96.00 % and for 15 class pests test data is 93.00 %.

Fig. 19, illustrates the classification report for the test dataset for 5, 10 and 15 pest classes using Faster R-CNN Efficient Net B4. Classification Accuracy of 98.00 %, 95.00 %, and 90.00 % is achieved for 5, 10, and 15 pest classes based on Faster R-CNN Efficient Net B4. The Precision, recall, and F1 score is 98.00 % for 5 classes, 10 class pest is around 95.00 % and 15 class pests is 90 %.

#### F. Comparative Analysis

Y. Liu et al. investigated using Back-propagation Neural Network for five pest class dataset of IP102 dataset and achieved an accuracy of 63 %, 50 %, and 43.5 % of classification accuracy for 10 %, 20 %, and 30 % test data set [34]. When compared to BP Neural Network, the Single shot Multi-box detector performed better for identifying the crop pests and achieved an accuracy of 90.6 % for a five pest class [35]. Kasinathan et al. proposed a CNN model for five pest classes and obtained an accuracy of 93.9 % [22]. Our Faster-CNN model outperformed when compared with the other two models for recognizing the pests and obtained a classification accuracy of 99.00 % for 10 % of test data, 98.4 % for 20 % of test data, and 95.5 % for test data. When the training of the

pest images is increased by 70 % to 90 %, the classification accuracy improves. When compared to 30 % of test data our Faster R-CNN model has an accuracy of 95.5%, whereas for BP Neural Network and SSD Mobile Net is around 43.5 % and 85.70 % as shown in Fig. 20.

Comparison was done for the other existing methods for 9 and 10-class crop pests as shown in Fig. 21. Among all these models, bio-inspired methods achieved an accuracy score of 92.50 % [12], with inference we can say that these models used deep learning methodology to detect crop pests. Our proposed Faster R-CNN model outperforms other existing methods and achieved an average accuracy score of 96.00 % for a 10-class crop pest test dataset.

The performance of the proposed method Faster R-CNN Efficient Net B7 and Faster R-CNN Efficient Net B4 is compared with existing methods for the IP102 dataset as shown in Table I. From Table I we can infer that the proposed Faster R-CNN Efficient Net B7 method outperforms the latest competitive approaches in terms of Accuracy for 5 and 10 class crop pests.

## V. CONCLUSION

In this study, the investigation was done on the Faster R-CNN method to detect and classify different insect pests for 5, 10, and 15 classes, and the results were compared. To improve the performance and accuracy, each one of the pest images has been resized, pre-processed, and augmented to increase the dataset. When the image background is more challenging and the insect classes are more numerous, as in the IP102 dataset, our proposed Faster R-CNN Efficient B7 model achieved an average classification accuracy of 99.00 %, 96.00 %, and 93.00 % for 5, 10, and 15 class insect pests outperforming other existing models such as SSD Mobile Net, Bio-inspired method and Faster R-CNN ResNet 50. In future work, the proposed Faster R-CNN model will be used for higher number of insect classes and subclasses of insect pests that will be useful for farmers to detect insect pests for detection and classification.

**Abstract**—In the biomedical field, automatic disease detection by image processing has become the norm in the current days. For early illness detection, ophthalmologists have explored a variety of invasive and noninvasive procedures. Optical Coherence Tomography (OCT) is a noninvasive imaging technique for obtaining high resolution tomographic images of biological systems. The image quality is degraded by noise, which degrades the performance of noisy image processing algorithms. The OCT images captured with speckle noise and prior to further processing, it is critical to use an effective approach for denoising the image. In this paper, we used Median filter, Average filter or Mean filter, Wiener filter, Gaussian filter and Bilateral filter on OCT images in this paper, and discussed the advantages and drawbacks of each approach. The effectiveness of these filters are compared using the Peak Signal to Noise Ratio (PSNR), Mean Square Error (MSE) and Contrast to Noise Ratio (CNR).

**Keywords**—Average or Mean filter; Bilateral filter; denoising image; Gaussian Filter; Median filter; optical coherence tomography; Wiener filter

## I. INTRODUCTION

Many practitioners have recently embraced Optical Coherence Tomography (OCT) as a means of gathering data from the human eye in order to diagnose problems. In today's world, OCT is a well-known imaging technology that is used to monitor retinal illnesses in the medical industry. Although, during the data acquisition phase of OCT, a grainy prototype known as speckle noise is always present. The attendance of speckle noise in OCT images limits image processing, making patient diagnosis harder for a practitioner. Due to the attendance of speckle noise in OCT images, blood vessels and layer bounds appear to be disconnected. The working approach to obtain OCT images is nearly identical to that for collecting ultrasound images, with the exception of the medium utilised to obtain it. Fig. 1 shows the OCT images of human eye. In the OCT image acquisition technique, light beams are employed as an alternative of the sound beams used in ultrasound imaging [1]. OCT imaging has been shown to play a key responsibility in the diagnosis of disorders associated to the retina and

glaucoma in the medical realm [2-4]. OCT is one of the greatest techniques in the medical sector for finding the inside structure of the retina and high-intention images of the retina [5-8]. It has been discovered via the observations of several specialists that retinal layer width improves experimental results in the field of optometrist. In the case of glaucoma development and macular degeneration, retinal layer segmentation also improves clinical findings. The speckle noise in OCT images degrades picture quality and reduces the image's contrast to noise ratio. A despeckle method is necessary as a pretreatment step in the denoising operation of OCT images to defeat the effect of speckle noise and to maintain the excellent details of the OCT images. Preprocessing OCT images is therefore a crucial step in ophthalmology to improve clinical findings. The motivation of this research work is to choose the best denoising method to reduce speckle noise in the retinal OCT images without removing the details in the image. We analysed the Median Filter, Gaussian Filter, Bilateral Filter, Wiener Filter, and Average or Mean Filter denoising methods on OCT images and proved the Wiener filter is the best denoising method to reduce speckle noise in retinal OCT images.

There are six sections in this paper. Introduction given in Section I, the brief description about the different types of noise is given in Section II, Section III contains denoising methods such as the Median Filter, Gaussian Filter, Bilateral Filter, Wiener Filter, and Average or Mean Filter, the implementation is given in Section IV and Section V discusses the performance measuring methods such as PSNR, CNR, and MSE, as well as how these measurements are used to evaluate results. Section VI concludes with a conclusion.

## II. LITERATURE REVIEW

OCT is a technique that is frequently used to detect and track retinal conditions. However, despite technology advancements, speckle noise continues to significantly impair its scans. Speckle noise lowers the accuracy of measurements and the dependability of subsequent equipment. Mahnoosh Tajmiriahi et al. used a lightweight convolutional AE (Auto Encoders) used to simulate a recently developed state-of-the-art OCT picture denoising technique [9].

Xiaojun Yu et al. developed a two-step filtering method to reduce speckle noise, which consisting of Augmented Lagrange function minimization and Rayleigh alpha-trimmed filtering (AR) scheme. This mechanism examines the effects of speckle noise distributions on the OCT despeckling process [10].

Nahida Akter et al. proposed deep learning based method to remove noise from OCT images. The authors created and trained a U-Net model using OCT artifact-filled and artifact-free B-scans for investigation and shown that the U-Net performed better in terms of SSIM and PSNR values in removing the artefacts [11].

Bin Qiu et al. developed a deep network architecture. In the study, the authors used a most well-known frequently used modified DnCNN was used to denoise the OCT images [12].

Lirong Zeng et al. suggested progressive feature fusion attention dense network (PFFADN) for removing speckle noise from OCT images. In order to create a residual block, the authors sequentially connected the shallow and deep convolution feature maps that were retrieved from each dense block. This is done by arranging densely connected dense blocks in the deep convolution network [13].

Ling Chen et al., used the SC-based denoising database creation is the central component of the described approach, SC-DnCNN. Since FF-OCT images don't require registration before SC due to their unique image characteristics, they outperform point scanning OCT in terms of producing clear images. This method allows for the inclusion of both noisy and relatively clear images as training data, the embedding of a spatial adaptive mapping based on the compounding database, and the reduction of the effect of the speckle [14].

Yan Hu et al. provided an adaptive-SIN filtering technique to address the problem of minimising the noise in OCT images of various types. The suggested square-root transform converts the Poisson noise in the OCT pictures to the Gaussian noise in order to enable the best noise removal by the subsequent shearlet transform. The edge information in the photos as well as other image fine features may be preserved by the 3D shearlet transform [15].

## III. TYPES OF NOISE

Unwanted information causes image quality to deteriorate. The type of noise there in the original image plays a crucial impact in the image noise removal procedure. Noise having a Gaussian, salt and pepper sharing corrupts typical images. Speckle noise, which is multiplicative in nature, is another example of a typical noise. The following sections detail the behaviour of each of these noises.

### A. Gaussian Noise

Gaussian noise is geometric noise with a normal distribution probability density function, commonly known as Gaussian noise. That is, the noise's possible values are Gaussian-distributed. The noise with a Gaussian amplitude sharing is correctly defined as Gaussian noise [16].

### B. Salt and Pepper Noise

Quick, unexpected perturbations in the image signal generate salt and pepper noise, which appears as at random dotted white or black pixels over the image. In salt and pepper noise, the black pixels appear in bright areas and brightly pixels appear in dark areas. Dead pixels, analogue to digital converter problems, and transmission bit mistakes can all contribute to this form of noise [16].

### C. Speckle Noise

All fundamental aspects of logical imaging, particularly clinical ultra sound imaging, are affected by speckle noise. Sound processing of backscatter signals from several spread targets is the cause. Signals from basic scatters generate speckle noise. Speckle noise is referred to as texture in pharmaceutical literature, and it may include diagnostic information Smoothing the texture may be less desirable for visual interpretation. Physicians prefer the original noisy photos to the smoothed versions more willingly because the filter, even if it is more sophisticated, can eliminate some important image information. As a result, it's critical to create noise filters that maintain the traits that matter to doctors. To reduce speckle noise, several methods are utilised, each based on a distinct mathematical description of the phenomenon. For eliminate speckle noise in ultrasound pictures, we recommend hybrid filtering techniques [16].

## IV. FILTERING TECHNIQUES

A variety of filtering techniques are obtainable in the literature for the elimination of noise. Linear filtering techniques and non-linear filtering techniques are the two main categories. A linear-output filter's is the same as the input, whereas a non-linear-output filter's is different.

### A. Mean Filter or Average Filter

The mean filter counts each pixel in a picture by replacing it with the mean or average value of its neighbours. So in the output image the pixel values that are out of character with their surroundings are deleted. It's built on a kernel, which, like other convolutions, represents the structure and width of the sampled neighbourhood when computing the mean. As shown in Fig. 2, a  $3 \times 3$  kernel is commonly employed, but greater kernels, such as  $5 \times 5$ , may be utilised for more severe smoothing.

### B. Median Filter

Median filtering is a nonlinear smoothing technique. Restore the value of each pixel with the median value of neighborhood element, which is better ordered for decreasing salt and pepper noise. That is, we choose a kernel and sort all elements in the neighbourhood by grey value, with the group's median acting as the output element for the neighbourhood centre. When an element in the proximity of other elements is

unusual, use the grey value of the elements in the field. That is the value that is halfway between the two extremes [17]. Take the field's element grey value when a element neighbourhood of element number is even. In the middle of two scales, it is the sort value. The median filter reduces noise while maintaining image edge clarity. When the window size is increased in median filtering, noise is successfully reduced [18].

$\frac{1}{9}$	$\frac{1}{9}$	$\frac{1}{9}$
$\frac{1}{9}$	$\frac{1}{9}$	$\frac{1}{9}$
$\frac{1}{9}$	$\frac{1}{9}$	$\frac{1}{9}$

Fig. 2. 3x3 Average Kernel Often used in Mean Filter.

### C. Max and Min Filter

In max and min filter, it assigns a new value to each pixel in an image based on the greatest or smallest amount of value in the neighbourhood around that pixel. The filter's shape is represented by the neighbourhood. Contrast enhancement and normalization [19], texture description [20], edge detection [21-22], and thresholding [26] have all employed maximum and minimum filters. The filters are dilation and erosion counterparts with a grey value.

### D. Gaussian Filter

Gaussian filters are thought to be the best time domain filters. It's a type of lowpass filter that isn't uniform. Such filters have a Gaussian impulse response, and Gaussian filters are those that have a Gaussian function. It has the shortest feasible grouping delay. The fundamental purpose of a Gaussian filter is to reduce distortion in lowest and highest signals [23]. A Gaussian obscure, also known as Gaussian smoothing is an after-effect of concealing a picture with a Gaussian capability in image processing. This Gaussian smoothing superintendent is usually a 2-D convolutional superintendent that is used to obfuscate images and remove subtle element and clamours. Gaussian filter is frequently more difficult with salt and pepper. When compared to other filters, one of the key disadvantages of the Gaussian filter is that it takes a long time. As a rule, Gaussian filters do not overshoot a stage work input while restricting the climb and fall times [24].

### E. Bilateral Filter

The bilateral filter is defined as a loaded average of pixels, similar to the Gaussian convolution. The bilateral-filter, on the other hand, maintains edges by taking intensity variations into account. Bilateral filtering is based on the concept that two pixels are adjacent not only if they engage adjacent spatial regions, but also if their photometric ranges are comparable [25].

### F. Wiener Filter

Inverse filtering, sometimes known as generalised inverse-filtering, is a technique for restoring deconvolution. Inverse-filtering or generalised inverse-filtering can be used to improve an image that is dim using a known lowpass filter. Conversely, inverse filtering is extremely intuitive to additive-noise. We

can create a restoration method for each type of deterioration and then join them using the "one degradation at a time" technique. Inverse filtering and noise smoothing are most stable when Wiener filtering is used. It reduces additive noise while also inverting blurring. In terms of MSE, Wiener filtering is the best option. It minimizes the overall mean square error. A linear-estimation of the unique image is used in Wiener filtering. A probabilistic foundation underpins the procedure. The Wiener-filter in the Fourier-domain can be written as follows because of the orthogonal principle:

$$W(f_1, f_2) = \frac{H^*(f_1, f_2)S_{xx}(f_1, f_2)}{|h(f_1, f_2)|^2 S_{xx}(f_1, f_2) + S_{\eta\eta}(f_1, f_2)} \quad (1)$$

where  $S_{xx}(f_1, f_2)$  and  $S_{\eta\eta}(f_1, f_2)$  are correspondingly value spectra of the initial image and the additive- noise, and  $H(f_1, f_2)$  is the blurring- filter. As can be seen, the Wiener filter has two separate parts: a noise smoothing part and inverse-filtering part. It not only uses inverse filtering (highpass filtering) to deconvolve the data, but it also uses compression to reduce the noise (lowpass filtering).

## V. IMPLEMENTATION

The implementation process of comparison is depicted in the block diagram, Fig. 3. On six separate OCT images of an eye, we employ five noise removal techniques: Mean or Average, Median, Bilateral, Gaussian, and Wiener filters, and the efficiency of each filter is evaluated using PSNR, CNR, and MSE values.

The filtering techniques are implemented using Python. The original images are converted into grayscale images and then the filtering techniques are applied on those grayscale images. The sample resultant filtered images are given in Fig. 4.

## VI. EVALUATION AND RESULTS

### A. Mean-Squared-Error (MSE)

The MSE value is the Mean-squared-error between the enhanced image  $Y(I, j)$  and the actual image  $I(i, j)$ , which for a high-quality image is negligible. The MSE of a given image of range  $M \times N$  is calculated as follows:

$$MSE = \frac{1}{MN} \sum_{i=0}^{M-1} \sum_{j=0}^{N-1} [I(i, j) - Y(i, j)]^2 \quad (2)$$

Fig. 3. Block Diagram of Implementation Process of Comparison.

Fig. 4. Four Images are Passing through All Five Filtering Technique before and after, (a) OCT Image 1, (b) OCT Image 2, (c) OCT Image 3, (d) OCT Image 4.

It is determine by squaring the difference between the denoised (images after filtering) and noisy images and then taking the average of the difference [17]. Table I shows the MSE values of various filtered images. Fig. 5 shows the MSE graph after applying the median, wiener, bilateral, Gaussian, and average filters on all six images. Lower values of MSE specify improved image quality. When compared to the other four filters, Wiener has the lowest MSE value.

TABLE I. MSE VALUE OF FILTERED IMAGES

MSE Comparison						
Filters	OCT Image 1	OCT Image 2	OCT Image 3	OCT Image 4	OCT Image 5	OCT Image 6
Median	20.29753	21.86683	30.02484	20.54619	21.85792	27.43176
<b>Weiner</b>	<b>17.51171</b>	<b>19.10760</b>	<b>29.29777</b>	<b>17.57836</b>	<b>18.47427</b>	<b>26.82416</b>
Bilatera l	26.06070	21.61373	39.38961	23.83720	19.67814	35.18031

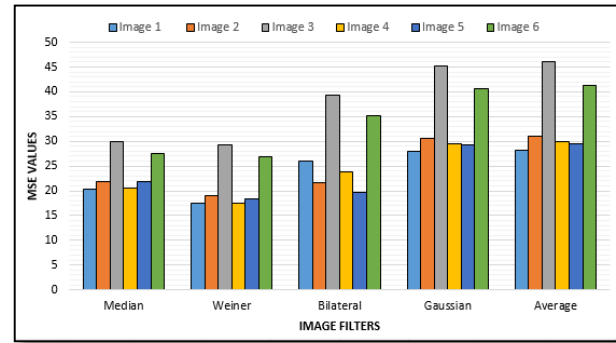

Fig. 5. Comparison of MSE Values of the Filtered Images.

### B. Peak Signal-To-Noise Ratio (PSNR)

PSNR is defined as the relational of a signal's greatest value to the noise value that affects the signal's quality. PSNR is an image quality metric that provides a metric of noise that affects image quality. It determines the quantity of noise that has an impact on image quality. The image quality improves as the PSNR score rises. The PSNR value is calculated using the root-to- mean-square-error (RMSE), which is the square- root of the error between the input-image and the enhanced- image. For the largest possible pixel values, if RMSE will decrease, the PSNR will increase. As a result, greater PSNR values suggest better image improvement. PSNR has the advantage of being computationally and logically straightforward to optimise. One downside of root-mean-squared error is that it changes in lockstep with image intensity. PSNR's mathematical formulation is as follows:

$$PSNR = 10\log(S^2/MSE) \quad (3)$$

The greatest pixel value that can be assign in an image is S. For an 8-bit image, S=255. It can alternatively be defined as the ratio of greatest signal power to maximum noise power. This rate is expressed in decibels (dB). Table II shows the PSNR rate of all six images after going through various filters and Fig. 6 shows the comparison of PSNR values after applying the median, wiener, bilateral, Gaussian, and average filters on all six images. When compared to the other four filters, Wiener has the highest PSNR score.

TABLE II. PSNR VALUE OF FILTERED IMAGES

PSNR Comparison						
Filters	OCT Image 1	OCT Image 2	OCT Image 3	OCT Image 4	OCT Image 5	OCT Image 6
Median	35.0563 dB	34.7329 dB	33.3559 dB	35.0034 dB	34.7347 dB	33.7482 dB
<b>Weiner</b>	<b>35.6975 dB</b>	<b>35.3187 dB</b>	<b>33.3666 dB</b>	<b>35.6810 dB</b>	<b>35.4651 dB</b>	<b>33.8455 dB</b>
Bilateral	33.9709 dB	34.7835 dB	32.1769 dB	34.3582 dB	35.1909 dB	32.6678 dB
Gaussian	33.6593 dB	33.2632 dB	31.5786 dB	33.4303 dB	33.4737 dB	32.0419 dB
Average	33.6140 dB	33.1991 dB	31.4998 dB	33.3651 dB	33.4479 dB	31.9674 dB

C. Contrast to Noise Ratio (CNR)

CNR is a metric for determining the quality of an image. The measure SNR is a like to the CNR, with the exception that it subtracts a term before calculating the ratio [27]. When there is a considerable bias in an image, such as from haze [28], this is critical. The intensity is quite strong, as can be seen in the image to the right, even though the image's features are washed out by the haze. As a result, while this image has a higher SNR measure, it has a lower CNR measure. One method to define difference to noise rate is [29, 30]:

$$C = |S_A - S_B| / \sigma_o \tag{4}$$

$S_A$  and  $S_B$  are signal strengths for signal produce structures A and B in the region of interest, while  $\sigma_o$  is the SD of the clean image noise. Table III shows the contrast to noise ratio of the six images after processing through various filters and Fig. 7 shows the CNR graph after applying the median, wiener, bilateral, Gaussian, and average filters on all six images. Lower values of CNR specify improved image quality. CNR value for Wiener is least as compare to other four filters.

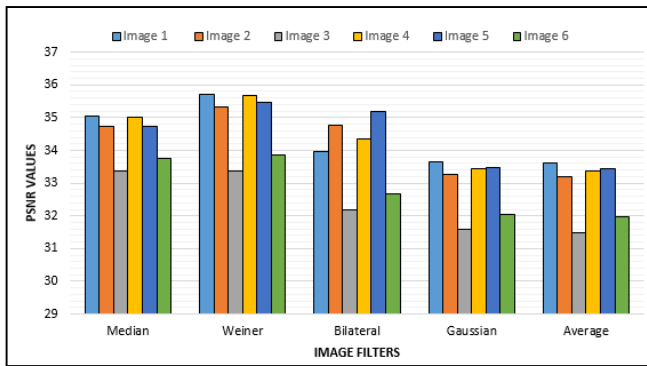

Fig. 6. Comparison of PSNR Values of the Filtered Images.

TABLE III. CNR VALUE OF FILTERED IMAGES

CNR Comparison						
Filters	OCT Image 1	OCT Image 2	OCT Image 3	OCT Image 4	OCT Image 5	OCT Image 6
Median	0.01458	0.02405	0.01017	0.01696	0.01680	0.01045

Average	0.00345	0.00441	0.00203	0.00365	0.00332	0.00221

Fig. 7. Comparison of CNR Values of the Filtered Images.

VII. CONCLUSION

Due to the chaos in OCT images, ophthalmologists have difficulty in correctly detecting disease. It is also a barrier to the automatic segmentation of biomedical images for illness diagnosis. The Wiener filter functioned well on all six OCT images, according to the results in Section V. The Wiener filtering algorithm significantly decreases speckle noise, while also preserving retinal formation and reducing the stairway effect. Tables I, II, and III show that among the several despeckling filters evaluated here, the Wiener filtering algorithm is the most excellent way for reducing the produce of speckle noise while keeping the edges. Further, this work can be extended by analysing other denoising methods and quality matrices such as SSIM, SNR, ENL and MAE on retinal OCT images.
