# Editorial Preface

## *From the Desk of Managing Editor...*

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

**Thank you for Sharing Wisdom!**

# Editorial Board

## Editor-in-Chief

### **Dr. Kohei Arai - Saga University**

*Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation*

---

## Associate Editors

### **Alaa Sheta**

#### **Southern Connecticut State University**

*Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems*

### **Domenico Ciuonzo**

#### **University of Naples, Federico II, Italy**

*Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things*

### **Doroła Kaminska**

#### **Lodz University of Technology**

*Domain of Research: Artificial Intelligence, Virtual Reality*

### **Elena Scutelnicu**

#### **"Dunarea de Jos" University of Galati**

*Domain of Research: e-Learning, e-Learning Tools, Simulation*

### **In Soo Lee**

#### **Kyungpook National University**

*Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning*

### **Krassen Stefanov**

#### **Professor at Sofia University St. Kliment Ohridski**

*Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design*

### **Renato De Leone**

#### **Università di Camerino**

*Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming*

### **Xiao-Zhi Gao**

#### **University of Eastern Finland**

*Domain of Research: Artificial Intelligence, Genetic Algorithms*

# CONTENTS

Paper 1: Eye-tracking Analysis: College Website Visual Impact on Emotional Responses Reflected on Subconscious Preferences

*Authors: Hedda Martina Šola, Fayyaz Hussain Qureshi, Sarwar Khawaja*

**PAGE 1 – 11**

Paper 2: Improving MapReduce Speculative Executions with Global Snapshots

*Authors: Ebenezer Komla Gavua, Gabor Kecskemeti*

**PAGE 12 – 22**

Paper 3: Recognizing Safe Drinking Water and Predicting Water Quality Index using Machine Learning Framework

*Authors: Mohamed Torky, Ali Bakhiet, Mohamed Bakrey, Ahmed Adel Ismail, Ahmed I. B. EL Seddawy*

**PAGE 23 – 33**

Paper 4: Leaf-based Classification of Important Indigenous Tree Species by Different Feature Extraction Techniques and Selected Classification Algorithms

*Authors: Eugene Val D. Mangaoang, Jaime M. Samaniego*

**PAGE 34 – 41**

Paper 5: A Novel Deep-learning based Approach for Automatic Diacritization of Arabic Poems using Sequence-to-Sequence Model

*Authors: Mohamed S. Mahmoud, Nermin Negied*

**PAGE 42 – 46**

Paper 6: An Investigation of Cybersecurity Issues of Remote Work during the COVID-19 Pandemic in Saudi Arabia

*Authors: Gaseb N Alotibi, Abdulwahid Al Abdulwahid*

**PAGE 47 – 53**

Paper 7: Patent Text Classification based on Deep Learning and Vocabulary Network

*Authors: Ran Li, Wangke Yu, Qianliang Huang, Yuying Liu*

**PAGE 54 – 61**

Paper 8: IoT Technology for Intelligent Management of Energy, Equipment and Security in Smart House

*Authors: Fangmin Yuan, Yan Zhang, Junchao Zhang*

**PAGE 62 – 76**

Paper 9: The Effect of Augmented Reality Mobile Application on Visitor Impact Mediated by Rational Hedonism: Evidence from Subak Museum

*Authors: Ketut Agustini, Dessy Seri Wahyuni, I Nengah Eka Mertayasa, Ni Made Ratminingsih, Gede Ariadi*

**PAGE 77 – 88**

Paper 10: Developing a Computer Simulation to Study the Behavior of Factors Affecting the Flooding of the Gash River

*Authors: Abdalilah G. I. Alhalangy*

**PAGE 89 – 93**

Paper 11: Pinpointing Factors in the Success of Integrated Information System Toward Open Government Data Initiative: A Perspective from Employees

*Authors: Wahyu Setiawan Wibowo, Ahmad Fadhil, Dana Indra Sensuse, Sofian Lusa, Prasetyo Adi Wibowo Putro, Alivia Yulfitri*

**PAGE 94 – 109**

- Paper 12: Autism Spectrum Disorder Detection: Video Games based Facial Expression Diagnosis using Deep Learning  
*Authors: Morched Derbali, Mutasem Jarrah, Princy Randhawa*  
**PAGE 110 – 119**
- Paper 13: An Improved SVM Method for Movement Recognition of Lower Limbs by MIMU and sEMG  
*Authors: Xu Yun, Xu Ling, Gao Lei, Liu Zhanhao, Shen Bohan*  
**PAGE 120 – 124**
- Paper 14: Bidirectional Recurrent Neural Network based on Multi-Kernel Learning Support Vector Machine for Transformer Fault Diagnosis  
*Authors: Xun Zhao, Shuai Chen, Ke Gao, Lin Luo*  
**PAGE 125 – 135**
- Paper 15: DataOps Lifecycle with a Case Study in Healthcare  
*Authors: Shaimaa Bahaa, Atef Z. Ghalwash, Hany Harb*  
**PAGE 136 – 144**
- Paper 16: Evaluation of e-Service Quality Impacts Customer Satisfaction: One-Gate Integrated Service Application in Indonesian Weather Agency  
*Authors: Aji Prasetyo, Deny Irawan, Dana Indra Sensuse, Sofian Lusa, Prasetyo Adi Wibowo, Alivia Yulfitri*  
**PAGE 145 – 152**
- Paper 17: Investigating the Input Validation Vulnerabilities in C Programs  
*Authors: Shouki A. Ebad*  
**PAGE 153 – 160**
- Paper 18: An Optimized Method for Polar Code Construction  
*Authors: Issame El Kaime, Reda Benkhrouya, Abdessalam Ait Madi, Hassane Erguig*  
**PAGE 161 – 165**
- Paper 19: Current Multi-factor of Authentication: Approaches, Requirements, Attacks and Challenges  
*Authors: Ali Hameed Yassir Mohammed, Rudzidatul Akmam Dzyiauddin, Liza Abdul Latiff*  
**PAGE 166 – 178**
- Paper 20: Arabic Dialogue Processing and Act Classification using Support Vector Machine  
*Authors: Abraheem Mohammed Sulayman Alsubayhay, Md Sah Hj Salam, Farhan Bin Mohamed*  
**PAGE 179 – 190**
- Paper 21: Tree-based Machine Learning and Deep Learning in Predicting Investor Intention to Public Private Partnership  
*Authors: Ahmad Amin, Rahmawaty, Maya Febrianty Lautania, Suraya Masrom, Rahayu Abdul Rahman*  
**PAGE 191 – 195**
- Paper 22: VHDL based Design of an Efficient Hearing Aid Filter using an Intelligent Variable-Bandwidth-Filter  
*Authors: Ujjwala S Rawandale, Sanjay R. Ganorkar, Mahesh T. Kolte*  
**PAGE 196 – 200**
- Paper 23: Performance Evaluation of Photovoltaic Projects in Latin America  
*Authors: Cristian León-Ospina, Heyner Arias-Zarate, Cesar Hernandez*  
**PAGE 201 – 212**

**Paper 24: Ransomware: Analysis of Encrypted Files**

*Authors: Houria MADANI, Noura OUERDI, Abdelmalek Azizi*

**PAGE 213 – 217**

**Paper 25: MMZ: A Study on the Implementation of Mathematical Game-based Learning Tool**

*Authors: Nur Syaheera Binti Sulaiman, Hamzah Asyrani Bin Sulaiman, Nor Saradatul Akmar Binti Zulkifli, Tuty Asmawanty Binti Abdul Kadir*

**PAGE 218 – 224**

**Paper 26: An Improved Poisson Surface Reconstruction Algorithm based on the Boundary Constraints**

*Authors: Zhouqi Liu, Lei Wang, Muhammad Tahir, Jin Huang, Tianqi Cheng, Xiping Guo, Yuwei Wang, ChunXiang Liu*

**PAGE 225 – 232**

**Paper 27: Data Augmentation for Deep Learning Algorithms that Perform Driver Drowsiness Detection**

*Authors: Ghulam Masudh Mohamed, Sulaiman Saleem Patel, Nalindren Naicker*

**PAGE 233 – 248**

**Paper 28: An Improved Ant Colony Algorithm for Virtual Resource Scheduling in Cloud Computing**

*Authors: Chunlei Zhong, Gang Yang*

**PAGE 249 – 261**

**Paper 29: Deep Analysis of Risks and Recent Trends Towards Network Intrusion Detection System**

*Authors: D. Shankar, G. Victo Sudha George, Janardhana Naidu J N S S, P Shyamala Madhuri*

**PAGE 262 – 276**

**Paper 30: Qdijbo Metaheuristic Optimization Algorithm for Computation of Real-Parameters and Engineering Design Optimization**

*Authors: Ikpo C V, Akowuah E K, Kponyo J J, Boateng K O*

**PAGE 277 – 297**

**Paper 31: Modeling of Whale Optimization with Deep Learning based Brain Disorder Detection and Classification**

*Authors: Uvaneshwari M, M. Baskar*

**PAGE 298 – 305**

**Paper 32: A Study on the Designation Institution for Supercomputer Specialized Centers in Republic of Korea**

*Authors: Hyungwook Shim, Yonghwan Jung, Jaegyeon Hahm*

**PAGE 306 – 312**

**Paper 33: Time Series Forecasting using LSTM and ARIMA**

*Authors: Khulood Albeladi, Bassam Zafar, Ahmed Mueen*

**PAGE 313 – 320**

**Paper 34: Enhancing the Intrusion Detection Efficiency using a Partitioning-based Recursive Feature Elimination in Big Cloud Environment**

*Authors: Hesham M. Elmasry, Ayman E. Khedr, Hatem M. Abdelkader*

**PAGE 321 – 330**

**Paper 35: Parameter Extraction and Performance Analysis of 3D Surface Reconstruction Techniques**

*Authors: Richha Sharma, Pawanesh Abrol*

**PAGE 331 – 336**

**Paper 36: Classifying Weather Images using Deep Neural Networks for Large Scale Datasets**

*Authors: Shweta Mittal, Om Prakash Sangwan*

**PAGE 337 – 343**

**Paper 37: Exploring College Academic Performance of K to12 IT and Non-IT-related Strands to Reduce Academic Deficiencies**

*Authors: Marilou S. Benozza, Thelma Palaoag*

**PAGE 344 – 355**

**Paper 38: AI based Dynamic Prediction Model for Mobile Health Application System**

*Authors: Adari Ramesh, C K Subbaraya, G K Ravi Kumar*

**PAGE 356 – 365**

**Paper 39: Reducing Cheating in Online Exams Through the Proctor Test Model**

*Authors: Yusring Sanusi Baso, Nurul Murtadho, Syihabuddin, Hikmah Maulani, Andi Agussalim, Haeruddin, Ahmad Fadlan, Ilham Ramadhan*

**PAGE 366 – 370**

**Paper 40: A Framework of Outcome-based Assessment and Evaluation for Computing Programs**

*Authors: Wasan S. Awad, Khadija A. Almhoson*

**PAGE 371 – 380**

**Paper 41: A Hybrid Filtering Technique of Digital Images in Multimedia Data Warehouses**

*Authors: Nermin Abdelhakim Othman, Ahmed Ayman Saad, Ahmed Sharaf Eldin*

**PAGE 381 – 392**

**Paper 42: Agro-Food Supply Chain Traceability using Blockchain and IPFS**

*Authors: Subashini Babu, Hemavathi Devarajan*

**PAGE 393 – 399**

**Paper 43: Implementation of Flood Emergency Response System with Face Analytics**

*Authors: E. Mardaid, Z. Zainal Abidin, S. A. Asmai, Z. Abal Abas*

**PAGE 400 – 406**

**Paper 44: A Novel Smart Deepfake Video Detection System**

*Authors: Marwa Elpeltagy, Aya Ismail, Mervat S. Zaki, Kamal Eldahshan*

**PAGE 407 – 419**

**Paper 45: Three on Three Optimizer: A New Metaheuristic with Three Guided Searches and Three Random Searches**

*Authors: Purba Daru Kusuma, Ashri Dinimaharawati*

**PAGE 420 – 429**

**Paper 46: An Empirical Study on the Affecting Factors of Cloud-based ERP System Adoption in Iraqi SMEs**

*Authors: Mohammed G. J, MA Burhanuddin, Dawood F. A. A, Alyousif S, Alkhayyat A, Ali M. H, R. Q. Malik, Jaber M. M*

**PAGE 430 – 441**

**Paper 47: A Learning-based Correlated Graph Model for Spinal Cord Injury Prediction from Magnetic Resonance Spinal Images**

*Authors: P. R. S. S. V Raju, V. Asanambigai, Suresh Babu Mudunuri*

**PAGE 442 – 449**

Paper 48: The Practices of Online Assessment in a Digital Device in the Context of University Training: The Case of Hassan II University

*Authors: Fatima-ezzahra Mrisse, Nadia Chafiq, Mohammed Talbi, Kamal Moundy*

**PAGE 450 – 455**

Paper 49: Comparative and Evaluation of Anomaly Recognition by Employing Statistic Techniques on Humanoid Robot

*Authors: Nuratiqa Natrah Mansor, Muhammad Herman Jamaluddin, Ahmad Zaki Shukor, Muhammad Sufyan Basri*

**PAGE 456 – 464**

Paper 50: Queueing Model based Dynamic Scalability for Containerized Cloud

*Authors: Ankita Srivastava, Narander Kumar*

**PAGE 465 – 472**

Paper 51: An Improved Breast Cancer Classification Method Using an Enhanced AdaBoost Classifier

*Authors: Yousef K. Qawqzeh, Abdullah Alourani, Sameh Ghwanmeh*

**PAGE 473 – 478**

Paper 52: Efficient Multimedia Content Transmission Model for Disaster Management using Delay Tolerant Mobile Adhoc Networks

*Authors: Sushant Mangasuli, Mahesh Kaluti*

**PAGE 479 – 484**

Paper 53: The Effect of Thermal and Electrical Conductivities on the Ablation Volume during Radiofrequency Ablation Process

*Authors: Mohammed S. Ahmed, Mohamed Tarek El-Wakad, Mohammed A. Hassan*

**PAGE 485 – 493**

Paper 54: A Light-weight Authentication Scheme in the Internet of Things using the Enhanced Bloom Filter

*Authors: Xiaoyan Huo*

**PAGE 494 – 501**

Paper 55: Generalized Epileptic Seizure Prediction using Machine Learning Method

*Authors: Zarqa Altaf, Mukhtiar Ali Unar, Sanam Narejo, Muhammad Ahmed Zaki, Naseer-u-Din*

**PAGE 502 – 510**

Paper 56: The Impact of COVID-19 on Digital Competence

*Authors: Syerina Syahrin, Khalid Almashiki, Eman Alzaanin*

**PAGE 511 – 519**

Paper 57: A Survey on Cloudlet Computation Optimization in the Mobile Edge Computing Environment

*Authors: Layth Muwafaq, Nor K. Noordin, Mohamed Othman, Alyani Ismail, Fazirulhisyam Hashim*

**PAGE 520 – 532**

Paper 58: Proof-of-Work for Merkle based Access Tree in Patient Centric Data

*Authors: B Ravinder Reddy, T Adilakshmi*

**PAGE 533 – 539**

Paper 59: Water Tank Wudhu and Monitoring System Design using Arduino and Telegram

*Authors: Ritkhal, Yuggo Afrianto, Indra Riawan, Fitrah Satrya Fajar Kusumah, Dwi Remawati*

**PAGE 540 – 546**

Paper 60: Risk Analysis of Urban Water Infrastructure Systems in Cauayan City

Authors: Rafael J. Padre, Melanie A. Baguio, Edward B. Panganiban, Rudy U. Panganiban, Carluz R. Bautista, Justine Ryan L. Rigates, Allisandra Pauline Mariano

PAGE 547 – 558

Paper 61: Mitigate Volumetric DDoS Attack using Machine Learning Algorithm in SDN based IoT Network Environment

Authors: Kumar J, Arul Leena Rose P J

PAGE 559 – 568

Paper 62: Customer Sentiment Analysis in Hotel Reviews Through Natural Language Processing Techniques

Authors: Soumaya Ounacer, Driss Mhamdi, Soufiane Ardchir, Abderrahmane Daif, Mohamed Azzouazi

PAGE 569 – 579

Paper 63: Performance Comparison of the Kernels of Support Vector Machine Algorithm for Diabetes Mellitus Classification

Authors: Dimas Aryo Anggoro, Dian Permatasari

PAGE 580 – 585

Paper 64: Image Segmentation of Intestinal Polyps using Attention Mechanism based on Convolutional Neural Network

Authors: Xinyi Zheng, Wanru Gong, Ruijia Yang, Guoyu Zuo

PAGE 586 – 593

Paper 65: A Novel Hybrid DL Model for Printed Arabic Word Recognition based on GAN

Authors: Yazan M. Alwaqfi, Mumtazimah Mohamad, Ahmad T. Al-Taani, Nazirah Abd Hamid

# Eye-tracking Analysis: College Website Visual Impact on Emotional Responses Reflected on Subconscious Preferences

Dr Hedda Martina Šola<sup>1</sup>, Dr Fayyaz Hussain Qureshi<sup>2</sup>, Sarwar Khawaja<sup>3</sup>

Centre for Applied Research and Entrepreneurship, Oxford Business College, Oxford, UK<sup>1,2</sup>

**Abstract**—This study examined students' behaviour on the college website and the content of information they were able to obtain. With the eye-tracking sensor, this study aims to investigate the university websites' effectiveness, satisfaction, and efficiency and collect data regarding users' visual impacts. The research was carried out using mobile phone neuromarketing tools of eye-tracking, facial coding, and supplementary short memory post-survey. The study was focused on two web pages, the homepage, and the CARE page. The analysis results from both web pages were then compared and further discussed. The results suggest that participants mostly elicited sadness (29.55%), neutrality (33.19%), and puzzlement (13.60%) while browsing the homepage, regardless of the areas of interest (AOI). They also elicited slight disgust (4.33%), fear (3.51%), joy (5.21%), and surprise (29.55%). The heat map for the CARE page reveals that the top of the CARE page was a point of attraction for participants. The study found that participants' negative feelings were more intense than good ones concerning homepage scrolling. Also, their pleasant mood intensity increased moderately when they looked at regions with only photos in a subdued color scheme or where brighter colors were used to emphasize essential textual information such as upcoming events and student blogs. This reveals that the website's complexity further affects the cognitive load. Therefore, making it more accessible will be beneficial to students. According to the student's responses, change such as the page's design, color, and text could be implemented.

**Keywords**—Neuromarketing; eye-tracking; student behavior; college website analyses; mood intensities; visual impact; website conversions

AOI: Areas of Interest

TTF: Time to First Fixation

## I. INTRODUCTION

A college's website is becoming an effective tool for students to collect information in the decision-making process for higher education. The first impressions of potential students are affected by the website. Thus, the digital presence of a

college is crucial since it has been discovered that browsing the website first is a prelude to visiting the campus. Colleges and universities use websites to attract prospective students [1]. Every year, most students decide to pick the higher education institute that will have far-reaching consequences for the rest of their lives. This choice will impact their career, wages, and professional growth. In 2005, private schools spent approximately \$2,073 per new student to apprentice, making communication and recruitment efficiency significant for institutions [2]. Where do awaited students go to learn about colleges and universities? They look through the websites developed by universities and colleges [2]. An appropriate Web-User communication system must be present to catch students' attention, thus, beginning with highlighting the specific users that extensively rely on web pages, the concerns on which the Web page focuses, or the message it wishes to convey to the users [3]. Therefore, it is crucial to investigate the whole process, for instance, how students approach a Web page and how they conclude it. This process must strive for an admiring emotional influence in visual content focused entirely on the student's experience. The basic scheme favors consumers' methods to develop an interactive web design. Eye tracking is an existing tool that allows for carrying out this task. Although its primary purpose has been the retail industry [4,5,6], it has applications in research and commercial grounds underlying human thinking and behavior. Eye tracking is heavily used in studying the influence of imaging to drive new consumers [7,8], but it also has wide use in clinical studies [9,10]. Understanding the visual impact from an emotional perspective is an attractive topic [11] and crucial to different disciplines. However, limited studies attempted to understand students' behavior in learning [12,13] and even lesser to website visual interpretation [14].

Since Students rely on visiting colleges' websites to help make their selection, the aspects influencing their decision are fundamental. Therefore, the current study analyzes the emotional responses to website conversion stimulated by visual impacts. Our main aim is to examine the effectiveness, satisfaction, and efficiency of university websites using eye-tracking analysis and collect data regarding the visual impacts of users. Eye-tracking recognizes the human pupil and traces and analyses the eye movement and fixation when viewing images or websites to allow the investigator to identify where a person is looking at a given period and the arrangement in which their eyes travel from one side to the following [15]. An

eye tracker is a device that measures the location of the eyes [16]. The software will then generate a so-called "heat map" through which the colors will identify the viewers' focused attention [15], permitting investigation of students' emotional reflections on websites.

Due to the development of sophisticated and economical technologies such as wearable sensor techniques, affective computing researchers are increasingly interested in emotion detection. Hence the current study emphasizes the following:

How visual impact can evoke emotional responses reflects website conversion and the eye-tracking analysis of college websites.

This research comprises several steps that initiated the creation of a public link on the OBC official website and served as an invitation to participate. The study was performed using online neuromarketing research technologies from mobile phones for their numerous uses by the students and everybody who visits their website. The experiments were performed in real-time operating neuro metrics combined with supplementary short memory post-survey questions. No additional hardware or application was required due to the advanced development of mobile cameras and machine learning algorithms. Tobii Sticky provided a way to acquire large-scale eye-tracking data.

## II. MATERIALS AND METHODS

A sample of 529 OBC students (both genders, 18-50) participated in the study, exploring how visual impact can evoke emotional responses and reflects on website conversions. Three hundred thirteen participants completed the entire experiment, from which we got one hundred eighty-six usable recordings whose gaze and/or emotion was trackable during their session (i.e., had proper lighting and did not move). One hundred twenty-four participants partially were involved in the study (participants who started the experiment but closed the browser or had timed out before reaching the end), zero participants were excluded from the study, and ninety two were screened out (participants that ended their session based on a screen out the question or did not meet technical requirements).

This study lasted ten days and was accessed via a pop-up banner on the OBC's website specifically created for study purposes. To ensure that the desired level of power and significant results are achieved, the required sample size was calculated a priori using G\*Power [17]. Based on the G\*Power output to detect the effect with 95% power, a two-sided significance level of 5% and a sample size of  $n=23$  for the OBC homepage and  $n=35$  for the CARE page are required (see Appendix). Tested subjects were recruited from the database of Oxford Business College. Participation in the study was voluntary, and no incentives were given.

The Institute for Neuromarketing Ethics Committee approved this research and supervised the study to be underlined with local and international ethical guidelines officially posted on the official Institute's website. Following the British Educational Research Association's ethical guidelines for educational research [18], all participants were informed about the study. They gave their written, informed

consent in digital form before participating in the study. Participants' data were treated according to standard practice and in compliance with GDPR (General Data Protection Regulation).

The online platform for advanced quantitative research, 'Tobii Sticky,' was used to measure eye-tracking and facial coding. According to the results, Sticky's average gaze error in a real-world (non-lab) environment is 1.6 to 1.8 degrees (~5% of the screen width and 7% of screen height) on a laptop which is more than accurate to the vital outcome. Therefore, since this research is conducted outside the laboratory without physical control over the ISO eye-tracking standards, to avoid data obtained from participants who did not meet entirely technical requirements, only recordings labeled as "usable" in Tobii Sticky were utilized. Participants were also provided with a set of images with instructions to ensure compliance with the technical requirements of the eye calibration test. The task started with a 5-point-eye-tracker calibration, a standard procedure for eye-tracking devices. After the calibration, all participants looked for 25 seconds at the identical two website pages (main page and CARE page) at the domain <https://oxfordbusinesscollege.ac.uk/> pre-recorded in the form of the scrollable image, presented in the same order as on the OBC's website page. They could not skip a certain part of the research, but with mouse clicks, it was measured how many participants wanted to stop the research. Such data indicated the total number of participants interested in the content published on the official website of the OBC. While browsing through the two website pages as they usually do, participants' gazing activity and emotional expression were measured over time using webcam-based eye-tracking. After each website page was presented, participants were given five statements to rate, assessing their conscious preferences and opinions about the seen website. They had 10 seconds to do that. The total duration of the study was 1 minute and 93 seconds per link (See 3.1.3.).

Participants' data were treated according to standard practice and in compliance with GDPR and the European Code of Ethics for Research. Since the study was conducted outside a controlled laboratory environment, participants received participation details with the html link. Participants received two 'html' links to participating in this study. One link led to the homepage of the OBC website, while the other led to a subpage related to the brand CARE. They were asked to exclusively access the study from their mobile devices with a working webcam due to the website analytics on how most visits are applied from the mobile phone. We have limited participants to access from mobile; according to the stats, the majority of OBC students participate in the website through mobile devices only.

In the first task, participants were asked to navigate through the OBC's homepage as they usually would, while in the second task, they were asked to browse through the CARE page to find more information about the research resources offered since the goal of the research was threefold: 1) to determine how much the content on the homepage is following the preferences of visitors; 2) how the website can be improved based on the obtained neurometrics; 3) to get an insight into participants' attentiveness levels leading to encoding and recall

of information based on the page design. During this website testing, participants' gazing activity was measured over time to calculate their attention distribution. Heat maps were utilized to observe the movement pattern around the website, and emotions were analyzed through facial coding to obtain insights into participants' behaviour and reactions to the website. In the end, participants were also asked to answer five questions to gauge their user experience, learn about their expectations and reasons for visiting the website, and test their attentiveness levels.

### III. RESULTS

The experiment data obtained from participants were grouped into two subgroups: homepage and CARE page, each representing one website at the official OBC website link: [www.oxfordbusinesscollege.ac.uk](http://www.oxfordbusinesscollege.ac.uk).

#### A. Homepage

The participants' results from the homepage test were investigated through the analysis of the eye tracking data, the facial coding, and the survey data.

1) *Eye-tracking data:* Regarding the eye-tracking measurements, a one-way repeated-measures ANOVA was performed for time to first fixation (TTFF), percentage of participants who fixated on the AOI, number of fixations within AOI, and time spent fixating on the AOI. The heat map for the OBC's homepage reveals that the top of the homepage was a point of attraction for participants (Fig. 1). This is not surprising as the top part is immediately visible once you open the webpage, while to see other information, one needs to scroll the website. The seen order indicates that participants first notice the part of the homepage in the middle of their screen and their eye level height (AOI 2), followed by the upper part of the homepage (AOI 1).

Based on the obtained heat map, in this browsing-only condition, gaze points were concentrated from left to center, meaning that most information presented on the right was not seen. For the quantitative eye-tracking analysis, the OBC's homepage was divided into five areas of interest (AOIs) (Fig. 2).

A one-way within-groups analysis of variance (ANOVA) was used to assess the impact of AOIs of the OBC's homepage page on the attention metrics (i.e., Number of fixations, time to the first fixation, time viewed, Number of visits, Fixating Percentage) (Table I, Table II).

Null hypothesis: There are no significant differences between the number of fixations, number of visits, time to the first fixation, time viewed, and a fixating percentage between AOIs of the homepage.

The result of the analysis showed there was a significant difference within the number of fixations between the AOIs of the OBC's homepage ( $F(5, 180) = 7.223, p = .000$ ). The post hoc analysis demonstrated that the total number of fixations of AOI 1 was significantly higher than that of AOI 3 (mean difference = 21.07), AOI 4 (mean difference = 30.70), and AOI 5 (mean difference = 29.83). The total number of fixations of

AOI 2 was significantly higher than AOI 4 (mean difference = 28.30) and AOI 5 (mean difference = 27.43). The total number of fixations of AOI 6 was not significantly higher or lower than any other AOIs on the homepage.

Fig. 1. Heat map and seen order for the OBC's homepage.

TABLE I. SUMMARISED STATISTICS FOR OBC'S HOMEPAGE

Number of Fixations		$F(5, 180) = 7.223, p = .000$

Fig. 2. AOIs for OBC's homepage.

A significant difference was observed within the time until noticed between the AOIs of the homepage  $F(5, 180) = 16.205, p = .000$ . The post hoc analysis demonstrated that the meantime, until notice of AOI1, was only significantly lower than that of AOI3 (mean difference = -4.18), AOI4 (mean difference = -7.64), AOI5 (mean difference = -8.04), and AOI6 (mean difference = -7.69) of the home page.

The mean time until noticed of AOI2 was only significantly lower than that of AOI3 (mean difference = -5.44), AOI4 (mean difference = -8.90), AOI5 (mean difference = -9.30), and AOI6 (mean difference = -8.95) of the home page. The mean time until notice of AOI3 was only significantly lower than that of AOI4 (mean difference = -3.46) and AOI5 (mean difference = -3.86).

The analysis result also showed a significant difference within the time viewed between the AOIs of the homepage  $F(5, 180) = 7.244, p = .000$ . The post hoc analysis demonstrated that the mean time viewed of AOI1 was only significantly higher than that of AOI3 (mean difference = 1.38), AOI4 (mean difference = 2.01), and AOI5 (mean difference = 1.95) of the home page. The mean time viewed by AOI2 was only significantly higher than that of AOI3 (mean difference = 1.29), AOI4 (mean difference = 1.92), and AOI5 (mean

difference = 1.86) of the home page. Finally, the mean time viewed by AOI6 was not significantly higher or lower than any other AOIs on the homepage.

AOI 1 and AOI 2 have the highest number of gaze points (AOI 1 = 1301; AOI 2 = 1229), the shortest time to first fixation (AOI 1 = 1.66; AOI 2 = 0.40), and the longest dwell time (AOI 1 = 2.95; AOI 2 = 2.76), suggesting that they attract the most visual attention and all of the important information for visitors should be placed there.

A significant difference was observed within the number of visits between the AOIs of the homepage  $F(5, 180) = 9.082, p = .000$ . The post hoc analysis showed that the total number of visits of AOI1 was only significantly higher than that of AOI 4 (mean difference = 3.13), AOI 5 (mean difference = 2.80), and AOI 6 (mean difference = 3.77) of the home page. The mean number of visits of AOI2 was only significantly higher than that of AOI 3 (mean difference = 3.23), AOI 4 (mean difference = 4.43), AOI 5 (mean difference = 4.10), and AOI6 (mean difference = 5.07) of the home page.

No significant difference was observed in the fixating percentage between the AOIs of the homepage ( $F(5, 180) = 0.896, p = 0.519$ ). While all of the AOIs had high fixating percentages (AOI 1 = 96.67%; AOI 2 = 100%; AOI 3 = 96.67%; AOI 4 = 83.33%; AOI 5 = 90%, AOI 6 = 60%), only AOI 1 (188) and AOI 2 (227) had the highest number of visits suggesting again that these AOIs attracted participants' visual attention the most.

2) *Facial coding*: Tracking of facial expressions elicited during the exposure to the website's homepage was used to pinpoint the emotional activity of the website.

The results suggest that participants mostly elicited sadness (29.55%), neutrality (33.19%), and puzzlement (13.60%) while browsing the homepage, regardless of the AOI (Fig. 3). They also elicited slight disgust (4.33%), fear (3.51%), joy (5.21%), and surprise (29.55%). When combined with survey responses, such emotions can be attributed to the colour scheme used, difficulties in reading the material due to inadequate text colour contrast, and a mismatch between presented information on the homepage and participants' motivation for visiting the page.

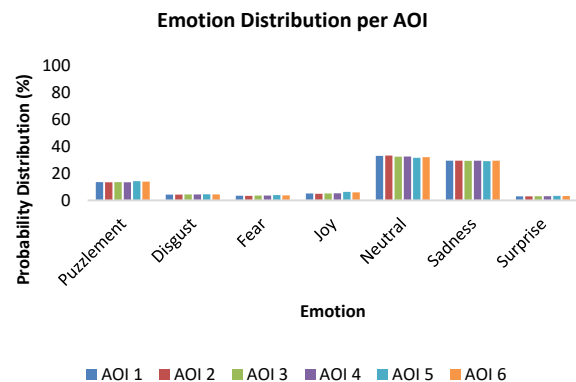

Fig. 3. Probability distribution of elicited emotions per AOI on the OBC's homepage.

Fig. 4. Emotional valence intensity during OBC’s homepage browsing.

During the 20-second interval of scrolling the homepage, the chart suggests that participants seemed to subconsciously show aversiveness towards the material presented on the website (Fig. 4). A slight decrease in aversiveness was observed between the second and fourth minute as, in that period, participants were looking at the images with the muted colour scheme. With the slight increase of aversiveness as time passed, it is possible that participants did not find the information they wanted and that the colour scheme used created a sensory overload.

Throughout homepage browsing, participants had relatively higher intensities of negative emotions than positive ones (Fig. 5). The most significant difference was observed towards the end of browsing. Scattered gaze points across the homepage in that period could be attributed to the fact that: 1) after the 12th second, nothing was interesting enough to capture their attention; 2) the page layout did not meet their expectations, and they did not find the information they were looking for; 3) the colour scheme used was overly stimulating to hold their attention for a more extended period.

A slight increase in the positive mood intensity was observed when participants looked at the areas with only images with muted colour schemes or used brighter colours to highlight crucial textual information such as upcoming events and student blogs (AOI 4 & AOI 5).

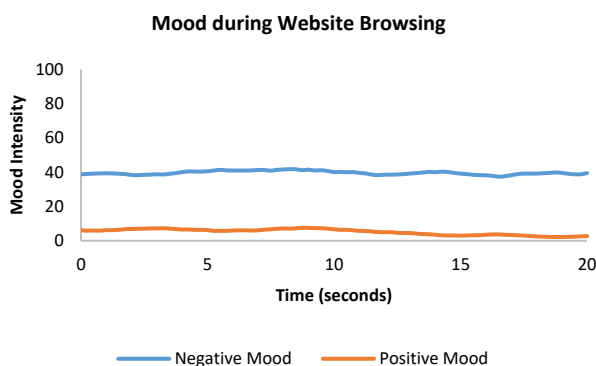

Fig. 5. Intensity of positive and negative emotions while browsing OBC’s homepage.

3) *Survey*: Participants had different reasons for visiting the website: to learn more about different courses (25.5%), to get updates on events (21.8%), to read interesting news (16.4%), and to learn more about research opportunities (18.2%). Several participants (18.2%) also had other (unknown) reasons. While 34.1% of the participants said it was neither hard nor easy to navigate the OBC website, 25% found it somewhat easy, and 20.5% very easy. However, 15.9 % found it somewhat hard, and 4.5% found it hard (Table III).

Regarding the preferences on the website, 45.7% would not change anything, while 42.9% would change the design, colours used, and text. A few participants would change everything (2.9%), while 8.6 % needed to know what they would like to change (Table III). Some of the comments regarding changes were that the text colour on the slider makes the text unreadable, change text colour or background, the website does not look like a college website because of too many colours, and add courses on the homepage.

Most participants did not know the answer (81.6%). A few (15.8%) gave the wrong answer, while only 2.6% answered correctly. Taken together with the heat map, this result suggests that this vital information was not encoded despite being seen.

**B. CARE Page**

The heat map for the CARE page reveals that the top of the CARE page was a point of attraction for participants (Fig. 6). The seen order indicates that participants first notice the page’s heading (AOI 1); however, the most significant point of attraction was the upper part of AOI 2, which is located in the middle of their screen and their eye level height. In contrast, the area dedicated to research resources was not seen at all (AOI 3).

TABLE III. WEBSITE VISITS, NAVIGATION EASINESS, AND PREFERENCES

Participants’ reasons for visiting the website	
Learn more about different courses	25.5%
Event updates	21.8%
News	16.4%
Research opportunities	18.2%
Other	18.2%
OBC website navigation level of easiness	
Hard	4.5%
Somewhat hard	15.9%
Neither hard nor easy	34.1%
Somewhat easy	4.5%
Very easy	20.5%
Preferences	
Change nothing	45.7%
Change (design, colour, text)	42.9%
Change everything	2.9%
Unsure	8.6%

Fig. 6. Heat map and seen order for the OBC's CARE page.

Results also reveal that in this text-based webpage, participants used the 'F' pattern scanning of text where the first few words on the left of each line at the top of the page receive more fixations than subsequent words on the same line, while text towards the end is not seen.

The CARE page was divided into three AOIs to obtain quantitative eye-tracking metrics (Fig. 7). A one-way within-groups analysis of variance (ANOVA) was used to assess the impact of AOIs of the OBC's CARE page on the attention metrics (i.e., Number of fixations, time to the first fixation, time viewed, Number of visits, Fixating Percentage) (Table IV, Table V).

Null hypothesis: There are no significant differences between the number of fixations, Number of visits, time to the first fixation, time viewed, and the fixating percentage between AOIs of the CARE page.

Alternate hypothesis: There are significant differences within the Number of fixations, Number of visits, time to the first fixation, time viewed, and the fixating percentage between AOIs of the CARE page.

Fig. 7. AOIs for CARE page.

TABLE IV. SUMMARISED STATISTICS FOR CARE PAGE

Number of Fixations		F (2, 180) = 21.347, p = .000	
AOIs		Mean Difference	p-value
AOI 1	AOI 2	-128.43	.000*
	AOI 3	-9.33	.869
AOI 2	AOI 3	119.10	.000*
Number of Visits		F (2, 180) = 29.372, p = .000	
AOI 1	AOI 2	-10.80	.000*
	AOI 3	.13	.995
AOI 2	AOI 3	10.93	.000*
Time to First Fixation		F (2, 180) = 33.249, p = .000	
AOI 1	AOI 2	-2.48	.243
	AOI 3	-11.72	.000*
AOI 2	AOI 3	-9.24	.000*
Time Viewed		F (2, 180) = 22.024, p = .000

	AOI 3	-.63	.860
AOI 2	AOI 3	7.96	.000*
Fixating Percentage		F (2, 180) = 0.171, p = .848	

TABLE V. AVERAGE VALUES OF EYE-TRACKING METRICS FOR THE CARE PAGE

Time to First Fixation (s)	
AOI	M
AOI 1	0.16
AOI 2	2.63
AOI 3	15.49
Number of Fixations	
AOI 1	1715
AOI 2	5568
AOI 3	1995
Number of Visits	
AOI 1	148
AOI 2	472
AOI 3	144
Time Viewed (s)	
AOI 1	3.77
AOI 2	12.37
AOI 3	5.75
Fixating percentage (%)	
AOI 1	100
AOI 2	100
AOI 3	76.67

A significant difference was observed within the number of fixations between the AOIs of the CARE page (F (2, 180) = 21.347, p = .000), where the total number of fixations of AOI 2

was significantly higher than that of AOI 1 (mean difference = 128.43) and AOI 3 (mean difference = 119.10)). The total number of fixations of AOI 3 was significantly lower than that of AOI 2 (mean difference = -119.10).

A significant difference was observed within the time to first fixation between the AOIs of the CARE page (F (2, 180) = 33.249, p = .000), where the average time to first fixation of AOI 1 was only significantly lower than that of AOI 3 (mean difference = -11.71) and the average time to first fixation of AOI 2 was significantly lower than that of AOI 3 (mean difference = -9.24).

A significant difference was also observed for the time spent looking at a particular AOI (F (2, 180) = 22.024, p = .000), where the average time viewed of AOI 2 was significantly higher than AOI 1 (mean difference = 8.59) and AOI 3 (mean difference = 7.96). No significant difference in the average time viewed was observed between AOI 1 and AOI 3.

Taken together, AOI 2 has the highest number of gaze points (5568) and the longest dwell time (12.37 s) when compared to AOI 1 (1715; 3.77 s) and AOI 3 (1995; 5.75 s), suggesting that it attracts the most visual attention. Since AOI 1 has the shortest time to first fixation (0.16 s), followed by AOI 2 (2.63 s) and AOI 3 (15.49 s), the information about research resources from AOI 3, to be seen, should be placed between AOI 1 and AOI 2, as it is the vital point of the CARE.

A significant difference was observed within the total number of visits between the AOIs of the CARE page (F (2, 180) = 29.372, p = .000). The post hoc analysis demonstrated that the total number of visits of AOI 2 was significantly higher than that of AOI 1 (mean difference = 10.80) and AOI 3 (mean difference = 10.93). In contrast, no difference was observed in the total number of visits between AOI 1 and AOI 3.

No significant difference in the fixating percentage was observed (F (2, 180) = 0.171, p = .848).

#### IV. DISCUSSION

Eye-tracking behaviour neurometrics from OBC's homepage suggest that the top parts of the webpage are noticeable, especially those in eye-level height. Since gaze points were concentrated on the webpage's upper left and center positions, it is suggested to position all the vital information regarding offered courses, events, and research opportunities (Fig. 4) there. In that way, not only will visitors' attention be grabbed, but most importantly, they will also be given the requested information and will even be motivated to scroll down the page afterward.

A comparison between the homepage and the CARE page suggests that the time to the first fixation, the number of fixations, the number of visits, and the time viewed highly depend on the visited page. In contrast, the fixation percentage is the only observed metric varying in the same range regardless of the visited page (Table VI). Moreover, all the metrics were higher for the CARE page, indicating that the latter requires higher visual attention than the homepage.

TABLE VI. COMPARATIVE TABLE FOR OBC'S HOMEPAGE AND CARE PAGE

M (OBC's homepage)	M (CARE page)
<i>Time to First Fixation (s)</i>	
0.40-9.70	15.49-0.16
<i>Number of Fixations</i>	
1301-746	5568-1715
<i>Number of Visits</i>	
277-75	472-144
<i>Time Viewed (s)</i>	
2.95-1.00	12.37-3.77
<i>Fixating percentage (%)</i>	
100-60	100-76.67

Observed sadness, puzzlement, and neutrality regardless of the AOI within the homepage, together with survey answers, could be attributed to the colour scheme used (overly stimulating), difficulties reading the material due to inadequate colour-text contrast, and mismatch between the order of presented information on the homepage and participants reasons for visiting the page. This was also supported by an observed increase in the intensity of positive mood and a decrease in the aversiveness in the page areas where images with the muted colour scheme were used. In the future, it is suggested to use neutral colours for backdrops and one or two stimulating, bright colours to highlight materials of interest [19].

Based on the eye-tracking behavioural neurometrics, emotion analysis, and survey answers, a re-design is recommended as information of interest for visitors needs to be optimally positioned on the website, and most of it goes unnoticed. Even if noticed, it does not get encoded and recalled due to inappropriate colour-text contrast(as seen in the survey on slide 13) [20].

## V. CONCLUSION

The findings of this research showcased the importance of college websites and their crucial role in attracting regional and international students. Colleges must build better, more user-friendly websites as current and prospective students increasingly rely on technology. The gaze activity was assessed over time to determine their attention distribution. The heat maps were essential in observing the movement pattern around the website. Emotion analyses using facial coding to gain insight into their behaviour and reactions to the website played an imperative role during this website testing. The results showed that participants' negative feelings were more intense than their good emotions when the content required page scrolling, while a difference was noticed near the end of the browsing session. However, looking at regions with just photos in a subdued colour scheme or where brighter colours were used to emphasize essential textual information such as forthcoming events and student blogs, the participants' pleasant mood intensity increased somewhat. Lastly, participants employed the 'F' pattern monitoring of text on the text-based homepage, where the first few words on the left of

each line at the top of the page received more fixations than other words on the same line, while text near the end was not viewed. According to these lines, this research demonstrates how with the help of neuroscientific research tools, an insight into students' behaviour and their subconscious preferences. Despite the use of online study with the webcam-based eye tracking solution (15Hz), the obtained results are an example of how very accurate and valuable marketing insights of the consumer's subconscious on the website's perceived process and preferences can be obtained. The limitation of the study was the big screenout (92 subjects) and 124 participants who partially were involved in the study (participants who started the experiment but closed the browser or had timed out before reaching the end), where we presume this is due to the reason what participants did not receive any incentives for attending to this research. In addition, the software used is susceptible and discredits the participant at a slight shift of the head, which gives us merit results at the very end. Since the research was limited to the mobile device based on the website stats of visitors per device, to achieve the best results possible, the total sample size needed to be increased on other devices, too, which will result in a better percentage of quality recordings.

### A. Recommendations

In this age, where everything relies on technology, providing students with appropriate websites they can depend on to find the needed information is necessary, as they often need an alternative. Both homepage and CARE required a certain amount of attention with varying magnitude depending on the website's content.

### B. Homepage

For this case, enhancing the user's experience by:

- keeping the text clear and concise and avoiding complex language.
- using bright colours.
- using text alternatives such as images, videos could be used.

### C. CARE

The higher metrics (Number of fixations, time to the first fixation, time viewed, number of visits) compared to the homepage reveal that further action should be taken to reduce the page complexity and the cognitive load and to make it more accessible to students. Such action includes changing the page's design, colour, and text since over 42% opted for such changes.

Similar suggestions to the homepage can enhance the number of fixations, and time to the first fixation, time viewed. Moreover, the higher number of visits can be improved by providing ways to help the visitor get around the website, identify the main content, and where the navigation is.

## ACKNOWLEDGMENTS

This study was done in collaboration with the Institute for Neuromarketing, Zagreb, Croatia, which provided support for neuromarketing equipment and data analysis. The research was conducted exclusively for development and scientific advancement. The authors would like to acknowledge the

support of Oxford Business College in paying for the Article Processing Charges (APC) for this publication and the Institute for Neuromarketing for covering all neuromarketing research costs.

### APPENDIX

G\*Power output for OBC homepage and CARE page.

Based on the G\*power output [16], to detect the effect with 90% power and a two-sided significance level of 5%, a sample size of n=23 for the OBC homepage and n=35 for the CARE page is required.

Survey questions used in the study:

- 1) How often do you visit this website?
- 2) Never / Very Rarely (once per month) / Rarely (2-3 times per month) / Occasionally (2-3 times per week) / Frequently (1-2 times per day) / Very Frequently (more than three times per day)
- 3) Why are you visiting this website?  
To learn more about the offered courses / To read interesting news / To get updates on events / To learn about research opportunities and resources / Other (please specify)
- 4) How easy was it to navigate this website?  
Very Hard / Somewhat Hard / Neither Hard nor Easy / Somewhat Easy / Very Easy
- 5) What would you like to change on this website?
- 6) What is the name of the recent award that OBC got?

# Improving MapReduce Speculative Executions with Global Snapshots

**Abstract**—Hadoop’s MapReduce implementation has been employed for distributed storage and computation. Although efficient for parallelizing large-scale data processing, the challenge of handling poor-performing jobs persists. Hadoop does not fix straggler tasks but instead launches equivalent tasks (also called a *backup task*). This process is called Speculative Execution in Hadoop. Current speculative execution approaches face challenges like incorrect estimation of tasks run times, high consumption of system resources and inappropriate selection of backup tasks. In this paper, we propose a new speculative execution approach, which determines task run times with consistent global snapshots and K-Means clustering. Task run times are captured during data processing. Two categories of tasks (i.e. fast and stragglers) are detected with K-Means clustering. A silhouette score is applied as decision tool to determine when to process backup tasks, and to prevent extra iterations of K-Means. This helped to reduce the overhead incurred in applying our approach. We evaluated our approach on different data centre configurations with two objectives: *i*) the overheads caused by implementing our approach and *ii*) job performance improvements. Our results showed that *i*) the overheads caused by applying our approach is becoming more negligible as data centre sizes increase. The overheads reduced by 1.9%, 1.5% and 1.3% (comparatively) as the size of the data centre and the task run times increased, *ii*) longer mapper tasks runs have better chances for improvements, regardless of the amount of straggler tasks. The graphs of the longer mappers were below 10% relative to the disruptions introduced. This showed that the effects of the disruptions were reduced and became more negligible, while there was more improvement in job performance.

**Keywords**—MapReduce; Hadoop; speculative executions; stragglers; consistent global snapshots; K-means algorithm

## I. INTRODUCTION

The Hadoop software environment provides a widespread implementation for distributed data storage and MapReduce computing [1], [2], [3]. However, the challenge of handling poor-performing jobs persists. Hadoop launches equivalent tasks (also called a *backup task*) in place of straggler tasks to finish the computation faster. This process is Hadoop’s speculative execution [4].

Previous research into speculative execution has shown efforts to improve job performance in MapReduce. Past strategies such as LATE [5] and MCP [6] recognize straggler tasks based on self-estimation of the tasks’ remaining time. SAMR [7] and ESAMR [8] use historical information to classify nodes into slow map and reduce nodes. SECDT [9] predicts the remaining time of running tasks based on real-time information on tasks. However, these previous approaches

have various problems. Most have challenges with the accurate estimation of the remaining time of slow tasks. Some have significant overheads during the estimation of straggler tasks’ remaining times.

Our work proposes a new speculative execution approach, which estimates task runtimes with consistent global snapshots and K-Means clustering. Task progress is captured consistently during data processing. Two categories of tasks (fast and straggler) are identified with K-Means. A silhouette score is applied as decision tool to determine when to process backup tasks. This helped to reduce the overhead incurred in applying our approach since, the stragglers were quickly detected and rescheduled.

We evaluated our approach on different data centre configurations. The data centre configurations were selected after considering Hadoop cluster requirements from the industry. We focused our experiments on two objectives: *i*) the overheads caused by implementing our approach and *ii*) job performance improvements. Two categories of backup tasks were considered in our experiments. *i*) backup tasks that can transfer their states when shifting from one node to another and *ii*) backup tasks that need to restart after their transfer (i.e. tasks supported by Hadoop’s original speculative execution).

We experimented with mappers as there are typically more of them in a Hadoop application than reducers. Since reducer handling is done the same way as mapper handling in Hadoop, our results are applicable to both. We also focused on different durations of mappers, which provided the details of how long the mappers took to process data. From these, we concluded on the following *i*) the overheads caused by applying our approach is becoming more negligible as data centre sizes increase. The overheads reduced by 1.9%, 1.5% and 1.3% (comparatively) as the size of the data centre and the task run times increased. *ii*) longer mapper tasks runs have better chances for improvements, regardless of the amount of straggler tasks. The graphs of the longer mappers were below 10% relative to the disruptions introduced. This showed that the effects of the disruptions were reduced and became more negligible, while there was more improvement in job performance.

The remainder of this paper is structured as follows. In Section II, we reviewed concepts and related works about MapReduce and Speculative Executions. In Section III, we present our methodology for detecting straggler tasks and proposed improvements. In Section IV, we discussed the

Fig. 1. MapReduce structure.

Fig. 2. Speculative execution.

procedure for evaluating our approach via experiments and we analysed the results. Section V concludes the paper with recommendations for future work.

## II. CONCEPTS AND RELATED WORKS

### A. Concepts

In this subsection, we briefly discuss few concepts related to the MapReduce programming model.

1) *MapReduce*: MapReduce (MR) is a programming model for massive data computing used in Apache Hadoop. MapReduce is used for writing applications that process and analyse large data sets. These applications ran in a parallel fashion on large clusters in a scalable and fault-tolerant manner. A MapReduce job breaks and divides the input data into chunks which are first processed by the “Map phase” in parallel and then by the “Reduce phase” [10], [11] as seen in Fig. 1.

2) *Hadoop*: Apache Hadoop is an open-source software implementation of MapReduce. The core of Hadoop includes a distributed file system, and a MapReduce processor [1]. The Hadoop distributed file system (HDFS) works closely with MapReduce by distributing storage and computation across large clusters [12], [13]. During job processing on Hadoop, if a task of a job requires an abnormally long execution time, the total completion time of the job is affected. Such a task is called a straggler task. MR reruns straggler tasks on a different machine to finish the computation faster. The process of diagnosing straggler tasks and assigning them to other nodes is called *speculative execution* [14]. These faults are mainly due to IO contentions, background services, hardware behaviours, unbalanced load or uneven distribution of resources and other reasons [15]. Some straggler tasks run significantly slower than other tasks as shown in Fig. 2, where the straggler tasks take more processing times than the normal MR tasks [4].

3) *Prior speculative execution strategies*: A couple of research activities have been conducted to solve poor-performing tasks.

The Hadoop Naïve Method was implemented with the Hadoop architecture. However, most of the tasks processed during runtime were detected as slow tasks and processed as backup tasks. This affected job completion because there was no improvement in job completion time after processing the backup tasks. Also, this strategy is not suitable in heterogeneous environments. Therefore, an approach that distinguishes straggler tasks from the normal tasks during job processing will ensure job performance improvements.

Zaharia et al. [5] developed the Longest Approximate Time To End (LATE) algorithm. LATE is a simple, robust scheduling

Fig. 3. Structure of task performance monitoring algorithm.

algorithm that uses estimated finish times to detect straggler tasks. LATE is not suitable in heterogeneous environments. Therefore, a dynamic approach that works in all types of environments will help estimate the task runtime to ensure the improvement of job performance.

Chen et al. [7] proposed a Self-Adaptive MR Scheduling Algorithm (SAMR). SAMR uses historical information to classify nodes into the slow map- and reduce-nodes. This makes SAMR dependent on previous tasks information. Therefore, an approach that applies the information of current tasks without depending on previous nodes will be welcomed in the research community.

Sun et al. [8] designed an Enhanced Self-Adaptive MR Scheduling Algorithm (ESAMR) as an improvement on SAMR by utilising the K-means clustering algorithm to classify historical information. Therefore, the reliance of ESAMR on previous task information makes it only applicable when there is historical information. Moreover, the K-means clustering algorithm utilised was not validated to determine the straggler tasks. Therefore, an approach that is not affected by changes in dataset and validates the kmeans clustering will allow users to better assess tasks behaviours.

Chen et al. [16] proposed the Maximum Cost Performance approach, which considers the cost performance of cluster computing resources to estimate the slow tasks. However, in the map phase, task satisfying data localisation executes faster than those not satisfying data localisation. This provides an unfair comparison between the tasks at the same level. Therefore, an approach that considers all tasks at the same level will ensure an appropriate estimation of task run times.

Huang et al. [9] proposed a new Speculative Execution Algorithm based on C4.5 Decision Tree (SECDT) to improve predicted execution times among previous research resulting in poor job performance. However, navigating the decision tree implemented by this strategy is prone to significant

overheads. Therefore, an approach that determines task run times via snapshot captures will enable the improvement of job performance.

In summary, the existing speculative execution strategies still encounter challenges in managing straggler tasks in Hadoop. We now discuss the design of our proposed approach.

### III. METHODOLOGY

This section focuses on the design of our approach which is designed to improve job performance on MapReduce Hadoop (MRH). The approach consists of two algorithms that are interconnected to ensure correct determination of task run times, appropriate selection of backup tasks and reduction in the consumption of system resources. The goals of this section are:

- To design an algorithm that captures task run times during data processing on mappers and reducers. This is achieved by repetitive capturing of the task run times at specific intervals.
- To design an algorithm that monitors task performance on their nodes to foster the rescheduling of straggler tasks to available nodes for reprocessing.
- To implement K-means clustering algorithm to determine straggler tasks. The K-means clustering algorithm is applied with the Silhouette Coefficient to validate the outputs of the clustered data sets.
- To assess the algorithms on scalable configurations of MRH to prove their applicability. A survey of industry and real-life MRH configurations is conducted to ensure that the solution is applicable in industry.

#### A. Consistent Global Snapshots on MapReduce

This approach comprises of snapshot capturing and task performance monitoring algorithms as seen in Algorithms 1 to 2, and Fig. 3 to 5. Fig. 4 shows state transitions during the capturing of task run times. The two algorithms work together to ensure that straggler tasks are detected correctly and processed as backup tasks.

This approach is designed to dynamically collect real-time data from all types of environments. The collected real-time data fosters the early detection of straggler tasks to reduce high consumption of system resources. Moreover, this approach is applicable in most environments compared to a few existing approaches which struggle in heterogeneous environments. Additionally, some of the existing approaches have limitations with accurate estimation of remaining time of straggler tasks. Also, some have significant overheads during the estimation of straggler tasks' remaining times. The details of the algorithms are discussed below.

1) *Snapshots capturing algorithm*: Algorithm 1 is applied to explain the snapshots capturing process. The algorithm is designed with specific parameters to foster its comprehension.  $T_s$  and  $C_s$  are utilised to model tasks state transitions (*Task\_state*) and the snapshot capturing state transitions (*Snap\_state*) during job processing as seen in Fig. 5 and 4. These two parameters

---

#### Algorithm 1 Snapshot Capturing Algorithm

**Require: Variables:**  $T_s = Task\_state, C_s = Snap\_state,$   
 $N = Node$   
**Require: Variables:**  $Q_I = Tasks\_Instances,$   
 $i = counter\ for\ Q_I$   
**Require: Variables:**  $G_s = captured\_snapshots$   
**Require: SnapStateFunction:**  
 $SnapState : C_s \rightarrow \{snap\_ready,$   
 $snapping, snap\_paused, snap\_completed\}$   
1: **for**  $i < Q_I$  **do**  
2:   **if**  $T_s = ready$  **then**  
3:      $C_s := snap\_ready$  // Snap\_state updates to ready  
      when tasks processing begins.  
4:   **else**  
5:      $C_s := pause\_snapping$   
6:     check the system and restart the task  
7:   **end if**  
8:   **while**  $T_s = running$  **do**  
9:      $C_s := snapping$  // Snap\_state updates to snapping  
      during tasks processing.  
10:     Save the captured snapshots  
11:      $G_s = G_s + 1snapping$   
12:   **end while**  
13:    $i = i + 1$  // Tasks are monitored until they are  
      processed.  
14: **end for**  
15: **if**  $T_s = terminated$  **then**  
16:    $C_s := pause\_snapping$  // Snap\_state pauses when a  
      task is terminated with task\_state updated to terminated.  
17: **end if**  
18: **while**  $i \leq Q_I$  **do**  
19:    $C_s := snapping$  // Task run times capturing continues  
      until all tasks are processed.  
20:   Save the captured snapshots  
21:   **if**  $T_s = completed$  **then**  
22:      $C_s := snapping\_completed$  // Snap\_state updates  
      to snap\_completed when tasks processing ends.  
23:     Save the captured snapshots  
24:      $G_s = G_s + 1snapping$   
25:   **end if**  
26:    $i = i + 1$   
27: **end while**

---

together with the *SnapStateFunction* and the *TaskStateFunction* help to describe the status of task processing and snapshot capturing at any specific period.

Algorithm 1 initialises with task processing to foster the capturing of task run times as seen in Fig. 3. Nodes ( $N$ ) are monitored before task processing begins. This is done to capture the commencement of task processing (*start times*), as seen in the snapshot capturing state diagram in Fig. 4. When job processing commences, data is uploaded into the system for task processing to commence.

*SnapStateFunction* is activated, which causes *Snap\_state* ( $C_s$ ) to be updated to *ready\_snap* as seen in lines 1 to 3 of Algorithm 1. However, if a task is not ready (due to a fault),  $C_s$  is updated to *pause\_snapping* and the system is checked (for the task to be restarted) as seen in lines 4 to 7.

While the updated data is being processed,  $C_s$  is updated

Fig. 4. Snapshot capturing state transition diagram.

Fig. 5. Tasks state transition diagram.

from *snap\_ready* to *start\_snapping* as as seen in lines 8 to 13. Task run times are captured and saved as seen lines 9 to 10. Task run times are captured on all nodes and saved on snapshots text files. Snapshots are captured repeatedly for all the tasks running on nodes. The accumulated local snapshots captured constitute the global snapshots ( $G_s$ ). The details captured include (i) task start-time, (ii) task completion-time, (iii) the node ( $N$ ) on which the task is running, (iv) task identification, and (v) task status. The task start-time is the specific time the processing of a particular task  $t$  commences. While the completion-time is the specific time the processing of  $t$  ends. The task identification is the unique key given to every task  $t$  when their processing commences. The task status is reflective of the current state of  $t$  as seen in the state transition Fig. 5.

Additionally, the *TaskStateFunction* is activated, which causes *task\_state* ( $T_s$ ) to be updated from *ready* to *running* as seen in the task state diagram in Fig. 5.  $T_s$  remains unchanged until all the tasks are completely processed. Then, it transitions from *running* to *completed*. However, when a task's run time is unnecessarily longer that expected, the task is suspended, which causes  $T_s$  to be updated to *terminated* and  $C_s$  to *pause\_snapping* as seen in lines 15 to 17.

When a configurable percentage of the tasks have been processed with captured run times as seen in Fig. 3; K-means clustering algorithm is employed to classify the captured data on the snapshots text files, to determine the straggler tasks. The straggler tasks identified are then processed as backup task on available nodes. This causes  $T_s$  to be updated from *terminated* to *rescheduled* as seen in Fig. 5.

When the tasks rescheduling is completed, the re-processing of the backup tasks commences. This causes  $T_s$  to transition from *rescheduled* to *ready*. The backup tasks are processed together with the snapshot capturing until all the tasks are completely processed as seen in lines 18 to 27 of Algorithm 1.

2) *Task performance monitoring algorithm*: The task performance monitoring and the snapshot capturing algorithms work concurrently to ensure job performance improvement, as

### Algorithm 2 Task Performance Monitoring Algorithm

**Require: Variables:**  $Q_I = Tasks\_Instances$ ,  
 $T_R = running\ tasks$ ,  $i = counter\ for\ Q_I$   
**Require: Variables:**  $N_i = Node$ ,  $A_n = AvailNodes$ ,  
 $T_C = completed\ tasks$   
**Require: Variables:**  $Q_I = \{t_1, t_2, t_3, \dots, t_n\}$ ,  $T_s = Task\_State$   
**Require: Variables:**  $T_{ET} = task\ execution\ time$ ,  
 $T_{MET} = task\ maximum\ execution\ time$   
**Require: TaskStateFunction:**  
 $TaskState : T_s \rightarrow \{ready, running, terminate, reschedule, completed\}$   
1: *Begin Tasks Processing in the Map or Reduce Phase*  
2: **for**  $i \leq Q_I$  **do**  
3:  $status \leftarrow checkTasksStatus$   
4: **switch** ( $status$ )  
5:  $T_s := ready$  // task is ready for processing.  
6: **case** *still\_Running*:  
7: *monitor the progress of the task*  
8:  $T_s := running$   
9: **if**  $T_{ET} > T_{MET}$  **then**  
10: *terminate the task*  
11:  $T_s := terminated$  // straggler tasks are stopped.

seen in Fig. 3.

Algorithm 2 is applied during task processing to monitor and evaluate task performance. When data processing begins, all tasks i.e.,  $t = t_1, t_2, t_3, \dots, t_n$  are expected to process data at the same rate. These tasks are allocated processes on compute nodes as seen in lines 1 to 2.

The *TaskStateFunction* is activated which causes  $T_s$  to be updated to *ready* as seen in line 5. Tasks-instances ( $Q_I$ ) are monitored to determine whether they are still running ( $T_R$ ) or are completely processed ( $T_C$ ) as seen in lines 6 and 18.

During task processing, tasks which have relatively longer run times than the maximum execution times ( $T_{MET}$ ) of the

Fig. 6. Structure of algorithm implementation with k-means clustering.

$$J(V) = \sum_{i=1}^{C_d} \sum_{j=1}^{C_i} (|x_i - y_j|)^2 \quad (1)$$

Also, the K-means algorithm is implemented with a validation technique as a decision-making tool in our work. It directs whether to process backup tasks or not. There are cases where the dataset presented for clustering is uniform. However, K-means still tries to cluster it. Thus, clustering results require validation to determine the goodness of fit of the clusters created as seen in Fig. 7.

tasks being processed are terminated as seen in lines 6 to 10. This causes  $T_s$  to be updated to *terminated* as seen in line 11 and Fig. 5. The K-means algorithm is applied to cluster all the captured task run times as seen in Fig. 6 on page 16. The tasks identified as straggler tasks are rescheduled as seen in lines 12 to 14.  $T_s$  transitions from *terminated* through *rescheduled* to *ready* as seen in Fig. 5.

The states of the tasks which do not exhibit relative longer run times, transition from *ready* through *running* to *completed*. This enables their compute nodes to be availed for processing backup tasks, and reduces the number of task instances. These processes are seen in lines 18 to 25.

A vital aspect of this algorithm is the monitoring of task instances ( $Q_I$ ). The number of tasks are monitored throughout their processing stages. When the number of active tasks are exhausted, job processing ends. Otherwise, the task processing continues until the jobs generated are completely processed seen in lines 26 to 32.

### B. Identifying Straggler Tasks with K-Means Clustering Algorithm

The identification of straggler tasks during job processing was a challenge that required addressing in our approach. This was achieved via the adoption of a clustering technique.

Clustering was considered because it is the type of unsupervised machine learning where its goal is to partition sets of objects into groups called *clusters*. These groups can be mutually exclusive or they may overlap, depending on the approach used. It is in contrast to the supervised learning techniques where the goal is to make predictions about output value  $y$  given an input object or instance  $x$  [17]. This made the choice of clustering suitable for our approach since there was no need for training any data set to achieve our groupings.

Additionally, we considered K-means clustering as the clustering technique for our approach because it is a hard clustering algorithm which delivers mutually exclusive groupings. K-means partitions a set of  $n$  objects into  $k$  clusters, so that the resulting intra-cluster similarity is high but the inter-cluster similarity is low [18]. It was the most suitable clustering algorithm for our approach since two distinct groups are required; thus fast tasks and straggler tasks.

Our approach applied the K-means clustering algorithm to categorise task run times (dataset) received from the snapshot capturing algorithm. The dataset saved on snapshots text files during the map or the reduce phases are clustered into fast and straggler tasks as seen in Fig. 6. K-means optimizes the distance between the task run times to their centre points, as seen in eq. (1) [19].

In order to ensure the effective creation of clusters, four clustering validation techniques were considered. These are Dunn [20], Davie-Bouldin, Calinski-Harabasz indices, and the Silhouette score [21]. However, the silhouette score was selected for our approach. The first three were not implemented because of the following: first, although the Calinski-Harabasz index defines how dense and separated a cluster is, the absence of upper- and lower-bounds ranges made it inapplicable. Second, the Davies-Bouldin index utilizes zero (0) as the upper bound; and values closer to zero indicate a better partition. Moreover, the Davies-Bouldin index did not have a lower bound. In the case of the Dunn index, higher indices indicate better clustering. However, the absence of a lower bound makes it inapplicable in our context. Since, without a closed range of clustering validation values, a deterministic algorithm based on them would be unreliable. Also, the presence of the upper-lower bounds fosters faster determination of the goodness of fit of clusters created. Its absence introduces extra overheads into our strategy and makes the choice inappropriate for our research. Nevertheless, the Silhouette score  $S_i$  utilizes an easy-to-evaluate metric to determine the goodness of the clustering. Silhouette score values have a closed range of -1 to 1 [22]. Thus, the silhouette score was chosen for this work.

Algorithm 3 is utilised to identify the suitability of a clustering output for fast and straggler tasks. This algorithm validates the silhouette scores after the clustering exercise. It utilizes the values to decide whether to process backup tasks or not. For instance, Fig. 7 shows two very close data clusters which is difficult to ascertain the fast tasks or poor-performing ones. However, Fig. 8a to 8d on page 17 show well defined data clusters which will require rescheduling of straggler tasks.

#### Algorithm 3 Kmeans Clustering Validation Algorithm

**Require:** Set the  $S_i$  threshold lower – bound as  $Z_x = 0.685$   
**Require:** Set the  $S_i$  threshold upper – bound as  $Z_y = 0.99$

- 1: Initialize the clustering output as an array  $A[k]$
- 2: **for**  $k = 1$  **to**  $A.length$  **do**
- 3:   **if**  $S_i > Z_x$  &  $S_i \leq Z_y$  **then**
- 4:     Reschedule tasks on available nodes
- 5:   **else**
- 6:     Run the tasks on current nodes
- 7:   **end if**
- 8: **end for**

The results from the silhouette score are utilized to determine the goodness of the K-means clustering. If the silhouette

Fig. 7. Data processing execution times on 20 nodes with 8 individual cores.

Fig. 8. K-means clustering of run times from experimental scenarios.

score is higher than a threshold lower-bound value  $Z_x$  but less than a threshold upper bound value  $Z_y$ ; backup tasks are required for the cluster with the straggler tasks as seen in line 3. Otherwise, no intervention is applied to the task executions. The remainder of the tasks are then processed on their original nodes as seen in line 6.

Our silhouette score threshold (i.e., lower and upper bound) values were determined from several clustering experiments carried out on our dataset to ensure that the range given satisfies all possible scenarios.

#### IV. EVALUATION

The goal of our evaluation was to assess our approach via two major experiments to prove its applicability. They are (i) strategy implementation overheads experiments (ii) job performance experiments. The experiments enabled us to draw the necessary conclusions on the benefits of using our approach. The experiments aimed to detect and process straggler tasks as backup tasks to improve job performance. The experimental setup is described below.

#### A. Experimental Setup

The following objectives were considered in order to achieve the goal of the experiment:

- To determine the start-time of task processing.
- To determine the completion-time of task processing.
- To capture snapshots of task execution times.
- To capture task run times at specific intervals.
- To terminate straggler tasks.
- To restart straggler tasks on available nodes.

The first two bullet points foster the determination of the overheads introduced by this approach. The last four bullet point ensures the measurements of the jobs improvement performance. The termination and restart of the straggler tasks reduces the high consumption of system resources. The experiment was conducted on our extension of HDMSG MapReduce (a MapReduce simulator with Simgrid as the main backbone) available on GitHub<sup>1</sup>.

In order to utilise HDMSG for the development of this approach, a couple of features had to be added to the simulator to make it applicable. Several methods and classes were created for specific functions. A task monitoring method was created to monitor the tasks running on nodes on the MapReduce Hadoop cluster. This method was responsible for terminating long running tasks. A task rescheduling method was created to move the terminated task to available nodes to be processed as backup tasks. A snapshot capturing method was created to capture the start times and completion times of tasks on nodes. These captured task run times were saved on text files for k-means clustering. A disruption injection method was created to send extra tasks unto arbitrary nodes to serve as background activities. These extra tasks caused the map or reduce task on those nodes to experience longer run times. The methods for the creation of map and reduce tasks were extended to foster the scalability of the framework. A node scheduling class was created to foster the chronological processing of data nodes to enable the capturing of snapshots. Also the class fosters the selection of available nodes as exhibited in the Hadoop infrastructure.

Tasks were divided into ten-equal-length subtasks to simulate the snapshot capturing behaviour with simgrid. This was done to ensure that the snapshot could capture the start-times and completion-times of subtasks. The experiments required the capturing of task processing timelines (i.e. when a particular subtask ends and when the other begins). Therefore, dividing a task into ten-equal-length allowed the runtime behaviours of each subtask to be monitored and captured as snapshots.

In setting up the experiments, the infrastructure of HDMSG with Simgrid were defined. The infrastructure was defined in terms of the following: the number of nodes, CPU cores, bandwidth, latency metrics, and the nodes' speed. Additionally, the number of mappers and reducers, file input size (in megabytes), and block size (HDFS chunk size in megabytes) were configured to foster MR computations.

<sup>1</sup>[https://github.com/EbenezerKomlaGavua/MapReduce\\_Snapshots](https://github.com/EbenezerKomlaGavua/MapReduce_Snapshots)

To determine real life MR cluster infrastructure and application configurations, two surveys about Hadoop cluster requirements were carried out. The first survey focused on identifying typical hadoop configurations and the second one focussed on organisations actively utilising Hadoop clusters for their data processing in industry.

Several keywords such as hadoop clusters (requirements), industry cluster infrastructure (setup, configurations) were employed on several search engines to locate current MRH cluster configurations. The first survey identified Hadoop cluster configurations such as basic or standard deployments, advances deployments, hadoop cluster hardware recommendations for batch processing, in-memory processing, medium data size and large data size. The first survey found that the most used CPU speed was 2-2.5Ghz, data block sizes were between 128-256MB, network bandwidth was 1-10Gbps, cluster nodes was 4-40, number of mappers and reducers were 5-12 per node, disk capacity range was 32 GB to 1.2TB and total system memory was 16-512 GB. All hadoop cluster configurations modes were fully distributed.

The second survey found over one hundred and twenty top companies actively utilising hadoop clusters from several websites. Notable companies amongst the list include Alibaba, AOL, Yahoo, Spotify, Last.fm, Ebay, University of Glasgow-Terrier Team and Criteo. From this list, the modal CPU cores per node identified was eight and the modal cluster nodes was forty.

The findings of the survey fostered the selection of four infrastructure scenarios (displayed in Table I) for our experiments. The experimental scenarios comprise data nodes that ranges from 20 to 100 nodes. The range of CPU cores was 8 to 16. Aside the values displayed in the infrastructure scenarios table, network bandwidth of 10Gbps was simulated for all infrastructure scenarios. The smallest data block size employed was 128MBs. All the experiments were run on fully distributed hadoop cluster mode to foster conformance with industry standard.

The details identified from the survey ensure the modelling of real life applications on the above infrastructures as described below. The number of mappers per node was obtained via eq. (2), as stipulated in<sup>2</sup>:

$$Y = \frac{3Cores}{2}, \quad (2)$$

where  $Y$  is a positive rational number that represents the number of mappers per node.  $Cores$  is a positive integer which represents the CPU cores per node.

The number of reducers per node was obtained via eq. (3), as stipulated in<sup>3</sup>:

$$R = 0.95 \times N \times T, \quad (3)$$

Where  $R$  is a positive rational number representing the number of reducers per node,  $T$  is a positive rational number

TABLE I. EXPERIMENTAL INFRASTRUCTURE SCENARIOS

Features	20N × 8c	20N × 16c	40N × 8c	100N × 8c
No. of Nodes	20	20	40	100
No. of Cores	8	16	8	8
Mappers per node	5	5	11	5
Total Reducers	38	38	76	190
Total Mappers	107	213	213	533
Input Size	13696	27264	27264	68224

Fig. 9. Structure of algorithm implementation with expected overheads.

representing the mapred tasktracker reduce tasks maximum value.  $T$  is the maximum number of reduce tasks that will be run simultaneously by a task tracker (2 was used, since it is the default maximum value).  $N$  is a positive integer representing the number of nodes running on the cluster.

The proposed approach applies to both mappers and reducers. However, the evaluation was centred on mappers; since the number of mappers are bigger than reducers. Hence, the effects of our approach are expected to be more on mappers than reducers.

### B. Determining the Overheads of our Strategy

This experiment determined the overheads introduced into the infrastructure by the implementation of this approach. The overheads were caused by the effects of the snapshots capturing process on the infrastructure as seen in Fig. 9. The comprehension of the effects of the overheads fosters the appreciation of the challenges and benefits in applying this approach on MRH.

The experiment was conducted on the four data centre scenarios discussed in sub-section IV-A. Mapper tasks with execution times from 0.5 to 2000 seconds were utilized. The range for the experiment was derived via the multiplication of the single values of one, two and five with the power series of ten. The value of negative one produced 0.5 seconds and we scaled the task run times until the graph converged at 2000 seconds. This process was done in order to obtain a scalable range of task run times.

Since this approach involves capturing snapshots during the processing of subtasks, two measurements were taken. These are (i) the commencement of tasks processing and (ii) The completion of task processing. To determine the overhead on a single mapper, the differences between the *completion-times* of the processed portion of the task and the *start-times* of the next portion of that same task are determined (i.e. the period for snapshot capturing). The summation of the differences of these values (i.e. differences between *completion-times* and *start-times*) is subtracted from the task's run times (which is the ten-equal-length subtasks) as shown in Fig. 10. The value realized

20	18	15	15	8
50	8	7	7	3
100	7	5	5	1
200	5	3	3	~ 0
500	3	1	1	~ 0
1000	1	~ 0	~ 0	~ 0
2000	~ 0	~ 0	~ 0	~ 0

Fig. 10. Strategy overheads.

is the overhead on a single mapper as shown in eq. (4) and Fig. 10.

$$Q^H = 100 - \frac{100(T_E^H - (\sum_{i=1}^{n-1} t_c^{H,i} - t_s^{H,i}))}{T_E^H} \quad (4)$$

Where  $Q^H$  is the overhead of applying our approach on a mapper  $H$  in percentage.  $T_E^H$  is the task runtime of the given mapper.  $t_s^{H,i}$  is the time the  $i^{th}$  snapshot of the mapper  $H$  was started to be captured. Similarly,  $t_c^{H,i}$  is the time when we finished capturing the snapshot of the same task. Equation 4 is exemplified in Fig. 10.  $T_E^H$  is obtained from subtracting  $U$  from  $V$ . The letters  $a$  and  $c$  are the start times of the first two subtasks, whilst  $b$  and  $d$  are the completion times of the first two subtasks. Hence subtracting  $b$  from  $c$  produces the first gap ( $x_1$ ) introduced because of our approach. These gaps  $x_1$  to  $x_n$  are summed up and divided by the task run times to generate the overhead of a task.

### C. Discussion of the Overheads of our Strategy Experiment Results

The overheads of a single mapper were measured on the four data centre scenarios as seen in Tables II and illustrated in Fig. 11.

- **Scenario 20N×8c:** The impact of applying our approach was gradual. The overheads were high at the initial stages of the experiment. However, the impact of the approach caused the high overheads to reduce gradually with longer runtimes, as seen in Fig. 11. Therefore, in such small infrastructures, our approach is only advisable to use with long run times.
- **Scenarios 20N×16c and 40N×8c:** The two scenarios exhibited similar overhead behaviours during task runs. Therefore, only the 40 nodes by 8 cores set up was shown in Fig. 11. The initial overheads observed

Fig. 11. Cluster overheads.

were 1.5% lower (relatively) than the 20N×8c data centre scenario. The figure shows that the larger infrastructure scenarios converged faster than the previous. Also, this graph shows that the overheads of larger data centres improve better than smaller ones when our approach is applied. Moreover, the overheads of applying our approach with long run times have a higher chance of improving than smaller ones.

- **Scenario 100N×8c:** This demonstrates how our approach deals with larger data-centres. The overhead further reduced over the above scenarios. The initial overheads were 1.9% lower (relatively) than scenario 20N×8c and 1.3% lower (relatively) than the other two scenarios (i.e. 20N×16c and 40N×8c). Also, as the task run times increased, the overheads reduced drastically. Therefore, applying our approach to this scenario shows that initial overheads are mostly lower in large data centres. Additionally, the graph shows that with the large configurations, the overheads reduce faster with long mapper run times than in the other scenarios.

Therefore, from the experiments and industry surveys, it is recommended that infrastructures with 14 to 20 cluster nodes (with eight cores) should use scenario 20N×8c data centre configuration. Infrastructures with 25 to 35 cluster nodes (with eight or sixteen cores) should use our 20N×16c data centre configuration. Infrastructures with 40 to 60 cluster nodes (with eight cores) should use 40N×8c data centre configuration. Finally, infrastructures with 100 to 150 cluster nodes (with eight cores) should use 100N×8c data centre configuration. Aside the above recommendations, our approach is customizable to suit user data configurations preferences.

### D. Application Performance Experiments

This experiment determined the impact of our approach on job performance. Four measurements were taken to evaluate our approach. These are:

- Total execution times when there was *no disruption* on the MapReduce set-up (i.e. a dedicated Hadoop cluster scenario).

- Total execution times when *disruptions* were introduced on arbitrarily nodes on the infrastructure. These disruptions were created to interfere with task processing so that the task will have long run times than expected (this experiment was meant to represent a Hadoop cluster hosted in a multi-tenant environment). These *disruptions* were introduced via the running of extra tasks on arbitrarily nodes which were not linked to the original map or reduce tasks. The extra tasks were designed to consume extra system resources during the map and reduce phase. Also, the *disruptions* represent background services, IO contentions or uneven distribution of resources on data nodes for industry research.
- Total execution times when tasks were terminated and processed as backup tasks (*reschedule*) on a different node. This represents situations where mappers can restore their mid-execution states. This is applied by applications with the capabilities of storing their states during data processing. When such applications get terminated abruptly (due to factors contributing to speculative execution); the applications resume task processing on available nodes from the point they were halted.
- Total execution times when tasks were terminated and processed as backup tasks (*restart*) on a different nodes (providing insight into applications which cannot take advantage of state restoration).

These measurements were utilized to draw the graphs shown in Fig. 12. The graphs of *no disruption*, *reschedule* and *restart* were drawn relative to the *disruption* graphs which are shown in Fig. 13. The graphs were drawn relative to the *disruption* graphs, because we wanted to observe the levels of job improvements in light of the disruptions introduced into the system. The details of the various scenarios are discussed in the next sub-section.

### E. Discussion Performance Experiments Results

First, Fig. 12a displays the behaviour of scenario 20N×8c data centre when our approach was applied. The task improvement on this data centre was gradual as seen in the figure. In relation to the *disruption* graph, the slope began from above 80% and reduced gradually below 10%. Furthermore, *reschedule* backup tasks improve better with our approach than *restart* backup tasks after disruption.

Second, scenario 20N×16c data centre demonstrated considerably more job performance improvement than the previous data centre as most of the graphs were below the 80% mark as seen in Fig. 12b. Also, tasks that transfer their states perform better with our approach than those that cannot. Tasks with long run times exhibited big improvements as their values were below 10% relative to disruption. This means that as the tasks are processed for long run times, the effects of the disruptions were reduced as the graphs approached the 0% mark. For industry practitioners, it is advisable to apply our approach for long run times.

Third, scenario 40N×8c data centre improved more compared to the previous two scenarios as seen in Fig. 12c. Finally,

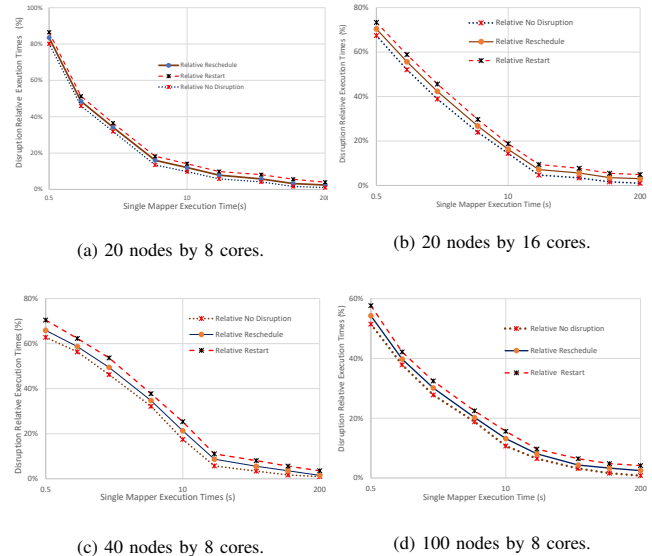

Fig. 12. Tasks improvement experimental scenarios.

TABLE III. KMEANS CLUSTERING SILHOUETTE SCORES

Fig.	Silhouette Scores
7	0.685
8a	0.985
8b	0.985
8c	0.985
8d	0.985

scenario 100N×8c improved more than all the previous scenarios as the graph showed a gradual improvement from below the 60% as seen in Fig. 12d. The figure showed that tasks with long run times had higher chances of improvement in this data centre. As most of the graphs were below 10% relative to disruption. Also, *reschedule* backup tasks improved much better than the (*restart*) backup tasks. Since the *reschedule* backup tasks have the capability to save their states, it was easily for them to continue data processing when they were moved to other nodes. In contrast, the *restart* backup tasks do not store their states, hence they could not reschedule their states, which delayed their task processing durations when moved to other nodes.

In conclusion, larger data centres have a higher chance of improvement when applying this approach. This approach works better with larger data centres because the sizes fosters scalability with long run times, which also ensures reduction in system overheads.

### F. Disruption Identification with K-Means Clustering

The task run times captured during the experiments were utilized for the K-means clustering. Two categories of results were observed after the clustering. Disruption-induced and disruption-free categories. The straggler tasks formed the disruption-biased data clusters are seen in Fig. 8a to 8d on page 17. The large magnitudes of the straggler tasks, enabled k-means to properly create the two categories.

Silhouette score was applied to validate the data clusters

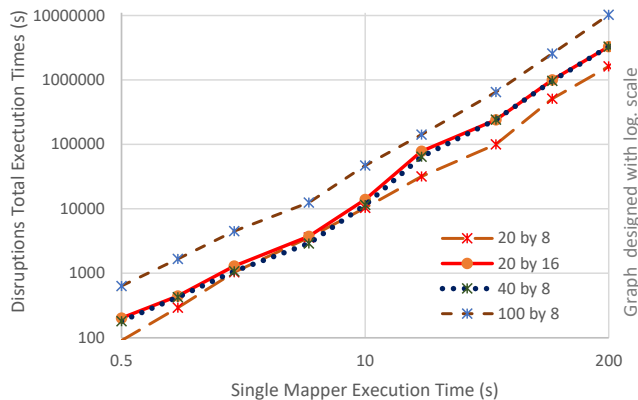

Fig. 13. Scenario disruptions.

and to foster overhead reduction in the application of the kmeans clustering algorithm. Once the dissimilarities between the dataset was detected, the clustering process was stopped. Table III shows the disruption-free and disruption-induced map task runtime data clusters and their respective silhouette scores. The result of Fig. 7 was closer to our silhouette score threshold lower-bound value. Since the data clusters created were not separated enough to ensure task transfer, the task were not shifted to other nodes. However, the rest of the experiments show significantly higher silhouette scores resulting in identifiable straggler tasks. The straggler tasks were then moved to available nodes as either a *reschedule* or *restart* backup tasks.

## V. CONCLUSION

This paper proposed a new speculative execution approach to estimate task run times with consistent global snapshots and K-Means clustering. Our approach applied two algorithms to monitor and capture task run times as snapshots. A K-means clustering technique was applied to classify the captured run times into two categories (fast and straggler tasks). We applied a silhouette score as a decision-making tool to determine when to process backup tasks on available nodes. The silhouette scores also helped to reduce the number of iterations by the K-means. We evaluated our approach on different data centre configurations. These were selected based on a survey of industry requirements for Hadoop clusters and applications. Our experiments were focused on two objectives; (i) the overheads caused by implementing our approach and (ii) job performance improvements. Our experiments enabled us to show that (i) the overheads caused by applying our approach were reduced faster with large data centres than the smaller data centres. The overheads reduced by 1.9%, 1.5% and 1.3% (comparatively) as the size of the data centre and the task run times increased. (ii) Mapper tasks with typical longer task durations had better chances for improvements. The graphs of the longer mappers were below 10% relative to the disruptions introduced. This showed that the effects of the disruptions were reduced and became more negligible. This approach measured the job performance improvement achieved via the *restart* back up tasks. A further work was done for applications capable of transferring their states as *reschedule* back up tasks. Most of

the previous approaches did not consider measurements for *reschedule* back up tasks.

For future work, we consider implementing auto-scaling algorithms on MapReduce Hadoop clouds. Our Snapshot capturing algorithm will be applied to foster a comparison with the job performance approach. Also, a couple of classification and clustering techniques will be considered to provide further extensions.

**Abstract**—Water quality monitoring, analysis, and prediction have emerged as important challenges in several uses of water in our life. Recent water quality problems have raised the need for artificial intelligence (AI) models for analyzing water quality, classifying water samples, and predicting water quality index (WQI). In this paper, a machine-learning framework has been proposed for classify drinking water samples (safe/unsafe) and predicting water quality index. The classification tier of the proposed framework consists of nine machine-learning models, which have been applied, tested, validated, and compared for classifying drinking water samples into two classes (safe/unsafe) based on a benchmark dataset. The regression tier consists of six regression models that have been applied to the same dataset for predicting WQI. The experimental results clarified good classification results for the nine models with average accuracy, of 94.7%. However, the obtained results showed the superiority of Random Forest (RF), and Light Gradient Boosting Machine (Light GBM) models in recognizing safe drinking water samples regarding training and testing accuracy compared to the other models in the proposed framework. Moreover, the regression analysis results proved the superiority of LGBM regression, and Extra Trees Regression models in predicting WQI according to training, testing accuracy, 0.99%, and 0.95%, respectively. Moreover, the mean absolute error (MAE) results proved that the same models achieved less error rate, 10% than other applied regression models. These findings have significant implications for the understanding of how novel deep learning models can be developed for predicting water quality, which is suitable for other environmental and industrial purposes.

**Keywords**—Water quality; artificial intelligence; machine learning; deep learning; classification analysis; and regression analysis

## I. INTRODUCTION

In the new green economy, monitoring and evaluating water quality is a central issue for the life of all organisms. Using the classical monitoring ways that depend on chemical monitoring is not enough to evaluate the consequences of some influences and stresses, as predicting the interactive effects of different chemical variables on water microorganisms is very difficult [1]. Rapid industrial development has deteriorated water quality at an alarming rate. In addition, the infrastructure, with the absence of public awareness, and the low quality of hygiene, greatly affects the quality of drinking water [2].

Polluted drinking water is very serious and can adversely affect organisms' health, as well as many environmental, and infrastructural impacts. According to a United Nations (UN) report, roughly, more than 1.5 million people die every year due to water-polluted diseases. In third-world countries, it has been declared that 80% of health issues are due to polluted water. Moreover, 2.5 billion illnesses and five million deaths are reported annually [3], and these are truly terrifying numbers.

Due to the lack of robust water monitoring techniques, many countries are unable to enhance their water systems and there are shortcomings to produce effective water recovery systems. These shortcomings may lead to a greater level of uncertainty when developing water resource management policies [4].

Recently, there has been a marked increase in the development of rapidly developing biological monitoring and biological assessment tools for water resources that are reliable enough to manage many degraded water bodies in the USA, Europe, South Africa, and Australia [5]. However, with the huge increase in data generated by monitoring devices and the futility of manual coding, the shortcomings began to appear in those systems due to the lack of an effective mechanism for processing that huge data. However, with the growth of artificial intelligence based on machine learning and deep learning techniques, it can introduce a perfect solution to that problem, such as artificial intelligence is characterized by many predictions, clustering, and classification techniques to produce effective solutions to water quality problems [6]. Research of the past decades has focused largely on analyzing the water quality of rivers based on artificial intelligence (AI) techniques [7]. Using AI models, water quality forecasting, classification, and risk assessment can be achieved easily. Moreover, advanced early warning systems and effective management policies can be designed to add more control and monitoring services to rivers and water bodies [8, 9].

In this paper, a proposed machine learning framework has been introduced for analyzing water quality. It consists of two subsystems; the first subsystem is responsible for classifying water quality based on nine AI models that have been applied, tested, and compared to classify various samples of drinking water as safe to drink or unsafe to drink. The applied nine AI

models are: Extreme Gradient Boosting (XGBoost) [10], Light Gradient Boosting Machine (Light GBM) [11], Decision Tree (DT) [12], Extra Tree (ET) [13], Multi-layer Perceptron (MLP) [14], Gradient Boosting (GB) [15], Support Vector Machine (SVM) [16], Artificial Neural Network (ANN) classification [17], and Random Forest (RF) Classifier [18]. The second subsystem is responsible for predicting water quality index (WQI) based on six regression models, LGBM regression, XGB regression, ExtraTrees regression, DT Regression, RF regression, and linear regression. These models have been applied to a dataset called Water quality, which was downloaded from [19]. The experimental results proved the superiority of the LightGBM model compared with the other eight AI models with an accuracy of 97% in classifying water samples to recognize the safe drinking water samples. Moreover, the predictive analysis of the used regression models clarified outperforms of LGBM regression, and Extra Trees Regression models in predicting water quality index according to training accuracy, testing accuracy, and mean absolute error (MAE) compared to the other four regression models.

The rest of this article is designed as follows: Section II reviews the related work. Section III explains the proposed machine-learning framework for analyzing water quality. Section IV presents and discusses the implementation results. Section V presents the conclusion of this work.

## II. LITERATURE REVIEW

A growing body of literature has investigated the efficiency of using machine and deep learning models for monitoring, analyzing, and predicting water quality index. The literature introduced some reviews that discuss various AI models for solving water quality prediction problems [9,20,21]. There are several large cross-sectional studies, which introduces multiple machine and deep learning to predict water quality index.

Ali Najah et al. [22] applied four machine learning models, an enhanced Wavelet De-noising Techniques (WDT)-based Neuro-Fuzzy Inference System (WDT-ANFIS), Adaptive Radial Basis Function Neural Networks (RBF-ANN), Neuro-Fuzzy Inference System (ANFIS), Multi-Layer Perceptron Neural Networks (MLP-ANN), and to predict water quality parameters (i.e. pH, ammonia nitrogen (AN), and suspended solids (SS)) of Johor River in Malaysia. The experimental results clarified outperform of the WDT-ANFIS model in prediction accuracy for all the water quality parameters compared to the other three used models.

Amir Hamzeh et al. [23] used the support vector machine (SVM) algorithm, Artificial Neural Network (ANN), and group method of data handling (GMDH) models for analyzing the water quality prediction of Tireh River in Iran. Different types of the kernel and transfer functions were validated and tested, and the practical results clarified that both ANN and SVM are better models than GMDH in predicting the water quality of Tireh River.

Umair Ahmed et al [24] introduced supervised learning models for evaluating WQI prediction based on four features of water elements, namely, turbidity, temperature, pH, and total dissolved solids. The proposed models achieved acceptable

accuracy and fewer error rates using a minimal number of features in predicting the WQI in real-time.

Abubakr Saeed et al. [25] proposed an efficient machine learning algorithm based on the SVM model to forecast the WQI of Langat River Basin based on the investigation of six variables (Dissolved Oxygen (DO), pH, Chemical Oxygen Demand (COD), Suspended Solids (SS), Ammonia Nitrogen (AN), and Biochemical Oxygen Demand (BOD)) of dual reservoirs that are located in the catchment. The experimental results showed that this model could accurately predict WQI value with small mean absolute error.

Mourad Azrou et al. [26] investigated the efficiency of machine learning algorithms for evaluating WQI prediction value based on four water features: pH, temperature, turbidity, and coliforms. The experimental results have proven the efficiency of used regression algorithms in predicting WQI. Moreover, the artificial neural network proved that it is the most highly efficient model in classifying water quality compared to other models in the literature.

They H et al. [27] utilized advanced AI models to evaluate WQI prediction value and classifying water goodness. The authors applied nonlinear autoregressive neural networks (NARNET) and long short-term memory (LSTM) as deep learning algorithms for predicting WQI. Moreover, three learning techniques, namely, K-nearest neighbor (K-NN), Naive Bayes, and SVM have been applied for the water quality classification task. The Prediction results showed that the NARNET algorithm performed slightly better than the LSTM for predicting WQI values. On the other hand, the SVM model has achieved the greatest accuracy (97.01%) for water goodness classification compared to the other classification models.

Siti Nur Mahfuzah et al. [28] investigated the efficiency of two machine learning algorithms, the Random Forest algorithm and the Random Tree algorithm for Classifying River Water Quality. The practical results have proven that Random Forest gives a higher classification accuracy compared to the Random Tree algorithm.

Junhao Wu et al. [29] proposed a hybrid model based on discrete wavelet transform (DWT), an ANN model, and LSTM model to predict the water goodness of the Jinjiang River. The prediction results clarified the efficiency of the proposed hybrid model in predicting water quality index compared to other models such as the ARIMA model, the LSTM model, nonlinear autoregression (NAR) model, the ANN-LSTM model, multi-layer perceptron model, and the CNN-LSTM model.

NguyenHien Than et al. [30] investigated water quality monitoring for the Dong Nai River at different times based on a novel architecture of the neural network model FFNN, and LSTM-MA hybrid model at different time series. The validation results proved that The LSTM-MA model provided more reliable prediction and achieved faster training time than the NAR, NAR-MA, ARIMA, and LSTM models. Moreover, the proposed hybrid model produced classification results for water quality in close agreement with the actual monitoring data.

Other hybrid machines and deep learning models have been developed for investigating water quality index, for example, one-dimensional residual CNN (1-DRCNN) and bi-directional gated recurrent units (BiGRU) have been utilized for predicting Water Quality in the Luan River [31]. Moreover, a hybrid deep learning model based on the CNN and LSTM model has been applied, tested, and compared for predicting water goodness based on real-time monitoring of water quality variables [32].

### III. WATER QUALITY ANALYSIS FRAMEWORK

Automatic analyzing drinking water quality from a given dataset, a framework consisting of two phases is proposed. The first phase is responsible for classifying water samples from a given dataset into two classes, safe or unsafe for drinking based on nine classification algorithms, whereas, the second phase is responsible for predicting the water quality index (WQI) based on six regression algorithms. In the following, the two phases are discussed in more detail:

#### A. Phase 1: Water Samples Classifications

To classify water samples to recognize safe drinking water samples, nine-machine learning techniques have been used, tested, and compared. Fig. 1 depicts how these models can be used for classifying water samples from a given dataset. The classification phase starts by doing a preprocessing step for cleaning, splitting, and resampling the used dataset. In the second step, the given dataset is divided into training (70%) and testing (30%) data parts. The third step focuses on extracting water features that may impact water quality through a feature selection step. The final step, the classification step sequentially calls nine classification algorithms (i.e. learning model) one after one for performing the classification task. The used classification models can be briefly described as follows:

Fig. 1. Water quality classification model.

1) *Extreme Gradient Boosting (XGBoost)*: It is depending on supervised machine learning, decision trees, ensemble learning, and gradient boosting. It is one of the most powerful techniques for building stochastic models for regression, classification, and ranking problems [33]. It provides a parallel tree boosting approach to fix errors made by prior boosted tree models [34].

2) *Light Gradient Boosting Machine (Light GBM)*: It has been developed by Microsoft, which is a popular algorithm

used for ranking and classification problems. Its structure is also based on decision tree models. LightGBM is being distinguished by training speed and accurate prediction results. This is because of adding an automatic feature selection procedure as well as focusing on boosting instances with greater gradients [35].

3) *Decision Tree (DT)*: It is a common supervised learning algorithm used for regression and classification problems [12]. The idea is to use learning decision rules deduced from the data features to perform classification or prediction tasks. What makes DT an effective classification model is: 1) the DT model can be prepared with little data. 2) Training a DT model is logarithmic in the number of data points. 3) A DT model can be validated by statistical tests. 4) Its performance doesn't affect any violation in predefined assumptions with the original model from which the data were created. 5) DT models can be visualized easily and can be understood without mysterious [36].

4) *Extra Tree Classifier (ETC)*: It is a class of ensemble learning approaches. The classification results are collected from a forest of several de-correlated DT models [37]. It differs from Random Forest Classifier in DT constructions way, where DT models are constructed in a "forest". The forest construction and creation of multiple de-correlated DT models of this classifier are based on extracting a random sample of features that leads to the best classification results based on some mathematical conditions.

5) *Multi-layer Perceptron Classifier (MLP Classifier)*: It is a class of feed-forward neural network models [38]. There may be multiple nonlinear hidden layers between the input and the output layers for mapping input data to output data. This classifier is based on the functionality of the sigmoid activation function for doing the classification task.

6) *Gradient Boosting Classifier (GBC)*: It is a common boosting classifier algorithm [39]. The functionality of gradient boosting works based on training N Trees based on the repeated fixing errors resulting from the predecessors of predictors to form the ensemble of data. The training step of the GBC model is done by training the predictors with the error labels produced by the predecessor of those predictors. The prediction results of each tree model are based on "a shrinking routine".

7) *Support Vector Machine (SVM) Classifier*: it is a supervised learning model used for both regression and classification problems [40]. The main goal of the SVM model is to identify a hyperplane in an N-dimensional space for classifying data items. The kernel of SVM is a procedure that depends on low-dimensional input space and converts it into higher-dimensional space. Therefore, SVM is suitable for non-linear classification problems. SVM has some advantages that make it an efficient classifier such as memory efficiency, effectiveness in high dimensional cases, and possible to customize kernel functions.

8) *Artificial Neural Network Classification (ANN)*: This class of ANN is one of the simplest types of neural networks

[17]. It is also a fed forward algorithm as it passes information in one direction from input neurons through one or more hidden layers to output neurons. The main advantages of using an ANN classifier are the ability to work with incomplete knowledge, storing information on the entire network, having a distributed memory, and having fault tolerance.

9) *Random Forest Classifier (RF)*: It is a non-linear classification technique, which consists of a group of decision trees. [18]. It integrates multiple decision trees to get more accurate predictions. Each decision tree model is used when employed on its own. This algorithm is called random because they choose predictors randomly at a time of training. In addition, it is called a forest since it takes the result of multiple trees to make a decision. The main advantage of Random forests compared to decision trees is the large number of uncorrelated tree models that work as a single unit will always outperform the individual tree models.

**B. Phase 2: Water Quality Index Prediction**

The second phase of the proposed framework is responsible for the predictive analysis of the water quality index. In this phase, we examined the impact of the water quality index (WQI) in predicting water quality using six regression models. This analysis started by calculating WQI for the dataset using a

mathematical model specified in equations 1, 2, 3, and 4 [41]. After that, six regression models have been applied for predicting water quality. These models are LGBM regression, XGB regression, Extra Trees regression, Decision Tree Regression, Random Forest regression, and linear regression [42]. Fig. 2 explains how the six regression models are applied to predict the water quality index.

$$K = \frac{1}{\sum(\frac{1}{S_i})} \tag{1}$$

Where,  $S_i$  is the standard value for each variable of water elements, and  $K$  is a constant.

Then, the weight value  $W_i$  of each element can be calculated as in equation 2.

$$W_i = \frac{k}{S_i} \tag{2}$$

The Quality Impact  $Q_i$  value for each element in the water dataset can be calculated as in equation 3.

$$Q_i = 100 * \left( \frac{\text{observe values } (oi) - \text{initial value } (li)}{\text{standard value } (si) - \text{initial value } (li)} \right) \tag{3}$$

Finally, the water quality index  $WQI$  can be calculated as in equation 4.

$$WQI = \sum_{i=1}^N W_i * Q_i \tag{4}$$

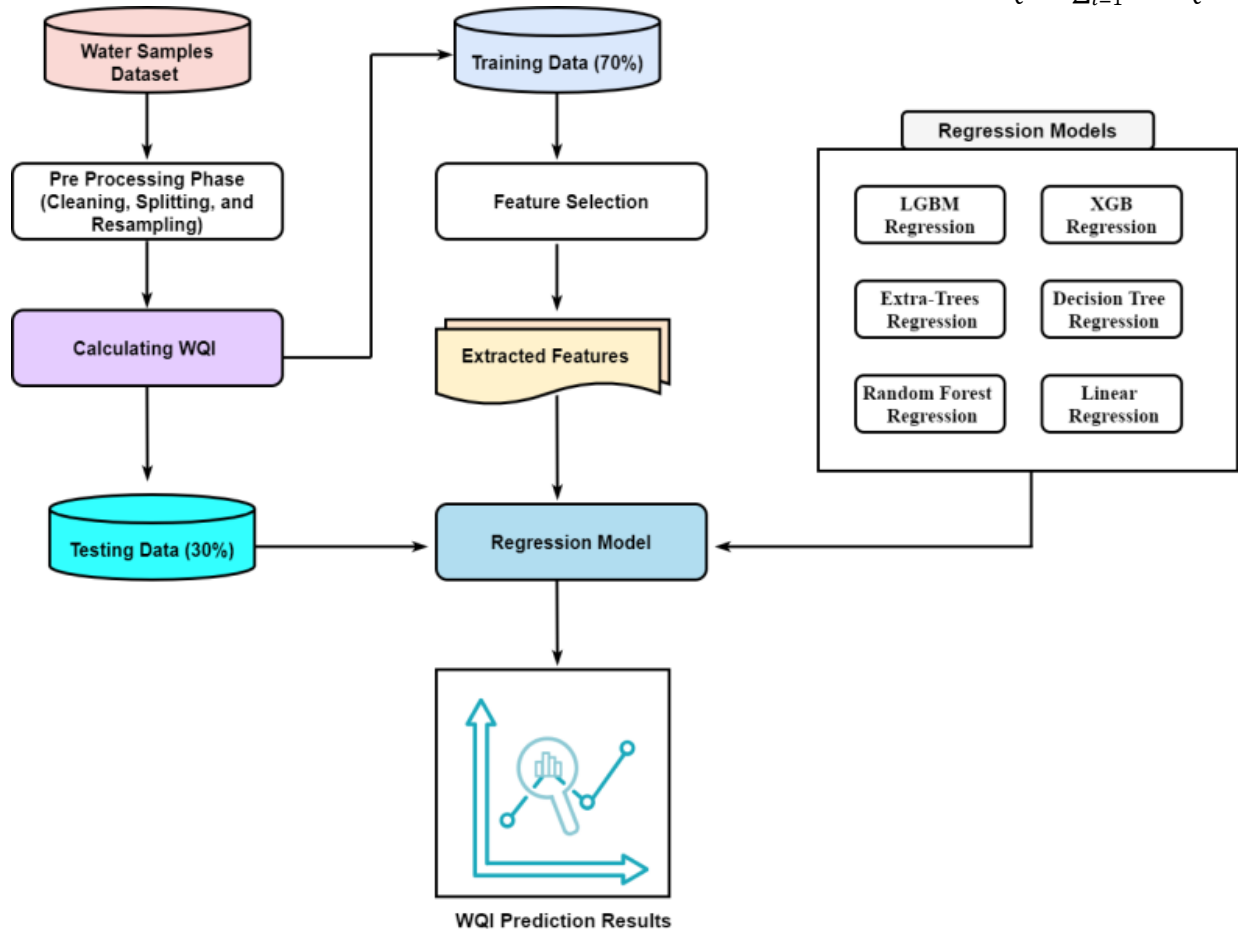

Fig. 2. Water quality index prediction model.

#### IV. EXPERIMENTAL RESULTS AND DISCUSSION

In this section, we present two types of analysis for investigating the efficiency of the proposed machine learning approach in predicting water quality. Subsection A discusses the classification analysis of water samples using nine classifiers, while subsection B discusses the predictive analysis using five regression models:

##### A. Classification Analysis

The first set of analyses examined the efficiency and accuracy of nine machine learning models used in the proposed framework (as explained in section 3.1) for classifying water samples to recognize that good samples are suitable for human drinking. These performances of these models have been applied to a dataset called Water quality, which was downloaded from [19]. The used dataset consists of 7996 samples of water and 19 features (i.e. variables) that impact water quality. The data has been segmented into training data (6396 samples, 19 features), and testing data (1600 samples, 19 features). The main objective was to classify water samples as suitable for human drinking or not suitable for human drinking. The performance of the nine machine learning models used in the proposed framework has been tested and evaluated using twelve measures as detailed in Table I. The best performance among the nine machine learning models according to each measure is being highlighted. The obtained results clarify that although the random forest algorithm achieved the best training accuracy, the Light GBM outperformed the other classifiers in recognizing good water samples regarding testing accuracy, sensitivity, AUC, F1-score, recall, precision, and mean square error. Fig. 3 and 4 present the comparison results of classification analysis metrics and mean square error (MSE) to nine classifiers, respectively. In addition, Fig. 5 to 13 depicts

the performance matrices (or confusion matrices) and the corresponding receiver operating characteristic (ROC) curves of nine machine-learning models, respectively.

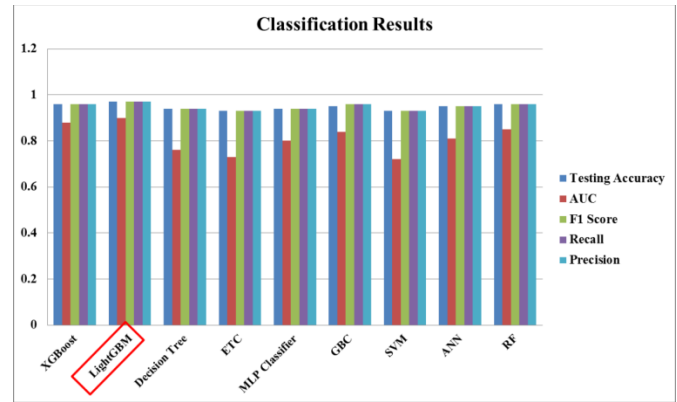

Fig. 3. Comparison results of classification analysis to nine classifiers.

Fig. 4. Comparison of results of Mean Square Error (MSE) to nine classifiers.

**B. Predictive Analysis**

The second set of analyses examined the efficiency and accuracy of six regression machine learning models used in the proposed framework (as explained in section 3.2) for predicting WQI. Table II summarizes the predictive analysis results of the six regression models after applying the mathematical model of WQI in the dataset. The obtained results have been evaluated based on the common regression metrics, training accuracy, testing accuracy, R2, Adjusted R2, and Mean absolute error (MAE).

The regression analysis results show the superiority of LGBM regression, and Extra Trees Regression models in predicting water quality index according to training and testing accuracy as well as the mean absolute error (MAE) compared to the other regression models. Fig. 14 to 16 visualizes the prediction results of the six regression models, respectively. Fig. 17 presents the comparison results of regression analysis of the used six regression models.

## V. CONCLUSION

The present article was designed to investigate the efficiency of using a proposed machine-learning framework to classify drinking water samples and predict water quality index. The classification tier of the proposed framework consists of nine classification models, Extreme Gradient Boosting (XGBoost), Light Gradient Boosting (LightGB), Decision Tree (DT), Extra Tree (ET) classifier, Multi-layer Perceptron (MLP) classifier, the Gradient Boosting (GB) classifier, Support Vector Machine (SVM), Artificial Neural Network (ANN), and Random Forest (RF) classifier. The performance of those models has been validated on a benchmark dataset consisting of 7996 water samples, and 19 features. The obtained results clarified good classification results to the nine models with average accuracy. 94.7%. However, the obtained results clarified that, although the Random Forest (RF) algorithm achieved the best training accuracy, 100%, the Light GBM outperformed the other classifiers in recognizing good water samples regarding testing accuracy, 0.97%. The second goal of this study was to investigate the efficiency of the regression tier through applying six regression models for predicting water quality index. The regression analysis clarified the superiority of LGB regression, and Extra Trees Regression models in predicting

water quality index according to training and testing accuracy as well as the mean absolute error (MAE) compared to the other regression models. Taken together, these findings suggest a role for using machine learning models in promoting the analysis and prediction of water quality. Moreover, these results have significant implications for the understanding of how novel deep learning models can be developed for predicting water quality, which is suitable for human drinking, irrigation of plants and crops, and other industrial or environmental purposes.

# Leaf-based Classification of Important Indigenous Tree Species by Different Feature Extraction Techniques and Selected Classification Algorithms

Eugene Val D. Mangaoang<sup>1</sup>, Jaime M. Samaniego<sup>2</sup>

Department of Computer Science & Technology, Visayas State University, Baybay City, Philippines<sup>1</sup>  
Institute of Computer Science-University of the Philippines-Los Baños College, Laguna, Philippines<sup>2</sup>

**Abstract**—The machine learning algorithms, namely, *k*-Nearest Neighbor (KNN), Support Vector Machine (SVM), Back-Propagation (BP) networks, and Convolutional Neural Networks (CNN) are four of the mostly used classifiers. Different sets of features are required as input in different application domains. In this paper, a set of significant leaf features and classification model was determined with a high accuracy in classifying important indigenous tree species. Leaf images were acquired using a scanner to control the image quality. The image dataset was then duplicated into two sets. The first set was labeled with their correct classes, preprocessed, and segmented in preparation for feature extraction. The leaf features extracted were leaf shape, leaf color, and leaf texture. Then, training and classification was done by KNN, SVM, and BP networks. On the other hand, the second set was unlabeled for training and classification by CNN. A CNN model was built and chosen with the best training and validation accuracy and the least training and validation loss rate. The study concluded that using all three leaf features for classification by BP networks resulted in a 93.48% accuracy with training done by supervised learning. However, the CNN achieved a high accuracy rate of 98.5% making it the best approach for classification of tree species using digital leaf images in the context of this study.

**Keywords**—Machine learning; feature extraction; convolutional neural network; leaf classification

## I. INTRODUCTION

Computer vision is divided into image acquisition, image preprocessing, feature extraction and description, and classification. In the case of plant species classification, an image of a part of a plant is acquired using a camera. The image is then preprocessed in preparation for the next step. Operations include eliminating noise, correcting geometric distortions or degraded image data, and segmentation. The aim is to emphasize the features of the image that are relevant for further processing while suppressing the undesired distortions. After image preprocessing, features are then extracted based on the descriptors established. These descriptors are a set of numbers that describe the part of the plant in the captured image. Finally, the plant species is recognized using all the features that have been extracted [1].

Feature extraction is a vital stage in image-based classification when it comes to the accuracy and precision of the classifier. This is because the underlying machine learning principles utilize the features that are supplied into the network.

Feature extraction techniques need to be selected thoroughly so that the image is well-perceived hence, providing the classifier enough information for a more accurate and precise classification [2].

After all the features of the subject in the image have been understood, classification is done by a mathematical classifier. There are numerous classification algorithms and each one requires a different set of features as input. Among the mostly used classifiers for image processing are *k*-Nearest Neighbor (KNN) algorithm, Support Vector Machine (SVM), Back-Propagation (BP) networks, and Convolutional Neural Networks (CNN) [2, 3, 4, 5, 6, 7, 8, 9]. In this study, the accuracy of classification of each of the algorithms were measured to determine which is best for leaf-based tree species classification.

Leaves are the suitable plant organs for computerized plant classification as these are numerous and acquired for most of the year rather than flowers and fruits since plants produce these in a limited period [10]. This is especially true for trees since it may take years to produce flowers and fruits. The bark of a tree is another organ aside from its leaves that can be used for tree recognition. Although these two organs are present throughout the year, tree recognition based on its bark can be very difficult and can add confusion [11]. In this study, leaf-based tree species classification was done using computer vision techniques.

As mentioned previously, the classification algorithms, KNN, SVM, BP networks, and CNN, require different sets of features extracted from an image for an accurate classification. These sets of features will always differ for different application domains. In the case of leaf-based tree species classification, there is a need to determine the significant features to be extracted so that there is a high accuracy in classifying tree leaf species.

The general objective of the study aimed to determine which combination of leaf features and classification algorithm provides an accurate and consistent classification of tree species through tree leaf images. Specifically, this study aimed to: (1) extract features from digital images of leaves of important indigenous tree species using image processing techniques, (2) implement classification algorithms for tree species classification, and (3) evaluate the accuracy of each of the classification algorithms.

Tree species classification has always been essential for understanding biodiversity conservation. Forests function well if there is a diversity of trees as they gather nutrients, which are then released when the trees die and decompose. These functions include growing wood to be used for furniture and timber among others, counteract climate change, and prevent soil erosion and regulate the water cycle. Forests that have diverse trees should provide better ecosystem goods and services to humans than those that have monocultured trees [12]. Scientists working to document and study forest flora and fauna, which is key to biodiversity conservation, are overwhelmed with the rich forest species biodiversity due to limited taxonomic expertise making it very difficult to abate the rapid degradation of forests [13]. On the other hand, inexperienced persons will even find it more difficult to classify the surrounding trees. Hence, the development of a program with enough tree taxonomic knowledge that enables recognition of tree species in a quick manner is significant to overcome this challenge. With the proposed tree recognition system, users will now have a tool that can classify trees. Users will be given good information and are likely able to make informed choices about which trees are suitable for biodiversity conservation.

This paper continues first by investigating which leaf features are commonly used in leaf classification in previous works. Then, KNN, SVM, BP networks, and CNN are also investigated in previous works. The performance of these classification algorithms against datasets in previous works were noted as well as the leaf features used for leaf classification. Next, the paper explains how the dataset was prepared for supervised and unsupervised learning and for classification. The results are then discussed, and the accuracy of the classifiers are indicated. The paper then concludes which classification algorithm worked best in the context of this study, and recommendations are also mentioned for future work.

## II. RELATED WORKS

### A. Leaf Features

There are many techniques that have been introduced to extract features from digital leaf images. Leaf shape is the most common extracted feature for classification. It is often used because of significant differences between leaf shapes of different plants. Important indigenous tree species in Leyte exhibit differences in their leaf shapes as well. Among the various works on leaf classification, the most common extracted representations of shape features are the following: aspect ratio, eccentricity, compactness / roundness, and rectangularity [14, 15, 16].

In some research, the leaf's texture is also considered in its classification [14, 17, 18, 19]. This is also an effective way of differentiating leaves as some have different textures compared to others, especially at a very small scale. The grey level co-occurrence matrix (GLCM) is commonly used to extract the leaf texture features. There are 14 textural features suggested to be computed [20]. These statistical features determine differences in the intensity of the pixels and the spatial relations between them.

Leaf color can also be used for plant species classification especially when there is a difference in leaf color among different species [17, 18]. Leaf color features are usually extracted along with another attribute, usually leaf shape and texture, when there is a subtle difference between leaf color among the species. Leaf color features are represented by the distribution of color in the image in each of the three color planes (red, green, and blue). If an image follows a certain distribution, then the color features can be used to identify the image.

### B. Mathematical Classifiers

This study assessed which of the classification algorithms, namely  $k$ -Nearest Neighbor, Support Vector Machine, Back-Propagation networks, and Convolutional Neural Networks would provide the most accurate results when classifying tree leaf images of important indigenous tree species. Related research works regarding the use of the algorithms are investigated. The commonly extracted features utilized by the classifiers are also taken into consideration.

1) *k*-Nearest Neighbor (KNN) algorithm: The author in [15] implemented the  $k$ -Nearest Neighbor (KNN) classifier for tree taxonomy. The leaf's shape features were extracted. It was concluded that the classifier best performed when eccentricity, a moment invariant and maximal indentation depth were the features used. The performance of the KNN classifier was low when all the features were used. This was because some of the features were redundant and hindered the success rate. Also, the success rate improved to almost 90% when the user inspected more nearest neighbors (specifically, when the  $k$ -value was 10). The author in [16] used three shape features: slimness (aspect ratio), roundness (compactness), and dispersion for classifying leaves using the KNN algorithm. The Flavia dataset was used which consists of 32 classes of 1907 leaf images. The classifier performed best when the  $k$ -value was 3, with an overall accuracy of 94.37% in classification. The author in [14] combined leaf shape features and leaf texture features for classifying leaves using the KNN algorithm. The shape features included aspect ratio, rectangularity, narrow factor, circularity, and solidity. Meanwhile, contrast, homogeneity, correlation, and energy were the texture features extracted using grey level co-occurrence matrix (GLCM). The classification had an accuracy rate of 94%. The author in [6] used leaf venations in identifying selected dicot plant species. The leaf venations were represented as a graph and relevant graph metrics were computed. Each of the graph metrics of the plant species served as input to different classifiers including the KNN algorithm. The study also used the Support Vector Machine (SVM) and Back-Propagation (BP) networks, specifically, Multilayer Perceptron (MLP), mathematical classifiers which are discussed in the next sections. The KNN classifier achieved an accuracy of 21.64% while the SVM and MLP classifiers reached 24.85% and 23.65%, respectively. According to the authors, this was due to the low cardinality of the dataset which was only ten leaves for each of the 50 plant species.

2) *Back-Propagation (BP) networks*: In [21], the accuracy rate of back-propagation (BP) neural networks and *k*-nearest neighbors (KNN) were compared. It was concluded that the BP networks produced a higher accuracy rate of 93.3% than the KNN, which had an accuracy rate of 85.9%, for a large dataset. For an otherwise small dataset, the KNN classifier outperforms the BP networks approach. The author in [10] also used BP networks in leaf-based classification of plants. The classifier produced 96% accuracy rate in classification. Both studies used the Flavia dataset and used shape features for classification.

3) *Support Vector Machine (SVM)*: The author in [18] utilized SVM for plant leaf recognition. The authors extracted the leaf texture and color features which were used by the classifier. With color features alone, the classifier produced low accurate results. This was because of the high similarity between the colors of the leaf images. But, when texture and color features were used, the accuracy rate of classification went up to 92%. The author in [17] also extracted leaf texture and color features for use of the SVM classifier. According to the authors, SVM performs well when compared to the KNN classifier. The system implemented in their work attained an average accuracy of 93.26%. The author in [19], on the other hand, only extracted texture features for classification using SVM. The classifier had an accuracy of 90.27%. The authors concluded that this may be improved if other leaf features could also be considered.

4) *Convolutional Neural Networks (CNN)*: In the study [7], CNN was employed for plant leaf recognition. The image dataset used was the Flavia dataset and the sizes were changed to 229x229 to fit the model. The structure of their proposed model had five convolution layers followed by their proposed inception module, then the pooling layer of size 8x8. Input images also included discolored leaves and damaged leaves. Despite the discoloration and damage of the leaves, the system has a recognition rate of above 94%. Another work in [8], uses a deep convolutional network model. It consists of 16 weight layers: 13 convolutional layers and 3 fully connected layers. The Flavia dataset was used, and the input images were resized into 224x224 pixels. Data augmentation was also performed which added the transformations of the initial image dataset as input. Because of this, using deep convolutional neural network, the system achieved an accuracy of 99.9%. The author in [9] also used data augmentation on the Flavia dataset. In their work, the images were resized to 256x256 pixels. There were three convolutional layers with an addition of a PReLU activation function after each convolution. The accuracy rate for the trained model is greater than 94.6% on 32 kinds of plants.

### III. METHODOLOGY

The tree species identified were limited to important indigenous tree species in Leyte due to the small number of tree classes which can all be classified through the tree's leaves. The 25 tree species to be classified are listed in Table I. The leaves of important indigenous trees were

collected from the forest reserve of the Visayas State University. The trees from which the leaves were collected have already matured spanning the ages between 15-20 years old. The framework shown in Fig. 1 depicts the different processes that were involved in the study which mainly applies image processing and the leaf classification techniques. Supervised learning is when the dataset was labeled. This was when KNN, SVM, and BP networks were used for training. Meanwhile in unsupervised learning, the dataset used was unlabeled and CNN was used for the training phase.

#### A. Image Acquisition and Preparation

With the help of an expert on taxonomic classification of important indigenous tree species, leaves were collected and scanned immediately using a scanner to control the image quality. The images were manually categorized according to its species and stored in their respective folders. A sequence of pre-processing techniques was performed that would make these images appropriate for extracting related information. The techniques included cropping, to emphasize the region of interest; scaling, to reduce the image size; and applying noise removal operation, to improve the image quality.

TABLE I. LIST OF TREE SPECIES CLASSIFIED

Family Name	Scientific Name	Local Name
Anacardiaceae	Dracontomelon dao	Dao
Calophyllaceae	Calophyllum blancoi	Bitanghol
Dipterocarpaceae	Shorea astylosa	Yakal
Dipterocarpaceae	Hopea plagata	Yakal Saplungan
Dipterocarpaceae	Shorea contorta	White Lauan
Dipterocarpaceae	Shorea almon	Almon
Dipterocarpaceae	Shorea squamata	Mayapis
Dipterocarpaceae	Dipterocarpus grandiflorus	Apitong
Dipterocarpaceae	Shorea falciferoides	Yakal Yamban
Dipterocarpaceae	Shorea guiso	Guijo
Dipterocarpaceae	Hopea philippinensis	Gisok-gisok
Dipterocarpaceae	Dipterocarpus validus	Hagakhak
Dipterocarpaceae	Parashorea malaanonan	Bagtikan
Dipterocarpaceae	Shorea polysperma	Tanguile
Dipterocarpaceae	Dipterocarpus kerrii	Malapanau
Dipterocarpaceae	Hopea malibato	Yakal Kaliot
Euphorbiaceae	Securinega flexuosa	Anislag
Fabaceae	Afzelia rhomboidea	Tindalo
Fabaceae	Pterocarpus indicus	Narra
Fagaceae	Lithocarpus llanosii	Ulayan
Lamiaceae	Vitex parviflora Juss.	Molave
Lecythidaceae	Petersianthus quadrialatus Merr.	Toog
Myrtaceae	Xanthostemon verdugonianus Naves	Mangkono
Sterculiaceae	Pterospermum acerifolium Willd.	Bayog
Tiliaceae	Diplodiscus paniculatus Turcz.	Balobo

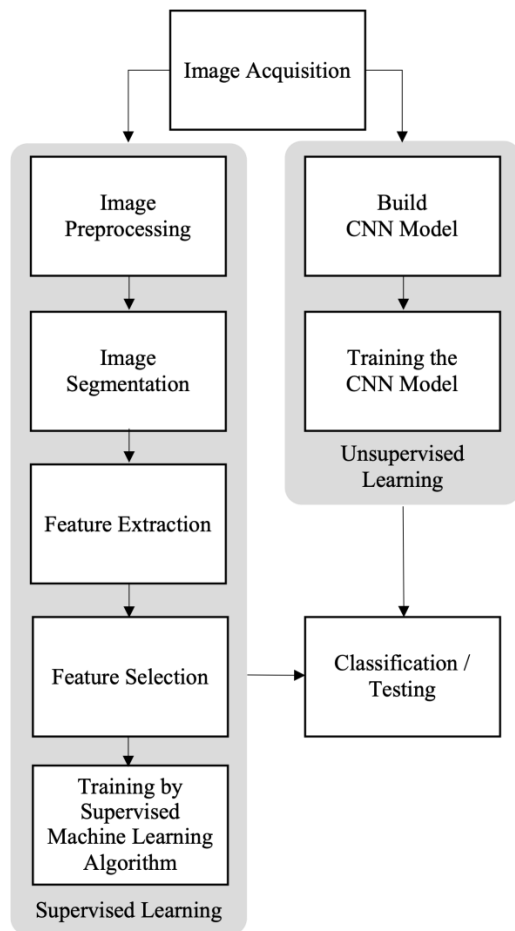

Fig. 1. Conceptual framework of the study.

### B. Image Segmentation

The leaf images were first converted into grayscale. Afterwards, Gaussian filter of size (25, 25) was applied to smooth the image. Next, adaptive image thresholding using Otsu's thresholding method was applied. Lastly, morphological closing was applied to close any holes present in the leaf. Fig. 2 shows how the image was transformed in preparation for feature extraction.

Fig. 2. Image segmentation techniques.

### C. Feature Extraction

Feature extraction was performed to get useful information that served as basis for leaf classification. Shape, color, and texture features were extracted from the leaf images. Boundary extraction was first done before calculating the shape features. Leaf boundary extraction was done using contours. The shape features that were calculated from the leaf images are area, roundness, aspect ratio, eccentricity, and rectangularity. For leaf color feature extraction, the original colored image was converted from RGB to HSV to get the hue, saturation, and value. The mean, standard deviation, skewness, and kurtosis of the HSV values were calculated. The texture features were extracted using the grey level co-occurrence matrix (GLCM). The 14 Haralick textural features (angular second moment, contrast, correlation, etc.) were computed. The original colored image was converted from RGB to grayscale before computing for the 14 features.

### D. Feature Selection

All the extracted features, especially the texture features, may be correlated to each other. This means that there may be redundant features that do not contribute information for classification. So, feature selection was employed to find the most suitable features to improve the accuracy of classification. Feature selection was done using Pearson's correlation through the Waikato Environment for Knowledge Analysis (Weka) tool.

### E. Training and Classification Phase

The training dataset was composed of 80% of the total number of acquired images. To determine which set of leaf features was best for classification, shape, texture, and color features were first used individually for training and classification then, a combination of two features, and finally, all three leaf features were used as basis for classification. The KNN, BP, and SVM classification algorithms were used for training and classification of the tree leaf species through the Weka tool.

For training and classification through CNN, TensorFlow was used to build the classification model. 80% of the image dataset was also used for training and 10% of the image dataset was used for validation. The mini-batch gradient descent learning algorithm was applied on the dataset with 32 batches processed at each time. This means that 789 batches per epoch were processed to go over the 25,271 images. The learning process went for 250 epochs and the validation dataset was used as reference to determine the performance of the model for each epoch.

When compiling the model, the standard cross-entropy loss was used to calculate the error rate of prediction from the original value. Categorical class classification was used to predict from 25 tree species/classes. The adam optimizer was used to adjust how the model learns during the training process. Finally, the accuracy was used to determine how the model can correctly predict the tree species using the validation dataset during training phase.

F. Testing Phase

The remaining 20% of the total number of images was used as test dataset. The same feature extraction processes were performed on the dataset and then classification was carried out by the classifiers. For testing the best CNN model, 10% of the image dataset was used. The accuracy of the classifiers was computed using (9):

$$\text{Accuracy} = \frac{\text{number of correctly classified images}}{\text{total number of testing images}} \times 100 \quad (1)$$

In addition, the following evaluation metrics for classification models were also computed:

$$\text{Precision} = \frac{\text{True Positives (TP)}}{\text{True Positives (TP)} + \text{False Positives (FP)}} \times 100 \quad (2)$$

$$\text{Recall} = \frac{\text{True Positives (TP)}}{\text{True Positives (TP)} + \text{False Negatives (FN)}} \times 100 \quad (3)$$

$$\text{Specificity} = \frac{\text{True Negatives (TN)}}{\text{True Negatives (TN)} + \text{False Positives (FP)}} \times 100 \quad (4)$$

$$\text{F1 Score} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \times 100 \quad (5)$$

G. Building the CNN Model

The CNN architecture used in this study, shown in Fig. 3, was inspired by a similar architecture albeit with modifications to the parameters and configurations used in [22]. The dataset first passes through convolution layers followed by activation layers, and then pooling layers. This sequence of layers is repeated twice to add more hidden layers. Lastly, the fully connected network acts as the classifier for the model.

Fig. 3. Convolutional neural network architecture of the study.

The convolutional layers extract features from the input images. The number of filters follows the trend of 32-64-128 filters. Rectified Linear Unit (ReLU) activation was used for the activation layers. Pooling layers have a filter size of 2x2 with a stride of two which shrinks the dimensions of the data by half. After passing through the convolution-activation-pooling sequence twice, the final output was flattened into a vector and fed into a fully connected dense network. The first dense layer has 256 nodes followed by a batch normalization layer which standardizes the input before being activated by a ReLU function. Dropout layer follows next to prevent

overfitting. The last dense layer has 25 nodes activated by softmax activation layer which allows the model to predict from 25 tree species with the highest probability. Table II depicts the layers and their corresponding output shape as well as the number of parameters.

TABLE II. SUMMARY OF THE MODEL

Layer (type)	Output Shape	Param #
conv2d (Conv2D)	(None, 126, 126, 32)	896
activation (Activation)	(None, 126, 126, 32)	0
max_pooling2d (MaxPooling2D)	(None, 63, 63, 32)	0
conv2d_1 (Conv2D)	(None, 61, 61, 64)	18496
activation_1 (Activation)	(None, 61, 61, 64)	0
max_pooling2d_1 (MaxPooling2D)	(None, 30, 30, 64)	0
conv2d_2 (Conv2D)	(None, 28, 28, 128)	73856
activation_2 (Activation)	(None, 28, 28, 128)	0
max_pooling2d_2 (MaxPooling2D)	(None, 14, 14, 128)	0

IV. RESULTS AND DISCUSSIONS

The total number of leaf images scanned is 31,508. This includes both the top and underneath sides of the leaf. The distribution of the images per tree species is shown in Table III.

TABLE III. NUMBER OF IMAGES PER TREE SPECIES

Class	No. of images	Class	No. of images

**A. Supervised Learning Results**

The shape, color, and texture features were computed through Python code and saved in a .csv file. These were then used for training and classification by KNN, SVM, and BP networks using Weka. Fig. 4 shows the accuracy of the classifiers with the corresponding leaf features as input.

Fig. 4. Accuracy of classifiers through supervised learning.

The individual sets of leaf features produced relatively low values of accuracy, the lowest being only 51.3% using the leaf color features by the SVM classifier. As the number of leaf features used was added, the accuracy improved. Among the two sets of leaf features used, color and texture features produced the best accuracy by the three classifiers with BP classifier having an accuracy of 90.65%. With the color, shape, and texture features used, the KNN classifier displayed 91.873% accuracy, and the SVM classifier displayed 89.873% accuracy. Meanwhile, the BP classifier showed the best accuracy among the three with 93.4762%. Table IV shows the time taken to build the models with the corresponding combination of leaf features extracted.

TABLE IV. TIME (IN SECONDS) TO BUILD THE MODEL THROUGH SUPERVISED LEARNING

Features Extracted	KNN	SVM	BP
Color	0.02	4.98	147.67
Shape	0.01	2.39	115.01
Texture	0.01	6.36	265.35
Color + Shape	0.03	4.46	188.51
Color + Texture	0	6.8	403.79
Shape + Texture	0	5.9	306.68
All three features	0.02	6.63	463.54

Using the model built through back-propagation network, a confusion matrix was derived. Table V shows a high performance of the BP model in classifying tree species through leaf images with up to 99% precision.

**B. CNN Model Results**

The training and validation performance of the CNN model is shown in Table VI. It took an accumulated time of about 50 hours to finish the training and validation phase due to the numerous digital leaf images. For choosing the best CNN model, it is generally ideal to choose a model with the best training and validation accuracy as well as the least

training and validation loss rate. The best training accuracy rate is 98.62% at epoch 240 while the least loss value is 0.0431 at epoch 245. However, the best model can be observed at epoch 249, with a significant validation accuracy rate of 98.79% and a loss value of 0.0554.

yakal kaliot	100.00%	99.18%	100.00%	99.59%
yakal saplungan	100.00%	92.50%	100.00%	96.10%
yakal yamban	96.83%	100.00%	99.87%	98.39%

The trained CNN model at epoch 249 was used for classifying the testing image dataset. Out of 3,151 images, the model was able to correctly classify 3,104 leaves according to their tree species. Therefore, the model has an accuracy rate of 98.5%.

A confusion matrix was derived from classifying the 25 tree species using the CNN model. Evaluation metrics were derived from the confusion matrix as shown in Table VII. This reflects the model’s high performance in classifying the 25 tree species especially the bitanghol and tanguile tree species with a recognition rate of 100%.

## V. CONCLUSIONS AND RECOMMENDATIONS

The study was able to extract the leaf color, shape, and texture features from digital images of leaves of important indigenous tree species using image processing techniques. A combination of these features was used for classification by three machine learning algorithms: *k*-Nearest Neighbor algorithm, Backpropagation networks, and Support Vector Machine. Among the possible leaf features combinations, it shows that using all the three features provides higher accuracy of classification compared to using just one or a combination of two leaf features. BP networks also provides the highest accuracy with 93.48% out of the three supervised machine learning algorithms for this study. However, the model built using Convolutional Neural Network has an accuracy rate of 98.5% making it the best approach for classification of tree species using digital leaf images in the context of this study.

It is recommended to include more tree species for classification as well as adding more shape features, and even more leaf features like leaf venation, in the case of supervised learning. This may reduce the likelihood of Type I and Type II classification errors. Modifying the configurations in building the CNN model is also recommended to further increase the accuracy rate. The models could also be trained in order to recognize unknown classes or images that are outside of the training dataset. Additionally, using other devices to acquire more detailed leaf images, such as digital SLR cameras or hyperspectral imaging devices, could also be used to extract more features from leaves for a more accurate classification.

## ACKNOWLEDGMENT

The authors would like to thank Dr. Eduardo O. Mangaoang of the Visayas State University, for his expert knowledge on taxonomic classification of important indigenous tree species and for facilitating the leaf collection in the forest reserve of the Visayas State University. Heartfelt gratitude is also given to the authors’ friends and colleagues whose valuable insights contributed to this study’s success. This study was also supported by the DOST-ASTHRDP scholarship grant.

**Abstract**—Over the last 10 years, Arabic language have attracted researchers in the area of Natural Language Processing (NLP). A lot of research papers suddenly emerged in which the main work was the processing of Arabic language and its dialects too. Arabic language processing has been given a special name ANLP (Arabic Natural Language Processing). A lot of ANLP work can be found in literature including almost all NLP applications. Many researchers have been attracted also to Arabic linguistic knowledge. The work expands from Basic Language Analysis to Semantic Level Analysis. But Arabic text semantic analysis cannot be held without considering diacritization, which can greatly affect the meaning. Many Arabic texts are written without diacritization, and Diacritizing them manually is a very tiresome process that may need an expert. Automatic diacritization systems became a demand as an initial step for processing Arabic text for any Arabic Language Processing application as Arabic diacritization is very important to get a readable and understandable Arabic text. For this reason, many researchers recently worked on building systems and tools that automatically diacritize un-diacritized Arabic texts. This work presents a novel deep learning-based sequence-to-sequence model to diacritize un-diacritized Arabic poems. The proposed model was tested and achieved high diacritization accuracy rate.

**Keywords**—Text diacritization; deep learning; sequence-to-sequence; regex; tokenization; ANLP

## I. INTRODUCTION

Arabic language is spoken by more than 360 million people, and its speakers are distributed in the Middle East, and many other neighboring regions. It is noteworthy to know that it is one of the six official languages of the United Nations. Some ANLP work in literature includes sentiment analysis [1], machine translation [2], dialect identification [3], Named Entity Recognition NER [4], question answering [5], summarization [6], etc. What makes Arabic special and challenging at the same time is the diacritization. Diacritics play an important role for understanding the meaning of Arabic statements. Undiacritized Arabic sentence may be ambiguous and difficult to understand. Arabic text is naturally written in some percentage of diacritics to avoid misleading meaning. The percentage of these diacritics depends on the context or the domain. For example, religious text like the

Holy Quran is fully diacritized to minimize chances of understanding it incorrectly. Hadeeth books are also diacritized with high percentage. So are kids' educational books. Classical literature and poetry tend to be partially diacritized as well. However, newspapers and other genre are rarely diacritized. Naturally Arabic text consists of two classes of symbols: letters and diacritics. Letters comprise long vowels such as A, y, w as well as consonants. Diacritics on the other hand comprise short vowels, gemination markers, nunation markers, as well as other markers (such as hamza, the glottal stop which appears in conjunction with a small number of letters, dots on letters, elongation, and emphatic markers) which in all, if present, render an exact precise reading of a word. The remaining of this paper is organized as follows: A literature survey of the recent work in this area can be found in the following section. Section III describes the approach proposed by this paper. Experimental work is demonstrated in Section IV. Section V presents the Results and Discussion. Conclusion and suggestions for future work can be found in Section VI.

## II. LITERATURE REVIEW

A lot of Arabic Natural Language Processing ANLP work has been done in literature. For instance, Farghaly and Shaalan started their investigations in 2009. Their research showed the significance of the Arabic language and its properties. Their work also discussed the challenging characteristics of the language like agglutination and morphological non-concatenation [7]. Habash in 2010 [8] has wrote a comprehensive survey about Arabic language characteristics and features. The survey wasn't limited only to Modern Standard Arabic (MSA) but also, it's dialects. Habash's survey extended to talk about different orthographic, morphological and syntactic aspects of this language in details. Five years later another ANLP comprehensive survey of Shoufan and Alameri [9] has been published. The authors proposed a general categorization of dialectical Arabic language processing into four main classes: (1) Basic Language Analyses (BLA). (2) Building Resources (BR), (3) Language Identification (LI) and (4) Semantic-Level Analysis (SemA). Their survey can be considered as a reference for knowing relevant contributions that address a specific ANLP aspect for Arabic dialects.

Moving to automatic Arabic diacritization attempts found in literature, Diab and Habash [10] studied the impact of Arabic diacritization on statistical machine translation (SMT). Their research confirmed that the SMT performance is positively affected by the presence of diacritization to the extent that would make it robust to slightly high OOV rates. They reported that diacritization step is needed before translation attempts to achieve high SMT performance. In 2008, Shaalan et al [11] used SVM to diacritize undiacritized Arabic text and they achieved accuracy rate of 95.3% and 82% F-measure, but their technique only adds diacritics to the last letter of the word, while the diacritization of internal letters can affect the meaning, for example عمان means (Amman – Capital of Jourdan) and عُمان (Oman - Arabian Country). In 2016, Bouamor et al [12] limited their study to three types of diacritical marks: short vowels, nunation, and shadda (gemination). They were mainly interested in reducing the time consumed in Diacritizing undiacritized Arabic text, so they conducted a pilot study for a minimum diacritization scheme. Their proposed scheme mainly encoded the most relevant differentiating diacritics to reduce confusability among words that are homographs but not homophones. They finally confirmed that it is difficult to build such a scheme because of subjectivity and they promised to dig deeper in future work. In 2017, Darwish et al [13] built an Arabic diacritizer using a Viterbi decoder to diacritize every word including stems and all morphological patterns. Their diacritizer also used transliteration mining combined with sequence labeling to diacritize named entities that have English transliterations. They also used SVM but combined with some filters, and they achieved good results for case ending diacritization. In the same year, Fashwan and Alansari [14] used morphological and syntactic processing to discretize Arabic texts, in which Morphology-dependent that selects the best internal diacritized form of the same spelling, whereas Syntax-dependent that detects the best syntactic case of the word within a given sentence using the parsing tree of that sentence. In their discussion section they stated that they need to improve their system through adding more morphological and syntactic Arabic rules. In 2018, Alosaimy et al [15] have created a tool for accurate diacritization of highly cited texts by automatically “borrowing” diacritization from other citations using n-grams matching, and they used the well-known sunnah book ‘Riyad Al Salheen’ to test their tool. They reported a high accuracy in their conclusion, but their tool only works with highly cited texts. Darwish et al [16] in the same year, limited their study to Moroccan and Tunisian Arabic, using deep neural networks DNN, and they reported a small error rate for both languages. In 2019, Fadel et al [17], used Feed-Forward Neural Network (FFNN) and Recurrent Neural Network (RNN), to diacritize Arabic texts. Their models were trained using 50 epochs and tested only on the available benchmark datasets, and they reported a good diacritization results. M. Madhfar, A. M. Qamar in 2021 [18], used simple baseline deep learning model, encoder-decoder model, and encoder model that is used in text-to-speech system. The authors mainly studied the impact of presence and

absence of diacritics on a text-to-speech, and they concluded that diacritics play a major role in the successfulness of almost all ANLP applications. They also stated that there is a big difference between Modern Standard Arabic (MSA) and Classical Arabic (CA) language, the fact that makes the problem more challenging and data demanding. Abuali and Kurdy in 2022 [19], studied the relationship between the full diacritization of the Arabic text and the quality of the speech synthesized in screen readers, and they came up with a conclusion that it is mandatory to diacritize Arabic text before converting it to audio. Thompson and Alshehri [20] in 2022, stated that training a diacritizer to diacritize and translate Arabic text is much better than training the model to only diacritize the text as it resolves a lot of ambiguity issues. The authors used the standard data splits of Diab et al. [21], and they achieved a low error rate of 4.8% on the Penn Arabic Tree-bank datasets.

### III. DATASET

In this work, we collected a variety of textual sentences along with their diacritized version. The sentences varied in lengths and contexts (talking about different topics) in Arabic Language. Fig. 1 depicts the histogram of the different sentence lengths in our data (number of characters is used to measure sentence length). As you can see from the figure, nearly all the data are concentrated at lengths less than half of the maximum length in both the un-diacritized (Yellow) and diacritized sentences (Blue) which is a good reason to use the half of the maximum length as a padding length in the data preprocessing stage. More about the padding and data preprocessing will be explained in the next section.

The collected data contains 2000 sentences being represented as an ordered set of characters in the input and their equivalent 2000 sentences characters and their diacritization in the output Table I. This research, unlike related work in literature covers all types of diacritization of Arabic language (Harakat) such as: Fataha, Kasara, Damma, Skoon, Fathatan, Kasratan, Dammatan and Shaddah.

Fig. 1. Histogram of the lengths of the sentences diacritized (Blue) and un-diacritized (Yellow).

TABLE I. EXAMPLE OF INPUT / OUTPUT TEXT SEQUENCE

<p><b>Input Sequence</b></p>	<p>كذلك كان من أهداف حركة الاستشراق خدمة مخططات اليهود في هدم الإسلام والتمكين لهم في فلسطين عن طريق تشويه التاريخ العام، وتأكيد حق اليهود في فلسطين، وذلك ما يشير إليه المرحوم الدكتور نجيب البهي بقوله: إن هؤلاء أقبلوا على الاستشراق لأسباب دينية، وهي محاولة إضعاف الإسلام والتشكيك في قيمته وإثبات فضل اليهود على الإسلام بادعاء أن اليهودية هي مصدر الإسلام الأول، ولأسباب سياسية تتمثل بخدمة الصهيونية فكرة أول، ثم دولة ثاني. ولا يغيب عن بالنا أن المستشرقين هم الذين طرحوا على إنجلترا فكرة إنشاء وطن قومي لليهود في فلسطين في مؤتمر لندن المنعقد في سنة سبع وتسعمئة وألف</p>
<p><b>Output Sequence</b></p>	<p>كذلك كان من أهداف حركة الاستشراق خدمة مخططات اليهود في هدم الإسلام والتمكين لهم في فلسطين عن طريق تشويه التاريخ العام، وتأكيد حق اليهود في فلسطين، وذلك ما يشير إليه المرحوم الدكتور نجيب البهي بقوله: إن هؤلاء أقبلوا على الاستشراق لأسباب دينية، وهي محاولة إضعاف الإسلام والتشكيك في قيمته وإثبات فضل اليهود على الإسلام بادعاء أن اليهودية هي مصدر الإسلام الأول، ولأسباب سياسية تتمثل بخدمة الصهيونية فكرة أول، ثم دولة ثاني. ولا يغيب عن بالنا أن المستشرقين هم الذين طرحوا على إنجلترا فكرة إنشاء وطن قومي لليهود في فلسطين في مؤتمر لندن المنعقد في سنة سبع وتسعمئة وألف</p>

IV. THE PROPOSED APPROACH

Using our collected diacritized dataset, the proposed methodology exploits techniques in Deep Learning and Text Analysis to diacritize un-diacritized Arabic text. The objective is to take an input un-diacritized text and output its equivalent diacritized text. Unlike most of work in literature that used regular text analysis or statistical text classification to partially diacritize un-diacritized Arabic text, we used sequence-to-sequence model to diacritize text through mapping the input sequence of un-diacritized characters into diacritized ones. In our work, we clean the input and output texts and generate a parallel map between the two texts as a first stage to be able to train the deep learning model as a second stage. A further explanation of both stages can be found in the following subsections:

A. Data Preprocessing

In the data preprocessing stage, several text processing techniques were utilized. At first, data cleaning was used to remove irregular characters from the data such as “\ufeff” and “\u200f” which appeared so often because the data was stored in a bytes-like fashion. Then, regular expressions were used to remove any irregular character to Arabic language from the data including but not limited to English characters, question marks, dashes, dollar signs, asterisks, etc. Fig. 2 shows the regex we used to remove all the strange characters from the data. After that we tokenized the input and output text into their letters and diacritization (character wise tokenization). The character tokenization was done to make the model predicting the diacritic per character not per word. Following tokenization, we padded the sequences to a maximum length which we chose to be half of the maximum length and because of limitations on computational power. After the padding, we extracted all the unique tokens from the

input text and output diacritized text which was 36 (Arabic characters count) and 44 characters (Characters + diacritics) respectively. The strength of the regex we used was the main reason to be able to extract the unique characters of the data and to make it ready for use. We then used these unique characters to do one hot encoding of the data to be able to use them for deep learning training. Fig. 3 depicts the steps of the text preprocessing stage.

```
Regex [?!$%&'()*+,-./:;<=>@|~|^|_|`|{|}|\xa0|/|_|-|-|-]
```

Fig. 2. Regex symbols used in this work to clean data.

Fig. 3. The basic steps of text preprocessing stage.

B. Sequence-to-Sequence LSTM Model

After the text preprocessing stage, a sequence-to-sequence language model was built. The input to the model was the padded sequence one hot encoding of characters obtained from the text preprocessing stage. The sizes of the input data array and output data array were (4000, 4994, 36) and (4000, 9124, 44) respectively. The 4000 represents the total number of sentences we had that is why it is fixed in both input and output arrays. 4994 and 9124 indicate the padding length of the inputs and outputs respectively (half of the maximum length of both). Lastly, the 36 and 44 represent the number of unique tokens in the input and output respectively. The sequence-to-sequence model can generally be seen as encoder-decoder model. The encoder model has an input layer and an LSTM layer of 200 nodes. The decoder model has also input layer, LSTM layer of 200 nodes and output dense layer of the 44 output nodes (the unique output tokens). The activation functions used was SoftMax in the output layer. The model has in total 394,444 trainable parameters. We used Adam optimizer, and categorical\_cross\_entropy loss. 25% of the data were used for validation with 200 epochs. We used LSTM layer because of its ability to capture long sequence dependencies which is of great help in language modeling. The results obtained are discussed in the next section.

V. RESULTS AND DISCUSSION

This section demonstrates the experimental work done to evaluate our model. We used Google Colab GPU using a high RAM station to train the model. Training the 200 epochs took more than 6 hours. Due to the very long time of training, we used the first 50 epochs to show the accuracy results that was 92.12. However, after training the model for the complete 200 epochs later, we obtained an accuracy rate of 96.83%. The accuracy was a good metric for testing the model predictions

because the padding length didn't use lots of zeros because most of the data were concentrated in that length. However, we also used loss as an evaluation metric. The Model loss for the first 50 epochs is recorded in the figures below (Fig. 4). It reached below 0.19 for training and below 0.22 for validation. After the end of the 200 epochs, the loss obtained was 0.074 and the validation was 0.080. It seems clearly that the model isn't overfitting and obtaining excellent results.

To test the model, we needed to convert the sentence into all its corresponding characters and feed them into the trained model and recollect the characters predicted to get the output correct sequence. The results are clearly outperforming previous methods and are a good potential for the use of sequence-to-sequence modeling for automatic text diacritization. We can see that the main reasons for obtaining these excellent results are due to the correct data cleaning/preprocessing using regex and ell the text preprocessing steps. In addition, the padding length does not allow the use of lots of zeros in the sequence the thing that made the data represented in an excellent manner. In addition, the size of the validation data along with the absence of correlation between the features (because of one-hot encoding) allowed the model not to be overfitting. One of the main strengths of this work also, was that we extracted the exact unique tokens of both input and output which allowed the sequence-to-sequence model to perform excellently and outperform preceding sequence-to-sequence models. In the most recent research in literature RNNs and LSTMs were used but without the text preprocessing steps and size settings, they failed in obtaining high results using sequence-to-sequence models due to their inability to extract the exact unique tokens of diacritics and Arabic language.

Fig. 4. The Accuracy/Loss vs epochs for the model training for the first 50 epochs.

## VI. CONCLUSION AND FUTURE WORK

This work achieved a high accuracy rate and low loss rate that outperforms results found in literature using sequence-to-sequence model to diacritize Arabic text. The main strength points in this work compared to related work in literature are:

- 1) The coverage of all Arabic diacritics rather than focusing on certain diacritics.
- 2) Diacritizing the whole word rather than diacritizing the end of it, and
- 3) The good text preprocessing and the extraction of unique tokens before using the LSTMs to diacritize the undiacritized text.

As a future work, we are planning to gather more data for further evaluation of our proposed model. We are also planning for using transfer learning to evaluate different deep learning models applied for the same problem.

Royal Commission for Jubail and Yanbu, Jubail Industrial City, Saudi Arabia<sup>2</sup>

**Abstract**—COVID-19 pandemic has dramatically changed the public life style as well as the daily work activities across the world. This indeed has led both public and private sectors to attempt to adapt thereby shifting to remote work and adopting and enabling new technologies and online services in order to sustain their businesses while saving people lives. Unfortunately, a decent number of those endeavors have been undertaken unwarily in a hurry without taking the due diligence of all relevant aspects including cybersecurity and privacy. This survey aims at exploring the current state of the practice during the Covid-19 pandemic lockdown and the revolving challenges of using and publishing online services in Saudi Arabia. It also investigates the needs for investment in the cybersecurity field which would increase the trust on and reliability of them; and thus encouraging organizations to move confidently towards the real digital transformation.

**Keywords**—Cybersecurity issues; investigative survey; remote work; COVID-19 Pandemic; Saudi Arabia

## I. INTRODUCTION

COVID-19 pandemic has changed the life style of people in many aspects including social and work perspective. Indeed, the reliance on the Internet has become one of the daily life activities since the internet services have been used in most of the world countries. These activities include a variety of fields such as social network, entertainment, shopping, studying, and working. Therefore, about 4 billion users access the Internet, spending an average of 170 minutes daily – the majority of which was on social media [1]. However, the COVID-19 lockdown has forced the countries and their organizations in public/private sectors to empower remote working to keep their organizations running. Remote work is the means that allow employees to perform some or all of the work from home or any location other than their work site.

According to the statistical survey conducted by [2] to measure the remote system experience of epileptologists before and after the pandemic, they found that those who experience remote system have dramatically increased from about 63% to 86% within few months. In the UK, the remote working hits about 38% of the employees during the lockdown raising from 21% in 2019 [3]. This unforeseen noticeable changes in the policies and procedures of working that permeate over countries have made some challenges. These issues might be related to different aspects such as place, technology, and

security. The Forbes survey of remote workers showed that 72% of employees are not working from a dedicated office place [4]. In addition, the majority of them (56%) has faced a difficulty to bring their work equipment to their homes. In the report published by Global advisory and accounting networks [5], cyber security concerns were raised thereby showing that nearly 65% of organizations announced they have been either breached or exposed to cyberattacks during remote work. On the other hand, about 13% of the organizations were not prepared at all, compared to 45% somewhat prepared and 42% claimed they have prepared very well for the transformation in the work manner. Consequently, the damage of their income was incredibly hard in the majority of organizations across the world. According to the Office for National Statistics (ONS), the UK economy is still not close to the pre-corona virus output levels [6]. The report anticipated that the damage of the lockdown just in April 2020 might hit 15 billion to 20 billion GBP. Globally, the crisis could lead over 2020 and 2021 to an overall loss of around 9 trillion USD which is greater than two countries' economies such as Japan and Germany [7].

The cyber security aspect has been considered as main pivotal pillar in the remote work status. The struggle becomes clearer with the technology and security in response to the quick transfer in the work environment and probably paradigm. Indeed, the number of cyber attacks has dramatically increased to those organizations whilst processing information about the pandemic. For instance, during the pandemic crises, the World Health Organization (WHO) has mentioned that the number of cyber attacks to its staff and emails have surged more than five times compared with the same period a year before. Consequently, it is moving to a more secure authentication system after a leakage happened in its system [8].

Generally, the studies about the remote work have focused on the services that can be remotely provided. For example, [9] emphasized on some of the security challenges that need to be considered in each level of the cloud to secure the remote access to the site such as implementing and managing Identity and Access Management (IAM) systems. However, the pandemic incidence has forced organizations to think for a reasonable manner that can help in this partial or complete shift in their daily work. The author in [10] carried out a study focused on using PKI certificate and mobile device

management platform to secure the organization system during this accelerating change.

In this work, we investigate the challenges that have faced organizations within Saudi Arabia during moving to the remote work. In addition, it is going to concentrate upon the cybersecurity aspect and to what extent it might be limiting and/or enabling remote work transformation. The subsequent section explains the design methodology of the conducted survey. The Results Analysis Section presents a detailed illustration of the responses received and then followed by exploring and discussing them and succeeded by some drawn conclusions with a set of relevant future directions.

## II. METHODOLOGY

The survey was designed to explore and assess the maturity level of the organizations run in Saudi Arabia and its surroundings when they have moved to the remote work and challenges they have faced. Furthermore, it sought to explore the encountered information security breaches and utilized techniques during the COVID-19 pandemic. This was to answer the following research-related questions:

- What is the current state of the practice in the Saudi public and private sectors during the COVID-19 pandemic lockdown in relation to the growth of using and publishing online services and the revolving challenges and issues?
- Are cybersecurity concerns one of the vital issue(s) that may delay the digital transformation to online services?

A number of questions were devised and piloted with a number of specialized academic colleagues in order to obtain their perceptions on whether they are understandable and serve the purpose. After a few revisions based on the received inputs, the final version contained 28 questions and divided into four sections and structured as follows:

1) *Personal demographic:* Exploring the participants' demographic characteristics, related to gender, age, qualification, and job level.

2) *Organization information:* Establishing background of the organizations at which the participants work, in term of the type, field, size and location.

3) *Exploration of the current state of the practice:* Understanding technologies that were utilized into moving to remote work and during it, in addition to what extent online services have met the demand and requirements of stakeholders.

4) *Investigation of cyber security related issues:* Studying the reason(s) that has/have hindered or may hinder the growth of/ transformation to the remote work as well as security techniques that were used during it, their vulnerabilities and potential solutions.

The survey was set to be conducted over the Internet via an online questionnaire hosted by survey monkey website. Public users were targeted with three conditions: they are 18 years and above as well as were employees and worked in any means during the COVID-19 pandemic in Saudi Arabia. Those were

recruited via e-mail besides other social media, such as WhatsApp, Twitter and LinkedIn from acquaintances and professional societies and groups.

## III. RESULTS AND ANALYSIS

A total of 300 participants completed the survey over a period of eight weeks, during which the survey was active. Table I depicts that the majority of them (49%) belonged to the age group of 30-39 years, followed by 26% from the age group of 40-49 years. A huge gap between the proportionality of male and female participants was observed. About 89% of the partakers were male, reflecting the unequal participation of the different genders. However, as the investigated aspects of this research related to the organizations' employees, it is more likely to be common practices regardless of the genders. With respect to educational qualifications, the majority of the participants held bachelor's degree, followed by Master's, and Ph.D. – indicating high literacy levels of them and hence high probable informed responses.

Moreover, the majority of the participants assumed high job positions including mid-senior (41%), director (21%), and executive (7%) – showing good work experience and exposure with various areas of business operations. Accordingly, most partakers were working on the area of technology (30%), followed by 27% in education sector, and 12% in industrial field.

Fig. 1 shows that the participants were from diverse fields of work, representing more realistic and reflecting results.

TABLE I. SUMMARY OF PARTICIPANTS' DEMOGRAPHIC CHARACTERISTICS

Demographic Factors	Characteristics	Relative Frequency
Age	18-29	16.79%
	30-39	49.38%
	40-49	25.68%
	50 and above	8.15%
Gender	Male	89.38%
	Female	10.62%
Qualification	High School/ Associate Degree/ Diploma/	6.91%
	Bachelor	39.75%
	Masters	30.12%
	PhD	23.21%
Job Position	Entry Level	11.60%
	Associate	19.01%
	Mid-Senior	40.99%
	Director	21.23%
	Executive	7.16%

Fig. 1. Distribution of participants fields of work.

In addition, two thirds of the participants worked in public enterprises, while a third worked in private enterprises, indicating the distribution of participants in the two main sectors of the economy. In terms of the size of participants' organizations, 53% of the participants' organizations employed a thousand employees or more; 21% had between 100 and 999; and 19% had less. Thus, the size of the participants' organizations reflects the consideration of different small, medium, and large scale organizations, thus improving the analysis coverage of the results of this study.

Focusing on the strong technical infrastructure of the organizations that meets the needs of participants, it was identified that more than 77% of the participants stated that their needs were met. However, considerable number of participants (18%) were neutral, and about 5% stated that their needs were not met as illustrated in Fig. 2. Therefore, it can be a cause of concern for enabling and maintaining remote working conditions, suggesting a need for improvement in the technical infrastructure of the organizations.

Analyzing the use of devices in remote working conditions (as demonstrated in Fig. 3), it is identified that the majority of the participants relied on personal devices. 48% were using personal laptops, 17% personal desktop, besides 40% used personal smartphones/tablets for remote working. On the other hand, organizational laptops, desktops and smartphones/tablets were also being used by 48%, 23% and 10%, respectively. This increase in the use of personal devices for remote working may reflect the escalation in the security threats, as personal devices may be more prone to security attacks if proper security configuration is not maintained. Additionally, the diverse platforms usage indicates that most of the current remote workers probably own/use many digital devices with different operating systems and configurations –emphasizing the need to consider universal applicability as a crucial aspect in any proposed mechanism/solution.

Moreover, Fig. 4 represents the type of network connection utilized during remote working. The majority of the participants relied on private Wi-Fi connections (61%), indicating a more secured network compared to public Wi-Fi that was used by 6%. This may probably lead to potential security attacks that might affect the organizations and result in

huge losses. Whilst 43% utilized Fiber Optic and 12% relied on broadband services, 44% used mobile internet services. The latter indicates the possibility effect on the work flow due to mobile low speed or loss of connection. In this context, only 22% of the participants strongly agreed and 49% agreed that their internet service provider has met their expectation in terms of speed and connectivity. In addition, almost 13% of the participants stated that their internet service provider did not meet their expectations, while 17% were neutral. These results indicate that the internet and communications infrastructure was not fully upgraded/reliable in order to meet the requirements of remote working system.

Fig. 2. The extent to which participants' organization meet their needs.

Fig. 3. Usage of digital devices during remote working.

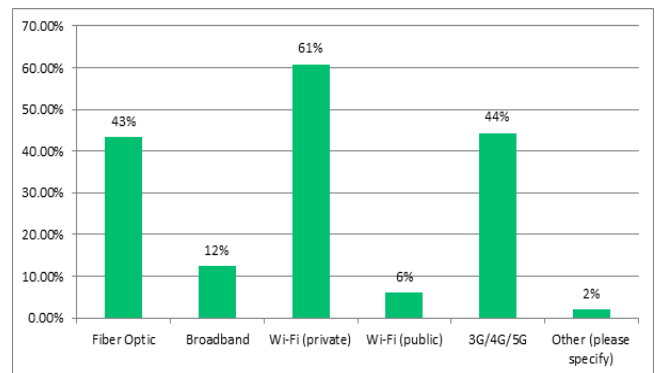

Fig. 4. Types of internet connections in use.

Considering the cloud services usage illustrated in Fig. 5, only 7% of the participants indicated that they do not use cloud services. Corporate cloud email services (60%) were the most preferred option by the participants, followed by the generic cloud file sharing services (34%) such as Google Drive, One Drive, Dropbox, iCloud, Nextcloud. As more than 90% of the participants used cloud computing services, it is likely that sensitive information may be accessed and updated during the remote working, leading to potential rise on privacy concerns. This, in addition to considering the diverse devices and network connections (from Fig. 3 and Fig. 4) used by the participants, cloud services may be more effective as they offer broad spectrum of universality and acceptability.

Regarding the security practices during remote working, Fig. 6 shows that only 5% of the participants did not use any authentication or security methods. Password/PIN/Pattern is the most commonly used authentication method adopted by the majority of participants (52%), followed by using VPN (39%) for remote working, and OTP (28%) for remote authentication. Face recognition and hardware token are other practices used by few participants. These results indicate that participants have adopted a range of security methods reflecting the use of multiple or a variety of security methods (44%) which adds an additional security layer for various activities during the remote working. Such practices improve security and privacy, thereby avoiding potential online security threats or loss of data.

Analyzing the impact of lockdown on the daily work of the respondents illustrated in Fig. 7, it can be identified that half of them stated that their daily work was affected, with 31% not affected and 19% was neutral. The results clearly indicate that lockdown has severely impacted their daily work routine while working remotely, indicating a greater influence of external factors (not internal to organization) on the daily work. Lockdown has not only affected the employees, but also the organizations, and their work culture. Most of the organizations shifted to remote working model in a far larger way than ever before. In this context, 76% of the participants stated that home Lockdown (Curfew) has encouraged or pushed their organizations to publish or enable more online services; while only 5% stated that it had no impact on their organizations in enabling more online services. Therefore, it can be inferred that there is a significant impact of lockdown on the organizational work paradigm, steeping more towards remote work.

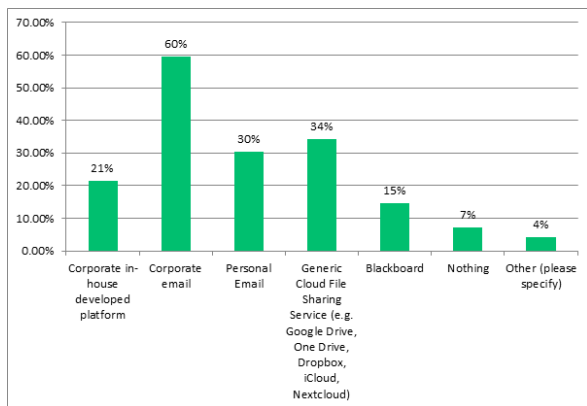

Fig. 5. Types of cloud file sharing services.

Fig. 6. Types of security / authentication practices.

Fig. 7. Impact of lockdown on the daily work of the respondents.

Due to the sudden change in work culture, it is common that there could be many issues that might have to be dealt with by employees and organizations in shifting towards complete online services. In this context, Fig. 8 demonstrates the various challenges encountered by the participants and their colleagues during the remote working from home. The lack of high speed or quality connectivity infrastructure was the most common challenge identified by many participants (37%). These findings can be correlated with the earlier mentioned low satisfaction about their ISPs. Thus, it is evident that the lack of high-speed internet infrastructure in some areas of Saudi Arabia [11] and other states in the Middle East [12] was one of the major challenges affecting the remote working culture in the organizations. In addition, other major challenges included the lack of appropriate software (27%), the lack of appropriate hardware (23%), and the lack of appropriate skills/awareness (23%). These results indicate the lack of readiness of the employees and organizations in handling the unexpected change. However, it is unsurprising to note that 26% of the participants mentioned that they could not identify any challenge related to remote working during the lockdown, indicating an effective change management practices adopted by few participants and organizations during the lockdown.

Considering these sudden changes in the work culture, it is essential to compare the offline and online practices in order to improve the online services. Therefore, participants were asked to compare the organizational outcomes of online and offline services of their organizations. It is interesting to note that 62% of the participants reflected their opinion that online services used by their organizations delivered better outcomes than their counterpart offline services. Only 6% of the participants

indicated that offline services delivered better outcomes than online services. The results signified that adopting the online services and remote working culture resulted in better outcomes compared to offline practices - implying the advantages of remote working. Aspects such as flexibility, convenience, saving travel time and transport expenses might probably have contributed to the improved work efficiency of the participants while remotely working from home during the lockdown.

Fig. 9 indicates that Zoom was identified to be the most commonly used platform, followed by Cisco Webex, Microsoft teams, Blackboard, Skype for Business, and Google Meet. Due to its easy-to-use feature with limited required resources or memory, applications such as Zoom might have been preferred over other commercial applications such as Skype. Availability and adoption of various platforms for online meetings, as illustrated in Fig. 9, may improve the communication and interactivity among the various employees and entities within online environment resulting in improved process and operational efficiency leading to better outcomes. On the other hand, it was identified that password security method was the most commonly applied authentication technique by the majority of participants (58%) for joining online meetings. In addition, other authentication techniques used included OTP, VPN and multi-factor authentication. These security practices adopted online meetings can be correlated with the adopted general security practices (Fig. 6), reflecting similar practices.

Focusing on the various factors that may hinder the transformation from traditional work practices to online services, various important issues were identified by the participants. Cybersecurity, lack of infrastructure, and lack of trust were the three major issues identified for transforming traditional services into online services, as illustrated in Fig. 10. In addition, the lack of staff and users' skills and awareness were the succeeding key challenging factors identified in this study against moving towards digital teleworking. Accordingly, 82% of the participants held an opinion that cybersecurity may be adversely affected by the online services.

In this context, the participants were asked about the probable vulnerabilities that might occur due to the increase in online services and remote working. Fig. 11 presents that information/data leak was identified to be the most important vulnerability by the majority of the participants (76%). Furthermore, identity theft (55%), and unauthorized information access (41%) were the following most vulnerabilities identified.

In view with the use of different devices with different configurations, and the increased usage of personal devices illustrated in Fig. 3, the potential risk of security attacks would be higher. Accordingly, information leak/theft, unauthorized accesses are some common vulnerabilities that could occur, but can have huge impact depending on the type of data loss. Thus, the results indicate that there is a high probability of security attacks or vulnerabilities in remote working process. In reference to the probability of vulnerabilities occurrences, the

participants were asked if they had experienced any security incidents during working from home. Even though 73% indicated they did not experience any security incident, a non-negligible number of participants (16%) indicated that they did. This result can be in line with the level of cyber incidents in the Middle East, which may not only affect the remote working infrastructure, but also affect the organizations in a number of aspects. Moreover, 10% of the participants stated that they do not know if they have experienced any security incident. Unawareness about cyber incidents is another major issue, which may result in continuous exploitation by the attackers/hackers without being detected.

Fig. 8. Challenges faced by the participants in remote working during the lockdown.

Fig. 9. Types of platforms used for online meetings.

Fig. 10. Challenges in moving towards online services during the lockdown.

Fig. 11. Types of vulnerabilities that may occur during remote working process.

Considering the risk of security incidents during the remote working, it is important to analyze if the organizations are ready to invest in more effective cyber security solutions. Fig. 12 elucidates that over 80% of the participants strongly agreed and agreed that their organizations would invest more in cyber security solutions, indicating a growing importance for deploying effective security infrastructure in the process of transformation to online services. From the employees' perspective, it is essential to assess the impact of investments in cyber security solutions on trust and reliability in shifting to online services. In this context, over 87% of the respondents strongly agreed and agreed that the growth of investment by organizations in cyber security solutions will increase their trust and reliability in the growing online services and remote working.

Fig. 12. Organizations' Readiness to invest more in cyber security solutions.

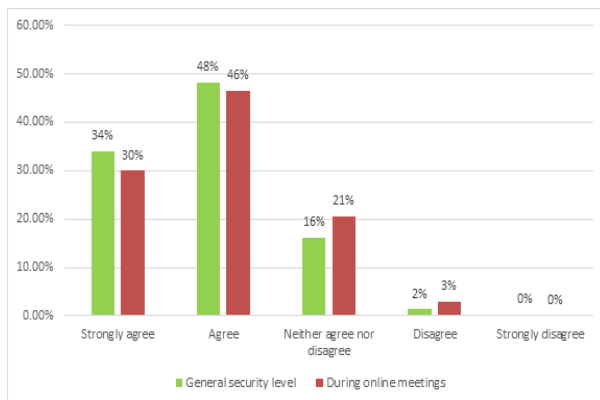

Fig. 13. Influence of transparent continuous authentication on enhancing the security levels.

With regard to the use of transparent and continuous authentication, participants' opinions were gathered whether it could enhance the security level in general and during online meetings specifically. Fig. 13 demonstrates similar results in both conditions, indicating a greater expectation and acceptance of transparent continuous authentication process.

#### IV. DISCUSSION

The respondents of the survey were from a diverse population with respect to age, qualification, job position, work field and enterprise sector and size, making it quite representative in relation to the investigated issues. Despite the overwhelming belief on the strong technical infrastructure of the organizations, there is an apparent increase in the use of personal devices for remote working, leading to potential surge of security threats due to the usual relaxed security practices while interacting with personal devices. Nevertheless, employing proper mobile device management (MDM) solutions would lead to more suited security measures and maintenance, hence alleviating cybersecurity vulnerabilities and attacks.

It is apparent that most of the current remote workers own/use a number of digital devices with different operating systems and configurations. This is coupled with the evident adopted several online meeting platforms and cloud services, emphasizing the need to consider universal applicability and interoperability as a crucial aspect in any offered security mechanism.

Given the fair range of applied security authentication practices, still the knowledge-based methods outweigh the others, rendering the remote working susceptible to its well-known shortcomings that affect the security level. This prevalence can be attributed to the fact that these approaches are the main provided ones by the majority of platforms, portals and services besides other low accurately configured and more intrusive alternatives such as the biometrics of fingerprint and facial recognition. Users' inclination to the ease of use may yield to apply the PIN/Pattern method, for example, at the expense of a further layer of protection that is introduced with biometrics as a single factor or an additional factor. However, implementing them in a usable and robust manner would lead to a resilient online working environment with less effect on the day to day tasks than what was declared. This can also be aided by better early preparedness in terms of appropriate devices, applications, quality internet connections, and staff skillsets and awareness in order to have improved smooth transition of processes and operations leading to efficient online remote or hybrid work paradigm.

It is observed that cybersecurity and the lack of infrastructure and trust are the major challenges of digital work transformation. This also can be seen by the respondents' perceptions regarding the wide range likely vulnerabilities during remote working including data leakage and unauthorized modification and identity theft. Therefore, an intelligent security solution that balance the higher protection and usability is required and can be provided by continuous and transparent authentication approach which gained high acceptability and expectancy by participants, stemming to a potential success. This is also supported by the anticipated

increase in investment in cybersecurity solutions by respondents' organizations.

## V. CONCLUSION

The survey findings were derived from a fair range of participants' backgrounds with regards to demographics, employments, as well as organization types, fields, sizes and somewhat locations. Exploring their state of the practice, it was found that a variety of technologies were adopted and operated into transforming to remote work and during it, in terms of devices, connectivity, Cloud File Sharing Services, and online meeting platforms.

Despite the acceptable level of satisfaction about the used and offered online services in meeting the demand and requirements of stakeholders, still a number of challenges were raised and needed to be tackled, such as cybersecurity and the lack of high speed/quality connection infrastructure, appropriate software/hardware/device(s), and technical skills/awareness.

With reference to issues that hindered or may hinder the growth of or the transformation to the remote work, cybersecurity had the highest concern including confidentiality, authenticity, integrity, malware and availability (in order). Moreover, the lack of infrastructure, trust, and financial support were of those matters to be considered with potential solutions for better remote work experience. Although many organizations have moved relatively fast to the remote work and to some extent fulfilled their tasks, many of them have faced difficulty to offer appropriate scale of online services. Therefore, more investment in cybersecurity techniques and employee training could be an incentive towards a more effective, efficient and smooth remote work environment.

**Abstract**—Patent documents are a special long text format, and traditional deep learning methods have insufficient feature extraction ability, which results in a weaker classification effect than ordinary text. Based on this, this paper constructs a text feature extraction method based on the lexical network, according to the inner relation between words and classification. Firstly, the inner relationship between words and classification was obtained from linear and probability dimensions and the lexical network were constructed. Secondly, the lexical network is fused with the features extracted from the deep learning model. Finally, the fusion features are trained in the original model to get the final classification result. This method is a classification enhancement method that can classify patent text alone or enhance the accuracy of various types of neural networks in patent text classification. Experimental results demonstrate that the accuracy of BERT combined with lexical network method is as high as 82.73%, and the accuracy of lexical network method combined with CNN and LSTM is increased by 2.19% and 2.25% respectively. In addition, it was demonstrated that the lexical network feature extraction method accelerated the convergence speed of the model during training and improved the classification ability of the model in Chinese patent texts.

**Keywords**—Text classification; deep learning; network vocabulary; patent; feature extraction

## I. INTRODUCTION

As the main carrier of scientific and technological information, patents contain about 90% of global technical information. In 2021, the effective number of Chinese invention patents will be 3.597 million, facing a large number of patent applications, patent text review takes up a lot of time for patent examiners. Patent classification is an important part of the patent review, which can reduce the time and cost of subsequent retrieval and management of patent documents. At present, the main patent classification used in China is the International Patent Classification [1]. IPC classification has five levels, belonging to a multi-level and multi-label classification system. At present, China mainly uses manual methods to classify patents. For example, after receiving patent application documents, patent examiners need rich professional knowledge to accurately classify patents, making subsequent patent texts easy to review and retrieve. In the face of massive patent texts, intelligent and effective implementation of

automatic classification of Chinese patent texts has become the focus of the industry and academia.

Automatic text classification is one of the important fields in NLP (Natural Language Processing). In recent years, there has been much research on text classification using machine learning and deep learning, Early text classification models generally refer to the support vector machine[2][3], Bayesian classifier[4][5], k-Nearest Neighbor algorithm[6][7] and other machine learning[8] methods for text classification. However, text classification of machine learning methods relies on manually constructed features and ignores the context between words and sentences, which makes it difficult to improve the accuracy of such methods. After Hinton[9] and others first proposed the concept of deep learning in 2006, scholars proved that deep learning technology has good performance in text classification. Since then, in the field of text classification, deep learning has gradually replaced machine learning as the mainstream research direction.

Therefore, on the basis of previous studies, based on the analysis of a large number of patent data, this paper proposes a deep learning feature extraction method based on a vocabulary network, which improves the accuracy of deep learning on patent text classification through feature fusion between the extracted features and the deep learning model. The practice shows that this method combined with deep learning has a certain improvement in Chinese patent text classification, which confirms the contribution of this paper in the following aspects.

1) In this study, a method of combining deep learning with vocabulary network feature extraction is proposed theoretically.

2) It is proved in practice that this method combined with other deep learning models can speed up the model convergence and improve the accuracy of model classification.

The rest of this paper is organized as follows: In Section II, we introduced the relevant work and our contributions. In Section III, we introduce our research framework. In Section IV, we selected text data to verify and illustrate the relevant parameters of this model. Finally, the conclusion and further work are given.

## II. RELATED WORK

Automatic patent text classification is a technical means to use computers to classify and mark the text according to a specific label system, which is convenient for the patent document management and text search. This paper mainly solves the task of automatic patent text classification through deep learning. Therefore, this section mainly introduces the current research status of scholars using deep learning methods to classify text.

Deep learning text classification is mainly represented by a neural network model, attention mechanism and pre-training model.

1) The text classification method based on the neural network model presents the text in low dimension by word embedding and achieves the classification effect by using an encoder. Representative models include convolutional neural network (CNN)[10], recurrent neural network (RNN)[11] and graphical neural network (GCN)[12], Among them, CNN can acquire local relations[13], RNN uses a recurrent neural network to have the ability to learn long-distance texts[14], GCN can effectively integrate the features of references.

2) Compared with the neural network model, the attention mechanism can focus on a part of the information related to the classification task while ignoring the irrelevant part when processing tasks, In 2014, Bahdanau et al[15].Used the attention mechanism to perform machine translation tasks for the first time, making great progress in machine translation. In text classification tasks, the attention mechanism is often combined with the neural network model, She et al[16]. Proposed a text classification algorithm based on the hybrid CNN-LSTM model, used the feature vector output from CNN as the input of LSTM and used Softmax classifier for classification, which can effectively improve the accuracy of text classification. Yang et al[17]. Based on the combination of convolutional neural networks and long-term and short-term memory, are used to capture local features to enrich feature information and use weight values to adjust the enhancement intensity.

3) The pre-training model is represented by the BERT model, and the improvement of model classification results mainly depends on the adjustment process of the model[18]. BERT has a strong sentence and word expression ability and has an excellent performance in NLP tasks at the word level[19]. Lu et al[20]. Proposed the VGCN-BERT model, which combines BERT's capabilities with vocabulary graph convolutional network (VGCN). The different layers of BERT interact to enable them to interact and jointly build the final classification representation. Zheng et al[21]. Proposed a BERT-CNN model for text classification. By adding CNN to the task-specific layer of the BERT model, you can obtain information about important fragments in the text.

Some of the above methods have been successfully applied to patent text classification tasks, and have achieved some results. As a branch of special long texts in text classification, Chinese patent texts are difficult to improve the accuracy of

classification. Many scholars have carried out a lot of research on this. For example, Wen et al. [22] proposed a multi-level patent text classification model, called ALBERT-BiGRU, which combines ALBERT and bidirectional gated loop units. The dynamic word vector pre-trained by ALBERT is used to replace the traditional static word vector, and the BiGRU neural network model is used for training, which preserves the semantic association between long-distance words in the patent text to the maximum extent. Roudsari et al[23]. Studied the effect of applying the DistilBERT pre-training model and fine-tuned it to complete the important task of multi-label patent classification. To sum up, domestic and foreign scholars' patent text classification methods based on deep learning mainly focus on the fusion application of deep learning models, the adjustment of pre-training models or the introduction of attention mechanisms to extract relevant features. Although these methods can achieve the goal of improving the classification effect, they are all cumulative applications of existing methods, which not only affect the model classification efficiency but also difficult to improve the patent classification effect.

In previous studies, the focus has been on improving the models, while ignoring the specific structure of the data itself, making it difficult to improve the accuracy of patent text classification. Based on this, a generic feature extraction method is considered for patent text feature extraction to improve the accuracy of automatic patent text classification, mainly considering the intrinsic connection between words and classification as the basis for feature extraction, and introducing the extracted features into the deep learning model to fuse with the features extracted by the model to improve the model classification effect.

## III. PROPOSED WORK

Through the analysis of previous text classification studies, it is found that LSTM has more advantages than CNN in text classification because of its contextual characteristics[24], which has also been confirmed in many long text classification studies. However, in the classification of Chinese patent texts, there is an exception in that the accuracy of CNN is equal to or slightly higher than LSTM. Through the analysis of patent data and experimental reproduction, it is found that patent documents belong to a special format in long texts, and are insensitive to the context, but sensitive to the words divided by social production practices such as industry and industry. Therefore, in the neural network feature extraction stage of deep learning, the parameters extracted by traditional feature extraction methods in patent texts have the low feature density required for classification, and the existence of multi-word synonyms in feature words increases the difficulty of classification, which makes the full connection layer learning feature inefficient and feature learning incomplete in deep learning, ultimately leading to low accuracy of Chinese patent text classification. In order to solve the problem that the feature extraction ability of Chinese patent text of neural network is insufficient, this paper proposes a feature extraction method based on a vocabulary network to strengthen the feature extraction ability of Chinese patent text of deep learning network, so as to improve the accuracy of Chinese patent text classification.

A. Deep Learning Model based on Vocabulary Network  
Feature Extraction

This paper proposes a feature extraction method of a deep learning model based on a vocabulary network. This method combines the extracted features with the extracted features of the original model and expands the features on the basis of retaining the features of the original model to improve the classification accuracy. Fig. 1 is a schematic diagram of the LNFE method of deep learning model fusion, which includes four parts: text vector representation, feature extraction, feature

fusion and text classification prediction. In the figure,  $P_i$  is patent data,  $W_i$  is patent text information after word segmentation, and  $F_i$  is the feature information extracted from text. In the training or prediction process, the patent text is first segmented and processed separately. In the deep learning network feature extraction, the data is extracted in the original feature extraction layer and LNFE, respectively, and then the extracted features are spliced and fused, and then the appropriate parameters are trained in the full connection layer to classify the subsequent data.

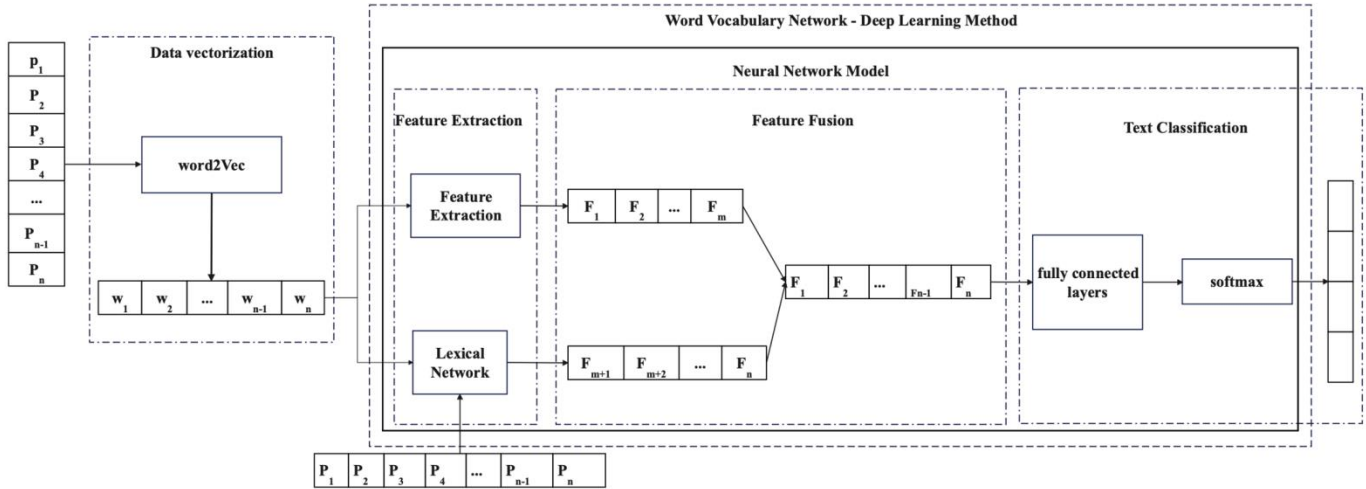

Fig. 1. Schematic diagram of vocabulary network and model fusion

B. Vocabulary Network Generation

The lexical network is a key step in feature extraction, which includes synonym clustering of words in the patent, the internal relationship between words and classification and other information. In the subsequent feature extraction process, the characteristic words of patent text can be accurately extracted using the lexical network as a reference. Fig. 2 is a schematic diagram of the generation of a vocabulary network.

First, the word vector (Word Embedding) representation of each word in all texts is obtained by unsupervised learning of Word2vec, and the word vector similarity is calculated by using the cosine formula of Formula 1 to cluster and merge synonyms in words, thus avoiding the problem of slow model convergence caused by synonyms in the feature extraction stage.

Fig. 2. Schematic diagram of vocabulary network generation

$$\text{Sim}(\vec{v}, \vec{w}) = \sum_i^N v_i w_i \quad (1)$$

Where  $\vec{v}$  and  $\vec{w}$  are word vectors trained by Word2vec respectively, Sim is the similarity between vector  $\vec{v}$  and  $\vec{w}$ ,  $v_i$  and  $w_i$  is the value of the vector  $\vec{v}$  and  $\vec{w}$  at different latitudes.

Each group of word vectors after merging has corresponding label labels. According to Formula 2 and Formula 3, the prior probabilities of words and classifications are obtained from the two dimensions of probability and linearity through Label information and word vector

information, and each word vector is given a classification feature weight by weighting.

$$\rho = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2 \sum_{i=1}^n (y_i - \bar{y})^2}} \quad (2)$$

$$P(B_i|A) = \frac{P(A|B_i)P(B_i)}{\sum_{i=1}^n P(A|B_i)P(B_i)} \quad (3)$$

Where the  $\rho$  Is the correlation between word vector and classification,  $x_i$  is the frequency of word change in patent No.  $i$ ,  $\bar{x}$  appears in this category  $\bar{x}$  Average frequency of.  $y_i$  is  $x_i$

Classification of  $y$  in  $i$  word patent,  $\bar{y}$  is the average of the categories in the patents with  $x_i$  words. In Formula (3),  $P(B_i|A)$  represents the probability of being classified as  $B_i$  when the word  $A$  appears,  $P(A|B_i)$  is the probability of occurrence of  $A$  in  $B_i$  classification,  $P(B_i)$  is the probability of occurrence of  $B_i$  classification.

### C. Classification Model Design

Based on the characteristics of existing models, this paper selects CNN, LSTM and Bert models to combine with LNFE as the new deep learning model, and designs LNFE, CNN, LSTM and Bert classical models as the contrast to judge the classification effect of the new deep learning model.

- LNFE-CNN model

LNFE can use patent text feature extraction to form a vocabulary network. CNN cannot extract the context, semantic information of the patent text. The LNFE-CNN model combines the characteristics of a vocabulary network and convolutional neural network to improve the training speed. Fig. 3 is the schematic diagram of the LNFE-CNN model.

Fig. 3. Schematic diagram of the LNFE-CNN model

- LNFE-LSTM model

LNFE-LSTM model short-term memory is a special RNN network, which is mainly used to solve the problem of gradient disappearance and gradient explosion during long sequence training. LSTM mainly has three gate structures: forgetting gate, input gate and output gate. The forgetting gate, mainly decides to give up the information and leave important information. The input gate, mainly determines which information is added, and the output gate determines which

information can be output after judgment. The supplementary calculation formula of the LNFE-LSTM model is as follows:

Forgotten Gate

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \quad (4)$$

Input gate

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \quad (5)$$

$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C) \quad (6)$$

$$C_t = f_t \cdot C_{t-1} + i_t \cdot \tilde{C}_t \quad (7)$$

Output gate

$$O_t = \sigma(W_O \cdot [h_{t-1}, x_t] + b_O) \quad (8)$$

$$h_t = O_t \cdot \tanh(C_t) \quad (9)$$

In this paper, we propose an LNFE-LSTM model, which can accurately extract patent features through LNFE, combine LSTM text classification to deal with long text classification problems, and has the characteristics of context semantic features.

- LNFE-Bert model

The Bert model perfectly considers the bidirectional semantic features, while retaining the maximum meaning of the text according to the context word order features. This paper accurately extracts the patented features through LNFE, combines Bert (Bidirectional Encoder Representations from Transformers) [25] with the bidirectional transformers encoder, trains the model through the masked language model and next sentence prediction, Have strong sentence expression ability. The supplementary calculation formula of the LNFE-Bert model is as follows:

$$(\theta, \theta_1, \theta_2) = L_1(\theta, \theta_1) + L_2(\theta, \theta_2) \quad (10)$$

$$L_1(\theta, \theta_1) = -\sum_{i=1}^M \log_p(m = m_i | \theta, \theta_1), m_i \in [1, 2, \dots, |V|] \quad (11)$$

$$L_2(\theta, \theta_2) = -\sum_{j=1}^M \log_p(n = n_j | \theta, \theta_2), n_j \in [IsNext, NotNext] \quad (12)$$

### D. Evaluation Indicators

In order to evaluate the classification effect of the LNFE method combined with deep learning, this score uses Precision, Recall and F1 values as evaluation indicators, and judges the feature extraction ability of the LNFE method by comparing various indicators of LNFE, CNN, LNFE CNN, LSTM, LNFE LSTM, Bert, and LNFE Bert models. Formula (13-15) is the calculation formula of the P value, R-value and F1. Generally, the higher the P value is, the higher the prediction accuracy is which proves that the stronger the prediction ability of the model is, the higher the R-value is, the better the model is, and the better the classification effect is. Since the single expression of the P value and R-value may lead to incomplete measurement standards due to the uneven distribution of data, F1 value can better evaluate the model by means of a weighted average.

$$P = \frac{\text{Predicted number of correct samples}}{\text{All predicted results}} \quad (13)$$

$$R = \frac{\text{Predicted number of correct samples}}{\text{All results in the sample}} \quad (14)$$

$$F_1 = \frac{2 \cdot P \cdot R}{P + R} \quad (15)$$

#### IV. MODEL EVALUATION AND RESULT ANALYSIS

##### A. Experimental Platform and Parameter Selection

The processor of the experimental platform used in this paper is Dual Core Intel Core i7, the memory is 8 GB (2133 MHz) LPDDR3, and the GPU is Nvidia 2080Ti. The operating environment is Python 3.9, the network framework is PyTorch, and the training models are CNN, LSTM, BERT, LNFE, LNFE-CNN, LNFE-LSTM, and LNFBERT. Among them, CNN, LSTM and BERT are general comparison networks in current patent classification research, and LNFE is a neural network that only uses the LNFE method as a feature extraction method. LNFE-CNN, LNFE-LSTM and LNFE-BERT are neural networks constructed by combining the extracted features of LNFE with the original features. Through analysis, it is found that the LNFE method has a high correlation with the classification in the first 40 words on average in the extracted feature times, so the LNFE method intercepts 40 words for training. In the training process, Table I is selected as the parameter of the neural network for training.

TABLE I. NEURAL NETWORK PARAMETER SETTING

net	learn rate	bach size	word size	word vector
CNN	5.00E-4	64	240	200
LSTM	5.00E-4	64	240	200
BERT	3.00E-5	32	240	200
LNFE	1.00E-3	32	40	240
LNFE-CNN	1.00E-3	64	240+40	200
LNFE-LSTM	1.00E-3	64	240+40	200
LNFE-BERT	5.00E-5	32	240+40	200

##### B. Data Source and Preprocessing

In this experiment, the "part" in the main IPC classification number is selected as the classification basis. The classification data is from the incoPat patent database. The obtained patent information includes the title, abstract, IPC main classification number, independent claims and other information. The uniform distribution of data in the learning features of the model is conducive to improving the learning effect of the model. Therefore, patent data are randomly selected from the eight IPC ministerial classifications of patents, and 125064 patents are screened through data denoising. In order to evaluate the effectiveness of the model, cross-validation method is adopted. The paper experiment extracts 80% of the collected data as the training set, 10% as the verification set, and 10% as the test set. The data distribution of the patent data set is shown in Fig. 4.

Fig. 4. Data distribution

##### C. Patent Text and Word Vector

The title and abstract of a patent are a summary of patent documents. Independent claims fully represent technical solutions and necessary technical features. This information can be used as a feature source of patent classification. To classify patents using deep learning, we first need to import the text to a word vector into the neural network, so we need to use Word2vec to convert Chinese patent text information into a word vector and then import it into the neural network for learning. This paper combines several neural networks, including Word2vec, CNN, LSTM, Bert, and so on. The vocabulary length of the training text is fixed during the training process. Table II shows the statistics of the vocabulary length of patent texts. The vocabulary queue of most patent texts is between 200 and 400, with an average vocabulary length of 241. In this paper, 240 words are used as the text cutting position, and the missing parts are filled with 0 vectors.

TABLE II. MODEL PARAMETER SETTINGS

Data	Sample length below 200 words	200 words - 400 words	Sample length above 400
Training	12309	62819	20192
Validation	712	13890	1201
Test	819	13210	1192

##### D. Vocabulary Network Generation

In the process of vocabulary network generation, 125064 patent documents generated 272141-word vectors, and 241524-word vectors remained after removing stop words and merging synonyms. By calculating the Spearman correlation and Bayes probability weighting of words and tags, 30080 words with strong correlation characteristics were obtained and classified, and their word network is shown in Fig. 5. Each point in the vocabulary network represents a word. The position of the point is the mapping of the high latitude of the word vector in the low dimensional. The shorter the distance between the points, the closer is the part of speech. The colors of the dots represent different parts of the patent classification related to the word. It can be found from the number of related words that a large number of words have a strong relationship with some categories. From the distribution of words, the meaning of words is also related to classification, which also confirms the above statement that "Chinese patent texts are sensitive to words classified by social production practices such as industries and industries".

Fig. 5. Vocabulary network diagram

### E. Model Training

The deep learning model used for classification is usually trained at the full connection layer after feature extraction. Finally, the data are classified through SOFTMAX. After repeated training, the accuracy of classification is improved. In order to verify whether the LNFE method has the ability of

Fig. 6. LNFE training process

Word2vec+LNFE method is slightly higher than other networks; it is lower than traditional neural networks combined with the LNFE method. This is because the LNFE method only extracts features in probability and linear dimensions, while

feature extraction, the LNFE method is used as the feature extraction layer of the neural network to test the classification results. First, after removing the stop words and vectorization of the Chinese patent text, the similarity analysis of the word meaning with the words in the vocabulary network is conducted, and the words in the word segmentation results of the patent text are replaced with highly similar words in the vocabulary network to merge the multi-word consent words. According to the weighted results of words and classification, the word vector of 40 words with the highest weight is selected as the feature, which is sent to the network layer for training. The training process is shown in Fig. 6. After several iterations of training, the accuracy of the model can be found to improve rapidly. This result confirms that the LNFE method indeed extracts classified feature data.

### F. Accuracy Verification

After the LNFE method is confirmed to have the feature extraction capability, this section verifies the feature extraction effect of LNFE by comparing it with other networks. Table III shows the comparison results between the LNFE method and other networks. During the validation process, it is found that traditional neural networks have improved after combining the LNFE method, while Bert has limited improvement ability to Bert due to its excellent feature searching ability. Although the

traditional networks consider more dimensions. Because the LNFE method has the characteristic of being Embeddable for neural networks, it has practical value.

TABLE III. CHINESE PATENT TEXT CLASSIFICATION RESULTS

Number	Model	P/%	R/%	F1/%
1	Word2vec + LNFE	81.16	73.24	77.00
2	Word2vec + LSTM+ Attention	78.83	65.23	72.20
3	Word2vec + LNFE-LSTM + Attention	81.02	69.12	74.60
4	Word2vec + CNN	79.32	66.43	72.89
5	Word2vec + LNFE-CNN	81.57	74.51	77.88
6	Bert	82.31	76.13	79.10
7	LNFE-Bert	<b>82.73</b>	<b>78.31</b>	<b>80.27</b>

### G. Data Analysis

The classification results after CNN and Bert classify separately and combined LNFE method is shown in Fig. 7. Because the text features found by the LNFE method are more explicit, LNFE CNN has a faster convergence speed than CNN. At the same time, LNFE CNN may learn more text features than CNN, so the accuracy of LNFE CNN is slightly higher than CNN. The LNFE method has the prior probability of

words in the patent text so that LNFE Bert can find the complex functions of features and classification earlier than the Bert model in the training process, that is, the LNFE Bert model converges earlier than the Bert model. However, Bert's model pays more attention to the feature extraction of text. After a lot of training, the accuracy of the Bert model and LNFE Bert is almost the same. Therefore, it can be determined that the LNFE method can improve the learning ability and classification accuracy of traditional deep learning models.

### V. CONCLUSION

When comparing many text classification materials, it is found that the accuracy of the classification results of Chinese patent texts is lower than that of other texts. Through repetition experiments and analysis and verification, it is concluded that patent documents are insensitive to context due to special formats, and the traditional deep learning model has insufficient ability to extract features of Chinese patent texts. These two reasons lead to slow convergence speed and low accuracy of the model. In order to solve this problem, this

paper proposes an LNFE feature extraction method, which uses Spearman and Bayes to obtain the prior probabilities of vocabulary and classification from the probability and linear dimensions respectively, constructs the network relationship between vocabulary and classification in a weighted way, and uses the features extracted from the vocabulary network to fuse with the features extracted from the deep learning model for classification. The method differs from the traditional method of improving the accuracy of the model by altering the neural network, by extracting the patent text features in depth through the prior probability of the text, thus allowing the combination

of various neural networks to enhance the performance and accuracy of the network in patent text classification. The experimental results demonstrate that the method speeds up the convergence of the model to a certain extent and improves the classification accuracy of the model. However, in this paper, only a ministerial lexical network is constructed to validate the method for Chinese patent text classification. In future work, we will try the method for more fine-grained patent classification in the case of feature extraction, and try the method in other text classification to verify whether the method is universal.

In future research, we will enrich the construction methods of patent text features based on how to make more subtle potential features of patent text, so as to improve the classification performance of the model. At the same time, it will also further explore the performance of the model applied to other tasks in the field, and consider how to deal with multi-classification problems to provide better help for researchers.

**Abstract**—The Internet of Things means that many of the daily devices used by humans will share their functions and information with each other or with humans by connecting to the Internet. The most important factor of the Internet of Things is the integration of several technologies and communication solutions. Identification and tracking technologies, wired and wireless sensors and active networks, protocols for increasing communication and intelligence of objects are the most important parts of the Internet of Things. In this article, an attempt has been made to determine the parts that can be used to make a house smart among the concepts and technologies related to web-based programs based on Internet of Things technology. Since it is very time-consuming to investigate the effect of all the Internet of Things technologies in smart homes, by studying and examining various types of research, the web-based program based on the Internet of Things is selected as an independent variable, and its effect on smart home management is investigated. For this purpose, a web-based program based on the Internet of Things for intelligent building energy management, intelligent equipment management, and intelligent security has been designed and implemented. As experimental results shown the proposed method the proposed method achieves better results compared to other existing methods in energy consumption by 33.8% reducing energy usage.

**Keywords**—Internet of things technology; smart homes; intelligent energy management; fuzzy logic

## I. INTRODUCTION

At the end of the 20th century, with the development of smart technologies, the development of communication networks and the Internet, the development of sensor networks and sensors, extensive efforts and studies began to use these technologies in order to provide solutions to improve human life [1-5]. One of the important applications of these technologies was communication with objects and obtaining information through these objects. This paradigm was presented for the first time by Kelvin Ashton in 1998 in a mockery. In fact, solutions are presented that could be used to communicate with anything through the Internet at anytime and anywhere and to identify them in the network. Access to environmental information and its status provided new forms of communication between people and objects and even between the objects themselves. It led to the introduction of the Internet of Things, which, in addition to people and information, also contained objects [6,7]. The definition of objects, according to European research projects on the Internet of Things, are all active participants in business, information,

and processes that can interact and communicate with each other and with the surrounding environment and exchange data and information in the environment. They deal with sensitive things, and they also have the possibility of reacting to real and physical world events. Objects have an effective role in the running processes. They also have the possibility of creating actions and services with or without direct human intervention. The Internet of Things is one of the new technologies that can be used in exploration and production processes, refineries, petrochemicals, pipelines, transportation, and distribution. This technology in the industry increases employee security, identifies health and safety issues, optimizes production, tolerates errors, and reduces operating costs. After the publication of the Internet of Things as a solution to communicate with objects and collect information from them, architectures were presented to establish and implement this solution.

IoT, which also includes machine-to-machine (M2M) communication, is a new technology that is used to connect all objects through the Internet for remote measurement and control. The Internet of Things uses several other technologies, such as wireless sensor networks, robotics, Internet technology, and smart devices. Conceptually, Internet of Things technology means a network of real-world entities, each of these entities or objects has a unique address and communicates and interacts with each other based on standard communication protocols. In fact, the Internet of Things technology makes it possible for objects around humans or objects in a building and house to exchange information with each other virtually, and by creating synergy; it causes a significant growth in optimal energy consumption and human life quality [8-10]. Currently, Internet of Things technologies are available, and its services and achievements can be used in various fields. Knowing the capacity and potential of the above technology is very important. While choosing the correct path to use in business and life, its opportunities and threats should be considered. Intelligence is one of the topics that has attracted the attention of many researchers in all branches of the modern science in today's world. Even today, cities can have the concept of intelligence. A smart city is where traditional networks and services are made flexible, efficient, and sustainable using information, digital, and communication technologies to improve city operations for the benefit of its residents and create a greener, safer smart city. They are more, faster, and friendlier [11-14]. These components make cities smart and efficient. Information and communication technology (ICT) is the key to transforming traditional cities into smart ones. Two

technological infrastructures named IoT and big data (BD) make smart cities efficient and responsive.

The construction industry is not exempted from this category. Significant actions have come to the fore during the last three decades. One of the most important developments in the construction industry is the issue of smart homes, which is manifested in residential and non-residential buildings of the 21st century with the advancement and integration of new technologies and with the help of electronic, computer, and network sciences. The possibility of its increasing development during the coming years has been provided. A collection of tools, techniques, and technologies for better management and control of homes to increase the comfort and peace of the home space is referred to as a smart home. In general, a smart home is a type of building equipment to create a pleasant environment that can turn the home space into a building with higher security, optimal energy consumption, and more security [15-18]. Nowadays, the development of smart homes to help people live more comfortably has been the focus of many researchers. Helping elderly and disabled people, creating more security [19], energy consumption management [20], and medical care [21] are among the motivations for the development of such environments.

The main work and the items needed for the temporary implementation of this research work is a browser that can communicate directly with an active device on the Internet. Devices that can cooperate have the ability to communicate with sensors, actuators, and other devices. One of the important features of web-based programs is their usability. The web pages in these programs are not simple pages that only contain a series of colors and simple images; each of these pages works like a web-based program, and due to the quick modifications, that can be made in the usability of the content of these pages. The web has happened. The content of web-based programs can be presented to users more dynamically than before. These programs extract data online from various sources and display it on web pages through browsers. Also, the growth and expansion of the smart grid are accompanied by fundamental changes in the distribution networks. These changes cover different areas from consumers to distribution companies and electricity retailers. On the one hand, electric energy retailers confront consumers with real-time or near-real-time changes in the price of delivered electric energy. On the other hand, with the growth and advancement of technology, scattered products in home sizes and with an acceptable initial cost will be available to consumers. Therefore, home consumers face a problem in the time and amount of use of the electric energy sources they need. In addition to this issue, the time of using the required household appliances during the day, taking into account the level of consumer satisfaction, adds to the complexity of the problem. With the growth and expansion of factors in smart electric networks, this article considers the design of a decision factor to solve this issue. The purpose of this factor is the optimal use of various sources of electric power supply available to the consumer, including sources of distributed household production and electricity purchased

from the grid, taking into account the level of satisfaction of the consumer from the time of using their household appliances [22-25].

In control systems, different approaches are used to receive information, measure the situation, and how make decisions and react. One of the widely used and common approaches in control systems is the fuzzy approach and fuzzy logic. Fuzzy logic is a form of logic used in expert systems and artificial intelligence applications [26,27]. Fuzzy logic is more general than other conventional logical approaches. The main factor of this generality can be seen in having the attitude of solving a complex problem in the form of a search space and making a decision based on the status of the question, answer, and control. This logic provided a basis for developing new tools, interacting with natural language, and displaying knowledge. An automatic lighting control system automatically turns off unnecessary lighting sources. Automatic lighting control systems by turning on and off lighting sources at different times and situations, as well as reducing the brightness of the lighting source based on the state of external factors around that source, will reduce energy consumption and increase the lifespan of lighting equipment [28-30]. Conventional control design methods use mathematical models to develop control systems and controllers. Fuzzy control refers to the concept of control from the point of view of linguistic description. Standard fuzzy logic can be easily applied and used in industry and industrial applications because it has a simple control structure, and its design is not a complicated and costly process. Based on fuzzy logic studies, dynamic fuzzy logic control has a more suitable performance than fuzzy logic control. In order to control the controller, several dynamic fuzzy technologies have been proposed, as examples of which we can point out the regulation of membership, the regulation of the input/output scale factor, and the regulation of descriptive rules. In this study, a fuzzy control system will be used to regulate the input and output of electricity and control the voltage of the smart home. For this purpose, after examining the fluctuations in the input voltage of the house, the designed system decides to turn off or light the house in such a way that the goal is to create maximum stability of the activity of the smart home components. The main goal is to design and implement a smart building management system using Internet of Things technology.

The main objectives of this study are as follows:

- 1) To develop a method to determine the parts that can be used to make a house smart among the concepts and technologies related to web-based programs based on Internet of Things technology.
- 2) To implement a sensor-based automation system based on the Internet of Things for intelligent building energy management, intelligent equipment management, and intelligent security has been designed and implemented.
- 3) To use a fuzzy inference system to control smart home operations in Internet of Things technology.

## II. LITERATURE REVIEW

The improvement of energy management, home security, environmental control, and other areas of smart home automation systems has been the focus of several research publications and existing literature. For analysis, prediction, and classification purposes, machine learning techniques have also been used in the IoT sector. The articles in this section of the IoT library address machine learning applications in intelligent systems and smart home automation.

A smart home automation system leveraging IoT technologies was presented by Govindraj et al. [34] to replace the current home automation system. Through the use of a satellite station and a radio frequency transceiver, the suggested system employs an Android application to monitor and regulate household appliances, temperature, motion, and gases. The ThingSpeak cloud platform is used to store sensor data. The essential commands for home control are delivered by a base station. Additionally, a mobile application with a graphical representation of sensor readings was developed to connect to the satellite station, base station, and cloud server for overall control of the house.

Rani et al. [35] suggested an artificial intelligence (AI) and natural language processing (NLP)-based voice-controlled home automation system. Voice commands are sent to a mobile phone to operate household appliances, and the phone's built-in natural language processing system decodes them. The system was simply utilized to operate household appliances; it was not expanded to include other parts of home automation like control, monitoring, and motion and intrusion detection.

A low-cost smart home system design and prototype implementation was presented by Aadel and Ali [36]. The system was made to regulate the temperature, power, lights, and doors in the house. An Arduino board, servo motors, LED lights, temperature, and motion sensors were used to demonstrate a prototype implementation of the system. The INA219 high-side DC sensor was used to monitor the drop and supply of power, the DHT11 temperature and humidity sensor was used to measure the temperature and humidity in the house, and the door and windows were controlled by servo motors. The communication method employed by the system was Bluetooth, which has a limited range of communication.

Parsa et al. [37] suggested a system for the optimal and autonomous regulation of electrical home equipment. By automatically turning on and off the smart plugs connected to certain home appliances at the proper times, the suggested system is designed to reduce power usage. To choose the ideal period of use prior to implementing the automatic switch in accordance with the established criteria, an optimization approach was applied. The system's design gives the supplier the upper hand over the household's electrical user.

The design of an embedded smart house control and monitoring system employing an STM32 microcontroller was presented by Xiaodong and Jie [38]. Their technology was created for home control and interior environmental conditions monitoring (temperature, humidity). To communicate remote control and Zigbee terminal connectivity between the home gadgets, the authors used a GSM and GPRS module. Their

method was implemented using a combination of coordinated remote control, feedback, and embedded real-time operating system (COS-II) for home appliances.

## III. PROPOSED METHOD

The proposed load model assumes that each user has different devices with different energy needs, power demands, and working hours. Equipment can be divided into two categories: permanent load and temporary load, and each load model have its characteristics. Devices with constant load (refrigerator, heating, cooling, water heater, electric kettle, air conditioning, etc.), this type of load are known as energy consumption/production, which covers the entire time interval of the energy simulation program. Temporary load devices, this type of load is known by the start time and end time of the operation. This subcategory can be divided into two other subcategories such as (TV, lighting, cooking, hair dryer, etc.). The first one represents the devices that are the main choice of users and cannot be used backward (such as laptop chargers, washing machines, etc.), which is a "transferable burden". The second subcategory is more flexible and can be used at other times. Each of these two load models can be control or binary devices. Control devices are devices with different states to stay on, and binary devices have only two states, on or off. The proposed system of this research combines different factors that react to their environment based on a set of predetermined instructions. An agent is an entity that is created to perform tasks. An intelligent agent is an autonomous entity that perceives its environment through sensors and responds to the environment using stimuli [31]. This agent tries to maximize his desired productivity.

### A. Coordinating Agent Modeling

Considering a set of  $A=\{a_1, a_2, \dots, a_N\}$  devices in which each device has its proportional energy consumption. For each  $a \in A$ , the energy consumption vector of  $Y_a$  is calculated as equation (1).

$$Y_a = [y_a^1 \dots y_a^H] \quad (1)$$

Where  $H=24$  hours,  $H$  is the timing range that indicates the number of hours per day that can be used by  $a \in A$  device. The coordinating agent considers the computational domain  $H$  to decide on the energy consumption schedule.  $y_a^j (j \in \{1..H\})$  represents the energy consumption for a device ( $a$ ) in one hour. For each  $a \in A$ , the user specifies the convenience of the  $(a_a < \beta_a)$   $a_a, \beta_a \in H$  range, while the beginning and end of a time make it possible to schedule energy consumption for the device. But  $(\beta_a - a_a)$  must be greater than the time required for  $(t_a^{req})$  to complete the normal process of the device ( $a$ ) as described in equation (2).

$$\beta_a - a_a \geq t_a^{req} \quad (2)$$

where  $a$  is the start time of the device operation,  $\beta$  is the end time of the device operation. Also, the total daily energy consumption for each device is defined as equation (3).

$$EC_a^o = \sum_{h=a_a}^{\beta_a} y_a^h \quad (3)$$

$y_a=0$  is expected to be for all  $h>\beta$  and  $h<a_a$ . Upper and lower limits have been specified for  $y_a$ , which are used in the selection of the energy consumption scheduling vector.

$$\delta_a^{\min} \leq y_a \leq \delta_a^{\max} \quad (4)$$

where  $\delta_a^{\min}$  is the minimum standby power level, and  $\delta_a^{\max}$  is the maximum power level. For each center, the total energy consumption per hour must be less than or equal to the predetermined energy threshold ( $E^{\max}$ ), as calculated in eq. (5).

$$EC^{oTotal} = \sum_{a \in A} y_a^h \leq E^{\max}, \forall h \in H \quad (5)$$

where  $E^{\max}$  and  $EC^{oTotal}$  are used as the input/output of the fuzzy system, respectively as an index of the fuzzy threshold limit and power demand. By combining eq. (3) to (5), energy consumption timing vector choices are determined. Therefore, the timing set  $Y$  for all  $y_a$  can be determined as eq. (6).

$$\left\{ \begin{array}{l} y | EC_a^o = \sum_{h=a_a}^{\beta_a} y_a^h, \\ \forall a \in A, \beta_a - a_a \geq t_a^{req}, \\ \delta_a^{\min} \leq y_a \leq \delta_a^{\max}, \\ \forall a \in A, h \in [a_a, \beta_a], \sum_{a \in A} y \leq E^{\max} \end{array} \right. \quad (6)$$

where  $y=(y_a; A_a \in A)$  represents the energy consumption scheduling vector that contains all the variables for all devices. Therefore, a vector  $y$  is true only when  $y \in Y$  is true.

### B. Permanent Factor Modeling

The permanent factor is related to any permanent load device. In this subcategory, loads flow regularly and depend on the device's internal temperature. Also, the comfort range depends on the high and low levels of  $[T_{ac}^{\min}, T_{ac}^{\max}]$  temperature. The permanent agent tries to maximize the satisfaction function of each permanent load device.

$$SF = \left\{ T \left| \begin{array}{l} SF(T) = SF(T_{ac}^{\min}) = SF(T_{ac}^{\max}) = 100, \\ \forall T \in [T_{ac}^{\min}, T_{ac}^{\max}] \end{array} \right. \right\} \quad (7)$$

A constant load device's satisfaction function depends on its descriptive variable. For example, the air conditioning service is dependent on its temperature (T), which is seen in Fig. 1, and a user is satisfied if the temperature of the room in which he is sitting is 21°C to 22°C.

In order to avoid the peak load demand without affecting the user's comfort, the permanent agent uses the scheduling operation method, shown in relations (4) and (5). The flexibility of this service comes from the possibility of editing the quantities of energy consumed/produced in all periods. Therefore, it increases or decreases the factor with the assumed limits  $[\delta_a^{\min}, \delta_a^{\max}]$  of each device.

Fig. 1. Depending on the satisfaction of air ventilation

### C. Temporal Agent Modeling

The temporary factor is related to any temporary load device. Mandatory execution load starts when the user requests execution. Since the force consumption is constant, there is no other option but to regulate its operations in the normal force demand and these tasks do not need scheduling. However, in periods of high-power demand of the provider, the operator is instructed to use the fuzzy system to control the required load operations. The transferable load starts its duty when the temporary factor (such as the dishwasher) is according to the comfort zone of the user  $[a_a, \beta_a]$  and the limit of the relationship (3) of the operation of each device. The satisfaction function of a temporary load device is dependent on the transfer time in service  $[a_a, \beta_a]$ , which is also dependent on the optimal time of the user's request, shown in equation (8). For example, the user wants his clothes to be cleaned at 9:30 AM, which can be seen in Fig. 2.

$$SF = \left\{ t \left| \begin{array}{l} SF(t) = SF(a_a) = SF(\beta_a) = 100, \\ \forall t \in [a_a, \beta_a] \end{array} \right. \right\} \quad (8)$$

The temporary agent used the existing list of priorities prepared by the coordinator and then used three types of fuzzy logic based on the control strategy as an efficient solution to transfer the required power of the devices in periods of high demand.

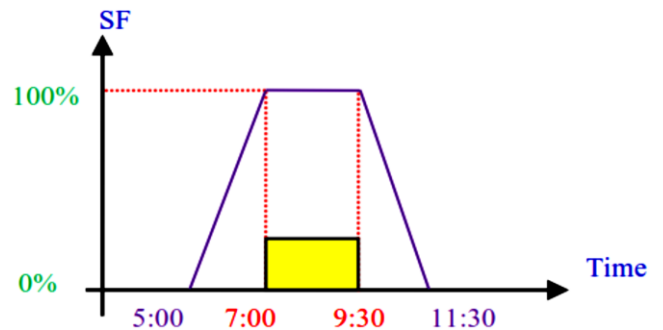

Fig. 2. Washing machine satisfaction function

## IV. PROPOSED FUZZY INFERENCE SYSTEM

In this section, the proposed fuzzy inference system is discussed. Principally the controlling of smart devices in IoT systems is not contained absolute value to control the various processes. Therefore many-value with approximate number ids

required to use in these systems Fuzzy logic is a form of many-valued logic in which the truth value of variables may be any real number between 0 and 1. It is employed to handle the concept of partial truth, where the truth value may range between completely true and completely false [33].

Fig. 3 shows the block diagram of the proposed fuzzy inference system.

The proposed method has two inputs and one output variable. In the fuzzification stage, the fuzzy controller receives the inputs and maps them to their membership functions, called fuzzy sets. The degree of membership in the fuzzy set  $\mu$  for the input  $x$  is determined in the fuzzification step. This degree of numerical membership is between 0 and 1. The value 0 means that  $x$  is not a member of the fuzzy set; the value 1 means that  $x$  is completely a member of the fuzzy set. The values between 0 and 1 specify the fuzzy members, each of which partially

belongs to the fuzzy set. The membership function (MF) is a curve that specifies how to map each point in the input space to the membership value (or degree of membership) between 0 and 1. Sometimes the entrance space of the community is also called the entrance. The most used shapes for membership functions are triangular, trapezoidal, and Gaussian. In the proposed method, membership functions assigned to input and output variables are considered triangular. The edges of the triangle can be specified by the triplet  $(a, b, c)$  (where  $a < b < c$ ). The parameters  $\{a, b, c\}$  of the  $x$  coordinates of the three edges of the desired triangular function are specified. Fig. 4 shows a triangular membership function  $(2, 4, 6)$ . Point 4 has the largest value in the membership function.

In this study, the fuzzy set includes a maximum of 4 states, which are different for each input membership function, which is explained in the following sections.

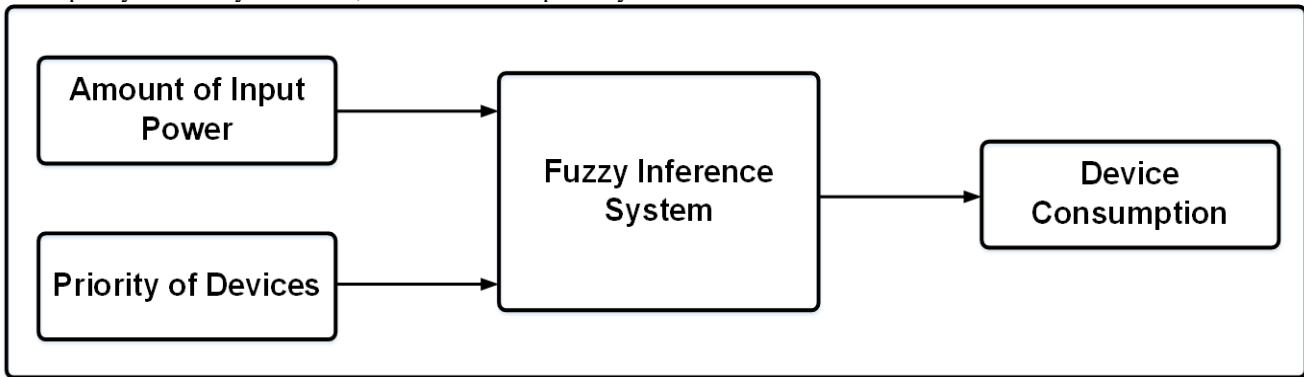

Fig. 3. Proposed fuzzy inference system.

Fig. 4. An example of a triangular membership function.

#### A. Input Power Membership Function

It is assumed that the number of input power modes equals (normal, less than normal, medium, and weak). The value of 0

indicates that the input power is weak, and more care should be taken regarding its distribution. While the value of 500 indicates the normality of the input power. The triangular membership function maps the number of input power states

from 0 to 500 watts according to the degree of membership into 4 fuzzy sets (Weak, Medium, Less Than Normal, and Normal). This allocation is shown in Fig. 5.

According to Fig. 5, the fuzzy sets of this function are {Weak: triangle [0 0 1800]}, {Medium: triangle [0 1800 3500]}, {Less Than Normal: triangle [1800 3500 5000]}, {Normal: triangle [3500 5000 5000]}.

### B. Priority Membership Function

The Priority membership function determines the priority of the device, which in this research includes (low, medium, important, and very important) states. A value of zero for this function indicates a low priority state, a value of 1 indicates a medium priority, a value of 2 indicates an important priority, and 3 indicate a very important state. The triangular membership function maps the number of device priority states from 0 to 3 according to the degree of membership into 4 fuzzy sets (Low, Medium, Important, Very Important).

This assignment is shown in Fig. 6. The fuzzy sets of this function are {Low: triangle [0 0 1]}, {Medium: triangle [0 1 2]}, {Important: triangle [1 2 3]}, {Very Immortan: triangle [2 3 3]}.

### C. Device Usage Membership Function

The Device Usage member function specifies the amount of device usage. In this study, the Device Input Type variable is determined, which includes (control and binary) modes. Suppose it is a control device such as a fan. In that case, the amount of consumption of the device is decided by reducing the input power and the priority of the device. This type's device consumption includes (off, low, medium, and high) modes. For example, a ceiling fan with a consumption value of [65 75], a value of zero for this function indicates that it is off, a value of 65 low consumption and 120 consumption It is average, and the value of 175 shows a high state. The triangular membership function maps the number of device usage states to 4 fuzzy sets (Off, Low, Medium, High) according to membership degree. This allocation is shown in Fig. 7. The fuzzy set of this function is {Off: triangle [0 0 65]}, {Low: triangle [0 65 120]}, {Medium: triangle [65 120 175]}, {High: triangle [120 175 175]}.

If the type of input device is binary, we will have only two states, off and on, which determine the amount of consumption of the device. In this case, the Device Usage membership function will be Fig. 8.

The fuzzy set of this function in this type of device is {Off: triangle [0 0 1]}, {On: triangle [0 1 1]}. The input variable states with these diagrams do not change quickly from one state to the next. Instead, when the input changes, it loses a value in one membership function while gaining another value in the next state. In other words, an input variable with a specific membership degree is a part of two membership functions. For example, in Fig. 7, when the Input Power is equal to 200 watts, the input completely belongs to the membership function of Medium. However, when the Input Power is equal to 280 watts, the input is partially (0.5 each) a part of two membership functions, Medium and Important. Generally, a fuzzy system is formed based on human

experience and expert information. The limits of the modes are also defined in the same way.

### D. Fuzzy Inference System

An inference engine is equipped with fuzzy rules to decide on an output channel based on the current state of the network. An inference engine with a set of linguistic statements to describe the system using the number of conditional rules (if-then) where the if-then part is specified by (precedence) and the then part is specified by (tail). Usually, the knowledge of an expert is used to form the rules of the fuzzy inference system. Table I contains rules used in the proposed method for control devices with two fuzzy inputs and one fuzzy output. This table contains different output values for different input ranges. Filling a data table with fuzzy attributes (scalability) is a matter of taste.

Table II contains rules that are used in the proposed method for binary devices with two phased inputs and one phased output. These tables are prepared based on basic knowledge about the effect of each criterion on the overall performance of the proposed method.

The fuzzy rules usually combine several assumptions using fuzzy operators such as fuzzy intersection (AND) and fuzzy union (OR). If the rule uses the AND relationship to map two input variables, at least these values are used as output. In contrast, for the OR relationship, the maximum is used. In the proposed method, the AND operator is used to combine the fuzzy inputs.

The example in Fig. 7 helps clarify the issue. Input Power and Priority parameters have values of 250 and 1.8, respectively. As shown in Fig. 9, Input Power is a part of the membership functions of Medium and Less Than Normal, and the part of each membership function is 0.5. The Priority entry is a part of Medium and Important membership functions, shown in Figure 10. In this case, the degree of membership for membership functions Medium and Important is 0.2 and 0.8, respectively. The fuzzy sets of this function are {Weak: triangle [0 0 0.33]}, {Medium: triangle [0 0.33 0.66]}, {Less Than Normal: triangle [0.33 0.66 1]} {Normal: triangle [0.66 1 1]}.

Fig. 9 and 10 shows the Input Power and Priority values, the four combinations between Input Power and Priority are shown in Fig. 11(a) Input Power: Medium and Priority: Important, Fig. 11(b) Input Power: Medium and Priority: Medium, Fig. 11(c) Input Power: Less Than Normal and Priority: Important, Fig. 11(d) Input Power: Less Than Normal and Priority: Medium.

### E. Composition and Defuzzification

Defuzzification is the process of producing a measurable result in fuzzy logic and converting the fuzzy control action to a definite value. The output of all rules must be collected and converted into a single output. Two methods are widely used for defuzzification. Method 1 Center of Gravity (CoG): This method finds the geometric center. Also, this method selects the output with the largest area. Method 2: Maximum mean (MoM): This method gives the values that have the maximum degree of membership according to the fuzzy membership function.

It is simpler but loses useful information, while CoG, which is used as a common method, is more efficient. CoG is our chosen defuzzification method to produce a definite value in this research. In the phase of defuzzification, the four output values obtained in Fig. 11 are combined, and a single output is extracted using the center of gravity method. As shown in Fig. 12, the fuzzy outputs of the membership function with the

same output are added together, while the values in different membership functions are taken together (that is, their maximum value is considered).

The output value can be calculated from eq. (9).

In this case, the output value is equal to eq. (10).

$$\text{Obtained DeviceUsage} = \frac{\text{Obtained DeviceUsage}}{\text{Degree of Membership Functions}} \tag{9}$$

$$\text{Obtained DeviceUsage} = \frac{(0.33 \times 0.2) + (0.33 \times 0.5) + (0.33 \times 0.2) + (0.66 \times 0.5)}{0.2 + 0.5 + 0.2 + 0.5} \cong 0.45 \tag{10}$$

$$EC^{oTotal} = \sum_{a \in A} y_a^{h=1} = 420 + 300 + 1800 + 1500 + 2000 = 6020W \tag{11}$$

$$ES(\%) = \left(1 - \frac{EUA_{After}}{EUB_{Before}}\right) \times 100 \tag{12}$$

$$EUB_{Before} = 420 + 300 + 1800 + 1500 = 4020W ,$$

$$EUA_{After} = 210 + 267.6 + 1274.2 + 666.7 = 2418.5W ,$$

$$ES = \left(1 - \frac{2418.5}{4020}\right) \times 100 = 39.8 \tag{13}$$

According to this formula, the degree of the membership function of each rule is multiplied by the maximum value in the membership functions in the output value and then divided

by the sum of all the values of the membership function. In this example, the power consumption of the device is set to Medium in Fig. 13.

### V. SIMULATION EVALUATION

In this section, the simulation results are evaluated. The simulation was done with MATLAB software. Each load group is coordinated with a scheduling policy to reduce energy by compressing power demand or postponing requests. In this section, some devices' power demand control behavior and the type of control used have been analyzed. Refrigerators and freezers can be used for a short time, provided the temperature is kept within a certain range. The agent can predict the energy needed for the next time by observing the T parameters and the time the door is open. The permanent agent uses the scheduling policy according to the comfort range of  $[T_{ref}^{min}, T_{ref}^{max}]$ .

The washing machine and dishwasher are binary devices with only two states, on or off. Therefore, the temporary agent predicts its consumption and gives users the price of electricity at the time of use, which the provider provides. The user can benefit from washing at night at a lower price. For example, the user expects the dishes to be ready by dinner, so he sets the time of use as  $\alpha=2$  PM and  $\beta=6$  PM. So, suppose it is at the peak of electricity consumption or during the electricity fluctuation. In that case, this device will be turned off and transferred to a more suitable time. Television is a device whose power level is flexible. The TV has three functions with three levels, so the temporary agent uses a scheduling policy. If the threshold is soon reached, and some devices cannot be stopped, the agent switches the TV's function to ambient light or standby mode. Be with the level. TV is a device whose power level is flexible. The TV has three functions with three levels, so if the threshold is reached soon, the temporary agent will use the timing policy. Some devices cannot be stopped, so that the agent will adjust the TV function to the ambient light or mode. Ready to work with level  $y_a = \delta_a^{min}$ . The water heater is very important when the user wants a quick shower. However, for the user who has planned his bath time, the agent can heat the water before the specified time. In addition, this factor can cut off the boiler's power for an hour without the user noticing. The permanent factor controls the daily energy of the water heater using the scheduling policy.

In this section, we analyze the power consumption control in three types of devices in the state of peak power demand in Fig. 14. The simulation was divided into 15-minute segments during the hours of the day. A set of  $(t \in Time)$  time segments was created in which  $Time = \{1, 2, 3, \dots\}$  etc.} is The minimum

and maximum power of the devices used in the strategy are refrigerator (140 to 420 W) control device, with priority 4, TV (100 to 300 W) control device, with priority 2, water heater (750 to 1800 W) control device, with Priority 3 and time satisfaction function 22-24, air heater (500 to 1500 watts) control device, with priority 3 and temperature satisfaction function 20-22 degrees Celsius, dishwasher (2000 watts) binary device, with priority 1 and time satisfaction function 14-18. Fig. 14 shows the output phase system of the refrigerator. Power below 140 watts will cause the refrigerator to turn off, and 300 watts will cause low consumption of the refrigerator, and the most consumed time of the refrigerator is 420 watts.

Fig. 15 shows the fuzzy system of TV output. Power below 100 watts will turn off the TV, and power of 200 watts will cause low consumption of the TV, and the most consumed time of the TV is equal to 300 watts.

Fig. 16 shows the output phase system of the water heater. Power below 750 watts will turn off the water heater, and 1400 watts will cause low consumption of the water heater, and the most consumed time of the water heater is 1800 watts.

Fig. 17 shows the output phase system of the air heater. Power below 500 watts will turn off the air heater, and 1000 watts will cause low consumption of the air heater and the most time-consuming air heater is 1500 watts.

Fig. 18 shows the fuzzy output system of the dishwasher. Power below 2000 watts causes the dishwasher to turn off, and power below 2000 watts causes the dishwasher to stay on.

In one hour, the house's energy is calculated based on equation (4) and should be a maximum of 3000 watts ( $E_{max}=3000$ ). If all the devices are on and have their maximum consumption, the total consumption power is calculated according to equation (11). The total power consumption is 6020 watts, which is more than the maximum consumption. Therefore, the coordinating agent predicts the peak power and performs some tasks in advance. The operation of the dishwasher can be moved to midnight. The TV will work in a low-power mode. The refrigerator can be used for one hour as long as the door is closed. The agent of the satisfaction function checks the water heater and the air heater, schedules their operations in case of peak power demand, and cuts off the devices with a low priority. The power consumption output by the proposed system is shown in Fig. 19.

In the first 15 minutes of the simulation, the refrigerator consumes 210 watts, the television consumes 267.6 watts, the water heater consumes 1274.2 watts, the air heater consumes 666.7 watts, and the dishwasher consumes zero watts. Therefore, the TV and dishwasher are turned off, and the refrigerator, water heater, and air heater are on with low consumption. In 15 minutes of the 20th simulation, the refrigerator consumes 250 watts, the television 150 watts, the water heater 900 watts, the air heater 1023.2 watts, and the dishwasher consumes 0 watts. Therefore, the dishwasher is turned off, and the refrigerator, TV, water heater, and air heater are on with low consumption. In the 56th 15 minutes of the simulation, which is the time dependent on the satisfaction of the dishwasher, the refrigerator consumes 140 watts, the television 100 watts, the water heater zero watts, and the air heater 750 watts, and the dishwasher consumes 2000 watts. Therefore, the water heater is turned off, the refrigerator and air heater are on with low consumption, and the dishwasher started working for half an hour. After the dishwasher is finished, the

water heater is turned on and continues its operation. The reduction of 15 minutes is due to the reduction in water heater consumption. In all cases, the red line in Fig. 19 shows the amount of energy consumption without the proposed research method. As can be seen, the consumption of the proposed method is always lower than the method of the article [31]. The amount of energy saving can be obtained by equation (12).

Where  $EUA_{After}$  indicates the energy consumption after the proposed algorithm and  $EUB_{Before}$  indicates the energy consumption before the proposed algorithm. In fact, building energy saving is defined as the difference ratio of energy use before and after the implementation of the proposed algorithm in the same period. Energy saving has been calculated in two intervals. In the interval [1 1], the first 15 minutes, the total energy consumption is calculated in eq. (13). In this case, the force has been reduced by 39%. In [32 39], the total amount of consumed energy was equal to 2990, and the proposed method reduced the energy by 29.1%.

## VI. CONCLUSION

The proposed load model assumes that each user has different devices with different energy needs, power demands, and working hours. Devices are divided into two subgroups: permanent load and temporary load, each of these two "load" electricity amount models can be controlled or binary devices. The proposed model of this research consists of two inputs named (amount of input power) and (device priority) and one output (device consumption). Decision-making for an output channel based on the current state of the network is equipped with fuzzy rules. The number of input power modes equals (normal, less than normal, medium, and weak). The priority of the device includes modes (low, medium, important, and very important). Suppose the device is of a control type. In that case, the device's consumption is decided by reducing the input power and the device's priority. This type's device consumption includes (off, low, medium, and high) modes. Suppose the type of input device is binary. In that case, we will have only two states, off and on, determining the device consumption amount. Building energy saving is defined as the difference ratio of energy use before and after implementing the proposed algorithm in the same period. This criterion has been used to evaluate the proposed method. According to comparison result among the proposed method with other existing methods, this method achieves better results compared to methods in energy consumption by 33.8% reducing energy usage.

**Abstract**—This study expands our comprehension of museum visitor impact within a system quality, information quality, and augmented reality (AR) media content quality on mobile applications. Museums meet new defiance of escalating expectancies of their visitors. As a result of the universal mobile phone tool, AR has arisen as the latest technology offered to the museum to increase its visitors. These expectancies are fostered by the improvement of modern technologies like AR on the mobile app. Across an online survey of 241 visitors, the study determines the constructs affecting visitor impact within museum' mobile apps and the consequential results of AR-linked visitor impact. The study proposes a recent set of AR features, explicitly, system quality, information system, and AR media content quality, and establishes their influence on rational hedonism and satisfaction experienced, thus enhancing visitor impact. The findings also show that the rational hedonism and satisfaction experienced are positioned as full mediators for the relationship between system quality & information quality and visitor impact. In contrast, these mediators partially influence the indirect relationship between AR media content quality and visitor impact. Moreover, the results affirm that AR media content quality within the mobile application is the most critical construct to directly enhance visitor impact, whereas the system quality and information quality have no influence yet. From a practical point of view, the importance of AR technology for the museum can support entice new visitors to museums and improve to make more incomes.

**Keywords**—System quality; information quality; augmented reality media content quality; rational hedonism; satisfaction experienced

## I. INTRODUCTION

The importance of museums as artistic and heritage organizations is established, which have a substantial part in magnetizing new visitors to endpoint. To entice visitors and deliver them with good experiences, museums have begun to embrace modern technologies. Some scholars propose which are still significant alterations among museums based on high-tech tools, determined by the sum of aspects such as museums' size, site, income, and managerial control in where museums in emerging states are a significant burden to foster their technological capabilities [1][2].

Museums meet recent challenges of increasing the prospects of their guests. These outlooks are fostered by

improving the latest technologies such as virtual reality and augmented reality on mobile applications [3]. The escalation of information technology and digital forms altered how museums involved their visitors [2]. The improvement of digital media with mobile devices through augmented reality (AR) technology has gained a place in various users' hearts and many supporting applications [4]. AR has distinctive capability features to interlace the virtual and the material, implying museum visitors can suppress themselves in virtually improved experiences touching historical objects such artifacts, lontars, Subak (Balinese irrigation system) via AR apps. This study contends which AR media content provides creative potentials for assigning the unique features of historical objects, influencing satisfaction experienced and the enjoyment of the tour, like hedonism, and consequently increasing visitor impact [5].

Thus far, the recognition of AR mobile still meets several defiances explicitly for customer shopping engagement as the limited quality of media content and low quality of media layout[6]. Additionally, other concerns are linked to using the mobile application, such as lack of information quality and lack of system quality with mobile application because it is difficult to operate the function and content is not interactives [7][8]. These challenges can potentially increase visitors' resistance to using the AR mobile application. Conversely, there has been a lot to assess the influence of AR mobile's quality, system, and information on the acceptance of technology. System quality of the mobile application is essential to a beneficial user experience of mobile applications [9]. Determining the quality of AR mobile application is a multidimensional practice concentrating on several features of a system like system attributes, quality attributes, serviceability elements, and other aspects linked to technical matters [10]. System quality is the degree of easiness of utilizing and conveying out of assignments [11]. It also exhibits the significance of navigability, user-friendliness, organize, graphic logic, and stable mobile systems for enhancing a sound visitor capability and acquiring [12][13]. Some cosmetic, fashion and sports companies have implemented AR media to improve the authentic experience of their objects and assist customers through decision making [14]. Therefore, this paper tries to focus on the research gap by scrutinizing the impact of

the implementation of the AR mobile application on visitors in the Subak museum.

To fulfill the research gap, drawing from collaboration among the theory IS success model, the theory of Unified Theory of Acceptance and Use of Technology (UTAUT2) [13], and pure happiness theory [15][16], we construct and empirically emphasize a composition propositioning which, namely actual rational hedonism and satisfaction experienced respectively mediate the connection among system quality, information quality and AR media content quality, and visitor impact. The objective of this study is three aims. First, to investigate the constructs which affect visitor impact through AR attributes on mobile apps. Second, to evaluate the effect of rational hedonism to bridge the relationship between AR features and visitor impact. Thirdly, to assess the influence of satisfaction experienced as the mediator of the link between AR features and visitor impact.

## II. BASIC THEORY

### A. Factors Affecting Adoption of AR Mobile

Furthermore, IS success model draws information quality as an essential element to an information systems accomplishment [17]. A primary function of an AR mobile is to deliver visitors with figures appropriate to the historical objects [18]. Information, which is evident, recent, appropriate, precise, comprehensive, and consistent is trusted to be of excellent quality [19]. The performance of a technological system such as augmented reality is significant in instruction for consumers to implement and utilize such technology [20]. Then, a high-tech system is regarded as simple to utilize, which lets individuals finish duties, foster their output while also improving their performance and productivity [21]. In the context of this study, information quality and system quality extend to a visitor's view of the expectancies of significant others concerning the utilize of AR via mobile app.

Subsequently, UTAUT2 was initiated to comprise human behavior and practice [22]. The enjoyment reflects hedonism that has been considered a critical aspect of technology theory [22]. It is the action of expanding a particular system that is enjoyable in its own right, away from any performance effects ensuing from system use. The empirical study draws which enjoyment can affect mobile app utilization [20]. AR media content is imagined delivering a positive and performing experience [23]. Then, hedonism has converted into a fundamental construct in interpreting the adoption and utilization of the latest technology.

Regarding the pure happiness theory, the characteristic of a person's life is dependent on happiness, that is, the cognitive aspect, the hedonistic aspect, the mood aspect (emotional), and the hybrid aspect [15]. In this study, we try to implement the combination of cognitive and hedonistic views called rational hedonism. Each person is slightly hedonistic modestly because every person desires to experience an enjoyable life [24]. So, rational hedonism involves the pursuit of pleasure, a happy condition regarded on rational principles that create more significant comfort.

As a result, through integrating each theory (IS success model, UTAUT2, and pure happiness), the study encapsulates

technology, social and self-correlated constructs in the improvement of the theoretic model, which scrutinizes the part of rational hedonism and satisfaction experienced in enlightening visitors' degree of engagement by AR mobile software.

### B. Hypotheses Development

Particularly, virtual portrayals can influentially create the quality and historical objects via the mobile system; an improved configuration of a virtual object with visitor carries a new figure of exclusiveness; the cover of the virtual artifact-linked object on physical environments can generate object proximity and thus in-depth resonance by visitors than looking directly. The previous empiric has recognized how AR encourages sensorial elements and enhances individual performance [25][26]. Thus, the hypothesis is intended:

H1a: Higher system quality has a positive influence on visitor impact.

The magnitude of the system quality establishes a significant effect on the mobile application [27]. The system quality of mobile would interface which discovers new methods for collaboration between real and virtual surroundings simultaneously [28]. Additionally, it would enhance the attentiveness of the visitor. The accessible interface enables more artifact visualizations to their visitors, thus increasing the level of enjoyment. Such a platform enables the user to walk through the virtual museum and indicates the virtual depictions super-imposed on physical environments [29]. Correspondingly, Imaginings generation as augmented reality affordance permitting visitors to visualize 3D object portrayals in contrast to the actual condition [14].

Furthermore, system quality is acknowledged as easiness of learning, easiness of utilizing, the ease of accessibility, the effectiveness of system attributes, system complication, system attributes, and response time of IS [30]. It is as a degree of how well a supplied system meets visitor hopes such as effectual, reliable, adaptable, practical, customized, and fulfills the requirements [8]. Because visitors frequently settle in the comfortable system for longer time, the robust system makes enjoyment to consistently use the app, which aids encourage visitors' experiences [31]. The excellent system frequently causes visitor interfaces, which convey a perception of consistency, receptiveness, assurance, and compassion that can help visitors reach their aims and prospects more knowledgeably or, in this context, achieve hedonism [32]. Some empirical studies have revealed which people with these features positively generate pleasing and enjoyable experiences for visitors [33][32]. Then, the hypothesis is intended:

H1b: Higher system quality has a positive influence on rational hedonism.

System quality contains the required features (e.g., easiness of utilizing, flexible system, and reliable system) of mobile application [34]. Determining the quality of IS is a multi-aspect procedure converging on some attributes of a system like system attributes, quality attributes, usability attributes, and other attributes linked to technical concerns [35]. Characteristic determines system excellence in conventional studies involve response time and robustness [36]. AR mobile system

generates more revelational moments by indicating magnificence features in an immersive and sensory-rich approach. AR features create historical object components proximal and graphically high-up in physical environments, even though the scenery of the linked experiences varies [29]. Captivating this contextual museum, more excellent system quality is estimated to increase satisfaction experience. Thus, the hypothesis is composed:

H1c: Higher system quality has a positive influence on satisfaction experienced.

Information quality emphasizes the quality of a visitor's mobile's outcome (i.e., the information quality which the mobile delivers) and its helpfulness. It has been exhibited to be a critical success aspect while examining whole information system accomplishment [37]. Rich substance delivers the quality of the content concerning its practicality, comprehensibility, and robustness [38]. Some empirical studies have shown which information quality positively influences the individual impact [39][17][40]. Based on this discussion, information quality enhances the museum visitor impact.

Mobile informativeness positively influences purchase intentions, while information declines the degree of improbability to the products and enhances the possibility of shopping linked decision-making [41]. The information generated by the mobile system is the relative link and significance of a mobile regarded on consumer's requirements and concerns [42]. The mutual interaction and the quantity of information shared online affect cognitive contribution [43][44]. Similar to the museum context, the more informative and AR mobile, the more visitors endeavor to take back information that improves their participation [41]. Then, the following hypothesis is proposed:

H2a: Higher information quality has a positive effect on visitor impact.

The information quality portrays the exactness and precision of the information delivered by the mobile application; rightness is an alternative key indicator of information quality which information must be produced within proper and correct. So, visitors can get the latest adequacy data related to historical objects; adequacy is another attribute of information quality that should be appropriate and should comprise all information needed to the end-user [45]. Understandability is a valuable attribute of information quality, which must be simple to recognize and not be complicated and hard to comprehend. Conciseness is an attribute of information quality generated by the IS [46]. Moreover, information quality shows the outcome features of the mobile app's information, which corroborates the appropriate information toward museum visitors. The essential information is accessible at the exact time to the right man; the info delivered by the information mobile must be clear to the end-users [47].

Moreover, the spending of information related to history and culture can be inferred as a configuration of edutainment since visitors can acquire something and relish it simultaneously [48]. This is aligned with museums' aim of delivering knowledge and amusement, which relates with a dual method to recent visitor conduct where 'cognitive and

emotional aspects are concurrently at perform' [49]. It suggests that information generated by mobile enhances the level of psychological developments like enjoyment, hedonism, and affections [50]. The more helpful information generated by mobile applications provides the latest and relevant information; further, it is seen as informative, and visitors have more delight through the collaboration [41]. Thus, the hypothesizes that:

H2b: Higher information quality has a positive effect on rational hedonism.

Information quality can improve to enhance the satisfaction of the experienced visitor in the museum [51]. This empirical matches study from the perspective of museum visitors that exposed collaborative information affects the satisfaction experienced when visiting the museum [52]. Information quality plays a vital part in expanding positively to the advantages of handling a particular information technology (IT) [53]. It is viewed as the primary antecedent of user satisfaction [35]. Also, the increase of visitors' satisfaction due to it encourages them greater than static demonstrations. Visitors have more participated in the display while they can apply interactive displays [54]. Thus, the hypothesis is:

H2c: Higher information quality has a positive influence on satisfaction experience.

The existence of high-tech in museums turns out to be vital and must not be ignored. For instance, the revolution of museum experiences aims to the significance of interactive technology devices that can assist in accomplishing the preferred alters with the aid of explanatory texts and feasible activities [55]. Consistently, which museum experts believe AR technology is a museum instrument whose incorporation into museums generates the foundation for interface via involved entertainment [56]. Using multimedia features such as AR with interactive content can positively affect learning development [57]. Similar to the museum context, virtual object generated by AR app enhances learning progression by sustaining the visitors' engagement. For instance, the implementation of videos and virtual animations can enlighten complicated concepts more effectively rather than concern the text [57]. Regarded above this discussion, the AR media content quality corroboration aspect can act as a vital aspect in leveraging the museum visitor impact. Thus, the hypothesis is:

H3a: High AR media content quality has a positive influence on visitor impact.

AR is the incorporation of digital data with the user's situation. It utilizes the present surrounding and overlays the latest information on top. This technology enhances the digital creation with physical targets, letting a real-domain customer flawlessly interrelate with digital elements [58]. The AR utilization in an art museum has a vital role in the recent improvements linked to acquiring technology that considers the latest high-tech instruments as a proposal to encourage the learning process [58]. Furthermore, AR is present converting human developments by speeding up competencies progress and encouraging guidance.

The amazement of AR is escalating because it carries components of the virtual object into the actual environment,

then augmenting the objects for seen, heard, and perceived. It conveys computer-created objects into the reality surrounding, but the visitor can look at the historical object. When utilizing AR apps, the user imagines a mix of synthetic and natural brightness [59]. Overlaying pictures are projected above historical objects, which allocates the figures and collaborative virtual objects to be on top of the user's interpretation of the natural environment. AR can be very proper for replications, specifically in the museum zone [51].

Furthermore, AR technology integrates aspects of amusement and collaboration into museum propose to entice new visitors, particularly the children and teenager segment[60]. For instance, the Art Museum in the USA utilizes the influence of technology to involve visitors enthusiastically. With the aid of the AR app, visitors can perform a mainly intended museum game. They are encouraged to reconstruct the stances of the sculptures in the museum's gallery. Then they are delivered by information related to the art they are attempting to reconstruct in the game. In this approach, a visitor has amusing and learns together with the support of collaborative technology. By embracing AR media content, interactive installments entice visitors and create them more dynamic for an extended time than standard static displays [54]. Collaborative link technologies create the apparent authenticity of visitors' familiarity in a museum [50]. The museum embraces content entertainment through displays that foster all visitors to absorb more about themselves and others while they go to the museum [51]. So, technologies in museums (AR) can induce visitors' emotional reactions such as enjoyable and hedonism [50][6]. Thus:

H3b: High AR media content quality has a positive influence on rational hedonism.

AR technology delivers objects to improve the visitor tour by expanding magnificence features animatedly through diverse touchpoints crossways the tour itself [29]. AR's virtuality authentically replicates and increases the more excellent quality of objects while covered in the natural realm or lined up with visitors' looks. Moreover, objects can implement AR to certify the easy extension of the tour via facilitating fewer jarring alterations between virtual and physical touchpoints. This study highlights how AR content aids historical objects in delivering high-end facilities through zooming the high resolution for their objects, which satisfaction [61]. So, AR generates more revolution moments by demonstrating magnificent content in an immersive and sensory-rich approach. Its features generate object media proximal and graphically prominent in physical environments, so that increase satisfaction experience. Thus, the following hypothesis is proposed:

H3c: High AR media content quality has a positive effect on the satisfaction experience.

Regarding the pure happiness theory, the characteristic of a person's life is dependent on happiness, that is, the cognitive aspect, the hedonistic aspect, the mood aspect (emotional), and the hybrid aspect [15]. In this study, we try to implement the combination of cognitive and hedonistic views called rational

hedonism. Cognitively evaluating one's life as an entire in a positive approach makes to perceive rationality. Each person is slightly hedonistic modestly because every person desires to experience an enjoyable life [24]. So, rational hedonism involves the pursuit of pleasure simply, which is a happy condition regarded on rational principles that creates more excellent support to comfort.

Rational hedonism is linked with a fun and exciting experience which may ensue in enjoyment. An enjoyable and fun mobile application creates positive hedonic contagion by augmented reality (AR) technology [62]. Since augmented reality (AR) media implements the natural surrounding and overlays recent information above it which appears to augment the digital domain with physical objects, letting a real-world visitor flawlessly interrelate with digital elements [59]. It serves users to avoid tediousness to rest; hedonism can be a vital feature to generate unique sensory emotion [29]. In entirety, hedonic understandings create changes in the users' emotional testifies, making a positive response that enhances their aims to use AR mobile.

Hedonism distributes with the customers' affections (happy and adoring) and has arisen as a vital aspect in influencing social behavior [63][64]. The joyful and ludic part of visiting the shop is that visitors are more involved with the practical part (fun) of relaxation [65]. In the museum context, visiting emphases are considered the hedonic value [66]. Visitors appreciate obtaining engaged in the touring process and are more attracted to the fun aspect of the touring experience [67]. Scholars have discovered which faithfulness of AR app improves if the visitors are satisfied with the visual involvements, i.e., degree of enjoyment [64]. Hedonism has been realized to affect the satisfied visitor positively, then encourage the visitor to revisit [68][6]. Then, the hypothesis is proposed:

H4: Rational hedonism has a positive influence on visitor impact.

The satisfaction experience has a substantial effect on behavioral intentions [69]. The feelings customers create are bound to the aptness of the services obtained (i.e., the contrast between performance and hopes [70]). They construct potential developments of engagements on their level of satisfaction [71]. Satisfaction with a product or service is the essential enthusiasm to persist applying it as satisfaction indicates which advantages originated from visualizing media content by AR application. In the museum context, the satisfaction experience with AR mobile would indicate the achievement of the estimated advantages, improving the visitor impact to use this application to maintain acquiring these advantages [72]. In the AR mobile context, the visitor impact enables acquiring local knowledge "Subak"; to improve the exploring historical object; to makes easier using the application; to improve technological skills. The increased visitor satisfaction experience will consequently influence visitor impact. Then, the hypotheses is:

H5: High satisfaction experienced has a positive effect on visitor impact.

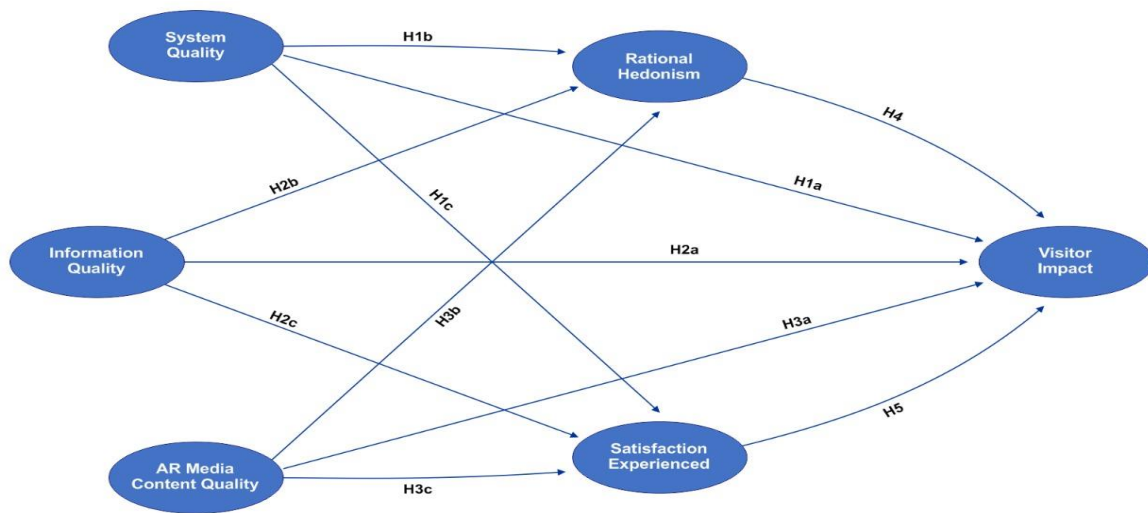

Fig. 1. Conceptual model.

Based on the above arguments, the satisfaction experienced, and the rational hedonism has a significant role in mediating the total effect of system quality, information quality, and AR media content quality on visitor impact. Thus, the hypotheses proposed are (Fig. 1):

H6a: The rational hedonism mediates the impact of system quality on visitor impact.

H6b: The rational hedonism mediates the impact of information quality on visitor impact.

H6c: The rational hedonism mediates the impact of AR media content quality on visitor impact.

H7a: The satisfaction experienced mediates the impact of system quality on visitor impact.

H7b: The satisfaction experienced mediates the impact of information quality on visitor impact.

H7c: The satisfaction experienced mediates the impact of AR media content quality on visitor impact.

### III. METHODOLOGY

#### A. Data Collection and Sample

The research employed a quantitative approach. Collected information on the critical research was obtained by the visitors of the Subak Museum at Bali Province, Indonesia. The data were gathered employing a survey handled through google form between May 2021 and July 2021. All items were calculated using five-point Likert scales, varying from totally disagree (1) to totally agree (5). A pilot study was performed on a group of 30 museum visitors who were not involved in the primary survey to examine the instrument. An overall of 427 e-mails was disseminated in May 2021, specifying the hyperlink to the survey and requesting its contribution. Two hundred seventy-nine responses were obtained toward the end of July 2021, which relates to a 65.33 percent response rate. Thirty-eight responses were dropped due to inadequate, resting 241 (56.44 percent) with valid and finished responses. In Table I, the resulting data were gathered from 241 visitors that visited Subak Museum in Indonesia.

TABLE I. DEMOGRAPHIC PROFILE OF RESPONDENTS (N=241)

Demographics Respondent Percentage (%)	Frequency	Percentage
<i>Gender</i>		
Male	140	59,29%
Female	101	40,71%
<i>Age-Group</i>		
17-30 years	137	56,85%
31-40 years	86	35,68%
41 years above	18	7,47%
<i>Education</i>		
High School or below	104	43,15%
Undergraduate degree	87	36,09%
Bachelor	37	15,35%
Master's degree or higher	13	5,39%

#### B. Profile of Subak Museum

The Subak Museum is a museum that displays a collection of traditional agriculture tools utilized in farming and the traditional Balinese irrigation termed as Subak. It is one of the tourist objects for study tours, which many students and travelers from domestic and foreign tourists visit. Subak Museum is one of Bali's icons that stores agricultural tools of Balinese cultural heritage through the concept of Subak network has been recognized by the World Health Organization (WHO) as a World Cultural heritage. Museum is located in Banjar Anyar Village, Kediri District, Tabanan Regency, Bali - Indonesia. The distance from Denpasar City is approximately 21 KM. The number of visitors to Subak Museum from 2016 to 2020 decreased from 28,355 to 21,104 visitors.

History of the Subak Museum was established on August 17, 1975, to preserve the Subak traditional institution

as a noble cultural heritage of the nation and introduce the younger generation and tourists to the unique traditional irrigation system in Bali. Subak is an organization of farming communities in Bali that deals explicitly with the regulation or system of irrigating rice fields/irrigation in a traditional/conventional way.

The Subak Museum provides an experience for visitors to see, recognize and learn all things related to agriculture and traditional equipment commonly used in agriculture in Bali, such as rice cutting and pounding tools, rice plowing tools, etc. Furthermore, here visitors get complete information about how the Subak irrigation system and processing rice fields from start to finish. Such as how to open rice fields, share the water, make water tunnels, measure waterways, and complete the process of religious ritual ceremonies.

**C. Instrument Development**

Based on previous studies, five constructs have been established by the author for supporting student performance (System Quality; Information Quality; AR media content Quality; Rational Hedonism; Satisfaction experienced; Individual Impact). Four items determined system Quality: AR mobile is simple to navigate; easy to use; admits visitors to search the information; offers proper functionality [73]. Information Quality was measured by four items that information provided by AR mobile is practical, understandable, attractive, reliable [7]. Four items measured AR media content quality: AR mobile desires enhancement of object reality; delivers powerful momentary; creates captivating aesthetic simulations; create real-time interactivity between virtual and physical elements [74][75][29]. Rational hedonism was measured by four items that visitor enjoys their tour through the AR application; have incredible emotion through the AR technology; have exciting times to explore the historical object; have a discovery of local knowledge [76]. The Satisfaction experienced was measured by four items that the visitors feel satisfied with their experience; the experience matches what visitors expect, the experience has succeeded as well as visitor contemplates, the getting auratic from the visual object [6][29]. The visitor impact was measured by four items that museum visitors enable to acquire local knowledge, “Subak”, to improve the exploring historical object; to enhance technological skills; to make easier using the application [7]. The questionnaire was obtained from empirical studies which analyzed the variables in an inquiry in the current research.

**IV. DATA ANALYSIS AND RESULTS**

To recognize the direct and indirect effect of system quality, information quality, and AR media content quality on visitor impact with the mediating impact of rational hedonism and satisfaction experienced at museum visitors in Indonesia. For evaluating the entire measurement model, statistical SmartPLS software was applied, and analyzing for data was utilized by PLS-SEM (Partial Least Square-Structural Equation Modelling).

**A. Measurement Model**

Convergent validity and discriminant validity have been examined. We have evaluated convergent validity by examining factor loading greater than 0.7, composite

reliabilities greater than 0.8, and the average extracted variance (AVE) must greater than 0.5 for all variables (Fornell and Larcker, 1981). All factor charges in our model are greater than 0.7 and measuring objects are removed if their factor loads are less than 0.70. The finding results show that our model meets the standard of convergent validity. With Cronbach  $\alpha$ , we examined the internal reliability of scales. Table II states the loading factor, AVE, CR and (C- $\alpha$ ) of all constructs.

The latest approach was applied to confirm discriminant validity in the Heterotrait-Monotrait (HTMT) formula, and the HTMT values are displayed in Table III. If the HTMT is greater than 0.90, then the test of discriminant validity is the failure[77]. As all the results of HTMT are lower than the threshold portrayed in Table III, discriminant validity has been confirmed [77]. The measurement of the goodness-of-fit model was revealed to be satisfactory (Standardized Root Mean Square Residual [SRMR]=0.071, and Normal Fit Index [NFI]=0.928) and established the proposed model because of SRMR value < 0.08 and NFI value > 0.9 [78]. Conclusively, we postulate that tests of convergent and discriminant are valid, thus satisfactory to examine the hypothesis for the study.

TABLE II. CONVERGENT VALIDITY

Constructs	Items	Factor Loadings	Cronbach $\alpha$	Composite Reliability	AVE
System Quality (SQ)	SQ1	0,897	0,851	0,899	0,690
	SQ2	0,736			
	SQ3	0,801			
	SQ4	0,879			
Information Quality (IQ)	IQ1	0,885	0,722	0,770	0,703
	IQ2	0,712			
	IQ3	0,814			
	IQ4	0,853			
AR Media Content Quality (AR)	AR1	0,689	0,778	0,834	0,605
	AR2	0,854			
	AR3	0,766			
	AR4	0,787			
Rational Hedonism (RH)	RH1	0,908	0,725	0,836	0,645
	RH2	0,845			
	RH3	0,649			
	RH4	0,826			
Satisfaction Experienced (SE)	SE1	0,893	0,802	0,884	0,717
	SE2	0,812			
	SE3	0,834			
	SE4	0,745			
Visitor Impact (VI)	VI1	0,863	0,766	0,864	0,679
	VI2	0,758			
	VI3	0,848			
	VI4	0,793			

TABLE III. DISCRIMINANT VALIDITY

	SQ	IQ	AR	RH	SE	VI
SQ						
IQ	0,455					
AR	0,284	0,701				
RH	0,509	0,272	0,408			
SE	0,349	0,798	0,759	0,684		
VI	0,509	0,812	0,743	0,351	0,682	

**B. Hypothesis Examining**

The study examines the structural relationships among the variables by investigating the diverse mediation effects across a path analysis. Path analyses were applied to test hypotheses in the conceptual model employing the Smart-PLS software. The research shown in Table IV depicts path coefficients of the study model. Table IV and Fig. 2 describes which the path values from System Quality to Visitor Impact was positive and non-significant ( $\beta = 0.121$ ;  $p > 0.1$ ), in contrary the path values from System Quality to Rational Hedonism was also positive and significant ( $\beta = 0.544$ ;  $p < 0.01$ ) and the path coefficients from System Quality to Satisfaction Experienced was also positive and significant ( $\beta = 0.278$ ;  $p < 0.05$ ). Therefore,  $H_{1a}$  is not supported but  $H_{1b}$  dan  $H_{1c}$  are supported. The path coefficient from Information Quality to Visitor Impact was positive and non-significant ( $\beta = 0.095$ ;  $p > 0.1$ ), whereas the path coefficient from Information Quality to Rational Hedonism was positive and significant ( $\beta = 0.162$ ;  $p < 0.1$ ), and the path coefficient from Information Quality to Satisfaction Experienced was positive and significant ( $\beta = 0.145$ ;  $p < 0.1$ ). Then, there is enough evidence to support  $H_{2b}$  and  $H_{2c}$  but  $H_{2a}$  was not supported. The path coefficient from AR Media Content Quality to Visitor Impact was positive and significant ( $\beta = 0.257$ ;  $p < 0.05$ ), and the path coefficient from

AR Media Content Quality to Rational Hedonism was positive and significant ( $\beta = 0.201$ ;  $p < 0.05$ ), also the path coefficient from AR Media Content Quality to Satisfaction Experienced was positive and significant ( $\beta = 0.473$ ;  $p < 0.01$ ). Thus, there is enough evidence to support  $H_{3a}$ ,  $H_{3b}$  and  $H_{3c}$ . The path coefficient from Rational Hedonism to Visitor Impact was positive and significant ( $\beta = 0.295$ ;  $p < 0.01$ ), and the path coefficient from Satisfaction Experienced to Visit or Impact was positive and significant ( $\beta = 0.254$ ;  $p < 0.05$ ). Therefore,  $H_4$  and  $H_5$  are supported.

Additionally, the indirect relationship of System Quality, Information Quality, and AR Media Content Quality on Visitor Impact through Rational Hedonism as mediator was also positive and significant respectively ( $\beta = 0.161$ ,  $p < 0.05$ ;  $\beta = 0.048$ ,  $p < 0.1$ ;  $\beta = 0.059$ ,  $p < 0.1$ ), that  $H_{6a}$ ,  $H_{6b}$ , and  $H_{6c}$  are supported. Then, the indirect effects of System Quality, Information Quality, and AR Media Content Quality on Visitor Impact through Satisfaction Experienced as mediator was also positive and significant ( $\beta = 0.071$ ,  $p < 0.1$ ;  $\beta = 0.036$ ,  $p < 0.1$ ;  $\beta = 0.12$ ,  $p < 0.05$ ), that state  $H_{7a}$ ,  $H_{7b}$ , and  $H_{7c}$  are confirmed. Based on the explanation above, we determine that Rational Hedonism and Satisfaction Experienced partially mediate the relationship between System Quality, Information Quality, and AR Media Content Quality and Visitor Impact.

TABLE IV. HYPOTHESES TESTING

Hypothesis	Relationship	Standard Coefficients	Test Result
$H_{1a}$	System Quality → Visitor Impact	0,121	Non-Significant
$H_{1b}$	System Quality → Rational Hedonism	0,544*	Significant
$H_{1c}$	System Quality → Satisfaction Experienced	0,278 **	Significant
$H_{2a}$	Information Quality → Visitor Impact	0,095	Non-Significant
$H_{2b}$	Information Quality → Rational Hedonism	0,162***	Significant
$H_{2c}$	Information Quality → Satisfaction Experienced	0,145***	Significant
$H_{3a}$	AR Media Content Quality → Visitor Impact	0,257 **	Significant
$H_{3b}$	AR Media Content Quality → Rational Hedonism	0,201 **	Significant
$H_{3c}$	AR Media Content Quality → Satisfaction Experienced	0,473 *	Significant
$H_4$	Rational Hedonism → Visitor Impact	0,295 *	Significant
$H_5$	Satisfaction Experienced → Visitor Impact	0,254 **	Significant
$H_{6a}$	System Quality → Rational Hedonism → Visitor Impact	0,161 **	Significant
$H_{6b}$	Information Quality → Rational Hedonism → Visitor Impact	0,048***	Significant
$H_{6c}$	AR Media Content Quality → Rational Hedonism → Visitor Impact	0,059 ***	Significant
$H_{7a}$	System Quality → Satisfaction Experienced → Visitor Impact	0,071 ***	Significant
$H_{7b}$	Information Quality → Satisfaction Experienced → Visitor Impact	0,036***	Significant
$H_{7c}$	AR Media Content Quality → Satisfaction Experienced → Visitor Impact	0,12**	Significant

Note: Significant at \*1%, \*\*5% and \*\*\*10% levels

Fig. 2. Results of Path Analysis.

## V. DISCUSSION

The current study results establish which the system quality does not influence the visitors' impact in Subak museum, which corroborates the findings [79]. Some museum visitors have difficulty finding information contained in AR mobile, and some of the existing features are still unstable. Concurrently, several visitors suppose technological constraints often obtained in new, inventive technologies, such as arduousness in installing the related software, deficiency of computer literacy, and malfunctioning of the AR applications (e.g., slow response speediness, cartoony object pictures). Then, AR is assumed to be at the growing phase, requiring extra scope to enhance to be adored and utilized by more visitors. On the other hand, another empirical study reveals which system quality has a significant effect on rational hedonism, which aligns with the findings [80][81]. Therefore, the system quality is an essential aspect for hedonic-seeking visitors while they involve in openness services. Some visitors obtain it central for the system delivered to be stable with their hopes. Then, AR applications should endeavor to recognize their visitors' desires and support them in accomplishing their aims also is expected to provide a playful and entertaining experience for visitors. Moreover, the other finding shows that system quality has a significant effect on satisfying experiences, which aligns with the findings [6][79][8]. The system technology's ability enables visitors to cooperate more, handle and suit immersed with objects. Possibly, AR delivers visitors with the most interactive kind of technology accessible, where persons have managed over their manipulation in

joining both the actual object and virtual object environment [82]. The AR capability can create mental figures which reproduce historical objects and experiences, which is the main competency through visitors observing the artifact. Visitors have long tried to visualize the objects at the museum to understand their applicability before looking at the actual objects.

Conversely, the other empirical finding shows that the information quality does not influence visitor impacts in Subak museum, which aligns with [7]. The display of information on the application screen is less reliable with the information in the physical diorama, so that there is a misinterpretation for museum visitors. For this reason, visitors could not fully capture the explanation given from the application, such as information about artifacts with precision. In contrast, another empirical study reveals that information quality positively affects rational hedonism, which aligns with the findings [83][80]. The information generated by AR apps enables visitors to personalize content to their personal preferences and fascinations. Moreover, AR applications could deliver further historical objects information like supplementary video media and text matter comprising the process of Subak irrigation and material information of artifacts. The function that originates from this unique subject is possible to improve a visitor's enjoyment by having exciting times to explore the historical object, obtaining local knowledge, and getting incredible emotion. The following finding shows that the information quality has a positive effect on satisfaction experienced, which aligns with the findings [84][72]. Information is evident, recent, appropriate, precise, comprehensive, and consistent and

is of excellent quality [85]. This paper shows which higher-quality information is a vital aspect in attaining satisfaction with AR mobile. It offers visitors information, which is recent, wide-ranging, simply explicable, and converges the information required to enhance a visitor's degree of satisfaction. Information could air to improve the sensed realism of the museum experienced visitors. They expect AR mobile to offer capable and reliable information which would satisfy their information necessities. This result match by study from the viewpoint of museum visitors that revealed interactive information significantly influences the sensed realism of the museum [50]. So, visitors displayed with more excellent informative object visualizations (i.e., artifacts) indicate a more positive experience.

Furthermore, the other finding demonstrates that the AR media content quality influences visitor impacts in Subak museum, which aligns with the findings [2]. AR technology generates and provides content in an approach that visitors favor using. It could enhance the sensed realism of material objects, which supports museums in describing and interactively showcasing the objects. For example, the Subak Museum applies museum's high-tech facility intensifies with praxis, its capability to transform and explain collections subject improves to generate attractive and impressive museum experiences [82]. Moreover, another empirical study shows that the AR media content quality positively impacts rational hedonism, which aligns with the findings [29][6]. AR content could support improving the sensed enjoyment of the visitor because it involves them more than motionless expositions. Visitors have more participated in the expositions while they have a chance to utilize interactive displays. Virtual reality overlays on or is incorporated as a role, and physical environments can graphically point out the delicate materials and artifacts. The visitor has the facility to improve the magnificence aura by envisioning object heritage. Application authentically replicates and strengthens the more outstanding quality of historical objects while covered in the natural environment. The development of supporting virtual finest object materials with visitors' emergence attributes is central for fitting visitor necessities and customizing the object trial. Mainly, virtual depictions could realistically imitate the quality and resolution of historical heritages in a way not previously likely through a website; the overlay of virtual object-related content on physical surroundings can create object proximity and, therefore, a deeper resonance with visitors than online browsing. The following finding shows that the AR media content quality positively affects satisfaction experienced, which aligns with the findings [29][6]. Regarding museum experience, this research identifies that AR media content provides an attentiveness of historical object stimuli round detailed dioramas. Specifically, it allows historical objects to induce influential emotions in visitors via AR mobile, short-term faces which are intensively satisfied due to the high-quality resolution and unique content for particular objects. Conversely, auratic magnification provides a new approach to constructing an object's distinctive aura – for example, by envisioning the object's realism artifact and distinction in an immersive method. For essentially encouraged museum visitors, the acquiring experience might be improved by AR media content, which becomes a crucial aspect of the visitor's

experience. It provides visitors with information, which is up-to-date, complete, simply comprehensible, and matches the information requirement enhances a visitor's degree of satisfaction. So, AR technology helps museums obtain attractiveness by facilitating visitors to achieve experiences that are concurrently aesthetically educational and entertainment [86].

The following finding shows that rational hedonism has a positive effect on visitor impact, which aligns with the findings [21][6]. Hence, enjoyment might be caused due to the inventive visualization experience delivered by AR as visitors can manipulate objects and have the possibility to generate themselves a customizable experience. During a customer's experience, enjoyment can be obtained by simulating 3-D virtual objects [18][87]. Thus, a diversity of AR media attributes that deliver interaction and lucidity to visitors via AR might be adept at elevating a visitor's imaginative composition progression through their experience, incorporating their natural surroundings with the virtual environment to acquire a fun experience within the visualization of new objects. The other results reveal that the satisfaction experienced positively influences visitor impact, which aligns with the findings [80][72]. Museum visitors turn into satisfied, delighted, and relaxed with their judgments to utilize in AR mobile while the application could meet their necessities and facility offerings match their hopes. Furthermore, visitors feel a positive appraise while they trust that they have obtained reasonable offers for AR attributes. The visitor felt value could be determined by comparing what they give up (e.g., financial, time, power, and affection) with what they obtain (i.e., auratic experiences when looking at virtual objects). The satisfaction experienced by the visitor is obtained by quality of the museum experience, as well as the level of visitors fascinate, causes to overall museum visitors' satisfaction [88]. The opinion of visitors' satisfaction improves while the worth incorporation progression outcomes in a positive result are naturally more likely to foster positive effect.

## VI. THEORETICAL AND MANAGERIAL IMPLICATIONS

Theoretically, this study cooperates the collaboration among the theory IS success model, the theory of Unified Theory of Acceptance and Use of Technology (UTAUT2), and theory of pure happiness, also information quality, system quality, AR media content quality to increase visitor impact through rational hedonism, and satisfaction experienced in Subak Museum. The rational hedonism and satisfaction experienced are positioned as full mediators for the relationship between system quality and information quality and visitor impact. In contrast, these mediators partially influence the indirect relationship between AR media content quality and visitor impact. This exemplifies the new model, which fulfills the research gap among information quality, system quality, and AR media content quality on visitor impact. Additionally, the results affirm that AR media content quality within the mobile application is the most critical construct to directly enhance visitor impact, whereas the system quality and information quality have no influence yet.

From a practical point of view, the paper influences the stream of exploring the magnitude of AR technology for

museums. Introducing AR media content for museum delivery (offline & online) can support entice new visitors coming to museums, and therefore improve make more incomes. In achieving the interactivity of the visitor experience, the museum manager needs to recognize how the media content might be employed in the museum's proposal. The level of satisfaction experienced, and rational hedonism is summarized as a crucial aspect in influencing visitor impact. Then, managers must recognize the vital function AR content performs in improving visitor interactivity as the involvement of their getting satisfaction experienced from utilizing AR app. Lastly, the robust system quality of AR mobile creates perceived enjoyment that is termed as rational hedonism to increase visitor impact.

## VII. CONCLUSION AND LIMITATIONS

These empirical outcomes have provided some substantially beneficial shreds of proof of the role of system quality, information quality, and AR media content quality to increase visitor impact in the Subak Museum in Indonesia through rational hedonism and satisfaction experienced. The satisfaction experienced is more influential in the linkage between AR media content quality and visitor impact rather than system quality, and information quality as antecedents, whereas rational hedonism is more influential in the linkage between quality system and visitor impact. Thus, the study suggests which rational hedonism and satisfaction experienced fully mediate the relationship between system quality & information quality and visitor impact. Finally, the indirect relationship between AR media content quality and visitor impact is only bridged by rational hedonism and satisfaction experienced.

There are constraints that propose some future research. This analysis employs a cross-sectional design that will let a longitudinal study be applied for the following research to scrutinize the influences of features AR mobile application on rational hedonism and satisfaction experienced that also increases visitor impact. Lastly, this study is only conveyed by a single type of museum, and it is attractive lead to collect data from other museums to provide more corroboration of results.

## ACKNOWLEDGMENT

The authors would like to thank for the Directorate General of Research and Development, Ministry of Education, Culture, Research and Technology of the Republic of Indonesia which had provided funding for this research through research grant number: 1219/UN48.16/LT/2022. The authors also would like to thank for Rector and Chair of the Research and Community Service Institute of Universitas Pendidikan Ganesha who provided the opportunity, guidance, and support to complete this research on time.

# Developing a Computer Simulation to Study the Behavior of Factors Affecting the Flooding of the Gash River

Abdalilah G. I. Alhalangy

Department of Computer Sciences-College of Science and Arts-Ar Rass, Qassim University, Saudi Arabia

**Abstract**—In recent years, the city of Kassala has suffered from frequent flooding disasters in the Gash River, which is the city's lifeblood. But the problem of frequent flooding of the river has made it a life-threatening nightmare. The importance of research lies in the fact that it is one of the few attempts to discuss and study the causes and effects of the Gash River floods. It aims to identify the factors affecting river floods. It proposes an algorithm to simulate flooding by randomly generating different factors that effectively affect river flooding. The descriptive analytical approach, the analytical, inductive approach, and the analytical deductive approach to desk research were used, taking advantage of the primary statistical method in its observation and evaluation, which relies on primary and secondary information to help make scientific, practical, and objective. The research came out with significant results related to the problems that threaten the town of Kassala from the frequent floods of the Gash River. The study's results proved that there is a deviation and discrepancy between the floods rate during the year, which gives a negative indication, and that deposited quantities vary in different proportions from one period to another, which causes a significant threat in the future. The research suggests other solutions that help reduce the problems and their effects. In addition to the above, the study proposes various recommendations that will be the basis for future studies to reach the required solutions and goals.

**Keywords**—Gash river; flood simulation; influencing factors to flood; simulation

## I. INTRODUCTION

Floods frequently result in significant economic losses and harm to people and the community [1]. Flood forecasting and management have thus always been difficult for the government and local governments [2, 3]. As more and more computer models are used for flood management [4], there is an increasing need for innovative and effective ways to visualize large amounts of data about floods. In addition, because interaction is one of the most critical factors in modern decision-making tools, simulation effectiveness has become a significant factor [5, 6]. Flooding in urban contexts is typically associated with a complex landscape involving technical, social, economic, and environmental issues [7]. The Gash River is a seasonal river that descends from the Eritrean plateau and reaches the Sudanese border, 30 km south of Kassala. It passes through the city of Kassala, passing through the Gash Delta Agricultural Project, to end at the Gash Delta, about 91 km north of the area of Kassala [8]. The natural features of the Gash River are unique characteristics,

including the steep slope, which is six times the sharpest stream in Sudan, as its slope within the Sudanese borders is 1.3 m / km at Kassala city, which gave it the ability to bring high loads of siltation [9].

Soft, sandy soils and fragile banks characterize the riverbed banks. It is easily eroded by high currents and fragmentation and change course from one place to another. These factors combined lead to the occurrence of flood phenomenon [7]. The area of the basin of the Gash River is estimated at 21.000 km<sup>2</sup>. Most of it is located within the Eritrean lands and at contour heights ranging between 2000 and 1100 m above sea level. This basin is located between longitudes 36.5 and 39.5 east and latitudes 14 and 15.5 north. The river in Eritrean territory has a steep slope that reaches 5.5 meters per kilometer. The transition from about 2000 meters above sea level at its source to only about 550 meters at the Sudanese border [9] makes the flood waves rush very quickly. It reaches 2 meters/sec sometimes [8]. Therefore, the Gash is among the fastest rivers in the world [10]. The river's slope within the flat Sudanese plain is estimated at 1.3 m / km.

The importance of the study lies in the fact that it reveals the role of technical means in reducing water losses due to Flooding and benefiting from them in drinking, agriculture, and creating new projects in the agricultural field. And this study takes a fresh look at the country's flood management, and explores methods for lessening the likelihood of flooding and the damage it might cause [11].

In addition to reflecting technical progress, designing a computer simulation model for the behavior of factors affects flooding.

The Gash River has become a source of fear and anxiety because it floods and damages the economy, society, and environment. These floods are caused by many factors work together. Which is difficult to predict and control, and whatever the matter is, floods are a natural phenomenon that spreads in all parts of the world, and this is not the dilemma, but rather the difficulty remains in that we avoid its occurrence and prevent the disaster before it occurs and to what extent we contribute to it [12].

The study is concentrated in Kassala State. Kassala State, its capital, is the city of Kassala. The area of Kassala State is 55.374 square kilometers, and it is located between latitudes 12-34 and 36-57 east and longitudes 12-14 and 12-17 north. In the east, the state's borders are shared with the country of

Eritrea. Internally, it borders the Red Sea, Gezira, and Gedaref states [13]. The state enjoys a prominent geographical location that helped its growth and made it a center for many commercial and investment activities. It provides essential services and all factors that help investment. It is known for its beautiful scenery and lush gardens, which make it the most important place for tourists to visit. There are many agricultural projects, such as sugar cane production, corn and wheat too. The populace also engages in trading and pastoral work.

## II. MORPHOLOGY OF THE GASH RIVER

The Gash River is known from the morphological point of view as a cascading river, where the river is wide and shallow. In this type of river, the current takes several directions, is unstable, and constantly changes its course and characteristics [8].

The Gash River carries large quantities of Silt (primarily fine sand and Silt). Due to the sharp decrease in the river's slope when it crosses the Sudanese lands, these quantities exceed the river's ability to transport it. It is deposited along the course of the river until its end, which caused the river's steadily reducing capacity and inability to transport it. Passing High Floods Safely [9].

## III. METHODOLOGY

The research method used in the study is the descriptive analytical method, and this approach is also called the in-depth descriptive method. In this method, the research describes various scientific phenomena and problems in detail, allowing good explanations and results. Using the descriptive-analytic approach, different things are compared to similar items. This allows data to be collected about the differences and similarities between things, which are the most important things that make the descriptive-analytical approach different from other scientific approaches [15].

The descriptive-relational approach is also used because it is related to the nature of the study. It also relies on analyzing the existing system and using diagrams, graphs, flowcharts, algorithms, design, and software to create a more accurate and efficient system. According to the explanatory method, relational studies define problems and analyze them into their essential elements [15] by presenting events and facts and analyzing them. Also, the inductive-analytical approach involves immersing in the details and reasoning behind the points to identify significant patterns, themes, and interrelationships, after which the results are confirmed using analytical principles rather than rules [14]. The study also follows the deductive analytical desk research approach, in which the literature related to the subject of the study is reviewed.

## IV. MODEL DESCRIPTION AND ALGORITHM

To study the current situation, the study dealt with the problem of the Flooding of the Gash River by simulating the factors affecting the Flooding in the form of randomly generated variables within the program environment.

### A. Factors Affecting the Flooding of the Gash River

There are many factors affecting the Flooding of the Gash River. Still, they can be limited to natural, technical, and other artificial causes attributed to some harmful practices.

### B. Flood Estimate

The Gash River is distinguished for its wide fluctuations in its water revenue throughout and between seasons (Table I). Evidence indicates changes in the river's hydrology as a result of changing the natural properties of the upper river basin in the State of Eritrea, especially the removal of vegetation and soil erosion, which made the flood wave more severe and shorter in time. This is in addition to the global climatic changes that began heralding the high precipitation rates in 2007 AD [9].

TABLE I. SHOWS THE RIVER'S DISCHARGES FROM 1997-2010 (AL-JIRA STATION) [8]

Year	Total Revenues Upstream - Million Cubic Meters	Year	Total Revenues Upstream - Million Cubic Meters
1997	111.58	2009	452.57
1998	565.21	2010	680.69
1999	1386.66	2011	1007.41
2000	1240.00	2012	704.04
2001	1007.41	2013	888.89
2002	704.04	2014	1313.09
2003	1449.49	2015	1300.66
2004	874.97	2016	440.00
2005	1101.00	2017	760.00
2006	1207.75	2018	663.80
2007	1760.00	2019	450.85
2008	665.20	2020	673.02

We note from the above table the great variation in the river's revenues during the season. We also notice the difference in the discharges and returns of the river during a number of selected years at the Al-Jira monitoring station at the source (Fig. 1) illustrates this.

Fig. 1. Shows the discharges and revenues of the river at the Jira station upstream.

Flood estimation methods aim at modeling the relationship between falling rain and the resulting surface runoff. In general, these methods can be divided into three groups. The first group is called simple methods - such as the logical method and implicit equations - from which the value of the peak behavior can be estimated quickly and based on a Small amount of information. The CN Curve Number method is one of the methods of the second group or group of medium complexity [16]. The third group includes straightforward or more complex methods, which depend on the study of each element involved in the phenomenon, the transformation of rain into a surface runoff, and detailed and in-depth analysis. The number curve method is the most prevalent in engineering studies and natural resource management projects, especially in the US states [17].

C. *The Nature of the Gash River (The Strength of the Gash River Current)*

The significant fluctuation represents the characteristics of the Gash River in the flow, the steepness, the high speeds, high loads of Silt, the broad stream, and the fragile banks combine to form a community that threatens the river's bridges and its widths.

D. *Silt*

Problem of Silt is one of the most important problems associated with irrigation, drainage, floods, and natural rivers. Generally, dredged Silt represents about 5 to 25% of the total Silt carried, but its importance is that it affects the roughness and stability of the stream. Table II shows the quantities of dredged Silt during periods of years from 2010 to 2020.

As can be seen in Table III, the amounts of Silt vary significantly not only from season to season, but even within a season.

TABLE II. SHOWS THE QUANTITIES OF DREDGED SILT DURING THE PERIOD FROM 2010 TO 2020

Year	Total - mm3	The upper limit is 3 mm
2010	1290	470
2011	0930	385
2012	0810	370
2013	1430	870
2014	0400	205
2015	0535	365
2016	1165	575
2017	1010	395
2018	0960	290
2019	0540	295
2020	0540	295

TABLE III. SHOWS THE DIFFERENT AMOUNTS OF SILT

Date	Attributed	Suspended Silt (ppm)
21/08/2020	508.0	1753.7
22/08/2020	507.0	1450.5
25/08/2020	506.9	13458
27/08/2020	506.8	13300
29/08/2020	506.6	11976

The table shows that silt quantities vary seasonally and within seasons.

The amount of Silt in the water decreases according to the amount of water (water levels). The higher the group, the higher the amount of Silt attached to the water. We find the rise of the stream bed in the two divided sectors of the river, in front of and behind the network of bridges and wide's, receiving their share of the Silt carried from the upper reaches of the river [9].

E. *Various other Reasons*

There are many harmful practices carried out by the population that affects negatively, including some activities around the river basin have adverse effects such as planting trees around bridges, erecting buildings, constructing bridges and beams inside the bay, taking soil from bridges, or digging latrines and wells in the areas adjacent to the bridges [18].

F. *Elevation of the Levels of the Gash River*

This is due to three main reasons:

First: the climatic and hydrological changes represented in the disappearance of the vegetation cover and the increase in water and silt discharges, the engineering works that prevented the natural venting that was occurring in the Tajuj region at high levels, and the collapse of the dams built on the Gash River in the State of Eritrea.

Second: Weakness of the conveying capacity of the gutter as a result of the presence of suffocating facilities such as bridges and bridges.

Third: the morphological changes that led to the rise of the riverbed due to sedimentation due to the lack of slope.

All these reasons combine to cause a catastrophe, as happened in 2003. Climate change is a global phenomenon that warns of more variation in precipitation and high waves of floods. The rise in the river water level as result of heavy rains was accompanied by the collapse of some dams in the country of Eritrea, which exacerbated the severity of the floods [8].

---

Program algorithm generating random numbers to simulate the factors influencing Flooding

---

```

1. Start
2.1 let I= 1
2.2 sum=0
2.3 pita=300
3. Let      Z=random (10)
4. If (z = 0)
{x=0}
Else
{x=pita*Z}
5. Near the value x to an integer
6. If (x=0)
{M=pita/4 Go to 8}
7. Let M=ceil(x)*1/4
8. Sum = sum + ceil(x)
9. Print value ceil (m), ceil(x)
10. Let I=I+1
11. If (I<=10)
{Go to 3}
12. Print Report
13. End
    
```

---

In the algorithm

I: represents the loop counter.

Pita: means the amount of water.

Z: represents the randomly generated number from the random function. The random process generates random numbers for unrelated events; the Ceil function approximates the correct number.

M: represents the amount of Silt, which is calculated by the formula  $m = \text{pita}/4$ .

Fig. 2 shows the sequence of steps of the above program and algorithm through the following flowchart.

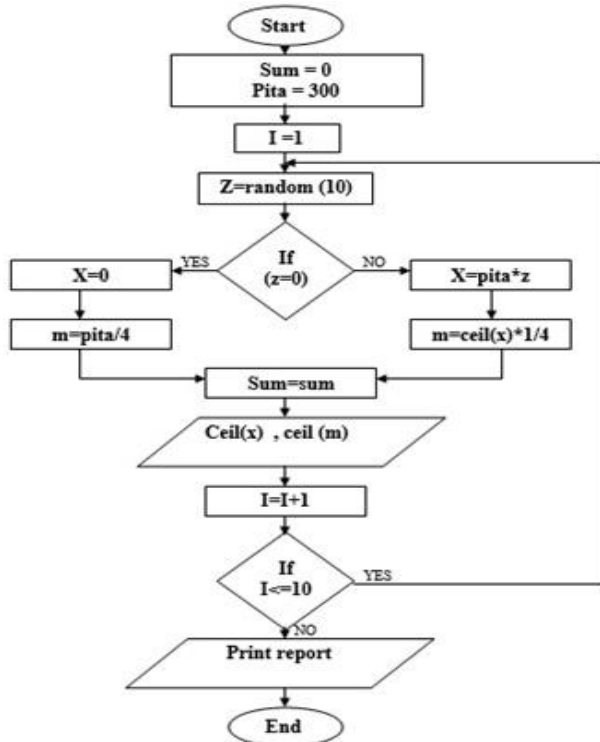

Fig. 2. Flow chart of algorithm.

Fig. 3 illustrates the implementation of the program, and we find that the sediment quantities vary in different proportions from one period to another, which causes a great threat in future periods.

Fig. 3. Shows the program execution screen.

TABLE IV. SHOWS THE OUTPUT OF THE PROGRAM

Year	M (The amount of clay)	X (Quantity of Water)
1	1800	450
2	2400	600
3	0300	075
4	1800	450
5	1200	300
6	2400	600
7	0600	150
8	1800	450
9	0300	075
10	1800	450

Table IV shows a reflection of the implementation of the program shown in (Fig. 3) and shows the relationship between the amount of water in the river and the amounts of suspended silt for ten consecutive years generated randomly.

The total amount of Silt after 10 years is 3600 m.

## V. IMPLEMENTATION

A Markov distribution was used to generate random numbers and compare unrelated cases with equal probability distribution using the beta parameter calculated from the entire population.

A sample of 10 years was taken to take the average from the actual reality of the cascade generation that occurs annually starting from the base year. Table V shows the average level of the river level during specific years at the Al-Qash Gash Bridge monitoring station in the city center, as well as the lowest rate, highest rate and the standard deviation.

By comparing the result of the program and the actual reality, we find the relationship between the level and the Silt is correct.

Benefit from the program in calculating the amount of Silt deposited after each number of years.

TABLE V. AVERAGE RIVER LEVEL DURING SELECTED YEARS - AL-GASH BRIDGE MEASURING STATION

Year	The Lowest Rate	Highest Rate	Standards deviation
1990	15.00	210.00	31.2842
1999	504.00	506.00	0.3167
2003	504.00	505.90	0.2563
2005	504.05	505.95	0.3553
2008	505.40	506.01	0.2986
2010	504.70	505.95	0.1951
2015	504.90	506.10	0.2346
2019	504.19	506.45	0.3481

## REFERENCES

The results of the study proved that there is a large deviation and variation between sedimentation rates during the year, which gives a negative indicator, and that the amounts of sediment vary in varying proportions from one period to another, which causes a great threat in future. It is also expected that the amount of Silt deposited by this algorithm will be about 8.450 mm<sup>3</sup> in the year 2035 AD. Different river speeds, revenues, and flows reveal a clear relationship between the volume of water and its rate and the amount of Silt drifting and traveling from one place to another within the same season. The study also proved that the annual average of rain is not considered a good factor for the strength of the rainstorm in estimating the severity of the flood, as it is possible for the power of one of the rainstorms to exceed this annual average.

The study also concluded that increased sediment quantities over the years led to a rise in the river level higher than the level of agricultural lands. This was one of the primary reasons and systematic risks that allowed the river to stray from its intended path. Changing the course of the river may pose a danger in the future.

## VI. CONCLUSION

Developing this model includes all elements have an indirect effect, such as evaporation, soil type, and wind.

The model works on developing a distant understanding, a broad horizon, and an open mind in the applied aspects at all administrative levels, especially about the applications of simulation models.

Also, this model benefits in the field of forecasting and future estimates of the quantities of silt and water for the Gash River.

The application of this model in the investigation and exploration of the river is a powerful technique through which we can provide planners of water resources with an acceptable estimate of the amount of running water and the quantities of suspended Silt that are expected to be deposited.

The results of the model can also be used to help city planners and decision-makers make plans for the future of Kassala city; applying this modern technical method (simulation models) in flood management in the country.

The researcher suggests that there will be future studies that follow the technical method on the basin's area, the mainstream's length, and the peak discharge.

It is also suggested that there be studies of the geological formation, soil permeability, and type of land use around the course of the Gash River to avoid the risks of floods in the future.

Similarly, more in-depth studies reach more detailed results to advance this region and develop it in the future in terms of economic and social aspects.

**Abstract**—As the Supervisory Institution in Statistics, Badan Pusat Statistik (BPS) launched an integrated information system (IS) to exercise the Open Government Data (OGD) initiative and to impose the One Data Policy Act. Albeit challenges arise, BPS manages to provide more than 120 thousand publicly accessible datasets. With the success of OGD, many scholars have opted to examine a similar issue from the perspective of users/citizens. However, employees' perspective remains substantial as employees are the OGD provider. This research administers employees' views to pinpoint influencing factors in the success of OGD adoption through an IS. The authors seek to comprehend the factors from IS and acceptance manner, thus integrating the Information System Success Model (ISSM) and Unified Theory of Acceptance and Use of Technology (UTAUT) as the measurement model. This study also administers a cross-sectional questionnaire with close-ended questions to obtain data from 253 IS users in BPS. Using structural equation modelling (SEM), the authors find that all ISSM constructs influence the success of IS while only one construct from UTAUT plays a pivotal role in defining the success. Information Quality, System Quality, Service Quality, User Satisfaction, and System Use remain paramount to the successful implementation, while Performance Expectancy becomes the sole influencing UTAUT factor affecting success. This study therefore offers substantial benefits by aiding other researchers in OGD-related areas and providing in-depth evidence for practitioners in implementing IS for OGD initiatives.

**Keywords**—Open data; open government data; OGD; employees' perspective; ISSM; UTAUT; success factors; acceptance; impact; integrated IS; One Data Policy; BPS; SEM

## I. INTRODUCTION

Since its inception in 2009 [1], [2], Open Government Data (OGD) have grown exponentially [3] in the last few years and has served as the bedrock for a data-driven nation. Correspondingly, governments have collected a plethora of data to perform their tasks and made it available to the public [4]. OGD therefore holds an increasingly pivotal role [5]. In 2016, President Joko Widodo coined One Data Initiative or "Satu Data Indonesia" (SDI), followed by a regulation in 2019: Presidential Decree Number 39 of 2019. Similar to principles of open data by the Open Knowledge Foundation [1] and the United Kingdom's Government [6], Indonesian ministries/agencies must comply with four fundamental principles (*data standard, metadata, interoperability, and*

*reference code*). Through SDI, the government intends to deliver accurate, up-to-date, integrated, accountable, accessible, and interchangeable data for national development agendas [7].

As SDI's Central Data Supervisory Institution (Pembina Data) in Statistics, Badan Pusat Statistik (BPS) introduced<sup>1</sup> an integrated information system (SIMDASI) that administers SDI principles: interoperability with other ministries/agencies [8]–[10] and compliance to data standards, metadata, and reference code<sup>2</sup>. Supported by derivative policies, SIMDASI establishes itself as the bedrock of the OGD initiative, dispensing most of the open data on the organisation's website<sup>3</sup> with the finest quality through synchronisation processes [8]. Presently, SIMDASI houses more than 120 thousand publicly accessible datasets<sup>4</sup>; thus, SIMDASI remains paramount in the OGD initiative for BPS.

Likewise, Information and Communications Technology (ICT) adoption for employees becomes tedious [11] and information systems (IS) cannot engender benefits should employees refuse or fail to use IS accordingly [12]. In measuring the success of government systems or services, Martono et al. (2020) [13], Puspitarini & Ardhani (2022) [14], Stefanovic et al. (2016) [15], and Gangga Dewi & Fajar (2021)[16] successfully exercised DeLone and McLean Information System Success Model (ISSM) [17] to measure the IS success. Accordingly, Stefanovic et al. (2021) [18] reaffirm that ISSM is the most widely used measurement to measure IS success within the e-government context. Stefanovic et al. (2016) [15] also evaluate the IS success of an e-government system from the view of employees in the Republic of Serbia. The result shows that the use of an e-government system influences the net benefits perceived by the employees.

At the organisational level, moreover, many scholars stress the challenges hindering OGD adoption: lack of technical skills

<sup>4</sup> <https://simdasi.bps.go.id/>. Accessed: 7 November 2022

from employees, staff shortage, and organisational understanding [19]–[25]. Wang et al. (2019) [24] even address that the United Kingdom's OGD programme relies on employees' enthusiasm, skills, and goodwill. Subedi et al. (2022) [26] also imply that individual and organisational factors influenced OGD adoption by Nepali government officials. Hence, the acceptance from employees has proven substantial in the OGD adoption.

In assessing the acceptance, the Unified Theory of Acceptance and Use of Technology (UTAUT), developed by Venkatesh et al. (2003) [27] and perfected by Venkatesh et al. (2012) [28], becomes one of the baseline models to explain user intention to use an IS in an organisation setting such as in e-government research [12], [26], [29]–[38]. Their findings prove that the four construct (Performance Expectancy, Effort Expectancy, Facilitating Conditions, and Social Influence) affect the intention to use, which subsequently influences the system use. Further, Stefanovic et al. (2021) [18] explain that many scholars combine UTAUT in the ISSM construct to complement their studies [12], [14], [29], [38], [39].

In OGD-related research, however, many scholars employed the citizens' perspective [31], [37], [39]–[43] to measure the success of OGD, although Syuhaini and László (2022) [12] highlight the importance of taking employees' perspective as they design, implement, run, and expand the systems. Talukder et al. (2019) [43] propose additional dimensions from ISSM to clarify the usage intention of OGD users. Prior studies have yet to discuss the benefits of IS as the foundation of OGD and employees' acceptance as OGD providers for the public; they stop at the behavioural intention to use OGD. Considering the gaps and the limited number of research on OGD from employees' perspective, this study formulates the following research questions:

RQ1. What are the IS factors that influence the use of SIMDASI?

RQ2. What acceptance factors from employees affect the use of SIMDASI?

RQ3. What direct factors determine the success of SIMDASI as an OGD adoption tool?

To address the research question, the authors propose an UTAUT-integrated ISSM model aimed at unearthing benefits from administering SIMDASI as an OGD adoption tool from employees' perspective. The model

The study therefore is organised as follows: Section II elaborates theoretical background and hypotheses; Section III explains the research methodology; Section IV expounds on the research results; Section V explicates the discussion regarding the research objectives and the implications; Section VI closes the research with the conclusion and limitation of the study.

## II. LITERATURE REVIEW AND HYPOTHESES

### A. DeLone & McLean Information System Success Model (ISSM)

ISSM offers a comprehensive metric to gauge the success of an information system [44], [45]. Correspondingly, this approach proposes an idea in which system quality and information quality affect the use and the adoption of IS, resulting in individual and organisational impact [43], [45]. DeLone and McLean (2003) [17] further propounds upgrades with the inclusion of the service quality dimension to help explain the effectiveness of an IS [45]. DeLone and McLean (2016) [46] then recommended the integration of *intention to use* and *use* into the *system use* dimension, of which the model measures the degree of usage in a mandatory IS —*the case of SIMDASI*. The ISSM model thus stipulates six dimensions as follows:

#### 1) Information Quality (IQ)

Providing users with accurate, timely, and relevant information becomes the driving force for IS applications; hence, the IQ dimension remains paramount in the model [45]. DeLone and McLean (2016) [46] argue that IQ contributes to user satisfaction and declares that this dimension should be viewed as a success metric independent from end-user satisfaction measurements. Further, they assert that IQ has been demonstrated to be substantially correlated with system usage and net benefits in both individual and organisational settings [44]–[46].

Stefanovic et al. (2016) [15] and Martono et al. (2020) [13] also prove that IQ influences the usage of e-government systems. Correspondingly, Talukder et al. (2019) [43] pinpoint that IQ influences citizens' usage of OGD. For the satisfaction issue, Gangga Dewi & Fajar (2021) [16] verify that IQ affects employees' satisfaction in using IS at Kominfo, Indonesia, similar to the research by Puspitarini & Ardhani (2022) [14].

This study therefore refers to the IQ dimension as a measurement of SIMDASI following the criteria: *relevance, usefulness, understandability, accuracy, reliability, completeness, and timeliness* [45], [46]. Accordingly, the authors suspect that IQ influences system use and user satisfaction.

#### 2) System Quality (SQ)

DeLone and McLean (2003) describe that SQ constitutes the desired attributes of an IS; thus, SQ subsumes measures of the IS itself [44]–[46]. These measures typically emphasise usability aspects and performance attributes of the examined IS. DeLone and McLean also reiterate that there is no universal measurement in SQ; thus, they establish *ease of learning, ease of use, availability, system reliability, and system interactivity* as ways to gauge the SQ [44]–[46].

In this model, SQ influences the system use and user satisfaction of the IS examined. Puspitarini & Ardhani (2022) [14], Talukder et al. (2019) [43], and Stefanovic et al. (2016) [15] demonstrate how SQ affects both *intention to use* and *user satisfaction* in their research. In addition, Martono et al. (2020) [13] uncovered that SQ has a significant influence on *system usage*, and Gangga Dewi & Fajar (2021) [16] have verified the correlation between SQ and user satisfaction in their research.

The authors suspect SQ significantly influences *user satisfaction* and *system use* in the model.

### 3) Service Quality (SEQ)

SEQ, the updated ISSM dimension, denotes the quality of assistance provided to users by the IT support team or IS department, such as training, hotline, or helpdesk [44]–[46]. DeLone and McLean (2016) [46] reclarify the SEQ dimension, which they believe is misunderstood and understudied, merits inclusion as a component of IS success because SEQ enhances individual performance. They further propose that the key measures for today's digital environment are *reliability*, *empathy*, *responsiveness*, *contact*, and *interactivity*.

Puspitarini & Ardhani (2022) [14] and Gangga Dewi & Fajar (2021) [16] evince that SEQ influences both system use and user satisfaction. Stefanovic et al. (2016) [15], on the other hand, verify the relationship between SEQ and system usage in their research but fail to identify the correlation between SEQ and user satisfaction. The same goes for Martono et al. (2020) [13], as they failed to determine the connection between SEQ to either user satisfaction or system use.

As SIMDASI remains a mandatory system for OGD adoption and a specific department is available to assist users with technical and nontechnical support [8], the authors believe that the inclusion of SEQ is beneficial and thus argue that SEQ has a significant influence on system use and user satisfaction.

### 4) System Use (SU)

DeLone and McLean (2016) [46] explain that SU is the degree and manner in which employees utilise IS capabilities. Further, they also rectify the misconceptions among many scholars to omit SU where the system is mandatory. Realising the system's benefits is expected to be significantly impacted by variations in quality and intensity [46].

While prior studies stop at the SU, Stefanovic et al. (2016) [15] and Gangga Dewi & Fajar (2021) [16] seek to uncover the relationship between SU and the net benefits, which leads to the realisation that SU has a significant influence on the net benefits either for organisations or individuals.

The authors then suggest using SU as the mediating factor from IQ, SQ, and SEQ to the net benefits. Accordingly, DeLone and McLean (2016) [46] highlight indicators to measure SU: *frequency of use*, *duration of use*, *nature of use*, *appropriateness of use*, *number of functions or features used* (*extent of use*), *thoroughness of use*, *attitudes toward use*, and *intention to reuse*.

### 5) User Satisfaction (US)

The US dimension constitutes users' satisfaction when utilising an IS and is considered an essential factor in

measuring IS success. As SIMDASI remains mandatory, employing this dimension becomes favourable [44]–[46]. Gangga Dewi & Fajar (2021) [16] have proven the relationship between US to SU and US to net benefits, further proving the notion from Stefanovic et al. (2016) [15]. Urbach and Müller (2012) [47] also argue that US has a strong relationship with both system use and net benefits. The authors believe that US mediates IQ, SQ, and SEQ to SU and net benefits. The measurement of *effectiveness*, *enjoyment*, and *overall satisfaction* is an effective way to gauge US in this model. This study hence employs this US dimension as part of the measurement model.

### 6) Individual Impact (II)

DeLone and McLean (2016) [46] splits net impacts into *individual* and *organisational impacts*. This dimension explains the extent to which IS contributes to an individual's success, such as improved personal productivity. This paper suggests the inclusion of the II construct to measure the success of SIMDASI among individual levels that attribute the success of OGD adoption. The measurement of *learning*, *decision quality*, *decision time*, *productivity*, or *task performance* is proven effective.

### 7) Organisational Impact (OI)

DeLone and McLean (2016) [46] also propose measuring *cost reduction*, *overall productivity*, *improved outcomes*, and *e-government positioning* through the OI construct at the organisation level. As this study intends to unravel the success of SIMDASI to OGD initiatives in BPS, the authors propose using OI in the measurement model.

Given the above, the authors establish the proposed hypotheses to measure IS usage in the following lists:

H1. IQ positively and significantly influences on SU to operate SIMDASI for OGD adoption.

H2. IQ positively and significantly influences on US to operate SIMDASI for OGD adoption.

H3. SQ positively and significantly influences on SU to operate SIMDASI for OGD adoption.

H4. SQ positively and significantly influences on US to operate SIMDASI for OGD adoption.

H5. SEQ positively and significantly influences on SU to operate SIMDASI for OGD adoption.

H6. SEQ positively and significantly influences on US to operate SIMDASI for OGD adoption.

H7. US positively and significantly influences on SU to operate SIMDASI for OGD adoption.

### B. The Unified Theory of Acceptance and Use of Technology (UTAUT)

The UTAUT, a modified TAM model, uses two variables from TAM and expands them into four constructs (performance expectancy, effort expectancy, social influence, and facilitating conditions) affecting the behavioural intention to use a technology and/or technology use [27], [28]. Venkatesh et al. (2003) [27] imbue the construct with eight IT adoption theories, perfecting the theory. The eight standards

used in the construct are the Theory of Reasoned Action (TRA), Technology Acceptance Model (TAM), Motivational Model (MM), Theory of Planned Behaviour (TPB), a model that combined TAM and TPB, Model of PC Personal Computer Utilization (MPCU), Innovation Diffusion Theory (IDT), and Social Cognitive Theory (SCT).

Venkatesh et al. (2003) [27] have also tested the UTAUT resulting in a variance of 70%. Many scholars hence deem the UTAUT as the most comprehensive model in predicting employee behaviour in the e-government setting [12], [13], [29], [30], [38], [39]. Venkatesh et al. (2003) [27], Venkatesh et al. (2012) [28], and Taherdoost (2018) [48] report that, compared to other frameworks, the UTAUT boasts a better explanatory capability in forecasting the behavioural intention toward an IS. This study therefore employs the following constructs to complete the measurement:

### 1) Performance Expectancy (PEX)

The *Performance Expectancy* construct defines the degree of individual belief in which one feels that using the system will help improve his or her job performance [27], [45]. In general, Puspitarini & Ardhani (2022) [14] have established the evidence that PEX influence the usage of a technology. Further, in the e-government area, Yavwa and Twinomurinzi (2018) [33] failed to validate the connection between PEX and the usage behaviour. Yet, many scholars have successfully verified the correlation between PEX and usage behaviour [30]–[32], [34]–[36]. Mutaqin and Sutoyo (2020) [36] even prove that PEX stands as the most influential factor in the behavioural intention of e-government usage.

In the area of OGD-related study, Zainal et al. (2019) [39] propose an UTAUT-based model, which includes PEX, to measure the use of OGD in the academic setting. Further, Subedi et al. (2022) [26] certify the presence of PEX construct as the influential factor among OGD use by Nepali users. Hence, the dimension measured in this construct comprises *perceived usefulness, job-fit, and outcome expectations* [27], [28], [45] to gauge the acceptance of SIMDASI with the following hypothesis:

H8. PEX positively and significantly influences on SU to operate SIMDASI for OGD adoption.

### 2) Effort Expectancy (EEX)

The notion of the *Effort Expectancy* construct introduces a level of comfort related to using the accepted technology [27], [30], [45]. In the integrated model, Puspitarini & Ardhani (2022) [14] establish definitive proof that EEX affects the behavioural usage of the system. Albeit Taiwo et al. (2012) [34] dismissed the link between EEX and system usage, many

researchers propose evidence from their findings point to the connection between EEX and the usage of e-government services [30]–[33], [35], [36], [38].

In their research, Zainal et al. (2019) [39] expound on the correlation between EEX and system usage. In addition, Subedi et al. (2022) [26] depict the link between PEX and OGD use in Nepal. The authors thus propose this construct with the following measurement dimensions: *perceived ease of use, learning time, and complexity* [27], [28], [45]. For this dimension, the authors also formulate the hypothesis:

H9. EEX positively and significantly influences on SU to operate SIMDASI for OGD adoption.

### 3) Facilitating Conditions (FC)

The notion, known as the *Facilitating Conditions* construct, depicts how much one assumes the organisational and technological infrastructure support using the system. [27], [45]. Although Subedi et al. (2022) [26] ignore this construct, other scholars using the FC approach have presented the evidence. They claim that FC influences the behavioural use and the use of the system [30], [32]–[36], [39]. As for the measurement, this construct proposes the following criteria: *perceived behavioural control, facilitating materials, and compatibility*. Thus, the authors postulate the following hypothesis:

H10. FC positively and significantly influences on SU to operate SIMDASI for OGD adoption.

As for the *Social Influence* (SI), the authors believe that mandatory IS [8] compels employees to use the system without the influence of people around them. Al-Swidi & Faaeq (2019) [32] and Faroqi et al. (2020) [35] have proven that SI does not influence the usage behaviour in e-government services; the authors then decide to omit this construct from the model.

Finally, to unravel the benefits of SIMDASI in the context of OGD adoption. The authors formulate the following hypotheses:

H11. US positively and significantly influences on OI from SIMDASI as the OGD adoption tool.

H12. US positively and significantly influences on II from SIMDASI as the OGD adoption tool.

H13. SU positively and significantly influences on II from SIMDASI as the OGD adoption tool.

H14. SU positively and significantly influences on OI from SIMDASI as the OGD adoption tool.

Fig. 1 illustrates the measurement model in this study.

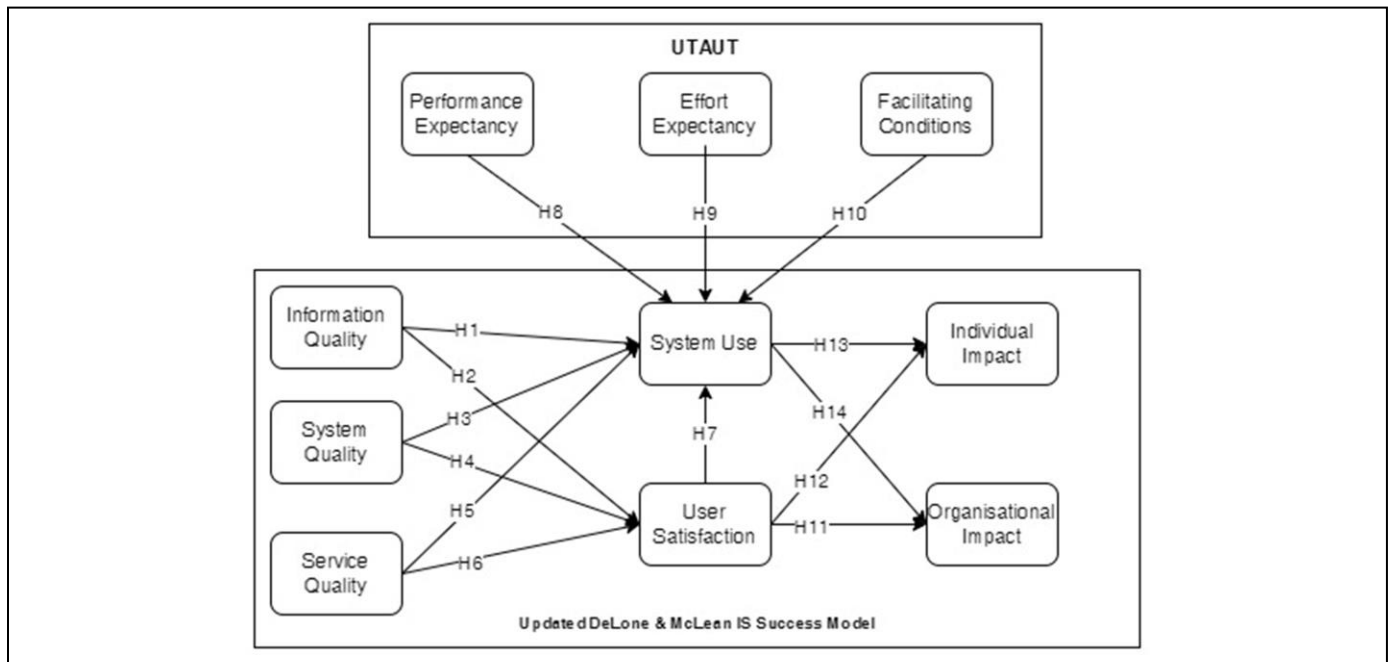

Fig. 1. Proposed measurement model

### III. RESEARCH METHODOLOGY

#### A. Design of the Study

This study outlines findings on the factors influencing OGD adoption through an integrated system based on employee views. The authors identify four endogenous constructs (system use, user satisfaction, organisational impacts, and individual impacts) and two mediating factors (user satisfaction and system use). Fig. 1 depicts the suggested model, which incorporates two models (ISSM and UTAUT), resulting in ten latent variables: *Information Quality (IQ)*, *Service Quality (SEQ)*, *System Quality (SQ)*, *User Satisfaction (US)*, *System Use (SU)*, *Performance Expectancy (PEX)*, *Effort Expectancy (EEX)*, *Facilitating Conditions (FC)*, *Individual Impacts (II)*, and *Organisational Impacts (OI)*.

The authors further establish fourteen different paths among the variables. In IS usage measurement, the authors construct seven hypotheses (H1–H7), while in uncovering employees' acceptance, the authors employ three hypotheses (H8–H10). Finally, the authors also hypothesise that SU and US are predictors of individual and organisational impact with four hypotheses for direct effects (H11–H14) [Fig. 1].

Furthermore, the authors employ a quantitative technique to obtain data, utilising questionnaires as the instrument. To pinpoint the correlation between one or more independent/dependent variables, the authors also use the structural equation model (SEM) methodology [49]. This study also focuses on BPS as the leading sector of OGD in Indonesia,

hence resulting in a *small sample size*. With addition of a *complex measurement model* in the study (many indicators and relationships), the authors hence select the partial least square (PLS) SEM as the modelling technique for the study [50]. Previous studies show that PLS SEM helped researchers in performing statistical analysis in a similar setting [13], [14], [16], [31], [32], [35], [43].

As for data analysis, the authors administer PLS software called SmartPLS 4 [51] to execute PLS-SEM [50], [52] and one-tailed bootstrapping tests [50], [53]. Finally, as advocated by Hair et al. (2017) [50], the authors utilise two-stage analysis: *measurement model assessment* and *structural model assessment*.

#### B. Instrumentation

The authors then collect the data using a cross-sectional questionnaire with close-ended questions. The questionnaire used in this study is designed in two parts: *respondents' information* and *respondents' view* regarding the proposed model. The first part of the questionnaire comprises eight questions that collect basic information about the respondents: *name, email, phone number, location (office), gender, age, education level, and working experience*. The second part contains 44 indicators to evaluate the proposed model. Each item is assessed on a five-point Likert scale: *1-strongly disagree; 2-disagree; 3-neutral; 4-agree; 5-strongly agree*. Appendix A exhibits the measurement items for this study and Fig. 2 depicts the recommended indicators for the model.

Fig. 2. Proposed measurement model with 44 indicators

C. Participants

The authors sent the questionnaire to approximately 613 employees who operate SIMDASI frequently. The authors then distribute through emails registered to SIMDASI from all BPS offices (headquarters, provincial offices, and regency/municipality offices), of which 253 responses were collected between 9 and 18 November 2022. In collecting the data, the authors inform and guarantee the security of the answer as their responses will remain secret and used only for academic purposes.

$$n = \frac{N}{1 + Ne^2} \quad (1)$$

To determine whether the collected responses have met the minimum sample requirement, the authors employ Slovin's formula to check the validity in equation (1), where *n* equals the required sample size, *N* means population size, and *e* is the margin of error. As Tejada et al. (2012) [54] recommended, the authors use a 95% confidence level or 5% of margin error, resulting in a 242 minimum sample size from a known 613 population. In a similar fashion, Kock & Hadaya (2018) [55] propose a sample size of 146 or 160 should researchers do not know the value of path coefficient with the minimum absolute magnitude. Thus, this study has met the required sample size.

Furthermore, as seen in Table I, 88,2% of the valid responses come from regional offices (province and regency/municipality offices), with most of the respondents being male (58,9 per cent). Then, nearly half of the respondents are 30–39 years of age (48,2 per cent). Then, nearly 99 per cent of respondents possessing higher education (diploma to doctorate) backgrounds and 39,5 per cent of the participants had worked for 11 to 20 years in BPS.

TABLE I. RESPONDENTS' PROFILE (N=253)

Item/Description	N	%
<b>Location (Office)</b>		
Headquarter	30	11.9
Provincial Office	66	26.1
Regency/Municipality Office	157	62.1
<b>Gender</b>		
Male	149	58.9
Female	104	41.4
<b>Age (years)</b>		
20–29	73	28.9
30–39	122	48.2
40–49	39	15.4
> 50	19	7.5
<b>Education Level</b>		
High School	1	0.4
Diploma	4	1.6
Bachelor's Degree	170	67.2
Master's Degree	77	30.4
Doctorate	1	0.4
<b>Working Experience (years)</b>		
< 5	51	20.2
5–10	68	26.9
11–20	100	39.5
> 20	34	13.4

#### IV. RESULT

##### A. Measurement Model Assessment

Hair et al. (2017) [50] and Hair et al. (2019) [52] recommend tests for examining the measurement model: *reflective indicator loadings, internal consistency, convergent validity, and discriminant validity.*

##### 1) Reflective indicator loadings (outer loadings)

Hair et al. (2017) [50] employ indicators of a reflective construct as a different technique for evaluating the same construct. The higher the outer loadings, the more common are the associated indicators on a construct. According to Hair et al. (2017) [50], an indicator's outer loading should be greater than 0.708 and, in most cases, 0.700 is adequate. Further, when an outer loading of an indicator is < 0.40, Hair et al. (2017) [50] recommend deleting the reflective indicator, while an outer loading between 0.40 and 0.70 should be analysed to check the increases of *average variance extracted (AVE)*.

From the calculation in Table II, two latent variables possess < 0.700 outer loading values, namely, IQ5 and SQ5. Accordingly, the authors prompted another reflective indicator loadings test by omitting **IQ5** and **SQ2** to examine changes in AVE. As identified in Table III, the AVE from IQ and SQ increase to 0.052 and 0.082, respectively. Thus, the authors agree to exclude IQ5 and SQ5 from the proposed model, resulting in above 0.700 outer loading values for all indicators shown in Table IV.

TABLE II. INITIAL REFLECTIVE OUTER LOADINGS

Indicator	Loading	Indicator	Loading
EEX1	0.826	OI5	0.879
EEX2	0.887	PEX1	0.852
EEX3	0.925	PEX2	0.915
EEX4	0.915	PEX3	0.935
EEX5	0.861	PEX4	0.903
FC1	0.840	SEQ1	0.917
FC2	0.792	SEQ2	0.924
FC3	0.843	SEQ3	0.941
FC4	0.789	SEQ4	0.888
II1	0.872	SEQ5	0.915
II2	0.909	SQ1	0.836
II3	0.931	SQ2	0.879
II4	0.907	SQ3	0.833
IQ1	0.748	SQ4	0.728
IQ2	0.800	<b>SQ5</b>	<b>0.608</b>
IQ3	0.848	SU1	0.830
IQ4	0.784	SU2	0.906
<b>IQ5</b>	<b>0.696</b>	SU3	0.870
OI1	0.865	US1	0.918

Indicator	Loading	Indicator	Loading
OI2	0.924	US2	0.882
OI3	0.879	US3	0.926

TABLE III. CHANGES IN THE AVE BEFORE AND AFTER EXCLUSION

Latent Variable	AVE		Changes
	Before	After	
EEX	0.781	0.781	0.000
FC	0.666	0.666	0.000
II	0.819	0.819	0.000
<b>IQ</b>	<b>0.604</b>	<b>0.656</b>	<b>0.052</b>
OI	0.793	0.793	0.000
PEX	0.813	0.813	0.000
SEQ	0.842	0.842	0.000
<b>SQ</b>	<b>0.613</b>	<b>0.695</b>	<b>0.082</b>
SU	0.756	0.755	0.000
US	0.829	0.829	0.000

According to Table IV, Service Quality, SEQ3 obtains the most significant loading with 0.946, while the most negligible loading alluded to System Quality, SQ4 (0.718). After analysing the indicators, forty-two items were incorporated for the following assessment:

##### 2) Internal consistency reliability

The subsequent measurement to be examined is internal consistency reliability: *Cronbach's Alpha (Alpha)* and *Composite Reliability (CR)*. Alpha assumes that all indicators are equally reliable and are used to measure internal consistency reliability. Due to its limitations, Hair et al. (2017)[50] introduce an additional measure called CR, which accounts for different outer loadings of the indicators. Additionally, Hair et al. (2017) [50] and Hair et al. (2019) [52] emphasise that both CR and Alpha should be above 0.700.

Table VI shows that both Alpha and CR for all structures are acceptable, exceeding the appropriate level. For the acceptance factors (EEX, FC, PEX), the recorded Alphas are 0.929, 0.834, and 0.923, consecutively. As for the CR, these factors counted 0.947, 0.889, and 0.946, respectively. Regarding IS success, the measured factors (IQ, SQ, SEQ, US, SU, II, and OI) possess Alpha values in the following order: 0.825, 0.852, 0.953, 0.931, 0.840, 0.926, and 0.935. As for the CR values, the IS success factors recorded 0.884, 0.901, 0.964, 0.951, 0.902, 0.948, and 0.950.

##### 3) Convergent validity

Convergent validity constitutes a measure that correlates positively with alternative measures of the same dimension. Therefore, the indicators should converge, sharing a considerable proportion of variance. Hair et al. (2017) [50] state that the appropriate measure for convergent validity is AVE with a value above 0.500 or more, explaining 50% or

more of the variance. Table IV shows that all constructs received AVE values higher than the 0.500 variances.

4) *Discriminant validity*

Discriminant validity represents how a construct differs from others by empirical standards, implying the uniqueness among the variables. *The Fornell-Larcker criterion* and *heterotrait-monotrait ratio (HTMT)* are the best measurements to gauge the discriminant validity of the model [50], [52].

The Fornell-Larcker construct compares the square root of the AVE values with the latent variable correlations [50], [52]. The correlation between the two variables should be lower than the *square root of the AVE*. Appendix C exhibits this concept;

the square root of EEX AVE (0.781) is 0.884, and the correlation between FC and EEX is 0.750, which means that FC and EEX achieve discriminant validity.

Furthermore, HTMT translates as the ratio of the between-trait correlations of indicators among all variables. To obtain discriminant validity, the HTMT should be below 0.900. Appendix B depicts all HTMTs from the latent variables that are < 0.900 and vary from one another. Through the Fornell-Larcker criterion and HTMT examination, the authors hereby declare that the proposed model achieves discriminant validity.

TABLE IV. INDICATOR LOADINGS, INTERNAL CONSISTENCY RELIABILITY, AND CONVERGENT VALIDITY

Latent Variable	Item	Loading	Alpha	CR	AVE	Latent Variable	Item	Loading	Alpha	CR	AVE
Effort Expectancy (EEX)	EEX 1	0.826	0.929	0.947	0.781	Performance Expectancy (PEX)	PEX 1	0.852	0.923	0.946	0.813

	OI4	0.904					US4	0.914			
	OI5	0.879									

B. *Structural Model Assessment*

In assessing the structural model, Hair et al. (2017) [50] assert that PLS-SEM is beneficial in estimating the parameter to maximise the explained variance of the endogenous latent variable(s). The key criteria for evaluating the structural model are *collinearity*, *path coefficients*, and *coefficient of determination (R<sup>2</sup> values)* [50], [52].

1) *Collinearity*

Collinearity refers to the degree of correlation between two predictor constructs; thus, a high level of collinearity is crucial [50], [52]. To measure the collinearity, Hair et al. (2017) [50] recommend administering *variance inflation factor (VIF)*, and, in the context of PLS-SEM, the VIF value should be in a range between 0.20 and 5. Appendix D delineates the VIF statistics from the inner model and shows that all VIFs are within

recommended values. Therefore, collinearity is not a concern for the model used in this research.

2) Path coefficient ( $\beta$ )

Representing the hypothesised relationships among the constructs, the path coefficients ( $\beta$ ) possess standardised values between -1 and +1 [50], [52]—the closer  $\beta$  value is to 0, the weaker is the relationship. Then, to check whether the  $\beta$ s are significant, the authors attempt a one-tailed bootstrapping test procedure with 5,000 resamples, resulting in t-values and p-values. The authors compare the critical value and inspect the significance of every hypothesis.

Table VI informs the estimation results for the proposed hypotheses in this study. The path from user satisfaction to individual impact possesses the highest value ( $\beta=0.662$ ;  $t=10.508$ ), while the relationship from facilitating conditions to individual impact and organisational impact with 0.018 value for both paths. In addition, Table VI also confirms that eleven out of fourteen proposed hypotheses are supported.

3) Coefficient of determination ( $R^2$ )

$R^2$  value becomes the most applied measurement to assess the structural model by measuring the model's predictive capability [50], [52]. This approach allows researchers to examine the coefficient between exogenous latent variables' combined effects on the endogenous variable [50]. Table V explains that all endogenous model variables possess moderate effects [50], with individual impact receiving the highest  $R^2$ , meaning that system use and user satisfaction explain 71.1% of the variance. Moreover, information quality, system quality, service quality, and user satisfaction explain a 55.8% variance in system use, the lowest  $R^2$  value in the model.

TABLE V. COEFFICIENT OF DETERMINATION FROM THE MODEL

Endogenous Variable	$R^2$
Individual Impact	0.711
Organisational Impact	0.654
System Use	0.558
User Satisfaction	0.644

TABLE VI. ESTIMATION RESULTS FOR PROPOSED HYPOTHESES

Hypothesis	Relationship (from $\rightarrow$ to)	Path ( $\beta$ )	t-value	p-values	Result
H1	Information Quality $\rightarrow$ System Use	-0,003	0,033	0,487	Not Supported

V. DISCUSSION

The findings from this study provide insightful information into the factors influencing the success of IS as the mediator for OGD adoption. Through the integration of ISSM and UTAUT, the study successfully unravels the influencing factors in IS and acceptance manner from employees' perspective.

The proposed forty-four indicators establish ten latent variables developed. The authors exclude two indicators through outer loadings assessment, leading to valid constructs for further assessment. The forty-two indicators establish internal consistency reliability and validity through convergent and discriminant tests. In the structural model assessment, the

VIF values verify that no collinearity exists in the model. With the path coefficient test, the authors test the hypotheses at 1% and 5% significance levels. In addition, the authors also determine the  $R^2$  value to explain the model's predictive power. The authors then also investigate internal documents [8]–[10] for further analysis.

*RQ1: What are the IS factors that influence the use of SIMDASI?*

IQ provided by SIMDASI shows no sign of effects on SU from employees (H1) ( $\beta=-0.003$ ;  $t=0.033$ ); however, IQ possesses a significant correlation with US in operating SIMDASI (H2) ( $\beta=0.329$ ;  $t=5.123$ ). H2 resonates with the previous studies proving that IQ influences US [14], [16]. H1,

however, shows that IQ provided from SIMDASI has no influencing power in the use of SIMDASI. This finding differs from previous studies by Stefanovic et al. (2016) [15], Martono et al. (2020) [13], and Talukder et al. (2019) [43] that identified IQ as a salient construct affecting system use. The nature of employees working in data-driven departments [8]–[10] might cause the absence of a positive correlation between information quality and system use (H1), as employees are accustomed to working with all types of data and information quality.

Then, SQ exercised by SIMDASI resulted in a proven correlation to SU (H3) ( $\beta = 0.163$ ;  $t = 2.013$ ) and a causal effect to US (H4) ( $\beta = 0.308$ ;  $t = 4.281$ ). H3 and H4 further prove the same results from Puspitarini & Ardhani (2022) [14], Talukder et al. (2019) [43], Stefanovic et al. (2016) [15], Martono et al. (2020) [13] and Gangga Dewi & Fajar (2021) [16]. This research shows that the system's quality is a driving factor leading to more usage and higher satisfaction among employees in BPS. To put differently, employees are keen to use the system when it offers adequate usability and performance.

SEQ provided by the department in charge of SIMDASI has significant connections for both SU (H5) and US (H6) with  $\beta$  values of 0.107 and 0.291 with t-value of 1.525 and 5.506, consecutively. This outcome further proves the notion from Puspitarini & Ardhani (2022) [14] and Gangga Dewi & Fajar (2021) [16]. The presence of service personnel providing a hotline and helpdesk [8] becomes the main reason in this finding. The findings prove that aid from service personnel becomes paramount in the use of the system and the employees' happiness, corresponding to the original theory from ISSM [44]–[46].

Table VI also confirms the existence of the US-SU correlation (H7) with  $\beta$  value of 0.191 and a t-value of 1.676. This finding reaffirms the evidence from Gangga Dewi & Fajar (2021) [16] and Stefanovic et al. (2016) [15]. The results above prove that only IQ, SQ, and SEQ influence the employees' happiness in operating SIMDASI. Then, three IS-based constructs remain influential regarding using SIMDASI: SQ, SEQ, and US.

In view of the above, the authors find that the quality of system and services, along with satisfaction among employees, become the influencing factor from SIMDASI, which affects its usage. In addition, IQ, SQ, and SEQ are the predictor of US, which subsequently affects SU.

*RQ2: What acceptance factors from employees affect the use of SIMDASI?*

In the acceptance factors, Table VI validates that PEX plays a significant role in determining system use (H8) with  $\beta$  value of 0.242 and a t-value of 2.953. This finding matches the same result from previous studies [30]–[32], [34]–[36]. This finding depicts that when employees perceive SIMDASI as valuable and influential to their job performance, their intention to use it increases, corresponding to the original theoretical foundation of UTAUT [27], [28].

On the other hand, EEX (H9) and FC (H10), surprisingly, are proven to be noninfluential for the use of SIMDASI. H9 ratifies the same result from Taiwo et al. (2012) [34], of which

they find no correlation between EEX and system usage. The findings elaborate that employees in BPS presume that the usage of SIMDASI requires effort (H9) and lacks support by an organisation and technological infrastructure (H10), reflected in the internal evaluation documents (such as lack of knowledge transfer, incomprehensive training, and medium to low participation from regional areas) [9], [10]. This study proves that the increase of effort expectancies or facilitating conditions plays no part in the increase of system use. The mandatory of SIMDASI could also lead to this finding, as the employees have no choice but to use it to disseminate OGD in BPS.

Hence, this study proves that performance expectancies remain the only independent variable from the acceptance factors that influence the use of SIMDASI.

*RQ3: What direct factors determine the success of SIMDASI as an OGD adoption tool?*

For the direct effect, US and SU are proven to be strong predictors for II and OI at a 1% significance level. The US in this model possesses the two highest path coefficient values in determining the net benefits: 0.604 (H12) of  $\beta$  to II and 0.570 of  $\beta$  to OI (H11)—denoting the findings from Stefanovic et al. (2016) [15] and Gangga Dewi & Fajar (2021) [16]. The use of the system and employees' happiness impact OGD adoption in individual and organisational contexts and empower employees and organisations via the adoption of OGD. This finding also corresponds to the updated theoretical foundation of ISSM [17], [46] that explains the predictors from II and OI are SU and US.

This study therefore concludes that system use and employees' satisfaction become the predictor variables in determining the success of SIMDASI toward OGD initiatives in BPS. Those two variables account for 71.11% of the variation in II and 65.4% of the variance in OI.

This research contributes to the literature by proposing an integrated model while also demonstrating a valuable paradigm for understanding the following:

- Information Quality, Service Quality, and System Quality strongly influence employees' satisfaction in operating SIMDASI.
- Service quality, system quality, and user satisfaction become influential in escalating the use of SIMDASI among employees.
- Performance expectancies may also improve employees' usage of SIMDASI.
- The rise in usage of SIMDASI and employees' satisfaction leads to positive development for individuals and organisations alike.

#### A. Theoretical Implications

The proposed model comprises seven constructs, namely, IQ, SQ, SEQ, US, PEX, EEX, and FC are used as potential dimensions that may influence the use of SIMDASI. In comparison, three constructs are established to explain user satisfaction: IQ, SQ, and SEQ. US and SU constructs are then

evaluated to examine the influential power for personal and organisational impact from SIMDASI to OGD initiative.

This research employs two frameworks (ISSM and UTAUT) to assess the findings. The significant theoretical impacts and implications of this research are elaborated below:

- The ISSM model has been proven to be an ideal framework for understanding Information Quality, Service Quality, and System Quality in enhancing employee satisfaction (H2, H4, and H6), which subsequently could improve the use of the system (H7). This model also helps explain the predictor variables from individual and organisational impacts: user satisfaction and system use (H11–H14).
- The UTAUT model has offered evidence that performance expectancies (H8) play an increasingly pivotal role in using SIMDASI as the medium of individual and organisational benefits. However, in a mandatory setting, effort expectancy and facilitating conditions become less influential for system use (H9 and H10).
- The integrated model covers the weaknesses of each model, resulting in a better predictive power to uncover the benefits of IS for an organisation from the employees' perspective.

#### B. Practical Implications

This study possesses a wide array of practical implications for decision-makers in the government. This study also promotes a variety of priorities to comprehend employees' acceptance of using IS and strengthen employees' happiness with operating the IS by combining two ideas of IS and acceptance: ISSM and UTAUT. Although some hypotheses regarding acceptance constructs are not supported, one of the acceptance factors, such as PEX, holds predictive power in explaining the increase in system use. PEX subsequently influences the individual and organisational benefits through the medium of system use.

The following are the key findings of the study in a practical manner:

- In increasing satisfaction among employees, decision-makers should be more mindful of the quality of the information provided by the system (usefulness, understandable, engaging, and reliable), the availability of services to aid the employees (willingness, personal attention, punctuality, resourceful, and completeness), and the performance of the proposed system (easy to use and navigate, interactive, and accessible).
- With the increase in employee satisfaction, service quality, and system quality, the decision-makers have the upper hand in enhancing the use of the system; thus, all involved parties must attend to this matter.
- Decision-makers should also establish employees' beliefs regarding how the IS may improve their job performance. This perception may alter the use of the proposed system in the process. Decision-makers should attend to the resources and knowledge available

for the employees, the compatibility with other technologies, and the presence of a specific person for assistance.

- Government ministries/agencies could benefit from an integrated IS should they adopt OGD. Consequently, the adopters must pay close attention to the satisfaction of employees as they operate the system on a frequent basis.

#### VI. CONCLUSION

This study aims to pinpoint factors contributing to the success of an integrated IS to OGD initiative from the employees' perspective. The authors declare the objectives for this research: (1) to investigate the IS factors affecting the use of SIMDASI in OGD initiative; (2) to examine acceptance factors in the usage of SIMDASI; (3) to uncover influencing factors from the success of SIMDASI employees' point of view in adopting OGD. Thus, with the integration of ISSM and UTAUT, this paper covers the IS success factors and user acceptance by measuring ten different latent variables: IQ, SQ, SEQ, US, PEX, EEX, FC, SU, II, and OI. The authors then postulate twenty-six hypotheses to answer the objectives.

The authors then administer a quantitative method using a cross-sectional questionnaire with close-ended questions. Between 9 and 18 November 2022, the researchers collected 253 responses from the employees in BPS who use SIMDASI. The authors also decide to employ SEM in determining the correlations among the latent variables with the help of SmartPLS 4.

Moreover, this paper examines the validity and reliability of the proposed measurement model of ISSM-UTAUT through measurement model assessment. The test resulted in the exclusion of two indicators among 44 initial indicators. Reflective indicator loadings, internal consistency reliability, convergent validity, and discriminant validity—these are the tests conducted to confirm the model's validity. In addition, this paper also conducts a test on the structural model to verify the proposed hypotheses using the path coefficient. Eleven out of fourteen hypotheses are supported and the additional test of  $R^2$  values presents comprehensive information about the variance caused by exogenous factors.

The accepted hypotheses give insight into the research objectives. Although information quality influences employees' satisfaction in operating the system, information quality remains noninfluential for the usage of the system. However, the quality of the system and the services (provided by a specific department) are proven to affect system use and employees' happiness.

Regarding the acceptance factors, employees' belief in using the system to improve their job performance (PEX) has become the driving factor leading to the acceptance of SIMDASI. Nevertheless, this paper disproves the connection between employees' degree of ease (EEX) associated with SIMDASI and the use of SIMDASI. The same goes for the organisational and technical infrastructure support (FC) plays no part in defining the use of SIMDASI.

In general, this paper uncovers the influencing factors from the benefits generated by SIMDASI to OGD initiatives: individual and organisational benefits. The outcome of the assessment shows that system use and user satisfaction are predictors of the benefits from the view of IS. The result also clarifies that only performance expectancy has a part in defining the benefits of SIMDASI to OGD initiatives. Therefore, the use of system and employees' happiness stand as the explanatory variables for organisational and individual impact in OGD initiatives.

#### A. Limitations of Study

Albeit this study presents exciting findings, it has certain limitations: *participants and the measurement model*.

First, is the limitation of sample size and the focus on a single type of organisation. As the Central Data Supervisory Institution in Statistics, BPS owns a better understanding of disseminating statistical data; hence the OGD adoption might be acceptable. Additionally, with relatively supporting policies available, adopting new technologies becomes more straightforward. Thus, the findings of this study may reflect different factors in other government ministries/agencies.

Second, is the measurement model. The measurement model lacks specificity for the observed area by only integrating two predefined models. Other factors that might contribute to the success of IS in adopting OGD such as experience/habit, characteristics of technology and task, or employees' training prior to the use.

Finally, despite the limitations, this study successfully pinpoint the influencing factors using IS to OGD adoption.

#### B. Future Work

The authors suggest expanding the sample size and more coverage from government organisations such as ministries/agencies from central to local. Moreover, employing a longitudinal approach may result in more accurate findings to explain the behaviour of the employees. The data collection method could be improved by administering an assisted interview method to help respondents understand the questions better.

Future research could also exercise the same measurement model in different backgrounds: different countries or types of organisations, thus, validating the extent of the model used in this study. Additionally, since this study employs ISSM and UTAUT constructs, future research could extend this model by updating the model with the current version, such as UTAUT2. Next, introducing novel factors outside ISSM and UTAUT construct could provide a broader understanding of how IS influences the success of OGD adoption from employees' perspective. Task-Technology Fit (TTF) or Fit-Viability theory could help explain the impact of an integrated IS for government ministers/agencies in OGD initiatives.

Therefore, the authors believe that many possibilities are available in the future regarding this research—A better way to understand how an information system affects the adoption of open government data.

#### AUTHORS' CONTRIBUTIONS

WSW collects the data, performs data curation and statistical analysis, validates the research methodology, interprets the result, and writes the original manuscript. AF conducts research conceptualisation, interprets the data, and writes the original draft. DIA, SL, PAWP, and AY supervise the study, validate the results from WSW and AF, revise the mistakes, and review the original manuscript. All writers have reviewed and approved the final manuscript.

#### CONFLICT-OF-INTEREST STATEMENT

The authors with this declare that there is no conflict of interest in this study. All co-authors have reviewed and authorised the manuscript's contents; hence, the authors certify that the submission is authentic and is not currently under consideration by another publisher.

#### ACKNOWLEDGMENT

The authors would like to express their deepest gratitude to the Ministry of Communication and Information Technology (KOMINFO) for financial aid in carrying out this research. WSW and AF would also offer sincere appreciation to KOMINFO for supporting them during their study at Universitas Indonesia

APPENDIX A: MEASUREMENT ITEMS

Dimension	Code	Items	Reference
<b>Information Quality (IQ)</b>	<b>IQ1</b>	The information provided by SIMDASI is useful.	
	<b>IQ2</b>	The information provided by SIMDASI is easy to understand	
	<b>IQ3</b>	The information provided by SIMDASI is interesting	[15], [17], [44], [46], [47], [56]
	<b>IQ4</b>	The information provided by SIMDASI is reliable.	
	<b>IQ5</b>	The information provided by SIMDASI is up to date	
<b>System Quality (SQ)</b>	<b>SQ1</b>	SIMDASI is easy to use	
	<b>SQ2</b>	SIMDASI is easy to navigate	
	<b>SQ3</b>	SIMDASI provides interactive features	[15], [17], [44], [46], [47]
	<b>SQ4</b>	SIMDASI is accessible	
	<b>SQ5</b>	SIMDASI provides integration with other systems	
<b>Service Quality (SEQ)</b>	<b>SEQ1</b>	The responsible service personnel are always highly willing to help whenever I need support with SIMDASI.	
	<b>SEQ2</b>	The responsible service personnel provide personal attention when I experience problems with SIMDASI.	[17], [44], [46], [47], [56]
	<b>SEQ3</b>	The responsible service personnel provide services related to SIMDASI at the promised time.	
	<b>SEQ4</b>	The responsible service personnel have sufficient knowledge to answer my questions regarding SIMDASI.	
	<b>SEQ5</b>	The SIMDASI overall service quality from assigned personnel is complete	
<b>System Use (SU)</b>	<b>SU1</b>	I spend 3 to 4 days weekly on SIMDASI to complete my task	
	<b>SU2</b>	I try new features and functions in SIMDASI for specific tasks to make me more efficient than others	[17], [44], [46], [47]
	<b>SU3</b>	I feel at ease when using SIMDASI	
<b>Facilitating Condition (FC)</b>	<b>FC1</b>	I have the resources necessary to use SIMDASI.	
	<b>FC2</b>	I have the knowledge necessary to use SIMDASI.	[27], [28], [45], [56]
	<b>FC3</b>	SIMDASI is compatible with other technologies I use.	
	<b>FC4</b>	A specific person is available for assistance with SIMDASI difficulties.	
<b>Performance Expectancy (PEX)</b>	<b>PEX1</b>	SIMDASI would be useful for me to complete my tasks.	
	<b>PEX2</b>	SIMDASI would allow me to complete my tasks more quickly.	[27], [28], [45], [56]
	<b>PEX3</b>	Using SIMDASI would increase my productivity levels.	
	<b>PEX4</b>	Using SIMDASI would improve my performance.	
<b>Effort Expectancy (EEX)</b>	<b>EEX1</b>	It would be easy for me to become skilful at using SIMDASI.	
	<b>EEX2</b>	Learning how to use SIMDASI is easy for me.	
	<b>EEX3</b>	My interaction with SIMDASI would be clear and understandable.	[27], [28], [45], [56]
	<b>EEX4</b>	I would find it easy to get SIMDASI to do what I want it to do.	
	<b>EEX5</b>	Overall, I believe that it is easy to use SIMDASI to support my tasks.	
<b>User Satisfaction (US)</b>	<b>US1</b>	I was very content with SIMDASI.	[15], [17],

	<b>US2</b>	I was very satisfied with the information in SIMDASI.	[44], [46], [47]
	<b>US3</b>	I was satisfied with the efficiency of SIMDASI.	
	<b>US4</b>	Overall, I felt delighted with SIMDASI.	
<b>Individual Impact (II)</b>	<b>II1</b>	I have learnt much through the presence of SIMDASI.	
	<b>II2</b>	SIMDASI enhances my awareness and recall of job-related information.	[15], [17], [44], [46], [47]
	<b>II3</b>	SIMDASI enhances my effectiveness in the job.	
	<b>II4</b>	SIMDASI increases my productivity.	
<b>Organisational Impact (OI)</b>	<b>OI1</b>	SIMDASI has resulted in cost reductions (e.g., administration expenses or data collection activities).	
	<b>OI2</b>	SIMDASI has resulted in overall productivity improvement in BPS.	
	<b>OI3</b>	SIMDASI has resulted in improved outcomes or outputs (e.g., data quality).	[17], [44], [46], [47]
	<b>OI4</b>	SIMDASI has resulted in improved business processes.	
	<b>OI5</b>	SIMDASI has resulted in better positioning for Open Data in BPS.

# Autism Spectrum Disorder Detection: Video Games based Facial Expression Diagnosis using Deep Learning

Morched Derbali<sup>1</sup>, Mutasem Jarrah<sup>2</sup>, and Princy Randhawa<sup>3</sup>

Department of IT, Faculty of Computing and IT, King Abdulaziz University, Jeddah, Saudi<sup>1,2</sup>  
Department of Mechatronics Engineering, Manipal University Jaipur, Jaipur, India<sup>3</sup>

**Abstract**—In this study, a novel method is proposed for determining whether a child between the ages of 3 and 10 has autism spectrum disorder. Video games have the ability to immerse a child in an intense and immersive environment. With the expansion of the gaming industry over the past decade, the availability and customization of games for children has increased dramatically. When children play video games, they may display a variety of facial expressions and emotions. These facial expressions can aid in the diagnosis of autism. Footage of children playing a game may yield a wealth of information regarding behavioral patterns, especially autistic behavior. You can submit any video of a child playing a game to the interface, which is powered by the algorithm presented in this work. We utilized a dataset of 2,536 facial images of autistic and typically developing children for this purpose. The accuracy and loss function are presented to examine the 92.3% accurate prediction outcomes generated by the CNN model and deep learning.

**Keywords**—Autism in children; machine learning; deep learning; convolution neural network (CNN); video games; prediction

## I. INTRODUCTION

Autism is a complicated, behaviorally defined, static condition of an immature brain which is of significant concern to practicing pediatricians due to a staggering 55.6 per-cent rise in pediatric incidence from 1991 and 1997, surpassing spina bifida, cancer, and Down syndrome [1]. Rather than new environmental effects, this increase is due to increased awareness and evolving diagnostic criteria. Autism is a condition with numerous nongenetic and genetic origins, rather than a disease. Autism (autism spectrum disorders) is defined as a group of developmental disorders characterized by deficiencies in three behavioral domains: [2]

- 1) interpersonal interaction.
- 2) a diverse set of areas of interest and hobbies; and
- 3) speech, communication, and creative play.

### A. Autism and its Characteristics:

Early childhood autism is a pervasive developmental disorder. Autism affects communication, relationships, and self-control. Infants often get autism. Autism is a "spectrum disorder" that affects people differently. It has many traits. [3].

Early diagnosis can help a person with autism live a full life. According to the DSM-5, autism is characterized by

persistent differences in communication, interpersonal relationships, and social engagement [4]. Example: Being nonverbal or having abnormal speech patterns, having trouble understanding nonverbal communication, developing and maintaining relationships, and having trouble maintaining a traditional back-and-forth conversational manner [5]. Repetitive habits, interests, and behaviors. Excessive awareness to or significantly reduced sensitivity to many sensory stimuli, repetitive sounds or phrases (echolalia), preference for homogeneity and complexity with transition or regimen, rigid or heavily restricted and strenuous interests, hyper sensitivity to or dramatically reduced sensitivity to many sensory stimuli, rigid or severely regulated and intense interests, hyper sensitive. According to the American Psychological Association's Diagnostic statistical, autistic traits must be present in early childhood, but they may not fully express until social pressure builds the person's strength to deal with them, and difficulties may be covered up by learned coping skills [6].

### B. The Role of Video Games in Autism

According to research, enabling youngsters to play games using smart phones might help detect autism. Dr. Jonathan Delafield-Butt, a senior professor in childhood development, said it was important to detect autism early so parents and children could receive a variety of support services. [7]. Autism is a neurodevelopmental disorder with many shared traits, challenges, and abilities. Many autistic people have visual-spatial thinking, pattern identification, and a visual preference. Games that require visual clues and spatial skills are rewarding to such people. Games are creative but structured. RPGs and scrolling shooters satisfy research participants' desire for imagination without requiring self-generated creativity, which many autistic people lack. Video games have many audio and visual cues. Autistic people value rules and objectivity more than neurotypical people. To avoid anxiety and sensory meltdowns, follow clear guidelines. Video games reinforce clear expectations. Autistics need routine and repetition. Unknown circumstances cause anxiety, discomfort, and a desire to escape. Video games allow for controlled practice and mastery [8,9]. Games are more controlled than real life. Autism makes unpredictable human behavior difficult. Understanding social signs, idioms, humor, sarcasm, and satire can also cause anxiety. Playing a game that becomes more familiar each time helps autistic gamers overcome these challenges in a safe, controlled environment.

Parents and educators worry that autistic students spend too much time gaming instead of socializing. Playing has many benefits if encouraged and controlled [10].

## II. RELATED WORK

Modern diagnostic tools for mental diseases were developed in the late 1800s, although their origins may be dated back to the 4th century B.C (Before Christ) Era [11]. The gold standard for diagnosing often these mental-disorders relies heavily on information gathered from various respondents (e.g., parents, teachers) about the onset, direction, and duration of various behavioral descriptors, which is then considered by providers when making a diagnosis predicated on DSM-5 (Diagnostic and Statistical Manual) Categorization of Diseases-10th Installment (ICD-10) requirements [12]. Providers employ a variety of strategies to collect this data, ranging from subjective (e.g., assessment scale) and unstructured (e.g., semi - structured or unstructured interviews) to much more objective (e.g., actual observations) and organized (e.g., structured diagnostic interviews) [13].

Fig. 1. Machine learning model for prediction and classification

Fig. 1 shows the architecture of the machine learning model that is used commonly for prediction of machine learning along with video games. The video of the child playing the game is captured and then the data is preprocessed, and machine learning is applied on it to predict the results.

Autism spectrum disorder (also referred to as ASD) and attention deficit hyperactivity disorder (also referred to as ADHD) are both conditions that are relatively common in children and can continue into adulthood. Autism spectrum disorder (ASD) is a developmental condition that causes patients to have difficulties with speech, behavior, and social interaction. Patients with ASD also tend to engage in repetitive behavior, have impatience issues, and attention problems. Since the publication of the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5), the term autism spectrum disorder (ASD) has been used to refer to a more comprehensive diagnostic entity that formerly referred to a number of distinct disorders, including Autistic Disorder, Asperger's, and other Pervasive Chromosomal Anomalies [14]. According to findings from recent studies, the prevalence of autism spectrum disorder (ASD) in children and adolescents has increased from 1 in 100 to 1 in 59 in the past 14 years (from the year 2000 to 2014). Inattention, hyperactivity, and impulsivity are all symptoms of attention deficit hyperactivity disorder (ADHD), which is a common

brain condition found in children and adolescents. Both autism spectrum disorder and attention deficit hyperactivity disorder (ADHD) tend to continue into adulthood. A diagnosis of the condition is made in approximately 5.9–9.4% of all infants. Because autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD) are so common in children, accurate and timely diagnosis of these conditions is critical. [15,16,17].

The field of artificial intelligence known as machine learning has the potential to significantly improve the use of computer methods in the field of neuroscience. A significant amount of research has been done to establish machine-learning models and deep-learning approaches in order to interpret high-dimensional MRI (Magnetic Resonance Imaging) data in order to simulate neural networks that regulate the brains of people who suffer from a variety of mental illnesses. [18,19]. These studies resulted in the development of machine-learning methods for the classification of Alzheimer's disease, mild cognitive impairment, right temporal epilepsy, schizophrenia, Parkinson's disease, dementia, attention deficit hyperactivity disorder, autism spectrum disorder, and major depressive disorder [20]. These statistical algorithm-based machine-learning models are well-suited to complex issues that require a combinatorial explosion of options or non-linear processes. This is because typical computer models fail in terms of quality or scalability in these situations, but these statistical algorithm-based machine-learning models succeed [21].

Senju et al, discussed the approaches to early detection of autism in infants. Early detection here refers to before 18 months of age. It gives an overview of the known processes of early social development in children that can fall under the category in which "core deficits" are manifested in young children and summarizes a criterion for the same. The paper concludes by discussing how the preferences for social stimuli changes in the infants over time [22]. They develop a preference for familiar people in first couple of months of life. They begin to have one to one interaction with their caregivers between three and six months of age. This is the period where they understand the interactive styles of their usual social partners. During four to seven months, infants can differentiate between emotional expressions of the face. Soon they develop preferences for caregivers and after 12 months, they display a pattern of response to separation and reunion that demonstrates what they have learned to expect from their experiences with their caregivers [23].

So, in the case of the infants with autism, one would speculate that the dyadic interactions would be less intense and lower capacity to recognize the emotional expressions of others. However, by three to five years of age, autistic children would be capable of forming secure attachments to their caregivers. The author concluded that similar patterns of attachment security and insecurity are found in typically developing children, it is very unlikely to be considered as a core deficit in autistic infants. In infants, failure to discriminate emotions can be considered as an important feature to characterize autism. But however, the rate of false positives could be very high. Children with autistic tendencies make use of different methods and skills to develop secure

attachments and to obtain the capacity to differentiate between the facial expressions and emotions than the typically developing children.

Whalen et al. [23,24] discovered that using a computer game to teach children with autism improved motivation and engagement when compared to the traditional methods of trying to teach children with autism. They established the computer game Teach Town to assist autistic children improve social, emotional, academic, and adaptive skills [25]. Whalen's findings are in line with what others in the area have found: video-game-like tools are beneficial with students with ASD because they are constant and predictable, entail few social variables, and enable children to control and set the speed of the activity. Many children on the autism spectrum have visual-spatial abilities that create videos actual gameplay an area of expertise. While it's normal to be concerned about inattention, behavioral concerns, and even addictions, there really are simple ways that may help autistic children get the most out of computer games and computers without causing additional problems at home or at school. The digital world provides a wealth of resources for teaching issue, social skills, adaptability in new contexts, and even motor skill development. Raising autistic children may be difficult, but apps, games, and technologies can make contacting and educating autistic children simpler. Tbatrah et al [26] laid out a principle called anger superiority hypothesis as its foundation. This hypothesis states that "angry faces capture attention faster than happy faces" in common individuals. The authors aim to test and compare the threat detection abilities in autistic people with individuals with a history of typical development using a facial visual search paradigm.

Thabtah et al [26] theory is based on building classification systems using machine learning, specifically a new method called Rules-machine Learning. This approach helps in detecting autistic traits and offers user knowledge bases (rules) which enables the professionals to make better analysis of the reasons behind the classification.

The primary objective of this technique is rule discovery by search method which can be done using covering classification. Then, evaluation is performed on the discovered rules to discard any redundancies and to optimize it further by reducing the number of discovered rules. In order to improve the overall efficiency of the training process, this phase contributes to the narrowing of the search space for individual data items. The classifier, which is utilized to make predictions regarding the value of the class, is more comparable to an outcome of the rule evaluation phase described above. For the purpose of generating the necessary data from the participants, a mobile application known as ASD Tests is utilized [27]. It implements four screening methods for toddlers, children, adolescents, and adults based on the Q-CHAT-10 (Quantitative Checklist for Autism in Toddlers), AQ-10-child, AQ-10-Adolescent, and AQ-10 adult, respectively. The Q-CHAT-10 is a quantitative checklist for autism in toddlers. In addition to this, the author made use of the datasets that were previously deposited in the University of California Irvine Data Repository by the authors.

Wu et al [28] analyzed the performances of various ML techniques such as Bagging, Boosting, rule induction, and decision tree classifiers on child, adolescent and adult ASD screening datasets. The error rates of adult dataset for the above techniques were between 5.68 and 8.23 per cent whereas the Rules Machine Learning (RML) model outperformed them with an error rate less than 5.6 per cent. Hence the paper was concluded by clearly revealing how ML approaches like covering can be used for obtaining promising results [29].

Jacob et al [29] obtained a high standard clinical data of children at risk for ASD to implement machine learning algorithms. The aim is to build a low-cost and easy to use ASD screening tool. To implement this, the author chose to proceed with a combination of two approaches. Two different algorithms are trained to combine their outputs as a final screening assessment. One is based on the short, structured parent- reported questionnaires and the second is based on tagging key behaviors from casual home videos of the test subjects. The first classifier was trained using data from ADI-R (Autism Diagnostic Interview) score sheets with labels corresponding to established clinical diagnoses. The training of second classifier i.e., the video classifier was done using ADOS (Autism Diagnostic Observation Schedule) instrument score sheets and diagnostic labels. To ensure sufficient training volume, progressive sampling was used in both the cases. After evaluating multiple machine learning algorithms, the author chose Random Forests for its robustness against overfitting [30].

In the clinical sample, the results showed that the parent questionnaire classification approach performed better than some of the more established screening tools, such as the M-CHAT (Modified Checklist for Autism in Toddlers) and the CBCL (Child Behavior Checklist). By combining the two different methods of classification into a single evaluation, performance was improved. The author concluded by stating how ML can play a crucial role in enhancing the performance of the behavioral health screeners and how this research demonstrated a significant improvement over established screening tools for autism. The author also mentioned how the research demonstrated how this research demonstrated significant improvement over established screening tools for autism. Chorianopoulou et al. [31] presented an ML-based approach to early diagnosis of ASD from videos of infants by identifying specific behaviours from them. This approach was based on using videos of the infants. They used a dataset that contained 2000 short videos with various behaviours of interest, such as directed gaze towards faces or objects of interest, positive affect vocalization, and other similar behaviours, all of which were manually coded by expert raters [32]. This dataset was used to conduct their research.

The authors addressed the issue by employing a deep learning model that was image-based and that was based on facial behavior features. Gorriz et al [32] has applied the various feature transformation techniques such as Log, Z-score, sine functions to the collected datasets of toddlers, children, adolescents, and adults [33]. In the next stage, various classification techniques were implemented with these

transformed ASD datasets, to evaluate and assess their performance [33].

For toddler dataset, the median highest result was calculated by Adaboost for Log transformation, Adaboost and SVM (Support Vector Machine) for Scale transformation respectively as 99.06%. The mean highest result which was reported to be 98.77% was calculated by SVM for Log and Sine transformations. The maximum highest result was recorded to be 100% was calculated by Adaboost, GLMboost and SVM for all feature transformation methods and C5.0 for Scale transformation [27, 34].

For child dataset, the median highest accuracy of 100% was achieved by LDA (Linear Discriminant analysis) and PCA (Principal Component Analysis) for Log and Scale

feature transformations. The mean highest accuracy of 97.2% was achieved by Adaboost for Log and Scale, respectively. Finally, the maximum highest accuracy of 100% was achieved by all classifiers and feature transformation methods [34,35].

For adolescent dataset, the median highest accuracy of 95% was obtained by C5.0, LDA, PCA where LDA and PCA for both Log and Scale as well as C5.0 for Scale. The mean highest result of 93.89% was obtained by PCA for Log and GLMboost for Scale, respectively. The maximum highest result of 100% were achieved by all classifiers and feature transformation methods [35,36].

Table I summarizes previous studies and its findings and limitations on usage of algorithms and the different features for the autism spectrum disorder

TABLE I. SUMMARIZED PREVIOUS STUDIES AND ITS FINDINGS FOR AUTISM SPECTRUM DISORDER

Reference	Findings	Limitations
Thabtah et al, 2018 [6]	Inside the ASD screening tool, SVM was used to integrate the ML algorithm. 97.6 % accuracy	Datasets were not balanced. The sample is small comprising 612 autism patients and 11 non-autism instances.
Thabtah et al, 2020 [26]	Rules-Machine Learning is a machine learning approach based on rule induction (RML). Covering learning was used to generate non-redundant rules in a simple method. RML classifies with greater prediction accuracy than typical algorithms such as boosting, bagging, and decision trees, thanks to the use of ten times cross-validation to split the dataset into ten subsets.	In terms of class labels, RML appeared to be ineffective when dealing with unbalanced data sets. There were no examples of toddlers in this article.
Vaishali et al, 2018 [27]	Optimal feature selection was automated using the Binary Firefly algorithm (ten out of twenty-one features were chosen as the best). There was no concern with class imbalance (there are 151 occurrences with class 'yes' and 141 instances with class 'no' in the ASD youngster's dataset). Models such as NB, J48, SVM, and KNN were used. SVM obtained the highest accuracy of 97.95 percent.	In the ASD kid dataset, there were some occurrences that are missing. There was a risk of model overfitting on the dataset because to the smaller number of occurrences in the dataset. Swarm intelligence wrappers had certain drawbacks (Binary Firefly algorithm)
Al banna et al, 2020 [33]	Analyzed the patient's condition using facial expressions and emotions, employing an AI system and sensor data. Sent out frequent messages to parents, assisting the patient in coping with ASD during COVID-19. A smart wristband with an integrated monitor and camera is linked to a smartphone app in this system. Used real-time grayscale photos from one Kaggle dataset of 35,887 images to detect ASD. The Inception-ResNetV2 architecture had the greatest accuracy of all the models, at 78.56 percent.	When compared to other methods, the accuracy is poor. The research is still in its early phases.
Sen et al, 2018 [37]	The authors devised a new algorithm that combined structural and functional characteristics. Drew many different depictions of the brain's functional connections. The results showed that incorporating multimodal characteristics improves case discrimination accuracy the most.	In contrast to earlier studies, the ML models utilized demonstrate a 4.2 percent improvement in the accuracy of the predictions for Autism. Datasets suffer significantly from fluctuations.
Van den et al, 2017 [39]	SVM, Naive Bayes, and Random Forest classification algorithms are used. There were 95,577 kid records with 367 variables, of which 256 were deemed to be adequate. Different qualities were well delineated. Created a dataset with four classifications (ASD: None, Mild, Moderate, Severe). The J48 algorithm attained the highest accuracy of 87.1 percent (2 class) and 54.1 percent (4 class) (decision tree)	Doesn't predict the severity of ASD. A cursory collection of traits (criteria) used to identify ASD, which may or may not always correspond to an instance of ASD.

### III. METHODOLOGY

This study demonstrated the use of Deep Learning and Image processing techniques for the detection of Autism using facial expressions. The initial approach was to build and train a neural network based on the available data on Autism. Following this, any video of the patient which clearly shows their facial expressions could be taken as the input through an interface created for the users. This input was used for the detection of autistic characteristics using the previously trained model [38].

The methodology followed can be divided into five steps as shown in Fig. 2:

- 1) Capturing the facial expressions while playing a Video Game.
- 2) Data Preprocessing.
- 3) Model Building and Training.
- 4) Prediction and Optimization.
- 5) Uploading the video to the Web Interface.

Fig. 2. Work flow of the method for the detection of facial expression while playing video games

#### A. Capturing the Facial Expressions while Playing the Video Game:

The facial expression of the child is captured while she/he is playing the video game using the web camera attached to the personal computer. The video is captured and saved locally and then the same video is uploaded to the website user interface and then the trained Convolutional Neural Network (CNN) model predicts if the child in the image broken down from the video is autistic or not [40].

#### B. Data Preprocessing

The collected image dataset was preprocessed by 3 processes so that the CNN model can train the dataset to predict if the child is autistic or not. They were:

1) *Dividing the video into frames:* OpenCV was used to fragment the video captured into images or frames. The video is captured using a webcam while the child is playing the game to monitor and analyze the video captured which would be broken down into images and then train the CNN model. The dataset consists of 2536 images belonging to the autistic and non-autistic classes in the training set and 300 images in the test set. The required image data is obtained from Kaggle. The ImageDataGenerator class of keras library enables us to read the images from the folders. Rescaling of images is done by dividing each pixel value of an image by 255. The images in the dataset are of various sizes which calls for resizing into one final size of 64x64 pixel and the same can be implemented using a function called “flow\_from\_directory” of the above class [40,41].

2) *Fix target size:* The collected image dataset had to be resized for uniformity in processing and to do so, all the images were resized to 64x64 pixel so that the convolution neural network model can be trained using those images [42]. This was done by using the function “flow\_from\_directory” and the argument to the function changed to 64x64 pixels. Whereas the neural network was training on the training data, the flow from directory () function was used to read photos straight from the directory and enhance them. The technique assumed that photos from various classes stored in separate directories but are all included within the same parent directory.

3) *Horizontal flip:* The images needed to be flipped horizontally to maintain uniformity, so this is achieved by using the function “ImageDataGenerator” and adjusting the arguments.

4) *Rescaling:* The ImageDataGenerator class may rescale pixel values from 0-255 to the recommended 0-1 range for neural network models. Normalization is the process of reducing data to a number between 0 and 1. Setting the rescale parameter to a ratio that may be multiplied by each pixel to produce the required range will do this [41,42].

#### C. Model Building and Training:

Deep learning is a technique for automatic learning that implements the use of examples to teach machines how to learn in the same way that people do. A self-driving car's ability to recognize a stop sign or differentiate between a pedestrian and a lamppost is dependent on its use of deep learning, which is an essential component of the technology. It makes it possible to control consumer electronics with one's voice, such as mobile phones and tablets, televisions, and hands-free speakers. The concept of "deep learning" has been receiving a lot of attention as of late, and with good reason. It's about achieving things that weren't possible before you started working on them.

During the process of deep learning, a computer model will learn to perform categorization tasks directly from either pictures, text, or sound. Models that use deep learning have the potential to achieve an accuracy that is on par with or even exceeds that of humans in certain circumstances. In order to train models, a significant amount of labelled data as well as various topologies of multilayer neural networks are utilized. The acronym "CNN" stands for "Convolution Neural Network". Image recognition and processing are two applications that make use of a type of artificial neural network known as a convolutional neural network (also abbreviated as CNN). CNNs are designed to focus specifically on analyzing pixel input. CNN was used to train the model based on the image data sets that were taken by the webcam of the computer that the child was using to play the video game on. CNNs are image processing, artificially intelligent (AI) systems that utilize deep learning to perform both generating and informative tasks. These tasks frequently include machine vision, which includes image and video identification, as well as recommendation systems for natural language processing (NLP) [40, -42]. A neural network is a piece of computer hardware and/or software that mimics the way neurons in the

human brain communicate with one another. Traditional neural networks were not intended to be used for image analysis, so in order for them to do so, they require the images to be broken up into smaller chunks. The "neurons" that make up CNN are organized more similarly to those in the prefrontal cortex, which is the part of the brain in humans and animals that is responsible for processing visual input. The difficulty of processing images in pieces that is inherent to traditional neural networks can be circumvented by arranging the layers of neurons in such a way that they cover the entirety of the visual field [48]. A CNN makes use of a technology similar to a perceptron that is designed to have minimal requirements for processing [43]. The layers of a CNN are comprised of an input layer, a layer, and a hidden layer. These layers are followed by several convolutional layers, average pooling, fully connected layers, and normalizing layers. A system that is significantly more effective and easier to train for image analysis and natural language [43] has been made possible as a result of the elimination of constraints and improvements in the efficiency of image processing.

#### D. Prediction and Optimization

Optimization plays a crucial role for any machine learning problem. Gradient descent is an optimization algorithm that finds the lowest possible value or the minimum value of a function through iterations. While the loss function which is also known as the cost function is all about calculating the loss/errors for every prediction that the neural network makes, gradient descent can be used to find the minimum of this loss function. The goal is to estimate the values of coefficients of a function that can minimize the cost function. In other words, the new coefficients will have a significantly lower cost.

This technique is initialized by taking small random values as coefficients for the function. The cost is then evaluated by inserting them into the function. The next step is to change the values of the coefficients in a direction that can lead to a lower cost in the next iteration. This direction can be estimated with the help of derivatives. The derivative gives a slope (gradient) at the desired point on a curve, or a function and the sign of that slope can be used to determine the direction in which the coefficients can be moved in further iterations [44]. Now that the algorithm is aware of the direction of progression of coefficients with the help of the gradient at current position, the next move is to make a step by scaling it and subtracting the obtained value from the current position. Subtracting is done as the aim is to minimize the function [40]. Another parameter called learning rate is used to scale the gradient and control the step size. Learning rate can affect the performance in a significant way. Smaller learning rate can lead the algorithm to reach the final iteration before even reaching the optimum point [41]. The Adam algorithm is implemented by

this optimizer. Adam optimization is a gradient descent approach based on adaptive first- and second-order moment estimation. The approach is "computationally more efficient, has small memory demand, is robust to diagonally resizing of gradient, and is well suited for situations with huge data/parameters," as according to Thabtah- et al., 2020.

#### E. Uploading the video to the Web Interface

Streamlit is one of the recent and fastest python-based model deployment tools. This open-sourced python based framework simplified the whole model deployment cycle along with providing an easy way to structure the functionalities of the interface [45,46].

Fig. 3. Web interface for prediction of the disease

Once the neural network was trained, the model of an epoch with the best validation accuracy was saved as a '.model' file. The interface enables the users to select the type of media file that is to be uploaded. If the selected media type is an image, the saved model is used to classify the uploaded image to Autistic/Non-Autistic for which the result can be displayed on the interface [45]. But if the selected media type is a video, then the uploaded video is divided into frames using OpenCV and each image is classified into Autistic/Non-autistic with the help of the saved model. The mean value of classification of all images is considered as the final classification for the entire video and displayed on the interface.

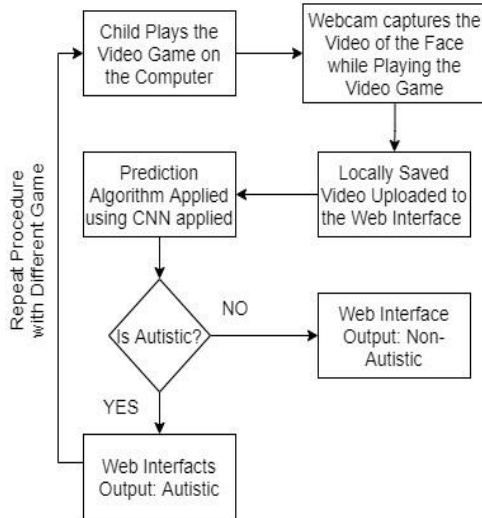

Fig. 4. Prediction mechanism if autistic or not

Fig. 3 describes the entire working of the prediction mechanism implemented in this project. The video of the child while playing the game is captured by a webcam and then the video is saved locally. The same video is then uploaded to the website interface for the CNN deep learning algorithm to work on it. After processing the file and after the prediction model is applied on the video, the outcome or result of the prediction is shown on the interface as “Autistic” or “Non-Autistic” as shown in Fig. 4.

#### IV. RESULTS AND DISCUSSION

This study explores the use of video games to discriminate between children with and without ASD. Compared to previous qualitative techniques, the activities and learning metrics in the evaluation game give a quantifiable depiction of children’s abilities, making the identification of ASD more accurate and practical. The use of these games as a supplementary tool in educational interventions for kids with ASD is also possible. In previous studies, the model has been trained using different algorithms such as SVM, Neural Network, RML Classifier, Random Forest, Naïve Bayes with a maximum accuracy of 97.5% [46]. They have used images of a facial expression and behavior of a patient while in our study we trained the model using CNN when the child is playing video game and capture the image of his behavior and facial expression. The Convolutional Neural Network (CNN) model is used to extract and produce the proper patterns of the face features when the child is playing video game and capture the image of his behavior and facial expression such as inappropriate snickering and laughing, Lack of pain sensitivity, Inability to maintain proper eye contact, unable to communicate with gestures, Inadequate reaction to sound etc. The model was trained in the cloud using Google Colab with python, which supports TensorFlow and Keras. The epoch number declared was 159 and it had a batch size of 20. The VGG model was used for implementing the convolutional neural network. Karen Simonyan & Andrew Zisserman of Oxford University’s Visual Geometry Group (VGG) proposed VGG models, which performed well in the ImageNet

Challenge [47 -48]. This model gets 92.7% top-5 accuracy on ImageNet’s 14 million photos from 1000 classes. 300 images were used for the testing and 100 images were used for validation of the CNN model [48].

The model achieved 92.3% accuracy for the testing dataset and 87.3% accuracy for the validation dataset. For this study, many evaluation metrics were calculated, and the results are summarized in the following sections. The results of the comparative prediction analysis of our model and existing model of the same dataset as shown in Table II.

TABLE II. COMPARISON OF THE RESULTS USING THE SAME DATASET

Author	Model	Accuracy
Haque et al [49]	ResNet50	89.2%
Shaik et al [50]	VGG19	84.0%
Our model	VGGFace	92.3%

#### A. Evaluation Metrics

Sensitivity, Specificity, Precision, Recall, F1 Score and Accuracy were calculated for evaluating the performance of the CNN model. The convention True Positive (TP), False Positive (FP), True Negative (TN) and False Negative (FN) were used.

1) *Sensitivity*: Sensitivity measures a model’s ability to recognize positive cases. TPR is sometimes called recall. Sensitivity measures how many positive cases a model accurately identified. High-sensitivity models have minimal false negatives, meaning they overlook some positive examples. Sensitivity is a model’s capacity to recognize good cases. We need our models to locate all good examples to generate accurate forecasts. True positive rate plus false negative rate equals 1. Higher true positive rate means model correctly identifies positive situations. The sensitivity was calculated using the following formula as shown in eq. (1):

$$\text{Sensitivity} = \frac{TP}{TP+FN} \quad (1)$$

The Sensitivity of the model was 0.9560 or 95.60%.

2) *Specificity*: Specificity assesses the model’s ability to identify real negatives. This means there will be a percentage of true negatives forecasted as positives, or false positives. True Negative Rate (TNR). True negative rate plus false positive rate equals 1 always. Low specificity suggests the model is mislabeling a lot of negative data as positive. The specificity was calculated using the following formula as shown in eq. (2):

$$\text{Specificity} = \frac{TN}{FP+TN} \quad (2)$$

The specificity of the model was 0.8865 or 88.65%.

3) *Precision*: Precision is the ratio of True Positives to total positive samples (either correctly or incorrectly). It is calculated using the formula as shown in eq. (3):

$$\text{Precision} = \frac{TP}{TP+FP} \quad (3)$$

The precision of the model was 0.9048 or 90.48%.

4) *Accuracy*: Model accuracy measures which model is better at finding correlations and patterns in a dataset based on training data. Accuracy is calculated using the formula as shown in eq. (4):

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+FN+TN} \quad (4)$$

The accuracy was found out to be 92.3% for the testing dataset consisting of 300 images and 87.3% for the validation dataset.

5) *F1 score*: The harmonic mean of accuracy and recall is used to get the F1 score. It is calculated using the formula as shown in eq. (5):

$$\text{F1 Score} = 2 * \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \quad (5)$$

The F1 Score was calculated to be 0.9297 or 92.97%.

6) *Confusion matrix*: A matrix called the confusion matrix is used to assess how well classification models perform given

a particular set of test data. As the model cannot afford to predict non-autistic when the patient is autistic, the confusion matrix was calculated as shown in Fig. 5, which indicates that the false positive condition case value should be lower. 155 of the 300 images were correctly classified.

	Autistic	Non-Autistic
Predicted Autistic	152	16
Predicted Non-Autistic	7	125

Fig. 5. Confusion matrix using CNN for autism spectrum disorder

Fig. 6. a) and b) . Model Training Accuracy and Training Loss

Fig. 6(a) and (b) depicts the plot of the model's training accuracy, training loss, respectively for 10 epochs. The highest accuracy achieved was 92.3 % with the VGG model by applying two dense layers with specific parameters. A loss function optimizes ML algorithms. The loss is determined during training and validation, and its interpretation depends on how well the model performs. It's the total of training or validation set mistakes per example. Loss value indicates model's performance after each optimization cycle. A performance metric measures the algorithm's accuracy. Model accuracy is generally estimated as a percentage based on model parameters. It measures how well your model predicts actual data.

## V. CONCLUSION

The study built a deep learning web app to diagnose autism using a convolutional neural network and camera footage of a youngster playing a video game. CNN's architecture can extract facial attributes by generating facial feature patterns and assessing facial landmark distances, classifying faces as autistic or not. VGG CNN Model produced accurate results. Testing accuracy was 92.3%, validation accuracy was 87.3%, and precision was 90.4%. Future research will improve this model by broadening psychologists' autistic kid diagnoses. This programme helps

identify ASD. A precise autism diagnosis can help pick a treatment plan for autistic children. More precision might improve autism diagnosis. The platform might reveal this neurological disease, bringing treatment closer. This research is part of how humans utilize technology to tackle the world's healthcare issues. Future studies may use machine learning and deep learning algorithms to help individuals recognize a range of ailments using the same platform. Although young, digital technologies offer unlimited potential. In the case of autism, a mix of digital tools and in-person therapy visits is expected. Autism therapy isn't one-size-fits-all. These tools will help researchers produce medicines for ASD patients more swiftly. Language is being studied for potential therapies. SFARI-funded researchers are employing cellphones and automatic transcription software to record speech from autistic youngsters. Based on the data collected by recording footage of children playing video games, a video game can be designed for children with autism or autistic symptoms. This game will help parents or guardians determine whether their kid has autism such as Kinect game.

#### ACKNOWLEDGMENT

The authors extend their appreciation to the Deputyship for Research & Innovation, Ministry of Education in Saudi Arabia for funding this research work through the project number 257835-G: 243-611-1443 and King Abdulaziz University, DSR, Jeddah, Saudi Arabia.

Institutional Review Board Statement: Not applicable.

Informed Consent Statement: Not applicable.

**Data Availability Statement:** Publicly available datasets were analyzed in this study. This data can be found here: <https://www.kaggle.com/code/basmarg/vgg-16-autism-image-data/data>

**Abstract**—Aiming at the problems that the movement recognition accuracy of lower limbs needs to be improved, the optimized SVM recognition method by using voting mechanism is proposed in this paper. First, CS algorithm is applied to optimize the kernel function parameter and the penalty factor for SVM model. And then, voting mechanism is used to ensure the recognition accuracy of SVM classification algorithm. Finally, the experiments have been implemented and different classification algorithms have been compared. The recognition results shows that the movement recognition accuracy for the lower limbs by the optimized SVM recognition algorithm using voting mechanism is about 98.78%, which is higher than other commonly used classification algorithm with or without voting mechanism. The recognition method for the lower limbs proposed in this paper can be used in the field of rehabilitation training, smart healthcare and so on.

**Keywords**—Surface electromyography; micro inertial measurement unit; support vector machine; voting mechanism

## I. INTRODUCTION

Along with the development of artificial intelligence technology, many researchers have focused on the study of human posture recognition [1-4]. Recognition for the movements of lower limbs is widely used in the field of rehabilitation training, physical exercise and so on [5]. As for the current research, there are many sensors used for the recognition of lower limbs, such as visual sensors, inertial sensors, surface electromyographic sensors, etc.

In the study of human behavior recognition using visual sensors, Nie proposed a view-invariant method for human action recognition by recovering the corrupted skeletons based on a 3D bio-constrained skeleton model and visualizing those body-level motion features obtained during the recovery process with images [6]. Based on the Northwestern-UCLA dataset, the classification accuracy of the 10 action images in the proposed algorithm is about 94.40%. Nieto-Hidalgo proposed an extraction system by analyzing image sequences to identify human gait features [7]. The recognition accuracy for the normal and abnormal gaits are both more than 90.00%. Based on the Kinect sensor, Min proposed an indoor fall detection method using SVM method according to the 3D skeleton joint array information [8]. The experiment result shows that the fall recognition accuracy is about 92.05%. Liu proposed an algorithm for human behavior recognition using skeletal joint information of deep sequences [9]. The angle and

position information between joints were captured by RGB video, and the obtained feature vectors were used as the input of the classifier. The experimental results showed that the average accuracy of behavior recognition is 95.00%. It is convenient to recognize the human behavior by using visual sensors, but the environment illumination, image resolution, and autofocus speed will affect the recognition accuracy. What's more, the huge amount of image processing will increase the hardware cost.

In the study of human behavior recognition using inertial sensors, Khatun proposed a sensor-based learning method for human activity recognition [10] based on a hybrid deep learning model coupling convolutional neural network and long and short term memory network. The system is based on the data set (H-Activity) collected by the smart phone sensor. The experimental results show that the accuracy of the self-collected data set trained by this method is 99.93%, and the accuracy of the model trained by the benchmark data set (MHEALTH) is 98.76%. Zhang proposed a SVM algorithm based on magnetometer and gyroscope sensors to classify the human motion postures [11]. Experimental results show that the average recognition accuracy for human motion posture is about 90.80%. Marron proposed a smart phone system with embedded inertial sensors in an indoor environment [12], in which the information of human biomechanical models is combined. The recognition average accuracy for human behavior is 95.00%. Guo proposed a novel monitoring framework of human motion sequences based on wearable inertial sensors [13], the recognition process can be divided into data acquisition, segmentation and recognition stages. At the recognition stage the HMM algorithm is used to recognize the motion sequence. The experimental results show that the average recognition accuracy for human movement is 92.75%. As for the inertial sensors used for the recognition of human behavior, it has the advantages of high efficiency, but the installation will affect the recognition accuracy.

In the study of human behavior recognition using surface electromyography (sEMG) sensors, Qi proposed a gesture recognition system based on the principal component analysis method and GRNN neural network [14]. By extracting the key information of human gestures, the specific action mode can be identified. Experiment results show that the system's overall recognition accuracy for 9 static gestures is about 95.10%. Zhang proposed a dynamic adaptive neural network algorithm based on multi-feature fusion of surface EMG signals [15] to

achieve accurate recognition of eight lower limb movements (walk (WK), left turn (TL), right turn (TR), stand up (TP), sit down (ST), go upstairs (UPS), go downstairs (DWS) and jog (CD)). Experimental results show that the recognition accuracy of this method is 94.89%. As for the application of sEMG sensors, human behavior recognition can be easily affected by some irregular movements of the human body, such as when somebody suddenly falls, it may cause a significant change in the sEMG signal of the leg muscles, which will affect the judgment of human leg movements.

From the aforementioned methods for the recognition of human behavior recognition, the accuracy still needs to be improved. In this paper, take the features of lower limbs into consideration, the improved SVM algorithm is proposed for the recognition of lower limbs by MIMU and sEMG sensors. First, in order to obtain the parameters of kernel function and penalty factor, Cuckoo search algorithm (CS) is used to optimize SVM model. Then, the voting mechanism is applied to improve the recognition accuracy of SVM algorithm. Finally, the experiment is carried out to verify the validity of the proposed method by seven movements of lower limbs.

## II. CLASSIFICATION ALGORITHM

### A. SVM Classification Algorithm

As for the complexity of the movements of low limbs, it is difficult to recognize the movements directly from the outputs of MIMU and sEMG. Thus, it is necessary to extract the features of the outputs and then use a kind of mapping algorithm to separate the features from the low dimensional space to a high dimensional space. SVM classification algorithm based on the principle of structural risk minimization has the advantages of good generalization ability [16-18]. In this paper, according to the features of outputs of MIMU and sEMG and take the complexity of the algorithm calculation into consideration, SVM classification algorithm is used.

As for SVM classification algorithm, suppose the sample set is  $D=\{(x_1,y_1),(x_2,y_2),\dots,(x_m,y_m)\}$ , where,  $x_i \in R^n$ ,  $y_i \in \{-1,1\}$ ,  $m$  is the number of samples.  $\phi(x_i)$  is the eigenvector after mapping. Then, the hyperplane is established for classification by:

$$f(x) = W\phi(x_i) + b \quad (1)$$

Where,  $W$  is the normal vector of the optimal hyperplane,  $b$  is the displacement. The problem to solve the optimal hyperplane can be converted by:

$$\begin{cases} \min \left( \frac{1}{2} \|W\|^2 + c \sum_1^m \xi_i \right) \\ s.t. \quad y_i [W^T \phi(x_i) + b] \geq 1 - \xi_i \end{cases} \quad (2)$$

Where,  $\xi_i$  is the relaxation variable,  $c$  is the penalty factor. Introducing the Lagrange multiplier  $\alpha_i$  by:

$$\begin{cases} \max \left[ \sum_1^m \alpha_i - \frac{1}{2} \alpha_i \alpha_j y_i y_j \kappa(x_i, x_j) \right] \\ s.t. \quad \sum_1^m \alpha_i y_i = 0, c \geq \alpha_i \geq 0, i = 1, 2, \dots, m \end{cases} \quad (3)$$

Where,  $\kappa(x_i, x_j)$  is the kernel function. And in this paper, the gaussian radial basis function is selected by:

$$\kappa(x_i, x_j) = \phi(x_i)^T \phi(x_j) = \exp(-g \|x_i - x_j\|^2) \quad (4)$$

Where,  $g$  is the kernel function parameter. Then, solving (3) and the following solution can be obtained:

$$f(x) = \text{sgn} \left( \sum_{i=1}^m \alpha_i^* y_i \kappa(x_i, x_j) + b^* \right) \quad (5)$$

In the process to solve the hyperplanes, the kernel function parameter  $g$  and the penalty factor  $c$  are the key parameters for SVM classification model. Thus, it is necessary to get the best kernel function parameter  $g$  and the penalty factor  $c$  for the SVM classification model to recognize the movements of the lower limbs.

### B. CS Algorithm

CS Algorithm is a heuristic algorithm, which solves the optimal parameters by simulating the parasitic brooding behavior of cuckoo birds [19,20]. It has the advantages of few parameters and fast convergence speed, so it is widely used for parameter optimization.

As for the parameter optimization of the kernel function parameter  $g$  and the penalty factor  $c$ , the finding probability  $p_a$  in CS algorithm will balance the local random optimization and global random optimization. The local random optimization will updates the position of the nest  $z=[g \ c]^T$  as follows:

$$z_i(n+1) = z_i(n) + \alpha s \otimes H(p_a - \varepsilon) \otimes (z_j(n) - z_i(n)) \quad (6)$$

Where,  $z_i(n+1)$  represents the position of the nest  $i$  updated at the  $(n+1)$  times of iteration,  $z_j(n)$  is the nest selected by random substitution,  $\alpha$  is the step scale factor,  $s$  is the step size,  $H(u)$  is the unit step function,  $\varepsilon$  is a random number.

Then, the global random optimization will update the position of the nest  $z=[g \ c]^T$  by:

$$z_i(n+1) = z_i(n) + \alpha L(s, \lambda) \quad (7)$$

Where,  $L(s, \lambda)$  is the Levy distribution.  $\lambda$  is a constant and in this paper it is 1.5 for the parameter optimization in CS algorithm.

As for the  $(n+1)$  times of iteration, the position of the nest will be updated, and it will be used as the input for the next iteration. According to the finding probability  $p_a$ , the highest accuracy nest  $z=[g \ c]^T$  for the whole nests will be obtained.

### C. Voting Mechanism

Voting mechanism proposed in this paper is a combination strategy for the movement recognition of lower limbs. The basic idea of it is using a sliding window to select the most recognition output label by the machine learning algorithm as the recognition output label for the middle position of this sliding window. Thus, it can correct the error recognition label.

The hardware for the recognition of the lower limbs in this paper is self-designed and the sampling frequency for the output data is 150Hz. According to the experiment for a consecutive movement of lower limbs, the self-designed hardware can collect at least 75 groups of output data. For the same movement recognition of lower limbs, it should be the same output label when using machine learning recognition algorithm. However, for the different movement recognition of lower limbs, the voting mechanism is necessary by the sliding window to identify and correct the error recognition label.

### III. EXPERIMENT FOR MOVEMENTS OF LOWER LIMBS

In order to verify the efficiency of the proposed optimize SVM classification algorithm, the movement recognition experiments for the lower limbs have been carried out. The designed recognition flow is shown in Fig. 1.

Fig. 1. Recognition flow for the lower limbs

The outputs of MIMU and sEMG will be collected by the signal detection module. And then the outputs will be preprocessed, during this process, the median filter is used to preprocess the outputs of the sensors which will remove the noise. Then, the features will be extracted by the mean absolute average (MAV) before they were sent to SVM classifier. What's more, the voting mechanism will be carried out to ensure the recognition accuracy. Finally, the movement labels for the movement of lower limbs will be shown.

#### A. Hardware for the Experiment

The self-designed hardware for the recognition of the lower limbs is shown in Fig. 2.

Fig. 2. Hardware for the experiment

MPU9250 and MyoWare muscle sensor is used for MIMU and sEMG. And the self-designed hardware will be worn on the lower limbs as shown in Fig. 3.

Fig. 3. Hardware worn on the lower limb

The muscles selected for the experiment should be close to the skin surface and there should be large enough to place the electrodes. Thus, we choose the tibialis anterior, extensor digitorum longus, gastrocnemius muscle, and soleus muscle to place the sEMG electrodes for the reason that the muscular contraction is obvious when there's movement of the lower limbs.

#### B. Definition of Movements of Lower Limbs

In this paper, there are seven movements of lower limbs needs to recognize, which are defined in Table I.

TABLE I. MOVEMENTS OF LOWER LIMBS

Movements of lower limbs	Labels
stand still	1
mark time	2
run with raised legs	3
go straight	4
run with speed	5
walk up the slope	6
walk down the slope	7

C. Recognition Test

There are 1072 sets data collect, we choose 872 sets of data as a fixed training set randomly, and then the following 200 sets of data are selected as the test set.

CS algorithm is used to optimize kernel function parameter  $g$  and the penalty factor  $c$  for SVM classification algorithm. As for CS algorithm, the number of parameters need to be optimized is 2, the number of nests is 20, the finding probability  $p_a$  is 0.25, the iteration time is 50, the upper bound of  $g$  and  $c$  is 10, and the lower bound is 0.01. Then, SVM classification model can be established.

As for the recognition, 30 independent recognition tests have been carried out based on 200 sets of data. Fig. 4 and Fig. 5 have illustrated one of the recognition results for the proposed optimized SVM classification model with and without voting mechanism.

Fig. 4. SVM classification without voting mechanism

Fig. 5. SVM classification with voting mechanism

As show in Fig. 4 and Fig. 5, it is obvious that the recognition accuracy has been improved when voting mechanism is used to correct the wrong movements' labels of lower limbs labels.

In order to verify the effectiveness of the proposed optimized SVM recognition method in this paper, the most commonly used algorithm for human motion recognition has been applied, such as generalized regression neural network (GRNN), probabilistic neural network (PNN), and extreme learning machine (ELM). 30 independent recognition tests have been performed by using the above algorithms with and

without voting mechanism. The recognition accuracy is shown in Fig. 6 and Table II.

Fig. 6. Recognition accuracy for voting and non-voting mechanism

TABLE II. STATISTICAL RESULTS FOR THE RECOGNITION

Recognition Methods		Standard Deviation	Average accuracy	Coefficient of Variation
optimized SVM	Non-voting	$8.55 \times 10^{-3}$	94.05%	$9.09 \times 10^{-3}$
	voting	$7.73 \times 10^{-3}$	98.78%	$7.83 \times 10^{-3}$
GRNN	Non-voting	$1.66 \times 10^{-2}$	67.57%	$2.46 \times 10^{-2}$
	voting	$6.32 \times 10^{-2}$	75.28%	$8.40 \times 10^{-2}$
PNN	Non-voting	$1.66 \times 10^{-2}$	67.97%	$2.44 \times 10^{-2}$
	voting	$6.32 \times 10^{-2}$	75.27%	$8.40 \times 10^{-2}$
ELM	Non-voting	$6.03 \times 10^{-2}$	52.47%	$1.15 \times 10^{-1}$
	voting	$8.30 \times 10^{-2}$	56.77%	$1.46 \times 10^{-1}$

Fig. 6 and Table II show that the average recognition accuracy of lower limbs by the optimized SVM recognition method is higher than other commonly used algorithm for human motion. What's more, the recognition accuracy by the voting mechanism is higher than that without voting mechanism.

For the statistical results of 30 independent recognition tests show in Table II, the standard deviation and the coefficient of variation for the proposed optimized SVM recognition method with the voting mechanism are the minimum values in the above methods, which indicate the stability of the proposed method.

IV. CONCLUSION

Aiming at the problems that the recognition accuracy and stability for the movements of lower limbs need to be improved, the optimized SVM recognition method by using voting mechanism is proposed in this paper. CS algorithm is used to optimize kernel function parameter  $g$  and the penalty factor  $c$  for SVM classification algorithm. Then, voting mechanism is carried out to ensure the recognition accuracy. Experiments have been implemented and different classification algorithms have been compared. The recognition results illustrated that the recognition accuracy by the optimized SVM recognition algorithm is higher than other recognition algorithms, which demonstrates the validity of the proposed optimized SVM recognition algorithm. And the accuracy for the recognition algorithm with the voting

mechanism is higher than the algorithm without the voting mechanism, which demonstrates the effectivity of the voting mechanism. The recognition method for the movement of lower limbs by MIMU and sEMG can be used for the application of smart healthcare, rehabilitation training of lower limbs and so on.

**Abstract**—Traditional neural network has many weaknesses, such as a lack of mining transformer timing relation, poor generalization of classification, and low classification accuracy of heterogeneous data. Aiming at questions raised, this paper proposes a bidirectional recurrent neural network model based on a multi-kernel learning support vector machine. Through a bidirectional recurrent neural network for feature extraction, the features of the before and after time fusion and obvious data are outputted. The multi-kernel learning support vector machine method was carried out on the characteristics of data classification. The study of multi-kernel support vector machines in the weighted average of the way nuclear fusion improves the accuracy of characteristic data classification. Numerical simulation analysis of the temporal channel length for sequential network diagnostic performance, the effects of multi-kernel learning on the generalization ability of support vector machine, the influence on heterogeneous data processing capabilities, and transformer fault data classification experiment verifies the correctness and effectiveness of the bidirectional recurrent neural network based on multi-kernel learning support vector machine model. The experiment result shows that the diagnosis performance of bidirectional recurrent networks based on a multi-kernel learning support vector machine is better, and the prediction accuracy of the model is improved by more than 1.78% compared with several commonly used neural networks.

**Keywords**—Multi-kernel learning; support vector machine; bidirectional recurrent neural network; fault diagnosis

## I. INTRODUCTION

A transformer, one of the key hub equipment in the power grid, act as an important link in energy conversion, distribution, or transmission. Transformer failure will cause huge financial loss and endanger public security. Therefore, timely and accurate diagnosis of transformer failure has important significance to make sure that the power system in safe state [1]. Characteristic gas method is often used for manual diagnosis of traditional transformer faults, but the differences in experience for fault identification often lead to errors. For transformer insulation maintenance, manual judgment requires not only a power failure of tested transformers but also regular maintenance of replaced equipment or parts. And a large part of equipment does not exceed its service life, which often causes a waste of resources and reduces the economy of the power system.

When the LSTM network conducts data analysis on time series feature quantity, the model is too simple and can only

consider a single time series. The fault data identification is not ideal and the accuracy of long-time series will decline. Besides, the ability to generalize is not high. In this paper, a Bidirectional Long Short-Term Memory (Bi-LSTM) network is proposed and Multi-Kernel Learning Support Vector Machines (MKL-SVM) combined optimization algorithm. In this method, a reverse sequential LSTM network is added to establish a Bi-LSTM network model, which can consider the feature quantity of the future time. Then, the kernel functions used by SVM are aggregated together by the weighted average method to establish the MKL-SVM model, and MKL-SVM is used to replace the Softmax function to achieve fault classification. The feature of SVM is applied to increase the classification generalization ability, and multi-kernel learning has more excellent characteristics for heterogeneous data classification. A failure in the transformer oil dissolved gas H<sub>2</sub>, CH<sub>4</sub>, C<sub>2</sub>H<sub>6</sub>, C<sub>2</sub>H<sub>4</sub>, C<sub>2</sub>H<sub>2</sub>, the characteristics of the gas is chosen to verify the effectiveness of multi-kernel learning support vector machine and bidirectional recurrent neural network for transformer fault diagnosis. Compared with several existing prediction models, the model can make a more accurate judgment on a few heterogeneous data, with stronger generalization ability and higher prediction accuracy.

The rest of this paper is consisted of as: Section II presents the related works. The proposed method is described in Section III and Section IV. Experimental results and performance analysis are discussed in Section V. Finally, this paper concludes in Section VI.

## II. RELATED WORK

Machine learning is used increasingly frequently and effectively to process and analyze data as a result of technological advancements. Zhang Hang et al. proposed to use support vector machine to improve the accuracy of motor fault diagnosis, but the model has many limitations, including poor generalization ability, low classification efficiency and high interference accuracy [2]. Zhang Xin, Wang Heng et al. come up with a model of a neural network optimized by a sparrow search algorithm, which in view of transformer fault diagnosis to increase the correctness more effectively. However, the number of probabilistic neural network neurons was affected by training samples, and the time it takes to train the model would be increased to get a better model [3]. For increase the stability of SVM, Qingchuan Fan come up with a whale optimization algorithm that introduced the

characteristics of a genetic algorithm to improve SVM but sacrificed part of the classification accuracy of SVM [4]. In view of the contradiction between the stability and accuracy of SVM, Yuhan Wu et al. proposed an SVM optimization algorithm that adopts adaptive probability formula to balance the squirrel search algorithm. The iteration cycle and accuracy of the model are increased [5]. Bing Zeng et al. proposed an optimized gray wolf algorithm Let-Squares SVM combining particle swarm optimization and differential evolution. The model got rid of the weakness which it was caught in local optimum frequently and improved the correct rate of the model, but the generalization ability of the model was greatly affected [6].

The emergence of deep learning brings new changes to machine learning. Miao Jianjie et al. proposed to use improved particle swarm optimization algorithm to optimize fuzzy neural network, automatically adjust parameters and accelerate convergence [7]. Gao Xincheng et al. proposed using improved genetic algorithm to optimize convolutional neural networks, which shortened the time to obtain the optimal weight and improved the convergence and accuracy of neural networks [8]. With the emergence of more complex neural networks, more deep-learning methods have been put into use for fault diagnosis. Taha Ibrahim B. M. et al. come up with an improved convolutional neural network suitable for noise environment, which perfected the accuracy of the Convolutional Neural Network (CNN) model. But the CNN model does not have a good classification effect on time series data and cannot effectively extract features from time series data [9]. In order to enable neural networks to better consider timing features, Fan Xiaodong et al. come up with apply Long Short-Term Memory (LSTM) network for transformer fault diagnosis, which has a better effect than CNN. When LSTM is applied to fault diagnosis, it has trouble to ensure the stability of the model and the accuracy of long-time series will decline as the number of training increases [10]. To improve the stability of the model, He Yigang and Wu Xiaoxin put forward a kind of complicated correlation characteristic of bidirectional Recurrent Neural Network (RNN). The stability of the model is higher and can be related to more features. However, when we use models, the ability to generalize is not high with only the specific training being set to get a better training result [11]. Omar Alharbi combine CNN and Bi-LSTM for generating the final features representation to be passed to a linear SVM classifier [12]. This method used for classification of Arabic reviews show that the method achieved superior performance than the two baseline algorithms of CNN and SVM in all datasets. The combination of multiple machine learning methods has a better development prospect.

### III. FAULT DIAGNOSIS PRINCIPLE OF TRANSFORMER WITH BIDIRECTIONAL RECURRENT NEURAL NETWORK

Dissolved Gas Analysis (DGA) in oil is often applied to transformer fault diagnosis, which has the merit of easy to operate and strong anti-interference ability. In order to ensure reliable data collection and effective analysis results, the DGA method is adopted in this paper. DGA is a series of classical time series data, which collects dissolved gas data in transformer oil in a fixed period without interruption in time sequence. Therefore, the bidirectional recurrent neural network can be used as the feature extraction part of the model to feature extraction of time sequence data in transformer oil. Make sure that the timing sequence feature extraction ability of RNN and the dependability of the real operation, in the passage adopts an LSTM network with better timing sequence extraction ability and stable operation.

#### A. Dissolved Gas Analysis Method in the Transformer Oil

Transformer faults are split into electrical faults, thermal faults, mechanical faults. Yet as the frequency of mechanical faults is the lowest with the rest of the several faults, the main analysis object of thermal faults and electrical faults.

When transformer is in the process of fault operation, the insulation oil of the transformer will be oxidized and cracked due to the action of discharge and heat. The main composition of the insulation oil hydrocarbon will produce hydrogen and low molecular alkenes, alkenes, alkynes, and other gases. With the severity of the fault, the rising rate of each gas is different, and the transformer fault type can be roughly judged according to the different types of gas and concentration. Table I lists the characteristic gases of different faults.

TABLE I. THE CHARACTERISTIC GASES OF DIFFERENT FAULTS

Fault Types	Main Characteristic Gases	Accompany Characteristic Gases
Oil overheating	Methane CH <sub>4</sub> , Acetylene C <sub>2</sub> H <sub>2</sub>	Hydrogen H <sub>2</sub> , Ethane C <sub>2</sub> H <sub>6</sub>
Oil and paper overheating	Methane CH <sub>4</sub> , Ethylene C <sub>2</sub> H <sub>4</sub> , Carbon monoxide CO	Hydrogen H <sub>2</sub> , Ethane C <sub>2</sub> H <sub>6</sub> , Carbon dioxide CO <sub>2</sub>
Partial discharge in oil paper insulation	Hydrogen H <sub>2</sub> , Methane CH <sub>4</sub> , Carbon monoxide CO	Ethylene C <sub>2</sub> H <sub>4</sub> 、Ethane C <sub>2</sub> H <sub>6</sub> 、Acetylene C <sub>2</sub> H <sub>2</sub>
Spark discharge in oil	Hydrogen H <sub>2</sub> , Acetylene C <sub>2</sub> H <sub>2</sub>	
Arc in oil	Hydrogen H <sub>2</sub> , Acetylene C <sub>2</sub> H <sub>2</sub> , Ethylene C <sub>2</sub> H <sub>4</sub>	Methane CH <sub>4</sub> , Ethane C <sub>2</sub> H <sub>6</sub>

According to Table I, the characteristics of gas under different fault types, the transformer insulating oil by electrolysis produces several kinds of characteristic gas for parameters. And the characteristics of gas concentration and velocity were analyzed in different operation conditions while the operating state of the transformer was assessed to decision the transformer fault types. The transformer oil is a dissolved gas analysis method. This analysis method has the advantage of supporting live online detection to spare it from being impacted by the signal of electric and magnetic fields and has a simple operation mode. DGA applied in transformer state monitoring and fault diagnosis [13-14].

H<sub>2</sub>, CH<sub>4</sub>, C<sub>2</sub>H<sub>4</sub>, C<sub>2</sub>H<sub>2</sub>, C<sub>2</sub>H<sub>6</sub>, and the other five gases in the gas concentration detection results are more accurate and can determine the transformer fault type. In this experiment, H<sub>2</sub>, CH<sub>4</sub>, C<sub>2</sub>H<sub>4</sub>, C<sub>2</sub>H<sub>2</sub>, C<sub>2</sub>H<sub>6</sub> were chosen as the characteristic gases of experiment by using transformer fault data. Fig. 1 shows the concentration curves of the five characteristic gases.

Fig. 1. The concentration curves of the five characteristic gases

### B. Long Short-Term Memory Network

The perfect forecast of dissolved gas in oil can more effectively understand the operation state of the transformer and make a timely judgment of the fault. The Neural structure of a Recurrent Neural Network (RNN) has a self-feedback function, which can retain both current and previous information at the same time and can be used to calculate the current output [15]. However, when the RNN model is used to analyze the long time series data, there are defects of gradient explosion or gradient disappearance present to delayed backpropagation during the training process. So the RNN network is not good at analyzing long-series data [16]. LSTM network is a kind of RNN model that can store time sequence information for a long time by adding a gating unit on the basis of a general recurrent neural network. As a way of deep learning, the recurrent neural network can extract data features from time series more efficiently and accurately. The quality of features determines the accuracy of classification, and accurate classification of fault data can make a more timely response to transformer faults. For increasing the precision rate of neural network feature extraction for time series data, Take LSTM model as the prototype, the reverse time-series memory

network was introduced to increase the dependence of characteristic gases on time series information and increase the precision rate gas prediction by the model.

The basic unit structure of the LSTM is shown in Fig. 2 is the input of the current moment while being the value of the previous moment in memory unit. The activation function  $\sigma$  usually used the sigmoid function. Compared with RNN, LSTM is characterized by a gating mechanism, which includes three parts, namely the forget gate, input gate, and output gate [17]. The responsibility of forget gate is selectively forgetting the historical information stored in the memory unit. The input gate retains the current external information and integrates it with the historical information. And the output gate decides whether to output. The output of the LSTM is determined jointly by the gating unit and the input.

$$f_t = \sigma(W_f[X_t; Y_{t-1}] + b_f) \quad (1)$$

$$i_t = \sigma(W_i[X_t; Y_{t-1}] + b_i) \quad (2)$$

$$o_t = \sigma(W_o[X_t; Y_{t-1}] + b_o) \quad (3)$$

$$c_t = f_t \cdot c_{t-1} + i_t \cdot g(X_t) \quad (4)$$

$$Y_t = o_t \cdot h(c_t) \quad (5)$$

In the above equation,  $W_f$  and  $b_f$ ,  $W_i$  and  $b_i$ ,  $W_o$  and  $b_o$  are weight and bias for the forget gate, input gate, output gate respectively.  $g(\cdot)$  and  $h(\cdot)$  are mappings of  $X_t \rightarrow c_t$  and  $c_t \rightarrow Y_t$  respectively represents matrix multiplication.  $c_t$  contains both the input state and the history state, which improves the stability of the neural network and solves the problem of gradient disappearance that often occurs in the RNN.

Fig. 2. The time sequence diagram of LSTM

The time sequence diagram of LSTM is shown in Fig. 2. In each epoch of LSTM, the output will affect the gating unit so that the information will not be lost. Because of the existence of the forget gate, LSTM can decide when to discard some unimportant time information, to maintain the updating speed and certain accuracy of the network in the long time series.

The dissolved gas data in transformer oil is typical time series data. The data at a certain moment is closely related to the data at the previous moment, and the general neural network cannot find this connection, thus limiting the accuracy of the model prediction. LSTM can store historical data at a certain time scale due to the existence of memory units. This structure gives LSTM great advantages in processing time series feature data.

#### IV. BIDIRECTIONAL RECURRENT NEURAL NETWORK BASED ON MULTI-KERNEL LEARNING SUPPORT VECTOR MACHINE DIAGNOSIS MODEL

Generally, the recurrent neural network uses Softmax function to classify, but classification effect depends on the data analysis of recurrent neural network and the ability of generalization is bad. For solving this problem, we use SVM to replace the Softmax function in a recurrent neural network. Dissolved gas in transformer oil analysis by recurrent neural network, there are often some heterogeneous data located at the edge of classification space. For single-kernel support vector machines, it is difficult to process heterogeneous data, and they often ignore the heterogeneous data. For making more effective use of the processed heterogeneous data, MKL-SVM is produced by combining multiple kernel functions. The bidirectional recurrent neural network model based on a multi-kernel learning support vector machine is composed of two parts. Feature extraction based on a bidirectional recurrent neural network is an important part. The classifier of the second part uses MKL-SVM.

##### A. Data Preprocessing

According to the selection of H<sub>2</sub>, CH<sub>4</sub>, C<sub>2</sub>H<sub>4</sub>, C<sub>2</sub>H<sub>2</sub>, and C<sub>2</sub>H<sub>6</sub>, the five characteristics gases, and the ratio of the total volume input of the model, the data normalization processing is carried out according to the (6).

$$x_m^{(i)} = \frac{x^i}{x^1 + x^2 + x^3 + x^4 + x^5}, i = 1, 2, 3, 4, 5 \quad (6)$$

In the above equation,  $x_m^{(i)}$  is normalized.  $x^i (i = 1, 2, 3, 4, 5)$  is the volumes of H<sub>2</sub>, CH<sub>4</sub>, C<sub>2</sub>H<sub>4</sub>, C<sub>2</sub>H<sub>2</sub>, and C<sub>2</sub>H<sub>6</sub> before normalization respectively.

##### B. Training Set Selection

For the volume fraction set of dissolved gas in oil, the K-fold cross-validation method is adopted to partition the data set into training and test two parts. The cross-validation times are 5. The training set is responsible for training model, and the accuracy is evaluated through the test set, which can avoid the phenomenon of over-fitting. For large data sets, a relatively small training set can meet the requirements of model training. For small data set, a relatively large training set is needed to train model. In this experiment, the size of data set is small, so training set and test set account for 80% and 20% each.

Based on the study of various representative characteristic gases of transformer faults in Table I, combined with the faults frequently encountered in actual production, a variety of faults are summarized according to the characteristics of faults to deal with faults faster in actual operation and optimized

classification ability. And the operation states of transformers are classified into six categories: (1) Normal, (2) partial discharge, (3) low energy discharge, (4) high energy discharge, (5) medium-low temperature overheating, and (6) high temperature overheating.

##### C. Bidirectional Circulation Structure

Generally, the data analysis of recurrent neural networks depends on time series. Recurrent neural network need the data of the previous moment to predict the change of future data. When data has a temporal relationship or the data is more time-dependent, such network structure will often produce large errors. In addition, the training of this kind of neural network requires large-scale training samples. If there are few elements in the training sample, it may be difficult to obtain an ideal model.

To solve these problems, a bidirectional recurrent neural network is adopted in this paper. On the basis of original recurrent neural network model, a reverse sequential recurrent neural network is added. Two recurrent neural networks share input and output. Fig. 3 shows the structure of the bidirectional recurrent neural network.

As Fig. 3 show, the recurrent neural network has two hidden layers. The data is simultaneously input into the forward and reverse timing sequence. W<sub>2</sub> is the forward timing sequence, and W<sub>5</sub> is the reverse timing sequence. W<sub>1</sub> enters the forward timing sequence, and W<sub>3</sub> enters the reverse timing sequence. W<sub>4</sub> and W<sub>6</sub> jointly constitute the output layer. Different from the general neural network, the forward cycle layer and reverse cycle layer in the recurrent neural network are not connected, which can effectively prevent the occurrence of the self-cycle phenomenon.

Fig. 3. The structure of the bidirectional recurrent neural network

##### D. Support Vector Machine

The recurrent neural network uses the Softmax function in fault classification process, but this function cannot perform well in a wide range of faults. When the Softmax function is multi-classified, its effect is similar to the Sigmoid function used for Logistic regression. Only when various types are mutually exclusive, can the Softmax function have good classification ability [18]. SVM has a good classification effect and generalization ability in the classification task and it is a common fault diagnosis method to combine data analysis and classification with a recurrent neural network. The LSTM-SVM model obtained by combining the LSTM network with the SVM classifier can simultaneously give full play to LSTM's ability to process long sequence information and SVM's ability to classify low-dimensional feature data, to

reduce modeling difficulty and computational complexity and improve the speed and accuracy of performance degradation prediction [19].

Fig. 4. The diagram of the hyperplane dividing two types of samples

The central theme of the SVM is classification learning. For a given training sample set, a classification hyperplane is found in the sample space as the decision boundary to separate samples of different categories [20]. Fig. 4 shows the diagram of the hyperplane dividing two types of samples.

The hyperplane described by the following linear equation:

$$0 = \omega^T \mathbf{x} + b \quad (7)$$

Sample points in the sample space satisfy the following equation:

$$y = \omega^T \mathbf{x} + b \quad (8)$$

In the above equation,  $b$  is the bias of the value,  $\mathbf{x}$  is the data set of the input,  $\omega$  is the classification hyperplane of the partition class.

The distance that sample arrive the hyperplane in the sample space expressed as follows:

$$r = \frac{|\omega^T \mathbf{x} + b|}{\|\omega\|} \quad (9)$$

The nearest sample that arrive the hyperplane in the sample space is called 'support vector', and the sum of distance between the support vectors of two classes and the hyperplane is as follows:

$$\gamma = \frac{2}{\|\omega\|} \quad (10)$$

The basic form of a support vector machine can be obtained by maximizing the geometric interval between the data set and hyperplane.

$$\min_{\omega, b} \frac{1}{2} \|\omega\|^2 \quad (11)$$

$$s.t. y_i(\omega^T \mathbf{x}_i + b) \geq 1, i = 1, 2, \dots, m.$$

From (11), the solution of SVM is a convex quadratic programming problem, duality problem got by using the

Lagrangian multiplier method. The Lagrangian function of the dual problem can be expressed by the following formula.

$$L(\omega, b, \alpha) = \frac{1}{2} \|\omega\|^2 + \sum_{i=1}^m \alpha_i (1 - y_i(\omega^T \mathbf{x}_i + b)) \quad (12)$$

Here,  $\alpha = (\alpha_1, \alpha_2, \dots, \alpha_m)$ . The partial derivatives of the Lagrangian function  $L$  are taken with respect to  $\omega$  and  $b$ , and they are set to zero respectively to get the optimal solution of the function.

$$\omega = \sum_{i=1}^m \alpha_i y_i \mathbf{x}_i \quad (13)$$

$$0 = \sum_{i=1}^m \alpha_i y_i \quad (14)$$

According to (11), the dual problem is obtained by substituting (13) and (14) into (12):

$$\max_{\alpha} \sum_{i=1}^m \alpha_i - \frac{1}{2} \sum_{i=1}^m \sum_{j=1}^m \alpha_i \alpha_j y_i y_j \mathbf{x}_i^T \mathbf{x}_j \quad (15)$$

$$s.t. \sum_{i=1}^m \alpha_i y_i = 0, \alpha_i \geq 0, i = 1, 2, \dots, m$$

According to (8), (13), and (14), the model is obtained.

$$f(\mathbf{x}) = \omega^T \mathbf{x} + b = \sum_{i=1}^m \alpha_i y_i \mathbf{x}_i^T \mathbf{x} + b \quad (16)$$

It can be seen from (11) that there are inequality constraints on  $\alpha_i$  and training samples  $(\mathbf{x}_i, y_i)$  in support vector machines.

$$\begin{cases} \alpha_i \geq 0 \\ y_i f(\mathbf{x}_i) - 1 \geq 0 \\ \alpha_i (y_i f(\mathbf{x}_i) - 1) = 0 \end{cases} \quad (17)$$

The above constraints stipulate that the training samples always have  $\alpha_i = 0$  or  $y_i f(\mathbf{x}_i) = 1$ .

Thinking about nonlinear case, the hyperplane model in the characteristic space is calculated below:

$$f(\mathbf{x}) = \omega^T \varphi(\mathbf{x}) + b \quad (18)$$

From (18),  $\varphi(\mathbf{x})$  is the expression generated after the two-dimensional sample  $\mathbf{x}$  to a higher dimensional feature space. According to (12), (13), and (14), a new dual problem is as follows:

$$\max_{\alpha} \sum_{i=1}^m \alpha_i - \frac{1}{2} \sum_{i=1}^m \sum_{j=1}^m \alpha_i \alpha_j y_i y_j \varphi(\mathbf{x}_i)^T \varphi(\mathbf{x}_j) \quad (19)$$

$$s.t. \sum_{i=1}^m \alpha_i y_i = 0, \alpha_i \geq 0, i = 1, 2, \dots, m$$

It is necessary to find a  $K(\mathbf{x}_i, \mathbf{x}_j) = \varphi(\mathbf{x}_i)^T \varphi(\mathbf{x}_j)$  function, namely the kernel function of SVM, which generally uses

linear kernel, Gaussian function kernel, polynomial kernel, and sigmoid kernel.

### E. Multi-Kernel Learning

Generally, single-kernel structures are used in support vector machines, which are classified based on a single feature space. The selection of kernel functions needs to be judged according to actual needs and then selected according to experiences. And different parameters are set. Such kernel function design is not convenient, and SVM is difficult to train the specific data in the training sample, resulting in lower accuracy of the classifier.

For solving above flaws of SVM, this paper adopts the combination of multiple kernel functions to establish the MKL-SVM model and improves the adaptability of support vector machine to complex data through multi-kernel learning. MKL integrates multiple sub-kernels into a unified optimization framework to seek the best combination. Using the multi-kernel model optimize the performance of the learning model and obtain explicable decision functions [21]. With the adoption of the multi-kernel learning method, the classification effect of a single support vector machine on a few specific data is changed, and the classification accuracy of fault data is improved.

The kernel function in multi-kernel learning is composed of several basic kernel functions.

$$K'(x_i, x_j) = \sum_{i=1}^m \lambda_i K_i(x_i, x_j), \lambda_i \geq 0; \sum_{i=1}^m \lambda_i = 1 \quad (20)$$

From (20),  $m$  is the number of kernels, and  $\lambda_i$  is the weight of each kernel. Before calculating the weight of each kernel function, we need to obtain the kernel matrix of each kernel function.

$$K_i = \begin{bmatrix} k(x_1, x_1) & \dots & k(x_1, x_m) \\ \vdots & \ddots & \vdots \\ k(x_m, x_1) & \dots & k(x_m, x_m) \end{bmatrix}, i = 1, 2, \dots, m \quad (21)$$

After the kernel matrix is obtained, the eigenmatrix  $M$  is calculated according to the eigenvectors that get by data set. Getting the weight of each kernel function, the trace of each matrix  $\text{tr}(K)$  and  $\text{tr}(M)$  is used to characterize the characteristics of each matrix. And then the Euclidean distance of each  $\text{tr}(K)$  and  $\text{tr}(M)$  is calculated as follows.

$$|X_i| = \sqrt{\text{tr}(K_i) + \text{tr}(M)}, i = 1, 2, \dots, m \quad (22)$$

Then the kernel matrix is substituted into the feature matrix to obtain the importance of each kernel matrix to the feature.

$$H_i = \frac{K_i M}{|X_i|} \quad (23)$$

Finally, the weights of each kernel function are obtained.

$$\lambda_i = \frac{H_i}{\sum_{i=1}^m H_i} \quad (24)$$

### F. Calculation Steps of the Fault Diagnosis Method

The flow chart of Bidirectional Long Short-Term Memory network based on Multi-Kernel Learning Support Vector Machine (Bi-LSTM-MKL-SVM) is shown in Fig. 5.

Sum the output values at the current time to get  $Y_t$ .

$$Y_t = Y_t^1 + Y_t^2 \quad (25)$$

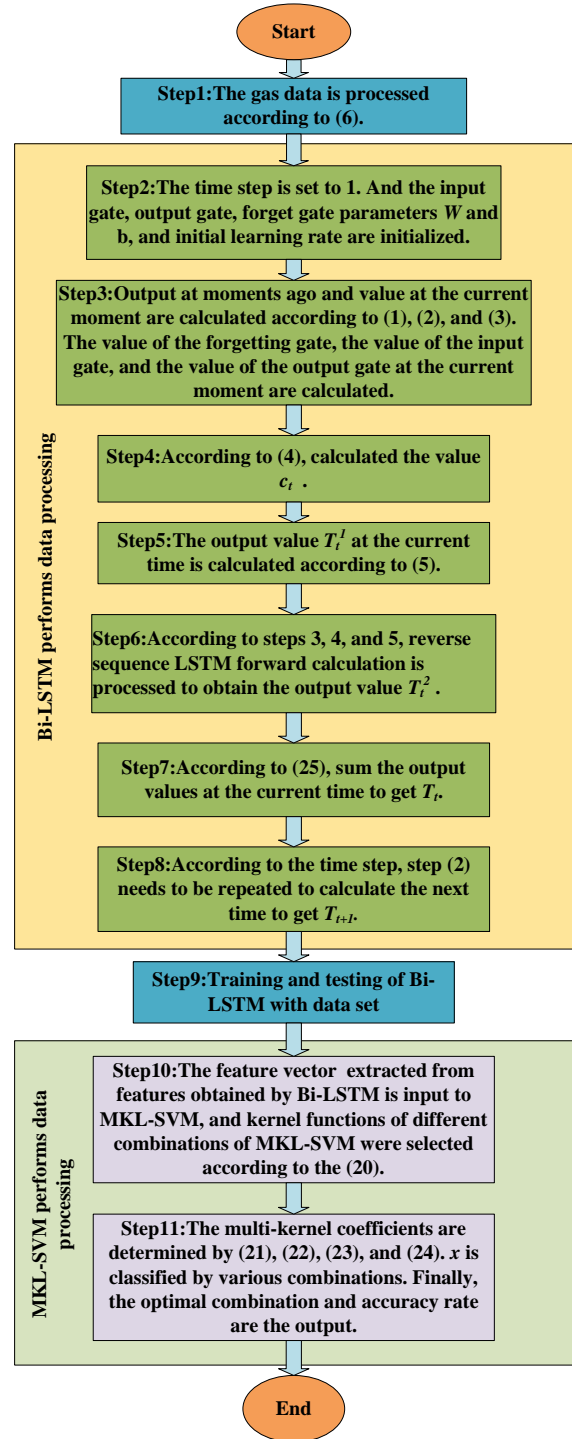

Fig. 5. The flow chart of Bi-LSTM-MKL-SVM

## V. EXPERIMENTAL ANALYSIS

### A. Selection of Training Times

Fig. 6. The accuracy of the training set and test set of Bi-LSTM

The accuracy of the training set and test set of Bi-LSTM is shown in Fig. 6. After 300 training times, the accuracy of the test set decreases obviously, and the model training has an overfitting phenomenon. Thus the number of sessions is set to 300 for the best results.

### B. Feature Extraction Performance Analysis of Time Series Data

In Table II, the model related parameters for using method in this paper are presented. It mainly includes the model mentioned in the paper and the parameters used in the model.

TABLE II. DESCRIPTION OF MODEL RELATED PARAMETERS

Abbreviation	Description
Bi-LSTM	It represents an LSTM with an additional reverse sequence
Bi-LSTM-SVM	Bi-LSTM is connected with SVM, and SVM is used to replace the classification function in Bi-LSTM
MKL-SVM	SVM is used by stacking multiple kernel functions according to a certain weight
Bi-LSTM- MKL-SVM	Bi-LSTM is connected with MKL-SVM, and MKL-SVM is used to replace the classification function in Bi-LSTM
Time step	The step size of each computation in LSTM
forget gate	It is responsible for controlling the persistence of memory cell
input gate	It is responsible for controlling the input of the immediate state into memory cell
output gate	It is responsible for controlling whether the current value is printed
Memory cell	It is responsible for storing long-term state

In order to validate the bidirectional recurrent neural network to improve the effectiveness of time-series analysis, training set input Bi-LSTM respectively with LSTM, RNN, and CNN model and then validated the accuracy of test set. The results of four kinds of models of time-series data feature extraction accuracy are shown in Table III.

TABLE III. THE RESULTS OF FOUR KINDS OF MODELS OF TIME-SERIES DATA FEATURE EXTRACTION ACCURACY

Table No	Models	Accuracy (%)
1	CNN	80.18
2	RNN	81.34
3	LSTM	82.83
4	Bi-LSTM	84.08

To ensure no interference to the sequential feature extraction ability of the models, the same Softmax function was used as the classifier for the four models. According to the data in Table III, RNN has higher accuracy than CNN in time sequence data because of its memorability. Compared with RNN, the LSTM network has higher accuracy in data analysis due to the gated unit, while RNN has the problem of gradient explosion due to the rugged search path. So pruning operation is required to decrease learning rate and increase training time. Among above recurrent neural networks, Bi-LSTM has the highest accuracy, which is more than 84%. In the process of model training, Bi-LSTM model not only speeds up the convergence rate of the model but also deepens the time sequence at the same time for the correlation of each parameter. It also corrects the training model, so that the model has better accuracy in prediction. The volatility of its accuracy is less than other recurrent neural networks and CNN. The experiment proves that the Bi-LSTM network can better complete the feature extraction task in time series data by adding a reverse time series recurrent neural network. MKL-SVM has a better classification effect on heterogeneous data. By comparing the confusion matrix between CNN and Bi-LSTM, we verify whether the heterogeneous data generated by Bi-LSTM is more suitable for MKL-SVM on the basis of Bi-LSTM having a better feature extraction ability on time series data. SVM, as a classical classifier, is compared with Bi-LSTM to verify the influence of feature extraction of time series data on data sample classification. The confusion matrix of CNN, Bi-LSTM, and SVM is shown in Fig. 7.

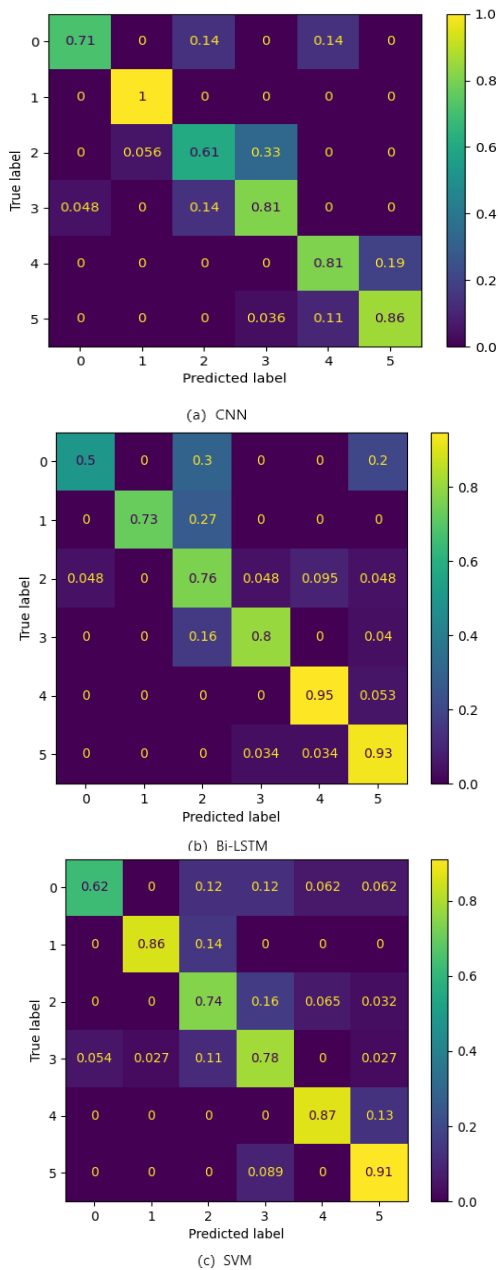

Fig. 7. The confusion matrix of CNN, Bi-LSTM, SVM

Both CNN and Bi-LSTM use the Softmax function as model classifier. CNN model only has a good classification effect on partial discharge fault type, but a poor classification effect on other fault types. The Bi-LSTM model has a good classification effect on multiple fault types. According to Fig. 7, the distribution range of Bi-LSTM classification results is wider, indicating that Bi-LSTM will generate more heterogeneous data in feature extraction of data and affect the classification effect of the classifier. SVM and Bi-LSTM have

similar fault diagnosis effects, but SVM has more misjudgment of fault types and the classification effect is not stable, indicating that the data extracted by feature can be more easily classified. The confusion matrix shows the classification performance of Bi-LSTM is significantly better than CNN and SVM. After feature extraction, the Bi-LSTM time series data generates more heterogeneous data and has a better combination with MKL-SVM.

### C. Diagnosis Result Analysis of Bidirectional Recurrent Neural Network Model based on a Multi-Kernel Support Vector Machine

In this section, MKL-SVM model will be established through kernel fusion to form a multi-kernel. In multi-kernel learning, multiple kernel functions can be used for fusion, or the same kernel function with different parameters can be used for fusion to ensure the diversity of kernel fusion. Fig. 8 shows the workflow of MKL-SVM.

Fig. 8. The workflow of MKL-SVM

To prove the effectiveness of Bi-LSTM-MKL-SVM network in improving the exactitude of time series analysis and prediction, SVM and Bidirectional Long Short-Term Memory network based on Support Vector Machines (Bi-LSTM-SVM), LSTM and Bi-LSTM and Bi-LSTM-MKL-SVM are used to compare and analyze the predicted results of test sets.

The micro-average PR curve of the five models is shown in Fig. 9. On the whole, under the influence of heterogeneous data, the classification performance of Bi-LSTM-SVM is not different from Bi-LSTM and LSTM. Bi-LSTM-MKL-SVM has better classification performance, while the SVM has the worst classification effect.

Fig. 9. The micro-average PR curve of the five models

Fig. 10. The PR curve of the Bi-LSTM-MKL-SVM model

The PR curve of the Bi-LSTM-MKL-SVM model is shown in Fig. 10. Bi-LSTM-MKL-SVM has good classification performance for each fault category under good overall classification performance. Compared with the SVM model, the combined model that extract time series information by the recurrent neural network can effectively improve the classification efficiency of the classifier. For the LSTM model, SVM classification can significantly optimize neural network performance. Feature extraction of time series data by Bi-LSTM will generate a lot of heterogeneous data. Using general SVM can not only improve the performance of the classifier but also cause interference with the classification ability of SVM. MKL-SVM is more effective for the classification of heterogeneous data. Bi-LSTM-MKL-SVM is used to solve the influence of heterogeneous data on model judgment better, improve the model's utilization ability of time-series data, and enhance the overall generalization ability of model, as well as improves its stability.

(a)SVM prediction results

(b)LSTM prediction results

(c)Bi-LSTM prediction results

(d)Bi-LSTM-MKL-SVM prediction results

Fig. 11. The comparison between the true label and predicted label

Fig. 11 shows the comparison between the true label and the predicted label. The data fitting and classification effect are shown in Fig. 11; the SVM model has a poor fitting effect on test samples. This shows that simple classification algorithm is difficult to complete accurate classification of complex data. The Bi-LSTM model has better fitting accuracy than the LSTM model. This indicates that adding a reverse timing network can effectively improve the accuracy of LSTM. Compared with the other three models, the Bi-LSTM-MKL-SVM model has the best classification and fitting effect on test samples, indicating that the Bi-LSTM-MKL-SVM model has a stronger ability to extract time series features. It proves that these optimizations are effective. SVM can significantly improve the generalization of neural networks. Multi-kernel learning can effectively optimize the classification effect of SVM on complex data.

TABLE IV. THE ACCURACY OF THE FIVE MODELS

Table No.	Models	Accuracy (%)
1	SVM	81.50
2	LSTM	82.83
3	Bi-LSTM-SVM	83.58
4	Bi-LSTM	84.08
5	Bi-LSTM-MKL-SVM	85.86

The accuracy of the five models is shown in Table IV. The Bi-LSTM network model is used to process time series data, which improves the classification efficiency of MKL-SVM, improves the accuracy and stability of the model as a whole, and effectively solves the shortcomings of neural networks and SVM used alone. It can be seen by comparing with the model prediction accuracy, MKL-SVM does better in heterogeneous data for more accurate judgment, and it can save time for SVM to adjust the parameter and reduce the possibility of error when choosing parameters based on experience. More basic kernel function combinations optimize the effect of MKL-SVM and its applicability.

## VI. CONCLUSION

In allusion to transformer fault diagnosis, the deep learning method has problems with the stability and the effective use of data samples. This paper comes up with a kind of model called Bi-LSTM-MKL-SVM and takes Bi-LSTM as the feature extraction part of model. MKL-SVM is used to replace the Softmax function in Bi-LSTM to classify the data after feature extraction. By adding reverse time sequence, the Bi-LSTM-MKL-SVM network model can consider more time sequence factors, achieve better prediction effects for time sequence data, and carry out more effective feature extraction for time sequence data. It has better classification ability for heterogeneous data and reduces the time used for reference adjustment depending on experience. The feature extraction ability and generalization ability of the Bi-LSTM-MKL-SVM network model were verified by the confusion matrix, PR curve, and accuracy comparison. The accuracy of the Bi-LSTM-MKL-SVM network model was higher. The Bi-LSTM-MKL-SVM network model can improve the accuracy of transformer fault diagnosis and reduce the misjudgment of faults in the operation of transformers, thus reducing the economic losses caused by transformer faults.

The model proposed in this paper has certain limitations on the analysis of gas data. Different fault types pay different attention to gas data. More accurate selection of the weight of each gas in different faults can effectively improve the accuracy of classification. Transformer failure is closely related to environmental factors, such as ambient temperature and humidity. Considering more influencing factors to improve the universality of the model is one of the future research directions.

## ACKNOWLEDGMENT

This work was supported by the Scientific Research Project of the Liaoning Provincial Department of Education (No. LJKZ0398) and the Scientific Research Foundation of Liaoning Petrochemical University (No. 2017XJJ-044). The authors also would thank reviewers for improving this article.

**Abstract**—The DataOps methodology has become a solution to many of the difficulties faced by data science and analytics projects. This research introduces a novel DataOps lifecycle along with a detailed description of each phase. The proposed cycle enhances the implementation of data science and analytics projects for achieving business value. As a proof of concept, the new cycle phases are applied in a healthcare case study using the UCI Heart Disease dataset. Two goals are achieved. First, a dataset reduction by features analytic in which the four most effective features are selected. Second, different machine learning algorithms are applied to the dataset. The recorded results show that using the four most effective features is comparable with using the full features (thirteen features), and both approaches show high accuracy and sensitivity. The average accuracy of the highest four features is 82.32%, and the thirteen features is 84.28%. That means that the selected four features affect the applications with 97.67% accuracy. Besides, the average sensitivity of the highest four features is 87.94%, while the thirteen features are 87.12%. The study shows an interesting and significant result that data modeling needn't be done for all data science projects which reduced the dataset.

**Keywords**—DataOps lifecycle; DataOps in machine learning; DataOps in healthcare; DataOps in data science; feature extraction; feature selection

## I. INTRODUCTION

The fields of data science, analytics, and machine learning are expanding at an incredible rate. Businesses are now searching for experts who can sort through the data goldmine and assist them in making quick, informed business decisions. Although today, organizations have a great opportunity to access data-driven tools and business intelligence software. Most organizations fail to make business value from their investments in data [1]. Thus, resulting from the lack of maturity in data science projects, most implementations are laptop-based research projects that never impact customers. In addition to, local applications that are not built to scale for production workflows, or high-cost IT projects. Therefore, selecting the method for implementing a data-driven project must be done carefully to help when maintaining or even adding a new feature(s).

The legacy architecture and tools that require special skills to use by data scientists have become bottlenecks for business stakeholders. These tools are costly resources, especially when producing unplanned data analysis. Machine Learning and Artificial Intelligence algorithms are just tips of the iceberg [2] for getting business and customer value from data.

Therefore, the operation of affecting data is the most crucial aim.

Data analytics is used in business to help organizations make better business decisions to meet and increase customer value. Data draws beneficial conclusions by collecting and organizing it; a data-driven process covering everything from data collection to analysis. DataOps has emerged to meet such requirements. *DataOps* is an emerging set of practices, processes, and technologies for building and enhancing data and analytics pipelines [3]. The term DataOps is a merge of data and operations which was first introduced by Lenny Liebmann in a 2014 blog post titled "3 reasons why DataOps are essential for big data success". The term wasn't popularized until Andy Palmer's 2015 blog post "From DevOps to DataOps". Since then, interest has grown when the term DataOps was included in Gartner's "Hype Cycle" for data management in 2018 [4]. As Agile has a manifesto [5] for its 4s principles. DataOps has its own manifesto [6] too, which consists of 18 principles, unlike Agile 12 principles. The DataOps manifesto has been published by Christopher Bergh, Gil Bengiat, and Eran Strod [4]. The DataOps manifesto principles have complemented the initiative that came out in 2018 called "The DataOps Philosophy".

The problem DataOps has come up for solving and minimizing analytics "cycle time" between the proposal of a new idea and the deployment of finished analytics. For example, many organizations require months of cycle time to deploy 20 lines of SQL. The long cycle times are the primary reason analytics projects fail [7]. This has led to discouraged and disappointed users and disturbing creativity. The factors that lengthen cycle time are *Poor Teamwork, Lack of Group Cooperation, Waiting for Systems, Waiting for Data Access, Over-Caution, Requiring Approvals, Inflexible Data Architecture, Process Bottlenecks, Technical Debt and Poor Quality*, which were mentioned in [8]. These obstacles pushed data experts to find an effective solution; therefore, DataOps came up. DataOps's goal for data science is to turn unprocessed data into a useful data science product. DataOps has provided utility to customers through a rapid, scalable, and repeatable process.

Data experts have given DataOps many definitions depending on their points of view. As a result, there have been several attempts to define the concept of DataOps. For example, Gartner [9] defined DataOps as a collaborative data management practice focused on improving the communication, integration, and automation of data flows

between data managers and data consumers across an organization. While Eckerson [10] Group defined DataOps as an engineering methodology and set of practices designed for the rapid, reliable, and repeatable delivery of production-ready data, operations-ready analytics, and data science models. DataKitchen [11] said that DataOps is a collection of technical practices, workflows, cultural norms, architectural patterns, and much more. However, the most appropriate definition adopted here is that DataOps is a methodology that applies Agile development, DevOps, and lean manufacturing principles [12], all together to data analytics development and operations where they are the intellectual heritage for DataOps.

Agile is an application of the theory of constraints to software development, in which smaller lot sizes decrease work-in-progress and increase overall manufacturing system throughput. DevOps is a natural result of applying lean principles, for example, eliminating waste, continuous improvement, and broad focus on application development and delivery. Lean manufacturing also contributes a relentless focus on quality using tools such as statistical process control, to data analytics [11]. Due to different DataOps definitions, trying to evaluate different solutions and determine whether they will help to achieve DataOps goals or not is a confusing matter. The authors in [13] introduced a [DataOps Vendors Landscape](#) which was organized by the six key capabilities required for DataOps success.

The major contributions of this paper are summarized in the following points:

- Introducing a novel approach for the DataOps lifecycle with a detailed description for each phase.
- The most effective features selection and extraction.
- Proving that data modeling is not necessary for all data science and analytics projects.
- Presenting a case study in healthcare as a proof of concept.
- Dataset reduction for the UCI Heart Disease dataset.
- A comparison between different machine learning algorithms that have applied to the dataset for both the highest four features and all (thirteen) features.

This paper is organized as it follows. Section II presents the related work. Section III introduces the proposed DataOps lifecycle. Experiments and recorded results for a case study in healthcare are shown in Section IV. Section V has the conclusion and future work.

## II. RELATED WORKS

This section will investigate both DataOps related works and the UCI Heart Disease dataset related works. The number of DataOps related works are quite a few because of being a new research field. The author in [14] has illustrated the broad character of DataOps and shown that it is not a particular method or tool. However, a collection of principles and a way of doing things on a cultural, organizational, and technological level. He differentiated between the exploration of DataOps as

a discipline, which includes methods, technologies, and concrete implementations, and the investigation of the business value of DataOps. While authors in [15] have defined DataOps as an application of DevOps to data, which means how effective data operations can be when DevOps concepts are applied to data for managing and deriving analytics. They also outlined the DataOps process and platform as well as the data challenges in the manufacturing and utilities industries. In [16], the authors said that DataOps is a new approach that aims to improve the quality and responsiveness of the data analytics lifecycle. In addition, they broadly organized dataOps into three steps: build, execute, and operate.

The lifecycle of a DataOps process has been illustrated in [17]. Besides, it illustrates the main collaborators in the DataOps process in charge of generating business value. In addition, they have gathered and highlighted good practices in DataOps reported in the academic literature, which serves as a starting point. While [18] defines DataOps as a method for accelerating the delivery of high-quality results through automation and orchestration of data life cycle phases. Furthermore, a case study in collaboration with Ericsson was conducted and introduced. They used the key phases of the data analysis methods to explore the key phases of the data besides checking their similarities to the popular DataOps approach. The common limitations of the above related works were either ambiguity of the DataOps lifecycle or the shortage of applications.

In [19], the model they proposed has four phases: first, data gathering that was the UCI Machine Learning dataset. Second, they used two methods for the features selection: Pearson's Correlation Heatmap where they selected 9 features and Chi Squared Test that selected 6 features. The third stage consists of K-Nearest Neighbors (KNN), Support Vector Machine (SVM) and Decision Tree (DT). After applying those algorithms, they have further used Stacking and Voting ensemble techniques for better results. Although, their model performed better when they have used Pearson's Correlation Heatmap selected features. Their model has some limitations that it has taken more time to generate outcomes.

While [20], they used Logistic Regression (LR), Naïve Bayes (NB), Decision Tree (DT), Random Forest (RF), Support Vector Machines (SVM), Xtreme Gradient Boosting Machine (XGBM), Light Gradient Boosting Machine (LGBM), and K-Nearest Neighbors (KNN) for the prediction of the UCI Machine Learning dataset individually. Then multi-model ensembles were created (Ensemble 1 and Ensemble 2), which have far higher accuracies than individual models. The models with the best values of the evaluated parameters were gathered. In order to train and test the models on five distinct folds and to determine the optimal values for the hyperparameters in each of the implemented classification algorithms, fivefold cross validation and GridSearchCV were employed. They used all the UCI Machine Learning dataset features in addition to, they grouped models to reach their accuracy and that were their limitations.

Also [21], chose the well-known Logistic Regression (LR), Naive Bayes (NB), Random Forest (RF), Decision Tree (DT), Support Vector Machine (SVM), and K-Nearest

Neighbor (K-NN) algorithms for the UCI Machine Learning dataset prediction; also, for Hungarian cardiovascular disease dataset. The proposed system consisted of data acquisition, pre-processing, feature/attribute selection, classifications, and performance evaluation. The FCBF and mRMR were the feature selection algorithms. They used the info gain function selection method that's available on Weka for actual feature ranking. The top 10 features were ranked, which was a limitation.

Authors in [22] present three approaches. First Approach was without doing feature selection and outliers detection. The second approach was with doing feature selection and no outliers detection. The third approach was doing feature selection and also outliers detection. In all approaches they used Logistic Regression (LR), Random Forest (RF), Decision Tree (DT), Support Vector Machine (SVM), K-Nearest Neighbor (K-NN), and XGBoost ML algorithms for the UCI Machine Learning dataset prediction. Their results they have been reached needn't to do three approaches. In addition, the feature they chose to be either important or not for heart disease predication were a limitation.

### III. PROPOSED DATAOPS LIFECYCLE

Data analytics projects are failing despite qualified people, powerful tools, and huge investments. Data scientists spend 75% [23] of their time massaging data and executing manual steps. Slow and error-prone development disappointed and frustrated data team members and stakeholders.

According to the adopted definition, to manage data in accordance with corporate objectives, DataOps combines DevOps and Agile approaches. For instance, DataOps would position data to make recommendations for better product marketing, converting more leads, if the goal was to increase lead conversion rate. While DevOps procedures are utilized for code optimization, product builds, and delivery, Agile techniques are employed for data governance and analytics development. DataOps uses statistical process control (SPC) to continuously monitor and verify the data analytics pipeline, much like lean manufacturing does. SPC increases data processing efficiency, improves data quality, and ensures that statistics are kept within reasonable bounds. SPC helps to notify data analysts right away in the event of an anomaly or error so they can respond.

This study proposes a novel DataOps lifecycle as shown in Fig. 1, along with a detailed description for each phase. The significance of this cycle is to investigate and highlight that data modeling is not necessary for all data science and analytics projects that reduce the dataset. The following subsections will illustrate each phase in detail.

#### A. Define Data Domain

A common mistake in data science projects is the confusion between defining a data area and a data domain. A data domain is a specific area in a large area. For example, if we have a data science project in healthcare, the area is healthcare, while the domain is heart disease. This is called the

first data domain definition. The second data domain definition is what disease in the heart disease area we're going to work with.

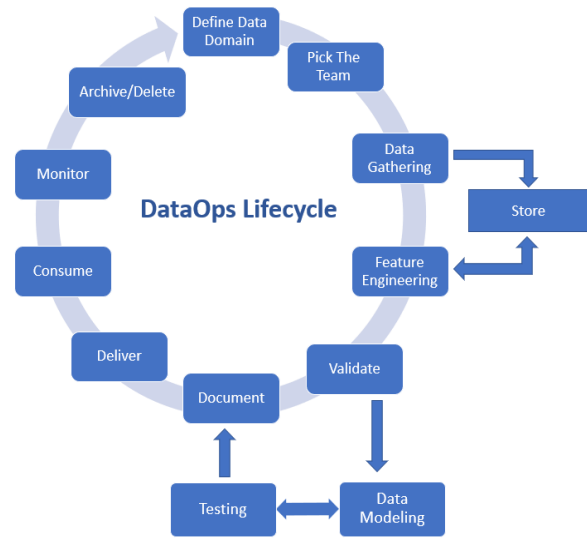

Fig. 1. Proposed DataOps lifecycle

#### B. Pick the Team

From this study point of view, this phase is the most critical phase that will determine the success of the coming phases or not. Data scientists have been working on different tools and outputting the results in different forms. This common problem adds another step to reorganize the output and merge all the results. Table I defines the criteria that must be met to approve each team member and the team as a whole.

Picking the team may differ from task to task. So, a smaller team would be selected by the unicorn for simpler problems. There are two main types of tasks, and each of them will be handled differently: First, system creation from scratch including data flow, data architecture, data schema, integration, etc. Second, solve smaller tasks from working with existing data or data that can be obtained. Each will require different handling methods and will be taken into consideration during the selection process.

#### C. Data Gathering

After everything was agreed upon, the team should start data gathering related to the domain. Data may be ready-made or performed from scratch. This phase should be done carefully as it may need to include any additional data, like performing surveys or scraping some data from the web. Then, the collected or performed data has to be stored.

#### D. Feature Engineering

Because not all data is important, this phase is concerned with obtaining and extracting the important data features. So, based on the data domain expert and, of course, the unicorn's opinion, the team tries to extract only the important features.

TABLE I. TEAM CRITERIA

Criteria	Criteria Details	
Members and Tasks	1. Data Unicorn	Data scientist who has the knowledge for all aspects of data science projects as, data engineering, statistical analysis, business analysis, ML, programming, or visualization. He must approve all the other members and he manages the whole project.
	2. An expert of domain knowledge	Any data project must have an expert in domain knowledge (with no experience in SWD) to explain all domain details and tricks the team want to know, i.e., educational expert in education project and medical expert in medical project.
	3. Data Analyst	Analyzes data (i.e., Visualizations: Charts, Graphs, Dashboards, Tables, Reports).
	4. Data Engineer	Develop, constructs, tests & maintain complete data architecture (i.e., Schema design, Data lakes).
	5. Data Scientist	Analyzes and interprets complex data in addition, he is a data wrangler who organizes (big) data.
	6. DataOps Engineer	He creates the mechanisms for workflow, manages cycle time and optimizes the quality.
	7. AI Engineer	Create end-to-end applications that include the data model(s).
	8. Operations Engineer	Deploying the applications into production environments and support service-level agreement.
Common Knowledge	They all must know source control, containerization, clean code, design pattern, security (to some level).	
Tools	All members must work with the same tool, or different tools that their output format is the same (provided that they will unify this later).	
Agreement	They must respect the data security and environment ethics.	

The next phase will be stepped to get the insights. The featured data may need to be stored or to store the featured criteria that have been adopted for similar data.

#### E. Store (Optional)

After collecting the data, it must be stored initially. Then, it might be restored or stored again in some other format after the next phase is done. For the sake of memory, the team might choose to store the data again or override the stored data based on its importance and size.

#### F. Validate

In this phase, the team seeks to gather all the collected insights. The task goal will be tried to reach based on the provided information. If they did, they wouldn't have to do the data modelling phase as results might be easily concluded only from the insights relying on the experience of the team. Data modelling leads to a lot of time, money, and resources; therefore, avoiding it on small tasks increases the speed. So, based on the problem type and the data, the team may also select a collection of algorithms and combine them together to obtain the best result for reaching the task goal. Thus, the team must successfully manage this phase in order to avoid the next if possible.

#### G. Data Modeling

If this phase is applied in the proposed cycle, it means that the team has tried every possible scenario to understand the data. Nevertheless, it was rather too complicated or critical for data modelling to be avoided. The team then must select the most perfect and appropriate algorithm for data modeling.

#### H. Testing

After reaching the goal, which of course, may differ from one task to another, in which data tasks need to be analyzed, visualized, modeled, processed, stored, or some of them, or all of them at the same time. The team must test whether the

results match the original goal or not. It must be checked step by step, there is no overfitting, underfitting, or any other data-related problems. The testing phase also must be reproducible. As the data modelling phase may be required to resolve a tested issue(s).

#### I. Document

All the work that has been done must be well described and documented. The documentation must be self-explanatory so that any member of any department can easily understand what has been done. Documentation may also involve technical writing for developers to complete from where the team stopped. Besides, if new data is created, a new data schema must be written to fairly describe the new changes. In addition to, the reasons why they needed to change the original data must be defined.

#### J. Deliver

The task delivery could be a tricky process. If the task contains new data, it must be put in the right place without any contradiction with the original data or any other data. If it contains reports, it must be very readable with visualizations to make the image clearer. Finally, if it has a new model delivered, it must be uploaded to the place where it will be used. So, an API could be created or maybe a model with a specific format. Therefore, the delivery must be teamwork to get the results in the right format to be used and easily deployed in production.

#### K. Consume

At an enterprise level, the published model(s) can be reused to derive various analytics required for business. "Recommend" solutions for understanding consumer preferences can be applied to a host of product lines. The tested and deployed solutions can be used with similar data sets to solve similar problems. This way not only does the enterprise save time by quickly applying proven

methodologies, but it also ensures the building of robust solutions through the continuous evolution process.

#### L. Monitor

Tasks delivery and doing investigations is not the end of the work. All the tasks delivered must be monitored to see whether the team succeeded in doing reliable work in the long term or not. For example, the team may have been assigned to work on a part that is rarely used. Besides, the team may have focused on the wrong features at first, and it was so obvious. Furthermore, monitoring is essential to predict and avoid an immediate system failure or even a small failure. Expect any changes before they happen. Detecting any possibility of performance reduction and being prepared for what changes may come may be enough. Thus, monitoring is essential for further improvement.

#### M. Archive/Delete

By the end, the organization might decide to cull out unwanted data or archive it to optimize resources and size management as well. Periodic data audits should be carried out to ensure production systems use fewer resources, running more efficiently and reducing storage costs overall. Data archiving plans have to be made for easy retrieval and more cost-effective information storage. Furthermore, irrelevant data needs to be purged.

## VI. EXPERIMENTS AND RESULTS

This section introduces a healthcare case study for the proposed DataOps lifecycle. Healthcare was chosen as it is the most sensitive data in which the results affect human life. According to WHO [24], cardiovascular diseases are the leading cause of death globally. It takes an estimated 17.9 million human lives each year. So, the chosen dataset was the UCI Machine Learning Heart Disease dataset [25]. This dataset contains 76 attributes, but all published experiments refer to using a subset of 14 (13 feature and target column) of them.

The "goal" which is the target, refers to the presence of heart disease in the patient. It is an integer valued between 0 (no presence) and 1 (presence). The other 13 features are:

- 1) **age**, that stores the age of the patient in years.
- 2) **sex**, where 1 is for males and 0 for females.
- 3) **cp**, chest pain type in which 1 = typical angina, 2 = atypical angina, 3 = non-anginal pain, and 4 = asymptomatic.
- 4) **trestbps**, which is resting blood pressure that was measured in mm Hg on admission to the hospital.
- 5) **chol**, serum cholesterol measured in mg/dl.
- 6) **fbs**, is fasting blood sugar > 120 mg/dl if 1 then true, while 0 = false.
- 7) **restecg**, resting electrocardiographic results that has three values 0 indicates normal, while 1 indicates having ST-T wave abnormality (T wave inversions and/or ST elevation or depression of > 0.05 mV) and 2 showing probable or definite left ventricular hypertrophy by Estes' criteria.
- 8) **thalach**, includes the maximum heart rate value achieved.

9) **exang**, exercise induced angina where 1 means yes and 0 means no.

10) **oldpeak**, that equals ST depression induced by exercise relative to rest.

11) **slope**, which is the slope of the peak exercise ST segment that has 3 values, if 1: upsloping, 2: flat, and 3: downsloping.

12) **ca**, includes a number of major vessels (0-3) coloured by flourosopy.

13) **thal**, where 3 = normal, 6 = fixed defect, and 7 = reversible defect.

The proposed DataOps lifecycle shown in Fig. 1 was applied as follows:

#### A. Define Data Domain

As illustrated in Section 3.1, the data area in this case study is healthcare. But the data domain is cardiovascular diseases.

#### B. Pick the Team

For this stage, as explained in Section 3.2. Choosing the team may differ from task to task. Therefore, in this case study, two main members from Table I must be present, in which they are an unicorn and a domain knowledge expert at least.

#### C. Data Gathering

After starting data gathering related to the domain. The UCI Machine Learning Heart Disease dataset has been chosen.

#### D. Feature Engineering

This phase has been done using Python 3 and the Jupyter Notebook IDE. Feature engineering has been done as follows:

- **Step 1:** Read/Load dataset.
- **Step 2:** Get the dataset information. The dataset information has displayed features(columns) name, each feature datatype, datatype, and total number of rows and columns.
- **Step 3:** Checking for null values.
- **Step 4:** Checking for duplicate.
- **Step 5:** Remove duplicate.
- **Step 6:** Generate Correlation heatmap. Where correlation heatmap is an essential step for data analysis, exploratory information in a visually appealing way. The value of the coefficient of correlation can take any value from -1 to 1 [26]. When the value is 1, it's a direct correlation between the two variables. That means when one variable increases, the opposite variable also increases. While if the value is -1, it's an indirect correlation between two variables, in which when one variable increases, the opposite variable decreases. Therefore, when 0 value, there's no correlation between two variables as the variables

change in a random manner with reference to one another.

E. Store

This stage may be visited many times. In this case, it has been visited twice. One for storing the gathered data and one after finishing the feature engineering stage.

F. Validate

In this phase, more data analysis has been applied to decide whether the data modelling phase is needed or not. Also, validate phase has been done using Python 3 and the Jupyter Notebook IDE. It may be done using author tools as Microsoft Excel or Power BI.

- **Step 1:** Display dataset description. A dataset description provides the following information for each feature: five number summary (minimum value, 25%, 50%, 75%, maximum value) in addition to mean, standard deviation, and count. For example, *age* feature five number summary (29, 47, 55, 61, 77 respectively). This means that minimum age in the dataset is 29, first quarter of age is 47, second quarter of age is 55, third quarter of age is 61, and maximum is 77 years. In addition to mean equals 54, with standard deviation 9, and count equals 303.
- **Step 2:** Generate correlation between target column and each feature in descending order. After tagging the absolute correlation values. This step gives the most effective features that correlate with target column. The most four effective features were *exang*, *cp*, *oldpeak*, and *thalach* as shown in Fig. 2.
- **Step 3:** Exploratory Data Analysis for each feature. This step gives more information about each feature. In addition, it represents heart disease root cause value for each feature. Table II illustrates each feature root cause value for having heart disease. The features have been arranged in descending order as same as in Fig. 2.

Fig. 2. Features correlation in descending order

Thus, in order to determine the most common causes of heart disease and what each cause truly affects, the validation

step is enough for doing that in addition to defining a set of values for heart prediction. While, if the task is the prediction of heart disease or not, data modelling needs to be done.

G. Data Modeling

For the heart disease prediction. This step has done to prove and support the proposed cycle. Two models have been developed. The same python code has been applied for both. One with all the features and the other with only the highest four features (*exang*, *cp*, *oldpeak*, and *thalach*) that highly affect the target. The two models were simply implemented. Using the following sklearn classifiers: Logistic Regression (LR), Naive Bayes (NB), Support Vector Machine (SVM), K-Nearest Neighbors (KNN), Decision Tree (DT), and Random Forest (RF). In addition to that, XGBoost and Neural Network models with only one hidden layer and just 300 epochs.

H. Testing

Two test cases have been done. Where accuracy, f1 score, sensitivity, and specificity have been used in evaluation. According to [35,36], accuracy is the number of correctly classified data samples over the total number of data samples.

$$Accuracy = \frac{TP+TN}{TP+FP+FN+TN} \tag{1}$$

An F1 score is a measure of a test's accuracy.

$$F1\ Score = \frac{2TP}{2TP+FP+FN} \tag{2}$$

Sensitivity is the accuracy of a test to properly identify patients with a disease. In other words, it is the number of true positives divided by the number of actual positives.

$$Sensitivity = \frac{TP}{TP+FN} \tag{3}$$

Specificity is the accuracy of a test to properly identify people without the disease. This means that is the number of true negatives divided by all actual negatives. The test is positive if the person has the disease and, therefore, the test is positive. While true negative means the person doesn't have the disease and therefore the test is negative. A false positive is when the person doesn't have the disease and therefore the test is positive. A false negative means the person has the disease and therefore the test is negative.

$$Specificity = \frac{TN}{TN+FP} \tag{4}$$

In Case 1, the results for both developed models, the models with the highest four features and the models with all features, have been recorded in Tables III and IV, respectively. In Table III, the highest four features model has achieved great accuracies especially, for the neural network that was developed only with one hidden layer and 300 epochs. The accuracy recorded was 87.32% against 86.89 for the developed model with all features.

TABLE II. EACH FEATURE ROOT CAUSE VALUE

Feature	Value	Comment
exang	0	Samples without exercise induced angina are much likely to have heart disease. The same result was mentioned in [27].
cp	3	Samples with non-anginal pain are much likely to have heart disease. The same result was mentioned in [28].
oldpeak	[0, 1]	ST depression induced by exercise relative to rest with values from 0 to 1 are much likely to have heart disease.
thalach	[140, 170]	Samples with heart rate value from 140 to 170 are much likely to have heart disease.
ca	0	Number of major vessels equals 0 is much likely to have heart disease.
slope	3	The down sloping samples of the peak exercise ST segment are much likely to have heart disease.
thal	6	Fixed defect thalassemia samples are much likely to have heart disease.
sex	1	Males are much likely to have heart disease which was also mentioned in [29].
age	>= 40	Age grater or equal than 40 years old samples are much likely to have heart disease as mentioned in [30].
trestbps	[140, 200]	Resting blood pressure value from 140 to 200 samples are much likely to have heart disease as mentioned in [31,32].
restecg	1	Resting electrocardiographic of value 1 indicates having ST-T wave abnormality is much likely to have heart disease.
chol	[200, 300]	Serum cholesterol samples value from 200 to 300 are much likely to have heart disease as also mentioned in [33].
fbs	0	Samples with fasting blood sugar less than 120 mg/dl are much likely to have heart disease as mentioned in [34].

TABLE III. MODELS WITH HIGHEST 4 FEATURES COMPARATIVE ANALYSIS

Classifier	Accuracy	F1 Score	Sensitivity	Specificity
LR	85.96	86.21	89.29	82.76
NB	82.46	83.87	92.86	72.41
SVM	84.21	85.25	92.86	75.86
K-NN	80	79.52	84.62	76.09
DT	77.19	77.97	82.14	72.4
RF	82.46	83.33	89.29	75.86
XGBoost	78.95	79.31	82.14	75.86
Neural Network	87.32	86.15	90.32	85.0

In addition, the accuracies of LR, SVM and XGBoost were also greater than the same classifiers accuracies in Table IV. This proves that highest four features (exang, cp, oldpeak, and thalach) really affected the target column. Moreover, the sensitivities of the highest four features model were either higher than (as LR, NB, SVM and XGBoost) or comparable with the sensitivities of all features model. Thus means, the highest four features model greatly classify samples with heart diseases.

In Case 2, the recorded results for machine learning classifiers in the model with the highest four features were comparable to the results of both P. Gupta et al.'s model (with 13 features) [20] and Bharti et al.'s model (with 13 features) [22]. Fig. 3 to 5 illustrates the accuracy, sensitivity, and specificity comparisons respectively. The highest four features model classifiers (LR, SVM, RF and XGBoost) achieved higher accuracies than the same classifiers in Bharti et al.'s model. In consideration, their results were recorded after applying three approaches. Also, KNN, RF and XGBoost accuracies in highest four features were higher than P. Gupta et al.'s model. Moreover, the average accuracy of the highest

four features model recorded 81.6% against 82.15% in P. Gupta et al.'s model and 80.88% in Bharti et al.'s model.

TABLE IV. MODELS WITH ALL (13) FEATURES COMPARATIVE ANALYSIS

Classifier	Accuracy	F1 Score	Sensitivity	Specificity
LR	85.25	86.96	88.23	81.48
NB	83.61	85.71	88.23	77.78
SVM	83.61	85.71	88.23	77.78
K-NN	84.21	86.67	90.69	75.76
DT	82.89	85.06	86.04	78.79
RF	90.16	91.18	91.18	88.89
XGBoost	77.63	80.0	79.07	75.76
Neural Network	86.89	88.0	85.29	88.88

The sensitivities, shown in Fig. 4, of all classifiers in the highest four features model were higher than both the sensitivities in both P. Gupta et al.'s model and in Bharti et al.'s model (except for KNN was 84.64% against 85%). This means that the highest four features model has classified the samples with heart diseases greatly better than both comparable models. While the specificities of P. Gupta et al.'s model classifiers were higher than the highest four features model which mean it has classified samples without heart diseases better.

#### I. Document

All the previous steps have to be documented step by step.

#### J. Deliver

After writing the documentation, it is time to deliver all that has been done to the operations team for being deployed in production.

### K. Consume

In this study, the introduced models were decided to be consumed.

Fig. 3. Accuracy comparative analysis

Fig. 4. Sensitivity comparative analysis

Fig. 5. Specificity comparative analysis

### L. Monitor

In real production, this phase must be done to observe models' behaviors.

### M. Archive/Delete

Choosing to do this phase will be an unicorn decision. In this study all the work has been archived.

## VII. CONCLUSION AND FUTURE WORK

This study proposed a novel DataOps lifecycle along with a detail for each phase that was applied to a healthcare case study. For this case, the UCI Machine Learning Heart Disease dataset has been used which has 13 features in addition to target column. The dataset has been analyzed without

modeling to find the best most effective features. This analysis came up with highest four effective features (exang, cp, oldpeak, and thalach) that affected the target column, indicating that data modeling is not necessary for all data science project which led to dataset reduction. Then, two models, with the same python code, have been developed for this dataset. The first included 13 features. The second one was with only the highest four (exang, cp, oldpeak, and thalach) features after removing duplicates in rows (20 rows). Two comparisons using accuracy, f1score, sensitivity, and specificity have been done.

Case 1 is the results of the developed model with 13 features and the model with only four features. The comparison showed that the highest four feature model produced higher accuracy and sensitivity, especially for neural networks, with 87.32% and 90.32%. Considering that the neural network model has been developed with only one hidden layer and just 300 epochs; also, the average accuracy and sensitivity of the highest four feature model was 82.32% and 87.94%, respectively.

Case 2, The results of machine learning classifiers in the four features model were comparable to both P. Gupta et al.'s model [20] and Bharti et al.'s [22] results. The comparison showed that DataOps gives great impact results when applied to machine learning model(s). The accuracy of classifiers in the highest four features model, with an average of 81.6%, was greater than the accuracy of Bharti et al., with an average of 80.88% and comparable with P. Gupta et al. with an average of 82.15%. The sensitivity of all classifiers in the highest 4 feature model, with an average of 87.6%, was greater than the sensitivity of both P. Gupta et al. with an average of 74.49% and Bharti et al., with an average of 81.24% while the specificities were comparable. In addition to that, Bharti et al.'s research mentioned that CP and thalach features [Fig. 5(c) & (e)] [22] were not important for heart disease unlike the proof from the proposed DataOps lifecycle.

For future work, the proposed DataOps lifecycle may apply to other fields such as the economy, education, or industry aside from applying it to deep learning model(s).

### NOTES

For any additional information or more explanation about either the proposed cycle or the code, feel free to contact co-author.

# Evaluation of e-Service Quality Impacts Customer Satisfaction: One-Gate Integrated Service Application in Indonesian Weather Agency

Aji Prasetyo<sup>1</sup>, Deny Irawan<sup>2</sup>, Dana Indra Sensuse<sup>3</sup>, Sofian Lusa<sup>4</sup>, Prasetyo Adi Wibowo<sup>5</sup>, Alivia Yulfitri<sup>6</sup>  
Faculty of Computer Science, University of Indonesia, Jakarta, Indonesia

**Abstract**—Badan Meteorologi, Klimatologi, dan Geofisika (BMKG) is the weather agency in Indonesia. It has One-Gate Integrated Service Application, also known as *Pelayanan Terpadu Satu Pintu* (PTSP) BMKG Application, which is a web-based e-commerce concept application. Its goal is to provide users with information and services related to Meteorology, Climatology, and Geophysics (MCG) by using information and communication technology. This is part of Indonesia's move toward e-government. Since January 2020, all MCG service and information activities through PTSP BMKG must be done using the application. With a questionnaire and multivariate analysis, this study aims to determine how the quality of service affects customer satisfaction with the PTSP BMKG application. Scientists use the E-S-Qual scale to prove that it works and is a good measure. The results of this study show that customer satisfaction is affected positively and significantly by efficiency, fulfillment, system availability, and privacy simultaneously. Partially, customer satisfaction with the PTSP BMKG application is affected positively and considerably by how well the application works and how well it meets customers' needs. This has implications for the evaluation that BMKG needs to do.

**Keywords**—e-Service quality; one-gate integrated service; e-government; multivariate analysis; Partial Least Square (PLS); Structural Equation Model (SEM)

## I. INTRODUCTION

The advancement of Information and Communication Technology (ICT) has provided convenience in social interaction, including in delivering public goods to the community [1]. The era of globalization, with the development of the ICT field, encourages a new paradigm, namely e-government, which is a reform of the implementation of government that refers to public information disclosure and gives responsibility to the government to provide information about government activities. Information technology is believed to have an essential role in changing the conventional way of doing government work to be more efficient and effective. Information technology is also one of the keys to supporting the implementation of e-government and good governance through increased government transparency and accountability.

Badan Meteorologi, Klimatologi dan Geofisika (BMKG), is tasked with carrying out government duties in meteorology, climatology, and geophysics [2][3]. It has been explained in the Presidential Regulation of the Republic of Indonesia Number 61 of 2008 that the need for data and information in the fields

of meteorology, climatology, and geophysics is necessary not only to support national development but also to protect society and minimize the impact of damage caused by disasters caused by nature. In all elements of the BMKG environment, in performing its duties, the BMKG must apply the principles of coordination, integration, and synchronization within the internal BMKG and in relations between central and regional government agencies [2][3].

The Public Service Act has mandated that every government institution establish an integrated service system formally and legally. Every institution has the right to have the authority to make public policies to provide services and increase participation in empowering society [4].

BMKG One-Gate Integrated Service Application, also known as PTSP BMKG Application is a web-based application intended to provide information and services related to MCG for users by utilizing information and communication technology so that it is hoped that public services can be achieved optimally in the digital transformation towards e-Government. PTSP BMKG application is currently focused on serving requests for data and information to customers, both individuals from the community and companies from Indonesia. Based on information from BMKG employees who participated in the development, this application is designed like a marketplace or e-commerce. e-Commerce refers to business conducted electronically or over the internet. Generally, it refers to individuals who use the internet to either purchase and sell goods or give paid services through payments and data flows [5][6]. In PTSP BMKG Application, Customers can choose the type of data, information, or services they want by entering the shopping cart, paying, and information can be downloaded on the application. The application can be accessed at <https://ptsp.bmkg.go.id/>.

Since January 2020, all MCG service and information activities through PTSP BMKG must be served using the application. Many complaints are related to services and information reported through the PTSP BMKG application. Of course, if not handled, the complaint will have a destructive impact on the government, especially the BMKG. Even worse is that it can generate distrust from users. In addition, based on Community Satisfaction Index Report in 2022 by the BMKG Database Center, the value of the "system" aspect experienced the highest decline. This component has an index value of 3.96 with a percentage of 79.12 percent in 2021, but it only reached a value of 3.81 with 76.29 percent in 2022. This can mean that

public satisfaction with the service system has decreased. Therefore, it is necessary to evaluate public services to direct actions that can positively impact the quality of services provided by the government [7].

Based on information from one of the BMKG Public Relations division employees, BMKG has surveyed customer satisfaction. Still, it has yet to include ICT aspects, especially web applications used by customers to obtain MCG services. Therefore, BMKG itself doesn't know whether there is an influence in terms of web quality on customer satisfaction in using the service.

e-Service Quality is a way to determine how a website can facilitate user activities that include product purchase and delivery transactions efficiently and effectively [8]. There are several measures for evaluating the quality of electronic services in the literature. The E-S-Qual measurement scale developed by Parasuraman et al. (2005) is well regarded and utilized by scientists to validate this scale's effectiveness [9][10][11]. To quantify the quality of electronic services more accurately from an e-commerce standpoint, this method successfully considers the concerns highlighted while maintaining the fundamental principles of E-S-Qual [12]. However, from previous studies [13][14][15], not all dimensions or variables of E-S-Qual can be accepted from hypothesis testing, so in this study, the authors tried to retest the dimensions contained in E-S-Qual for case the PTSP BMKG website as one of the government services, which has the concept of e-commerce. This study also aims to analyze the effect of service quality on customer satisfaction in using the PTSP BMKG application as one of the steps to evaluate BMKG services.

The study was organized into five sections. The first section is an introduction containing the research's background and objectives. The second section is a literature study containing previous research, explanations of fundamental theories, and conceptual framework. The third section describes the research methodology. The results and discussion are described in the fourth section. Finally, our work on this paper is concluded in the last section.

## II. STUDY OF LITERATURE

### A. Previous Research

We construct in this study a theoretical framework based on prior research on the measurement of E-S-Qual. Consider several dependent and independent variables, such as efficiency, fulfillment, system availability, and privacy, as a calculation of customer satisfaction.

Ahmed et al. (2020) used the E-S-Qual model to analyze customer satisfaction, the quality of electronic banking services, and the direct relationship between these two variables. The immediate research results showed that the E-S-Qual dimensions positively and significantly influenced customer satisfaction. The results of the indirect connection showed that customer satisfaction and E-S-Qual dimensions are mediated by perceived value and trust [13].

The E-S-Qual model has been the subject of more studies. The E-S-Qual technique is used by Dastane et al. (2018) to

research service aspects impacting customer satisfaction and loyalty. As a result, although efficiency, system availability, and responsiveness have no direct or indirect influence on customer happiness, fulfillment and security immediately impact it [14].

Research using E-S-Qual is also carried out in the public sector. This was done by Shafira (2021), who used the E-S-Qual methodology to research the quality of E-procurement services in Malaysia. In this study, three variables are E-S-Qual: efficiency, privacy, and system availability. The result is that efficiency, privacy, and system availability impact user satisfaction [15].

Based on these three studies, we need to retest all dimensions of the PTSP BMKG application used by BMKG to serve its users.

### B. E-S-Qual

The functional performance of a service when clients shop, buy and get it via electronic media is known as "e-service quality" [6][9]. In obtaining services and information from BMKG, customers are currently using electronic-based services, so electronic media presently facilitate the interaction between sellers and buyers in the form of sites specifically designed to carry out buying and selling transactions.

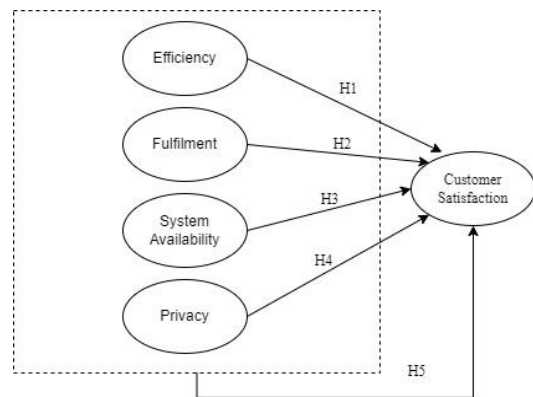

Fig. 1. Conceptual model

Several professionals have created electronic service quality measuring scales in various versions. One is E-S-Qual, which Parasuraman et al. created [9][11]. They argue that pre-existing measurement scale instruments still need to improve assessing the quality of electronic services because measurements cover only some stages in the interaction between users and services. Therefore, they developed two measurement scales, E-S-Qual, and E-RecS-Qual. There are four dimensions of E-S-Qual, including:

- Efficiency: The simplicity and quickness of utilizing the website.
- Fulfillment: How well the website delivers on its claims about order fulfillment and item availability.
- System Availability: the website's proper technical operation.
- Privacy: The website's level of security and privacy protection.

When an issue occurs throughout the service delivery process for customers, the E-RecS-Qual scale is used to gauge the quality of e-services [9]. In this study, the E-Recs-Qual scale was not included because in getting the service, customers can download data and information that has been ordered on the application or directly take it to the BMKG office.

C. Customer Satisfaction

According to Tjiptono, Customer satisfaction is the personal feeling of joy or disappointment generated by comparing perceived product performance (or results) with expected expectations [16]. In this study, we use several indicators of consumer satisfaction consisting of [17][18]:

- Expectation Conformity: Correspondence between consumer expectations and consumer perceptions.
- Returning Interest: Consumer willingness to revisit or reuse related services.
- Willingness to Recommend: Willingness of consumers to recommend recognized services to friends and family.

D. Conceptual Framework

Based on the theory in the literature study, Fig. 1 describes a research model that can be compiled that will be used to test the dimensions or variables of E-S-Qual on the PTSP BMKG application against its customer satisfaction.

From previous research, it is said that dependent and independent variables such as efficiency, fulfillment, system availability, and privacy have a positive effect as a calculation of customer satisfaction [13], so a hypothesis can be compiled in Table I.

TABLE I. HYPOTHESIS

Code	Description
H1	Efficiency positively and significantly affects customer satisfaction using PTSP BMKG Application.
H2	Fulfillment positively and significantly affects customer satisfaction using PTSP BMKG Application.
H3	System availability positively and significantly affects customer satisfaction using PTSP BMKG Application.
H4	Privacy positively and significantly affects customer satisfaction in using PTSP BMKG Application.
H5	Efficiency, Fulfillment, System Availability, and Privacy simultaneously positively and significantly impact Customer Satisfaction using PTSP BMKG Application.

Based on these five hypotheses, a questionnaire can be prepared. Customers of the PTSP BMKG Application will answer that by adjusting operational conditions.

TABLE II. STATEMENT OF QUESTIONNAIRE

Indicators (code)	Statement
Efficiency (X1)	<ol style="list-style-type: none"> <li>1. PTSP BMKG application makes it easy to explore what is needed related to Meteorology, Climatology, and Geophysics services and information [9][11].</li> <li>2. PTSP BMKG application makes it easy to quickly complete service transactions and information on Meteorology, Climatology, and Geophysics [9] [11].</li> <li>3. PTSP BMKG application can load pages quickly [9][11].</li> <li>4. All features in the PTSP BMKG application are well organized [9][11].</li> <li>5. The information in the PTSP BMKG application is well organized [9][11].</li> </ol>
Fulfillment (X2)	<ol style="list-style-type: none"> <li>1. PTSP BMKG application provides services according to what you need [9][11].</li> <li>2. PTSP BMKG application following the public service offer (completed within 14 working days) [9][11].</li> <li>3. PTSP BMKG application responds quickly to requests for services and information [9][11].</li> </ol>
System Availability (X3)	<ol style="list-style-type: none"> <li>1. PTSP BMKG application is always available when the user needs it [9][11].</li> <li>2. PTSP BMKG application rarely experiences errors [9][11].</li> </ol>
Privacy (X4)	<ol style="list-style-type: none"> <li>1. PTSP BMKG application doesn't disseminate customer personal information to other parties [9][11].</li> <li>2. PTSP BMKG application protects the personal information of its users [9][11].</li> </ol>
Customer Satisfaction (Y1)	<ol style="list-style-type: none"> <li>1. Customers are satisfied with the service of the PTSP BMKG application because the application service is in line with expectations. [17][18]</li> <li>2. Customers are satisfied with the PTSP BMKG application service, so they are interested in reusing it. [17][18]</li> <li>3. Customers are satisfied with PTSP BMKG application service to say positive things about the application to others [17][18]</li> </ol>

III. METHODOLOGY

This research is a quantitative study using primary data obtained from questionnaires. In Table II, the questionnaire is prepared based on the variables E-S-Qual and customer satisfaction. In each variable, statements are mapped based on the dimensions and indicators of each variable. The compiled questionnaire will be distributed to customers BMKG One-Gate Integrated Service Application. The stages of the study can be seen on the Fig. 2.

Fig. 2. The stages of study

### A. Data Collection

Data collection is carried out at BMKG by providing an online questionnaire that customers of the PTSP BMKG Application can fill out. The requirement to fill out the questionnaire is that the customer has transacted using the PTSP BMKG application. The population of this study is customers who have been registered and have used the PTSP BMKG application to obtain data and information from BMKG. However, in this study, using sampling, the number of respondents in this study was 72 respondents. A total of 85 respondents were distributed online questionnaires using email by attaching a google form link, assisted by the admin of the PTSP BMKG application; 13 customers did not fill out the questionnaire. The respondent's demographic profile of the data collection can be seen in Table III.

TABLE III. RESPONDENT'S DEMOGRAPHIC PROFILE

Items	Categories	Percentage
Gender	Male	68
	Female	32
Educational Background	High School	13
	The diploma I/ diploma III	7
	Bachelor's Degree	69
	Master's degree	11
Profession	Civil servant	17
	Private Employee	58
	Students	15
	Entrepreneur	4
	Others	6

The research questionnaire consists of several questions based on the E-S-Qual model and consumer satisfaction indicators. All items are measured using a Likert scale. The Likert scale was modified to clear doubts in respondents using a scale of four, including strongly agree, agree, disagree, and strongly disagree.

### B. Analysis

After collecting the questionnaire data, the next step is to process and analyze the data. The data obtained were processed using the *Smart PLS 4* application to test hypotheses and relationships between variables. This study uses a multivariate analysis method by testing the outer and inner models on PLS-SEM. A technique frequently used to process various variables is multivariate analysis [19]. The objective is to simultaneously look for these different variables' effects on an object. According to Hair et al. (2017b), by employing the PLS-SEM model, one can get beyond some of the drawbacks of covariance-based SEM, including data dispersion, limited sample sizes, complex models with numerous indicators, and model construction and testing [19] so that the results of the analysis can be used as the basis for evaluating e-service quality.

## IV. RESULTS AND DISCUSSION

### A. Assessing Reflective Measurement Models

According to Hair et al. [20], there are four stages in reflective measurement models: delivered *reflective indicator loadings, internal consistency, convergent validity, and discriminant validity*.

TABLE IV. OUTER LOADINGS

Code	Outer Loading	Code	Outer Loading	Code	Outer Loading
X1-1	0.822	X2-1	0.805	X4-1	0.902
X1-2	0.746	X2-2	0.784	X4-2	0.937
X1-3	0.793	X2-3	0.909	Y1-1	0.936
X1-4	0.872	X3-1	0.946	Y1-2	0.922
X1-5	0.855	X3-2	0.839	Y1-3	0.860

Based on Table IV, all outer loading on each indicator has a value above 0.708. More than half of the indicator's variability can be accounted for by the construct, which also ensures a sufficient level of dependability [20]. All indicators can proceed to the next stage.

Internal consistency reliability is the extent to which indicators measuring the same structure are related [19]. When evaluating internal consistency reliability, Joreskog's (1971) composite reliability should almost always be used [21][20]. The range of reliability values from 0.6 to 0.7 is considered "acceptable in research exploration," but the range of reliability values from 0.7 to 0.9 is classified as "satisfactory to good." However, results that are either equal to or higher than 0.95 are unsatisfactory because it is considered that these values are excessive, which can reduce the validity of the construct. Based on Table V, the composite reliability value on the fulfillment construct is the lowest, with a value of 0.873, and the highest in the system availability construct, with a value of 0.933. Therefore, all the construct validity is well accepted and satisfactory.

TABLE V. CONSTRUCT RELIABILITY AND VALIDITY

Indicators	Cronbach's alpha	Composite reliability	The average variance extracted (AVE)
Customer Satisfaction	0.891	0.933	0.822
Efficiency	0.877	0.910	0.671
Fulfillment	0.780	0.873	0.697
System Availability	0.763	0.888	0.799
Privacy	0.819	0.916	0.846

Convergent validity means a set of indicators explained by the construct. Representations can be demonstrated through one-dimensionality that can be expressed using Average Variance Extracted (AVE) values. An adequate convergent validity is defined as a construct's ability to account for more than 50 percent of the variance among its indicators [9][22]. In Table V, the AVE values for all variables are greater than 0.5; therefore, it can be concluded that all the indicators developed for this study demonstrate strong convergent validity [23].

Researchers employ discriminant validity to ensure that each construct's ideas are distinct. The purpose of validity testing is to determine how precisely a measuring instrument performs its measurement function [24]—calculating the discriminant validity of this study using the heterotrait-monotrait (HTMT) ratio. To evaluate the validity of the discriminants, Henseler, Ringle, and Sarstedt (2015) propose an alternative method based on the multitrait-multimethod matrix: HTMT [25][26]. Structural models with similar constructs should have a threshold value of 0.90 [20]. Based on Table VI, all indicators have a value of < 0.90; it can be interpreted that the matter is reasonable to describe the discriminant validity of each indicator used in this study.

TABLE VI. HETERO TRAIT-MONOTRAIT RATIO OF CORRELATIONS (HTMT)

Indicator	Y1	X1	X2	X4	X3
Y1					
X1	0.783				
X2	0.880	0.898			
X4	0.504	0.585	0.543		
X3	0.540	0.671	0.703	0.571	

**B. Assessing Structural Model**

The structural model should be checked for collinearity first, as stated by Hair et al. (2017). Examine the structural model's VIF values for each predictor construct [27]. In this study, no collinearity problems were found, which can be seen in Table VII. Collinearity values are still between 0.5 and 3.0. This follows what Cenfetelli & Bassellier (2009) said: It is possible to examine the VIF value, and if it is less than 3.0, multicollinearity is probably not a concern [28]. Testing bivariate correlations between construct scores is an alternate strategy. When the bivariate correlation is greater than 0.50, multicollinearity may impact the path coefficient's magnitude and/or direction [27].

TABLE VII. VIF VALUE

Indicators	Customer Satisfaction
Efficiency	2.572
Fulfillment	2.361
Privacy	1.374
System Availability	1.691

The next step is the significance and relevance of the path coefficients [17][22]. The results of the coefficient path test for direct effect can be seen in Fig. 3. The route coefficients are standardized numbers with a possible range of +1 to -1; however, they only sometimes get close to +1 or -1. This is especially true for large models with many separate structural elements [22]. This study found that efficiency, fulfillment, and system availability have a positive relationship with customer satisfaction, while system availability has a negative association with customer availability.

The following assessment recommended is multiple regression models or the coefficient of determination [27][22]. The coefficient of determination quantifies all endogenous constructions' in-sample prediction accuracy. Because the prediction only estimates the predictive power for the sample data used in the findings, R<sup>2</sup> should not be generalized to the population (Rigdon, 2012; Sarstedt et al., 2014) [22]. The results of the R<sup>2</sup> test showed a value of 59.6%. This can mean that 59.6% of customer satisfaction is due to efficiency, fulfillment, system availability, and privacy.

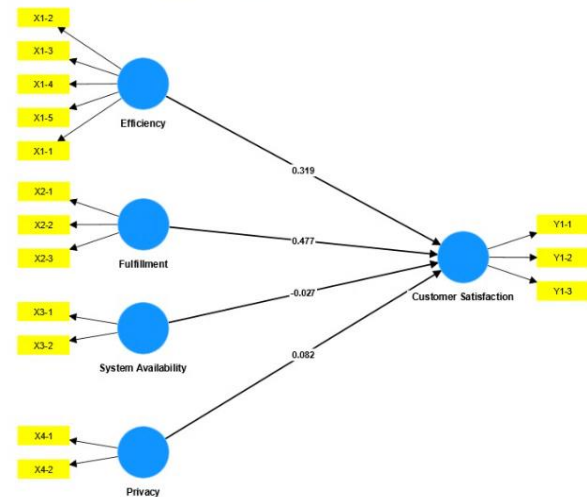

Fig. 3. Path coefficient

**C. Hypothesis Testing**

The first for hypothesis testing is the assessment of the T-statistics or P-value. The result can be seen in the table for the T-statistics is more than 1.96 ( $\alpha = 0,05$ ) [19] and for P-value less than 0.05 [20]. Based on the T-statistics and P-value in Table VIII, the first hypothesis (H1) is accepted since the score of the T-statistics is 2.086, more than 1.96, and the score of P-value is 0.019, less than 0.05. So that the first hypothesis, Efficiency positively and significantly affects customer satisfaction using the PTSP BMKG Application, is acceptable. Where Efficiency positively and significantly affects customer satisfaction is 31.9%. The effect of efficiency is 31,9% based on a value in the original sample.

The second hypothesis (H2) is validated by the T-statistics shown in Table VIII because the T-statistics score is 3,181, which is more than 1.96, and the P-value is 0.001, which is less than 0.05. So that the second hypothesis is that Fulfillment positively and significantly affects customer satisfaction using PTSP BMKG Application. The second hypothesis is

acceptable. Where Fulfillment positively and significantly affects customer satisfaction is 47.7%. The effect of Fulfillment is 47.7% based on a value in the original sample.

The T-statistics reject the third hypothesis (H3) in Table VIII because its score is 0,211, less than 1.96, and its P-value is 0.416, which is more than 0.05. So, system availability positively and significantly affects customer satisfaction using the PTSP BMKG Application is rejected. Based on the t-statistics, p-value, and original sample, System availability to customer satisfaction is negative and does not significantly affect customer satisfaction.

The fourth hypothesis (H4) is shown to be rejected by the T-statistics in Table VIII because the T-statistics score is 0.767, less than 1.96, and the P-value score is 0.222, more than 0.05. So, privacy positively and significantly affects customer satisfaction in using the PTSP BMKG Application is rejected. Based on the t-statistics, p-value, and original sample, privacy positively impacts customer satisfaction but does not significantly affect customer satisfaction.

TABLE VIII. ORIGINAL SAMPLE, T-STATISTICS, P-VALUES

Code	Original Sample	T-statistics	P-values	Conclusion
H1	0.319	2.082	0.019	Accepted
H2	0.477	3.181	0.001	Accepted
H3	-0.027	0.211	0.416	Rejected
H4	0.082	0.767	0.222	Rejected

To test the fifth hypothesis, we use simultaneous F testing. Simultaneous F tests are intended to find whether concurrently independent variables (simultaneously) impact dependent variables. The F test was performed to prove the impact of all free variables simultaneously on bound variables [24]. The test results found that the F value was 24.9 or greater than the F table, which were 2.51. This follows the fifth hypothesis (H5) that Efficiency, Fulfillment, System Availability, and Privacy simultaneously positively and significantly impact Customer Satisfaction using the PTSP BMKG application. Hence, the results of the fifth hypothesis are acceptable.

TABLE IX. F-SQUARE

Direct Relationship	F-Square	Impact
Efficiency → Customer Satisfaction	0.098	Small
Fulfillment → Customer Satisfaction	0.238	Medium
Privacy → Customer Satisfaction	0.012	-
System Availability → Customer Satisfaction	0.001	-

In this study, the F-square value is used to measure the extent to which several aspects of the PTSP BMKG application, including efficiency, fulfillment, privacy, and system availability, influence customer satisfaction. According to Hair et al. [29], if the value of f-square is more significant than or equal to 0.02 but is less than 0.15, then the effect has a minor influence and falls into the category of "small.". If the f-square value is greater than or equal to 0.15 and less than 0.35,

it belongs to the medium impact category. If the value of f-square is greater than or equal to 0.35, then it belongs to the category of a significant impact. Based on Table IX, the efficiency indicator has an f-square of 0.098, meaning that the efficiency indicator has a negligible effect on customer satisfaction using the PTSP BMKG application. At the same time, the fulfillment indicator has an f-square of 0.238. This can mean that the fulfillment indicator moderately impacts customer satisfaction using the application. The privacy and system availability indicators have a very small f-square value, so the two indicators have no impact on customer satisfaction using the PTSP BMKG application.

#### D. Implication of Study

This study has various implications for problems relating to the e-service practice paradigm, which affects consumer satisfaction in government apps utilized for public services, especially in the PTSP BMKG application, which is one of the BMKG services. BMKG needs to improve the quality of its application so that users can be more satisfied in obtaining services and information through PTSP, including in the dimension of efficiency, which focuses on ease of transactions, web speed, features, and information that is better laid out. Not only that, but the most crucial focus to be noticed and improved by BMKG is on the fulfillment dimension, where the speed of response to customer requests and submissions to get services is at most 14 working days.

This research can be used as a reference that demonstrates that E-S-Qual has developed into an efficient scale in government services with a concept like e-commerce, in which a website can help users with their activities, such as product purchases, and obtain transactions efficiently and effectively. Based on the theory explained by Parasuraman et al. (2005), efficiency and fulfillment are the most critical aspects of the quality of website services [6]. This is in line with the results of this study that these two dimensions have an impact on customer satisfaction in using applications to obtain data and information services from BMKG. The efficiency indicator itself is related to the design of the web application interface used by customers to get the information needed. Fulfillment indicators related to how all customer needs can be available and met quickly, as stated on the PTSP BMKG web application. Customers PTSP will feel more satisfied if the service can be obtained on time or faster than the promised time.

Wolfenbarger and Gilly (2003) claim that consumers who often use online applications to transact may not find privacy to be as crucial as they formerly did since experience may diminish worries about website security [30][9][14]. This is also in line with the results of this study that privacy does not significantly influence customer satisfaction who have transacted through the PTSP BMKG web application in obtaining data and information services from BMKG. Even so, BMKG must still maintain customer privacy, which has been regulated by the government so as not to cause leakage of customer data using the PTSP BMKG application.

The system availability aspect is an essential attribute in measuring overall customer satisfaction. However, BMKG does not fully control this dimension because the device and

internet used can affect this dimension [9]. System availability does not affect customer satisfaction with the PTSP BMKG application. It could be because customers using the application are fine with this dimension. It could also be due to the number of respondents, as said by Dastane et al. (2018) [14]. Even so, BMKG must still inform customers when the website is being maintained. BMKG must think of the right time to maintain the website PTSP BMKG so customers are not bothered when they want to use the application.

## V. CONCLUSION

BMKG Indonesia has changed how it serves the community conventionally to be more efficient and effective since 2020 by presenting the PTSP BMKG application. To improve service quality in obtaining customer satisfaction, it is necessary to evaluate the PTSP BMKG application. The research made use of the E-S-Qual instrument. Considering the outcomes of data analysis from 72 respondents of application users that have been carried out in this study, it can be concluded that the results of statistical calculations show Efficiency, Fulfillment, System Availability, and Privacy simultaneously has a positive and significant impact on customer satisfaction using the PTSP BMKG application.

But partially, we can conclude that the ease of users in searching to find what services and information are needed, the ease of completing transactions, the speed of loading web pages, and the features and availability of information that is better organized on the PTSP BMKG application have an impact on customer satisfaction in using the application. This is shown in the results of the H1 hypothesis test received, where efficiency positively and significantly affects customer satisfaction in using the PTSP BMKG application, so BMKG must be concerned about efficiency indicators so that customers can be more satisfied with the MCG data and information services obtained from the PTSP BMKG Application.

Moreover, the suitability of MCG's service and information needs and the speed of response to requests and submissions to obtain services and information will have a moderate impact on customer satisfaction in using the application. This is shown in the results of the H2 hypothesis test received, where fulfillment positively and significantly affects customer satisfaction in using the PTSP BMKG application. Customers will be happier if the service is provided on time or earlier than promised. Hence, BMKG needs to evaluate fulfillment indicators to be able to increase customer satisfaction with the PTSP BMKG application.

### A. Limitation of Study

This paper is focused on PTSP BMKG Application, which serves customers to get services and information from BMKG. This study only used E-S-Qual without involving E-Recs-Qual indicators in analyzing service quality's impact on customer satisfaction in using the PTSP BMKG application through a questionnaire survey of very limited respondents.

### B. Future Works

Furthermore, research can be continued by analyzing the usability aspect to determine the user experience to improve

PTSP BMKG Application services. In addition, further analysis can also be carried out to find out why this E-S-Qual model does not all dimensions have a positive relationship with customer satisfaction, especially in government services.

## ACKNOWLEDGMENT

Thanks to the PTSP Team and BMKG Indonesia, who have supported and assisted in this research. The Indonesian Ministry of Communication and Informatics Scholarship funds this study. Also, support from the Faculty of Computer Science, University of Indonesia.

# Investigating the Input Validation Vulnerabilities in C Programs

## Input Validation in C

Shouki A. Ebad

Department of Computer Science  
Faculty of Science, Northern Border University  
Arar, Saudi Arabia

**Abstract**—Input validation is a fairly universal programming practice that helps reduce the chances of producing protection-related vulnerabilities in software. In this paper, an experiment is conducted to specifically determine the input validation issues found in programs and the problematic functions that lead to such issues. The experiment evaluated 12 arbitrarily selected open source C projects written by different programmers. The top two most common input validation problems are buffer overflow/XSS and potential memory mismanagement. In addition, the functions that caused the first problem are: (a) strings/text functions (e.g., `strcpy` and `strcmp`), and (b) functions that read from standard input, `STDIN` (e.g., `scanf` and `gets`). In contrast, the functions that caused the second problem are (a) memory allocation/deallocation functions (e.g., `fopen` and `fseek`). Furthermore, the `goto` construct—to a small extent—plays a role. The recommendations are that (a) developers are encouraged to use memory-safe programming languages, otherwise, they should perform different types of checks for the validity of inputs as soon as they are entered, and (b) they should have the required knowledge of secure source code and use tools/suites to manage malformed strings.

**Keywords**—Input validation; buffer overflow; memory mismanagement; safe C functions

### I. INTRODUCTION

Input validation is accepted as good programming practice when writing reliable software. This practice is fairly universal and helps reduce the chances of introducing protection-related vulnerabilities in delivered software [1][2]. This practice can be applied regardless of the programming language (PL) used in development, although the way it is used depends on the specific PL and notations that are used for software development. Every software takes input from its environment and processes it. The specification of such an input makes assumptions about this input that reflects its real-world use. For instance, it may be supposed that an employee ID is always a 10-digit positive integer. However, the software specification does not determine the steps that should be taken in case of wrong input. The user often makes mistakes and sometimes enters the data incorrectly. Regardless of the type of source of unexpected inputs (human, IoT devices, sensors,

the system itself<sup>1</sup>, or other systems), the software can behave in an unanticipated way and provide incorrect values. Such inputs may lead to many security issues. One of these is memory error exploitation, which still ranks among the top three most dangerous software vulnerabilities [1][3].

Buffer overflow and SQL injection are two examples of memory and string-based attacks. The former may be executed using long input strings, and the latter may be performed when a user enters a piece of SQL that is interpreted by a server [4]. The decision that one makes if any validation check fails relies on the software type being developed. For example, while reporting the issue and requesting to re-input the value may be enough in a business application, the input value might have to be estimated according to previous data in a real-time system that should be operated continuously. In contrast, if the source of the input value is a sensor, the most recent valid value could be enough to use. The paper is structured as follows. Section II reviews the existing literature. The research approach is stated in Section III. In Section IV, the results are analyzed and discussed. Section V discusses threats to the study's validity. Finally, Section VI summarizes the article and presents plans for future work.

### II. RELATED WORK

Scholte et al. [4] proposed a technique to prevent the exploitation of cross-site scripting (XSS) and SQL injection vulnerabilities based on the automated data type detection of input parameters. They implemented the technique for PHP and validated it on five web applications with known XSS and SQL injection vulnerabilities. Their technique prevented 83% of SQL injection vulnerabilities and 65% of XSS vulnerabilities while incurring no developer burden. Veen et al. [3] presented memory errors and considered attacks, defenses, and statistics. During a short period in the 70s, they discussed buffer overflows and established CERTs, Bugtraq, and various important methods and countermeasures. A set of related research areas is also explored. Tirronen [6] proposed a technique to eliminate SQL injection attacks by enabling web applications to work with abstract syntax trees while ensuring uniform interpretation of the result. The method involved moving away from processing data as strings to implement a

<sup>1</sup> For configuration, a mobile app can directly read the inputs from itself [5]

non-trivial XSS-protected application with the method in a limited resource. Braz et al. [2] designed an online survey involving 146 participants to understand the extent to which programmers can(not) discover improper input validation vulnerabilities. The participants were assigned to changes with one of two vulnerabilities: (a) SQL injection, and (b) improper validation of specified quantity input. Only 45% of the participants found the vulnerability. There was a lack of knowledge and practices to detect vulnerabilities when an attack scenario is not visible.

Rodríguez et al. [7] analyzed over 50 documents to gather information on the techniques and tools that were used to discover XSS attacks. Their results showed that the trend was increasing in the analysis of content and patterns and decreasing in the use of artificial intelligence to reduce such attacks. Zhao et al. [5] demonstrated an important application of input validation, exposing input-triggered secrets such as backdoors and blacklists of unwanted items. They proposed a tool to find both the execution context of user input validation and the content involved in the validation to expose hidden functionality. The tool was tested with many mobile apps and it was found that they contained more than 12,000 and 4,000 backdoor secrets and blacklist secrets, respectively. Pereira et al. [8] studied a number of buffer overflow vulnerabilities in the Linux kernel, Mozilla, and Xen open-source C/C++ projects to analyze possible methods of improving their detection. The results showed that most of the vulnerable source code units were with defects in checking and dealing with input data types. Static analysis tools lack rules to detect missing or incorrect checking logic vulnerabilities. Moreover, there is no causality between buffer overflow existence and the value of software metrics. Khalaf et al. [9] explored detecting/removing bugs from client-side and server-side code using an input validation mechanism. They supported tests using easy-to-use and accurate models. A program statement that was vulnerable in SQL injection was checked according to static attributes. They also presented a script whitelisting built into the browser's JavaScript engine, where the SQL injection was detected and the XSS attack resolved using that mechanism.

In conclusion, in contrast to the existing literature, this study tries to identify the most common security issues related to input validation and the functions that are the source of such issues. This will help programmers and developers to give more attention to such functions.

### III. EXPERIMENTAL APPROACH

An experiment was performed to understand how well C programs follow input validation practices. The details of the experiment are discussed in the following subsections.

#### A. Research Questions (RQs)

The following RQs are investigated:

RQ1: What are the most common input validation vulnerabilities at source code level?

RQ2: Which functions are the source of the majority of the above input validation vulnerabilities?

#### B. Subjects and Variables

As a representative of software source code, C programs are used; they are collected from the GitHub repository<sup>2</sup>. C is still one of the most common PLs in the market [10]. A controlled experiment is conducted where the subjects of the experiment are 12 open source software (OSS) programs written in C; the subjects are arbitrarily selected. The software developer of the subjects is a factor that could have an impact on the results because individual developers could use the same input validation practices for all of their programs. Therefore, we control this variable by selecting software programs that were designed and developed by different people.

#### C. Data Source and Tools

In order to evaluate the RQs, the data source in our analysis is restricted to the C PL, since (1) it is widely used, and (2) it provides input validation functions or constructs. Additionally, the experiment can be performed without any confounding factors introduced by different PLs. By restricting to just one PL, the results can be placed in context, and we can have more confidence in the conclusions. Table I describes the data source used for this experiment. There is a diversity in domains: education, business, management, tourism, and health. The differences among experimental subjects (i.e., C programs) were not substantial. The well-known metric of non-commented lines of code (LOC) was used to measure the program size. The mean size is 728.2 LOC, indicating the programs are small and medium-sized.

Visual Code Grepper (VCG) was used to collect the input validation violations of C programs. VCG is a source code security tool (available on the web<sup>3</sup>) to handle different programs, including those written in C. The statistical data were analyzed using Microsoft Excel 2016.

## IV. RESULTS AND DISCUSSION

Table II shows the memory-related input validation issues that were discovered by VCG. According to Table II, the top two most common input validation vulnerabilities are potential memory mismanagement and buffer overflow. Before going into the main results in depth, we should first note that the reader is supposed to be familiar with memory and string functions in C. Interested readers can refer to any C textbook for more information.

<b>Mean</b>	30.3	1.2	0.8	0.6	0.4	0.7	33.9

### A. Potential Memory Mismanagement

This problem includes a variety of memory-related errors such as memory leaks, using memory inefficiently, invalid deallocation, double frees, heap corruption<sup>4</sup>, memory

<sup>4</sup> Memory leaks result from memory that is allocated but never freed. Using memory inefficiently happens when a program allocates memory and fails to use it for a long time. It doesn't constitute a memory leak, but can waste a significant amount of memory.

overhead, and file-access violation [3]. The reader is assumed to be familiar with such type of errors; interested readers can consult [3] for more information. Table III shows a sample of lines of code and functions that caused the memory mismanagement problems in C programs. From Table III, the functions and constructs that caused this problem can be divided into three groups:

- Memory allocation/deallocation functions such as memmove, malloc, free, new, and

delete.

- File manipulation functions such as `fopen`, `fprint`, and `fseek`.
- The `Goto` construct.

As a feature in C, the above C programs offered control on memory usage by allowing the optimization of memory allocation for their resources. However, this makes the developers responsible for tracking any memory that their programs dynamically allocate/deallocate. Otherwise, memory-related input validation problems will be introduced as in most cases in Table IV. Some of the above experiment subjects (e.g., CP12) accessed memory via pointers, which produced a memory access error. Use of `goto` should be minimized as much as possible; programmers have been urged to abandon the `goto` statement for more than 50 years on the advice of Dijkstra [11]. Despite this, it is still very much used in C projects [12]. Fig. 1 shows a sample of CP2's source code that uses `goto` in such a case. Use of `goto` came from the fact that C is a non-memory-safe PL in the input validation principle. In particular, it does not have explicit error handling and cleanup constructs like `try/catch` (for exceptions and errors handling) and `finally` (for cleanup activity) in Java; the programmers must therefore resort to using `goto` statements. Most of the current C projects that used `goto` are for these two purposes [12].

In general, tracking memory is not simple—even programs written by skilled programmers contain such problems. The issue originates when an unallocated area is corrupted, and a fatal error often happens in the coming allocation request. Besides the use of `goto` in not handling exceptions and input errors [12], there are three main causes of potential memory mismanagement problems [8].

- Passing a wrong parameter to an allocation function such as `malloc()` and `realloc()`.
- Passing invalid data to a deallocation function such as `free()` and `delete()`.
- Writing before/after the start/end of the allocated space, causing an underrun/overrun error.

### B. Buffer Overflow/XSS

Buffer overflow is a form of memory mismanagement problem. It happens when code goes beyond the portion of data assigned to a buffer. In particular, code with a limited-size buffer accepts unlimited length input. In such a case, the program can crash or malicious code can be executed. In recent years, this issue has grown rapidly with web applications; it is known as XSS attacks, which allow an attacker to insert client-side scripts into web pages that the victim can access; it is also known as internet buffer overflow [9]. As mentioned earlier, writing data to memory beyond a buffer occurs with non-memory-safe PLs like C and C++ that have no bounds checking. Table V shows a sample of lines of code and functions that cause the buffer overflow problem in C programs.

From Table IV, several C functions are known to be unsafe and the source of the vast majority of buffer overflow attacks. They can be divided into two groups:

- Functions to read from STDIN (standard input) such as `scanf()`, `fscanf()`, `sscanf()` and `gets()` where inputs are taken from the keyboard or file.
- Functions to manipulate strings/texts such as `strcpy()`, `strcmp()`, `strlen()`, and `strtok()`.

The advice herein is that C programmers should never use these functions. Fortunately, there are safer alternatives to such unsafe functions. The safer alternatives to `strcpy()` and `strcmp()`, for example, are `strncpy()` and `strncmp()`, respectively. However, the safer functions are not completely safe because `strncpy()` was a cause for buffer overflow in CP1 in Table V. This finding has been confirmed by previous researchers [8]. In particular, the unsafe `strcpy()` takes two arguments—destination and source—and the function copies the source, including the NULL character, to the destination. Contrary to this, the safe `strncpy()` function takes the same two arguments as well as `n`, an unsigned integral type; the function copies the first `n` characters of source to destination i.e., at most, `n` bytes of the source are copied. If there is no NULL character in the first `n` characters of source, the string placed in the destination will not be NULL-terminated. Therefore, there is no guarantee that the destination will be NULL-terminated i.e., a non-terminated string in C is waiting to destroy the program. The question is why such functions were then built in C? The answer comes from C's history; those functions were particularly designed to address specific problems in manipulating strings stored in the manner of original UNIX directory entries, which use a short limited-size array of 14 bytes, and a NULL-terminator was only used when the filename was less than the array.

### C. Timely Recommendations

Although this problem has been known for decades, it is still found in C/C++ software, as has been seen in this study. Any application must not be vulnerable to input validation-based attacks. Therefore there are three timely recommendations herein:

- Use memory-safe PLs. Developers should try not to use non-memory-safe PLs that fail to validate inputs; such a failing can not only lead to buffer overflow attacks (due to long input) but also DoS attacks (due to low memory). In contrast, safe PLs can address these challenges because they check, at runtime, that any access to the memory is within the declared bounds; they remove most buffer overflows at source.
- Perform input validation checks. The first recommendation would not always be a good choice due to the trade-off between performance and security. With memory-safe PLs, there is a necessary performance penalty for this validation, and, for that reason, much code will continue to be written in C. In such a case, the validity of the input should be checked

as soon as it is read. This check includes the specification of the format and structure of the expected inputs, especially considering there are different sources for input, as mentioned in Section 1. Input validation then relies on different checks; used in input checks when the software is implemented, four types of checks [1][5] are shown in Table V.

- Undergo training in writing secure code: The findings have indicated a lack of knowledge and practices to find vulnerabilities. This finding has also been confirmed by a recent study [8] that showed that most buffer overflow vulnerabilities are associated with missing checks (e.g., missing if construct around a statement) or incorrect checking (e.g., the wrong

logical expression used as a branch condition). Regardless of the PLs used in coding, developers should have the required knowledge, training, and practices of secure source code.

- Use appropriate security tools: they should also use static and dynamic analysis security tools that include the use of suites of prebuilt attacks and malformed strings that can quickly discover and eliminate different software vulnerabilities [13]. Examples of such tools that can help developers in this regard include Clang-Tidy, FlawFinder, and Loggly by SolarWinds, which focus on insufficient input validation, XNU memory, and log file analysis and SQL injection, respectively [14].

TABLE III. MAIN ERRORS OF POTENTIAL MEMORY MISMANAGEMENT REPORTED BY VCG TOOL

Subject no.	Problematic statement	Problematic function	Error description
CP1	<code>memmove(ptr, ptr + 1, --len);</code>	<code>memmove</code> <code>malloc</code>	Unrestricted memory copy function. Can facilitate buffer overflow conditions and other memory mismanagement situations.
CP2	<code>goto account_no;</code>	<code>goto</code>	Use of the <code>goto</code> construct. The <code>goto</code> construct can result in unstructured code that is difficult to maintain and can result in failures to initialize or de-allocate memory.
CP3	<code>file2 = fopen("tempfile.txt", "rb");</code>	<code>fopen</code>	Unsafe temporary file allocation. The application appears to build a temporary file with a static, hard-coded name. This causes security issues in the form of a classic race condition (an attacker creates a file with the same name shared between the application's creation and attempted usage) or a symbolic link attack where an attacker creates a symbolic link at the temporary file location.
CP4	<code>rewind(fp);</code>	<code>rewind</code> <code>fopen</code>	The <code>rewind</code> function is considered unsafe and obsolete. Using <code>rewind</code> makes it impossible to determine if the file position indicator was set back to the beginning of the file, potentially resulting in improper control flow. <code>fseek</code> is considered a safer alternative.
CP5, 6, & 11	Buffer overflow (See the next section)		
CP7	<code>fmeds=fopen("Medicines.txt", "r");</code>	<code>fopen</code>	Function used to open a file. Carry out a manual check to ensure that the user cannot modify filename for malicious purposes and that the file is not 'opened' more than once simultaneously.
CP8	<code>new_node = (struct node *)malloc(sizeof(struct node));</code>	<code>malloc</code> <code>fopen</code>	Potential memory mismanagement. Variable name: <code>new_node</code> <code>malloc</code> without free.
CP9	<code>ft=fopen("temp", "wb+");</code>	<code>fopen</code>	Unsafe temporary file allocation. The application appears to build a temporary file with a static, hard-coded name. This causes security issues in the form of a classic race condition (an attacker creates a file with the same name shared between the application's creation and attempted usage) or a symbolic link attack where an attacker creates a symbolic link at the temporary file location.
CP10	<code>rewind(fp);</code>	<code>rRewind</code> <code>fopen</code>	The <code>rewind</code> function is considered unsafe and obsolete. Using <code>rewind</code> makes it impossible to determine if the file position indicator was set back to the beginning of the file, potentially resulting in improper control flow. <code>fseek</code> is considered a safer alternative.
CP12	<code>layout-&gt;keysyms = realloc(layout-&gt;keysyms, sizeof(keysyms) * (i + 1));</code>	<code>realloc</code> <code>malloc</code>	Potential memory leak. On failure, the <code>realloc</code> function returns a NULL pointer but leaves memory allocated. The code should be modified to free the memory if NULL is returned. Dangerous use of <code>realloc</code> : the source and destination buffers are the same. A failure to resize the buffer will set the pointer to NULL, possibly causing unpredictable behavior.

```

add_invalid:
    printf("\n\n\n\t\tEnter 1 to go to the main menu and 0 to exit:");
    scanf("%d",&main_exit);
    system("cls");
    if (main_exit==1)
        menu();
    else if(main_exit==0)
        close();
    else
    {
        printf("\nInvalid!\a");
        goto add_invalid;
    }

```

TABLE IV. MAIN ERRORS OF BUFFER OVERFLOW REPORTED BY VCG TOOL

Subject no.	Problematic LOC	Problematic function	Error description
CP1	strcpy(dp->host, "localhost", MAXSBUF);	strcpy scanf memmove gets strcpy	The function appears in Microsoft's banned function list. Can facilitate buffer overflow conditions. While "safer", the current "n" functions include non-null termination of overflowed buffers and no error returns on overflow.
CP2	scanf("%d/%d/%d",&add.deposit.month,&add.deposit.day,&add.deposit.year);	scanf fscanf	The function directs user defined input to a buffer and so can facilitate buffer overflows.
CP3	strcpy(item.product_code, code);	scanf strcpy	As CP1
CP4	scanf("%d",&i);	scanf gets	As CP2
CP5	scanf("%d",&c);	scanf	
CP6	scanf("%d",&choice);	scanf strcpy	
CP7	gets(c1.name);	gets scanf	
CP8	scanf("%f", &new_node-> university_current_result);	gets scanf	
CP9	scanf("%ld",&p.mble_no);	scanf	
CP10	gets(e.duration);	gets scanf	
CP11	scanf("%d",&a);	scanf	
CP12	#define strtok_r(line, delim, pointer) strtok(line, delim	strtok scanf strcpy	

TABLE V. CHECK TYPES FOR INPUT VALIDATION

#	Check type	Description
1	Range checks	Inputs may be within a particular range. For example, any ratio should be between 0.0 and 1.0; the grade of student should be within the range 0 to 100, the date should be legal (e.g., not February 31st), and so on.
2	Size checks	Inputs are expected to be a given number of characters or upper limit. For instance, an employee ID should be represented with 10 integers, no name with more than 40 characters including family name, no address with more than 100 characters, and so on.
3	Format checks	Inputs may be of specific types; if a number is expected, no alphabetic characters should be allowed. For example, email address should include @ sign, the person's name must be alphabetic with no numbers or punctuation (apart from a hyphen) allowed, and so on.
4	Semantic checks	This check concentrates on the meaning of inputs. As an example, the reading of a household electricity meter should not be so far from that in the corresponding duration in the past year because it is known that the amount of electricity used is expected to be approximately the same.

## V. THREATS TO VALIDITY

Here, we present two threats to the validity of the study's results.

- **Internal validity:** Individual developers would probably carry out the same (insufficiently robust) practices in all programs. This variable was controlled by selecting programs that were written by different developers. In addition, the selection of subjects was arbitrary. The expected threat to internal validity, if there is one, may come from errors in the VCG tool.
- **External validity:** The 12 OSS projects are chosen from different domains to minimize the effect of domain-specific issues. Two factors may affect the interpretation and reduce the generality of the results; studying the input validation practices of developers from 12 OSS projects may not be sufficient, and all projects considered herein are OSS, i.e., not representative of all industrial domains.

## VI. CONCLUSION AND FUTURE WORK

An indicator of secure source code quality is input validation. It is believed that good practices improve program protection, which directly affects recoverability and reliability. In particular, it helps reduce the chances of producing security vulnerabilities in software. This paper conducts an experiment to identify the input validation vulnerabilities in programs and the problematic functions that lead to such issues. The experiment assessed 12 OSS projects written in C, a widely-used PL that provides input validation functions and constructs. The projects have different authors. The results show that buffer overflow (or XSS) and potential memory mismanagement are the top two most common input validation problems. The two types of functions that caused the buffer overflow problem are (a) strings/text functions such as `strcpy` and `strcmp`, and (b) functions that read from standard input, `STDIN`, such as `scanf` and `gets`. In contrast, the functions that caused the memory mismanagement are threefold: (a) memory allocation/deallocation functions such as `memmove` and `malloc`, (b) file manipulation functions such as `fopen` and `fseek`, and (c) the `goto` construct used in handling input errors or exceptions. Two main recommendations are discussed: (a) programmers are encouraged to use memory-safe PLs. Otherwise, they should perform different types of checks for the validity of inputs as soon as they are entered

(four checks are presented in this paper), and (b) in addition they should have the required knowledge of secure source code and should be able to use tools/suites for malformed strings. The results may not be very surprising for skilled C developers, but it is important that there is experimental evidence about the use of a set of C functions and constructs.

There is an open point for further research to examine the problems of using different mechanisms for (a) more than 12 software projects, and (b) real-world systems (not only OSS). However, in the second mechanism, there might be a "data scarcity" research problem due to a lack of sufficient data [14].

**Abstract**—Polar codes are traditionally constructed by calculating the reliability of channels, then sorting them by intensive calculations to select the most reliable channels. However, these operations can be complicated especially when, the polar code length,  $N$  becomes great. This paper proposes a new low-complexity procedure for polar codes construction over binary erasure and additive white Gaussian noise (AWGN) channels. Using the proposed algorithm, the code construction complexity is reduced from  $O(N \log N)$  to  $O(N)$ , where  $N=2^n$  ( $n \geq 1$ ). The proposed approach involves storing the classification of channels by reliabilities in a vector of length  $L$ , and then deriving the classification of  $M$  channels for every  $M$  where  $M \leq L$ . The proposed method is consistent with Bhattacharya parameter based Construction and Density Evolution with Gaussian Approximation (DEGA) based construction. In this paper, the Successive Cancellation Decoding algorithm (SCDA) is used. Thanks to its low complexity and its high error-correction capability.

**Keywords**—Polar codes; SNR; successive cancellation decoding; error correction; low-complexity; code construction; additive white Gaussian noise; Bhattacharya parameter; density evolution with Gaussian approximation

## I. INTRODUCTION

It is usual for communication links to suffer from errors due to random noise, interference and malfunctioning devices, etc. To correct errors in channel coded data streams, a set of algorithmic operations is applied to the original data stream at the transmitter. A second set of algorithmic operations is applied to the received data stream at the receiver. Encoding and decoding operations at the transmitter and receiver are collectively called channel coding operations in channel coding terminology. Research in channel coding is focused on developing high performance channel codes that mitigate the effects of errors in communication links. A real challenge here is to accomplish this with sufficient simplicity to allow practical implementation in silicon technology. Everything depends on the complexity of a code, including its power consumption, memory requirements, computation power requirements, and latency, which determine whether or not a code is appropriate for any given scenario. Channel coding is somewhat revolutionized by polar codes.

The polar codes proposed by Arikan in 2008 can achieve that capacity of any binary discrete memoryless channel [1], researchers from all over the world have been interested in polar codes ever since their introduction in [1], polar codes can be used in lot of applications like cryptography [2], speech communication [3], data storage [4]. Polar codes are also used

to develop new block [5]. Polar codes are composed of three main stages; namely the construction, the coding and finally the decoding. The construction of polar codes is a crucial step as they affect the performance of polar codes. In polar codes construction, synthetic channels are evaluated by reliability. Good channels are selected for information transmission and the bad channels are frozen. Where polar codes are capable to achieving channel capacity for any binary-input discrete memoryless channel [1].

Polar codes construction step encounters the following problem: given  $N$  code lengths and  $K$  information bit length, what is the best way to select  $K$  channels out of all the available ones, knowing that the remaining  $N-K$  bit channels are frozen and provided to the transmitter and receiver. An indication of the quality of a virtual bit channel  $W_N^i(\cdot)$  can be determined by using a variety of metrics. Polar codes take effect when the length of the code is very large, which implies a large number of computes to know the capacity of each channel, As a result, building polar codes is extremely difficult and requires a lot of resources. This paper considers the construction of polar codes over symmetric binary discrete memory-less channels by using a new method to reduce the complexity of the construction. Many methods have been developed previously in literature to build polar codes, Monte-Carlo simulations are proposed in [1] with a high complexity of  $O(TN \log N)$  where  $T$  indicates the number of iterations of Monte-Carlo simulations. In [6] and [7], polar codes construction is based on density evolution, where convolutions of functions are performed and numerical calculation precision is limited by the complexity of the process. In [8] bit-channel approximations are proposed with a Complexity under controlled conditions of  $O(N \cdot \mu^2 \log \mu)$  ( $\mu$  a user-defined parameter that limits the number of output alphabets at each step of the approximation process). Another type of algorithm can construct polar codes using Gaussian approximation (GA) of additive white Gaussian noise (AWGN) channels [9]–[11], this approximation function [11] inherently limits the GA method, with some restrictions on the length of blocks [11]. Bhattacharya parameters are used to construct polar codes in [1], other constructions methods with variable performance and complexity are located in [12]–[14].

This paper describes an efficient method of constructing polar codes to reduce their computational complexity, if the method suggested in this paper is compared to other ones in the literature, the method presented here is characterised by a reduced complexity.

In the following sections of this paper, polar codes are described, including their background, with a focus on the concept of channel polarization. Section III presents the traditional method of constructing polar codes, while Section IV provides numerical results that demonstrate the effectiveness of the proposed method compared to traditional methods and state-of-the-art techniques. Finally, the conclusion summarizes the key findings of the study and discusses potential future research directions.

## II. POLAR CODES

In general, all channel coding technologies work in quite similar ways, even if the excellent performance of turbo codes and LDPC (Low Density Parity Check) codes in practice, none of the last codes can be demonstrated to attain the capacity of channels exempt the binary erasure channel (BEC). Polar codes are members of the block code family since they operate on blocks of symbols/bits. To construct polar code, two key operations are required: channel combining and channel splitting. The channel combining process, carefully selected combinations of bits are mapped to specific channels.

Let consider N bits to be sent over discrete binary channel without memory (B-DMC) W. Each transmission represents a use of W, which means that each bit is passed through a copy of W as shown in Fig. 1.

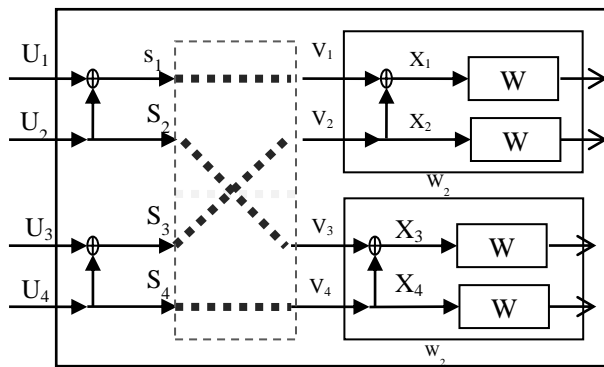

Fig. 1. Combination of two copies of W to form W2.

The map in Fig. 1 between the input  $u_2^1$  and the vector  $X_2^1$  can be represented by the equation (1):

$$X_2^1 = u_2^1 * G_2 \tag{1}$$

Where  $G_2$  is the basic matrix:

$$G_2 = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} \tag{2}$$

The same operation is repeated with  $W_2$  as the basic element to produce  $W_4$  like presented in Fig. 2. Generally At this step, the combined channels  $W_N$  is the virtual channel that map the input data  $u_N^1$  to the output  $y_N^1$ .  $W_N^i$  are divided into a set of N bit input channels  $W_N^i()$ .

These virtual channels  $W_N^i()$  are characterized by the transition probabilities provided by equation (3).

$$W_N^{(i)}(y_1^N, u_1^{i-1} | u_i) \triangleq \sum_{u_{i+1}^N \in X^{N-i}} \frac{1}{2^{N-i}} W_N(y_1^N | u_1^N) \tag{3}$$

$$(W_N^{(i)}) : X \rightarrow Y^N \times X^{i-1}, 1 \leq i \leq N \tag{4}$$

Fig. 2. Combination of two copies of W2 to form W4.

## III. THE NATIVE CONSTRUCTION

As mentioned earlier, building polar codes is like finding all the best positions of reliable bits positions. The selection of the information bits is one of the most important steps in polar coding. Polar codes are originally constructed using simple bounds on Bhattacharyya parameter bit channels [1], The Bhattacharyya parameter is linked to the Bhattacharyya distance, which measures the similarity of the probability distributions of two symbols [15]. It has been widely used to produce good polar codes because of its simplicity. By creating a system allowing one to access each bit-channel individually, one can send data only through those for which the Bhattacharyya parameter is close to 0. Bhattacharyya's parameter  $Z(\cdot)$  defined in (5) provides an upper bound on the error probability of transmission over W with maximum likelihood (ML) decisions when the channel is used only once.

$$Z(W_N^{(i)}) = \sum_{y_1^N \in Y^N} |X_{i+r}^N \cdot y_1^N| \cdot \sqrt{W_N^{(i)}(y_1^N, 0_{i-1} | 0) \cdot W_N^{(i)}(y_1^N, 0_{i-1} | 1)} \tag{5}$$

Accordingly, channels with  $Z(W_N^i) < \epsilon$  are almost noiseless, whereas channels with  $Z(W_N^i) > 1 - \epsilon$  are almost pure-noise channels where  $0 < \epsilon < 1$  [15]. However, it has been cited that the parameters' updates succeeded with equality just for the Binary Erasure Channel.

### A. Density Evolution with Gaussian Approximation (DEGA) Construction

Over AWGN channel the Density Evolution with Gaussian Approximation (DEGA) is the famous construction for polar codes. From the channel stage towards the decision stage, DEGA attempts to evolve the densities of the LLRs via the decoder. Regardless, precise if the begin is with Gaussian densities at the channel stage, the consequent densities at the following stages are not Gaussian anymore. The DEGA decoder relaxes this by supposing they are approximately Gaussian, and consequently it only tracks their mean and variance throughout the approach. The relationship between

mean and variance should survive at all stages [10]. The variance and the mean is defined in (6) where the LLR is defined in (7).

$$m = E\{L\} = \frac{2}{\sigma^2}, \quad \text{var}\{L\} = \frac{4}{\sigma^2} = 2m \quad (6)$$

The next update is accomplished by DEGA[9].

$$m_i^{(s)} = \begin{cases} \phi^{-1}\left(1 - \left(1 - \phi(m_i^{(s-1)})\right)^2\right), & \text{if node } f, \\ 2m_i^{(s-1)}, & \text{if node } g, \end{cases} \quad (7)$$

The function  $\phi$  is given by (8).

$$\phi(x) = \begin{cases} \exp(0.4527x^{0.86} + 0.0218), & 0 < x < 10 \\ \sqrt{\frac{\pi}{x}} \exp\left(-\frac{x}{4}\right) \left(1 - \frac{10}{7x}\right), & x \geq 10 \end{cases} \quad (8)$$

#### IV. NUMERICAL RESULTS AND DISCUSSION

This section analyses the classifications of polar codes virtual channels by reliability for different code lengths over AWGN and BEC, the information length is not tested because the construction of polar codes depends on the code length.

##### A. Classification of Polarizing Channels over BEC

This part starts by the comparison by reability of 8 BEC polarizing channels with erasure probability 0.1,0.2,0.3,0.4,0.5,0.6,0.7 and 0.8, the results are shown in Fig. 3.

The simulated results that are calculated using the relation (17) of [1] indicates that virtual channels are classified in the same way independently of the erasure probability. Fig. 3 shows that for all erasure probabilities, virtual channels are classified as below 8->7->6->4->5->3->2->1 (from the most reliable to the least accessible).

Fig. 4 shows the reliability of 16 virtual channels for the following erasure probabilities [0,1,...,0,9]. Fig. 4 shows that the classification of 16 virtual channels is the same for all erasure probabilities, the classification by consequence is

16-> 15->14-> 12-> 8-> 13-> 11-> 10-> 7-> 6-> 4-> 9-> 5->3->2->1.

Fig. 3. The Bhattacharyya for 8 BEC polarizing channels.

Fig. 4. Comparison of 16 BEC polarizing channels in terms of reliability with erasure probability [0.1, 0.2, ..., 0.9].

Fig. 5. Classification of channel by reliability for N=8 and N=4.

Fig. 5 compares the classification of virtual channels for different code lengths N=8 and N=4.

The results shown in Fig. 5 proof that the classification of virtual channels with index less than 4 is the same in both codes.

Table I provides the classification of virtual channels by reliability for several code lengths (N=1,2,4,8,16,32) where the erasure probability  $\epsilon=0,25$ . For ease of analysis, each channel index is characterized by the same color in each code length. The table shows that the classification is the same when the length of the code changes.

##### B. Classification of Polarizing Channels under AWGN

This section analyses channel classifications by reliability for different code lengths over AWGN, the Bhattacharyya parameters are used to evaluate the reability for each virtual channel, note that the same tests can be applied with Gaussian density approximation method.

In the beginning, reliability of eight virtual channels are compared under different values of signal to noise ratio (SNR). Fig. 6 shows the reliability of eight polarizing channels using SNR -2, -1, 0, 1, 2 and 3. It also worth nothing that the classification of the eight polarizing channels by reliability remains the same when SNR changes.

The Table II generalizes the simulation of Fig. 9 by presenting the classification of virtual channels by reliability for several code lengths ( $N=2,4,8,16$ ) where the  $SNR=2$ . For ease of analysis, each channel index is characterized by the same color in each code length. The table shows that the classification is the same when the length of the code changes.

Mathematically the proposed procedure to construct polar codes with low complexity will be described below in algorithm 1. This algorithm uses linear search where every element in a reliability vector is checked, starting at 0 and going through each element until the desired element is found. Otherwise, the search continues until the end of the list.

---

**Algorithm 1:** Find out all good channels index and bad ones

---

**Input :**  
Channel index vector classified by reliability  $I$  with length  $N_i$   
polar code length  $N$  where  $N \leq N_i$

**output:**  
 $S$ : virtual channel classified by reliability for polar code with length  $N_r$

```
1: for k=0 to N do
2:   for J=0 to  $N_i$  do
3:     if the value of  $N_i[J]$  less or equal N
4:        $S[k]= N_i[J]$ 
5:     endif
6:   endfor
7: endfor
8: Return S;
```

---

The latest algorithm uses linear search where each item in a list is checked, starting at 0 and going through each item until the desired item is found. Otherwise, the search continues until the end of the list. There is no better search algorithm. The complexity of the newly developed build algorithm is the same as the complexity of the search algorithm, which is  $O(N)$ .

To better understand the algorithm designed, let's take an example of building polar codes, assumes that Gaussian density was adopted firstly to construct polar codes. The new proposed algorithm for constructing polar codes can be applied here by storing in a particular vector ( $R$ ), the classification of virtual channels by reliability from the least reliable to the most reliable. Next the reliability calculation for each virtual channel will not be done in the next polar code construction, there is a need to select the most reliable channels of the  $R$  vector with an index less than the length of the new polar codes.

## V. CONCLUSION

The previous approaches of polar codes construction require one to one compute of the reliability for all synthetic channels and use only those that are sufficiently reliable [2]. For the gain in complexity and resources, it is worthwhile to

perform an optimized construction polar codes algorithm. the proposed method decreases the computation complexity in the construction of Polar Codes. Clearly, the complexity is reduced to  $O(N)$ . Note that when using this optimized construction approach, extra memory is allocated to store the vector of reliability.

The memory resources play a crucial part in the outcome of this study, these limitations do have a significant impact on the primary finding, future research could seek to reduce memory's impact by choosing the best value of the vector reliability length for every application.

**Abstract**—Now-a-days, with the rapid and broad emergence of local or remote access to services on the internet. Authentication represents an important security control requirement and the MFA is recommended to mitigate the weaknesses in the SFA. MFA techniques can be classified into two main approaches: based biometric and non-biometric approaches. However, there is a problem to maintain the tradeoff between security and accuracy. The studies that have been reviewed on both authentication mechanisms are found contradictory in the direction of others. In the direction of authentication-based biometrics the researchers tended to increase the recognition accuracy, while in the other direction, the researchers proposed to combine many authentication factors to increase the security layers. The main contribution of this survey is to review and spotlight on the current state of the arts in both authentication mechanisms to achieve a secure user identity. This paper provides a review of authentication protocols and security requirements. In addition to a detailed review with a comparison of secure one-time passcode generation and distribution. Furthermore, a comprehensive review of cancelable biometrics techniques, attacks, and requirements. Finally, providing a summary of key challenges and future research directions.

**Keywords**—MFA; authentication; OTP; cancelable; biometrics; security; identity

## I. INTRODUCTION

Lately, organizations worldwide have made a quantum leap in terms of online application as services expand to the customers' satisfaction [1]. This led to the manifestation of widespread modernized applications as example, users can easily perform various operations such as withdrawal, payment, and transfer over internet banking websites [2]. With the increment of using smartphone devices, authentication protocols can be classified into two approaches non-biometrics-based approach and based biometrics approach [3].

Online identity access management (IAM) is one of the most important services that require customer authentication during daily transactions of funds in a secure way [4]. Some current surveys emphasized various types of customer authentication protocols used for secured data transfer including Single Factor Authentication (SFA) and Multi-Factor Authentication (MFA). For instance, [5] elaborated in detail the significance of various factors used for authentication and compared these factors based on different parameters such as universality, uniqueness, collectability, performance, and usability. The evolution mechanism of the authentication systems is explained in [6] where MFA was implemented for

the user and Vehicle-to-Everything (V2X) interactions. A framework was proposed to identify the missing factors and further authenticate the users without supplying any sensitive biometric information. Consequently, it enabled an elastic in-car verification of the occupant using efficient integrated sensors.

In [1] authors analyzed the situation of 30 banks regarding the MFA execution in online banking, wherein the main aim was to determine the impact of the MFA protocols on the regulations, practices, and system security against attacks in the banking sector. It was acknowledged that although it is difficult to implement the MFA systems, wide adoption of the validators taking advantage of the inheritance factors can improve both the security and efficiency of the MFA systems. Broader adoption of authenticators that take the advantage of inheritance factors can improve the security and intricacy of the MFA systems. In the context of mobile devices, a comprehensive survey was conducted on the behavioral patterns of biometrics and constant verification methods [7]. In addition, the behavioral biometrics and verification of the mobile device; various methods of behavioral biometrics and feature extraction were analyzed with a focus on machine learning (ML) models' performance. The limitations of the ML models were discussed with respect to their usage due to the security, and usability as well as privacy concerns.

Also, [8] reviewed the current trends of various MFA protocols and analyzed the gaps in the current literature for future studies related to the perception of users' risks. Different identifiable trends in the MFA studies were found, indicating the need for new validation techniques. However, it lacked risk perception analysis. This work disclosed the presence of cultural and demographic biases in the user study designs. In general, a recruitment bias for the users was achieved in the context of an academic background.

While [9] argued that an increase in the attacks against the MFA mechanism is mainly related to the nature of the authentication protocols, factors, and their importance for the security of the advent of mobile money. The study conducted a literature review of the attacks and countermeasures in the MFA for mobile money. The authors recommended for a future authentication system use a secure multifactor authentication scheme Personal Identification Number (PIN), One Time Passcode (OTP), and biometrics features. Moreover, protect data during distribution and storage using end-to-end encryption methods. Furthermore, it was stated that despite the coverage of several attacks against mobile money other attacks

must be considered. Some of best practices are recommended by [10] to overcome the drawbacks of several mitigation strategies. Meanwhile, the implementation of many countermeasures like new families of hash functions was recommended for security. The study [11] presented a survey of the Cancelable Biometric (CB) methods of various types based on cryptography, filtering, transformation, multi-models, and hybrid methods. It also addressed requirements and performance measures as well as attacks and challenges.

Most of the related surveys are in the field of non-biometric factors and concern the issues related to the improvement of the authentication by improvement of MFA-based OTP generation and distribution. In the second direction, the studies tackle the authentication-based current trend of cancelable biometrics methods. Secure digital identity management is the main aspect of any authentication system that cannot be ignored [12].

Thus, this study refers to the most common performance metrics, requirements, and attacks for both approaches of the related studies [1], [4], [5], [6], [7], [8], [9], [10], and [11].

Although multifactor authentication is a growing and prospective research scope but lacks a comprehensive survey on this field is not available except for fewer research. This survey has made the following contributions:

- The paper has presented a comprehensive survey of both multi-factor of authentication approaches and the state of arts; MFA-based biometrics and non-based biometrics.
- Comprehensive review of various security attacks and performance measures used in CB.
- Comprehensive review of various security attacks and performance measures used in non-based biometrics approaches.

Section II provides a review of identity access management and discusses the authentication protocols, authenticators' classification, Authentication security requirements, and attacks with countermeasures. Section III presents MFA features, Biometrics types, requirements, attacks, and performance metrics of conventional and current trends of cancelable biometrics, and Section IV provides a review of the current state of the arts of cancelable biometrics approaches. Section V describes the authentication of non-based biometrics and provides a security analysis of the current OTP generation and distribution methods. Section VI emphasizes the key challenges. Section VII concludes the paper and presents the future directories.

## II. IDENTITY ACCESS MANAGEMENT PROTOCOLS

An Identity Access Management Protocol (IAM), is a controlled access that manages the identity provider (Idp), controls the client authentication (signed in), and authorizes (permissions) the use of the targeted resources. IAM organizes the resource's availability, and accessibility and preserves data privacy [4].

IAM protocols permit the digital verification of a client based on several factors. The recent advancement in innovative

communication, security authentication, computerized e-payment, and smartphone devices faced increasing authentication challenges due to diverse security threats from attackers or phishers [13].

A conventional SFA approach can keep approved access, login, or get to the secret content by utilizing a single factor-like username and password. Now, this approach was hardened by utilizing at least two factors in the combination process [14]. According to National Institute of Standards and Technology (NIST), the digital identity of a user is defined as a series of functions of authentication, authorization, and accounting of a client in a specific context in a unique way (for example a payment service) [4].

The authentication of the digital identity of a user is achieved in practice via the so-called authentication protocol to get authorization to get access granted to the resources (data, computer program, call object, or procedure). The access server is explained in [1] where requests additional user information for example in the earlier application layer protocol Remote Authentication Dial-In User Service protocol (RADIUS), OpenID, Kerberos, OAuth delegation framework.....etc. Modern identity providers (Idp) rely on Role-Based Access Control (RBAC) to access resources.

Access control utilizes authentication to verify the user identity (uid). In addition, the accounting process is the job to manage and keep the records of the user or any other related objects and works to provide an assertion of the authorized object to the Service Provider (SP) [15].

Furthermore, there are many protocols used to manage the assertion or to transfer the attributes pairs names and values like Security Assertion Markup Language (SAML) protocol. SAML protocol transfers the authentication, attribute, and authorization decision statements from the Idp to SP to perform an action on the requested resource among the relying parties as in Single Sign on (SSO) protocol [16].

SSO is supported by Azure Active Directory (Azure AD) SAML authentication sends requests AuthnRequest (authentication request) and receives the responses from the Idp (Azure AD), Fig. 1 describes the SSO processes sequences to use HyperText Transfer Protocol (HTTP) to post and bind the responding to the SP [16].

Fig. 1. Single sign on workflow.

### A. Authenticators Classification

Authenticators can be classified into different categories such as memorized and look-up secrets, out-of-band devices, token devices, and software as shown in Fig. 2. The salient attributes of these authenticators are briefly described hereunder [1].

1) *Memorized secret*: When a client shares memorable pieces of information with the server he/she has to recall including passwords, PINs, pass-phrases, and secret questions. The old methods keep the memorized secrets through encryption or salting. However, according to the recommendations of NIST, the memorized secrets must be stored in a form that can withstand both online/offline attacks. In addition, it must be hashed via the approved hash function [17].

2) *Look-up secret*: It can be electronic records of a secret set shared between the client and server to attest to a possession factor. Then to complete the transaction, the client has to provide the secret associated with definite positions in the records [18]. For example, the user or applicant may be asked by the verifier to give certain subsets of the alphanumeric characters or strings printed on a card in a tabular format [19].

3) *Authenticator device*: A small hardware device is used to generate an authenticator output. This authenticator platform may be constructed into a specific user's device and employed on the connected devices whereas the roaming verifier links to a device platform via transport protocols [20].

4) *Software authenticator*: It is sometimes called a software token, wherein the programs are executed to generate the authenticator's output. The software authenticator act as the coordinate of verifier devices for both SFA and MFA software authenticators. The authenticator based on the software may be implemented on laptops, tablet computers, or smartphones. For instance, a mobile application on the user's smartphone can be considered a kind of phone-based authenticator [21]. For security purposes and to prevent unauthorized access to the private or secret data domain, an authenticator based on the software might employ the Trusted Platform Module (TPM) on the client device or trusted execution environments of the processor. Authenticator devices or hardware are classified into SFA and MFA types as explained below [22]:

a) MFA is known as a Time based OTP key (TOTP) token. When the TOTP devices or software share the user's OTP periodically, OTP will be popped up to the user or reach his email or SMS box. Then, the user should manually enter the OTP into the input text box for the successful execution of an MFA protocol completely [22].

b) Using MFA, various devices or software generate tokens in the form of alpha-numeric string which needs some PIN, biometric or secret data for activation, thereby confirming both ownership [22].

5) *Out-of-band device*: These types of authenticators are shared exclusively over the specific secondary channels (for

example an SF device) that approve the possession factor initiated by a secondary mobile phone network channel. Usually, this kind of authenticator depends on a SIM card [4]. The MFA methods rely on mobile phones app where some depend on notification or OTP authentication (event and time-based). Upon receiving the OTP generated by the server and dynamical sharing the user can go for the online transaction [17]. The SMS notification is subjected to security concerns as analyzed afterward. The main flaw in the authentication process is that the user must carry many hard tokens for a different account like Universal 2<sup>nd</sup> Factor of authentication (U2F), Near Field Communication (NFC) devices, or Secure Digital (SD) cards. Another threat to the authentication of the user's account is related to the loss or theft of these devices. In addition, many organizations prohibit carrying the electronic devices to or outside the workplace due to security policies. Due to this reason, most of the mobile phones do not have flash memory ports. One cannot upgrade or update the hard tokens because they require a new hard token for each account up-gradation or reconfiguration [2]. High costs are involved in purchasing or exchanging tokens of this type.

Fig. 2. Authenticator's classification.

The MFA scheme for mobile and smartphones gives an option for the dedicated physical device. For the authentication process, one can use the security tokens in the dedicated device (only known by the individual user) and a one-time password usually 4 to 6 digits [23]. This OTP is sent to the mobile device of the customer via SMS. In short, smartphones are beneficial because the customer carries them most of the time and are free of cost [24], [25]. Regardless of the popularity of SMS verification, it is recognized as the most widely adopted method for user account authentication [2]. Google and Apple introduced an SFA process for their users with the notification of new events when OTP is being delivered to the user's phone. The SMS application depends entirely on the security of the mobile phone operating system [26].

### B. Security Requirements and Attacks

The most organization today focuses on information security policies to protect their data as the Confidentiality Integrity Availability (CIA) model or Availability Integrity Confidentiality (AIC) triad Fig. 3. Confidentiality, integrity, and availability objectives should be taken together to provide information security [27]:

1) *Confidentiality*: The sensitive and personal data of the user should be secured from illegitimate access where the failure to protect the data means there is a data breach or success of the adversary to get access to the data. Impersonating, replay masquerade, spoofing, social engineering, and phishing are the most common attacks against confidentiality. While using Encryption, Quick Response code (QR), Biometrics, username, and password represent the common countermeasures techniques against these types of attacks [3].

2) *Integrity*: The security control must be able to protect the data from being modified which means the accuracy of the reverted computational outcomes upon saving or transmitting the data over networks. Insider intruders or external Man-in-the-Middle (MITM) are the common types of attacks against integrity. While encryption of the data and error detection in the transmission are common countermeasure techniques against these types of attacks [27].

3) *Availability*: To ensure the authenticated user accessibility to the resources at need or the reliability of the system uptime. Denial-of-Service (DoS) and Distributed Denial-of-Service (DDoS) are common attacks against availability. While virtual systems are the common techniques to keep availability [28].

Fig. 3. CIA security requirements model.

Performance: Besides security requirements, it is important to refer to the most common requirement to implement and evaluate any authentication system performance. In addition to recognition patterns performance that its indicators can evaluate the system's ability to distinguish among the users to reduce the EER of biometric systems [29].

### III. MULTIFACTOR OF AUTHENTICATION TYPES

Authentication occurs when a user is prompted during the sign-in process to different kinds of resources like networks, devices, or apps that require the client to provide the identity. Using this identity, the client can access these resources together with authenticity proof [30] such as entering a code in the cellphone of the user or scanning a fingerprint. A basic form of authentication requires only one feature or factor, typically a password. To add another security layer, access to various resources might need over and above one factor so-called MFA whenever several factors of evidence are required [22]. There are many types of MFA as described below in Fig. 4.

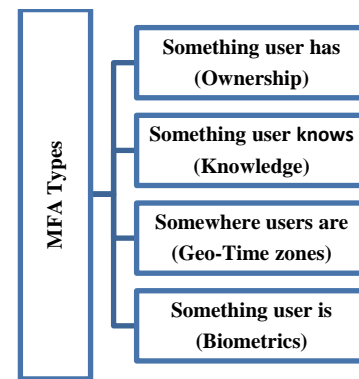

Fig. 4. MFA types.

#### A. *Something the user has (Ownership)*

Some physical things the user owns like a secret code flash drive, bank Automatic Teller Machines (ATM) card, credit card, master or visa debit cards, or hard tokens. In this regard, the Universal 2<sup>nd</sup> Factor (U2F) is an open standard that secures the transaction. It can be designed using USB or similar security technology-based Near Field Communication (NFC) devices [4], and the main drawback where the devices are stolen or lost without enough strength encryption.

#### B. *Something the user Knows (Knowledge)*

Some knowledge that only the user knows includes the password, PIN, secret question, answer, and so forth wherein the knowledge-based is the most commonly used. Herein, the user needs to reveal secret knowledge for obtaining the authentication. The password strength (complexity) represents the measure of how effectively a password can resist brute force and guessing attacks. Passwords require the use of long and random char types that are not found in the usual dictionary and might enforce the attackers to attempt all probable values [27], [31].

#### C. *Somewhere users are (Geo-Time-Zone)*

Employment of the user's geographical position acts as a location-based factor that deals with the customer's location at the login session including the physical location of the user. Upon being securely connected to the server, the user is only allowed to log in using the PIN code. While connected to the network the user might have to enter the password if necessary. This can be appropriate as access to the server for monitoring the plan depending on the time zone for the user [32], [33].

#### D. *Something user is (Biometrics)*

This type represents the biometric features that can be classified into the physical characteristics (biometrics) of the user like the fingerprints, iris, voice, facial, tongue, ears, and the vascular and micro medical biometrics like DNA, and ECG. The second type is the behavioral biometrics like typing speed, keystroke patterns, emotions, signature, gait, voice, height, gender, ethnicity, and so on are in the domain of something the user is. Biometric modal can be classified into two main types Unimodal and Multimodal [34].

1) Unimodal represents a single biometric feature.

2) Multimodal biometric systems Multimodal biometrics are developed by combining many biometrics features.

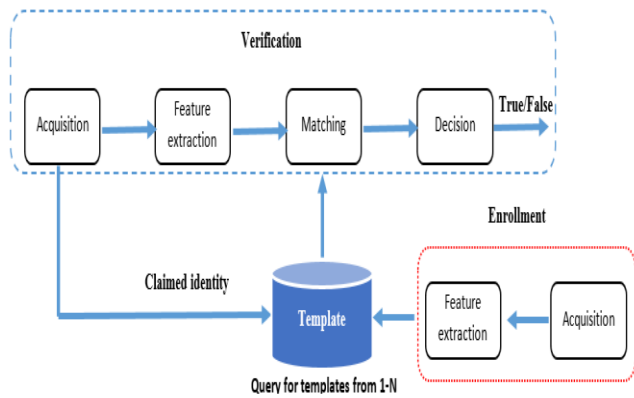

Fig. 5. Biometric system stages.

For authentication, multimodal biometrics features can be combined through fusion at different levels; sensor level, Feature-extraction level, Matching-score level, and Decision level [35]. Biometrics identity verification techniques can be used to measure the features of a user through sequences of processes Fig. 5 [36].

1) *Acquisition stage*: in a biometric system the first is to acquire the bio-data of users by sensors. For face and iris images, the sensor is typically a camera, the sensor like a camera is typically used to capture the face and iris, and the scanner is used for fingerprints and a microphone for voice. the quality of sensors has a significant impact on the performance of acquisition bio-data as environmental conditions like different sources of noises impacted the brightness, resolution of the captured image, or the depth per inch (dpi) [11] and [37].

2) *Feature extraction stage*: pre-processed to remove noise and abnormalities from the acquired bio-data to extract the bio-features for the individual ideally and uniquely. Like the fingerprint minutiae point where the position and orientation are used in the fingerprint image system to store these points during user enrollment.

3) *Matching and decision stage*: In this stage decision of accepting or rejecting is based on the matching scores comparing the features values of the stored template against the score that is generated from the enrolled stages comparing the matching score to a fixed threshold, the scores should be high to indicate the degree of similarity of the same individual (genuine matching) [38].

#### E. Biometric System Requirements

1) *Uniqueness*: The use of biometric features to identify the user's digital identity is one of the authentication methods, which must be unique, but twins can have identical features, and therefore the methodology is considered incomplete without adding other biometric factors such as fingerprints [11].

2) *Collectability*: The process of acquiring biometric properties should be easy, especially when assembled for a database system, and here it needs to be more acceptable.

3) *Performance*: As we have reviewed, the biometric system must achieve high accuracy and must be with low errors or failure to enroll, which represents the main concern of researchers and the extended challenge, Failure to Enroll (FTE), and an increase in the False Acceptance Rate (FAR) and False Rejection Rate (FRR) are among the challenges that constitute an added burden when designing multifactor authentication systems because the error is costly to the system and lead to invoke algorithms and other supporting methods when accessing the system [35].

4) *Spoofing*: There can be no guaranteed biometrics system. With the presence of various fraud methods, signatures can be forged, voices can be imitated, and fraud remains one of the most challenging attacks, as these attacks must be addressed [7].

In addition to the usual context of biometric requirements, the new requirements of the cancelable biometric systems.

1) *Non-inevitability*: original biometric template should be computationally hard to be recovered from the transformed if got compromised [11] and [29].

2) *Diversity*: should not use the identical biometric template in wide applications to prevent the reusability of the compromised templates [11] and [29].

#### F. Attacks on Biometrics System

Many attacks on the biometric system could attack at the sensor level like spoofing attacks, another at the application level like brute force attacks, and the database levels like inverse, pre-image, and dictionary attacks. Replay, presentation, MITM, and eavesdropping attacks are other types that thread the network and data transmission which can be countered through utilities time stamp or transmit the encrypted data over a secure channel [39]. On the other hand, clients' fears of bio-data breaches are one of the new challenges that the International Organization of the Red Cross has indicated, which is the refugees' fear of leaking their vital data upon receiving financial support from the organization, even in cases related to their biometric data and medical data [40].

The stolen and exposure of biometric data is not a theoretical concern, there are many existing real-world examples, in 2015 about six million fingerprints of people associated with the U.S. government sector of Office of Personnel Management breach. In 2019 of Suprema's BioStar 2 about 1 million fingerprints, as well as facial recognition information records, are stolen from the publicly accessible database [40]. In 2020 and according to Kaspersky's analysis, Kaspersky researchers referred that 37% of the servers that process and store biometric data were the target of malware attacks. [41] RSA Conference in San Francisco, In February 2019, the security expert demonstrated the success of real-time attacks like social engineering schemes, phishing SMS and emails, session hijack, and MITM attacks to intercept the traffic to circumvent the MFA[41] and [42]. In academic research, many attacks are proposed as [43] proposed an attack that used the distribution of order statistics to reverse the protected iris template of the ordinal ranking value of the

original stored iris templates. The proposed reverse-attack successes to recover greater than 95% of the template and can correctly correlate two templates of 100%. The author in [44] proposed MFA authentication of cancelable biometric hashing mechanism against the attacker is assumed to know the user's password that is bound in the bio-hash code of the face image, the scheme is based on 1-bit compressed sensing signal reconstruction by reducing the number of measurements required to acquire signals through sensing and achieved high security

### G. Biometrics System Performance Metrics

NIST SP 800-63B referred that biometrics can be utilized as important factors together with other factors (something users know). Furthermore, according to ISO/IEC 2382-37, in identification matching and authorization, the choice of the threshold value should be assigned carefully in a closed group of 0 for no match and 1 for the full match, an intruder or imposter matching score that exceeds the threshold give high FAR or the False Match Rate (FMR), while the genuine that less than the threshold gives high FRR or the False Non-Match Rate (FNMR) [42]. While the False positive (FP) denotes that exceeding the threshold of imposter scores, the False Negative (FN) sign that genuine client scores are below the threshold. Where the true positive refers to the genuine client and the true negative represents the imposter client [11], [36]. The relation of total scores can be defined in the below functions to measure the performance metrics:

- False Acceptance Rate/ False Positive Rate

$$FAR=FP/FP+FN \quad (1)$$

$$FAR = FPR = FMR * (1 - FTA) \quad (2)$$

- False Reject Rate (FRR)/ False Negative Rate(FNR)

$$FRR/FNR=FN/TP+FN \quad (3)$$

- True Acceptance Rate (TAR) or Genuine Accept Rate (GAR)

$$TAR = 1 - FRR \quad (4)$$

$$FRR=FNR= FTA + FNMR * (1 - FTA) \quad (5)$$

- True Acceptance Rate (TAR) or Genuine Accept Rate (GAR)

$$TAR = 1 - FRR \quad (6)$$

- Half Total Error Rate (HTER)

$$HTER=FNMR + FMR/2 \quad (7)$$

- Failure to Enroll rate (FTE): represents the total number of the user's failed attempts to enroll in the bio-system successfully or the number of unsuccessful attempts to enroll in the bio-system.
- The Receiver Operating Characteristic (ROC): this curve can plot the FMR on X-axis while plotting the FNMR along the Y-axis, or FAR vs FRR, or TAR vs the FAR.

- Equal Error Rate: It is another performance measurement to evaluate recognition where the FAR and FRR are equal.

$$Accuracy=TP+TN/ TP + FP + TN + FN \quad (8)$$

- Training Time: is the time of the learning algorithm to training data.
- Testing Time: this is the time of the process to test data in the learning algorithm.

### IV. AUTHENTICATION-BASED CANCELLABLE BIOMETRICS APPROACHES

The current trend of authentication research is to integrate biometric data through cancelable mechanisms that should fulfill the aforementioned cancelable biometrics requirements in subsection E of Section III. The concept of cancelability is derived from the concept of one-way functions through Cartesian, polar, functional, and hybrid transformations, but the disparity in the entries of the same user (intra-user variations) and subject to errors, and that is what we have been observed in most of the researches that attempts to improve the methods of transformation through two main approaches BioHashing, and BioEncoding [11]. [37] proposed cancelable biometrics based on a Hill cipher transformation of the biometric signals of face and palmprint as multimodal. The author in [45] proposed to use the deep Convolution Neural Network (CNN) to protect the face templates based on random projection. The first extract is the features vector from the face image with 224\*224 VGG face input. then, during the training of 15 layers 4096-dimensional output with dimensions of 1599\*4096 is projected randomly then reducing the dimension of the feature vector to 1024, the deep CNN is trained (to predict the binary code) by set neuron values to 1 if the threshold is 0.5 and 0 for else. Then the proposed deep CNN can remove the redundancies feature vector. [46] proposed cancelable biometric-based feature random projection to protect the template data against the Attack via Record Multiplicity (ARM), when the adversary may succeed to obtain multiple transformed templates from different applications to retrieve the original feature vector, which is critical to privacy and identity requirements. The basic matrix is connection with local feature slot to generate the key that is discarded after the use.

A valuable privacy-preserving research [47] proposed an authentication biometric key agreement based on cancelable biometrics. The proposed scheme integrated fuzzy commitment and Elliptic Curve Cryptography (ECC) cipher to guarantee the security of users' bio-templates against cybercrime thefts. the scheme is utilized the Random Distance Method (RDM )to generate non-invertible templates by using a random grayscale salting matrix that is added to the original feature vector values, then performing the median filter to divide each vector into two equal-size vectors to get the pseudo-biometric template.

In addition, [48] proposed protecting the transformed iris template by using ordinal ranking after XORed the user-specific string with the IrisCode string. Another proposal by [49] is to get better performance by enhancing Index First One

(IFO) hashing for iris templates. The binary confidence matrix considered the variation in noisy iris Biometric Template Protection (BTP) systems. the Fully Connected Architecture (FCA) and Bilinear Architecture (BLA) are used by [50] to hash a binary vector template. The proposed framework based on Deep Neural Networks (DNN) was tested on 50 subjects only. The author in [51] proposed a Multi-Instance Cancelable iris authentication Deep Learning (MICBTDL) and used a CNN (triplet loss) and trained to differentiate a positive image from a negative on IITD and MMU iris dataset images. Both [52] and [53] proposed to encrypt the Iris Codes using classical cryptography algorithms.

Table I presents the summarization regarding CB systems and provides an overall idea about the recent direction of authentication-based CB. Ten recent works have been summarized based on four categories which are: “purpose of the research”, then “proposed methods”, “Bio-Feature”, “Bio-Dataset” and finally “**Performance**” measurement of the research that has been used in the experiment.

TABLE I. SUMMARY ANALYSIS OF THE RECENT CB SCHEMES

Ref.	CB Scheme	Bio-Features	Bio-Dataset	Performance
[37]	Hill Cipher	Face Palmprint	Face={ORL, Indian Face, Yale} Palmprint={PolyU, CASIA}	EER
[49]	Confidence matrix	Iris	CASIA Iris v4-interval	EER
[45]	Random projection	Face	CMU-PIE, FEI, Color-FERET	GAR
[46]	Feature-adaptive random projection	Fingerprint	FVC2002 DB1-DB3 and FVC2004 DB2	EER
[52]	Encryption (3DES+Twofish)	Iris	CASIA-IrisV3	GAR
[47]	Random distance method (RDM)	Fingerprint Face Iris	Fingerprint={FVC2006} Face={CASIA-Face V5} IRIS={IRIS(LWIR)}	FAR, EER, ROC communication computational
[53]	Encryption (AES)	Iris	CASIA-IrisV3	EER
[48]	Local rank	Iris	CASIA Iris v3-interval	EER
[50]	Deep neural networks Integration	Face Iris	Face={ Casia-Webface} Iris={CASIA-Iris-Thousand}	GAR
[51]	MICBTDL	Iris	IITD+ MMU	EER

### V. NON-BIOMETRICS AUTHENTICATION METHODS

Previous literature demonstrates authentication-based cancelable biometrics to account for authentication mechanisms and the current methods to enhance the pattern recognition of biometric features.

In this section, non-based biometrics authentication methods have been summarized according to the methods for generation and distribution. Also, tabular evaluation matrices have been summarized in each section. These evaluation matrices provide a structured technique for the outcome of the metrics and the criteria of the proposed methods. In OTP Authentication Procedure The server customer or application (Object/Service) as a client has to register an online account and provide the mobile number and other required information

during the registration process so that online login to the bank server (as an example) is successful (Fig. 6).

1) The server exchanges the OTP code with the registered mobile number, email, or application, and the code is used as a second layer of the authentication mechanism for any transaction achieved through the following steps [10], [54].

2) The client requests a transaction to connect with the server using his credentials username and password.

3) The server checks the client validity and if successful then initiates the OTP generation algorithm.

4) The output of step ii should be encrypted using cryptography algorithms (Symmetric or Asymmetric) or hashing then forward to the client.

5) The client's application decrypts the obtained OTP if it is encrypted on the server side.

6) The client's application gets the OTP code in step 4 and enters it manually or automatically in the text box of the bank application.

7) The server receives the code from the client then checks the comparison condition if success then completes the transaction during the timer period. The server should acknowledge the client for the verification of the transaction status (success or failure).

Steps 2 and 3 being optional are recommended according to NIST special publication 800-63B privacy requirements [55] against various attacks such as birthday, offline/online guessing, impersonation, rainbow, a man in the middle, key-recovery, and collision types.

Fig. 6. One-time passcode workflow.

### B. One-Time Passcode Generation Methods

The first attempt to overcome the weaknesses of finite OTP generation for authentication was by [56] using a hush chain. The author in [57] proposed a model to generate OTP. The model addresses the weaknesses of the Lamport method when finite generation OTP and used the hash chain function. However, the bottleneck of the proposed model is the server generates an unlimited OTP code for each client login. The author in [58] proposed a model to overcome the weaknesses of the OTP model of Lamport using a Merkle tree an L-divided

tree (with the binary tree), and the hash chain. The author illustrated the proposed model examples without implementation. A model was proposed [59] for generating the OTP using the following steps. The first step was based on the certification authority's client login details user name and password and converting it to 8 bits. The second step converted the message's length to 8 bits. In the third step, a binary code is converted to decimal base (CB2D) was used to convert 16 bits ( $2 \times 8$  bits) to base decimal, the conversion result is two 3 decimal digits. Fourth step used 3 Vedic multipliers to get the OTP multiplied by two decimal digits. The proposed OTP generation method used the user name and the password credentials without encryption.

A novel method was introduced [60] for improving the verification in mobile banking using lightweight and solid OTP generators. The OTP generation model is based on three client factors (6 digits of the last transaction date DD: MM: YY. The last transaction amounted to 16 digits, wherein three login characters of the password were selected. The client must have an SD card containing initialization vectors (IV) set of 256 bits, AES-256-XTS encrypted random keys, each key of 256 bits was divided into two portions, each one containing 128 bits on the user's side and the other half on the server side. Then it was XOR'ed followed by concatenating and hashing together via the SHA 256 for using the AES-256-CBC to encrypt the OTP. Afterward, it was sent to the client via the internet to the mobile device of the client to make a comparison of the transaction is succeeded. All the used 256 keys were stored in the hardware component SD Card with the bank client. Later, the OTP was sent only through the internet only when the client application initiates a session of user online login. OTP length is 64 digits only, without considering using case-sensitive characters like uppercase letters or symbols, charset sizes are medium (0-9, a-z).

An OTP generation scheme is proposed by [31] for authentication purposes. The first step encrypts a randomly

selected image stored in the server database using Bitwise Masking Alternate Sequence (BWMAS). A two-step authentication model was proposed to generate the OTP on many intermediate operations. Then in the second stage, OTP was sent by e-mail to the client. The researchers in [61] proposed an algorithm for the implementation of secure OTP generation. OTP was a mixture of the present time value of 3 digits from the login time (HH: MM: SS) to shuffle the hex and octal which is obtained via the back-end server-generated value random operation. This value is 32-bits in size, producing an 8-digit of number combination. Fixed length OTP of 8 digits only is obtained without including the small or capital letters as well as symbols, generating a complexity of  $232 = 4294967296$  combinations.

Table II elucidates the OTP generation using various schemes [59] [60], [31], and [61] including the proposed methods, initial data of OTP generation, encryption mechanisms, hash functions, delivery methods types such as email, SMS, Internet, and the authentication protocol.

### C. One-Time Passcode Distribution Methods

First, the client has to enroll in the first phase at the server for receiving the OTPs. In addition, the client must declare the procedure of distributing the OTP via his/her email or SMS, or some apps [57]. An approach was proposed [62] for online e-banking authentication using OTP. This approach provided a mechanism for the generation of an infinite and forward OTP utilizing SHA3 and SHA2 followed by the dynamical concatenation understandable by humans. An inimitable verification scheme was employed with a distinct initial seed for generating several OTPs on the users' mobile devices. This method showed superior performance compared to the existing authorization techniques. This is due to the eradication, during the authorization process, of cellular networks. The findings that are critical for online transactions have shown a high degree of success and efficacy in the verification and authorization.

TABLE II. SUMMARY ANALYSIS OF DIFFERENT EXISTING ONE-TIME PASSCODE GENERATION STUDIES

Ref.	Methods	Initial data	Cryptography	Hash Functions	Media	Authentication
[59]	CBCD and 3 *3 Vedic Multiplier	Client's User name and Password	No	No	Internet	MFA
[60]	The OTP generation model is based on client factors and then encrypted and hashed them and forwarded to the server-side as a 64digits length	selected three client factors: last transaction date DD: MM: YY, Last transaction amount to 6 bits, three login password characters	AES-256	SHA2-256	SMS	MFA
[31]	OTP is generated by applying Bit-wise Masking and Alternate Sequence (BWMAS) on selecting a random image stored at the server database Provided by Clients to generate numeric OTP.	Biometric Fingerprint	No	No	Email/SMS	MFA
[61]	Server-generated random value OTP would be a combination of the current time value of 3 digits from the login time to shuffle the hex and octal to that combined value. This value is 32-bit in size, which produces an 8-digit number combination	Current Time of login session HH:MM: SS	No	No	SMS	MFA

The OTP is sent via cellular data to the client, without using encryption methods to protect data privacy. Generally, the methods for the OTPs distribution are multiple and have their own merits. The business organization looks for a method of OTP verification distribution, especially via SMS and email. The OTP-based SMS is usually utilized for the users' login and password resetting. Several organizations particularly the financial sectors send the OTPs via SMS and email as an additional confirmation step for the users. The following modes are used:

- 1) *Email-Based*: The OTP can be delivered to the client through his/her Email [63].
- 2) *SMS Based*: The OTP can be delivered to the client through his mobile phone over-the-air SMS or delivered to an OTP application [63].
- 3) *Push notifications*: These can be sent to the client's registered smartphone for out-of-band authentication which could not be intercepted at the point of password entry when the client approves the request. Then, the authentication application informs the server that the client is confirmed. The authentication-based push notification provides a higher level of security since it addresses the most important SMS and email shortcomings, such as vulnerability to replay attacks. It is even faster than typing in a passcode [64], [65].
- 4) *Hard copies*: Some banks provide clients with hard-printed OTPs for each transaction [63].

Many methods are used to distribute an SMS or email wherein each has its weaknesses. The OTP distribution schemes are simpler for the companies because of the abundance of the SMTP to SMS channels. No setting is required for the clients wherein they just request a code to log in. The ease of administration related to the delivery of OTPs via SMS and email is frequently utilized, enabling temporary access. Nonetheless, OTP is MFA which is something that the user knows, and the mobile devices (phones, computers, smart-watches, tablets, and so forth) something that the user is not essentially true.

Using email and SMS delivery protocols (something one has) the OTP is sent to the user. Presently, several phone numbers can be cloned which affects the authentication of the client identity [66], [67]. In this regard, email phishing, spear-phishing, and scammers can develop ways that entice the

clients to enter a username or password and follow a suspicious link or download malware applications. Thus, visiting certain authentic-looking websites permits the adversary to steal the credentials or gain control of the users' devices [62], [63].

The OTP overcomes the shortcomings of the SFA like traditional password because it's not reusable and it can be distributed through the Out of Bound (OOB) channel as well as not vulnerable to replay attacks. Therefore, it's more secure to transmit an OTP over a push notification. Due to the rapid adoption and fast growth of push authentication, it offers a low-cost, easy-to-use, and secure substitution for email and SMS distribution methods [68].

Table III shows the comparison of main property qualities such as security, message size, feedback possibilities, response time, and cost among SMS, email, and push notifications. It is argued that push notification is the best method that could be used for OTP distribution due to the low cost, high speed, and more secure than other methods of OTP distribution. While in [69] the authors proposed a model to improve the OTP distribution security using Elliptic Curve Cryptography (ECC) and Iris for key generation. The model encrypted the generated OTP and sends it as ciphertext, not as plain text. The use of ECC with the iris code-based public key could encrypt the OTP successfully and send it through email. The author in [70] utilized lightweight cryptography and text steganography to encrypt and hide OTP to send the stego text as an SMS to the mobile application of the client. This method was used to protect the delivery of OTP SMS where the OTP was encrypted and steganography ciphering was exploited for hiding it in a standard SMS. This process used the Date of Birth (DOB) of the customer with the secret four digits of PIN only as a key to encrypt and decrypt the OTP. The author in [71] proposed a mechanism for protecting OTP delivery from many types of attacks, especially smartphone Trojans. A virtual dedicated channel was used to secure SMS-based OTPs against cell phone Trojans stealing SMS. By assigning a port to transmit and receive OTP via TCP/ UDP from the service provider, and protect the mobile application's storage files internally.

Table IV enlists the secure end-to-end distribution of OTP [69], [70], [71] based on many categories such as proposed methods, encryption mechanisms, hash functions, delivery methods types (for example email, SMS, internet), and authentication protocol.

TABLE III. COMPARISON OF MAIN QUALITIES IN ONE-TIME PASSCODE DISTRIBUTION STUDIES

Parameter	SMS	Email	Push Notification
Security [20]	Medium	Low	High
Message size [72]	Limited (140 Bytes)	Long	Moderate (according to app settings).
Feedback Possibilities [73], [74]	Yes (If the sender is Known)	Yes (If the sender is Known)	Yes (according to app settings).
Response Time [73], [74]	Medium	Low	High
Usability of intuitive user interfaces[75]	Medium	Low	High
Cost [76]	High	Low	Low

TABLE IV. SUMMARY ANALYSIS OF DIFFERENT ONE-TIME PASSCODE DISTRIBUTION STUDIES

Ref.	Methods	Initial data	Cryptography	Hash Functions	Media	Authentication
[60]	Traditional OTP Generation and Distribution	Numeric (0-9)	No	No	SMS	MFA
[69]	Secure OTP distribution	Iris of client	Elliptic Curve Cryptography (ECC)	No	Email	MFA
[70]	Secure OTP distribution	Client date of Birth DOB	Steganography fixed key, lightweight Feistel cipher	No	Internet	MFA
[71]	OTP distribution	Assign a port to receive OTP in the user client's mobile phone	No	No	Use a virtual dedicated channel from ISP	MFA

## VI. MAIN CHALLENGES

The combination of new solutions is always challenging for both developers and managers for the implementation of a strong identity in usability and resistance against known attacks [5]. So it is worth mentioning that issues for authentication must be tackled regarding the other digital identity management mechanisms in authentication.

### A. This Paper has Concerned the MFA Regarding the Cancelable Biometrics Approach and Shows the following Challenges

1) Most of the biometric databases vary in type and version while low accuracy when in real use, beside train biometric recognition systems through machine learning or deep learning results in varying accuracy metrics.

2) Choosing a set of biometric features to design appropriate authentication systems is a critical challenge in designing MFA based on multimodal cancelable biometrics.

3) Low user adaptability due to additional hardware requirements for sensing and processing persists despite smartphone applications.

4) Concerns increase for biometric data leakage despite cancelable biometric requirements.

5) Difficulties in pattern recognition due to the noise, or the variations of large intraclass of transformed templates.

### B. In the Second MFA Approach (Non-based Biometrics)

The main challenge of non-based biometrics is explained in [77] where the impossibility of distinguishing the correlation between the ideal-random and pseudo-random sequences in the absence of unlimited computational capacity. While in some cases the clients may be unable to access the OTP codes offline or without a network (for example in an airplane during international journeys) [78].

In addition to the growth and success of session hijacking attacks, research on both approaches did not concern this type of attack. The surveyed studies did not concern with its proposing of authorization and accounting mechanisms, most of them were simulated without paying attention to the impacts of decision-making (only pattern recognition enhancement) by the identity provider based on the backend database and customer account data as well as the target resource, because the accessing to a particular resource must direct the matcher according to the conditions of access controls policies to direct or redirect the accessing of one or several resources.

Circle of verification and loop of authentication, this means without a controller or police (based biometric or non-based biometric) in algorithm design, the enrollment and verification of the client identity will repeat and will call or invoke the system resources (objects, algorithms, procedures) that require access from one moment to another and between one object and another, and this is costly due to consume the two parties of the communication system resources. While the researchers in [79] pointed threat of involving third-party authentication, especially when this requires the customer's biometric data. Also, the research [79] indicated one of the main challenges today is to ensure that the customer's biometric data is destroyed and not used again (no copy of such biometric data on the server side), and to confirm that to the customer.

## VII. CONCLUSION AND FUTURE DIRECTORIES

The digital identities and MFA are intensively combined in the context of advanced information communication technologies. This paper comprehensively reviewed various MFA in two approaches biometric and non-biometric mechanisms besides pointing out many standard protocols. Effective non-biometrics MFA schemes are required to combine many factors and protocols to secure the data distribution in an end-to-end. Cancelable biometrics approaches are proposed to transform the templates like iris to be difficult to obtain the original traits but still suffer from difficulties to maintain the tradeoff between security and performance while supporting effective biometrics recognition as shown in the literature. Also, we presented different performance measures used for cancelable biometrics in both identification and verification. Now, we also draw attention to future directions in cancelable biometrics. The readers may look for propose new mechanisms to transform the templates and maintain the recognition performance while protecting the privacy of biometric data. The employment of deep learning in CB requires a large number of training samples. In some cases there is only a single trait for each subject is available that imposes limits and constraints on the training. However, the future of MFA appears boundless with absolutely secured data exchange over the internet and cellular. Concisely, the ongoing extensive research activities in the MFA are likely to transform many facets of the forthcoming evolution and continue to be more secure.

# Arabic Dialogue Processing and Act Classification using Support Vector Machine

Abraheem Mohammed Sulayman Alsubayhay, Md Sah Hj Salam, Farhan Bin Mohamed  
School of Computing-Faculty of Engineering, Universiti Teknologi Malaysia (UTM), Johor, Malaysia

**Abstract**—Text classification is the technique of grouping documents according to their content into classes and groups. As a result of the vast amount of textual material available online, this procedure is becoming increasingly crucial. The primary challenge in text categorization is enhancing classification accuracy. This role is receiving more attention due to its importance in the development of these systems and the categorization of Arabic dialogue processing. In the research, attempts were made to define dialogue processing. It concentrates on classifying words that are used in dialogue. There are various types of dialogue processing, including hello, farewell, thank you, confirm, and apologies. The words are used in the study without context. The proposed approach recovers the properties of function words by replacing collocations with standard number tokens and each substantive keyword with a numerical approximation token. With the use of the linear support vector machine (SVM) technique, the classification method for this study was obtained. The act is classified using the linear SVM technique, and the anticipated accuracy is evaluated against that of alternative algorithms. This study encompasses Arabic dialogue acts corpora, annotation schema, and classification problems. It describes the outcomes of contemporary approaches to classifying Arabic dialogue acts. A custom database in the domains of banks, chat, and airline tickets is used in the research to assess the effectiveness of the suggested solutions. The linear SVM approach produced the best results.

**Keywords**—Dialogue processing; Act; Arabic language; linear support vector machine; without cue

## I. INTRODUCTION

Arabic is recognized as a challenging dialect by non-native speakers of the language in the field of automated language processing. The recognized dialogue acts provide accurate information when the user asks questions and remain silent are typically utilized as an input to the Dialogue Manager component to assist the system decide what to do next. Depending on the dialogue system domain, the Dialogue Acts taxonomy varies [1]. To identify speech acts in dialogues, a variety of techniques have been employed, ranging from rule-based approaches to deep learning and machine learning techniques. To overcome the lack of appropriate training data, novel language interpretation methods have been created [2].

The area of artificial intelligence is employed rarely. Several computer researchers and scientists are engaged in the humanities in order to create computer programmes that accurately scan Arabic writings and convert them into digital formulas. This is because Arabic and artificial intelligence are closely related fields of study. With the advent of new

approaches like Intersent, Elmo, wordszvec and Use, AI was impacted by the introduction of some sophisticated methods for presenting the semantic meaning of texts [3]. In text extraction and processing, conventional ML techniques are typically employed. These techniques include Naïve Bayes, Stochastic Gradient Descent (SGD), and SVM with a linear kernel. The STS problem is addressed using these techniques. Utilizing statistical-based, string and character-based and distance-based similarity metrics, several features are extracted and utilized [4]. The several perspectives for a specific speech sound have typically been represented by statistical methods like Gaussian mixture frameworks [5]. These methods can be employed in a variety of tasks since they are in fact rich in mathematical techniques.

The simplest language communication unit, or dialogue acts (DA) are those that convey the intention of the speakers. Automated dialogue act identification is a crucial indicator for many activities, including subject detection, machine translation, summarization, dialogue systems and human conversation interpretation. Annotation and segmentation are the two key subtasks in dialogue act detection [6]. These two phases can be completed separately—segmentation comes first, then annotation is joined in a single stage. In the context for recognizing dialogue acts, the annotation task is crucial. A label describing the user's intention for every segmented statement during the dialogue is assigned. ML techniques have been tested in studies to detect new DAs. Linear methods and vector-based methods are examples of supervised modeling techniques that are often employed [7]. Limited vocabulary limits are utilized to achieve high speech recognition rates. In reality, it is thought that this outcome is adequate for the majority of voice activation devices to be implemented. As a result, both the learning time and error rate are gradually reduced. Additionally, this rate is plainly erratic and is influenced by lexicon and language. Nevertheless, the creation of advanced ASR systems with increased speech recognition rates has emerged as an intriguing topic of interest for all academics working in the field of speech recognition. In fact, a number of categorization and parametric techniques have surfaced to complete the task. Various categorization techniques, including Gaussian mixture model, Decision tree, machine learning via ANN, K-Nearest Neighbor, Dynamic Time Warping (DTW) and HMM, have been utilized in a number of publications for isolated-words identification systems [8]. But these are inefficient and consume time while attaining the results.

In the Speech Recognition area, computer scientists provided particular consideration for creating effective

techniques to recognize spoken words. Because of the considerable advancements made in this area, Automatic Speech Recognition (ASR) technique is widely utilized. Voice recognition technology called ASR has been designed to assist individuals to communicate better with one another. By utilizing these ASR technologies, it is possible to overcome the challenges imposed on the world's various dialects. As a result, a number of strategies have been developed in the ASR field. An effective method for dialogue processing is the Support Vector Machine [9]. Support Vector Machine (SVM) is used as an estimator of posterior probabilities to improve the performance of identification systems as it has a strong predictive capacity and discrimination. They also have a structural risk minimization (SRM) foundation, where the goal is to create a classifier that minimizes a limit on the predicted risk instead of the empirical risk [5]. Segregating classifier of SVM is considered to have a few practical applications. An algorithm of machine learning for binary categorization is SVM categorization [8]. For multiclass assignments in the real life, it is necessary to change the system's decision-making portion.

SVM is initially intended to function in situations when data has only two classes. In other terms, binary classifier issues can be solved using it. The goal of the multiclass SVM issue is to label cases by selecting labels from a limited number of various elements. Reducing the single multiclass issue into many multiple binary classification issues is the conventional method for utilizing SVM to solve this issue. Building one-versus-all classifiers and selecting the class that correctly categorizes the test examples with the largest margin of error is the most widely used strategy in practice [10]. The presented method first transforms the reader's sound waves into Mel-Frequency Cepstrum Coefficients (MFCC) features before generating a features vector matrix. To train the modified SVM-based technique, portions of the retrieved features are utilized. The trained SVM performed really well when tested twice with the other portion of the collected information. The suggested SVM-based technique was examined employing real-world data. When assessing and contrasting the findings, the tests had very good outcomes. Utilizing the identical datasets of gathered waveforms, the outcomes of the presented SVM-based technique were evaluated with those of other methods for comparison study. The developed SVM-based method surpasses competing methods in terms of accuracy.

**Background:** The situation is complicated, nevertheless, by the degrading language used in speeches delivered by professionals. As a result, it becomes vital to create new tools to aid in the comprehension of flawed Arabic discourses. Speech that is illogical will then be automatically corrected [11]. In Arabic, there are four divisions: Model Standard Arabic (MSA), which is used in newspapers, books, broadcasts, documentaries, formal situations, or when the reader or audience is from a different nation of Arabic, and Dialectal Arabic (DA), which is a dialect of everyday experiences, are all still in use today. Ancient Arabic is no longer in use [12]. In formal situations like journalism, presentations, and courtrooms, the MSA is widely trained in schools and colleges. All countries that speak Arabic

acknowledge MSA as their primary language. Additionally, people frequently use their own languages in everyday conversation. These languages are taught in schools, but there is no organized written record of them. Arabic dialects have extremely distinct morphology, vocabulary, phonology, and syntax from MSA. Dialectal Arabic is the language that is organically spoken in daily life (DA). It varies from one country to the next and can be seen within a country [13]. The user's inquiries and silence are often used as input to the Dialogue Manager component to help the system decide what to do next. Recognized dialogue acts give accurate information when the user asks questions and remains silent.

The remainder of this strategy is distributed into the succeeding divisions: Section II presents the pertinent works and provides a comprehensive analysis of them. Section III describes the problem statement. A thorough review of the proposed method and analysis for the prediction of act classification is provided in Section IV. The results of the experiment are given, examined, and in-depth assessed in Section V, along with a comparison. Finally, the paper is concluded.

## II. RELATED WORKS

The paper [14] utilized DL-based method to show how the meaning of the original and suspect reports was identical. By projecting each potential investment onto its neighbors, the word2vec method did in fact identify the pertinent information. Sentence relating to various could then be produced by combining the acquired dimensions. CNN was then employed to gather more environmental data and determine the level of measuring the similarity. Due to the dearth of accessible to the public material, an edited collection was created using the skip gramme approach. It performed better when substituting an original term with one from language skills that was most comparable and belonged to the same grammatical class. In terms of precision (85%) and recall (86.8%), the work improved efficient environmental connection recognition between Arabic materials compared to earlier studies. for measuring semantic similarity and document modelling, CNN model with various statistical regularities was utilized. A word2vec-based Arabic paraphrased corpus was created for the trials due to the dearth of Arabic paraphrased materials that were accessible to the general audience. Every word from the OSAC source corpus was replaced with its vocabulary counterpart that was the most similar and shared the same grammatical class.

The automatic comprehension of Arabic dialogues for the Egyptian dialect at the utterance level is a challenge that addresses in the paper [15] utilized a machine learning approach, called YOSR. The extractor has been tested on a dataset of impromptu conversations and instant messages for the Egyptian dialect. The results from the YOSR classification are really encouraging. These are the first outcomes for comprehension of the Egyptian dialect that have been recorded, as far as aware. As a viewpoint, we intend to enhance YOSR by including standard call-center regarding the service, context-based characteristics, regional phrase modifications, and morphological information such the initial verb form and Lemma. In order to enhance the categorization

outcomes, also plan to expand the "JANA" dataset for training. However, the efficiency of the method is comparatively slow down the process.

Modern Arabic natural language processing, or ANLP solutions are being developed using machine learning techniques. ML algorithms are commonly employed in NLP because to their high level of accuracy regardless of how strong the input signal is and how simple they are to utilize. On the other hand, the method used in ML-based ANLP implementations entails a number of phases. This evaluation clarifies the concept in detail, illustrates how ML techniques were used to develop these tools, and identifies well-liked ANLP techniques. The paper [16] covers the importance and specifications of ANLP as well as the characteristics and challenges of the Arabic language. Arabic sentiment expressions in tweets can be difficult to distinguish in sentiments categorization software. The complexity of the Arabic script and the unorganized nature of Twitter usage may both contribute to this problem; however, Textual data usability evaluation still needs improvement.

The paper [17] utilized DNN framework was used for sentiment classification, text translation, and text analysis. To text categorization are assessed using a sequence-to-sequence encoder-decoder paradigm, which would consist of NN trained concurrently on outputs and inputs. DNN make use of huge datasets to enhance their accuracy. These linkages are supported by the method, which by identifying textual focal areas, may also be able to manage extensive texts more successfully. This work has re-implementing the basic text useful when analyzing and adapting the sequence-to-sequence structure to Arabic because Arabs have never seen the usage of this approach for text summarizing. About 300,000 elements make up the data set, and each one comprises the title that corresponds with the corresponding article information. After applying standard summarizing techniques on the prior data set, the results are contrasted using the ROUGE index. However, the volume of the AHS information created and raised to the Gig word collection, but it is not much larger than the CNN/Daily Mail database. Additionally, it might make use of other strategies that would be advantageous in the sequential design, such as See et AI demonstrations of a comprehensive approach that uses a various performance vector. The perfect place to concentrate on would be trying to infer new designs that are useful with this vocabulary knowledge in multiple languages, considering that Arabic is a particular textual phrase read from right to left. The research does not take the possibility of increasing the data set into account.

In [18], used an Arabic Alphabet Sign Language Recognition System that is vision-based. Four distinct stages make up the process. The technique can be used with three possible database types: data with hands bound and an alongside a dark tiled wood, information with bare hands and a white base, and data with face buried in a darker-collared glove. By using one of the offered methods in AArSLRS, a hand is first removed from the image and separated from the background before the hand features are eliminated using the search technique that was employed to eliminate them. For the classification of the 28-letter Arabic alphabet using 9240

pictures in this work used methods of supervised learning. To focused on categorizing the 14 special characters and using Quranic sign language to sign the first verses of the Qur'an. It has been proven that picking a resource allocation problem is the optimum choice and that the neighborhood k value of the K-mean clustering algorithm affects rating dependability. However, the method needs more time for the processing phase when compared with other methods.

For an experimental tests of the connection between traditional in the paper [19] employed SR corpus compensation approaches (feature vectors, data selection, sexual identity acoustic frameworks, and dialect-dependent/register-dependent variance across Arabic ASR samples). The first interaction examined in the paper was that between intermittent syntax variance and auditory tracking performance. By removing speakers with inadequate teaching data and switching to grapheme-based acoustic models instead of phone-based ones, discrete specific language difference can be rewarded for. The latter method also helps to make up for poor capture performance, which is further made up for by removing delta-delta acoustic features. Together, the three methods decrease Word Error Rate by 3.24 percentage points to 5.35 percentage. Alteration in the perfectly alright acoustic speech sounds from each phoneme in the phrase is the second feature of regional and registration diversity to be taken into account. Building way of predicting and dialect-specific algorithms contributes to significant reductions in WER since empirical findings show that sexual identity and language are the primary contributors to diversity in speech. Cross-dialect investigations are carried out to gauge how far different Arabic dialects are in terms of the acoustic variations between phone models needed for each of them.

Natural Language Understanding has been vastly enhanced by DL methodologies such as word representations and DNN architectures. This [20] work provides a method for Arabic home automation using DL approaches for text categorization and text categorization recognition. In order to achieve this, to provide an NLU component that can be additionally connected with ASR, a dialogue administrator, and a natural language generator component to develop a fully functional making the change. The procedure of gathering and categorizing the data, constructing the purpose classification and concept extraction frameworks, and eventually the evaluation of these techniques against benchmark datasets are all included in the study. The benchmark results showed that the LSTM effectiveness, with an F-Score of 92.0, was marginally superior to the CNN achievement for both intent classification techniques. The paper employed a hybrid representation of word representations and personality language models, which is then fed to a Bidirectional LSTM network, to retrieve the user objectives and purposes from the information. A high F-Score of 94.0 for the BiLSTM with the Char Embedding's test suggests that its efficiency is extremely comparable to the most recent English Named Entity Recognition benchmarks. However, to create an undertaking dialogue system, the Natural Language Understanding module can be combined with automatic speech recognition and natural language generation modules.

### III. PROBLEM STATEMENT

This issue may be exacerbated by the intricacy of the Arabic script and the disorganised Twitter usage. The evaluation of the usability of textual data still needs work, though. The potential for expanding the data set is not considered in the current research. When compared to alternative ways, the processing step of the current method takes more time. To determine how diverse Arabic dialects are from one another in terms of the acoustic differences between phone models required for each of them, cross-dialect examinations are conducted. However, the Natural Language Understanding module can be integrated with the automatic speech recognition and natural language creation modules to form a complex dialogue system. To develop a classification model for sentential act prediction, the existing technique used a selected group of features extracted from annotated utterances and applied in "YOSR", an SVM technique based on ML. SVM designs ought to be used as a result for improved processing.

### IV. METHODOLOGY

The suggested approach is based on Arabic conversation processing and employs a machine learning algorithm to classify Acts. The contact among the operator and clients in various industries is the subject of the study. The data was gathered from the Jana Corpus in three distinct industries, including banking, travel, and chat. The research's major objective is to establish a connection with the speaker and operator and help them comprehend the dialogue, whether it's a request, an obligation, or something else entirely. Previous

studies have used a variety of algorithms, including deep learning, gradient boosting, convolution neural networks, and natural language processing, but they have not been able to achieve higher accuracy rates. As a result, the research focused on interpreting Arabic dialogue without cues and makes use of chatbot technology and machine learning algorithms to increase productivity. The research is conducted in the stages listed below, and Fig. 1 shows the flow diagram based on the suggested method.

#### A. Dataset Collection

The data collection used in this study was compiled from a variety of sources, including chat, banks, and flights. The vast amount of material on the website is useful for any chatbot application. The CAMEL tool module for Python was used to parse Arabic content and retrieve data. To address a variety of issues, researchers present CAMEL Tools, a user-friendly Python toolkit for Arabic and Arabic dialect pre-processing, morphological modelling, dialect recognition, text categorization recognition, and sentiment analysis. The application programming interfaces (APIs) and command-line interfaces (CLIs) offered by CAMEL Tools cover these functions. This also processes Arabic dialogue using data from chat, planes, and banks. The bot can practise on a dataset, which is a collection of different input expressions and outputs. This effort will allow Arabic programmers to use more dialects of Arabic. The gathered data were split into training and testing samples, with training data making up 70% of the samples and testing data making up 30% of the samples. The sample's division for the testing and training processes is shown in Table I and Fig. 2.

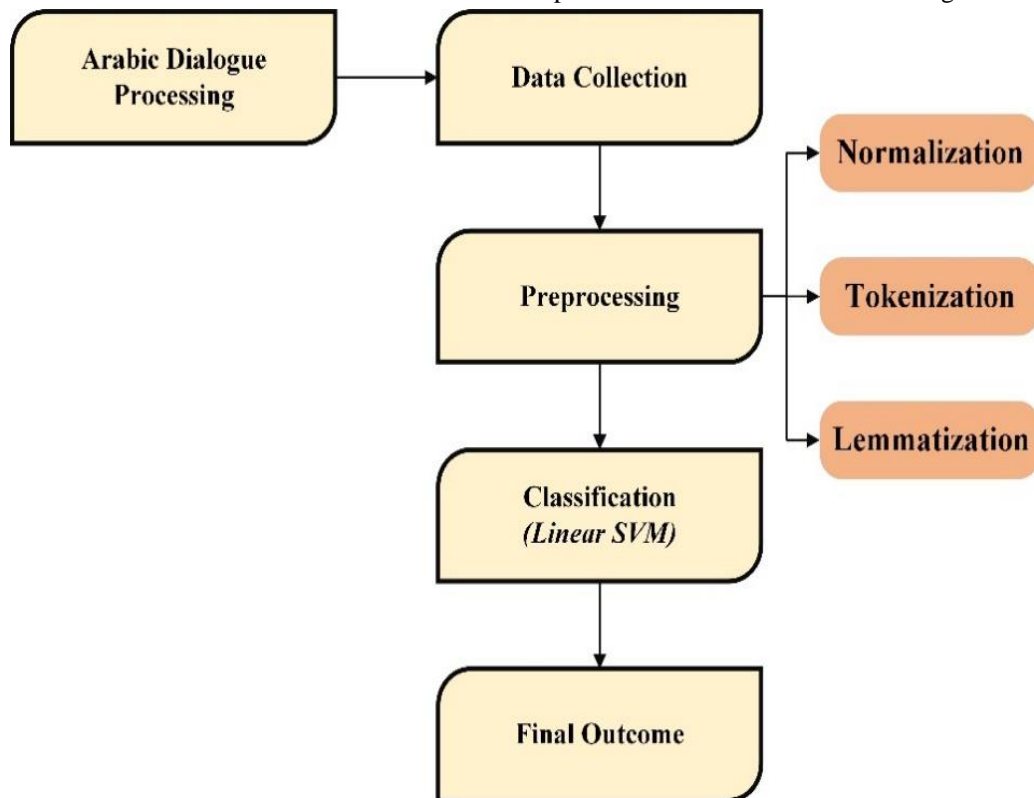

Fig. 1. Proposed method.

### B. Preprocessing

Preprocessing's function is to add morphological and other additional context to the lemmatizes (and other following elements') input in order to simplify the lemmatization process. The preprocessing performed by the lemmatization technique is quick and light in comparison to cutting-edge tools. Part-of-speech tagging, performed as a quick machine-learning-based sequence labeler, is used to first enhance the tokenized input text. A very basic word segmented component is used to progressively segment it, reducing the complexity and ambiguity of the words. The procedure's simplicity, which is described in full, can be attributed to the POS tagger's output of a wealth of morphological features, which makes word segmentation essentially easy [21].

In order to make the lemmatization process simpler, preprocessing's role is to add morphology and other contextual info to the lemmatizes (and other following sections') input. The algorithm performs tokenization, function word elimination, and lemmatization for each article in the database. There are numerous Arabic dialects. The analysis of dialect and vernacular terminology follows. Assessments are often written by researchers in their original tongues. Depending on the dialect, they use different terms to convey the same meaning. The solution to this problem was to create and use a dictionary of dialectical terms and their equivalents in standard Arabic [22].

### C. Morphology Analyzer

Morphological analysis is the first stage of text preparation. Breaking down morphologically complicated words into their individual morphemes is known as morphological analysis, also known as analysis of structures (word meaning parts). The morphological analysis of these phrases is then carried out using the Alkhalil analyzer. As a consequence, researchers are provided with all potential lemmas and associated morpho-syntactic information for each individual word in the text that has been analysed out of contextual [23].

### D. Normalization

Experts in Arabic dialogue processing typically employ orthographic normalization as a fundamental technique with the goal of reducing data noise. This is true whether the intention is to produce parallel texts for machine learning, information retrieval data, or computational linguistics text. Examples of normalizing include Tatweel elimination (an effort to eliminate the Tatweel sign), Diacritic removal, and alphabet normalization (variant forms to one form conversion) [24]. The tokenization procedure should become more confusing at this point even if these normalizations would help us in the search or discovering phase. As an illustration, if Ta-Marbuta (ة) and Ha (ه) are normalized, the latter could be tokenized as a pronoun. Because of this, normalizations are treated as a stepping stone for querying, finding, and other operations in the research.

### E. Tokenization

Reducing the raw text into smaller, more manageable chunks is tokenization. It is not an easy problem to solve since tokenization is "closely related to the morphology". This is especially true for dialects like Arabic, which have rich yet complex morphologies. Flowing text is divided into tokens by tokenizers so that they can be processed further by

morphological transducers or POS taggers. The tokenizer recognizes numbers, word boundaries, clitics, multi-word phrases, and abbreviations. By doing this, the original text is divided into tokens, or words and sentences. These tokens support simulation techniques for various processes or contextual comprehension. Tokenization makes it easier to understand the text's significance by looking at the word order. Stop words are typically eliminated in the initial phases of tokenization even though there isn't however a defined list of Arabic stop words [25]. There could be several degrees of Arabic tokenization built, depending on how complicated the linguistic study involved is. Researchers worked with the Arabic grammar to develop three distinct strategies, or frameworks, for Arabic tokenization. In terms of durability, adherence to the modular concept, and ability to remove unnecessary ambiguity, these systems differ greatly from one another. The tokenizer uses white space and punctuation to distinguish among major tokens. However, when defining sub-tokens, the tokenizer needs more morphological information. This information can be provided either deterministically or in-deterministically by a morphology converter or a token forecaster. In the end, both main tokens and sub tokens are identified by the same token borders, which are denoted by the symbol "@" throughout the entire article. It is believed that separating the text into primary tokens using capitalization and white spaces is a straightforward strategy [26].

1) *Utterance feature*: The smallest speech unit in spoken language analysis is termed an utterance. It is a continuous chunk of speech with a distinct pause at the start and the finish. Oral languages typically, but not always, have silence as their boundary. Only their depictions can be found in written language; utterances are absent. The following Table II shows the extraction of utterance.

The utterances' meta data could be used to help with dialogue act classification. Additionally, the classification procedure could benefit from knowing what happened before the current utterance. Researchers made use of:

*Utterance Speaking Style*: The speakers or listeners of the current utterance may be able to discern the act of speech based on their speaking style. The act of "Service-Question," for instance, relates to the customer because they contacted customer service to ask about just one service offered, whereas the acts of "Other-Question" and "Choice-Question" relate to the control system since the operator chooses one of the services offered or asks the client's identity.

*Previous Utterance Act*: The classification may anticipate the act of the present utterance by understanding the sequencing of previous statements in the dialogue. For example, the act "Confirm Question" almost immediately follows the acts "Agree" and "Disagree".

### F. Lemmatization

The main element of our lemmatization strategy is a classifier that uses machine learning. It accepts  $m$ -word segments as input along with their matching POS tag, taking context (utterances and labels) into consideration. The inherent ambiguity of Arabic words without diacritics, whose meanings are often inferred by both individuals and computers from context, justifies the learning-based method. The introduction of new cases necessitates retraining the analyzers. Another disadvantage is that classifications, like the one from OpenNLP that the researcher utilized, frequently settle on an output variable that may or may not be accurate. In this case, additional NLP processing methods from the entire collection of probable lemmas may be able to yield reliable results. To solve these situations, investigators supplement the learning-based lemmatize with a dictionary-based lemmatize.

Fig. 3 illustrates the results of the lemmatization. The analyzer is first used by researchers to look at the words in the database's vowelized version. Once this has been done, researchers only save lemmas whose given lexical tags (clitics, root, and stem) coincide with the word's in-document clitics, root, and stem. The analyzer has located and examined the corpus's words. One potential lemma of the phrases was also discovered during this initial step's study into prospective lemmas. Following the identification of the likely lemmas for each word in the corpus, researchers asked two linguists to select the appropriate lemma from the available options. If the correct lemma is not given among the potential lemmas, the speaker provides the proper lemma to the phrase.

After being lemmatized, the text is again processed to provide the class feature. The class feature obtained in this process is split into final features and final labels, as shown in Fig. 4 and 5. Out from clean text, the first word is acquired, the first verb is filtered and the class feature is extracted, and eventually the class feature is again filtered to obtain the last feature and final labels, as shown in Fig. 4 and 5. As part of this procedure, the provided data were divided into training and testing phases, which were used to classify the data using machine learning.

### G. Multilayer outcome and Three Layer Hierarchical Classifications

A kind of machine learning called multi-output classification predicts many outcomes at once. When generating any prediction in multi-output classification, the system would generate multiple or more outcomes. In other classes, the system usually forecasts just one result. Three models—one for each layer—are primarily used in the construction of the suggested technique. As a result, researchers believe that proposed method of classification is quicker than existing classification and may be a more effective dialogue act classification model in real-time systems. The second distinction is that, while "this approach" does not change with the number of dialogue acts or classes, the variety of models does change when binary categorization is utilized, as in the researchers' strategy [27].

1) *Three layer hierarchical*: Traditional classification requires the construction of 26 categories, one for each dialogue act, as opposed to hierarchical structure categorization, which is separate. Every word stated in a discussion is communicated to succeeding tiers to determine the next course of action, which is the fundamental tenet of a hierarchical organization. The recommended method classifies dialogue utterances using a three-layer hierarchical framework. In the first layer, the utterance had already been assigned to one of the three fundamental categories—request, answer, or other. The speech was categorized into various discourse actions in the second layer based on its primary

category, which was established or categorized in the first layer. Question, turn management, social responsibility, social courtesy, argumentation, response, and discourse structure are some of them. Fig. 6 illustrates the hierarchical classification that may be made using the multi-class classification technique.

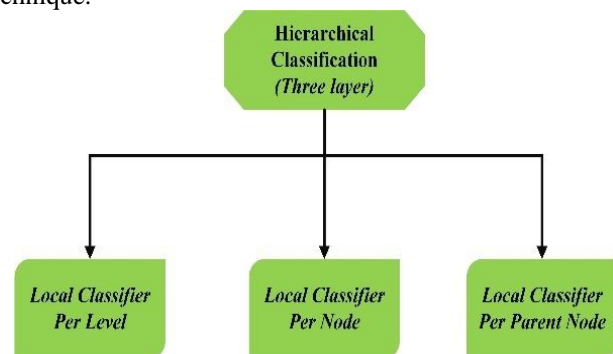

Fig. 6. Hierarchical classification.

Local Classifier per Level:

- For each level of the classification, there is a single multi-class classifier in this system.
- It is a trim, efficient categorization device.

Local Classifier per Node:

- Each node should have a binary classifier.

- Multi-labeling comes easy to this strategy.

Local Classifier per Parent Node:

- Every parent node receiving a single multi-class classifier.
- This is the most logical method.
- This strategy is far more frugal than the prior one.

#### H. Classification

The categorization process is conducted out following the lemmatization technique. In earlier studies, the majority of researchers classify the text using NLP, deep learning, SVM classifiers, gradient boosting, etc. Linear Support Vector Machine is utilized in this study to categorize the provided data. The given dataset was divided into test and training data, and the classification method was applied to the data.

1) *Linear support vector machine*: One of the most popular and well-known machine learning methods is called a support vector machine (SVM). SVMs are supervised learning models that are further used to evaluate and classify text data. SVM is also frequently used for regression evaluation and text classification. Research introduced and applied SVM in text classification and categorization in 1998. The basic purpose of the SVM training method is to create a model that classifies fresh documents into a number of predetermined groups. SVMs could also be employed as non-linear and linear classifiers. A relatively recent class of machine learning algorithms called Support Vector Machines (SVM) was first developed. Based on the data mining and machine learning theory's structure risk minimization concept, SVM seeks a decision surface to divide the training data points into two classifications and bases its judgments on the training examples that are chosen as the only useful components in the training dataset. The SVM Classifier is used for the classification of the input. The Stages convoluted in the procedure are:

- Stage 1: The necessary libraries are added.
- Stage 2: Including the necessary dataset.
- Stage 3: Data pre-processing is carried out.
- Stage 4: Preparing the training and test datasets
- Stage 5: The dataset is encoded to distinguish between labels, and values of 0 or 1 are assigned.
- Stage 6: involves converting text data to polygons. (The user may choose to utilize Term Frequency-Inverse Document Frequency TF-IDF)
- Step 7 involves utilizing SVM to accomplish machine learning.

According to the definition of natural language processing, this describes the conversion of any raw input into highly comprehending. Fig. 7 depicts the pre-processing stages that are involved.

Fig. 7. Preprocessing stages.

#### V. RESULTS AND DISCUSSIONS

Three datasets—the Banks dataset, the Flights dataset, the chat dataset is presented in the experimental findings. SVM, Nave Bayesian, and logistic regression approaches are used independently for each dataset. Moreover, the performance evaluation of different dataset for both multioutput classification and 3-layer hierarchical structure is also presented. Multioutput and local hierarchical classification apply to classifier 3-layer or 3 level structure (primary Categories, secondary Categories and dialogue act ) Primary Categories is (Request, Response, and Other) secondary Categories is (Question, Turn Management, Social Obligation, Social Courtesy, Argumentation, Answer, and Dialogue Structure. First classifier primary categorise next classifier second categories depends on the first classification and last act classification depends on first and second classification.

##### A. Performance Evaluation

Accuracy: Accuracy processes how accurately the system model operates. Usually, it is the proportion of correctly predicted observations to all observations. Accuracy is uttered in eq. (1),

$$A = \frac{\text{Total number of Dialogue act}}{\text{No of dialogue act classified} + \text{No of correct dialogue act}} \quad (1)$$

Precision: Precision is estimated as the number of correct positive estimates of the correct text. It is the fraction of precise identification of the text that is computed utilizing eq. (2),

$$P = \frac{\text{No of correctly classified dialogue act}}{\text{number of dialogue act classified}} \quad (2)$$

Recall: The recall is defined as the ratio of the entire true positives and false negatives to the right positive forecasting accuracy as shown in eqn. (3).

$$R = \frac{\text{No of correctly classified dialogue act}}{\text{number of correct dialogue act}} \quad (3)$$

F1-Score: The F1-score measurement combines precision and recall. Precision and recall are used to calculate the F1-score measure that is symbolized in eqn. (4).

$$F1 - score = \frac{2 \times \text{precision} \times \text{recall}}{\text{precision} + \text{recall}} \quad (4)$$

In the following research Arabic dialogue processing is carried out in machine learning algorithm and the accuracy is obtained and compared with the existing method.

### B. Logistic Regression

The following Table III displays the logistic regression's performance measure for the three parameters of recall, precision, and F1-score for various interactions, including Confirm inquiry, Correct, Disagree, Greet, Inform, misunderstanding sign, Pause, Self-introduce, Service response, Service question, Suggest, accepting request, Thanking, Other answer, other question Warning: Turn assignment.

TABLE III. ACT CLASSIFICATION AND PERFORMANCE MEASURE OF LOGISTIC REGRESSION

Act	Precision	Recall	F1-Score
Agree	0.93	0.80	0.86
apology	0.00	0.00	0.00
Closing	0.82	1.00	0.90
Confirm question	0.34	0.54	0.42
Correct	0.00	0.00	0.00
Disagree	0.63	1.00	0.77
Greeting	0.95	0.90	0.93
Inform	0.15	0.57	0.24
Mis-understanding sign	0.25	1.00	0.40
Offer	0.00	0.00	0.00
Other answer	0.59	0.62	0.60
Other question	0.61	0.86	0.71
pausing	0.38	1.00	0.55
Promise	0.00	0.00	0.00
Repeat	0.00	0.00	0.00
Self-introduce	0.76	0.94	0.84
Service answer	0.92	0.62	0.74
Service question	0.57	0.58	0.58
Suggest	0.00	0.00	0.00
Taking request	1.00	1.00	1.00
Thanking	1.00	1.00	1.00
Turn assign	0.67	0.85	0.75
Warning	0.10	0.75	0.18

### C. Performance Evaluation using SVM Multi-output Classification without Cue

Data are displayed without a cue in Table IV using local support vector machines. Without cues utilizing a support vector machine is explained in Fig. 8. For all datasets, data without cue using support vector machine classification produced better results in terms of recall, precision, accuracy, and f1-score for data without cue. Without employing cue data, a support vector machine was used to achieve an accuracy value of 0.83 and a recall value of 0.85.

A baseline system employing the suggested feature set even without hierarchical characteristics (the major category of the present utterance and the major category of the prior utterance) has been developed in order to assess the efficacy of a Local hierarchical classification in categorizing dialogue acts when used in discussions, flights, and banks. In terms of recall, F measure, precision, and accuracy macro averages, the proposed systems' performances are shown in the table and figure, with multi-output three-layer classification producing the largest result and highest result.

Tables V and VI depict the multioutput classification and local hierarchical structure to interpret data without cue. Performance assessment accuracy findings for bank datasets are higher utilizing Multioutput classification and the Hierarchical structure for supplemented data without a cue. Fig. 9 displays multioutput classification with enhanced data without a prompt. Fig. 10 illustrates data without a cue using a hierarchical structure.

TABLE IV. PERFORMANCE EVALUATION USING SVM

Performance Metrics	SVM Method
Accuracy	0.83
Precision	0.84
Recall	0.85
F1-Score	0.84

Fig. 8. Performance evaluation using SVM.

TABLE V. MULTI-OUTPUT THREE-LAYER CLASSIFICATION

Multioutput Classification				
	Accuracy	Precision	Recall	F1-score
<b>Banks</b>	0.96	0.95	0.95	0.95
<b>Chats</b>	0.96	0.95	0.94	0.94
<b>Flight</b>	0.95	0.94	0.95	0.94

Local hierarchical classification				
	Accuracy	Precision	Recall	F1-score
<b>Banks</b>	0.96	0.95	0.95	0.95
<b>Chats</b>	0.95	0.94	0.94	0.94
<b>Flight</b>	0.95	0.94	0.95	0.94

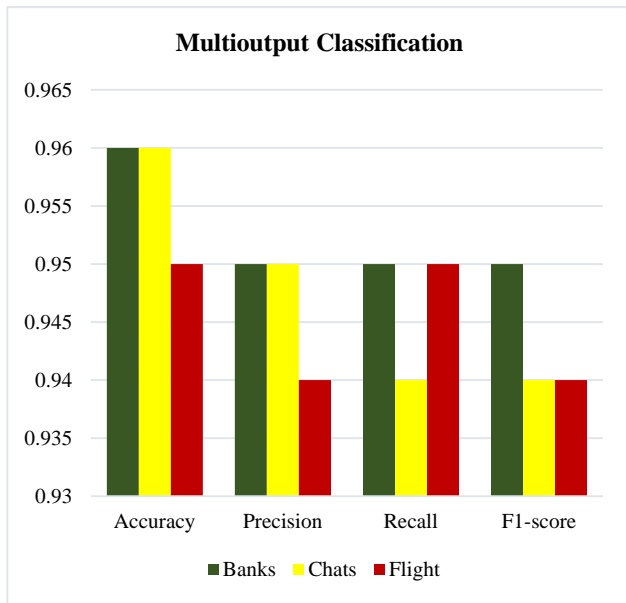

Fig. 9. Multioutput classification.

Fig. 10. Local hierarchical classifications.

#### D. Performance Comparison

Compared to the logistic regression approach shown in Table VII, the projected methodology support vector machine achieves a greater level of efficiency. Compared to performance assessed using the logistic regression method, the novel support vector machine produces greater accuracy which shown in Fig. 11. Using the support vector machine model, an accuracy level of 0.83 was achieved in this case. This suggests that a support vector machine is more effective at classifying acts than the logistic regression approach.

TABLE VII. ACCURACY COMPARISON

Method	Accuracy
<b>Logistic Regression</b>	0.72
<b>Linear SV</b>	0.83

Fig. 11. Accuracy comparison of logistic regression and linear SVM.

#### VI. CONCLUSION

The structure that supports Arabic dialogue processing has been modified for better machine comprehension. The proposed classifier was tested using the Jana corpus of real-world spoken dialogues, and the results are quite positive. Researchers made progress in this work by developing an Arabic Dialogue Processing that will allow users to interact via chat, banking, and flights using textual documents. Additionally, researchers provide the JANA corpus, a multi-genre collection of spontaneous Arabic dialogues that has been tagged at the utterance level in Arabic Dialogues Act Understanding. A technique for classifying utterances according to whether or not they contain function words was created in this work. Among the attributes of this methodology are a database and a set of function words. On the selected dataset, a number of classifiers were tried to see which one would be most useful over the long term. The support vector machine technique is employed in the study to find the customer and operator responses. Better accuracy is attained when comparing the classification system's performance metrics between the logistic regression approach and other methods in the results section. When compared to the other method, the accuracy of the support vector machine method is 0.83. Researchers want to eventually enable clients to make reservations over the phone by connecting our Dialogue Processing with an active booking system, banking, and chat.

To serve as a standard annotated corpus for testing and assessing several Arabic software applications in the future. Finding the appropriate Support Vector Machine parameters can increase accuracy, therefore future research will examine the impact of each parameter. Future study may focus on determining the best approach to integrate various dialogue act classification development techniques in order to enhance the utilization of any technique, even the most basic.

#### ACKNOWLEDGMENT

I'd like to express my heartfelt gratitude to Dr. Md Sah Hj Salam for his insightful and constructive suggestions throughout the planning and development of this research project. His generosity in donating his time has been greatly appreciated. The authors would like to thank Universiti Teknologi Malaysia (UTM) under UTM Encouragement Research grant PY/2020/04246 for the support in the research.

**Abstract**—Public private partnership (PPP) is the government initiate in accelerating public infrastructure development growth. However, the scheme exposes private sector to various risks including political risk which in turn affect financial performance and reporting of participating firms. Given that one of the issues facing the government is the lack of participation from the private sector in such arrangements. Thus, the main objective of this study is to observe the machine learning prediction models on private investor intention in participating the PPP program. Tree-based machine learning and deep learning are two different types of promising algorithms, which proven to be useful in widely domain of prediction problems but never been tested on the concerned problem of this study. Based on real data of investors for Indonesian listed firms, this paper presents the ability of the selected machine learning algorithms by means of different assessments point of view. First assessment is on the algorithms' performances in producing accurate prediction. Second assessment is to identify the variance of PPP attributes in each of the prediction model with the machine learning algorithms. The performance results show that all the prediction models with the machine learning algorithms and the PPP attributes were well-fitted at R squared above 80%. The findings contribute a significant knowledge to various fields of scholars to implement a more in-depth analysis on the machine learning methods and investors' prediction.

**Keywords**—Tree-based machine learning; deep learning; prediction; investor intention; public private partnership

## I. INTRODUCTION

The degree of development of a nation is determined by its capacity to provide for the needs of the general population, including infrastructure like power, internet, trains, roads, ports, and airports. Infrastructure investments may improve livelihoods and well-being since they make people's lives easier and better [1], [2]. However, many countries have several issues and difficulties when constructing public infrastructure. Financial factors, regional factors, demographic concerns, environmental difficulties, and human factors are some of the key causes of infrastructure development delays [3], [4].

In response to the financial constraint, the government has

initiated alternative funding programmes for the construction of public infrastructure and invited the private sector to participate. This special arrangement is known as public-private partnerships (PPP). PPP has developed in a number of developing countries since it was first used in the United Kingdom in the early 1990s, including Chile in Latin America, Colombia, Brazil, Bulgaria, and Slovenia in Eastern Europe, and Indonesia, Malaysia, and South Korea in Asia [5]–[7]. However, the degree to which PPPs are successfully implemented varies from country to country. For example, in Indonesia, despite the surge in PPP projects for infrastructure development, the private sector's participation is still low as the scheme dominated by Indonesian state-owned enterprise. Hence, this study aims to develop machine learning prediction model on private investor intention in participating the PPP program. This study has important contributions by extending prior works on PPP with non-financial factors to be analyzed based on the machine learning prediction models.

The following section provides a brief description on the data set of this study and the empirical steps of the machine learning research. Section III presents the results of the machine learning performances comparisons based on the PPP attributes. Finally, Section IV discusses the conclusions and future research directions.

## II. LITERATURE REVIEW

Prior research that applied machine learning on prediction, classification and detection studies in financial, accounting and finance research highlight the effectiveness and accuracy of such methods to that of traditional statistical methods in problems such as in detection of financial fraud [8], firm performance [9] and finance [10], [11]. Despite the wider use of machine learning in accounting and finance, yet study on machine learning prediction and classification on PPP investment is limited. To date, most of prior studies used machine learning to predict successful PPP projects [12]–[16] that highlighted the return benefits of deploying the intelligent approach for solving various issues of PPP. In [16], Random Forest has been identified as the most outperformed algorithm but the study has observed different aspects of PPP attributes that used in this study. Most of the researchers suggested that more advance research on the machine learning algorithms for

---

This research was funded by Ministry of Higher Education Malaysia under FRGS grant 600-IRMI/FRGS 5/3 (208/2019).

PPP is needed to accelerate the implementation of computational system for facilitating PPP projects and investments.

Prior studies on the determinants of PPP highlight several financial, economic and environmental factors such as general and operational risk [17],[18], return [18]; operational and cost recovery [19], ownership [20], risk of political instability [21]; risk of exogenous uncertainty [22] and environmental, development impacts and sustainability [20]. However, there are limited studies that have been conducted to examine how non-financial factors such as investor trust in the government, influence the decision of investors to finance public infrastructure through PPP arrangements. To provide a deepen current understanding on the private investor intention in participating in PPP programs, this study attempted to discover non-financial factors including government trust, service quality, transparency, and values of similarity as the determinants of PPP. Unlike the prior works, this paper presents the findings of analysis from the implementation of machine learning prediction models.

To date, more than hundreds of machine learning algorithms can be utilized for various domains of problem such as Decision Tree [23], Random Forest [24], Support Vector Machine [24] and Gradient Decision Trees [23]. Decision Tree, Random Forest and Gradient Decision Trees are categorized as tree-based machine learning. The tree-based machine learning is robust to be used for regression and classification problems. Additionally, Deep Learning [25] is very promising algorithm for prediction problems with massive attributes. However, to study its ability on simple attributes as proposed in this study will provide another useful knowledge to researchers from various fields of interest. The findings will be beneficial to the relevant PPP stakeholders for implementing vast and rapid data-driven recommendations and decisions.

### III. METHODS

#### A. Dataset

The machine learning algorithms were tested on dataset that consists of data from 165 top management of Indonesian listed firms. Based on the real collected data, Pearson correlation test was conducted to observe the weights of correlation coefficient each of the PPP attributes as the independent variables (IVs). Fig. 1 presents the PPP attributes correlation coefficient to the dependent variable (DV). The DV in the predictor model is the investor intention to the PPP. The PPP attributes is the investment intention factors namely based on government trust (*TrustOnGov*), perceived of government service quality (*GovServiceQ*), perceived of government transparency (*GovTransparency*), and similarity of values (*ValueSimilarity*).

Two of the PPP attributes present positive strong correlations (above 0.7 correlation coefficient) to the investor intention while the rest of two attributes have moderate correlation coefficient (0.5-0.6). In the machine learning predictive models, one important matter that need to be observed is the contribution of each attribute in providing

knowledge for the machine learning to make prediction. Two questions to be answered in this research are:

RQ1: Are all the four PPP attributes usable to each of the machine learning prediction model?

RQ2: Which of the attributes are mostly important to all the machine learning models?

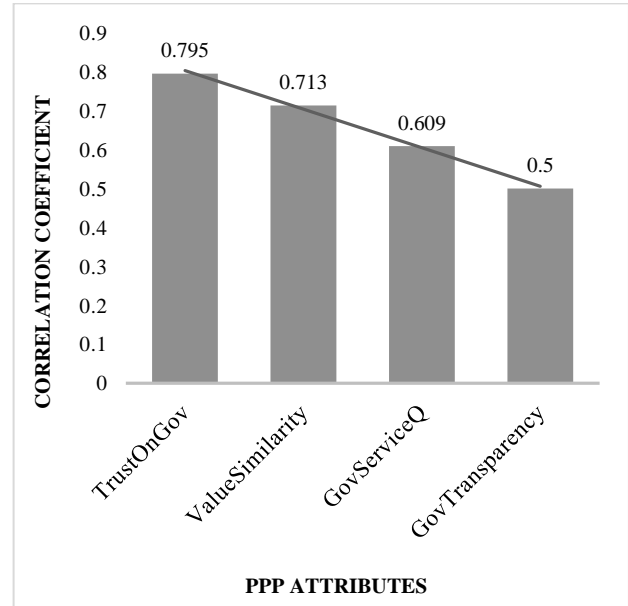

Fig. 1. Weights of correlation each PPP attributes to the DV.

#### B. Machine Learning

Two machine learning from the family of tree-based algorithms namely Random Forest (RF) and Decision Tree (DT) were used in this study. Additionally, acknowledging the wider used of Deep Learning algorithm, it is interesting to observe the algorithm ability in the case of PPP investor intention. Based on preliminary experimental series, the most optimal hyper-parameters of RF and DT is listed in Table I.

The range of number of trees for observing the RF accuracy were 20, 60, 100,140. For each combination, the worst error rate produced by RF was 11.6% while the best error rate was 10.5% with number of tress 140 and maximal depth 4. For DT, the range of maximal depth used in the preliminary testing is between 2 and 25. The most optimal value has been achieved by DT when the maximal depth was 4 at error rate 11.8%, slightly lower from the maximal depth value 2(11.9%). A similar value of error rate at 12.8% has been produced when the maximal depth was individually set as 7, 10,15 or 25. The production of prediction generated by Deep learning is depicted in Fig. 2. The number of layers is 4 that used Rectifier function for the input layers and Linear function as the output layer (layer 4).

#### IV. RESULTS AND DISCUSSION

Table II presents the performances comparison between the three machine learning algorithms by means of Root Mean Square Error (RMSE), R squared ( $R^2$ ) and the time required to complete (TTC) the processes of training and predicting. RMSE measures the accuracy error of the machine learning models while  $R^2$  is presenting the proportion of IVs variation in the prediction models.

Table II shows that all the predictive models with the PPT attributes have contributed at least 80% of the fitted data from the  $R^2$ . Random Forest provided the best results in line with the results in [16] but on this cases that used different PPP attributes, the  $R^2$  is lower that the results in [16]. Although the average error presented by the Relative Error and RMSE of all models are not very encouraging, the values are within an acceptable range to anticipated that the machine learning can relatively predict the data accurately. All the algorithms are reliable when tested on the PPP dataset as described through the results of small standard deviation ranges.

In term of efficiency, DT has taken the shortest time to complete followed by Deep Learning and RF. Furthermore, it will be useful to look the variance of each PPT attributes in the machine learning predictive models as listed in Table III.

As seen in Table III all the PPT attributes were contributed some degree of correlations in the prediction models of all the machine learning algorithms. Thus, all the PPP attributes used in this study were used by the machine learning algorithms, than answered the RQ1. Deep Learning received bigger weight of contributions from the trust on government and value of similarity. For all algorithms, trust on government has given a major influence the prediction models at weight above 0.5, which answering the RQ2 of this research. The lowest influence from the PPP attributes can be seen from the government service of quality. Furthermore, the following Fig. 3 and Fig. 4 show the Tree models generated by DT and RF, respectively.

TABLE II. THE PERFORMANCES RESULTS

Algorithm	Relative Error (+-std.dev)	RMSE (+-std.dev)	$R^2$ (std.dev) (+-)	TTC (ms)
RF	9.9% (3.8%)	0.487 (0.108)	0.826 (0.094)	553
DT	10.3% (2.5%)	0.5 (0.108)	0.802 (0.114)	61
Deep Learning	10.4% (2.5%)	0.477 (0.098)	0.824 (0.056)	342

TABLE III. WEIGHTS OF CORRELATION BETWEEN PPP ATTRIBUTES IN MACHINE LEARNING

Algorithm	Trust on Government (TrustonGov)	Value of Similarity (ValueSimilarity)	Government Transparency (GovTransparency)	Government Service of Quality (GovServiceQ)
RF	0.674	0.395	0.078	0.053
DT	0.597	0.230	0.055	0.048
Deep learning	0.717	0.662	0.028	0.029

Fig. 3. The decision tree.

Fig. 4. The random forest tree at 140 numbers of trees.

The depth of the tree models from DT and RF is 4 as set at the optimal maximal depth. The trust on government is the deeper attribute before the leaf of both trees that representing it as the important contribution to the model. Although the weights of similarity of value and government transparency are very low in DT and RF, the two attributes are still included in the tree models. Otherwise, government service of quality is utilized in RF but not in DT.

## V. CONCLUSIONS

This study aims to explore the non-financial issues that have influenced the investor intention in the public-private partnerships (PPP) based on the evidence from Indonesia. Acknowledging the role of machine learning to provide fast data-driven prediction and how complex is the challenge of future data expanding, this study attempted to discover machine learning techniques and has observed the effect of the pre-determined non-financial factors in the successful of PPP including Government Trust, Similarity of Values, Transparency in Government and Service Quality of the Government. Within the scopes of the tested data based on PPP in Indonesia, the attribute of Government Trust presents the most significant factor in the prediction models inside and outside of the machine learning implementations. This study can be further extending in the future by considering more PPP attributes as suggested in [16] that can improve the accuracy of the machine learning models and use different machine learning algorithms than the proposed study in this paper.

## ACKNOWLEDGMENT

**Abstract**—Filtering techniques have been elaborated in the HA field to improve signal clarity and enhance the hearing capacity of deaf people. However, public sounds are highly noisy, so filtering those signals is not an easy task. Hence, the present article has aimed to develop a novel Ant Lion based power Noise-Variable Bandwidth Filter (ALPN-VBF) for the HA applications. Here, the proposed optimized power efficient filter has incorporated several functions like de-noising and frequency tuning based on the word features. Here, the signal's noise has been removed with the maximum possible range with the help of High-pass-Filter (HPF) and low-pass filter (LPF). Finally, the developed model is tested with a few audiograms, and the filter parameters have been analyzed and compared with other models. The testing results have proved that the designed filter is better in frequency tuning and signal transmission than the previous approaches by attaining less delay and reduced power consumption rate.

**Keywords**—Hearing aid system; variable bandwidth filter; audiograms; matching error; power consumption; signal filtering

## I. INTRODUCTION

The response variable frequency properties are required in various telecommunications applications and software wireless applications [1]. In addition, the design of bandwidth filter with variable parameters has included adders, coefficient array, multipliers, and data array length [2]. The idea employed here reduces the relative filter bandwidth by functioning it in a lower sample rate [3]. Moreover, this process is balanced by an efficient resembling technique. Here, the down-sampled wave is treated by a fixed bandwidth and length, and the up-sampled return to the initial spectrum [4]. Hence, the combined strategy has decreased the filter's bandwidth [5]. Moreover, this approach is chiefly utilized in bandwidth reduction functions [6]. However, numerous applications may demand a higher bandwidth than the fixed-length filter's performance [7]. However, this could result in distortion of signal response outcome [8]. Besides, the non-zero bandwidth transition is the primary cause of distortion in fixed-length-filter [9]. The filter's length often depends on the bandwidth transition. In addition, to gain the undisturbed signal, reducing the filters distortion has to be minimized up to the desired level [10].

The chief advantage in using VBF is better tuning capacity based on the signaling and noise application. The resonant of frequencies have been tuned accordingly [11]. The basic function of VBF is detailed in Fig. 1. In addition, the complexity in VBF is noise removal [12]. If the data is

realistic, it has taken more resources and time to de-noise the signal; also, the conventional filter has afforded the average outcomes [13]. Several filtering approaches, such as a novel key element based on cloud serve VBF [14], parallel structure filter [15], etc., have been implemented in the past. But, the appropriate filtered output was not gained, so the current research work has aimed to design a novel power-efficient, optimized filter model for HAA application. At last, the performance of the designed filter is compared with other models and has obtained the finest results. The key contributions followed in this research is described as follows:

Fig. 1. Function of VBF

- Initially, different public audios were collected from the benchmark site and trained to the system.
- Consequently, a novel ALPN-VBF has been developed with suitable parameters to denoise and tune the signal frequency.
- Here, the possible level of noise signal has been reduced with the use of the HPF and LPF.
- Moreover, the desired signal range has been tuned by matching the maximum signal range in the ant lion fitness.
- Subsequently, the incorporation of the ant lion fitness in frequency tuning has afforded the finest outcome.
- Finally, the designed parameters were measured and compared with conventional paradigms in the relations of power consumption, delay, and matching error.

The current article's research arguments are organized as follows. Section II has detailed the associated works of the different filters in the HA system; the designed novel VBF

filter and function is highlighted in Section III. Moreover, the working performance of the designed Filtering strategy is summarized in Section IV, and the research discussion and achievements are concluded in Section V.

## II. RELATED WORKS

To enhance the tuning range of VBF, Ren et al. [14] have implemented a novel key element based on cloud services for the VBF system. The designed VBF has recorded the tuning rate between 0.3nm to 1.35nm by the experimental process. Also, the measured loss of insertion is 1.39dB. Hence, the tuning function of the VBF has been maximized. Also, it is flexible to change the response rate based on applications. However, it has required more power than the conventional VBF.

The parallel structure filter has been introduced by Swamy and Alex [15] for the HA system for better signal; frequency. Here, the filter is modeled with the reconfigurable parameters that contain several sub-bands to process the different frequency range signals. Moreover, this filter is tested with numerous kinds of Hearing Loss (HL) people data. Hence, the tested people data contains mild to severe HL data; in many cases, the signal has reached better. However, it has consumed more power.

The corrector filters with half bands have been described for the HA system by Niveditha et al. [16] to enhance signal transmission speed. The working of the designed filter is verified with the hardware HA application. The proposed filter has earned a reduced power consumption rate and high signal transmission speed. However, it has lacked in signal clarity.

Ma et al. [17] modeled the reconfigurable filter with multi bands and modularized design structure. In addition, the multiple distortion schemes of subbands have met the frequency range of several different audiograms. The designed filter has a reduced complexity rate than the conventional noise removal filter in HA systems. However, it has required more energy to execute the process.

The notch filter has been applied in the HA system by notch filter Marcum et al. [18] to maximize the hearing capacity of the aged hearing loss people. The key motive of this research is to measure the filtering rate by comparing the conventional filter. Hence, the filtering capacity was identified by using a different set of audio signals. However, it has required more resources to execute.

Several methods were discussed with its limitation and merits for the HA system. Hence, the common demerit in many cases is signal noise. If this problem ends, then the HA system's signal processing has been maximized. So, the current work has focused on implementing the powerful noise filter for HA applications.

## III. PROPOSED METHODOLOGY

The key motive of this HA system application is to improve the communication and hearing capacity of deaf people. Several kinds of HA system has been designed with different efficient filter parameters. But, still, the noise in the processing signal might reduce the signal frequency. So, the present work

has focused design a novel optimized VBF named ALPN-VBF for HA framework. Here, to enable the power noise mechanism, dual filters functions have been utilized that are HPF and LPF. Then to transform the optimal signal range, the maximum signal frequency range is modeled in the Ant lion fitness function. Hence, the optimization objective has been iterated repeatedly until the desired signal has been met.

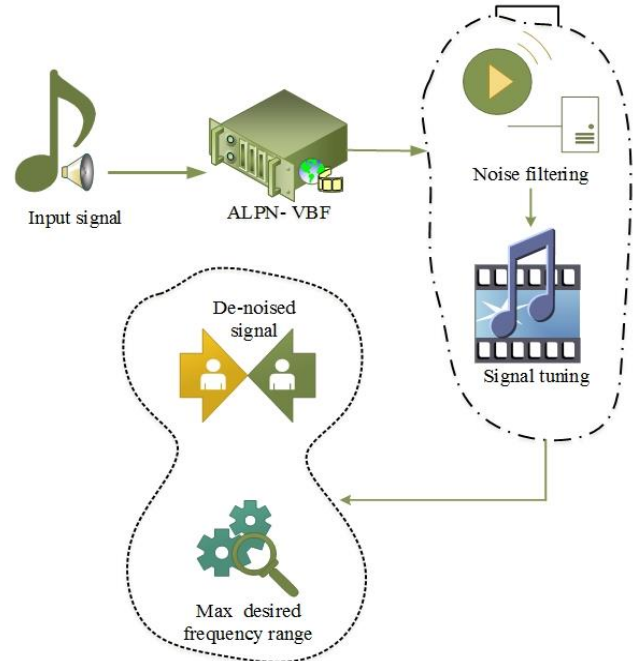

Fig. 2. Proposed architecture

The proposed architecture is detailed in Fig. 2. Finally, the working of the designed efficient VBF has been analyzed by validating the function parameters by applying any voice or sound. Subsequently, the improvement score has been measured by processing the comparison assessment.

### A. Design of ALPN-VBF for HA System

The present work has developed a novel optimized intelligent ALPN-VBF for the HA system to improve the signal clarity of the HA device. Hence, this technique incorporates LPF, HPF, and Ant lion procedures. Usually, the ant lion is inspired by their hunting intelligence by trapping the ant inside the pit. Here, this fitness is utilized to fix the maximum desired frequency and tune the frequency up to the fixed frequency.

$$c = \sum_{n=1}^x p_n 2^{S-n} \quad (1)$$

Here,  $c$  denotes filter coefficients, world length is determined as  $x$ , the required power is represented as  $S$  and signal features are described as  $p$ . Moreover, the  $p_n$  is signal coding that is defined as  $p_n = (-1,0,1)$ . Hence, the filter coefficient is described in (1).

$$F(y) = \|G_d(\omega) - G(\omega, y)\|_2 \quad (2)$$

Here, the response of the zero-phase frequency is denoted as  $G_d$  and  $G(\omega, y)$  is the present noise feature in the input signal. In addition,  $F(y)$  is the objective function signal tuning and filtering. Hence, (2) is utilized to neglect the present noise in the input signal. Moreover, the signal range has been tuned by fixing the maximum signal range and tuning the input signal during the execution of the signal processing (3).

$$A(y) = \max(0, u(y) - e_b) \quad (3)$$

Here,  $e_b$  is the detection parameter to find the equivalent fixed maximum signal range  $u(y)$  and  $A(y)$  is the threshold setting parameter. Now, the minimum frequency of the sound is fixed using (4),

$$\min F(y) = \beta_1 F_1(y) + \beta_2 A(y) \quad (4)$$

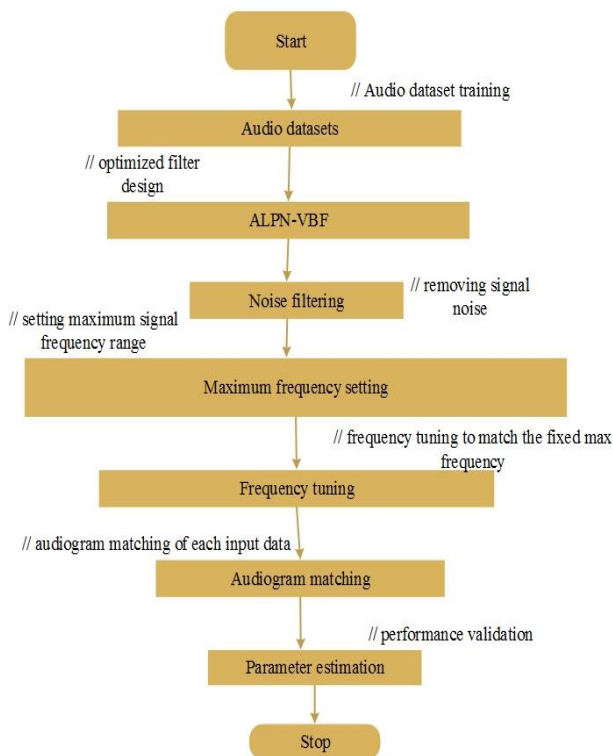

Fig. 3. Flow of novel ALPN-VBF

The design of ALPN-VBF Where,  $\beta_1, \beta_2$  are the signal's weight coefficients. In addition, the system is trained with more different signals; each signal has specific frequency metrics. Hence, the signal selected from the total set of the collected sound signal is processed by (5).

$$\begin{cases} 1 & \text{ifrand} > \max(u(y)) \\ 0 & \text{ifrand} \leq \max(u(y)) \end{cases} \quad (5)$$

Besides, the tuning process of the signal coefficients is detailed by (6), if the statement has been worked with 0 and 1 status. Hence, for the random selection process, 0's and 1's conditions were used.

$$T(s) = \frac{\max(u(y)) + \min(u(y))}{2} \quad (6)$$

$$\text{optimum frequency} = F(y), \text{ if } T(s) < \max(u(y)) \quad (7)$$

During the signal transmission process, the optimal range signal (7) has been obtained then the optimization iteration has been stopped. Otherwise, the iteration has been continued till the desired signal is met.

The function process of the novel ALPN-VBF is executed in the way of Fig. 3. The key function of this designed filter is to filter the noise signal with a highly appropriate range and to tune frequency based on the deaf people hearing capacity.

#### IV. RESULTS AND DISCUSSION

The planned research solution is implemented in the MATLAB framework, running in the windows 10 platform. Initially, benchmark data is collected from the standard sites, it contains several sounds like animals, birds, humans, etc., then a novel ALPN-VBF has been developed with desired tuning parameters. Consequently, the signal executing and frequency tuning performance have functioned.

##### A. Case Study and Performance Validation

To analyse the performance of the designed filter, benchmark data has been utilized. From that bird sound and public transport, sound has been processed to analyze the capacity of the noise filtration function and tuning performance.

Fig. 4. Input signal frequency

The generated signal plot after importing the sound dataset is described in Fig. 4. The frequency wave of the input signal is varied based on the audio maximum frequency range.

1) *Matching error*: In any filtering concept, finding the signal error or mismatch became the major concern for validating the filter functions. The matching error parameter has been estimated for three audiograms.

Fig. 5. Matching error assessment

In addition, to find the improvement score of the proposed model, a few existing models have been obtained, such as reconfigurable filter [19], Constrained-least-square (CLS) filter [20], and 3 level Filter (3LF) [21]. Here, the RF has obtained an error score of 2.54 dB for the first audiogram, 1.85dB for the second audiogram, and 2.87 dB for the third audiogram. Hence, evaluating these statistics, the method RF [22] has recorded the average matching error score as 2.4db. Furthermore, the CLS filter has gained the error score for the first audiogram is 2.09dB, 3.12 dB for a second audiogram, and 3.23 dB for the third audiogram. Hence, the recorded average error score by the method CLS [23] is 3dB. In addition, the method 3LF [24] has gained 2.32 dB for the first audiogram, 2.43 dB for the second audiogram, and 2.39 dB for the third audiogram. The average recorded score for matching error is 2.35dB. Considering all those existing models, the proposed approach has obtained 1.9dB for the first audiogram, 1.4dB for the second audiogram, and 1.2dB for the third audiogram. Hence, the obtained average matching error for the proposed model is 1.5dB. The matching error statistics is graphically represented in Fig. 5.

2) *Delay validation:* Measuring the time for the audio frequency transmission is called a delay. Mainly, the filters which have the complex function modules have required more time to execute; this causes time delay.

Moreover, the RF approach has achieved an 18.54 ms delay, the CLS filter has recorded a 7.9ms delay, 3LF has achieved the frequency delay as 12.9ms, and the proposed strategy has recorded the delay score to broadcast the signal frequency is 5ms. The delay statistics are described in Fig. 7.

3) *Power Consumption:* In digital signal application, power is the key metric for transferring the signal, the utilized power by the novel ALPN-VBF has been measured with Watt unit.

In the proposed research, dual filters were used: LPF and HPF, so power is a major concern for analyzing the maximum required power for HA system fitters. Besides, the reason for consuming high power is the poor filtering capacity. So, the method with less power consumption has a high noise removal rate. The CLS filter has gained the power consumption score of

0.05W; RF has obtained the power consumption score of 0.398W, and the proposed approach recorded the consumed power as 0.02W. The measurement of power utilization is described in Fig. 6 and the overall power consumption validation measurement of the proposed ALPN-VBF is tabulated in Table I.

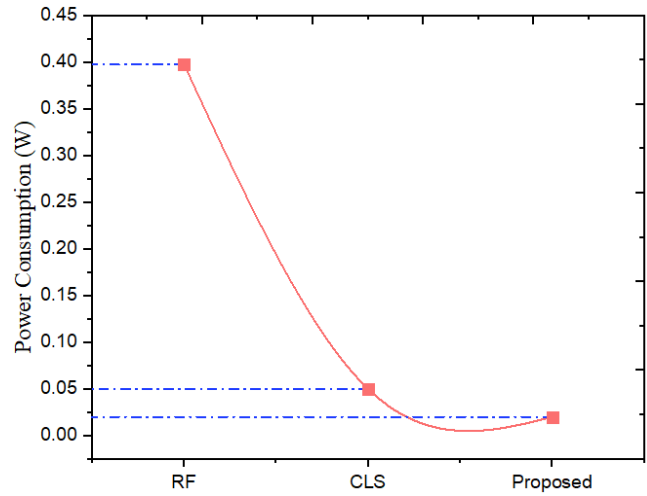

Fig. 6. Power consumption validation

TABLE I. THE OVERALL COMPARISON STATISTICS

comparison statistics					
Methods	Matching error dB			Power consumption (W)	Delay (ms)
	Audio1	Audio 2	Audio 3		
RF	2.54	1.85	2.87	0.398	18.54
CLS	2.09	3.12	3.23	0.05	7.9
3LF	2.32	2.43	2.39	0.03	12.9
Proposed	1.9	1.4	1.2	0.02	5

**B. Discussion**

The designed ALPN-VBF has recorded an outstanding performance from all the comparison assessments than the compared approach. This proved that the involvement of the combined HPF and LPF in one filter bank had provided the finest outcome.

TABLE II. OVERALL PARAMETER VALIDATION OF ALPN-VBF

Overall performance assessment		
Power consumption	0.02 W	
Delay	5ms	
Matching error	Audiogram 1	1.9
	Audiogram 2	1.4
	Audiogram 3	1.2

The overall metrics measurement of the proposed ALPN-VBF is tabulated in Table II. Hence, the designed filter procedure is suitable in HA application to maximize the hearing capacity of deaf people by affording the clarity sound frequency.

## V. CONCLUSION

Improving the performance of the HA application is the most required paradigm for deaf people. Hence, this present work has attempted to design a novel optimized power filter name as ALPN-VBF for the HA system. Initially, the set of audiograms was taken and trained to the system then the filtering process was performed to de-noise the signal. Consequently, the frequency range of the signal is tuned to the maximum desired level with the help of ant lion fitness. Once the desired level frequency has been met, it has transferred to the other end. Finally, the key metrics were calculated and compared with other models. The proposed model has achieved the minimum matching error of 1.5 dB; considering the other models, it has diminished the matching error up to 1%. Besides, the recorded power consumption is 0.02W; compared to other models, it has shown an improvement rate of up to 2%. The delay measure recorded by the designed strategy is 5ms, by comparing other models, has described the improvement rate up to 12%. Hence, the designed model is suitable for the HA system.

# Performance Evaluation of Photovoltaic Projects in Latin America

Cristian León-Ospina, Heyner Arias-Zarate, Cesar Hernandez  
Universidad Distrital Francisco José de Caldas, Bogotá D.C, Colombia

**Abstract**—Photovoltaic solar energy has been booming worldwide due to the scarcity of non-renewable resources, from there arises the need to modernize and innovate in the methodologies for the use of energy resources as well as in the correct installation of this system at an urban or level rural. In recent decades in Latin America there have been presented advances in the implementation of photovoltaic projects, which is why this document aims to evaluate the feasibility of these at a technical and technological level, so that they are in accordance with the systems implemented in Asia, Europe, and North America. The analysis determined that the main factors affecting the feasibility of a photovoltaic execution project are economic and technological, in addition to the adverse impacts found on the ecosystem and the local population, but in general it was observed that they are weaknesses that can be corrected, since there are different countries that are working on establishing strategies to educate their community, so there is an improvement in the quality of life in sectors with high CO<sub>2</sub> pollution and lack of fossil fuels.

**Keywords**—Evaluation; Latin America; photovoltaic; project

## I. INTRODUCTION

At present, due to the inconveniences presented by the scarcity of non-renewable resources that are used for energy generation in the world, it is necessary to implement new methods that take advantage of natural resources, as is the case of photovoltaic systems. In this procedure, solar energy is harnessed by storing, regulating, and transforming it into electricity for use in residential and industrial electrical installations [1].

The definition of solar energy refers to the electromagnetic radiation emitted by the sun that can be harnessed using multiple technologies. Modeling and simulation of these types of systems have become a widespread practice in the academic and industrial world [2]. They are essential tools for the design and installation of a solar plant, and for the estimation of its productivity.

Photovoltaic systems are recognized as a group of components that make it possible to harness and use electromagnetic radiation emitted by the sun to produce electricity. These types of systems are identified according to the types that compose them and the materials or elements with which they are manufactured and put into operation.

This document details the analysis of the factors that make it possible for a photovoltaic project to be carried out satisfactorily in a sustainable, energetic, and economic way. This analysis aims to contemplate the feasibility of these projects and contribute to the strengthening of knowledge

about photovoltaic energy and therefore motivate research and development of strategies that optimize it, to contribute to the improvement in the quality of life and in turn with the reduction of CO<sub>2</sub>.

This was done through specific IEEE bibliographic sources that document the axis of analysis of this project; these documents were compared by analyzing the different implementation strategies of photovoltaic projects in specific Latin American countries, using graphs, figures, and descriptions of each. To contemplate the factors those were most relevant when materializing this type of project.

This document brings a unique added value as it offers innovation and solutions for energy problems that are difficult to address. This means that this document stands out from other documents because of the usefulness of its content. Photovoltaic technology is especially useful for companies and organizations that seek to optimize production and service processes for communities with difficulties in accessing electricity. This makes it possible to save time and money by providing information that facilitates decision-making on critical factors of the project and at the same time improves the efficiency of the photovoltaic generation process.

## II. RELATED WORKS

In [3] performs a return analysis on the study of various photovoltaic systems, investigating three generations of photovoltaic technology taking into account efficiency, embodied energy and return on investment in energy to identify relevant elements that allow generating technological development. One of the main objectives is to find ways to reduce the financial costs of the production of photovoltaic systems. It is found that the first-generation wafer-based technology has a higher efficiency than the second-generation thin film, but at a higher cost per unit area and that for the third generation the technologies have not sufficiently emerged yet. But it is also highlighted that energy performance and environmental impacts or greenhouse gas emissions must be taken into account, which can be indicators of the benefits and costs, this was found that the thin film has the best advances in performance energetic and is currently working better [3].

In [4] described the impact assessment of net metering for Distributed Residential Photovoltaic Generation in Peru. The economic impact of what is known as net metering of the photovoltaic system interconnected to the grid is analyzed, where the user is able to deliver or receive energy from the grid depending on whether there is an energy surplus or not

receive missing energy from the network to meet their needs through bidirectional meters, in addition, an analysis of the legal and regulatory mechanisms that define as such the economic conditions of energy exchange with the electrical distribution network in the city of Arequipa is carried out. This basically provokes a discussion in terms of the advantages and disadvantages that both distribution companies and end users present, since the payback time of applying this methodology is quite long and the effectiveness depends on the geographical area. Because if the location has a sufficient level of solar energy, it is more likely that the investment will be recovered a little faster. On the other hand, the distribution companies would see their business affected since it depends on the end user's consumption being higher and not lower due to the injection of energy that they would generate on the grid, for which the prices in the market would be affected [4].

In [5] presents an analysis of the different subsidies provided by the Mexican government to those who promote projects that implement renewable energy, more specifically photovoltaic energy, taking advantage of the great growth that this has had in recent years, measuring the economic feasibility of said generation projects. will have on the energy market in the country, sustaining that the use of this type of technology mitigates climate change, that this type of energy does not generate greenhouse gases and is booming, so Mexico is taking advantage of this opportunity to strengthen the agricultural sector, taking into account that Mexican investors carefully evaluate the risks of contributing their capital for this type of project. In order to see what factors must be taken into account, a study is also made of the dates of different regions of the country to see how much solar energy could be counted on to consider the energy potential, and what investment mechanisms can be used taking into account the affectation that this will have to implement in the agricultural sector due to the strong initial investment that must be made, so the incidence of subsidies on the viability of these projects will also be evaluated due to the analysis of the cost of the energy generated and the return time of the investment, but according to the analyzes carried out, everything points to the fact that without these subsidies, due to the high costs, this type of generation would not be profitable [5].

### III. PHOTOVOLTAIC PROJECTS IN LATIN AMERICA

#### A. Scientific Databases

When delving into the research of photovoltaic projects in Latin America, it was used as query tools several databases among which IEEE Xplore and Scopus stand out. For this case IEEE publications that have been made on this topic in the last 20 years were used.

1) *Documents per year*: In this section we will recognize the evolution of research on issues related to photovoltaic systems in Latin America in the last 20 years according to the information provided by the databases. See Fig. 1.

2) *Documents by region*: The countries that have done the most research in the implementation of photovoltaic systems in this part of the continent are Brazil (87), Uruguay (61), Peru (38) and Ecuador (15).

3) *Types of documents*: It is highlighted that the documents issued by educational or academic institutions are conferences (228), scientific articles (123) and journals (3), generating a total of 354 documents.

4) *Most frequent keywords*: Based on the bibliometric analysis it was carried out using several tools such as VOS viewer, after was mapped for this case the keywords that are most used in the documents found the IEEE databases, thus recognizing which are the focuses of the research carried out in the area.

Fig. 2 shows the topics most frequently mentioned in the documents are solar energy, photovoltaic cells, photovoltaic systems, all implemented in Latin America.

#### B. Projects with the Highest Energy Production in Latin America

In this area of the continent the use of renewable energies is booming, in this case photovoltaic solar energy in recent years has excelled dramatically in several countries, some of the largest producers are: Brazil, Mexico, Chile and Argentina.

Fig. 1. Research trend in recent years.

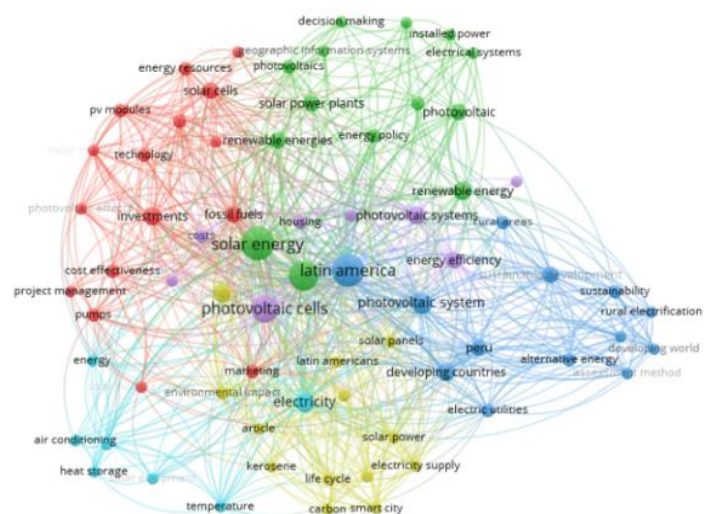

Fig. 2. Visualization of the network related to the keywords covered in the articles referring to photovoltaic systems.

Each of these nations was delved into to identify their most emblematic projects in this type of energy technologies, thus recognizing their technical specifications in order to demonstrate the current energy production and its contribution to the national interconnected system.

1) *Brazil*: It is the country with the largest population area in Latin America, because of this the increase in energy demand extends annually that is why they are implementing the use of new technologies for energy generation, among those are the photovoltaic systems who in recent years it has increased its power generation capacity exponentially as shows the Fig. 3.

Recognizing this renewable energy generation that the country has had, the attention will focus on the exploration of some of the largest solar farm projects that the country currently has, among which are:

a) *Ituverava solar park*: This solar park has been operating since 2017, being the largest plants in South America, has an approximate area of 600 hectares, houses around 850,000 solar panels, with a maximum production capacity of 550 GWh per year [7]. It is located in the state of Bahia in the municipality of Tabocas do Brejo Velho.

In the area where this solar park was built, the presence of a lot of biodiversity is evident, which is why mechanisms have been implemented to mitigate the environmental impact such as artificial nests for birds, recycling and water treatment systems and a mini solar farm. This is intended to supply a part of electricity to a neighboring community. On the other hand, the investment made by Enel for the construction and execution of this plant was around 4 billion dollars, which is intended to supply the energy consumption of around 268,000 homes, thus preventing the emission of approximately 318,000 tons of CO<sub>2</sub> [7].

b) *Nova olinda solar park*: It is currently one of the largest solar photovoltaic power generation parks in Latin America, its approximate installation area is 690 hectares, it has a total installed capacity of 292 MW, producing approximately a maximum capacity of 600 GWh [8]. It is located in the state of Piauí in the municipality of Ribeira do Piauí.

The company managing the service invested around 300 million dollars in the construction of nova Olinda, thus maximizing the energy coverage of around 300,000 homes, generating a reduction in greenhouse gas emissions of around 350,000 tons.

Both solar parks are managed by Enel, an Italian company that is one of the world's largest providers of renewable energy optimization for the purpose of cleanly electrifying the countries in which it operates.

2) *Mexico*: This Central American country has the second-best population in photovoltaic generation, due to the global energy crisis that has been presenting, Mexico has seen the need to implement new generation parks in order to meet the demand it currently has. The evolution it has had in the photovoltaic generation capacity in the last decade has grown

exponentially, amplifying its generation in the last 5 years. Fig. 4 shows the trend of this energy production.

Next, some of the largest photovoltaic solar generation parks in the country will be observed.

a) *Villanueva solar power plant*: Since 2018 the Villanueva solar photovoltaic plant has been in operation with an installation area of approximately 2,400 hectares, thus projecting a production of 1700 GWh per year when it is fully operational. There are around 200 to 300 of solar panels [9], this plant is located in the state of Coahuila in the town of Viesca.

The investment for this plant was US\$650 million, with a strong focus on environmental impact, waste management, CO<sub>2</sub> emission reduction and economic growth for the communities living near the solar plant.

b) *Magdalena II solar power plant*: In 2019, the construction of this work was completed, housing an area of approximately 800 hectares, at maximum capacity it could generate 600 GWh per year. [10].

One of the technological advances that this plant has is that its photovoltaic modules are bifacial, in order to take advantage of the incidence of the sun on both sides of the solar panel [10], and these panels have a monitoring mechanism which is programmed to obtain the greatest use of solar radiation.

Fig. 3. Photovoltaic solar production capacity in Brazil [6].

Fig. 4. Photovoltaic solar production capacity in Mexico [6].

This Park is located in the state of Tlaxcala and is intended to supply the consumption needs of approximately 456,000 Mexican households.

3) *Chile*: In this area of the continent there is the best solar radiation in the world, which is why the boom it has acquired in the last decade on the generation of photovoltaic solar energy has been wide.

It must recognize that lately the materials that are being used by the entities that execute this type of energy projects are of high efficiency, this in order to make the most of the energy resource. Fig. 5 shows the increase in the production capacity of gigawatt hours of photovoltaic solar energy.

Some of the projects that stand out most in the country are the following:

a) *Domeyko solar plant*: The construction of this project is in charge of Enel Power Chile, it has an approximate area of 700 hectares where approximately 473000 bifacial photovoltaic modules are installed [6], in order to generate greater use of the reception of solar radiation, It should be noted that in this area of the world is where there is greater energy efficiency regarding this type of energy. When the plant operates at its maximum capacity it can generate approximately 590 GWh per year. It is located in the region of Antofagasta.

The cost of this project was 164 million dollars, the execution of this was carried out during the pandemic therefore its workers complied with all safety protocols in order to guarantee their health and that of their community, this project aims to avoid the emission of CO<sub>2</sub> of approximately 439000 tons annually [6].

b) *Sol de lila photovoltaic park*: This solar plant is located in the Atacama Desert, has an installation area of approximately 720 hectares, where approximately 408,000 bifacial photovoltaic modules are installed [12]. when the maximum operation is found, it is expected to generate approximately 500 GWh per year, thus benefiting the surrounding population of the Antofagasta region.

The greenhouse gases that can be mitigated when this solar park is in execution would be approximately 372000 tones. The execution of this work was carried out by more or less 500 workers in times of pandemic, each of them maintaining safety protocols.

4) *Argentina*: In this country, despite being in an area where there is a great solar radiation, it had not invested much money in energy innovation due to its political and economic problems.

Despite the situation, it can be seen that in the last decade it has begun to increase its photovoltaic solar energy production capacity gradually since 2017, thus recognizing its need to implement renewable energies in the national interconnected system. Fig. 6 will show the increase in energy production.

Fig. 5. Photovoltaic solar production capacity in Chile [11].

Fig. 6. Photovoltaic solar production capacity in Argentina [11].

The most relevant solar plants in the country are:

a) *Caucharí solar plant*: The energy company Jemse started up the largest solar energy plant in Argentina, located in the Puna region, with an area of approximately 800 hectares and an installation of 90,000 solar panels, producing 215 GWh annually at maximum capacity [13].

The power that handles this solar plant is 300 megawatts, the implementation cost was 390 million dollars, pretending to cover the energy need of approximately 160,000 homes, it is located at 4020 m above sea level.

b) *Altiplano 200 photovoltaic solar park*: This solar park is located in the town of Olacapato, has an installation area of approximately 350 hectares, locating there a total of 500550 solar panels, producing at maximum capacity a power of 200 MW [14]. The investment for this project was 313 million dollars, this project was created by merging the projects of Puna and Altiplano. The project is managed by Cammesa for a period of 20 years.

#### IV. TECHNICAL AND ECONOMIC FEASIBILITY OF PHOTOVOLTAIC PROJECTS

##### A. Type of Environment or Geographic Area

The optimal environment to implement a photovoltaic system is one that allows the greatest solar radiation throughout the day, although this depends on some atmospheric phenomena that are listed in Table I.

TABLE I. ATMOSPHERIC PHENOMENA PRESENTED IN SOLAR RADIATION [25]

Phenomenon	Definition
<b>Absorption</b>	A large accumulation of solar radiation that is filtered by the gases present in the atmosphere thus preventing its transit to the surface of the earth.
<b>Diffraction</b>	It is a phenomenon that occurs when solar radiation transits through clouds, the incident ray when reaching these is fragmented in such a way that each of these has less energy.
<b>Dispersion</b>	For this case, the sun's rays are deflected by dust particles water molecules present, thus preventing their arrival on earth.
<b>Reflection</b>	This phenomenon has the characteristic that when it meets the particles that are suspended in the clouds, as well as the gases that it contains, they cause the sun's rays to be returned to space.

Complemented the above, it is necessary to emphasize that this energy resource has great variability also due to climatic factors such as the conditions that occur throughout the day, as well as the change at night and the time of year in which this system is used.

Photovoltaic installation depends on the place where it can be located, if they are generation parks at a macro level such as those managed by large energy companies in the world it is necessary that this is located in a desert or arid area allowing ease of construction and in turn the feasibility of the system mitigating its environmental impact, on the other hand if our photovoltaic installation is micro level this can be located anywhere in the world that is outdoors and can capture solar radiation.

Depending on the location it has at its latitude this will define an estimate for the angle of inclination that solar panels can possess if they are of fixed type. Fig. 7 shows a mapping of the areas where there is greater solar radiation in the world.

Fig. 7. World map of the areas with the greatest solar irradiation.

### B. Space required for the Installation of these Systems

1) *Solar parks*: When large photovoltaic projects are executed, it is necessary that these are located in areas where the greatest irradiation in the country is present, such as deserts, among others, this type of spaces must have a level ground so that when installing the structure of the solar panels there are no variations in the This would affect the optimal reception of this energy resource.

2) *Isolated photovoltaic systems*: This type of installation is intended to locate the solar panels in a clear area either located on the ground or attached to the roof of the place where they are going to be implemented, this in order to avoid deviations or obstructions of the solar radiation that is directed to the panels. For the rest of the components such as the inverter, batteries, regulator and protection systems, it is required that these be located in a place that is not outdoors and in turn allows a high flow of air in order to reduce the temperature of these electronic devices.

3) *Grid-connected PV systems*: When they are installed at the residential level you can follow the parameters seen in the isolated systems, there are other cases that are being presented at an industrial and commercial level in the continent are the integration of solar modules on the facades and terraces of buildings and factories in order to take advantage of the great irradiation that it reaches this type of structures and likewise contrasting with the architecture of these so that they do not lose their attractiveness. Some grid operators are encouraging this type of microgrid and are regulating its correct installation to minimize dependence on other types of non-renewable energy sources [17].

Some countries such as Brazil are conducting multiple investigations that are allowing to evaluate the energy performance of this type of systems, which is why certain scenarios propose to use several types of inclinations of solar modules in order to recognize what is the optimal angle for the reception of solar radiation , P Grams such as PVsyst allow us to model some of these scenarios to have great certainty about the nominal power that can be obtained in a period of time, thus corroborating what is calculated in the theory.

### C. Required Materials

In this section, attention is focused on the materials used for installation in a given site or area.

1) *Panel brackets*: The fastening systems aim to support the solar modules as well as to fix the inclination they must carry in order to receive as much of the energy resource or as possible. There are two types of supports which are fixed supports and variable supports. See Fig. 8.

2) *Solar modules*: This material is one of the most important for this type of energy generation systems, initially the panels were single-facial type thus allowing the reception of energy radiation only on one side, currently a new module has been implemented in the market that takes advantage of both sides called bifacial module as mentioned above allows the capture of solar radiation in the upper part and lower of it. In distributed generation it can be seen that there is a generation power limit of 5 MW as it happens in some Latin American countries, due to this restriction there has been the need to optimize energy capture in order to make the most of the implementation of these systems [18].

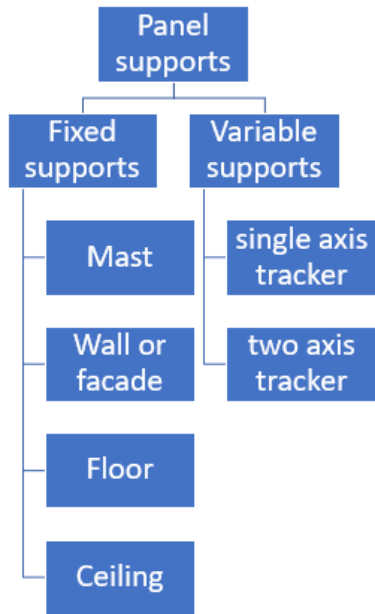

Fig. 8. Types of supports for solar panels [25].

3) *Cables*: For the correct installation of this type of systems it is necessary to implement electrical conductors that are dimensioned in such a way that they comply with the maximum admissible parameters according to the type and installation and that in turn is governed by the rules or regulations that it administers in each country as appropriate. Some of the characteristics of these elements will be summarized below in Table II.

TABLE II. TECHNICAL CHARACTERISTICS OF DRIVERS

Feature	Details
<b>Weather resistance</b>	Maximum conductor temperature resistance to external temperatures, resistance to UV rays, etc.
<b>Mechanical strength</b>	Impact, abrasion and tear resistant
<b>Mitigation environmental impact</b>	Low emission of corrosive gases, no fire spreader, halogen-free, etc.
<b>Life</b>	Endure a minimum of 30 years.

4) *Connectors*: The main characteristic of this type of elements is that they allow the connection of electrical conductors without the need for a splice and in turn have resistance to weathering, thus facilitating the protection of the integrity of the people who transit through the area or manipulate these connections at times of the year when there is high humidity or weather conditions are not the most favorable for the photovoltaic system.

5) *Electrical connection system*: To generate the control and correct distribution of the photovoltaic system and also of its protection elements such as thermomagnetic switches, commissioning systems and the distribution of the branch circuits contemplated for residential or industrial use, it is necessary to do it in a connection box. Among its characteristics is that it must be covered and preferably not outdoors, this in order to prevent the risks of an electric shock

when it occurs in a humid environment, the thermomagnetic switches or fuses that this connection box carries must comply with the electrical regulations of each country thus guaranteeing a maximum power support without risk to a short circuit or Overvoltage, CAD to element that is connected there must be labeled so that it can be clearly evidenced to which branch circuit it corresponds and the electrical conductors must comply with the color code presented by the local regulations.

D. Investment

Depending on the use that will be given to the photovoltaic installation, the influence of some evaluation criteria must be taken into account that allows the profitability of the projects to be recognized.

1) *Evaluation criteria*: Levelized cost of energy (LCOE): is a parameter that allows us to express the cost of a power generation system in a time interval. The variables that fall under this parameter are the net costs of the investment, the rate established for the discount and the total energy used. A project is viable if the LCOE has a lower value than the energy cost incurred in that investment. The expression defined for this case as shown in equation 1.

$$LCOE = \frac{I_0 + \sum_{t=1}^n \frac{A_t}{(1+i)^t}}{\sum_{t=1}^n \frac{M_{el}}{(1+i)^t}} \quad (1)$$

Internal rate of return (IRR): is a discount rate that generates a balance between expenses and income, thus causing the net present value to be zero. There is profitability in a project if the internal rate of return is greater than the profitability established for the investment, the expression is defined as shown in equation 2.

$$TIR = \sum_{T=0}^n \frac{F_n}{(1+i)^n} = 0 \quad (2)$$

Net present value (NPV or NPV): it is a parameter that makes the addition of cash flows in relation to the rate of capital cost, thus considers that a project has profitability at an economic level if the value obtained is greater equal to zero, the mathematical expression is shown in the equation 3.

$$VAN = \sum_{t=1}^n \frac{F_t}{(1+k)^t} - I_0 \quad (3)$$

2) *Smaller-scale investments*: Unfortunately investing in the implementation of this type of systems locally such as installing panels in a house can be relatively expensive, these values vary according to the place where the installation materials are purchased, the qualified, certified labor, regulation, and commissioning of the system. It foresees that this type of investment has a payback period of 5 to 15 years, although some countries are allowing that, if this type of systems are connected to the grid, they can then reduce the cost of the kWh that the network operator can charges thus reducing the recovery time.

3) *Larger-scale investments*: Large companies worldwide such as Enel Green Power, are pioneers in the implementation

of this type of systems and in the last decade have generated a large investment in unexplored areas in some Latin American countries, on average investments per project are around 250 million dollars [19]. Based on the type of investment, the company agrees with local governments to manage this energy system for a minimum of 15 years, thus allowing control of it, gradually impacting the percentage of energy generation in each country and guaranteeing the recovery of its investment in a short time.

#### E. Incentives

1) *Paid*: For small solar farms, there are economic rewards for using clean technologies in their electrical installations, these are reflected in the reduction of the cost of kWh and in some cases in the financing of the installation of this type of systems [16].

Companies that manage the largest solar projects in the region receive incentives for mitigating environmental impacts in the area where the project is executed, as well as for the amount of energy they can supply during peak hours, where there is high energy demand.

2) *Unpaid*: Unpaid incentives are those that are presented as support for humanity, such as the brief mitigation of greenhouse gas emissions, reduction in the generation of hazardous substances to the environment and support for the vegetation of the areas where this type of energy systems is implemented.

#### F. Environmental Impacts

1) *Soil*: Despite considering this technology as clean, the environmental impact cannot be completely mitigated since in the case of an installation of a solar park an average of 2 hectares per megawatt installed is required, this over time generates an alteration in the soil thus impacting the habitat that is around this installation, It should be noted that this only applies in areas where there is high vegetation and fauna, therefore a solution mechanism is to execute this type of projects in desert areas.

2) *Atmosphere*: A considerable amount of the environmental impacts that occur when generating photovoltaic solar energy are the presence of aerosols in the atmosphere, these prevent the efficiency of solar radiation therefore it is integral to carry out studies that allow us to

recognize this type of conjunctures and who that is can generate some type of solution in the short and medium term. [15].

3) *Impact on local flora and fauna*: Another type of environmental impacts that occur in this type of systems is when the flora and fauna of the area where it is going to be implemented is affected, as a result of this some projects have not been viable due to the damage they can generate to the population, in other places it has been possible to generate a common agreement between the population and the entrepreneurs with the in order to receive some series of incentives for allowing the construction of this type of works. [26].

## V. COMPARATIVE ANALYSIS OF PROJECTS

Recognizing the great importance that the implementation of large solar parks generates in a country, it is then possible to deepen this exploration in order to demonstrate what characteristics and parameters stand out between each of the projects, such as strengths, weaknesses, environmental impact, energy generated, investment costs and geographical location chosen for this document.

### A. Comparison between Projects in the Same Country

1) *Brazil*: Between Ponta Pora and Fortaleza is the largest area that produces the largest amount of photovoltaic potential in the country, currently Brazil is one of the largest generators of electricity by photovoltaic solar parks. In 2021, it was consolidated among the ranking of the best country is worldwide occupying box 13 [20], with an installed capacity of approximately 14 GW that are currently in operation, in the map of photovoltaic power that Brazil has, it can see in which areas are more prone to the installation of solar parks to ensure that the reception of the resource is optimized.

Recognizing this energy impact that is presenting worldwide, it is necessary to delve into the main characteristics of the most representative solar parks of this country, this in order to have a base that allows us to recognize what parameters of owning a large-scale photovoltaic solar installation in this part of the continent.

As mentioned in Section II, the solar parks of Nova Olinda and Ituverava are those that present at the moment the greatest capacity of energy generation, therefore, each of its primary particularities is synthesized in Table III.

TABLE III. COMPARISON BETWEEN THE PROJECTS CHOSEN

Variables	Brazil		Mexico		Chile		Argentina	
	New Olinda	Ituverava	Villanueva Solar Power Plant	Central solar Magdalena II	Domeyko Solar Plant	Sol de Lila photovoltaic park	Caucharí Solar Park	Altiplano 200 Solar Park
<b>Strengths</b>	They established a dialogue in common agreement with the surrounding indigenous communities and managed to generate an agreement in which they would provide work and educational training to a large part of the inhabitants of this area, this in order to generate social inclusion so that both parties are benefited from the execution of this project.	High reduction of carbon dioxide per year. Development of artificial nests to protect local fauna. Implementation of circular economy for the rational use of water.	Implementation of bifacial panels. CO2 reduction	Implementation of bifacial panels. CO2 reduction	Totake advantage of the energy resource since this plant was located in a desert. Use of bifacial panels.	Totake advantage of the energy resource since this plant was located in a desert. Use of bifacial panels.	State-of-the-art technology in solar panels and inverters.	Union of several distributed generation companies.
<b>Weaknesses</b>	Impact on the common evolution of the indigenous population the Quilombos.	Due to its location, it is predicted that in later years it will affect the soil and its rich production.	Effects on the local population in the cultivation of melon and grass.	Limitations in planting local growers	Limitation in its capacity.	Limitation in its capacity.	Effects on the local population.	Soil damage
<b>Environmental impact</b>	Medium-term damage to the soil in the area.	Effects on bamboo crops and endemic species.	EGO has implemented the sustainable construction site model in order to mitigate environmental impacts.	To mitigate the impact, water saving and waste recycling systems are implemented	Reduction of 439.000 tons of CO2	Reduction of 365.000 tons of CO2	Smog reduction annually	Limitation of CO2 emissions
<b>Potential [MV]</b>	292	254	754	220	204	161	215	200
<b>Location</b>	Piauí	Bay	Coahuila	Tlaxcala	Antofagasta	Atacama	Puna	Olacapato
<b>Cost [USD]</b>	\$ 300.000.000	\$ 400.000.000	\$ 650.000.000	\$ 165.000.000	\$ 164.000.000	\$ 135.000.000	\$ 555.000.000	\$ 313.000.000
<b>System Losses [MW]</b>	73	63.5	188.5	55	51	40.25	53.75	50

Based on this comparison, the magnitude of the investment in this energy technology is recognized, and how it can provide a better quality of life around 600,000 inhabitants of the surrounding areas, although it must be recognized if it generates certain environmental and social impacts that are not completely supplied, such as an affectation to the unique species of that region that despite the efforts to mitigate this impact will never be close to 0%, hence Ituverava presents a higher economic investment despite the fact that its generation potential is lower than that of nova Olinda. It should be noted that in most of its actions it is possible to recognize the great change that they are allowing the country to transcend at the technological and energy level in the medium term in order to mitigate the scarcity of non-renewable resources that is coming by leaps and bounds.

2) *Mexico*: This country has the characteristic of having a limitation in humidity and its vegetation is not very wide, which is why solar radiation is very large especially in the northern part of the country. Recognizing this favorability of the area and based on the limitations of fossil resources that this country can generate; it has been involved in the implementation of renewable energies in order to meet the energy demand [27]. Many of its technologies are similar to those it manages in the United States, all this based on a new law called the energy transition law that was published in 2015 which regulates the growth of clean energy in the national interconnected system.

Based on the above, entities such as Asolmex are at the forefront of irregularly enacting all projects related to solar energy, companies such as Enel have come to this part of the continent in order to generate investments that allow the

execution of high-quality projects with a high capacity of energy generation [21], Next, the characteristics of some of them are shown in Table III.

Many of the characteristics of these large photovoltaic projects are recognized. This multinational has great campaigns to mitigate the environmental impact and in turn generates studies that have also allowed it to reduce the social impact with the surrounding communities implementing in these centers of academic and labor training, as well as the generations of direct jobs with the company for the short and medium term [22].

3) *Chile*: Currently in the country is inserted in the national interconnected system about 25% of energy from photovoltaic solar parks, entering around 6500 MW to the system. In the country Several companies that own solar power plants, some of the most prominent are the following:

- Enel: 18 solar power plants.
- Engie: 9 solar power plants
- Prime energy: 14 solar power plants
- Colbún: 6 solar power plants

Some of the regions with the highest solar radiation and that have the constructions of this type of plants are Antofagasta, Atacama and Metropolitan [23].

Some of the characteristics of this type of energy in the country is that the energy is cheaper can mitigate the environmental impact is available anywhere in the country, its maintenance is easy, and energy can be supplied in places where the power line does not reach. To further complement the importance of the implementation of these solar power plants will proceed to recognize some of the characteristics in Table III that handle the solar plants mentioned in Section II.

It could appreciate that both solar parks have similar characteristics since they are located in a desert, thus taking advantage of the incidence of the sun in this area limiting its environmental impact with the flower and fauna of this country. Among its policies for mitigating the environmental impact are the use of circular economy for the rational use of water, recycling solid waste and the limitation of generation of gases that affect the ozone layer, on the other hand, from the social field EGP has generated jobs for people in the area, this in order to take advantage of the national workforce and provide academic training that allows the population a better quality of life while the project is in execution [24]. Some of the features that stand out most is the implementation of bifacial panels, although taking into account the area in which it is installed, it is then limited to the generation capacity since for this area it is expected that energy can be generated 2 or 3 times more than what they currently produce.

4) *Argentina*: In the regions of Neuquén to Jujuy, there is the largest solar irradiation that Argentina has, which is why the importance of the implementation of this type of energy generation sources will yield a new horizon at the economic and energy level for the country. In recent years, the creation of photovoltaic plants throughout the country has been

booming, which is why in the world ranking of energy generation it is ranked 42nd, largely supporting the national interconnected system with clean energies [14].

Some economic analysts indicate that the country would save around 300 million fuels if 1000 MW of renewable energy will be implemented, for this reason it is very important to recognize what characteristics one of the large solar parks that the country has can possess. Some of this information is provided below in Table III.

It can recognize then that this type of solar parks has required a large economic investment due to the environmental impacts they generate in the area, these impacts are of a social and ecological nature, therefore it was necessary that some generating companies will merge as is the case of altiplano 200 in order to maximize their profits by grouping each of the parks that had been created in the area [14]. There is an enormous energy potential of the country, but it is necessary that external agents invest this resource, countries such as China in the last decade have generated agreements and negotiations between energy peers of the country in order to establish some new solar plants that maximize the renewable energy generation of Argentina.

#### B. Comparison between Selected Projects

When entering each of the characteristics of the largest photovoltaic solar generation parks that Brazil, Mexico, Chile and Argentina have, it was able to show what strengths and weaknesses are presented in each of these projects, the ones that stand out below will be mentioned.

##### 1) Strengths

- Implementation of state-of-the-art technology such as bifacial panels.
- Social inclusion policies that allow a good execution of these projects in the area.
- Capacity of generation to do with it is in the national energy system.
- Weaknesses.
- Effects on the flora and fauna of some areas.
- Excessive water consumption in the construction and execution of these projects.
- Damage to the ground in the medium and long term.

Although it is seen that large companies that develop this type of projects in Latin America, such as Enel, have multiple mechanisms to mitigate many of the weaknesses mentioned above, but unfortunately in some areas where ecology thrives, environmental problems are occurring whose consequences are irreversible. That is why a call is made for this type of policies to be more optimized so that the damage to the environment when these projects are developed and executed have been mitigated to the maximum and not only focus on the reduction of greenhouse gases since this is not the only environmental damage that can be generated.

Loss of energy in solar panels is usually due to two factors, which correspond to the temperature and dirt that are detrimental in photovoltaic installations; where between 15% and 25% of the energy generated can be lost by photovoltaic modules. When designing a photovoltaic installation, consumption must be taken into account and also estimate the number of panels to be installed for the energy demand, in order to correct possible increases or decreases in electrical energy. To mitigate the problems in terms of dirt that occurs in the panels due to climatic factors, a possible solution is to manually clean said modules for the conservation of the photovoltaic plant.

VI. CHALLENGES AT THE LEVEL OF RESEARCH AND EXECUTION OF PHOTOVOLTAIC PROJECTS IN LATIN AMERICA

The gap opens so that researchers and education centers related to renewable energy generation can inquire about the problems that currently afflict this type of energy systems such as:

- Improve the efficiency of solar panels.
- Regulate the stability of the system.
- Mitigate the impacts on generation due to pollution.
- Portable implementation of these systems at low cost.
- Use of solar cells in public and private means of transport.

Among other projects or mechanisms that optimize the use of these systems.

The technologies that implement photovoltaic systems are relatively recent date back about four decades, which is why there are multiple problems derived from this type of technology thus preventing the increase of its efficiency gradually, the reasons affect the science of these systems are shown in Table IV.

Taking into account the aforementioned affectations, it is necessary to investigate technologies or mechanisms ken to minimize this type of losses to the photovoltaic system that is why some of these are mentioned in order to provide approach tools for future research related to this topic.

TABLE IV. EFFECTS ON SOLAR ENERGY SYSTEMS

Problems	Description
Climate impacts	The parameters that affect are the temperature of the surface of the panel and its corresponding radiation, climatic factors, wind and humidity of the area
Environmental impacts	Dust pollution in solar panels, spaces where shadows can be generated, soil degradation, etc.
Characteristic features	Damage to the structure that holds the solar modules, failure of solar cells, elements tearing, etc.
System losses	Losses in conductors, inverters, material with which the cells are manufactured, environmental contamination and distortion of solar radiation. On average, losses are estimated at 25% of the estimated generation.

A. Optimization Mechanisms

1) Control of system stability failures: Based on the great boom in photovoltaic generation worldwide, it can appreciate some challenges or problems arising from this implementation such as voltage stability, power oscillations and frequency regulations. The energy oscillations of the system They are a situation that occurs mostly in areas where its energy flow is directly derived from photovoltaic systems, which is why for this work it is imperative to establish parameters to control the oscillations thus guaranteeing the reliability of the system. [22].

The proposed strategy to mitigate this impact is the implementation of a new control mode that applies to the inverter that is in the photovoltaic network and in the storage system at the moment where the energy oscillations that are parallel to the frequency variations and the state of the load of the storage cell are presented, thus imitating the maximum and minimum values of load and discharge [22]. The hysteresis control allows avoiding the frequent change of the working modes, on the other hand, initially the battery has the role of moderating the energy that comes from the outside, a reactive power controller is also attached to this system, and these mechanisms are used according to the energy level of the battery as shown in Fig. 9.

2) Model for detecting dust accumulation in solar cells: The generation of energy in a photovoltaic system depends directly on the efficiency of its modules or solar cells, this parameter changes according to external factors such as the dirt that can occur in these elements generally in arid areas, as part of the challenges faced by this type of technologies is the mitigation of this type of physical pollution. To detect such a change, it is necessary to make the relevant measurements to a new or recently implemented photovoltaic system [23].

Fig. 9. Gram flow of the control coordination strategy [22].

As an object of this detection model, corresponding measurements of radiance, accumulated power, and temperature in a time interval in a desert of Saudi Arabia are implemented to establish the prediction model. The results of this analysis were that during a year in the months where more sandstorms occurred that is about half of the year, a loss of up to 20% of energy reception was created, thus recognizing the importance of implementing some technological mechanism that limits dust pollution in those months of the year where more losses are generated.

3) *Hybrid systems*: Starting from the premise that photovoltaic systems can only generate energy during the day, it is necessary to find a mechanism that allows generating energy at night. As a result of this problem, the connection of a wind system that allows generating energy at night has already been implemented so that it can be used 24 hours a day in energy generation [23].

Some of the limitations of the implementation of this type of system are that they can only be developed in isolated areas where power lines are limited. It should also be taken into account that to store this energy derived from a wind turbine, the transformation from AC to DC must be generated in order to regulate the load in order to adjust it to an energy that can receive the storage batteries, which are also implemented by photovoltaic systems.

#### B. New Technologies on the Continent

1) *Two-sided solar panels*: Currently some of the new technologies that are being implemented are the use of bifacial panels which allow the use of the entire area of the solar cells in order to increase the percentage of energy reception.

This type of panels has been used by corporations that implement large solar parks in countries such as Brazil, Chile, Mexico, among others. It is expected that in about 10 years all single-facial solar panels that are used in solar power plants will be updated in order to optimize the performance of this type of generation.

2) *Photovoltaic inverters*: Another of the advances that are being implemented is the use of photovoltaic inverters that control the stability of the system, this in order not to introduce harmonics in the laying by the electricity network in order to avoid losses due to this type of distortions. The strategy is to control the injection of active and reactive power into the system to improve the efficiency of generation and distribution of photovoltaic solar energy.

3) *Implementation in transport*: They are currently conducting studies and have some prototypes of vehicles that have solar panels on their roof that are used to generate electricity in the device. At the moment there are only vehicles with very small panels which means that the energy received is not enough to guarantee the autonomy of mobility in a journey of more than 50 km in hours where the traffic is strenuous. In some countries in Europe, North America and Asia, are very common and the use of solar panels in your transport systems such as buses, electric vehicles, trains or

ships thus allowing the non-dependence on fossil fuels and more now that due to the situation between Russia and Ukraine, the flow of oil and gas to the entire European continent has been limited.

#### VII. CONCLUSIONS

One of the main challenges in the study of the factors that affect the viability of photovoltaic projects is the lack of information on the different parameters such as geographic location, orientation of the installation, the amount of available sunlight, the level of solar irradiation and the level of energy captured. These limitations are important when evaluating the performance of a photovoltaic project.

In the future, photovoltaic projects are expected to be further developed in Central and South America feeding the electrical grid with clean and renewable energy. Additionally, projects can provide local employment and support economic development. These photovoltaic projects are gaining ground and are becoming a priority. This is due to the growing concern about climate change, as well as the intention to reduce imports of fossil fuels. Therefore, when analyzing the data, an overview of the situation in each country is given. Among the most important factors to consider were: the initial capital required, the installation costs, the geographical location and the cost recovery time, for which it is necessary to generate new knowledge and technologies that carry both the collection efficiency energy, either by improving the composition of the materials of each solar panel, adopting more intelligent economic and regulatory strategies, and becoming aware of the limitations that each country presents.

This article offers an overview of the main aspects that should be considered when evaluating a solar project. It can become a reference for students and professionals in the electricity sector, as it offers a concise and complete overview of the main factors to take into account when evaluating the feasibility of a photovoltaic project. This has led to a greater understanding and use of resources, as well as greater efficiency in the decision-making process.

It is recommended that for future work a study be taken into account that considers the effects that weather conditions and materials may have on the efficiency of the panels, since this can significantly affect performance. Therefore, for a complete evaluation of the viability of photovoltaic projects, this impact must be considered, analyzing how the components interact with each of the climatic conditions, emphasizing considering the resources that represent the best cost-benefit ratio and that can better benefit Latin American countries.

Taking steps to reduce the costs of photovoltaics is essential to ensure that the use of renewable energy is as economical as possible. A clear solution to reduce the costs of electricity is the improvement of solar panels, attacking this lack in energy capture by favoring the reduction of the costs of photovoltaic energy. Measures such as increasing research on solar panels, reducing production costs, and improving design must be taken to optimize performance and lifetime. Research and development in solar panels must be a priority to reduce production costs. This must include the development of new

technologies and materials to optimize efficiency. Given that this type of energy once put into operation is a solution in terms of greenhouse gas emissions. Since they do not produce them and also provides a great tool for governments to meet their sustainable energy objectives.

# Ransomware: Analysis of Encrypted Files

Houria MADANI<sup>1</sup>, Noura OUERDI<sup>2</sup>, Abdelmalek Azizi<sup>3</sup>  
Faculty of sciences, Mohammed First University, Oujda, Morocco<sup>1,2,3</sup>

**Abstract**—Ransomware is a type of malware that damage the system by encrypting all the files existing in the computer. To get access, the victim has to pay a ransom to get a key to decrypt his data. When the virus is running in machine, the user cannot stop it on the first try, so he may lose his entire files. One of the goals of this work is to detect ransomware based on encrypted files in real time and to minimize the cost of losing files. We will try to do an analysis of a received file (without opening it and seeing its contents). This scanning action can prevent a ransomware from spreading in the system. Most Ransomware files are sent in “.exe” format, but in this work, we will try to use other file formats that can accept malware, for example, .doc or .docx, .xls or .xlsx, .ppt or .pptx, .jpg, etc. In fact, an attacker can focus only on the files that contain useful data. In this paper, we are going to identify the types of files if they are suspicious or normal (without opening them) from their headers. For that first, we are going to analyze each extension separately (.docx, .exe, .pptx, .xlsx, .jpg, etc.) by identifying their headers and signatures. Then we will take several files with different extensions to analyze them by doing a program who detect if a file is benign or suspicious.

**Keywords**—Ransomware; encrypted files; signature; file format; static analysis

## I. INTRODUCTION

In recent years, ransomware attacks continue to explode exponentially around the world; the cost keeps falling and exploit different sectors.

Researchers and cybersecurity specialists are still looking for a solution to detect this attack and even to slow down its growth in order to find an effective and reliable solution. We see many solutions, but not 100% sure, because hackers are always attentive and updated with the new technologies, they use more sophisticated techniques to follow the evolution and bypassing the protection techniques.

This study focuses on the examination of the behavior and method in which ransomware encrypts files. Ransomware can infiltrate a device in various formats like .exe, .docx, .ppt, etc. A user may open a .docx file without realizing it is an unsafe file that contains metadata that can damage their computer. Therefore, we aim to analyze the files (without opening them) before and after ransomware encryption, in order to distinguish between a typical file and a suspicious one.

In this paper, we will make a study on files to differentiate between a normal file and a suspicious one. For that in Section II, we will approach some "state of the art" concerning the study of files to give you an idea of the current research on this subject. In Section III, we will see our objectives and working methodology to identify and detect a normal file from another suspect one. We will discuss the results that we have

had in Section IV. At the end, we sum up with a conclusion and some perspectives.

## II. STATE OF THE ART

As you know, attackers are very inventive when they want to target a victim and we find, often, that emails are the trickiest (more than 90%) way [1] for them to create a link between the attacker and the target. Fig. 1 explains how ransomware attacks your machine:

Ransomware detection techniques [2]–[5] are becoming more and more competitive, and each researcher has his own method and technique. If we take the detection of ransomware or malware in general, using file headers, several researchers work focus on a single file extension like PE (Portable Executable) files [6]–[8], but there is not enough research on the detection of ransomware using the headers of different extensions.

The authors in [9] proposed a new classification model based on machine learning techniques to detect and classify malicious and benign PE files based on their headers information. The experimental results proved that the Random Forest algorithm yields a higher accuracy (99.68%) compared to other algorithms. The tests were performed on 211,067 malware samples obtained from the VirusShare database [10]. Manavi and Hamzeh [11] presented a method for detecting ransomware using the PE header. They used a Convolutional neural network (CNN) to identify ransomware by converting the header bytes into 32\*32 pixel images. The use of a header is advantageous, but transforming it into an image would necessitate the use of a network with additional layers in order to extract its features.

To detect ransomware, the authors [12] used a static method. They proposed a method that is based on the bytes extracted from the header of the executable file using LSTM network to build the detection model.

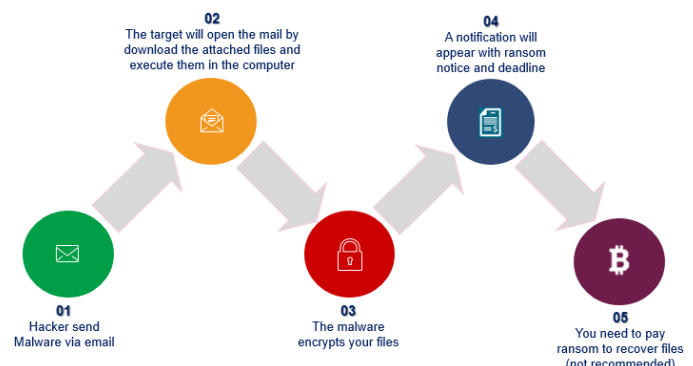

Fig. 1. Ransomware attack phases.

\*Corresponding Author.

The modification of the file header changes its structure. Therefore, they did the extraction of the executable file headers, then they processed the byte sequence that builds the file header with LSTM network, and they separated the ransomware samples, from the benign samples to form the template. With this technique, they managed to detect ransomware with 93.25% accuracy without running the program.

Subedi et al. [13] employed data mining techniques to recognize and detect ransomware families using both static and dynamic analysis at three different levels: assembly, function calls and library. They also created an analytical tool that uses reverse engineering to create signatures for identifying ransomware families. Arabo et al. [14] proposed a dynamic analysis approach to gather ransomware API properties, which is then utilized to test 9 Machine Learning classifiers and a neural network. The goal of this research is to understand the link between a process's behavior and its nature, to detect if it is a ransomware or not. With a detection rate of 75.01%, Random Forest surpasses other classifiers. The benefit of this technique is that it does not require a signature database, but rather a collection of ransomware and non-ransomware data. The detection rate of the classifiers may be better by improving the dataset.

Before encrypted files were moved to a backup disk, Lee et al. [15] utilized machine learning techniques to detect and classify infected files. The training step was implemented at the backup system according to their recommendation. It identified files from various users and file types, as well as determining file entropy thresholds. These thresholds were transmitted to client hosts in order to decide whether a new version of the file was encrypted or not. The authors in [16] suggest a two-stage mixed ransomware detection approach using Markov model with the Random Forest technique to detect ransomware. Random Forest has the best detection rate of 97.3%.

The paper [17] emphasizes the capabilities of behavior-based detection mechanisms to identify crypto ransomware, demonstrating the limitations of signature-based detection approaches. In [18], Nieuwenhuizen proposed a ransomware detection scheme using behavior analysis and machine learning. Although the specific features were not revealed, their created feature set included properties such as payload persistence, anti-system restoration, stealth methods, environment mapping, network traffic, and privilege elevation that were extracted from the behavior of a malicious set up. Author employed the support vector machine (SVM) method as the classification technique in addition to the behavioral features related with data transformation behavior, such as huge file encryption.

The effect of certain ransomware families on the Windows platform is demonstrated and analyzed by Mohammad [19]. He deduces that most families of ransomware behave in a similar way when it comes to affect file system and registry entities. Furthermore, all types of ransomware generate files in the Windows system files and rename other files. To do the experiments, the author used Windows 7, Oracle VirtualBox VM, Cuckoo sandbox, and Virtual windows 10. The author concludes that monitoring system file and registry activities

can protect against ransomware. He also mentions that Windows 10 is more effective than Windows 7 regarding malware. The best method to follow as a recommendation is to regularly back up company or individual data.

### III. METHODOLOGY

As mentioned at the beginning, our goal is to detect whether a file is suspicious or not (regardless of its content), from its header which will be identified from its extension. This leads us to detect ransomware from encrypted files in real time.

It is well known that each extension has a fixed header according to the standards. If the header differs from the standard state, we deduce that it is suspicious.

To achieve our goal, we took several files with different extensions, if we take an extension, for example “.docx”, and we open some files with the same extension using the Hexadecimal editor (Hex Editor Neo [20]), we found that they have the same signature, also called "Magic number".

Namely, each file extension (.docx, .pptx, .xls, .exe, .dll, .jpg, etc.) has a fixed and specific "Magic number".

Table I shows some files with different extensions and their signatures or Magic number, for clear and normal files.

According to a deep study on Microsoft Office files, we notice that their signature is different, the "x" added at the end made many differences. If we take the extensions .doc and .docx (the same thing for .xls, .ppt/.xlsx, .pptx), the differences are seen in Table II.

TABLE I. SIGNATURE OF FILES WITH DIFFERENT EXTENSIONS

File extension	Hex signature	Size	ASCII Signature
.doc , .ppt , .xls	<b>D0 CF 11 E0 A1 B1 1A E1</b>	8 Bytes	ĐĬ.ą±.á
.docx , .pptx , .xlsx	<b>50 4B 03 04 14 00 06 00</b>	8 Bytes	PK.....
.pdf	<b>25 50 44 46</b>	4 Bytes	%PDF-
.png	<b>89 50 4E 47 0D 0A 1A 0A</b>	8 Bytes	.PNG....
.jpg	<b>FF D8 FF E0</b>	4 Bytes	ÿØÿà
.dll	<b>4D 5A 90 00</b>	4 Bytes	MZ
.exe	<b>4D 5A</b>	2 Bytes	

TABLE II. DIFFERENCE BETWEEN .DOC AND .DOCX

	DOC	DOCX
<b>Version</b>	Came in when the Microsoft Word was 1 <sup>st</sup> delivered and was utilized until 2003 variant of "Word".	Came in with Word 2007 and has been the default extension from then for all new Word versions.
<b>Storage</b>	A DOC is saved in a binary file that contains all the related formatting and relevant informations.	A DOCX file is actually a zip file with all XML files associated with the document.
<b>File size</b>	The DOC format has a <i>greater</i> size than the DOCX format.	The DOCX format has a <i>smaller</i> size than the DOC format.

To analyze files, we have taken some files (.docx, .doc, .pdf, .exe, .png) as an example, and see their structures (this study of files is very difficult to make because there is a lack of information on the structure of the files, for example, for the header "how many bytes occupied", for the contents "where does it begin?", etc.):

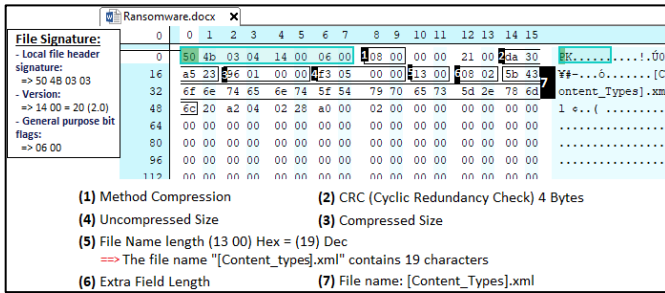

Fig. 2. ".Docx" File signature.

From the article [21], the header is always at the beginning of the file and is exactly 512 bytes in length. Fig. 2 and Fig. 3 show you some information about the header of the ".docx" and ".doc" file, respectively.

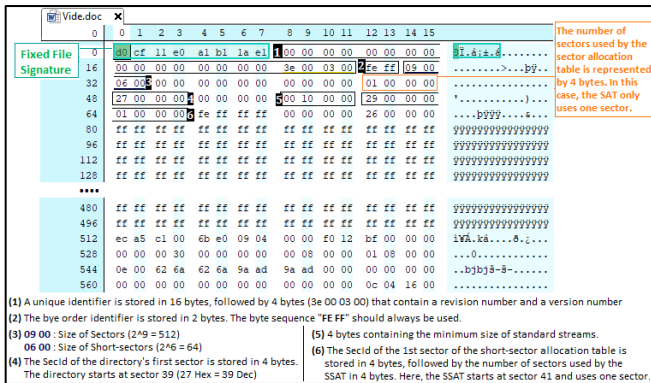

Fig. 3. ".doc" File signature (empty file).

Fig. 4 and 5 show you the structure and header of the ".pdf" and ".exe" files, respectively.

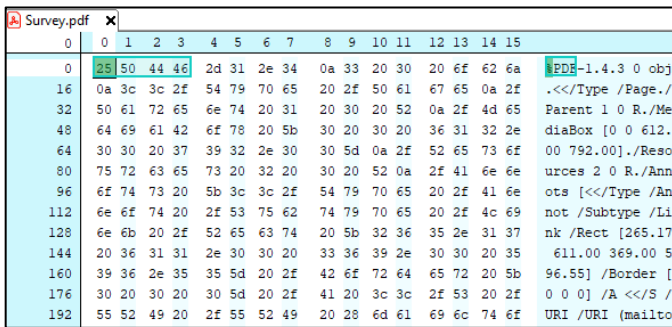

Fig. 4. ".PDF" File Signature.

Fig. 5. ".exe" file signature.

#### IV. RESULTS AND DISCUSSION

We took a corpus[22] that contains a large number of files with different extensions, and I encrypted them with a python program, adding to its files an '.enc' extension to make the difference between a clear file and an encrypted file. As an example, I took four files for each different extension (.doc, .docx, .ppt, .pdf); we got the following result:

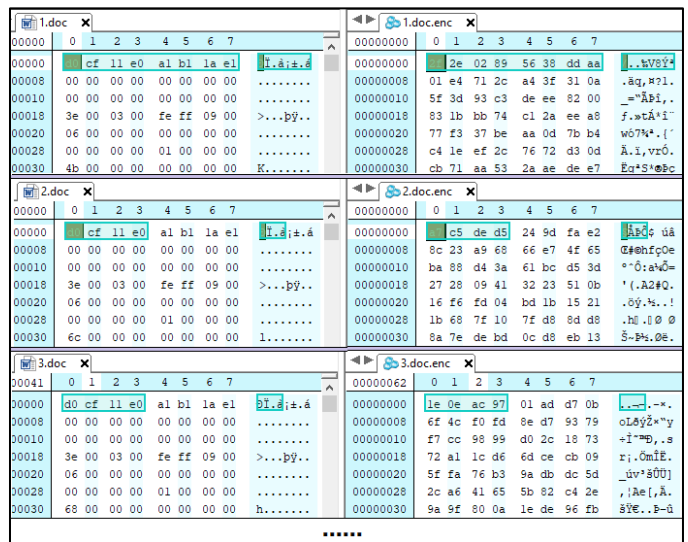

Fig. 6. The difference between encrypted and clear file headers [.doc].

For the files ".doc" (in Fig. 6), those on the left are clear files, their header should be normal [D0 CF 11 E0 A1 B1 1A E1]. While on the right, you see that there is an extension added at the end ".doc.enc", this means that they are encrypted files (the encrypted file of each clear file, e.g. "1.doc.enc" is the encrypted file of "1.doc"), and even their header is different. What is relevant is that each encrypted file has a different header from the other file, we have [2F 2E 02 89 56 38 DD AA], [A7 C5 DE D5 24 9D FA E2], etc.

The same thing for the files ".docx" (in Fig. 7), those on the left are clear files, their header should be [50 4B 03 04 14 00 06 00], while on the right you see the encrypted files and even their header is different. We have [A1 D1 05 C2 6C 8B 1D 19], [EF 34 21 9F FE 78 65 FC], etc.

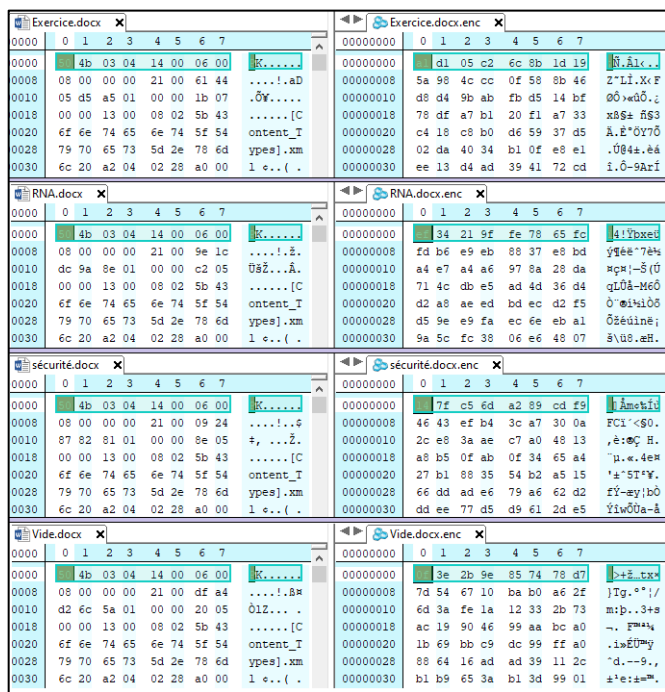

Fig. 7. The difference between encrypted and clear file headers [.DOCX].

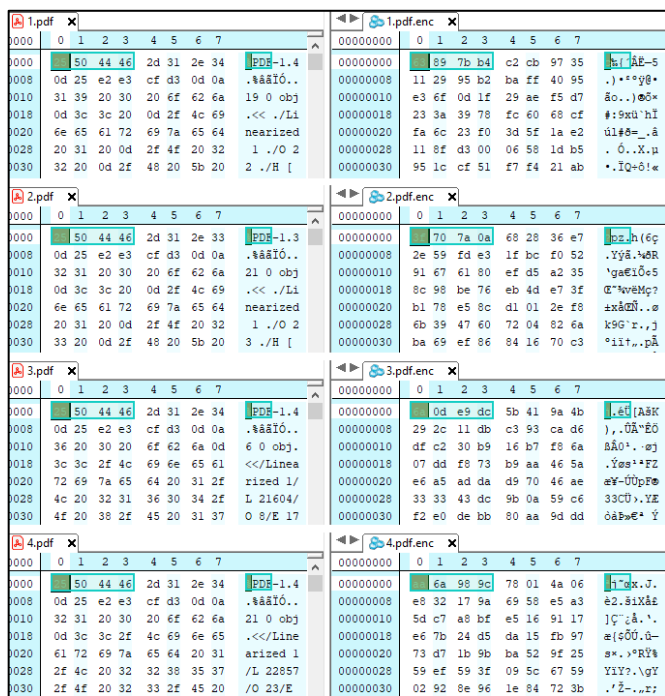

Fig. 8. The difference between encrypted and clear file headers [.PDF].

As you can see in Fig. 6, Fig. 7 and Fig. 8, the signature of a clear file and its encrypted is not the same; the case is the same for the other extensions. We also notice that the signature is fixed for any clear file (with different extension), but for encrypted files, it is not fixed and differs between each file.

The program is done by Python language to make this study and detect if a file is suspicious or normal from its signature.

Each extension has a "Magic Byte". We instantiated our dataset by creating a dictionary with the file extension as a key and its "Magic byte" as value, and then we analyze the file. If the file does not contain the corresponding signature, i.e. it has a different header than the one presented in our dataset; we deduce that it is a suspect file. We have also dealt with the case of a file without extension, if we give it to our program, it analyzes the header and if it does not find the corresponding signature, it sends us back that it's a suspicious file, otherwise, if everything is normal the result is: "This is a benign file, its extension is: ... ". Fig. 9 shows the result of a file without extension that is benign.

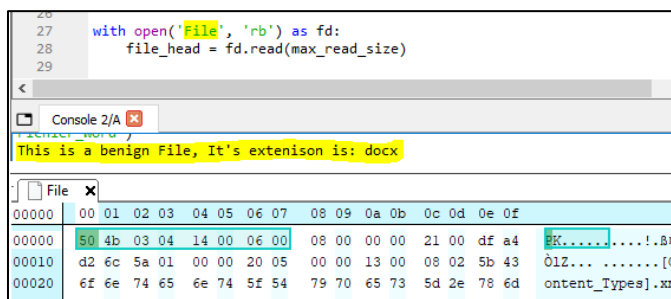

Fig. 9. Analysis of a file without extension.

Fig. 10 shows you that we have performed an analysis for several files with different extensions.

Fig. 10. Analysis of several normal files with different extensions.

If we take the example in Fig. 11, you can see that the result is "this is a suspicious file", even though the file has the extension ".doc". In effect, sometimes attackers send files that look normal with a legal extension, while the file is infected by the ransomware, so as you can see, our program perfectly analyzes the header of the given file identifying its signature, and it found that its signature does not match to the normal signatures.

Fig. 11. Analysis of a suspicious file.

We have tested our program on files encrypted by Ransomware with ".lmas", as you can see in Fig. 12, we have taken as an example the file "formation.xlsx.lmas", the ".lmas" extension is added after ".xlsx" extension. We got the followed result:

Fig. 12. Analysis of a file encrypted by Ransomware.

As you can see, Ransomware infects the file «formation.xlsx», it is encrypted and the attacker has added the extension ".lmas" to the file.

We know that ".xlsx" has a fixed signature (see Table I); in the Fig. 12, we can see that the first 4 bytes are similar to the first 4 bytes of the normal xlsx file (50 4B 03 04), but the difference is in the next 4 bytes. Therefore, our program was able to detect that this file is encrypted by ransomware so it is a suspicious file without opening it.

## V. CONCLUSION

In this work, we have made a Python program that allows to detect a suspicious file from another normal one, we started by studying the header of files of different extensions separately, later we extracted the header of each file and compared the headers of a normal file with another encrypted one. With this study, we could deduce that a normal file has a fixed and unchangeable extension, once it is changed the file is suspicious.

In the upcoming work, we will conduct a dynamic analysis by executing ransomware files in a simulated environment. This will allow us to extract ransomware encrypted files and analyze them in order to develop and implement our own neural network. This network will be trained to identify ransomware files by first learning the characteristics extracted from the ransomware encrypted files, and then using that knowledge to detect ransomware when a "vulnerable" file is downloaded onto a victim's device.

**Abstract**— Mathematic has always been one of the hardest subject to be learnt during school. This is the very same issue that student have been facing no matter the level of education that they are in, and this is the reason why Math Maze Zone or also known as MMZ had been developed. MMZ is a mathematical game-based learning tool for primary school students to help them prepare for their final examination for the mathematics subject. The proposed game will consist of mathematical questions and the game design will be focusing on a maze where user will have to search for a way out from the maze while going through the checkpoint within the maze. The checkpoint will consist of mathematical questions and when user answered correctly, they will be able to continue their journey to explore the maze. MMZ focused on 1 chapter only for now which is Chapter 8: Space and Shape. Although the game only consists of one-chapter, primary school students can play the game to enhance their knowledge and to help them to be more engaged with mathematics subject by playing the game. The results will be taken from the perspective of adult who have close relationship with standard six students. Five main sections will also be identified along with MMZ to ensure getting a good result.

**Keywords**—Primary school; educational mathematic game; game components

## I. INTRODUCTION

Having a high level of proficiency in math is vital for the economic success and growth of societies, as math is used in a wide range of fields and industries, including finance, science, engineering, and technology. Developing strong math skills can also open numerous career opportunities and increase an individual's earning potential [1][2]. There are few reasons as to why this is happening in which some students may not be interested in math, which can make it harder for them to learn and retain information. Other than that, Math can be abstract and difficult to understand, especially if students have not developed a strong foundation in math concepts. Moreover, Math also requires practice and repetition to fully understand and master concepts. If students do not have enough opportunities to practice or do not have access to support and resources, it can be harder for them to learn math [3][4].

With pandemic happening and children are unable to go to school for a long period of time, they are relying on the interactive media technology to gain more information and knowledge while staying at home. Not to mention, these children, especially standard 6 students in primary school will still have to take an important exam which will determine

which high school will they further their studies in. One of the methods for them to gain knowledge while learning for their future examination is through watching education videos on YouTube of, they can also play educational games that is related to their school syllabus. Higher availability, flexibility, and affordability of tertiary online education have also proved to have the potential to enable high-quality student learning. [5]

For this research, developing a mathematical interactive game that is suitable and matched the syllabus with primary school student to prepare for their examination will be done. The game will be called MMZ and will consist of mathematical questions. The game design will be focusing on a maze where user will have to search for a way out from the maze while going through the checkpoint within the maze.

The checkpoint will consist of mathematical questions and when user answered correctly, they will be given points. This research will be aimed to develop an educational mathematical game design that will help the primary school student where they can utilize the mathematics questions for their examination. MMZ will also include 5 different components to measure the effectiveness of the game such as the learning comprehension, user-friendliness, process of user learning, creative and critical thinking, and the effectiveness of MMZ towards the user.

There will be 4 sections that will be discussed in this research, which is section II, Background of the research that consist of mathematics examination and existing similar mathematic games. Section III, Methodology which consist of experimental setup and game design. Section IV, Results, and Section V, Conclusion.

## II. BACKGROUND OF RESEARCH

### A. Mathematics Examination

In Malaysia, students must take exams and assessments to move forward in their education. These results help them have a better chance to continue their studies. Although it is not the best way to measure a student's performance, it is currently the only way. For example, primary students must take final exams to have a chance to attend prestigious schools. Even though the UPSR exam is no longer used, students still need to learn math to move on to high school, especially as it relates to physics [6].

In Malaysia and worldwide, Mathematics is a crucial subject in schools. Students must master arithmetic to be

successful in math. Without this skill, they will have difficulty solving real-world problems. Since problem-solving is a vital part of math education, researchers have studied the success of problem-solving lessons [7]. To get into prestigious secondary schools, students need to do well in Mathematics, as it is a crucial subject. According to the National Council of Teachers of Mathematics, math is a widely used language that is important for communicating with people from different cultures and countries [8]. Other than that Mathematics are also a compulsory passing subject in Malaysian public examinations such as entrance examination and SPM.

In 2019, many students in Malaysia received an E grade in mathematics on the UPSR exam, ranking it as the second highest subject for E grades, according to the Ministry of Education Malaysia. English had the highest percentage of E grades, with 23.34% in writing and 14.87% in comprehension with Mathematics as the second subject with a 16.87% E grade percentage [9]. Below is the graphical illustration related to the comparison of percentages in every subject between 2018 and 2019 that can be seen in Fig. 1.

Kod & Nama Mata Pelajaran	Tahun	Peratus						Bilangan Calon
		A	B	C	D	Mencapai (A → D)	E	
011 - Bahasa Melayu-Pemahaman	2019	26.91	30.29	26.66	12.74	96.60	3.40	332,610
	2018	26.99	29.95	25.68	13.28	95.90	4.10	328,939

**B. Existing Similar Mathematic Games**

In this part, reviews about several existing games both in Malaysia and other countries that will be discussed along with

other existing games related to mathematics subject. The comparison MMZ with the other three existing games between the games developed by Malaysian and by other countries will also be discussed. There are six existing mathematics games and system that provide a similar kind of function with MMZ but have different kind of approach but are still using the same concept while developing for the game.

It can be observed that many games developed both in Malaysia and other countries share similarities in that they align with school syllabuses, which can aid students in better understanding the topics taught in school. The distinctions can be seen in Tables I and II, which will be presented below. The research conducted by various researchers in Malaysia will also highlight the principles employed, such as Norman's Seven Principles and Mayer's 12 Multimedia Principles in Table I while Table II will provide a comparison of research conducted by researchers from other countries.

TABLE I. COMPARISON OF EXISTING GAMES FROM MALAYSIA

Research Paper	Details	Norman's Seven Principles	Mayer's 12 Multimedia Principles.
Understanding of Number Concepts and Number Operations Through Games in Early Mathematic Education	Focuses on 1 mathematics topic that follows the NPSC, which is comparing the numbers through a game.	1. Visibility 2. Consistency	1. Multimedia Principle 2. Temporal Contiguity 3. Pre-Training
Pedagogical Change in Mathematic Learning: Harnessing the Power of Digital Game-Based Learning	Focuses on grade 1 to 3 mathematics syllabus. Every lesson on the game is different from one another.	1. Visibility 2. Consistency 3. Constraint	1. Multimedia Principle 2. Temporal Contiguity
Learning Math Through Mobile Game for Primary School Students	A mathematics-based game that consist of all the syllabus in each of the grade.	1. Visibility 2. Signifier 3. Consistency 4. Constraint	1. Multimedia Principle 2. Modality 3. Pre-Training
Math Maze Zone – A study on The Implementation of Mathematical Game-Based Learning Tool for Primary School Students From Adult Perspective	A mathematics-based game that consist of few selected chapter/syllabuses	1. Visibility 2. Feedback 3. Affordance 4. Constraint 5. Consistency	1. Coherence Principle 2. Spatial Contiguity Principle 3. Segmenting Principle 4. Multimedia Principle

TABLE II. COMPARISON OF EXISTING GAMES FROM OTHER COUNTRIES

Research Paper	Details	Norman's Seven Principles	Mayer's 12 Multimedia Principles.
Serious Gaming: Environmental Impact Through Math	Focuses on advance mathematics that universities students are learning.	1. Visibility 2. Mapping 3. Consistency	1. Multimedia Principle 2. Pre-Training 3. Redundancy
Space Chain: A Math Game For Training Geometric And Arithmetic Progressions	Assisting teenagers/students in learning about arithmetic and geometric progression in a comfortable and enjoyable manner.	1. Visibility 2. Consistency 3. Mapping 4. Affordance	1. Multimedia Principle 2. Modality 3. Temporal Contiguity
Game Based Learning For Math Learning: Fractions Case Study	Developed for children aged 6 to 10 for teaching fractions, as well as its pedagogic motivation and two preliminary tests with users	1. Visibility 2. Signifier 3. Consistency 4. Feedback	1. Multimedia Principle 2. Modality 3. Segmenting 4. Signaling

### III. METHODOLOGY

In this section, the experimental setup and game design in MMZ will be discussed.

#### A. Experimental Setup

In the game development process, the project can only move forward once all necessary experimental setup, including multimedia and graphic content, has been prepared. The Unity software platform will be utilized to build the application, with C# as the programming language used within Unity. The programming script will be created using Visual Basic software.

For the implementation process, all the planning should be done in action. Materials used in the project such as audio, video and 3D model should be developed properly. The system that has been developed should also be working properly. The application used to develop the project is by using Unity and Visual Basic software should also be downloaded to enable the application to be opened by using a computer. User should also be able to download the application through Google Store or other websites.

Other than that the scripting of the code for the game is working properly need to make sure. In this process, all programming script will be provided and the script will then need to be implemented in the game. Each scene needs to have script implemented in the game development. For each scene of the game, the script is used to instruct the game. For example, C# script is implemented in each of the button in order to help user to navigate to different scene. There is also a UI pop-out to shows what the user achieved after the user

completed a scene in the application. There will also be a script to allow user to play the video and audio in the application.

Next, in the user testing process, the application need to be tested each of its functionality. The user (which is the adults) who played the game will be conducting the user testing by playing the game and giving their feedback related to the game via the questionnaire and surveys in Google Form. This is the process that will help the developer to make some improvement to the game for it to be a better educational tool for the primary students.

Finally, in the evaluation process, the game will be evaluated based on the performance of the game itself whether it is functioning properly or if it is able to solve the problem statement. The game should also be able to achieve all the objectives and goals that have been set up earlier during the planning phase. Feedback will then be used to make some improvement to the game. If the final product does not meet up the expectation, revision will be needed, and the project will have to be re-analyzed so that a better game can be developed. Below is some of the information related to the development of the proposed game, which is the context diagram, use-case diagram, flowchart, storyboard, and the equipment. The gameplay of MMZ can be visualized through the flowchart presented in Fig. 2, as shown below.

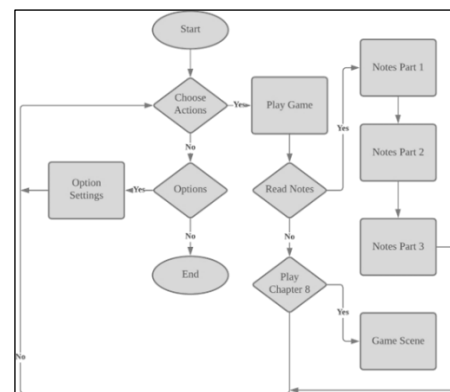

Fig. 2. Flowchart of the gameplay for MMZ

#### B. Game Design

In this section, the game elements, principle of human-computer interactions design and instructional design will be discussed.

##### 1) Game elements

Genre: MMZ is a game that belongs to the maze genre, which involves navigating through a series of twists and turns to reach a specific goal. In this type of game, players are typically faced with a problem that they must solve to progress, such as finding the correct path through a maze or solving a puzzle. By requiring players to think critically and try different approaches until they find a solution, maze games can help learners develop their problem-solving skills and become more strategic thinkers. In the case of MMZ, the goal is for players to navigate through the maze and reach the end, while also solving math problems at each checkpoint along the way. By combining the elements of a maze game with math concepts,

MMZ provides an engaging and challenging way for learners to practice and reinforce their math skills.

**Information:** When players start MMZ, they are provided with some initial information that can help them as they progress through the game. This information includes notes and objectives, which are designed to give players an overview of the game and provide them with the tools they need to succeed. The notes, which can be accessed before the game begins, provide players with important information that can help them understand the concepts being covered and solve the questions they encounter along the way. The objectives, which are also listed in the game, give players a clear sense of what they need to accomplish and allow them to track their progress as they move through the maze. By providing players with this information at the start of the game, MMZ helps to set them up for success and encourages them to stay engaged and motivated as they play.

**Game Objectives:** MMZ is a game that is designed to help learners practice and reinforce their math skills, specifically in shape and space. The objective of the game is for players to navigate through a maze while searching for checkpoints, at which they will encounter questions that test their understanding of math concepts related to shape and space. As they progress through the maze, players will need to use their problem-solving and critical thinking skills to find the correct path to the end, while also looking for an exit from the maze. The inclusion of a chapter on shape and space in the game allows players to focus on a specific topic and deepen their understanding of that concept.

**Quiz:** MMZ includes a quiz feature that allows players to strengthen their knowledge of math concepts. At each checkpoint within the maze, players will be asked a series of questions that test their understanding of the topic being covered. If a player gets a question wrong, they will be given the opportunity to try again, allowing them to loop back and review the material as needed. This iterative process of practicing and reviewing can be an effective way for learners to reinforce their understanding of math concepts and improve their skills over time.

**Game Mechanic:** The game mechanic for MMZ involves searching and exploring a maze while also solving problems at each checkpoint within the maze. As players navigate through the twists and turns of the maze, they will need to use their problem-solving skills to find the correct path to the end. Along the way, they will encounter challenges and obstacles that require them to think critically and apply their math knowledge to proceed. This combination of exploration and problem-solving can be an engaging and challenging way for learners to practice and reinforce their math skills.

**Feedback:** MMZ is a game that is designed to help learners practice and reinforce their math skills. As players progress through the game, they will receive a score or grade that reflects their performance. This can be a useful way for learners to track their progress and understand their strengths and weaknesses. By receiving feedback on their performance, learners can identify areas where they need to improve and focus their efforts on practicing those skills. Additionally, seeing their scores improve over time can provide learners with

a sense of accomplishment and motivation to continue playing and learning.

2) *Principles of human-computer interaction design:* HCI is a very essential part in an application since it will enable the application to be more successful, safe, useful, and functional. In the long run, it will also make the user's experience more delightful. It is also important to have HCI involved in all stages of product or system development. MMZ also followed the human-computer interaction (HCI) [10][11] which based on Norman's Seven Principles [12][13]. Below are some of the principles that MMZ have applied in the development of the game.

- **Visibility:** Users should be able to tell what their options are and how to access them just by glancing at an interface. This is very important in mobile, web and a game application because making everything visible inside the limited screen space is difficult; therefore, only the options that are required should be included. For example, MMZ provided a very large environment scenery. This is to make sure that the user can see everything in the screen where there is nothing that is hidden from the user. They can also move the mouse around to see more of their surrounding environment.
- **Feedback:** After each action, the user must receive feedback to determine whether their activity was successful. For instance, change the tab's symbol to a spinning wheel to show that a webpage is loading. With the example provided, MMZ applied this in the each of the scene. Every time user entered a scene, the scene name will be listed in the middle top of the screen. This is to make sure that the user will know in what scene they are currently in. Other than that, there is also checkpoint's name listed on top of the checkpoint to help user to know how many checkpoints they have gone through.
- **Affordance:** The link between how things seem and how they're used is called affordability. It is also important for digital apps where the design should be simple enough that users can access the information, they want merely by looking at the interface. For example, MMZ provided an instruction at the very beginning of the game. This is to make sure that user can know what their objectives are before starting to play the game. Other than that, the button in the interface used a familiar design to make sure that user can recognize the button just through the design of the button itself.
- **Constraints:** Constraints is important to prevent a particular form of interaction between an interface and the user. In this example, since the game used the theme of maze, there will be lots of walls where user is unable to go through the wall. User will have to find their way out by finding the correct path to the end of the maze while finding checkpoints and solve the mathematical questions. Other than that, user will also be unable to continue exploring the maze if they did not get the 49-right answer during in the checkpoint scene. They need

to make sure that they get the right answer even if more time is needed to solve the questions. This is to make sure that user can perfectly understand the question and are able to get the right answer.

- Consistency: Learning new patterns is a process that can be used to improve one's abilities. It is also a requirement to avoid frustration when one does not get the same output from the same project. For example, MMZ has the same pattern when the game is going to be played which is that player need to explore the maze while solving the mathematical question provided in the checkpoint. They will return to the maze after solving the questions in the checkpoint scene. Other than that if the player answered the question wrongly, they would have to start all over from the start of the question again. This is to make sure that they are certain and remember the answer for each of the questions.

3) *Instructional design*: The construction of learning experiences and resources in such a way that knowledge and skills are acquired and applied is referred to as instructional design. MMZ also followed instructional design (ID) which based on Mayer's 12 Multimedia Principles [14][15][16].

- The Coherence Principle: Coherence Principle [17] states that humans learn the best when extra and distracting material is not included. For example, MMZ does not have any extra text in the main game scene. User will only have to focus on walking around the maze while answering the question in the checkpoint and finding their way out from the maze.
- The Spatial Contiguity Principle: The Spatial Contiguity Principle [18] refers to the physical distance between the text and visuals on the screen, claiming that relevant information and visuals are best learned when they are physically close together. For example, in the question scene in each of the checkpoint, there will be an image provided with the questions. This is to help the user to answer the questions while referring to the image.
- The Segmenting Principle: Humans learn best when information is delivered in segments rather than in one single continuous stream, according to the Segmenting Principle. Mayer discovered that when students have control over their learning pace, they perform better on memory exams. For example, there are notes provided in the game to help the user to answer the question if they are yet to do any revision. Other than that, students can also repeat themselves answering the questions many times if they have gotten the answer wrongly.
- The Multimedia Principle: According to the Multimedia Principle, humans learn better from words and pictures than from just words. This notion, that visuals plus words are more effective than words alone, is the bedrock of all Mayer's principles. This is the reason why MMZ was developed. It is to help the user to learn mathematics through the game which consists of images, scenery that turns into an educational game.

Instead of learning mathematics in the traditional way, they can make a revision by playing the game where they can repeat many times in answering the questions to help them to become more familiar with the topic.

#### IV. RESULTS

As the pandemic happening, school is unable to be open which lead us to unable to gain an experimental result directly from the student themselves. However, the targeted audience has been changed from primary school students to the public which are differentiated by age. This is because adults can give a better opinion about the game in. Also make sure that the participant is someone who have a very close relation with the student in primary school. This is to ensure that the feedback that the survey will get can be used to improve MMZ. For example, parent, students who have younger siblings in standard 6 etc. There are three age category which is below 20 years old, 20 to 25 years old and 25 years old above. This is to make sure that the results can get different opinion from people so that improvement can be made to MMZ. A survey has been conducted to gain data and analysis for the proposed game.

Through the survey, the survey has managed to gather 19 respondents who are willing to participate and review MMZ. 9 of the participants (47.4%) are at the age of 19 and below, 7 of them (36.8%) are at the age of between 20 and 25 and 3 of them (15.8%) are at the age of 26 and above. The survey is also divided into five sections in which each of them represent different part. Fig. 3 shown below is the age of the respondent.

Fig. 3. Age of the respondents

The first section is about the usage of MMZ towards the learning comprehension. From the analysis gathered, 94.7% agreed that MMZ will be able to attract students to learn about mathematics. 89.5% agreed that students will be able to learn mathematics easily through the usage of MMZ. 94.7% agreed that MMZ are a suitable tool for student to do a revision. 94.7% agreed that students can gain more knowledge about mathematics through the usage of MMZ. 89.5% agreed that MMZ will be able to help students to increase their performance in learning mathematics.

The second section is about whether MMZ is a user-friendly application. 94.7% agreed that MMZ are very easy to be played with. 100% agreed that MMZ gameplay are easy to understand. 84.2% agreed that students will be able to learn with ease while playing with MMZ 100% agreed that students can learn while playing with MMZ. 94.7% agreed that students can play MMZ anywhere they want.

The third section is about the procedure of using MMZ. 94.7% agreed that the instruction given in MMZ is detailed and clear. 100% agreed that the language used in MMZ is easy to be understood 100% agreed that MMZ rules are easy to be followed. 100% agreed that MMZ achieved the level of comprehension for a student. 94.7% agreed that students can learn freely by using MMZ without needing a teacher's guidance.

The fourth section is about the usage of MMZ on student's creative and critical thinking. 100% agreed that MMZ can encourage students to think while answering the mathematical question. 100% agreed that MMZ can encourage students to make a discussion among their friends. 89.5% agreed that MMZ can encourage students to design a strategy to achieve success.

The fifth section is about the effectiveness of MMZ Here, the respondent gave an exact percentage of the marks that they can achieve while playing the game. 5.3% gained 40% marks, 36.8% can gain 60% marks, 36.8% are able to achieve 80% marks and 21.1% are able to achieve 100% marks. Overall percentage can see from Table III below.

TABLE III. OVERALL PERCENTAGE FROM THE FEEDBACK TAKEN

Category	Details	Results	
		Yes	No
Learning Comprehension	- Attract students to study	94.7%	5.3%
	- Easily understanding		
	- Reviewing learning	89.5%	10.5%
	- Gain knowledge	94.7%	5.3%
	- Improve learning's performance	94.7%	5.3%
User friendly	- Easy navigating	94.7%	5.3%
	- Easy to understand	100%	0%
	- Making it easier to study	84.2%	15.8%
	- Playing while Learning	100%	0%
	- Study anywhere	94.7%	5.3%
Procedure for MMZ	- Instructions given	94.7%	5.3%
	- Language easy to understand	100%	0%

	- Encourage planning	89.5%	10.5%
Effectiveness	- Learning Math through MMZ is effective		

## V. DISCUSSION

In this section, potential future improvements that have been identified through the analysis will be discussed. The following enhancements can be made to MMZ:

- **Dual-language:** The game should consist of dual language due to the lack of knowledge in term of the languages from the participant. They had issues in understanding the mathematical questions due to not being able to comprehend the meaning of the question.
- **Scoring System:** There should be a scoring system to help the user to understand their level of knowledge instead of them trying to answer the questions multiple times to get the correct answers.
- **More Challenges:** There should be more challenges provided in the game such as number of lives, enemies and traps provided in the game to make the game more challenging and fun to be played instead of them just wandering around the maze.
- **Voice-Over:** There should be a voice-over for each of the question in the checkpoint to help the user to be able to comprehend and understand the question better.
- **Answer Walkthrough:** There should be an answer walkthrough provided for the users who are unable to answer the questions correctly.
- **More Difficulty Level:** There should be more difficulty level according to the age of the students so that more students are able to use MMZ to help them learning mathematics much easier.

## VI. CONCLUSION

MMZ is a comprehensive and interactive educational game that has been specifically designed to assist standard six students in overcoming their difficulties and challenges in learning math subjects. By providing a fun and engaging way to practice and reinforce essential math concepts and skills, this game aims to enhance the students' confidence, motivation, and performance in math, and to support their overall academic success and growth. MMZ also implemented principle of HCI to make sure that the game can improve the ways in which people interact with computers and other digital devices. Instructional designs are also implemented to create effective, efficient, and engaging learning materials and experiences that support the learners' acquisition and retention of knowledge, skills, and attitudes.

The survey results provided valuable feedback about the game, and there are several suggestions for improvement that will make the game more effective as a learning tool for a wider audience. These suggestions include adding a dual language option, a scoring system, more challenges, voice-over, step-by-step explanations of answers, and different difficulty levels. By implementing the recommended suggestions, MMZ has the potential to not only become a more effective educational tool for primary school students, but also for students of other grade levels. While the UPSR exams had been dissolved, standard six students still have a final entrance

exam that will determine their academic standing and help them choose a suitable high school.

**Abstract**—The usage of the point cloud surface reconstruction to generate high-precision 3D models has been widely applied in various fields. In order to deal with the problems of insufficient accuracy, pseudo-surfaces and high time cost caused by the traditional surface reconstruction algorithms of the point cloud data, this paper proposes an improved Poisson surface reconstruction algorithm based on the boundary constraints. For large density point cloud data obtained from 3D laser scanning, the proposed method firstly uses an octree instead of the KD-tree to search the near neighborhood; then, it uses the Open Multi-Processing (OpenMP) to accelerate the normal estimation based on the moving least squares algorithm; meanwhile, the least-cost spanning tree is employed to adjust the consistency of the normal direction; and finally a screened Poisson algorithm with the Neumann boundary constraints is proposed to reconstruct the point cloud. Compared with the traditional methods, the experiments on three open datasets demonstrated that the proposed method can effectively reduce the generation of pseudo-surfaces. The reconstruction time of the proposed algorithm is about 16% shorter than that of the traditional Poisson reconstruction algorithm, and produce better reconstruction results in the term of quantitative analysis and visual comparison.

**Keywords**—Point cloud; moving least squares; Poisson reconstruction; Neumann boundary constraints

## I. INTRODUCTION

With the popularity of 3D reconstruction technology, the surface reconstruction has been widely applied in various fields, such as the mapping [1], driverless [2], medical technology [3], robotics [4]. For the methods of reconstructing surfaces based on the 3D point cloud data, they can be generally divided into two schemes: the local methods and the global methods. The local reconstruction methods divide all the point clouds into small blocks of data, which are then reconstructed locally and finally connect them together by using some kinds of stitching functions [5, 6]. This scheme retains the surface texture features well, but it is heavily sensitive to the noise. The global surface reconstruction is an approximation of all the point clouds, and the implicit surface is optimally reconstructed by solving extreme values and other methods [7]. It is under a high overall smoothness and is

suitable for the interpolation and the whole repair of irregular, non-uniform scattered data. As an implicit function-based surface reconstruction method, Poisson reconstruction method reconstructs a model with watertight closure features, geometric surface properties and detail characteristics [8]. After normal estimation on the input point cloud data, the objective of this algorithm is to estimate the indicator function of the model and extract the isosurface, and then complete the surface reconstruction using the moving cube algorithm based on the indicator function and isosurface [9]. Compared to the other algorithms, it allows a hierarchy of local basis functions to be divided and the reconstruction is projected to be a Poisson space problem, combining both of the advantages of the global and the local methods.

Recently, a large number of good works on the Poisson reconstruction has been reported by the famous scholars. For example, Kazhdan et al. proposed a screened Poisson surface reconstruction algorithm to keep the sparse point structure, and solved it by using a multiple mesh algorithm [10]. Z. Xu et al. proposed an adaptive bandwidth Gaussian kernel density estimator that facilitates the removal of the noise and anomalies in the 3D reconstruction process [11]. F. Gao et al. proposed a Poisson reconstruction algorithm based on the improved isosurface extraction, which can effectively eliminate the problems of surface holes and disconnect the surface features [12]. B. Ummerhofer et al. proposed a generalized convolutional kernel for 3D reconstruction with ConvNets from point clouds [13]. Though the above reconstruction methods have made great breakthroughs in this field, there still are some drawbacks to overcome. For example, the traditional Poisson reconstruction is prone to pseudo surface and normal inconsistencies. The time complexity of reconstruction method for improved isosurface extraction is too high. The method based on an adaptive bandwidth Gaussian kernel density estimator is not effective for the reconstruction of point cloud data with small density variation. Considering the entire above problem to deal with, this paper proposes an improved Poisson reconstruction algorithm and reduces the reconstruction time of the model to improve the reconstruction efficiency.

Fig. 1. The flowchart of the improved reconstruction algorithm

The remainder of this paper is organized as follows. Section II presents the proposed method of reconstruction for 3D point cloud. In Section III, the experiments are implemented to evaluate the method. Conclusions are given in Section IV.

## II. WHOLE METHOD

In Fig. 1, the proposed improved reconstruction algorithm consists the following steps: the set of gradients of the indicator function is determined by the normal vector of the point cloud data, so the accuracy of the normal estimation has a significant impact on the surface reconstruction results. Compared to the traditional Poisson algorithm which mostly uses principal component analysis for normal estimation, this paper proposes an improved method. Firstly, an octree is used instead of a KD-tree to search the nearest neighborhood; then the normal of the point cloud is estimated by moving least squares and accelerated by OpenMP [14], and then the normal direction is adjusted consistently by a least-cost spanning tree. The traditional Poisson reconstruction algorithm is prone to generate pseudo-surfaces. In this paper, the screened Poisson algorithm is implemented by introducing constraints on the location and gradient of the points to constrain the surface reconstruction process; and adding Neumann boundary constraints to make the solution of the indicator function more accurate and generate more accurate surface models. The whole flow of the specific algorithm is shown in Fig. 1.

### A. Octree and the Moving Least Squares

The octree is used to represent a three-dimensional space, and is a spatial extension of the quadtree [15]. The geometric entities in the three-dimensional space are first dissected into cubes, each with the same time and space complexity, and then the geometric objects in the three-dimensional space of size  $(2n*2n*2n)$  are dissected by a circular recursive partitioning method to construct a directional graph with a root node [16]. In the octree structure if the cubes being divided have the same properties, the cube forms a leaf node [17]; otherwise the

dissection of the cube into eight sub-cubes continues[18]. For  $(2n*2n*2n)$  size space objects are dissected at most  $n$  times, and the structure is shown in Fig. 2 [19]. The octree algorithm is more efficient than the KD-tree in searching point cloud data with high data volumes and is more automated, allowing optimization of the time for 3D reconstruction of point clouds [20, 21].

The Moving Least Squares algorithm is simple and easy to implement as a method for interpolating discrete data, with high fitting accuracy [22]. When a large amount of discrete data is distributed in a heterogeneous manner, the use of traditional least squares algorithms often requires the fitting of segments to the data, in addition to avoiding the problem of discontinuous and unsmooth fitting curves on adjacent segments [23]. Moving least squares introduces the concept of tight branches and the fitting function is constructed differently.

1) *The fitting function:* The fitting function [24] for the moving least squares in the local area is shown in Eq. (1).

$$(x) = \sum_{i=1}^n \beta_i(x)q_i(x) = q^T(x)\beta(x) \quad (1)$$

Fig. 2. The flowchart of the improved reconstruction algorithm

where  $\beta(x) = [\beta_1(x), \beta_2(x), \dots, \beta_n(x)]^T$  is the coefficient to be found;  $q(x) = [q_1(x), q_2(x), \dots, q_n(x)]^T$  is a polynomial of order  $k$  as a basis function; and the number of terms in the basis function is  $n$ . The basis functions for the linear and quadratic bases are  $q(x) = [1, x, y]^T$  and  $q(x) = [1, x, y, x^2, xy, y^2]^T$ .

In this paper, the quadratic basis is used to improve the accuracy of surface fitting and normal estimation [25]. The squared weight of the difference between the local approximation of  $f(x_i)$  and the nodal value  $y_i$  is minimized, the weighted residual equation is shown in Eq. (2).

$$J = \sum_{i=1}^m w(x - x_i) * [F(x) - y_i]^2 = \sum_{i=1}^m w(x - x_i) * [q^T(x_i)\beta(x) - y_i]^2 \quad (2)$$

where  $m$  is the number of nodes in the area of influence;  $w(x - x_i)$  is the weight function of node  $x_i$ . In order to determine the coefficient  $\beta(x)$ , it must be made to take a minimal value. The derived equation is shown in Eq. (3).

$$\frac{\partial J}{\partial \beta} = A(x)\beta(x) - B(x)y = 0 \quad (3)$$

where  $A(x) = \sum_{i=1}^m w(x - x_i)q(x_i)q^T(x_i)$  ;  $B(x) = [w(x - x_1)q(x_1), w(x - x_2)q(x_2), \dots, w(x - x_m)q(x_m)]$  ;  $y^T = [y_1, y_2, \dots, y_m]$ .

The coefficients of the fitting equation are shown in the following equation.

$$\beta(x) = A^{-1}(x)B(x)y \quad (4)$$

Substitute Equation (4) into Eq. (1) and let  $\varphi^k(x) = [\varphi_1^k, \varphi_2^k, \dots, \varphi_m^k] = q^T(x)A^{-1}(x)B(x)$ , the fitted function of the moving least squares is obtained as shown in Eq. (5).

$$f(x) = \sum_{i=1}^m \varphi_i^k(x)y_i = \varphi^k(x)y \quad (5)$$

where  $\varphi^k(x)$  is the shape function;  $k$  is the order of the basis function.

2) *The selection of the weight function:* The weight function  $w(x - x_i)$  in Eq. (2) is compactly supported in the moving least squares algorithm, that is, the weight function is only affected by the subdomain near  $x$ , which is called the influence region of point  $x$ . Beyond this region, its weight is small and the influence can be ignored. As an indispensable part of the moving least square method, the selection of weight function is very important to the fitting accuracy [26,27]. Generally speaking, the circle is chosen as the support domain of the weight function, and its radius is denoted as  $S_{max}$ , as shown in Fig. 3.

The common weight functions include the spline weight function and the Gaussian weight function [28,29]. When Gaussian weight function is used for the moving least squares surface fitting, the width of a single kernel is difficult to meet the feature requirements of the whole model. It needs to be selected according to the point cloud density and curvature distribution in the local neighborhood, and the kernel width is not easy to be determined. As reported in literature [30], the cubic spline weight function has continuity. Therefore, the cubic spline weight function is selected in this paper. Denoting

$s = x - x_i$ ,  $\bar{s} = s/s_{max}$ , the cubic spline weight function is shown as follows:

Fig. 3. The area of the impact region

$$w(\bar{s}) \begin{cases} \frac{2}{3} - 4\bar{s}^2 + 4\bar{s}^3 & |\bar{s}| \leq \frac{1}{2} \\ \frac{4}{3} - 4\bar{s} + 4\bar{s}^2 - \frac{4}{3}\bar{s}^3 & \frac{1}{2} < |\bar{s}| \leq 1 \\ 0 & |\bar{s}| > 1 \end{cases} \quad (6)$$

### B. The Normal Estimation and Direction Consistency

Define a local quadratic surface as  $S(r, v) = S(r, v, h(r, v))$ . The first order partial derivative of the surface at a point is then calculated as shown in the following equation.

$$\begin{cases} S_r = (1, 0, 2ar + bv + e) \\ S_v = (0, 1, br + 2cv + f) \end{cases} \quad (7)$$

where  $h(r, v) = ar^2 + brv + cv^2 + dr + ev + f$ . So the normal direction of the surface at this point is calculated by the following formula. Where,  $a, b, c, d, e$  and  $f$  are the coefficients of the surface equation.

$$n = \frac{S_r * S_v}{|S_r * S_v|} = \frac{(-2ar - bv - e, -br - 2cv - f, 1)}{\sqrt{(2ar + bv + e)^2 + (br + 2cv + f)^2 + 1}} \quad (8)$$

The normal direction calculated based on the moving least square method is ambiguous, that is, only the line where the normal line is located is obtained, but the direction of the normal line is not determined. Therefore, it is necessary to carry out direction consistency processing for the normal in the model to ensure its accuracy [31]. In this paper, the minimum spanning tree (MST) is used to adjust the normal direction uniformly [32,33]. Firstly, the algorithm defines a cost function for the point cloud in the model, as shown in the following equation.

$$cost(p * q) = |g * n_p + g * n_q| \quad (9)$$

Where  $g$  is the unit vector pointing from point  $p$  to point  $q$ .  $p$  and  $q$  are adjacent points, and  $n_p$  and  $n_q$  are normal to points  $p$  and  $q$ , respectively.

### C. Screening Factors

Because Poisson equation is a partial differential equation, some errors will cause the indicator function to shift, resulting in a large number of pseudo-closed surfaces at the edges of non-watertight surface connections [34,35]. In this paper, the process of surface reconstruction is constrained by introducing the position and gradient constraints, and then the screened Poisson reconstruction algorithm is implemented.

In the process of solving the Poisson equation, the indicator function  $\chi: R^3 \rightarrow R$  is solved for the directed point set  $\vec{V}: R^3 \rightarrow R^3$ , so that the gradient of the function and the directed point set form the best approximation, that is, the scale function is minimized to solve the problem  $\min_{\chi} \|\nabla\chi - \vec{V}\|$ ,  $E_{(\chi)} = \int \|\nabla\chi(h) - \vec{V}(h)\|^2 dh$ . In this paper, a point set  $S: S \rightarrow R \geq 0$  with weight  $\omega$  is given, and some gradient constraints and value constraints of discrete points are added to minimize the scale function to recalculate the sample point function. The constraint equation is shown in Eq. (10).

$$E_{(\chi)} = \int \|\vec{V}(h) - \nabla\chi(h)\|^2 dh + \frac{\alpha \cdot Area(S)}{\sum_{h \in S} \omega(h)} \sum_{h \in S} \omega(h) \chi^2(h) \quad (10)$$

where,  $h$  is the sample point of the input point set,  $\nabla\chi$  is the gradient of the indicator function,  $Area(S)$  is the surface region to be reconstructed,  $\alpha$  is the screening factor, which is used to measure the fitting gradient and the fitting value, and  $\omega(h)$  is the sample point weight. For the convenience of calculation, the weight  $\omega(h)$  of each sample point is set as 1 in this paper. Eq. (11) can be obtained by simplified to be:

$$E_{(\chi)} = \langle \vec{V} - \nabla\chi, \vec{V} - \nabla\chi \rangle_{[0,1]^3} + \alpha(\chi, \chi)_{(\omega, S)} \quad (11)$$

where,  $\langle \cdot, \cdot \rangle_{[0,1]^3}$  represents the standard inner product on the space of functions in the unit cube (scalar and vector values).  $\alpha(\chi, \chi)_{(\omega, S)}$  is the representation of the unit cube on the function space. This value is obtained from the weighted summation of the functions of the sampling points, as shown in Equation (12).

$$\langle F, G \rangle_{(\omega, S)} = \frac{\alpha \cdot Area(S)}{\sum_{h \in S} \omega(h)} \sum_{h \in S} \omega(h) F(h)G(h) \quad (12)$$

#### D. The Neumann Boundary Constraint

In order to satisfy the solution of the shielded Poisson equation and the boundary conditions in a given region, the algorithm bias error is reduced by introducing boundary constraints for solving the partial differential equation. There are three main types of boundary constraints: the Dirichlet boundary constraint [36], the Neumann boundary constraint and the Robin boundary constraint [37,38]. At the endpoints it is generally written in the form  $Ay + By' = C$ .

a) If  $B = 0$  and  $A \neq 0$ , it is called the Dirichlet boundary condition, also called the first type of boundary condition, and gives the corresponding value of the unknown function on the boundary.

b) If  $B \neq 0$ ,  $A = 0$ , then it is called Neumann boundary condition, also called the second type of boundary condition, and gives the directional derivative of the unknown function normal to the boundary outside.

c) If  $B \neq 0$ ,  $A \neq 0$ , then it is called Robin boundary condition, also called the third type of boundary condition, and gives a linear combination of the value of the function of the unknown function on the boundary and the directional derivative of the outer normal.

The Neumann boundary constraint is added to the Poisson reconstruction process to force the normal derivative of the implicit function to be zero at the boundary, which makes the

solution of the indicator function more accurate. Both the Dirichlet and Neumann boundary constraints require the implicit function to take a negative value outside the model. Since the gradient of the indicator function is equal to the vector field, Neumann boundary conditions are more conducive to the solution of the indicator function than Dirichlet. Neumann boundary conditions constrain the watertight surface and require the derivative of the implicit function to be zero on the boundary of the integral domain. This property is compatible with the gradient of the indicator function, since the vector field  $V$  is numerically set to zero in the region far from the point cloud sample. When the surface exceeds the boundary of the integral domain, the Neumann boundary constraint creates a deviation across the boundary of the domain.

### III. EXPERIMENTAL RESULTS AND DISCUSSION

To verify the effectiveness, accuracy and feasibility of the proposed algorithm, it is compared with the traditional Poisson reconstruction algorithm and greedy projection triangulation algorithm [39,40]. The 3D scanning datasets from Stanford University and GeometryHub are used in this paper. All experiments are performed on a computer with a quad-core AMD Ryzen 3 3100 CPU and 16GB RAM configured at 3.59 GHz. And the parallel acceleration is implemented by the OpenMP.

#### A. Results

In Fig. 4, the original point cloud data of Model 1, Model 2 and Model 3 are shown from left to right. Fig. 5 shows the normal estimation of the MLS algorithm for the three data respectively, and the calculated normal is ambiguous. Fig. 6 shows the initial normal is estimated by the moving least squares algorithm for three data, and then the minimum spanning tree is used to redirect the normal. Based on the point cloud data in Fig. 6, the proposed algorithm is compared with the traditional Poisson reconstruction algorithm, the greedy projection triangulation algorithm.

Fig. 4. The normal before redirection

Fig. 5. The normal after redirection

Fig. 6. The original point cloud data

In Fig. 7, Fig. 7(a), 7(d) and 7(g) show the model generated by the traditional Poisson reconstruction algorithm, Fig. 7(b), 7(e) and 7(h) show the model generated by the greedy projection triangulation algorithm, and Fig. 7(c), 7(f) and 7(i) show the model generated by the proposed algorithm in this paper.

In order to further optimize the reconstruction effect, the different parameters of the proposed algorithm are analyzed and compared with the point cloud data of the above models. The effect diagram of model 1 is shown in Fig. 8. Then the above point cloud data were reconstructed with three types of boundary conditions respectively. The experimental results are shown in Fig. 9 and Table II. Fig. 9(a), 9(d) and 9(g) is the surface reconstruction under Neumann boundary constraints, while Fig. 9(b), 9(e) and 9(h) is the surface reconstruction under Dirichlet boundary constraints. Fig. 9(c), 9(f) and 9(i) shows the surface reconstruction under Robin boundary constraints.

### B. Discussions

It can be seen from Fig. 5, the normal direction is confused, someone pointing to the inner side, and someone pointing to the outer side. If there is no redirection, further processing will lead to many reconstruction errors. Fig. 6 shows the use of normal redirection optimizes the consistency of the normal direction and provides a more accurate normal input for later reconstruction. As can be seen from the comparison of several groups of models in Fig. 7, the surface features of the traditional Poisson algorithm have poor sealing property, and it is easy to generate pseudo surfaces by misconnecting the regions that do not belong to morphological features at the edges, among which Fig. 7(g) is the most obvious. The model reconstructed by greedy projection triangulation algorithm has many small holes, and the model surface is rough. Compared with the former, the proposed algorithm can effectively solve the whole problem by introducing shielding factor and boundary constraint. And the overall model is more perfect in reduction and surface smoothness.

Based on the data in Table I, the reconstruction time of the traditional Poisson reconstruction algorithm, greedy projection triangulation algorithm and the proposed algorithm is compared. The reconstruction time of the proposed algorithm is about 16% shorter than that of the traditional Poisson reconstruction algorithm, but the reconstruction time is longer than that of the greedy projection triangulation algorithm. This is because the proposed algorithm uses the moving cube algorithm to extract the isosurface, which consumes a long time and needs further improvement. When calculating the point cloud model with larger data volume, the algorithm in this paper has higher reconstruction efficiency.

Fig. 7. The surface reconstruction results based on different algorithms

In Fig. 8, the higher the value of the screening factor, the more detailed the reconstructed model will be, but the longer it will take. At the screening factor of 4, the detailed features are well represented and take a moderate amount of time. As can be seen from Fig. 9, the accuracy of the reconstruction model under Dirichlet constraint is low, and many detailed features are lost. Although Robin boundary constraint is a combination of Dirichlet boundary constraint and Neumann boundary constraint, it takes the longest time and has a poor reconstruction effect on the edge, as shown in the Fig. 9(c) for the pseudo-surface marked by the red circle. The reconstruction time under the constraint of Neumann boundary is the shortest. Compared with the traditional Poisson surface reconstruction, the pseudo-surface is significantly reduced, and the effect is more ideal.

TABLE I. THE COMPARISON OF RECONSTRUCTION EFFECTS BASED ON DIFFERENT ALGORITHMS

The experimental data	Traditional Poisson reconstruction algorithm			Greedy projection triangulation algorithm			The proposed algorithm

#### IV. CONCLUSION

In this paper, we propose an improved Poisson surface reconstruction algorithm based on the Boundary Constraints. Firstly, octree is used to replace KD-tree for nearest neighbor search. Secondly, the normal vector is estimated by moving least square method, and the redirection based on minimum cost spanning tree is used to reduce the error. Finally, on the basis of traditional Poisson reconstruction, screening factor and Neumann boundary constraint are introduced to further improve the reconstruction effect.

The experimental results on different data show that the proposed algorithm achieves more accurate reconstruction results, which can effectively reduce the generation of pseudo-surfaces and also reduce the running time to a certain extent. The further work is to improve the extraction of isosurface on the basis of the proposed algorithm, and try to apply the modified algorithm to other fields to obtain high-quality reconstructed models.

# Data Augmentation for Deep Learning Algorithms that Perform Driver Drowsiness Detection

Ghulam Masudh Mohamed, Sulaiman Saleem Patel\* and Nalindren Naicker  
Department of Information Systems, Durban University of Technology  
Durban, South Africa

**Abstract**— Driver drowsiness is one of the main causes of driver-related motor vehicle collisions, as this impairs a person's concentration whilst driving. With the enhancements of computer vision and deep learning (DL), driver drowsiness detection systems have been developed previously, in an attempt to improve road safety. These systems experienced performance degradation under real-world testing due to factors such as driver movement and poor lighting. This study proposed to improve the training of DL models for driver drowsiness detection by applying data augmentation (DA) techniques that model these real-world scenarios. This paper studies six DL models for driver drowsiness detection: four configurations of a Convolutional Neural Network (CNN), two custom configurations as well as the architectures designed by the Visual Geometry Group (VGG) (i.e. VGG16 and VGG19); a Generative Adversarial Network (GAN) and a Multi-Layer Perceptron (MLP). These DL models were trained using two datasets of eye images, where the state of eye (open or closed) is used in determining driver drowsiness. The performance of the DL models was measured with respect to accuracy, F1-Score, precision, negative class precision, recall and specificity. When comparing the performance of DL models trained on datasets with and without DA in aggregation, it was found that all metrics were improved. After removing outliers from the results, it was found that the average improvement in both accuracy and F1 score due to DA was +4.3%. Furthermore, it is shown that the extent to which the DA techniques improve DL model performance is correlated with the inherent model performance. For DL models with accuracy and F1-Score  $\leq 90\%$ , results show that the DA techniques studied should improve performance by at least +5%.

**Keywords**—Data augmentation; deep learning; computer vision; drowsiness detection; road safety

## I. INTRODUCTION

Road accidents represent a major socio-economic challenge for individuals, industries, and nations [1]. Commuters involved in road accidents are affected in a variety of ways; such as death, sustaining physical injuries, psychological trauma, as well as incurring financial burdens from damage to property [1-4]. For industries, road accidents adversely affect supply chain performance and logistics, reducing operational efficiency [5-7]. The net result of this adversely impacts the economy of a country. Furthermore, for national authorities, road accidents cause traffic congestion; resulting damage to infrastructure and increased environmental pollution. Road accidents are a greater concern in developing countries, wherein more than 90% of accidents result in fatalities [1]. Of all developing countries, the World Health Organisation

reports that South Africa has the poorest road safety record, with approximately 14 000 deaths per annum and an accident fatality rate of 3.2% [2, 8, 9].

The factors that cause road accidents need to be identified before an effective solution can be developed. Studies, such as those presented by Machetele and Yessoufou [1] and Verster and Fourie [2], highlight that driver-related accidents account for 80% to 90% of fatal road accidents. A key cause of driver-related accidents is drowsiness (which may result from excessive alcohol consumption), as this impairs a person's concentration and focus [2, 10]. The detection of driver fatigue or drowsiness is hence essential towards improving road safety and reducing the accident rate [11, 12].

In light of the fourth industrial revolution, technology is becoming more ubiquitous and there is growing motivation to utilize artificial intelligence and machine learning to solve social problems, such as driver drowsiness detection. To this end, there have been a range of studies that apply deep learning (DL) techniques to solve the problem of driver drowsiness detection [13-19]. DL is a subset of machine learning that mimics the neural network of the human brain, thus creating an artificial neural network [14]. Artificial neural networks comprise of multiple nodes that model neurons of the human brain, which are organized into layers [20]. Data is propagated from the input layer to the output layer. These artificial neural networks have the potential to solve regression and classification problems, including image classification problems [20, 21]. In the context of image classification, each layer trains upon the output of the previous layer, enabling latter layers to identify more intricate elements of the images [21].

At a technical level, the aforementioned studies perform driver drowsiness detection by considering images of a driver's eye, and using DL algorithms to determine the eye state (i.e. whether the eye is opened or closed). By applying this technology to frames from a video feed of the driver, it is possible to determine whether eyes are closed for extended periods of time, which is an indicator of drowsiness. Some of the DL algorithms used in literature include: (i) convolutional neural networks (CNNs) of different configurations [14-16, 18, 22, 23]; (ii) the multi-layer perceptron (MLP) [13, 24]; (iii) the respective Visual Geometry Group 16 (VGG16) [25, 26] and 19 (VGG19) [17, 26] models; as well as (iv) the generative adversarial network (GAN)[27]. The reported accuracies of the models in these studies range between 75% and 96%.

Despite the high accuracies reported in the studies, real-world challenges during implementation were reported that adversely affected the accuracy of the trained models. Among these challenges were: (i) poor lighting, where lighting is either too bright or too dim [13, 14, 17, 19]; (ii) changes to the driver's seat position [22]; (iii) a change in the angle of the driver's face while driving [13, 22] the use of spectacles and/or sunglasses by drivers [14, 17-19, 24].

In this paper, the authors proposed to address these real-world challenges by performing data augmentation (DA) on the training image sets that are input into DL models for driver drowsiness detection. DA techniques introduce artificial images that simulate real-world effects [28], such as different lighting environments and changes to face orientation. This study also uses a training dataset containing images of drivers with and without eyewear to address the challenges associated with drivers wearing spectacles or sunglasses. The DA techniques are tested on CNN models, GAN models, MLP models and both the VGG16 and VGG19 models. Hyperparameter tuning is performed on all models to optimize their learning rate and enhance their overall performance. Literature has shown that careful selection of hyperparameters has a significant impact on model performance [28, 29]. The effect of the DA is evaluated by comparing the performance of models trained with and without DA in with respect to the following metrics: (i) accuracy, (ii) precision, (iii) negative class precision, (iv) recall, (v) specificity, and (vi) F1-score. It is hypothesized that the use of DA will result in improved performance of all models.

It is noted that previous studies in literature [14, 25, 27] have incorporated the use of DA in improving the performance of their specific driver drowsiness detection models. However, to the best of the authors' knowledge, there are no comprehensive studies that investigate DA techniques for a wide range of DL algorithms in the context of driver drowsiness detection, as is done in this paper.

The research in this paper makes the following contributions:

- 1) Presenting an overview of DA techniques to model the specific real-world scenarios that cause challenges for driver drowsiness detection systems.
- 2) Studying the DA techniques on a wide range of DL models that perform driver drowsiness detection and statistically analyzing the effects of the DA techniques.
- 3) Demonstrating the extent to which the DA techniques studied are able to improve DL models that perform driver drowsiness detection and proposing a design guideline for DL model developers on that conditions under which the DA techniques should be considered.

The rest of this paper is organized as follows. In Section II, a review of existing literature was presented. Section III presents the materials and methods used in this study, including providing an overview of a real-world drowsiness detection system. In Section IV the results of the investigations are presented and finally, conclusions and insights that were drawn from this study are presented in Section V. Section V also makes recommendations for future work.

## II. RELATED WORK

This section reviews the DL algorithms that have been extensively used in previous studies, to implement models and applications, for drowsiness detection in motorists.

A study by Jabbar et al. [14] proposed a drowsiness detection system that could be implemented on the driver's dashboard, using an Android phone. The system was able to predict the drowsiness of the driver based on their eye state. This study made use of a CNN network to implement a binary classification model that was able to classify the drowsiness in facial images. Data augmentation techniques were applied to the images, before they were trained on the model. The Dlib C++ library was used to extract the driver's facial landmarks from the images. These facial features were fed into the algorithm for training. The dataset was created using the extracted eye features. This model achieved an accuracy of 83.3%. A similar study by Zhang, Su, Geng and Xiao [18] was conducted to detect the drowsiness of a person, using the eye state. This proposed model was implemented on an Infrared video camera. The AdaBoost algorithm was used to extract facial landmarks from the images. The extracted eye landmarks were used to create the image dataset, to train the model on. The CNN model was used as the binary classifier for drowsiness. An accuracy of 95.8% was achieved by this study.

Sharan, Viji, Pradeep and Sajith [15] proposed a similar drowsiness detection system to Jabbar et al. [14] that could be implemented on the driver dashboard. However, this study proposed that a Raspberry Pi camera module be used to capture the drivers face. The drowsiness prediction was also based on the eye state. The Haar Cascade classifier was used for facial extraction during the implementation of this system and the CNN network was implemented as the binary classifier. Contrast Level Adaptive Histogram Equalization was applied to remove the noise and improve the picture quality, before they were trained on the CNN model. The CNN model was trained on an existing dataset, comprising of eye images. The study by Seetharman, Sridhar and Mootha [22] made use of a CNN network to classify the drowsiness in images. The prediction was based on the eye and mouth state of the extracted faces. The Dlib library was utilized to extract the facial regions from the images, similar to the study done by Jabbar et al. [14]. A dataset for the model was then generated using the extracted eye regions. The trained CNN model achieved an accuracy of 92.4%. In addition, this proposed model was intended to be implemented on a dashboard video camera. Chirra, Uyyala and Kolli [16] proposed a similar model for drowsiness detection, as a CNN network was used to predict the drowsiness in images. The eye state was the metric for prediction, with the Viola-Jones algorithm used to extract the facial landmarks from the images, during the implementation of this system. An existing dataset of eye images was used to train the CNN model. The model produced an accuracy of 96.42%. This model was also proposed to be implemented on a video camera for drowsiness detection, like the study conducted by Seetharman, Sridhar and Mootha [22].

A model using the VGG 19 model to detect driver drowsiness, based on the eye state, was proposed by Hashemi, Mirrashid and Shirazi [17]. This study made use of the Viola-

Jones algorithm to extract the facial landmarks from the images. The extracted eye landmarks were then used to create the dataset for this model. The Viola-Jones algorithm has been utilised in previous work [16]. This model obtained an accuracy of 94.96%, with its intended application in driver dashboard monitoring. A study by Ahuja, Saurav, Srivastava and Shekhar [26], proposed an approach to improved drowsiness detection, by using a knowledge distillation technique to reduce the size of DL models, whilst maintaining high accuracy. A large model will have high memory consumption and longer response times. Therefore, there was a need to reduce the size of the DL model. The Histogram of Gradient algorithm was used to extract the facial regions from the images, during system implementation. VGG19 and Visual Geometry Group 16 (VGG16) were the algorithms used to train their respective models, to classify the drowsiness in images. These models were trained on an existing dataset, consisting of eye images. The predictions were based on the eye state for both models. The VGG19 and VGG16 models, obtained the accuracy of 92.5% and 95% respectively.

Bajaj, Ray, Shedge, Jaikar and More [25] proposed a real-time drowsiness prediction system that will be implemented on an Android application, to monitor the driver's face from the dashboard. This system can predict the drowsiness using the driver's eye state. A comparative analysis of three DL algorithms, specifically: Inception, ResNet-50 and VGG 16 were performed. Data augmentation techniques were applied to the images, before they were trained on the models. The models were trained on an existing dataset, comprising of face images. The accuracy achieved by the Inception, ResNet-50 and VGG 16 models were 89%, 56% and 91%, respectively.

A study by Jabbar et al. [13] proposed a system for drowsiness detection that could be implemented on an android application, for dashboard monitoring. The prediction of this system was based on the driver's eye state. The Dlib C++ library was used to extract the person's facial landmarks from the images. This library has been used for facial feature extraction in previous work [14,25]. These facial features were used to create the dataset, which was fed into the MLP algorithm for training. The model was able to classify a driver as either drowsy or non-drowsy. An accuracy rate of 80.92% was achieved by this model. A similar study by Ghourabi, Ghazouani and Barhoumi [24] made use of the MLP algorithm to detect drowsiness in the images. The eye and mouth state were used to classify the drowsiness. The Histogram of Gradient algorithm was used to extract the facial regions from the images. These extracted facial regions were used to create the dataset that was fed into the model for training. The model is intended to be implemented for dashboard monitoring. This study obtained an accuracy rate of 74.9%.

Ngxande, Tapamo and Burke [27] proposed a framework to reduce the biasness of a model during the training process. A Generative Adversarial Network (GAN) model was trained on an image dataset. This model made predictions using facial landmarks and the eye state in particular. The extracted facial landmarks were used to create the dataset for model training. Data augmentation techniques were applied to the images before they were loaded into the GAN model. This helped to improve the performance of the binary classification model. An accuracy rate of 91.62% was achieved by this model.

Many of the studies have used facial and eye extraction algorithms, to create image datasets from real-time data, to train their models on. However, this study aimed to use existing datasets that were available online, to train the DL models. The reason for this was because, this study aimed on improving the performance of trained models, regardless of the source of data. Therefore, no facial and eye extraction algorithms were used on real-time data, in this study.

Literature has shown that many drowsiness detection models faced issues with prediction accuracy, due to poor lighting and the use of sunglasses [13,14,17,18,24]. The other challenge that affected accuracy was the positioning of the driver's face [13,22]. Another gap identified is the lack of pre-processing and data augmentation applied on the data before training. Data augmentation was used in [14,25,27], to create more comprehensive models that exhibits improved performance. DA was used to remove biasness from the models, thus improving the performance. However, not many of the previous studies have comprehensively studied DA to model real-world scenarios to improve model performance, on a wide range of DL algorithms that detect driver drowsiness, as done in this study.

Therefore, this study aimed to develop an improved approach towards drowsiness detection by using data augmentation. Data augmentation techniques were used to create training data that replicate real-life scenarios that correlate with the challenges faced in previous studies.

### III. MATERIALS AND METHODS

This section first provides an overview of a real-world driver drowsiness detection system and isolates the role of the DL algorithms that this study focuses on. The data sources and DA techniques utilized in this paper are then discussed. Thereafter, a technical summary of the DL algorithms considered is provided, along with the parameters used in this study. Finally, the authors present the different evaluation metrics that are used to quantify the performance of the DL algorithms.

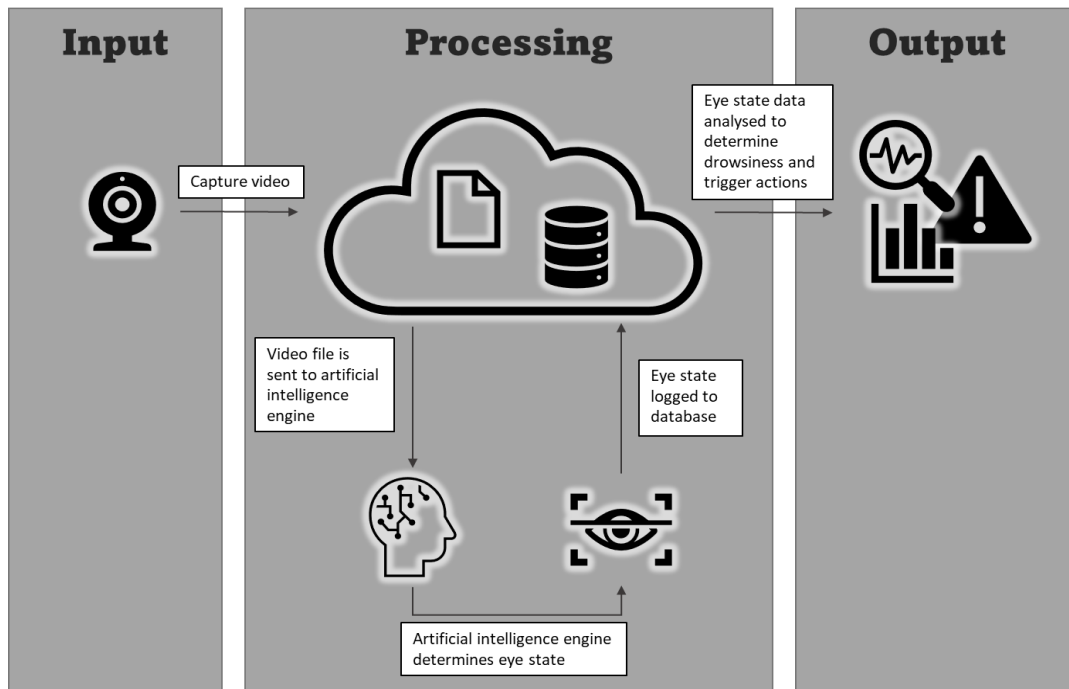

Fig. 1. Overview of a real-world driver drowsiness detection system

#### A. An Overview of a Real-World Drowsiness Detection System

Fig. 1 illustrates the process flow for a real-world driver drowsiness detection system. The process starts with a camera that captures a video of the driver's face, which serves as the input to the system. The camera can either be mounted to the dashboard or steering wheel of the vehicle. The captured video is then stored on cloud-hosted infrastructure, typically in some form of unstructured blob storage.

At the start of the processing stage of the system, the video file is passed on to an artificial intelligence engine, consisting of three sub-units. The first sub-unit extracts individual frames from the video file, which will then be treated as a series of sequential images. The second sub-unit uses image detection techniques to isolate the eye from each image of the driver's face. This produces a series of sequential images of the driver's eyes. Finally, the third sub-unit utilizes a pre-trained DL model to analyze the images and determine the state of the driver's eye (open or closed) in each frame. The eye state determined in each frame is then logged in a database, which is also typically cloud-hosted.

In the final stage of the system, the eye states stored in the database are analyzed and interpreted to detect the drowsiness of the driver. Drowsiness detected when the driver's eyes are in the 'closed' state for extended periods (multiple consecutive frames from the video feed).

#### B. Design and Configuration of Study

The research presented in this study focuses on the third sub-unit of the artificial intelligence engine, viz. the DL

algorithm that determines the driver's eye state, as described in Section III.A. Hence, for the experiments conducted, the inputs in this study were images of a driver's eye and the outputs were a categorical variable indicating the eye state. A binary categorical output was used, with the positive class label indicating the "open" eye state and the negative class label indicating the "closed" eye state. The experimental configuration used is depicted in Fig. 2.

In performing the experiments, appropriate datasets of eye images were first sourced. In selecting the datasets, the authors ensured that images where the eye was partially obscured by eyewear (spectacles or sunglasses) were included. By doing this, the DL models would learn to distinguish between eye states irrespective of the use of eyewear.

The datasets were then split into training and testing data using an 80:20 ratio. A copy of the training dataset was created, and data augmentation techniques were performed to model the real-world challenges of eye orientation and lighting conditions. Two DL models were trained: one was trained on the original (pre-treatment) training dataset, and the other was trained on the modified (post-treatment) training dataset. Depending on the architecture of the DL algorithm being investigated, any necessary data-shaping modifications were made to the images from the dataset.

The pre-treatment and post-treatment DL models were applied to the testing dataset to evaluate and compare their performance. As was the case with the training datasets, any modifications to the testing dataset required by the DL model architecture were made.

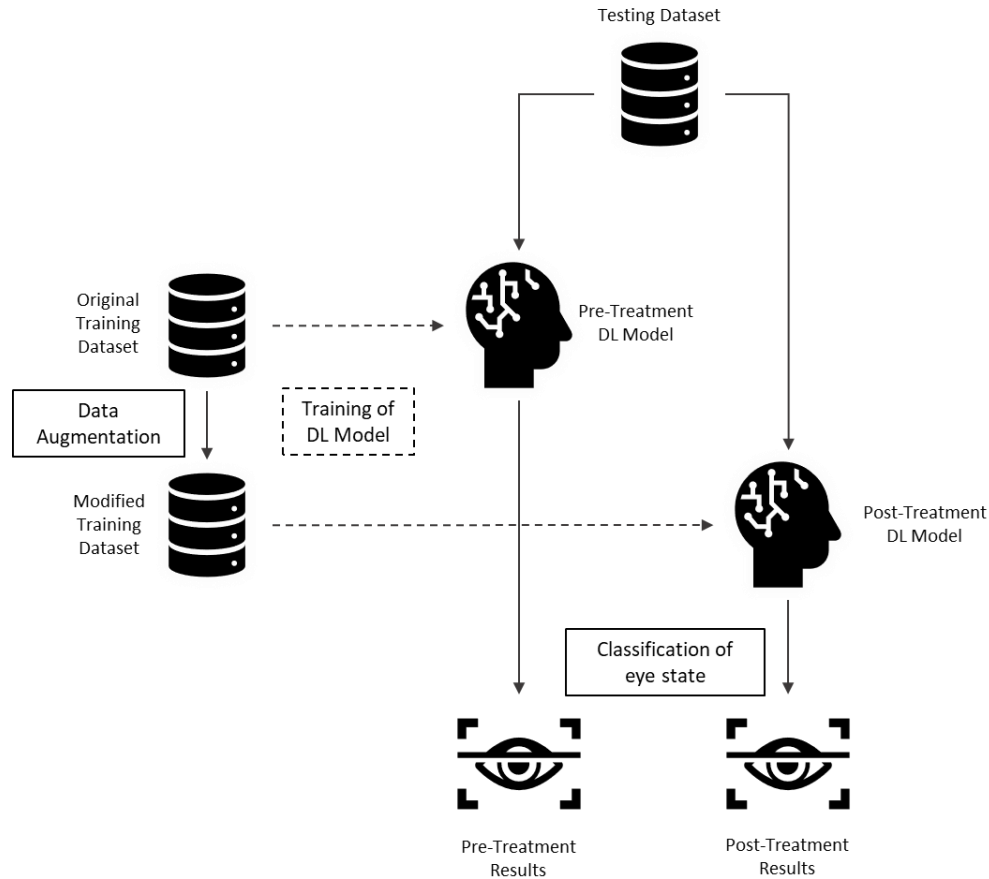

Fig. 2. Configuration of study

TABLE I. PROPERTIES OF DATASETS

Property	Dataset 1	Dataset 2
<b>Total number of images</b>	2 500	1452
<b>Eye Opened</b>	1 250	726
<b>Eye Closed</b>	1 250	726
<b>Image size (pixels)</b>	96 × 96	256 × 256
<b>Colour/Greyscale</b>	Greyscale	Colour
<b>File format</b>	Portable Network Graphics (PNG)	Joint Photographic Experts Group (JPEG)
<b>File compression</b>	Lossless compression	Lossy compression

The experiments were done using pre-built Python libraries on the Jupyter Notebooks development environment. A personal computer equipped with 8 gigabytes of random-access memory, an Intel Core i5-7200U processor and a 64-bit Windows 10 operating system.

1) *Selection of datasets*: There were two datasets utilised in this study, which were obtained from online repositories [30, 31]. Both datasets contained images of human eyes with and without eyewear, and images labelled according to the eye state. The properties of the datasets are presented in Table I.

The balanced distribution of eye states was preserved when splitting each of the datasets into respective training and testing

datasets, using an 80:20 ratio. The Scikit-learn Python library was used to implement the data splitting.

When exploring the datasets, it was also noted that both sets of data contained images from a diverse range of ethnicities. Different skin tones and complexions were noted, as well as different eye shapes. The authors further observed that among female eyes, the extent to which make-up such as eyeliner and false eyelashes were used differed.

2) *Data augmentation and pre-processing*: Data augmentation improves model performance by generating variations of training data [14]. This reduces overfitting and improves the model’s ability to make generalizations [14, 32]. The specific augmentations performed in this study were designed to simulate real-world scenarios and overcome some of the challenges indicated in literature.

The ImageDataGenerator class within the Keras library for Python [33] was used to implement pre-processing and DA in this study. The ImageDataGenerator class supports DA in real-time and makes sure that the model is trained with different variations of images during each training iteration (epoch) [34, 35].

The following pre-processing and data augmentation techniques were applied:

a) *Brightness adjustment*: Multiple studies in literature have shown that poor lighting conditions had a negative impact on the accuracy of DL models for driver drowsiness detection [13, 14, 17, 19]. While driving, ambient lighting conditions can change due to environmental conditions such as the time of day and the weather. For example, driving at night results in a very low brightness conditions and driving in bright sunshine results in very high brightness conditions. While driving, it is also possible for lighting conditions to change rapidly, such as when driving under a bridge/overpass on a sunny day or through the shadow cast by a building or other large structure.

To model scenarios with different lighting environments, this study applied a randomized change to image brightness when augmenting images. This is implemented through adding a constant,  $\delta$ , to all pixels in the image. The brightness adjustment function is mathematically described as:

$$f_b(p) = \max(0, \min(255, p + \delta)) \quad (1)$$

In (1),  $p$  is the value of the pixel and falls in the range  $0 \leq p \leq 255$ . Positive values of  $\delta$  increase the brightness of the image while negative values of  $\delta$  decrease the brightness of the image. The  $\max(\cdot)$  and  $\min(\cdot)$  functions ensure that the brightness-adjusted pixel value remains in a valid range.

b) *Horizontal flips*: The shape of a human eye may differ slightly between the left eye and the right eye. Creating artificial data by flipping the horizontal orientation allows the DL model to be trained to analyze either eye of the driver.

c) *Rotation, translation and zoom*: Literature showed that changes to the driver's face orientation was a real-world scenario that adversely affected the performance of DL models [13, 21]. Therefore, in this study, rotation, translation shifts and zoom transformations were used to model changes to the driver's face orientation. Rotation and translational shifts are useful to simulate movement of a driver's head while travelling. Zoom transformations model a change in depth between the camera and the driver's face, which may result from the driver changing their seat position or posture.

d) *Normalization, centering and standardization*: Normalization and standardization improve the learning rate and reduces the number of epochs required to train a DL model [36, 37]. These processes ensure that no individual input pixel dominates performance [38]. This is done by mathematically adjusting data such that it follows a Gaussian distribution with zero mean and unit variance [39].

Normalization involves rescaling the value of pixels to have a unit maximum, which reduces the computational power required to train the DL model. As all pixels have the same maximum value ( $p = 255$ ), the normalization function is described by [36]:

$$f_n(p) = \frac{p}{255} \quad (2)$$

Centering ensures that the data has a mean of zero, while standardization ensures that the data has a unit variance [36]. Setting these statistical properties of the data improves the rate at which a DL algorithm converges when training, as well as increasing model accuracy by eliminating statistical bias.

Centering and standardization can be applied to data in with respect to individual images (sample-wise) or with respect to the entire set of images (feature-wise). The functions for sample-wise centering (sc), feature-wise centering (fc), sample-wise standardization (ss) and feature-wise standardization (fs) are [39]:

$$f_{sc}(p) = p - \bar{p}_I \quad (3)$$

$$f_{fc}(p) = p - \bar{p}_D \quad (4)$$

$$f_{ss}(p) = \frac{p}{\sigma_I} \quad (5)$$

$$f_{fs}(p) = \frac{p}{\sigma_D} \quad (6)$$

In (2) – (6),  $\bar{p}$  represents the mean pixel value and  $\sigma$  represents the standard deviation of pixel values. The subscripts 'I' and 'D' respectively denote statistics calculated over pixels from a single image (I) and statistics calculated over the entire dataset (D).

In this study, each of the above pre-processing operations is performed on input data.

3) *Deep learning algorithms*: As discussed in Section I, DL is a subset of machine learning and involves mimicking the human brain. DL algorithms follow a common structure, to the extent that they adopt a layered architecture with multiple nodes at each layer. The DL algorithms for this study are designed to perform a binary classification in determining whether the eye state is 'opened' or 'closed'. A brief overview of the different DL algorithms implemented in this study for image classification is provided below.

a) *Convolutional neural network (CNN)*: The CNN is the most popular artificial neural network (at the time of writing). There are typically three classes of layers in a CNN: convolution layers, pooling layers and fully-connected layers [16, 40]. Fig. 3, re-produced from [41], illustrates the layout of these layers.

Convolution and pooling layers work together to perform feature extraction from the input image [16, 40]. First, input data representing pixels of an image is multiplying the kernel filters of a convolution layer to generate feature maps. Thereafter, a pooling layer is used to group features together and reduce the size of the feature maps. Pooling features together improves the computation time of the DL algorithm [16].

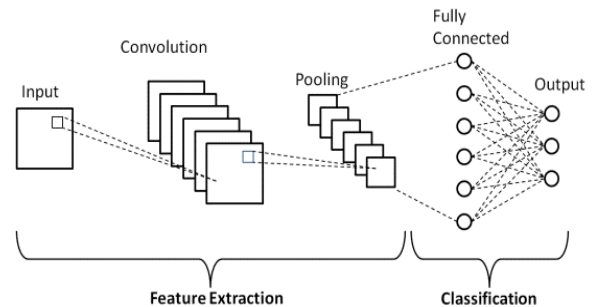

Fig. 3. Basic CNN architecture [41]

TABLE II. ARCHITECTURAL LAYERS OF CNN-C1

Layer Number	Properties
1	Convolutional Layer. 32 nodes, same padding, 3×3 kernel
2	Max pooling layer
3	Convolutional Layer. 32 nodes, same padding, 3×3 kernel
4	Max pooling layer
5	Convolutional Layer. 64 nodes, same padding, 3×3 kernel
6	Max pooling layer
7	Flatten layer
8	Dense layer with 128 units
9	Dense Softmax output layer with two units

TABLE III. ARCHITECTURAL LAYERS OF CNN-C2

Layer Number	Properties
1	Convolutional Layer. 8 nodes, same padding, 3×3 kernel
2	Average pooling layer
3	Convolutional Layer. 16 nodes, same padding, 3×3 kernel
4	Average pooling layer
5	Flatten layer
6	Dense layer with 120 units
7	Dense layer with 84 units
8	Dense Softmax output layer with two units

The processed feature maps are then fed into one or more fully-connected layers. The final layer is referred to as the output layer, and any fully-connected layers between the pooling layer and the output layer are referred to as hidden layers. Each node in a fully-connected layer performs a mathematical operation on its input data using an activation function. These activation functions are selected to map inputs to suitable outputs and perform classification [42].

Two different CNN model configurations were investigated in this study. For brevity, they are referred to as CNN-C1 and CNN-C2. Their respective architectures are shown in Table II and Table III.

Table II describes the first CNN architecture used in this study. These layers are arranged sequentially in a linear stack [43]. The first two convolution layers in this model have 32 nodes each, which are responsible for learning multiple spatial patterns and features from the input image [44]. The last convolution layer 64 nodes. A 3×3 kernel filter is used in each convolution layer, to generate the feature maps. Each convolution layer applied same padding to the input image, which enabled the image to get completely covered by the kernel filter, to generate a feature map [45]. Furthermore, each convolution layer was followed by a pooling layer that applies a maximum filter (max pooling). Once the convolution was completed, the data was then passed to the flatten layer to flatten the multi-dimensional feature map into one dimension

[46]. This single dimensional array was then forwarded into the dense layer of the network. A dense layer of 128 units is then used to perform the image classification, using the output from the convolution layers [47]. The last layer of this network was a two-unit output layer which made use of a softmax activation function that calculated the probabilities of each class [48]. There are only two units used in the output layer, because these models are binary classifiers, with predictions made for only two class labels. The output produced by the softmax layer, is represented in the form of a vector, which contains the probabilities of each class, for every sample data

In addition, a Rectified Linear Unit (ReLU) activation function was added to each convolution layer and dense layer, to ensure no negative values were passed to the subsequent layers [16]. The ReLU activation function is given by:

$$f_{\text{ReLU}}(x) = \max(0, x) \quad (7)$$

In (7),  $x$  refers to the input data to the activation function.

Table III describes the second CNN configuration used in this study, which also consists of sequential layers. This configuration uses fewer convolution layers than CNN-C1, but more fully-connected layers when performing classification. CNN-C2 also applies an averaging filter in the pooling layers (average pooling). As with CNN-C1, a ReLU activation function was added to each convolutional layer and dense layer, to ensure no negative values propagated through the network.

*b) Visual geometry group (VGG) networks 16 and 19:* The VGG have conducted extensive research into DL algorithms for image classifications that improve upon the traditional CNN [49]. The two VGG algorithms chosen were VGG16 [50] and VGG19 [51]. The VGG16 model consists of 13 convolution layers, five max pooling layers, two fully-connected layers and one softmax activation layer at the output [50]. The VGG19 model comprises of 16 convolution layers, five max pooling layers, three fully-connected layers and one softmax activation layer at the output [51].

The VGG19 and VGG16 models used in this study were built using the Keras pre-trained VGG library. As with CNN-C1 and CNN-C2, the output layer was configured to have two units with a softmax output representing the probability on an image falling into either classification.

*c) Generative adversarial network (GAN):* GANs are a class of DL algorithms that has been applied to image classification problems [52]. The structure of a GAN, shown in Fig. 4 [53], comprises of two sub-neural networks: a generator network and a discriminator network.

During training, both the generator and the discriminator learn concurrently. The function of a generator network is to produce new, artificial instances of data/images from the input features [52]. This is a form of data augmentation that occurs within the network architecture. The artificial images output from the generator network are evaluated by the discriminator to determine whether they adequately resemble images from the true training dataset. Back-propagation is then used to iteratively train the generator. Generator networks are typically seeded with randomized noise data.

Fig. 4. Structure of a GAN [53]

TABLE IV. ARCHITECTURAL LAYERS OF GAN (DISCRIMINATOR)

Layer Number	Properties
1	Convolutional Layer. 128 nodes, same padding, 3×3 kernel.
2	Max pooling layer
3	Convolutional Layer. 128 nodes, same padding, 3×3 kernel.
4	Max pooling layer
5	Convolutional Layer. 128 nodes, same padding, 3×3 kernel.
6	Max pooling layer
7	Flatten layer
8	Dense Softmax output layer with two units

The discriminator network is trained with images from both the actual dataset and the artificial images produced by the generator. When using a GAN, the discriminator is the final trained model that is tested and deployed in a system.

In the design of a GAN, the discriminator is often a CNN model, and the generator is often a de-convolutional neural network.

The GAN models in this study were built with the architectural layers described in Table IV. There were three convolutional layers used in this network with each layer having 128 nodes. Each convolutional layer was followed by a pooling layer to perform down-sampling. The data was then flattened and passed to a two-unit softmax output layer, where the output prediction was produced. The GAN models deployed a Leaky ReLU activation function, as described by (8), which was added to each down-sampling layer and dense layer. The Leaky ReLU activation function dampens the effect of negative values [54], but does not force them to zero like the standard ReLU function in (7).

$$f_{\text{Leaky ReLU}}(x) = \begin{cases} 0.01x & \text{for } x < 0 \\ x & \text{for } x \geq 0 \end{cases} \quad (8)$$

TABLE V. ARCHITECTURAL LAYERS OF MLP

Layer Number	Properties
1	Flatten Layer
2	Dense layer with 128 nodes.
3	Dense Softmax output layer with two nodes.

		True Eye State from Image	
		Open	Closed
Eye State Classification from Model	Open	True Positive	False Positive
	Closed	False Negative	True Negative

Fig. 5. Definitions matrix of model output classifications

d) *Multi-layer perceptron (MLP)*: The MLP is a more basic DL architecture than those derived from the CNN, as it only consists of fully-connected layers [55, 56]. The typical structure of an MLP consists of an input layer, an output layer and at least one hidden layer between the input and output layers. As such, the operation of the MLP is the same as classification stage of a CNN. As a result, MLPs require data to be flattened at the input layer.

The MLP models in this study were built according to the architectural layers described in Table V. The ReLU activation function was implemented in the hidden layer.

4) *Model evaluation*: When analysing model performance, this study considers a range of metrics collectively to provide a holistic evaluation of performance. The following performance metrics were used to evaluate the DL models: accuracy score, precision, negative class precision, recall, specificity and F1-score. These metrics are defined in (9) – (14), in terms of the number of true positive classifications ( $T^+$ ), the number of true negative classifications ( $T^-$ ), the number of false positive classifications ( $F^+$ ) and the number of false negative classifications ( $F^-$ ). These output classifications relate true eye state (based on the known label associated with an image) to the detected eye state (based on the output of the model). The definitions of the different output classifications are visually represented in Fig. 5.

a) *Accuracy score*: The accuracy score is a measure of how many correct predictions were made by the classifier, out of all the predictions made [57, 58]. This is hence the percentage of true output classifications with respect to all output classifications, and is mathematically described as:

$$\text{Accuracy Score} = \frac{T^+ + T^-}{T^+ + T^- + F^+ + F^-} \quad (9)$$

b) *Recall and specificity*: Recall defines how well the model can correctly classify positive outcomes [58, 59]. In the context of this study, recall indicates how many images of open eyes were correctly classified by the model. In addition, for a balanced evaluation of the predictions made for both class labels, the specificity metric was also used. Specificity indicates how well the model can correctly classify negative outcomes [58]. In the context of this study, it indicates how many images of closed eyes were correctly classified by the model. For the problem of driver drowsiness detection, being able to correctly identify when the driver's eyes are closed is of equal importance than identifying when the eye state is open. The mathematical definitions of recall and specificity are given in (10) and (11), respectively.

$$\text{Recall} = \frac{T^+}{T^+ + F^-} \quad (10)$$

$$\text{Specificity} = \frac{T^-}{T^- + F^+} \quad (11)$$

c) *Precision*: Precision defines how well a model can make classify positive outputs [60]. In the context of this study, this indicates the percentage of correct open eye state classifications from all open eye state classifications, as shown by (12). Similarly, the negative class precision represents the percentage of correct closed eye state classifications from all closed eye state classifications. The formula for negative class precisions is presented in (13).

$$\text{Precision} = \frac{T^+}{T^+ + F^+} \quad (12)$$

$$\text{Neg. Class Precision} = \frac{T^-}{T^- + F^-} \quad (13)$$

d) *F1-Score*: The F1-Score represents a weighted average between precision and recall and is hence considered the most appropriate measure of model performance in some literature [57, 61]. Equation (14) presents the mathematical formula to calculate F1-Score [61, 62].

$$\text{F1-Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (14)$$

#### IV. RESULTS AND DISCUSSION

This section presents and analyses the effects of data augmentation on model performance. Pre-treatment and post-treatment results are presented in Table VI and Table VII, and their descriptive statistics are presented in Table VIII. The

change in performance metrics due to treatment is presented in Table IX. While results for all performance metrics are presented, the main analysis focuses mostly on accuracy and F1-score, as the latter provides insight into the underlying precision and recall.

In the analysis carried out, the authors first confirmed that the DA techniques adopted in this study have improved the performance of the DL models that were investigated. Fig. 6 presents a box-and-whisker diagram of the statistical distribution of all evaluation metrics considered; and compares pre-treatment results with post-treatment results. From the results in Fig. 6, Table VII, Table VIII and Table IX, the following observations and interpretations were made:

1) The post-treatment mean and median values of all evaluation metrics are higher than the pre-treatment values (Table VIII and Table IX). This indicates that the average performance of all DL models studied improved due to the DA techniques applied. The average improvement of the most conclusive metrics, accuracy and F1-score, were +6.1% and +6.8% respectively.

2) The interquartile ranges (IQRs) and standard deviations of post-treatment results were less than for pre-treatment results. In terms of the most conclusive metrics, accuracy and F1-Score, the IQR of both metrics decreased from 13% to 3%. The standard deviation of accuracy scores decreased from 0.17 to 0.12. Similarly, the standard deviation of F1-Scores decreased from 0.20 to 0.14. This indicates that there is less variability in the expected post-treatment performance of all DL algorithms.

3) Outliers were noted in the results, which are clearly illustrated in Fig. 6. These arose from the VGG16 and VGG19 models which were trained on Dataset 1 and displayed inferior performance to the other models studied. Upon investigation, this has been attributed to the dimensionality mismatch between Dataset 1 images (96×96 pixels) and the input dimensions defined by the VGG16 and VGG19 architectures (224×224). While the application of DA techniques has shown the greatest improvement to these models, the post-treatment performance is still low compared to the other models studied. It is thus concluded that the VGG models are not suitable for Dataset 1, and in practice, should not be used with low-resolution cameras that produce smaller video frames/images.

TABLE VI. PRE-TREATMENT AND POST-TREATMENT EVALUATION METRICS (ACCURACY, RECALL AND SPECIFICITY)

Algorithm	Dataset	Accuracy Score		Recall		Specificity	
		Pre-treatment	Post-treatment	Pre-treatment	Post-treatment	Pre-treatment	Post-treatment
CNN-C1	1	93.8%	97.6%	100%	100%	88%	96%

Fig. 7. Statistical distribution of change in evaluation metric scores

Having confirmed the hypothesis that the DA techniques that were applied have improved the performance of the DL models studied, the next step was to attempt to quantify the extent of this improvement. The VGG16 and VGG19 models trained on Dataset 1 were excluded from this analysis due to their poor performance, as discussed previously. Table X presents the change in evaluation metrics due to the application of DA with these models removed. The statistical distribution of the data presented in Table X is illustrated in Fig. 7.

When analyzing the results, the following was observed:

1) A few instances were observed where applying DA treatment caused a reduction in individual evaluation metrics (recall, precision, specificity and negative class precision), as indicated by shaded backgrounds within Table X. However, despite this, the F1-Score increased for all models, indicating that these performance reductions were compensated for. The average increase in both accuracy and F1-Score was +4.3%, and the median increase in each of these metrics were +2.1% (accuracy) and +2.0% (F1-Score).

2) The box-and-whisker diagrams in Fig. 7 indicated that there is significantly more variability for recall, specificity, precision and negative-class precision than for accuracy and F1-Scores. As such, attempts at quantifying the expected improvement in DL model performance using the methods in this study can only reasonable be performed for accuracy and F1-Score. However, these are the most conclusive metrics to evaluate the DL models studied.

3) By analyzing the distribution of the change in accuracy and F1-Scores, it was observed that the data for these evaluation metrics was positively skewed. This resulted from the high pre-treatment accuracy scores and F1-Scores of some of the DL models studied, where there was not much room for improvement without over-fitting the model to the training dataset.

Prompted by the final observation listed above, the final analysis investigated the relationship between the change in evaluation metric scores and pre-treatment metric scores. The scatterplot presented in Fig. 8 illustrates this relationship, using data from Table VI, Table VII and Table X and excluding the outlier results resulting from the VGG16 and VGG19 models that were trained on Dataset 1. The trend lines show that all evaluation metrics exhibited a strong negative correlation, indicated by the  $R^2$  values of the correlation trend lines ( $R^2 > 0.7$  for all evaluation metrics). From this, it is concluded that the DA techniques under study have a marginal improvement when applied to DL models that already exhibit strong performance, but are much more powerful in enhancing weaker-performing DL models. From Fig. 8, an improvement of  $\geq +5\%$  to an evaluation metric occurs when the pre-treatment value of the metric is  $\leq 90\%$ . This indicates the type of DL models for driver drowsiness detection that will benefit most from the DA techniques presented in this study, and is recommended to developers as a design guideline when considering the implementation of the DA techniques presented in this paper.

Fig. 8. Relationship between pre-treatment evaluation metric score and change in evaluation metric score

The results confirm that by modelling real-world scenarios using the data augmentation techniques described in Section II.B.2, it is possible to train more robust deep learning algorithms that perform driver drowsiness detection. With respect to implementation of driver drowsiness detection systems, the deep learning model development and training would be performed before the model is deployed in the driver drowsiness detection system hardware.

## V. CONCLUSION

Many road accidents are caused by driver drowsiness. Previous studies have considered applying deep learning techniques to detect driver drowsiness and improve road traffic safety. In practically testing their systems, many previous studies have indicated that real-world scenarios such as unfavourable ambient lighting and movement of the driver while driving cause inaccuracies when detecting driver drowsiness.

In this study, the authors focussed on the deep learning algorithms that determine driver drowsiness based on the eye state of the driver. It was hypothesised that by modelling the real-world scenarios and using data augmentation techniques on a standardised image dataset, the performance of the DL models would improve. This study considered two different datasets, six different DL models: two CNN variations (CNN-C1 and CNN-C2), two architectures designed by the VGG (VGG16 and VGG19), a GAN and an MLP.

The performance of the DL models was evaluated primarily using accuracy and F1-Score, although other metrics such as precision, recall, specificity and negative class precision were also considered. In analyzing the results in aggregation, improvements across all metrics were noted. The average improvement in accuracy across all DL models was +6.1% and the average improvement in F1-Score was 6.8%, and the variability in model performance was reduced. However, there were some challenges noted when training the VGG models. These models trained on low-resolution images, exhibited poor performance and distorted these results. A more realistic indication of the benefits of DA for the DL models studied was obtained by excluding these outliers, yielding an average improvement of +4.3% for both accuracy and F1-Score.

The results further indicated that the extent to which the DA techniques studied improve DL model performance is strongly correlated with the pre-treatment DL model performance. From the analysis conducted, the data augmentation techniques presented are best suited for improving models with accuracy and F1-Scores  $\leq 90\%$  - although they are applicable to any DL model for driver drowsiness detection.

It was thus concluded that the use of DA techniques improves the performance of DL models for driver drowsiness detection under the isolated conditions of this study. However, since the conditions of this study focussed on testing the DL models on images from datasets, rather than testing being done on captured data from a real-world driver drowsiness detection system, this opens the possibility for future research. Future works should look at implementing the trained DL models

proposed in this study in practical driver drowsiness detection systems to validate these results.

## DATA AVAILABILITY

The drowsiness detection dataset (Dataset 1) is available online at: <https://www.kaggle.com/prasadvpatil/mrl-dataset>.

The yawn eye dataset (Dataset 2) is available online at: <https://www.kaggle.com/serenaraju/yawn-eye-dataset-new>.

## FUNDING

All funding in support of this research was provided by the Durban University of Technology.

## CONFLICTS OF INTEREST

The authors declare that there are no conflicts of interest.

## ACKNOWLEDGMENT

The authors acknowledge the support of the wider Faculty of Accounting and Informatics at the Durban University of Technology, and Mr Shaldon Wade Naidoo for his assistance.

# An Improved Ant Colony Algorithm for Virtual Resource Scheduling in Cloud Computing

## Methods to Improve the Performance of Virtual Resource Scheduling

**Abstract**—In order to solve the problems of uneven spatial distribution of data nodes and unclear weight relationship of virtual scheduling features in cloud computing platform, a virtual resource scheduling method based on improved ant colony algorithm is studied and designed to improve the performance of virtual resource scheduling in cloud computing platform by this method. After analyzing the information resource sequence change of the cloud computing platform, according to the STR - Tree partition graph, a simulated annealing-based algorithm is employed to classify the resource types after optimal scheduling into IO types, middle types and CPU types, and the time span and load balance are set as the measurement indexes. The simulation results show that after applying this method, the occupied resources of the main platform are 535 MB, which are much lower than the other two comparison algorithms, and the method has improved the allocation rationality, resource balance, maximum queue length and energy consumption. This result indicates that applying this virtual resource scheduling method can effectively improve the intelligent scheduling of virtual resources in the cloud computing platform.

**Keywords**—Improved ant colony algorithm; cloud computing; virtual resources; intelligent scheduling

### I. INTRODUCTION

Cloud computing is the mainstream way to provide services to users relying on resources deployed over numerous physical machines to be available regardless of their location. *Virtualization* is the key concept employed to provide a logical abstraction over physical resources running on data centers. This model considers data centers as nodes suitable for cloud computing and provides a unified and easy-to-use resource organization.

Different users request access and obtain resources according to their own needs, without paying attention to the specific location of resources. In order to provide users with the same or similar functions as the real layer, and to facilitate the stable operation of the upper layer system in the middle layer, cloud virtual resource scheduling is needed. Unlike other distributed computing platforms, virtualization provides more computing power and flexibility for applications, an advantage that fits well with the needs and main concepts of cloud computing [1].

In order to improve the usage of virtual resource in cloud computing, which considers hosting, network traffic, and other costs optimization, is not uncommon for multiple system resources, even from different organizations, to share a single physical server. Besides, a service application can also run over multiple service provider platforms to be accessed by multiple clients simultaneously. This scenario is tackled by the multi-tenant scheduling process, which aims for high resource utilization using the cloud computing network.

Laith & Ali [2] presented a hybrid ant colony optimization algorithm based on elitist differential evolution is proposed to solve the multi-objective task scheduling problem in cloud computing environment, which minimizes the maximum completion time, maximizes the resource utilization, and uses elitist differential evolution as a local search technique to improve its utilization ability and avoid falling into local optimization. In [3], by satisfying the constraint of security requirements, we find an optimal scheduling algorithm with minimum completion time and cost, and users can submit their security requirements to the cloud provider during the negotiation period. However, none of the methods mentioned before has solved the problems of indefinite weight relation of virtual scheduling features and uneven distribution of cloud platform information space, so it is difficult to realize virtual resource scheduling efficiently.

In order to solve the problems of the above methods, a cloud computing virtual resource scheduling method based on improved ant colony algorithm is proposed. The overall research technical route of this method is as follows:

- 1) This paper analyzes the characteristics of the sequence change of information resources on the cloud computing platform, and establishes the index relationship between spatial information objects through STR tree partition graph to solve the problem of data imbalance.
- 2) Simulated annealing algorithm is used to divide the optimized resource types into IO type, intermediate type and CPU type, and time span and load balance are used as indicators to complete the scheduling of virtual resources.
- 3) Experimental verification, taking the occupied space, load fairness, Allocation Rationality, resource balance, the longest queue length and energy consumption value as the test

indicators, the comparative tests of different methods are carried out.

By updating the above techniques, the proposed cloud computing virtual resource scheduling method can effectively solve the problems of uncertain feature weight relationship and uneven information space distribution in the virtual scheduling process, and it is expected that this method will improve the performance of cloud computing virtual resource scheduling and enhance new ideas for the field of virtual resource scheduling.

The structure of the study is divided into four main areas as follows. The first part introduces the current research status of cloud computing resource scheduling and compares it with the proposed algorithm. The second part introduces the virtual resource scheduling method based on the improved ant colony algorithm and describes its practical computing process. The third part is a performance test and application analysis of the virtual resource scheduling algorithm proposed in the study, and the results are organized and analyzed. The last part is a summary and discussion of the whole paper.

## II. CLOUD COMPUTING PLATFORM VIRTUALIZATION RESOURCE EXTRACTION

### A. Changes in the Sequence of Communication Network Information Resources of Cloud Computing Platforms

Each node in the cloud computing platform sends information to the center node to report according to the system load and user's demand [4]. In most cases, passive real-time monitoring is used to schedule resources. The client connects to the cloud server based on the control server.

When the client sends the computer application, Computer application is to study the theory, method, technology and system of computer application in various fields. Computer application is an activity that gives guidelines on how to participate and implement in social activities. The cloud server can store some data related to the user, Distributed storage is used to consolidate a large number of servers into a

supercomputer, providing a large amount of data storage and processing services. Distributed file systems and distributed databases allow access to common storage resources and realize IO sharing of application data files. By integrating computer, the resource scheduling server sends the calculation results to the user's computer, and the computer client returns the results. Calculate the data source through the server and wait for the next user request to obtain the communication network model of the cloud computing platform, as shown in Fig. 1.

In Fig. 2, the resource storage module adopts idt72v3680 memory produced by IDT Company. Idt72v3680 is one of the high-density supersynctm II 36 bit series memories idt72v3640 ~ 3690 of IDT company. Its storage structure is  $16384 \times 36$ . This series of CMOS process FIFO (first in first out) chips have great depth. The storage structure of this memory is  $16384 * 36$ , and the storage space can reach 1.125MB [5-8]. The internal circuit diagram of the memory is shown in Fig. 3.

According to Fig. 3, Memory is a memory device in a computer system that stores programs and data. All information in the computer, including input raw data, computer programs, intermediate running results and final running results are stored in the memory. It stores and retrieves information according to the location specified by the controller. The main function of the memory is to store programs and various data, and to complete the program or data access at high speed and automatically during the running of the computer. The memory has an independent chip structure. The storage rate of the memory can reach 100MHz, the working voltage is 3.15-3.45v, and the maximum working current is 400mA. In addition, the memory uses CMOS technology, belongs to high-density memory, and has great depth. During operation, idt72v3680 memory, as the transmission link between acquisition module and control module, can still realize efficient data storage without additional coordination under the condition of different rates of the two sides.

Fig. 1. The cloud server

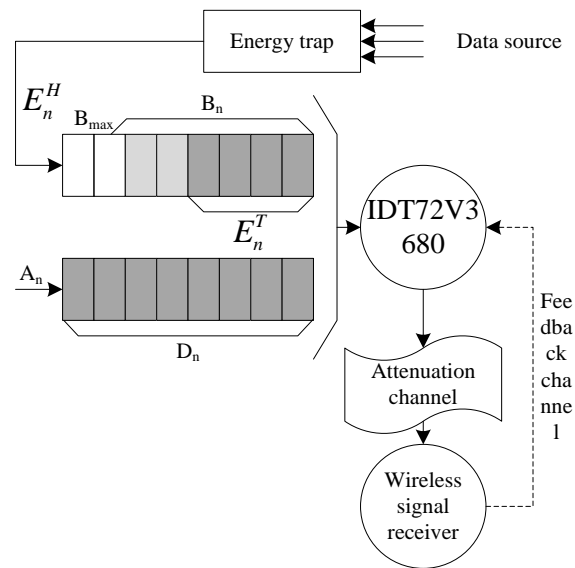

Fig. 2. Communication network model of cloud computing platform

Fig. 3. Internal circuit diagram of memory

If it is simply stored, it is difficult to complete the subsequent indexing steps. Therefore, in the process of establishing the storage mechanism, it is necessary to consider the indexing efficiency and divide and encode the data attributes [9]. The types and sizes of cloud data are different, and it is difficult to divide them. It is necessary to develop a reasonable strategy to divide them effectively [10]. In the process of partition coding, only the size, type and spatial distribution of data need to be considered to ensure the relative integrity of the cloud platform spatial information entity as far as possible, so as not to divide it into multiple scattered data blocks. If two data blocks are adjacent data in the information space, they can be consciously divided into the same interval

and given adjacent codes. In addition, if the data volume difference between the divided intervals is too large, it is easy to lead to the low balance of the distributed cluster, resulting in logical vulnerabilities. Therefore, when coding data nodes in partitions, this kind of data imbalance can be solved through STR tree. The main operation mechanism of STR tree is to establish the index relationship between spatial information objects through the external matrix between two data nodes, and code and sort their abscissa and ordinate between the two dimensions.

In the data storage space of a cloud platform, it is first necessary to determine the number of data partitions  $n$ , code

other data entities into  $A, B, C, \dots, X, Y, Z$ , etc., and divide the average total amount of data block space  $\cdot \sqrt{n}$ . In this way, the horizontal and vertical coordinates of all data can be indexed to  $\frac{N}{\sqrt{n}}$ , all data coordinates can be grouped into different data blocks, and all vertical and horizontal coordinates are  $\frac{N}{\sqrt{n}}$ . Determine the partition coding basis of STR tree, as shown in Fig. 4.

Fig. 4. STR tree zoning diagram

As shown in Fig. 4, STR tree can effectively solve the problem of uneven spatial distribution of information of data nodes in the cloud platform, so as to reduce the repeatability of data nodes. Before designing the virtual resource scheduling model of cloud computing platform, firstly, set the number of cellular users in heterogeneous units as  $m$  and the number of communication network users of cloud computing platform as  $N$ ,  $M = \{1, 2, \dots, M\}$  and  $N = \{1, 2, \dots, N\}$ . Multiple uplink resources are used simultaneously in the scheduling process, and the resource blocks do not affect each other.

In time period  $T$ , the transmission power of the  $n$ th cloud computing platform communication network at the  $m$ -th cellular user and its uplink resources is  $P^m(t)$  and  $P_n^m(t)$  respectively; The signal to dryness ratios of  $N$  on  $M$  to cellular users in time period  $T$  are  $SINR_n^m(t)$  and  $SINR^m(t)$  respectively. Set  $i, j \in N$ . Within the time period  $T$  [11], the communication between the cloud computing platform communication network and the cellular user is dry, as shown in formula (1):

$$SINR_i^m(t) = \frac{P_i^m(t)h_{ii}(t)}{N_0 + \sum_{j \in S_m, i \neq j} P_j^m(t)h_{ji}(t) + P^m(t)h_{mi}(t)} \quad (1)$$

Among them,  $h_{ii}(t), h_{ji}(t), h_{mi}(t)$ , and are the channel power gain of the communication network of the cloud computing platform, which are respectively used to describe the channel power gain of uplink resources from the information transmission end to the information receiving end at different times, and calculate the ratio of output power and input power of uplink resources at different times. If all multiplexing resource sets are  $S_m$  and the noise power spectral density is  $N_0$ , the signal to dryness ratio of the

primary user is:

$$SINR^m(t) = \frac{P^m(t)h_{mB}(t)}{N_0 + \sum_{j \in S_m} P_j^m(t)h_{jB}(t)} \quad (2)$$

Among them, the channel power gains from the user and the network to the base station are  $h_{mB}(t), h_{jB}(t)$  [12]. Calculate the maximum communication rate of cloud computing platform communication network to cellular users through Shannon channel capacity calculation formula:

$$R^m(P^m)_i = \log_2(1 + SINR^m(t)) \quad (3)$$

Where  $P^m$  represents the transmission power passing on the uplink resource.

Only when the uplink interference of the communication network users of the cloud computing platform to the cellular users is minimized can the communication efficiency of the cellular users be maximized. The resource allocation of the resource block can be expressed by formula (4), the time period is  $t$ , and the signal to dryness ratio threshold of the cellular user is  $\zeta_{Threshold}^m$ . Average maximum throughput of communication network resource scheduling in  $t$  [13]:

$$\arg \max = \frac{1}{T} \left[ \sum_{t=1}^T \left( \sum_{m=1}^N \log_2(1 + SINR^m(t)) \right) \right] \quad (4)$$

Among them,  $SINR^m(t) \geq \zeta_{Threshold}^m$ . There are network information resources arriving at the wireless signal transmitter in each time slot, and  $X_n$  is used to represent the number of information resources contained in the communication network, so the change process of the information resource sequence of the communication network can be described as

$$D_{n+1} = \max \{D_n - X_n, 0\} + A_n \quad (5)$$

In formula (1),  $D_{n+1}$  and  $D_n$  respectively represent the information resource sequence  $n+1$  of the communication network of the  $n$ th and  $t$ th time slots;  $A_n$  represents the number of data packets arriving at the wireless signal transmitter in the time slot.

### B. Cloud Platform Virtualization Resource Association Feature Extraction

Advantages of ant colony algorithm over other swarm intelligence algorithms: (1) the algorithm has general applicability: as long as the problem can be transformed into a connected graph, it can generally be solved by ant colony algorithm in scenes with low real-time requirements. (2) Randomness and certainty are interdependent: the heuristic function represents a priori knowledge, its weight represents the degree of certainty in selection, and the pheromone update criterion represents the mutual restriction between the two. Pheromone update, as the performance mechanism of positive feedback, reflects the degree to which the path is focused (certainty), while the volatilization coefficient participates as the negative feedback mechanism, the excellent path with too

much pheromone behind has the opportunity to catch up. The roulette algorithm increases the possibility of exploring a larger solution space (randomness). Under normal circumstances, the cloud platform communication process acts on the attenuation channel, which means that the network channel gain remains the same in any time slot, but there are some differences in the network channel states in different time slots. If the wireless network is in the form of adaptive coding modulation, the calculation formula of information resource transmission rate of communication network is

$$R_n = W \log_2 \left( 1 + \frac{G_n P_n}{\Gamma W N_0} \right) \quad (6)$$

Wherein,  $W$  represents the channel bandwidth of the communication network;  $G_n$  represents the channel gain in the time slot;  $P_n$  represents the transmission power of the wireless communication network;  $\Gamma$  represents the auxiliary constant;  $N_0$  represents the noise power density.

Then the energy required for information resource scheduling of communication network in time slot is

$$E_n^T = P_n \times \Delta T \quad (7)$$

Where  $\Delta T$  represents the length of each time slot.

Since there are many task types of cloud computing resources and applied resources, only tasks with matching types will be assigned to corresponding computing resources for task processing. In addition, multiple computing resources can work at the same time. The steps are as follows:

Step 1: after obtaining the energy data required for scheduling, place  $k$  ants on the energy samples required for scheduling, record the number of samples as  $M$ , and open the sample scheduling feature association pair at the same time;

Step 2: ants select the energy characteristics required for scheduling with transfer probability. At the same time, taboo table  $tabu_k$  and temporary pool  $temppool(k)$  are set,  $tabu_k$  is used to record the sample scheduling feature association pair selected by ant  $k$ , and application  $temppool(k)$  is used to save the probability value selected by ant [14]. Among them, under the limitation of energy required for information resource scheduling of communication network in time slot, the calculation formula of transfer probability is

$$p_{ij}^k(t) = \begin{cases} \frac{\alpha \cdot \tau_{ij} + \beta \cdot \eta_{ij}}{\sum_{r \neq tabu_k} \alpha \cdot \tau_{ij} + \beta \cdot \eta_{ij}} & j \neq tabu_k \\ 0 & \text{others} \end{cases} \quad (8)$$

Wherein,  $\alpha$  represents the weight parameter of pheromone quantity  $\tau_{ij}$ ;  $\beta$  represents the weight parameter of visibility parameter  $\eta_{ij}$ , which is calculated by  $1/d_{ij}$ , where  $d_{ij}$  represents the distance of a sample scheduling

feature association pair  $(i, j)$  among a plurality of pedestrians.

Step 3: in the process of path optimization, the population ant will leave the pheromone quantity  $\tau_{ij}$  in real time. The pheromone is the pheromone related to the scheduling order of the scheduled task. The scheduling order is the order in which the tasks in the taboo table are arranged to be processed by the corresponding computing resources. The pheromone here indicates whether a computing task may be assigned a specific order, In order to prevent the pheromone quantity of a path (Association pair  $(i, j)$ ) from increasing rapidly, resulting in the algorithm falling into local optimization, the initial pheromone quantity is set to  $\tau_{max}$  and the value range is  $\tau_{ij} \in [\tau_{min}, \tau_{max}]$ ;

Step 4: in the process of path selection [15-16], update the pheromone quantity based on local update rules. After the path selection, the pheromone update rule is changed to the global update rule. The global update rule expression is

$$\tau_{ij}(t+1) = (1-\rho)\tau_{ij}(t) + \Delta\tau_{ij} + \Delta\tau_{ij}^* \quad (9)$$

Wherein,  $\rho$  represents the pheromone quantity update coefficient;  $(1-\rho)$  represents the pheromone residue coefficient;  $\Delta\tau_{ij}$  means that  $(i, j)$  path pheromones are updated according to the path length ranking information of  $\sigma-1$  excellent ants, and the calculation formula is

$$\Delta\tau_{ij} = \sum_{\mu=1}^{\sigma-1} \Delta\tau_{ij}^{\mu} \quad (10)$$

Wherein,  $\mu$  represents the ranking of ants participating in path search in ant colony;  $\Delta\tau_{ij}^{\mu}$  indicates the amount of pheromone retained by the first ant on the associated pair.

Step 5: after determining the incidence matrix, record all the sample scheduling feature information to obtain the correct multi scheduling energy target feature data association results.

### C. Cloud Computing Virtualization Resource Scheduling based on Improved Ant Colony Algorithm

The original ant colony algorithm also has many shortcomings that are difficult to overcome by itself:

1) The ant colony algorithm framework operates on the basis of roulette algorithm. In the initial stage of solution space exploration, the utilization of prior knowledge is insufficient, resulting in a long time to search for a satisfactory solution. The certainty of the algorithm should be appropriately increased in the whole algorithm cycle [17-18].

2) After several rounds of search iteration, the evolution rate of the solution often decreases sharply, and even the basic gap between the found solutions is small, that is, the search stalls. The weight relationship between randomness and certainty should be dynamically adjusted according to different operation stages of the algorithm [19-20].

Therefore, simulated annealing algorithm is used to

optimize ant colony algorithm to overcome the above problems.

Combinatorial optimization problem is to solve the optimal solution. In the time period, set a non-negative objective function representing the solution goal on the ant colony path. The solid annealing process and combinatorial optimization problem have certain similarities, and the main advantages are as follows:

1) *Perform complex area search*: The algorithm is more suitable for searching in complex regions and obtaining regions with higher region values.

2) *Good parallelism*: The good parallelism of ant colony algorithm and simulated annealing algorithm can effectively solve various nonlinear problems. The good parallelism of the ant colony algorithm and the simulated annealing algorithm can solve various nonlinear problems effectively. The ant colony algorithm has very good time efficiency, but the ability to find the optimal solution needs to be improved, while the simulated annealing algorithm has very good ability to find the optimal solution, but the time complexity is high. By parallelizing the two, the advantages of both can be combined and the disadvantages of both can be compensated, and the final parallel algorithm not only has good ability to find the optimal solution, but also its time efficiency is high.

3) *Search with object functions*: Directly convert the objective function into fitness value to determine the search scope and direction in the next step.

Due to the slow development of physical state to low-energy state, in order to obtain better results, simulated annealing algorithm mainly selects the state with important contribution rate in the process of sampling.

Set the position representation state of the particle solid as the initial state, the energy is fixed, randomly form a small displacement change and produce a new state, set this state as an important state, the next state of the solid is sum, and the factor ratio corresponding to the probability ratio of the two states can be expressed as:

$$p(t) = \begin{cases} (E_i - E_j) \\ \frac{1}{Z(t)} \exp\left(-\frac{E_j - E_i}{k_B(t)}\right) \end{cases} \quad (11)$$

Where  $Z(T)$  represents the modified pheromone value on the ant path  $(i, j)$  at time  $t$ . It is set that the random number is a value formed by the random number generator, and the value range is within the range of  $[0,1]$ . Since  $p$  represents a value less than 1, assume  $p \geq A$ , indicating that it is sufficient to maintain the current state.

The resource types after optimized scheduling are divided into IO type, intermediate type and CPU type. When optimizing the scheduling, the resources are divided in combination with the running time sequence. The resulting resource division scheme is shown in Fig. 5.

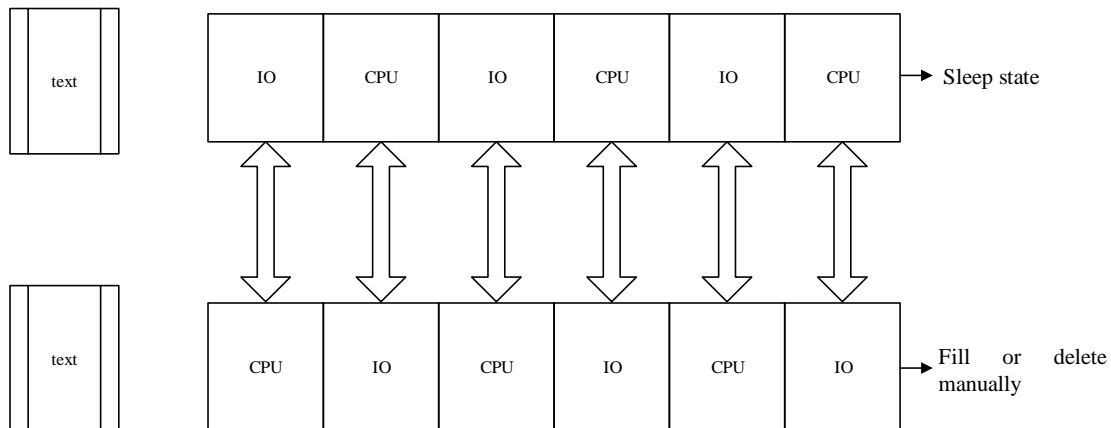

Fig. 5. Resource division scenario

As shown in Fig. 5, resource A and resource B consume the same disk (IO) and CPU, so both can be divided into intermediate types of resources. However, it can be seen from Fig. 4 that the time occupied by disk (IO) and CPU is completely crossed. Therefore, in the process of resource scheduling, the existence of AA or BB should be avoided as far as possible. In addition, missing and redundant data will be automatically filled or manually deleted in the process of resource optimal scheduling.

It is worth noting that the goal of the algorithm is to limit the number of physical hosts providing services in the cloud platform, and the trigger of any migration scheme is to migrate the virtual machine to an active physical machine.

However, when the current active physical machine cannot meet the requirements of the virtual machine to be migrated. The dormant physical machine will be activated as the destination physical host in the migration plan. A physical host is switched to sleep if and only if the virtual machines on it have been migrated. That is, when a physical host does not provide resources for any virtual machine, it will be converted to sleep state.

The important state is mainly set as the state with small probability acceptance and large current energy difference; In the high temperature state, the new state with large energy difference from the current state is accepted with a high probability and set as the important state.

In the actual application scenario of scheduling algorithm, due to the complexity and heterogeneity of cloud platform resources, the performance of physical hosts varies greatly, and the state of virtual machines relying on them will change dynamically with the deepening of task execution. In this case, it is easy to cause a large number of tasks to flow into the waiting queue of high-performance virtual machines and cannot be executed, resulting in service degradation and user experience degradation. On the other hand, there are a large number of idle virtual machines in the cloud platform, which are not favored by tasks due to limited performance, resulting in a great waste of cloud platform resources. As a result, the service life of overloaded machines is shortened, and the completion time of single tasks is not satisfactory. In order to solve this problem, it is necessary to analyze the needs of different users, calculate the matching degree of each demand corresponding to the task to the resource node, and add the matching factor  $Tm_i$ . Then the scheduling requirements in important states are expressed as follows:

$$Match_{ij} = \frac{1}{\sqrt{\sum_{i=1}^5 (Tm_i - Vm_j)^2}} \quad (12)$$

Set the mapping sequence  $Tm_i$  representing tasks and resources,  $Vm_j$  represents a sequence node. And the load balance degree can be expressed as:

$$Load(X) = \sqrt{\sum_{i=1}^n \left(1 - C_1 \frac{Y_i}{Lv_i}\right)^2} \quad (13)$$

Calculate the computing power of each resource node by weighting, that is:

$$Lv_i = w_1 \times n(v_i) + w_2 \times p(v_i) + w_3 \times r(v_i) \quad (14)$$

When pheromones accumulate to a certain extent, positive feedback suppression is needed, because with the deepening of iterative search, the total amount of pheromones rises to a certain threshold, which is prone to excessive positive feedback, that is, the influence of pheromones on ant colony covers the prior effect of heuristic function. In addition to ensuring the update speed of pheromones and highlighting the differences between high-quality paths and general paths, it is very important to comprehensively improve the load balance of resources. Therefore, the time span and load balance are set as the measurement indicators:

$$\begin{cases} F(X) = Load(X) \cdot Makspan(X) \\ Makspan(X) = \sum_{i=1}^n \sum_{j=1}^m s_{ij} \times E_{ij} \end{cases} \quad (15)$$

Above, mainly through simulated annealing algorithm for data center resource scheduling, the specific operation process is as follows:

- 1) Initialize all pheromones;
- 2) Setting up the main objective function and initializing each parameter;
- 3) When the ant starts the cycle, it needs to place all the tasks on a single resource.
- 4) Calculate the matching factor, set it as heuristic information, and select nodes in combination with the transfer probability.
- 5) Calculating the load balance degree and the value of the objective function, and the optimal solution of the ant colony algorithm.
- 6) The simulated annealing algorithm is used to optimize the path and update the pheromone.
- 7) Loop through the above steps until the maximum number of iterations is reached, then stop the operation and vice versa return step (3).

### III. SIMULATION EXPERIMENT

#### A. Experimental Data and Process

In order to verify the scheduling performance of the proposed method, comparative experiments are carried out. Provide 600 to 1000 cloud tasks in the resource submission window, and use the random number generator to randomly generate 50 waiting tasks with different requirements for cloud computing resources in the scheduling time window. It is estimated that the starting processing time is 0. Assuming that the time window is 40 minutes in length, the iteration is terminated under the condition that 6,000 ants all complete the iteration and the number of intelligent population is 100. When there is no change in the results of 10 consecutive iterations, the operation of the algorithm is stopped and an error is reported. Each set of data was analyzed 10 times and the average value was taken, and a parameter change was made to observe its impact on the delay time and solving efficiency of the task.

Hybrid cloud is a more advantageous infrastructure, which flexibly combines the internal capabilities of the system with external service resources, and ensures low cost. Hybrid cloud is a model that organically integrates public cloud and private cloud, allowing users to choose between the privacy of private cloud and the flexibility and cheapness of public cloud. Hybrid cloud can provide enterprises with more flexible cloud computing solutions. In the next few years, hybrid cloud will become the leading enterprise IT architecture, and more and more enterprises will benefit from hybrid cloud services. Considering the transport efficiency elements of cloud platform virtualization resources, a more commonly used cloud computing architecture is chosen as the experimental basis, as shown in Fig. 6.

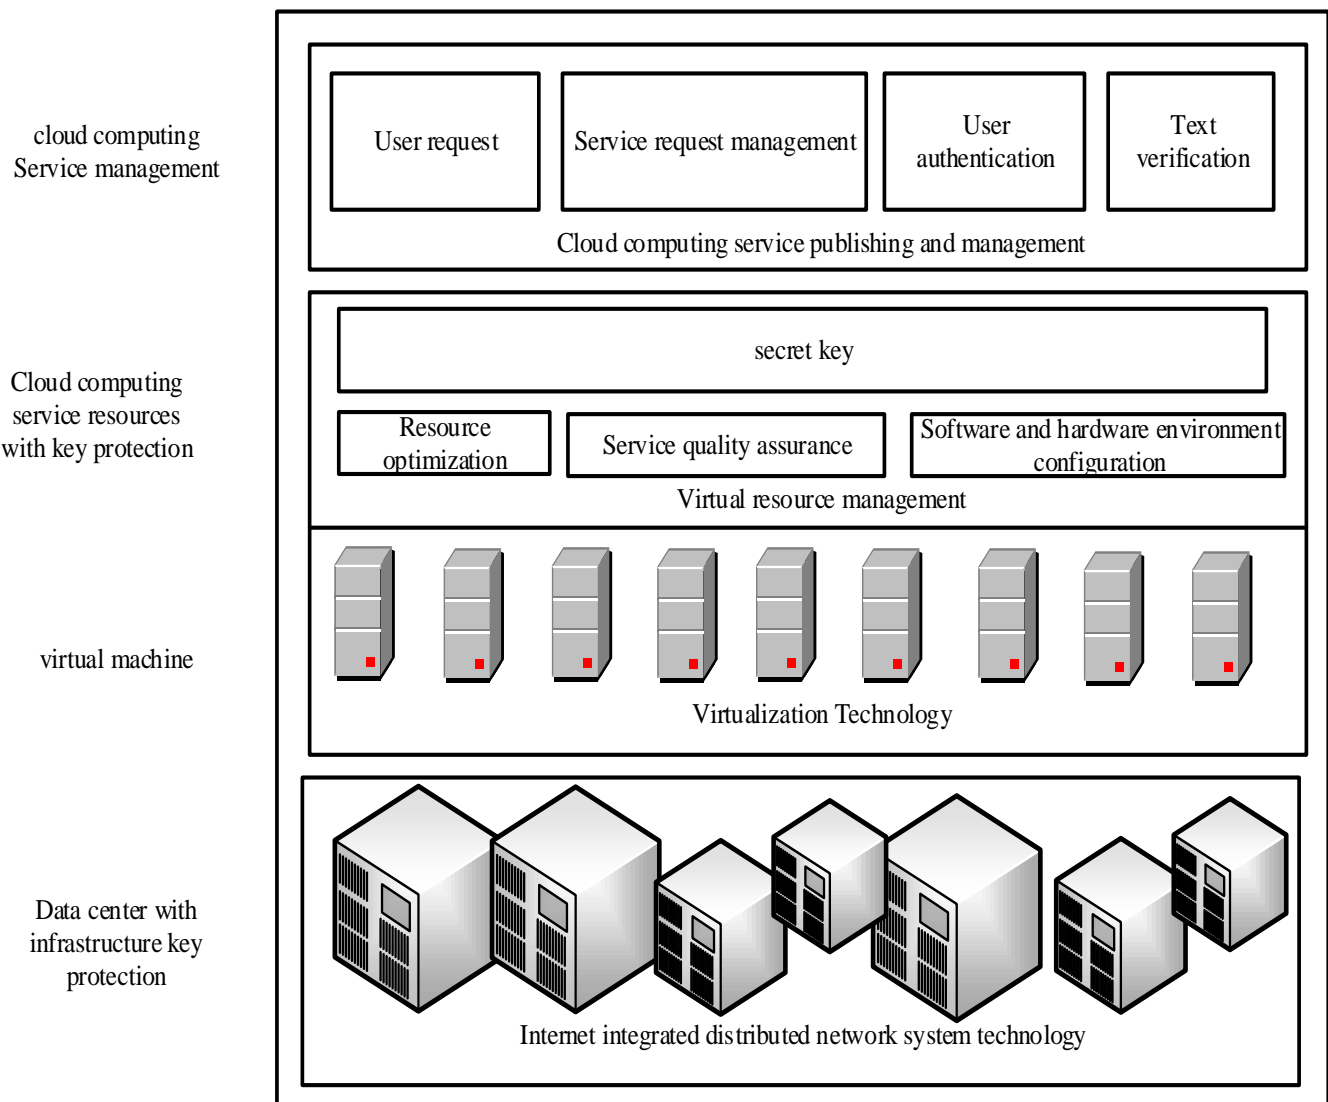

Fig. 6. Cloud computing architecture

In Fig. 6, according to the characteristics of multiplexed information, the structure of integrated distributed network and virtual machine is redeployed to ensure that the structure can completely load cloud computing virtualization resources.

The experimental parameters are shown in Table I.

TABLE I. EXPERIMENTAL PARAMETERS

parameter	analysis	numerical value
H	Total number of system storage nodes	6000
Size of File	Virtualization resource size	10GB
Backup Num	Number of backup copies	6000
Availability	System availability	>95%
P	Node availability	>95%

The simulation experiment goes through four processes, which are initialization stage, virtual resource access stage, virtual resource backup stage and virtual resource recovery stage. When the system is in the initialization phase, 6000 online nodes are built and node IDs are assigned. When the system is in the virtual resource access phase, the online phase needs to be divided into three categories: one is the service scheduling node, the other is the virtual resource backup node, and the third is the backup server. These three kinds of three wire nodes can achieve virtualized resource storage and backup through coordinated work. When the system is in the virtualization resource recovery stage, judge the node availability, and then use the backup server to recover the virtualization resources.

Several storage backup nodes are simulated in the MATLAB platform, the CPU speed and network bandwidth of the data center are configured, and the number and frequency of user information requests, as well as the start, end and peak time are set.

### B. Experimental Results

By comparing several different methods, taking the occupied space of the virtual resource scheduling process as the experimental index, and taking the methods of literature [2] and literature [3] as the comparison method, the simplicity of the application process of this method is verified. The experimental results are shown in Fig. 7.

As can be seen from the comparison effect of data occupation space shown in Fig. 4, the main and sub platforms have different storage capacity under the action of different data volume, but they are increasing with the increase of data volume. However, the initial occupation space of the method in this paper is the smallest and the growth fluctuation is low. This is because this method updates the pheromone quantity based on local update rules, that is, the pheromone quantity update rules are changed into global update rules to ensure that the task of type matching is accurately allocated to the

corresponding computing resources, which further increases the possibility of exploring a larger solution space.

Under different conditions, taking the load fairness test of cloud computing nodes as the experimental index, the comparison results of different methods are shown in Fig. 7.

As shown in Fig. 8, the higher the load fairness coefficient, the better the storage effect. When the amount of backup data increases, the load fairness coefficients of other methods continue to decline, while the decline rate of this method is the lowest. This is because this method analyzes the needs of different users, calculates the matching degree of tasks corresponding to each demand to resource nodes, directly converts the target function into fitness value, and sets the time span and load balance as measurement indicators, Highlight the difference between high-quality path and general path.

Calculate the physical machine node allocation rationality, resource balance, longest queue length and energy consumption of the three allocation schemes. The results are shown in Table II.

As can be seen from Table II, this method performs well in terms of Allocation Rationality, resource balance, longest queue length and energy consumption value. This is because

while constructing the communication network model of cloud computing platform, this method calculates the ratio of output power and input power of uplink resources at different times, and timely adjusts the scheduling demand according to the scheduling energy to reduce the scheduling energy consumption, effectively solve the problem of uneven spatial distribution of information of each data node in the cloud platform.

	500/100	0.751	8.055	53	7500

#### IV. CONCLUSIONS

In order to shorten the space occupation of cloud computing virtual resource scheduling and improve load fairness, the study combines the advantages of simulated annealing algorithm with ant colony algorithm, and applies the hybrid algorithm to cloud computing virtual resource scheduling. The results of the empirical analysis show that the virtual resource scheduling process of the proposed method in the primary and secondary platforms occupies 535 MB and 196 MB of space, respectively; the load fairness coefficient of the method is around 0.85, both of which are better than the comparison algorithms. Besides, it is also found that the resource scheduling algorithm proposed in the study has more reasonable allocation, more balanced resources, shorter longest queue length and less energy consumption compared with the comparison algorithm. The above results illustrate that the resource scheduling algorithm proposed in the study has better scheduling performance, and the method can be used to better schedule the resources in the cloud computing platform and improve the resource scheduling efficiency, thus improving the computational efficiency and reducing the running time of the platform algorithm, thus making better and faster use of virtual resources and saving time. In the future research work, we should further strengthen the research on the resource scheduling efficiency and improve the performance of the cloud computing virtual resource scheduling method comprehensively.

#### V. DISCUSSION

The resource scheduling method proposed in the study combines the advantages of simulated annealing algorithm and ant colony algorithm, and compensates the disadvantages of both of them to each other, thus improving the overall algorithm performance. The parallel algorithm based on simulated annealing algorithm and ant colony algorithm has better scheduling performance in the process of resource scheduling in the cloud platform. In addition, the study also uses adaptive coding and modulation to extract the association

features of virtual resources. The study transforms the pheromone update rules into global update rules through the good parallelism of ant colony algorithm and simulated annealing algorithm to schedule the cloud computing virtual resources one by one in a specific order. It expands the scale of the cloud computing center cluster, improves the scheduling capability of the whole platform, makes full use of the cloud platform resources, and gives full play to the advantages of cloud computing. In the subsequent research, the algorithms that can make up for each other's defects can be combined to obtain a better hybrid algorithm, and the optimized hybrid algorithm can be applied to the scheduling of virtual resources using the optimized hybrid algorithm in order to achieve better scheduling performance of cloud computing virtual resources.

**Abstract**—In the modern world, information security and communications concerns are growing due to increasing attacks and abnormalities. The presence of attacks and intrusion in the network may affect various fields such as social welfare, economic issues and data storage. Thus intrusion detection (ID) is a broad research area, and various methods have emerged over the years. Hence, detecting and classifying new attacks from several attacks are complicated tasks in the network. This review categorizes the security threats and challenges in the network by accessing present ID techniques. The major objective of this study is to review conventional tools and datasets for implementing network intrusion detection systems (NIDS) with open source malware scanning software. Furthermore, it examines and compares state-of-art NIDS approaches in regard to construction, deployment, detection, attack and validation parameters. This review deals with machine learning (ML) based and deep learning (DL) based NIDS techniques and then deliberates future research on unknown and known attacks.

**Keywords**—Network; dataset; communication; intrusion detection system; attacks; deep learning; machine learning

## I. INTRODUCTION

The Internet is ubiquitous everywhere that plays a vital role in daily activities. It almost pervaded every field of business activities, from retail to space research for storing and sharing confidential data [1]. A vital concern in businesses is to secure the network from external disturbances. The advancement of new communication technologies and services increases the number of interconnected devices [2, 3]. The escalation of Internet based systems also increases vulnerabilities and virtual attacks on the network. Cyber-crimes on the Internet are rising exponentially with the rapid growth of technology. The cyber-attacks are severe attacks on the network, and a failure in security may cause misleading information. Thus the network cannot meet its goals with the improper IDS [4]. Moreover, communication in the network is affected by individual hackers and malicious behavior, which seriously impacts the system [5]. Different types of attacks occur in the network, such as wormhole attacks, denial of services (DOS), black hole attacks, and flooding attacks. All these attacks prevent the user from accessing network

resources and services by dropping or adding unnecessary packets [6]. Additionally, variations in malicious software will increase the threats to the network through security breaches.

An intrusion detection system (IDS) has drawn considerable interest among academics since it protects the network against inside and outside attacks, a proactive ID tool. The IDS is a security application used after the antivirus software and firewall. The IDS alters the network when any faults occur in the system. The IDS not only detects intrusions but also stores the network traffic in the system [7]. The IDS alerts the system when the intrusion occurs at the host and network levels [8]. The available IDS have many limitations having difficulties coping with the cyber-attacks due to their dynamic nature. The IDS cannot be easily adaptable; thus, it cannot detect new malicious attacks [9].

Furthermore, the massive network size and the larger number of applications handled by the node have resulted in the IDS becoming a challenging task owing to the generation of huge amounts of data. The massive data generated in the network is communicated with other nodes inside the network will create new attacks [10]. Hence, several methodologies have been developed in the past few issues to deal with these issues.

Deep learning (DL) and machine learning (ML) approaches have recently been widespread in several applications. The DL based methods have functioned with the neural networks containing numerous layers. In ML, the algorithms analyze the data to solve the issues by learning and pattern discovery. These methods are found to be excellent in higher detection accuracy and better performance on dataset testing; hence, these methods are included in IDS. Thus this paper has reviewed traditional methods to ML and DL based methodologies for ID by considering different types of faults [11]. Recently, the DL and ML based approaches gaining more attention in the IDS context. In fact, the DL is used for feature extraction, selection and classification. The DL networks carry the learning process in supervised and unsupervised manners. The Internet is omnipresent in all fields, which is inevitable in network communication. Thus the applicability of IDS in networks is considered a vital

research topic for enhancing network security against attacks. However, several authors have made a review this topic. Some of the recent papers of review of IDS are listed below:

- A review on DL based IDS is conducted in [12, 13] that only examines the DL based methods in IDS, but that paper did not focus much on network attacks.
- Recently, the IDS in the Internet of Things (IoT) have been reviewed, and some solutions are suggested to overcome the issues [14].

The existing review papers provide a deep insight on DL, ML or existing approaches individually. However, they do not analyze up-to-date methods. Moreover, different types of datasets are not focused in deep. Apart from these recent reviews, this paper is intended to focus on the up-to-date methods for IDS thus it reviews traditional methods. The major aim of this paper is to review various IDS methods, ID behavior, performance efficacy and problems associated with IDS methods. Furthermore, the leading methods in the IDS are also discussed with their advantages. Although several techniques have been developed in this area, no single method covers all types of network attacks. In the paper, innovative content is added in terms of up-to-date methods by including all traditionally available methods for IDS in the network by considering different types of attacks in the network. Thus, this review has provided the growth of IDS and the issues the developed methods face.

The contribution of this paper is summarized as follows:

- To study the network security issues and point out the necessity of an IDS as a solution for detecting attacks.
- To emphasize attacks in networks, then provide the key role of IDS for network security.
- Highlight the challenges and advantages of the current works in intrusion detection.
- To bring an effective solution to overcome the issues associated with recently developed methods.
- Provide an excellent approach for detecting the harmful unknown intrusions in the network by resolving the issues in existing and newly developed methods based on the analysis.

The organization of this review paper is given as follows; section-2 deals with several attacks in the network, and Section 3 elaborates on the detection methods and their pros and cons. Section 4 explains the limitation of NIDS. Section 5 includes the conclusion and future scope for network ID.

## II. ANALYSIS OF ATTACKS IN THE NETWORK

Data transmission through the network may be subject to various threats and safety risks. Hence, it is often unable to be secure with new techniques. It is very important to analyze the intrusion and attacks in the network to secure it from failure. Malicious nodes in the network create a routing attack. Different security threats and network attacks are discussed below.

### A. Security Threats in Network

The network should meet some security measures to prevent intrusions from outside the network. An unauthorized user can enter the network if the organization fails to meet sufficient security concerns like prediction, securing and isolation. On the other hand, data management in the network is affected by a lack of bandwidth management. Because data communication in the network depends on bandwidth resource utilization, thus the excess utilization of bandwidth in the network will lead to bandwidth wastage. The severe issue in network transmission is data confidentiality. The lack of an encryption mechanism will lead to data leakage in the network [15]. Network attacks such as snooping, traffic, modification, denial of services and injection of intrusions are common in the network [16].

### B. Active and Passive Attacks

Attacks in the network are classified into two types: active and passive attacks. The intruder intercepts the data in the network during a passive attack, whereas, in an active attack, the intruder initiates a command to disturb network operation.

- Spoofing: In a spoofing attack, the sender can change the network topology due to the miss-present data of a malicious node.
- Modification: In this kind of attack, the data route is modified by a malicious node so that the message may be sent through a long route. Data routing through long-distance leads to communication delays [17].
- Wormhole attack: In a wormhole attack, the data transmission between two nodes is affected due to malicious nodes. This attack fakes a route instead of the short route in the network; thus, distance gets confused [18].
- Sinkhole: The sink-hole attack attracts network traffic through false routing metrics. The sink-hole attack invites many attacks in the network, sending false information [19].

- Denial of service attack: Most communication networks have limited energy resources; hence, they do not cope with sophisticated safety technologies. One of the common attacks in network communication is a DOS attack. The DOS affects almost all network layers, thereby disabling the proper functioning of the network. The DOS also abuse data in the network by allowing multiple attackers. The DOS attacks may lead to poor network performance, spam messages, packet delay and loss [20].
- Sybil attack: This attack uses fake identities to transmit data on the network.
- Traffic analysis attack: this kind of attack examines node behavior, network traffic and length of the message.
- Eavesdropping: Eavesdropping on ongoing communication may cause information leakage on cryptography or connection [21].
- Monitoring attack: The intruder can read the confidential data but cannot modify the data.
- Remote to Local (R2L) attack: The attacker gets access to the network without an account in the R2L attack, considered a critical attack in the network. This type of attack depends on host level and network-level features.
- User to Root (U2R) attack: The U2R needed semantic data that was hard to capture at the initial stages. U2R commonly happens in content-based fields where the attacker starts as a normal user and then becomes a superuser to abuse the network.
- Probe: It is illegal to gather network information about several services and sources to violate network security.
- Man-in-the-middle (MITM) attack: In the MITM attack, the attacker can access both ends of the communication channel, thereby manipulating the data. In such attacks, the attacker tries to initialize secure communication by sending messages. Finally, the attacker gets access to encrypt all the messages in the communication channel [22].
- Malware attack: In this kind of attack, the evade signature is matched by dynamically modifying the code. Due to the different purposes of the attackers, it becomes difficult to detect the attack.
- Phishing attacks: Spam e-mails are created to advertise a product, which is slightly modified to harm the user is known as phishing attacks financially. Phishing crimes are created by making a fake website the same as the original website and then creating fraudulent offers to the user [23].
- Distributed denial of service: This attack disrupts the normal traffic of the targeted server or network by overwhelming the target.

### III. BACKGROUND OF INTRUSION DETECTION SYSTEM (IDS)

Intrusions in the system are noticed by continuous observation of the system, in which the system administrator examines intrusions through user activities. The main aim of IDS is to examine the intrusions in the system. However, it is a difficult task, in fact, the IDS has not examined intrusions at all; that only examines the symptoms of intrusions. The symptoms gathered by the IDS are referred to as manifestation, where the collected evidence is not sufficient for detection, then the system can't access the intrusions at all. As the network attacks increased with time, the early form of intrusion detection methodologies is not scaleable.

The IDS is a significant tool for the network to examine security breaches. The IDS continuously monitors the network traffic entering and leaving the system, thereby examining network intrusions. The communication in the network is carried out through wire and wireless mediums. Thus, the network attacks increased dramatically in the network. Moreover, technological advancements increase new attacks on the network. The intrusion of attacks common in new computing environments such as wireless sensor network, fog computing, e-healthcare and cloud computing. IDS is vital security component that enables the computer network for IT organization. Hence, it is needy to construct IDS to defend the network from attacks. To provide a sufficient solution for IDS, it is important to investigate the up-to-date methods.

#### A. Principles of IDSs

IDS is nothing but the process of observing the events that occur in the system and then examining the intrusions through these events [24]. Intrusions can take several forms routing attacks, sniffer attacks, U2R attacks, man-in-the-middle attacks, Dos/DDos, and cyber-attacks [25, 26]. One of the major tasks of IDSs is to separate harmful attacks from normal traffic in an efficient manner. Connecting to a wrong system by wrongly typing the address is an example of normal traffic, which is considered a threat. Due to the timely detection of intrusions, IDS protects the system or network from failure. The major functions offered by IDS are listed below.

- Provide timely alarm while detecting threats in the system.
- Take necessary action to respond to the alarm detected [27, 28].

Factors to be considered for effective IDSs are summarized below:

- Robustness of the system
- Speed of detection
- Maximum detection rate.
- The minimum detection rate of normal traffic is a threat.
- Reduction in the system requirement, which includes hardware and software
- Accuracy in detecting threat location

- Integration with other technologies.

1) *Data collection & recording*: Initially, the network data are gathered to create the profiles of normal data compared with the observed data of the network. After initializing the profile of normal data, the network data are collected to check the intrusions. Since the volume of collected data is huge, creating small groups as vectors is useful in detecting intrusions.

2) *Identification of harmful intrusions*: Harmful threats in the network are observed by analyzing the data. In this step, the host and network data were examined for accurate detection of intrusions. In this stage, the undesired actions outside the network are recorded to detect intrusions.

3) *Alert*: In this stage, the condition of the network is examined by the judgement based on evaluated data, which examines whether intrusion occurred or not. Once it is acknowledged that the threat has happened, the IDS immediately communicate it with the administrator. Few IDSs can control attacks by utilizing network resources. Communication of threat occurrence is performed using various platforms like e-mails and messages in the user interface [29, 30].

#### IV. DETECTION METHODOLOGIES

The ID methodologies are classified a:

- IDS types by detection technique
- IDS types by monitored platform

##### A. IDS Types by Detection Technique

Further, the detection technique is categorized as,

- Anomaly based model
- Specification based
- Hybrid methods

1) *Anomaly-based (anomaly detection)*: Anomaly-based IDS detection approaches compare observed activities with definitions to predict malfunctions. Normally, anomaly-based detection has some rules to define basic network functioning based on the intrusions observed. Sultan et al. [31] proposed an anomaly based method using a variational encoder for the ID in the network. The intrusion was detected through a semi-supervised learning approach and unsupervised deep learning (DL) methods. Variational autoencoder (VAE) and autoencoder (AE) were employed using flow features to detect unknown attacks. The area under receiver operating characteristics (ROC) was calculated using these methods and compared with a one-class (OC) support vector machine (SVM). AE and VAE were used, and OCSVM were trained through semi-supervised learning. To detect intrusion on flow based data, that approach uses DL methods. But that proposed method increases the false alarm rate.

Whereas, Shubhra et al. [32] proposed an adaptive scheme that combines both the adaptive grasshopper optimization

algorithm (AGOA) and the ensemble of feature selection (EFS) method for identifying attacks. The EFS ranked the attribute from a selected subset of attributes having higher ranks, and the AGOA was adopted to find significant attributes from datasets. SVM was used as a fitness function to increase classification performance and efficient feature selection; the proposed method decreased proficiency. Hence to improve the classification, Bayu et al. [33] proposed a Two-Stage Classifier based IDS (TSE-IDS) to detect attacks. In order to minimize the feature size of datasets, hybrid particle swarm optimization (PSO), ant colony algorithm (ACO), and genetic algorithm (GA) were used. In addition, a reduced error pruning tree (REPT) classifier is used for improving classification performance and feature selection.

In order to improve dynamic network performance, Nguyen et al. [34] proposed anomaly-based network IDs (NIDS) using DL to consider false-positive rates and the unavailability of labelled data. The proposed method used Restricted Boltzmann Machines (RBM) and Autoencoder. The staked auto encoder performed better than RBM but consumed more time due to higher computation. Future work is needed to improve speed and reduce the oscillations in the slope of training error. Roshan Kumar and Deepak Sharma [35] proposed a hybrid ID algorithm focusing on reduced time consumption. That proposed method was developed by combining anomaly and signature-based approaches. That proposed method was more effective for detecting more attacks. But that proposed method had the drawback of higher time consumption.

TABLE I. ANOMALY-BASED IDS

Author	Method	Datasets	Outcome	Advantages	Drawbacks
Sultan et al. [31]	Variational Autoencoder	NSL-KDD	AUC – 0.7596	The detection rate is higher	A false alarm is more
Shubhra et al. [32]	Adaptive scheme	ISCX 2012	A-99.13 DR-99.23 FPR-0.067	predict the networks traffic behavior accurately	Decrease in proficiency
BAYU et al. [33]	Two-Stage Classifier Ensemble	NSL-KDD and UNSW-NB15	A – 85.8% S – 86.8% P-91.60% DR-88%	Improved precision metric and accuracy	Multi-class classification on problem
Nguyen et al. [34]	NIDS	KDDCup99	T-240sec	Effective in detecting and classifying intrusion into five groups.	Higher oscillation in the slope of training error
Roshan et al. [35]	HyINT	KDDcup99	T-14.773	Ability to detect unknown attacks	Time-consuming process

Above mentioned methods for anomaly-based IDS methods for network ID and their outcome and advantages are illustrated in Table I. In every table, the performance measures are indicated by Accuracy (A), Detection rate (DR), Precision (P), F-score (F), Connection rate (CR), Learning rate (LR), True Positive rate (TP), False Positive rate (FPR) and Ability to avoid misclassification (AUC), false alarm rate (FAR), false positive (FP).

2) *Specification-based NIDS*: Specification-based IDS uses manual specifications to detect network intrusion. Various specification-based methods are listed below.

Anhtuan Le et al. [36] proposed Routing Protocol (RP) for Low Power and Lossy Networks (RPL). That proposed method was constructed by a semi-auto profiling technique that generates high-level abstracts. That proposed approach includes protocol states and transitions on statics executed on several IDS rules. The power consumption was minimized by eliminating the overhearing of communication. Furthermore, the RPL information object and Information Solicitation (DIS) were introduced to alleviate the synchronization issues. But that the proposed method needs to be improved to detect internal threats.

Hence, Herson Esquivel-Vargas et al. [37] proposed a specification-based IDS using the BACnet protocol to enhance the detection rate. In that approach, fully automated deployment of IDS through BACnet protocol was used. In that protocol, the certified devices were demanded to document, representing network behavior. The prototype of that protocol was executed passively, and the attacks were detected on a single BACnet packet. But that proposed method needs to be improved to increase network security.

Above mentioned methods for specification-based IDS, along with its outcome and advantages, are illustrated in Table II.

TABLE II. SPECIFICATION-BASED METHODS FOR IDS

Author	Approaches/modules	Application	Outcome	Advantages	Drawbacks
Anhtuan Le et al. [36]	semi-auto profiling technique	RPL-Based Network Topology	OH-6.3%	Higher energy efficiency	An extension of IDS is needed for detecting internal threats
Herson Esquivel-Vargas et al. [37]	synthetic traffic	BACnet Protocol	P-99.85% R-99.57%	Attacks can be detected during real and synthetic traffic	System security needs to be improved

3) *Hybrid techniques*: Hybrid techniques are developed by combining two methodologies for ID. Thus, the hybrid methods overcome the drawbacks of single approaches. Various hybrid approaches for NIDS are given below.

Further improving network performance and addressing the issues of RPL, Areej Althubaity et al. [38] proposed an architecture by combining a centralized model with a sink and

a distributed module with RPL. That hybrid method was called Authenticated Rank and Routing Metric (ARM). That proposed approach validates the legitimacy of data transferred through RPL control data while constructing the route. Sajad Einy et al. [39] proposed hybrid anomaly and signature-based NIDS for enhancing network security. Suricata IDS was adopted with a neural network model to examine the network's malicious behaviour in that proposed model. The signatures of different types of attacks were examined by the neural network (NN) model. Then, the output from NN was given to Suricata IDS. In addition, an open-source blacklist internet protocol was adopted in that system.

That proposed method may create additional attacks in the network. Hence to avoid additional errors in the network, MavraMehmood et al. [40] proposed a hybrid approach by combining SVM and an adaptive neuro-fuzzy interference system (ANFIS). That paper adopted min-max and data transformation methods for data pre-processing. Then, optimum features were chosen by the random forest recursive feature elimination technique. Afterwards, ANFIS and SVM were used for ID and classification, respectively.

Above mentioned hybrid methods for IDS, along with its outcome and advantages, are illustrated in Table III.

TABLE III. HYBRID METHODS FOR IDS

Author	Method	Approaches/modules	Outcome	Advantages	Drawbacks
Areej Althubaity et al. [38]	hybrid specification-based IDS	Centralized and distributed models	Power consumption is 1966.711 mW	Extra overhead is minimized	-
Sajad Einy et al. [39]	Hybrid anomaly and signature-based IDS	Suricata IDS	A-96.11%	Different attacks are detected	Lower accuracy
MavraMehmood et al. [40]	ANFIS and SVM	random forest recursive feature elimination technique	A-99.3% Sp-0.998% P-0.999% R-0.992% F-0.995%	Higher accuracy	Higher cost

### B. IDS Types by Monitored Platform (Data Source)

The monitor-based IDS methods are classified as:

- Network based IDS
- Host-based IDS

1) *Network based IDS (NIDS)*: A NIDS detects harmful traffic on a network requiring promiscuous network access to examine the traffic. The IDS used some components to protect the network from attacks. The NIDS management console and management server were secreted from the remaining network. Therefore, the attacker cannot determine the location of the components.

Basant Subba et al. [41] proposed an artificial neural network (ANN) for IDS. The ANN optimization techniques

minimize the computational overhead and maintain high-level performance simultaneously. ANN consists of more interrelated nodes collaborating near each other to make a solution an exact task. ANN depend IDS model was suitable for real-time consumption. That proposed method requires more processing time. Hence to reduce the time consumption, Norbert Adam et al. [42] proposed NN based IDS to identify cruel behavior in the network. Ethernet taps were used to divide the signals and then distribute one branch to the original objective and another branch to the IDS. That technique tested for the nMap scanning attack, UDP flood attack, SYN flood attack and non-hateful statement.

Vrushali D.Mane & SN Pawar [43] proposed a back propagation ANN (BPANN) algorithm for detecting various network attacks to reduce FAR. The main objective of those methods was safeguarding the complete data with the support of a supervised neural network. In that approach, the neural network only used significant features of the KDD 99 dataset. The system performance was analyzed using 10% of the data from the KDD 99 dataset. The KDD training dataset contains a large number of signal connection vectors. The neural network needs a lot of time to test and train all datasets.

Further, Hossein Gharaee & Hamid Hosseinvand [44] proposed a GA and SVM for feature selection to improve network performance. GA drops the data dimension similarly, improving true positive detection and reducing the FP detection. In the feature selection method, input was considered traffic data that produces features (chromosomes) and then chooses chromosomes with higher categorization precision. SVM reduced computational time for training and achieved a low FPR with high accuracy. In that technique, KDD CUP 99 and UNSW-NB15 datasets were used for the testing. That proposed model was not suitable for large datasets.

IDS was a valuable device for analyzing and detecting malicious activities in the cloud network, and that was employed in organizations, enterprises and is important in cyberspace security. Kai Zhang et al. [45] proposed an intrusion action based correlation framework (IACF) for analyzing and correlating malicious behaviors in networks. IACF was used for improving the procedure of action extraction, scenario discovery and alerting. IACF alerts the network depending on the conception of intrinsic tough correlations. The sequence pruning algorithm (SPA) decreases false-positive impact and constructs the correlation. The IACF technique was used for predicting intrusion behavior depending on correlation graphs.

Basant Subba et al. [46] proposed a game theory (GT)-based false alarm (GTBFA) for reducing the FPA in signature-based IDS. A high FPA rate led to considerable utilization of network assets for monitoring against useless network fear. That proposed method links IDS alarms with network behavior to reduce the FPA rate of IDS. GTBFA uses more malicious activity scanners to scan the cloud network and generate a threat summary of the network. DARPA and IITG lab network datasets were used to reduce the FPA rate of IDS. A GT procedure was used to develop the network's sensible vulnerability set (SVS). This proposed method offer reduces

the detection rate of critical vulnerabilities. At the same time, network classification had long-term problems such as irrelevant features and redundancy. Priyadarsi Nanda et al. [47] proposed the least square (LS) SVM for IDS for feature selection. The KDD Cup 99, NSL-KDD and Kyoto 2006+ datasets were used to examine the performance of the LSSVM based IDS. Flexible, mutual information feature selection (FMIFS) was an efficient feature selection algorithm to decrease similarity. SVM was able to solve the binary classification problems.

Mobile malware could direct to some cyber security threats such as installing backdoors, stealing sensitive information, sending premium SMSs and ransomware attacks. The antivirus systems were not able to detect the advanced threats. Therefore, there is an additional layer of safety on the network to protect the users from threats. Sanjay Kumar et al. [48] proposed a machine ML dependent on NIDS. ML classifiers were built using a dataset consisting of labeled instances of network traffic features created through some malicious. NIDS was capable of identifying malicious traffic effectively where antivirus created false negatives. ML classifiers were used as the most efficient and traditional antivirus in that technique. The ML model was integrated into traditional IDS for detecting advanced threats and decreasing false positives.

Communication systems had two major challenges: privacy of user-specific data and computer security. The increasing uses of Internet connected devices had a certain increased to more number of vulnerabilities, which integrated assault on devices. Ayyaz-UI-Haq Qureshi et al. [49] proposed a novel random NN depending on IDS (RNN-IDS) for detecting malicious activity. The RNN architecture consists of one way to pass the signals or information where data or signal transfers from the input layer to the hidden layer. In that technique, performance was estimated by training dissimilar numbers of input and hidden layer neurons through a learning tariff on standard NSL-KDD datasets for binary classification. The gradient descent algorithm (GDA) was used for classifying the binary class of NSL-KDD datasets. A large number of input neurons were needed to improve detection accuracy. Moreover, the proposed method detects only a few attacks.

Thus, Sanchit Nayyar et al. [50] proposed an LSTM based ML approach for examining intrusions in the network. That proposed approach was tested on the CICIDS2017 data set with several attacks such as Web based Brute Force, DoS Hulk, DoS sloworis, DoS GoldenEye DoS slowhttpstest, DDoS LOIT and Patator based attacks. The neurons in the input and output layers were 77 and 2; 12 hidden layers were presented. That proposed approach requires an efficient algorithm for better classification. Nuno Oliveira et al. [51] suggested a sequential approach based on NIDS.

Moreover, the performance of multilayer perception (MLP), random forest and long short term memory was estimated on the CIDDS-001 dataset. That proposed model was evaluated on single flow and multi-flow. Above mentioned methods and their advantages are illustrated in Table IV.

TABLE IV. NETWORK BASED IDS

Author	Method	Datasets	Classifier	Outcomes	Advantages	Disadvantages
Basant Subba in 2016 [41]	ANN	NSL-KDD	ANN	A-95.05% DR-95.05%	High accuracy and detection rate	More processing time for large neural network
Norbert Adam in 2017 [42]	NNIDS	Train.txt	ANN	CR-1 LR-0.5	Recognize learned malicious activities	Spanning port per switch was allowed
Vrushali D.Man in 2018 [43]	BPANN	KDD 99	ANN	A-98.0% DR-92.80%	Minimize FAR	Sensitive to noise data
Hossein Gharaee in 2016 [44]	GA and SVM	KDD CUP 99 and UNSW-NB15	SVM	A-99.05% TP-98.47% FP-0.4%	High accuracy and low FPR	SVM was not suitable for large datasets
Kai Zhang in 2019 [45]	IACF	LLDOS 1.0	SPA	A-90%	Efficient in alert correlation	Less information in the infiltration scenario
Basant Subba in 2016 [46]	GTBFA	DARPA and IITG Lab	SVM	A-98.55% DR-91.87%	High accuracy	The detection rate was low against non-critical vulnerabilities

2) *Host-based IDS (HIDS)*: Host-based IDS protects our systems from many harmful intrusions occurring in the network. The host-based approach detects normal behavior by sequencing the system call. System sequences in the network create the sequences.

Chawla et al. [52] proposed Convolutional Neural Network (CNN) - Gated Recurrent Unit (GRU) language model for the just released Australian Defense Force Academy Linux Dataset (ADFA-LD). Training time is reduced by implementing CRR in the place of normal LSTM. Normal call sequence training is given to the model. In that approach, the next integer was predicted through training provided probability distribution. That proposed method had a lower convergence speed. Hence, Robin Gassais et al. [53] proposed host-based automated IDS by combining machine learning (ML) algorithms and tracing techniques to improve the convergence speed. That proposed approach used Random Forest (FT) Gradient Boosted Trees (GBT) for intrusion detection. Information on tracing was obtained from user space and kernel space. Adaptation based tuning for new devices are explained in that approach. The system has shown better accuracy in detecting threats and alerting the system. In that proposed approach, the network was analyzed only in series. Thus, it does not provide higher detection accuracy.

By focusing on higher network accuracy, Prachi Deshpande et al. [54] proposed HBIDS by analyzing system call traces and alerting users if any threats were detected. K-nearest neighbor (kNN) was used as a classifier for tracing. The kNN allows easy inclusion of new training data. The network was analyzed through the frequency of failed system calls over successful system calls. The host-based IDS methods and its outcome are illustrated in Table V.

TABLE V. HOST BASED IDS METHODS

Author	Method	Dataset	Outcome	Advantages	Drawbacks
Chawla et al. [52]	Convolutional Neural Network Gated Recurrent Unit	Australian Defence Force Academy Linux Dataset	TDR - 100% FAR - 60%.	More accurate with reduced training time.	Slow convergence speed

Prachi Deshpande et al. [54]	K-nearest neighbour Classifier	-	A- 96%	Improvement in Accuracy	Delayed Detection time

### C. Network Intrusion Detection Approaches

Since there are several methods were suggested by the authors to deal with intrusions into the network. Previous sections analyze host-based, specification-based, network-based and anomaly-based methods. Those methods do not perform well in detecting all kinds of attacks and have reduced detection accuracy. Moreover, the network intrusions are detected by clustering, hybrid and evolutionary algorithms reviewed in the upcoming section.

1) *Clustering based NIDS*: The clustering-based approaches are aimed at reducing network complexities and easing detection accuracy. Some of the clustering-based NIDS are listed below.

Luiz Fernando Carvalho et al. [55] proposed an unsupervised learning approach for NIDS for extracting features. A modified ant colony optimization algorithm was used to optimize the multi-dimensional flow of the network. That proposed method offers lower detection accuracy; hence, to overcome these drawbacks, Yanqing Yang et al. [56] proposed a fuzzy aggregation method using a modified density peak clustering algorithm (MDPCA) and deep belief networks (DBNs). In that proposed approach, the training sets were divided into sub-sets with the same number of attributes of various cluster centers. That proposed method enhances automatic feature selection.

Moreover, Wei Liang et al. [57] proposed a multi-feature data clustering optimization model to improve impersonation attacks' detection accuracy. Security coefficients and weighted distances were categorized based on priority thresholds in that proposed method. The similarity of multi-feature data was examined through distance metrics. That proposed algorithm halted the clustering while reaching the preset iteration or obtaining the best cluster.

2) *Evolutionary algorithm*: Evolutionary computing methods are also known as bio-inspired algorithms that are processed based on the behavior of biological organisms. Bio-

inspired algorithms are widely applied in many fields due to their simple processing. Evolutionary algorithm-based NIDS is given below.

Vajiheh Hajisalem and Shahram Babaie [58] proposed hybrid Artificial Bee Colony (ABC) and Artificial Fish Swarm (AFS) algorithms. In addition, the fuzzy C-means clustering and Correlation-based Feature Selection (CFS) techniques were adopted to avoid unnecessary features. The CART technique formulated the fuzzy rules for classifying normal and intrusion data in that approach. Further improving network intrusion classification, Chaouki Khammassi and Saoussen Krichen [59] proposed a genetic algorithm (GA) and logistic regression based learning algorithm. That proposed method was evaluated under the KDD99 dataset and the UNSW-NB15 dataset. In addition, three decision tree classifiers were adopted for performance evaluation. The performance measures examined for the KDD99 dataset are illustrated in the table.

3) *Classification based NIDS*: Classification-based approaches are adopted for classifying malicious and normal behavior of the network. The classifier is developed by training data and classifies network behavior in classification-based methods. The classification approaches are carried out in either a multi-class or single-class manner. Some of the classification approaches for NIDS are given below.

Jiyeon Kim et al. [60] proposed a CNN-based NIDS to examine the DOS attack evaluated on the KDD CUP 1999 dataset comprised of DOS, U2R, R2L and probing attacks. That proposed model detects attacks belonging to a similar category. Moreover, the CSE-CIC-IDS2018 is also used for examining advanced IDS attacks. That proposed method offers lower detection accuracy of 93%. To enhance detection accuracy for examining cyber-attacks, Guo Pu et al. [61] proposed a hybrid unsupervised cluster based NIDS by combining OC-SVM and subspace clustering methods. This proposed method was validated under the NSL-KDD dataset. The OCSVM was suitable for unlabelled data in which the data had a normal class only. That maps both the feature space with data under the kernel. The feature selection must be improved further for better performance.

Yang Jia et al. [62] proposed a new deep NN (NDNN) model for NIDS that comprised four hidden layers evaluated on KDD99 and NSL-KDD. In that model, the input, hidden, and output layers consist of 41 neurons, 100 neurons, and 5 neurons, respectively. The proposed model performs better in KDD99 datasets but cannot provide better detection accuracy. But the KDD99 provides better performance in different kinds of attacks. Ahmed Iqbal and Shabib Aftab [63] proposed a feed-forward and pattern recognition (PR) ANN model to improve detection accuracy. The ANN was trained by scaled conjugate gradient, training functions and Bayesian regularization. That feed-forward network had multilayer neurons that were trained by Bayesian regularization. Then the PR was trained by a scaled conjugate gradient function. Arun Nagaraja et al. [64] proposed a UTTAMA classifier for detecting network intrusion; moreover, the Apriori algorithm based Frequent Pattern (FP) max algorithm was used. That

proposed classifier was tested under KDD-41 and KDD-19 datasets.

4) *Hybrid approaches*: Hybrid approaches are developed by adding various classification algorithms, methods and techniques. Some of the hybrid approaches are listed below.

Ansam Khraisat et al. [65] proposed a hybrid C5 decision tree classifier and OC-SVM, estimated on network security laboratory-knowledge discovery in a database (NSL-KDD). The proposed model used the attributes of benign samples, which does not use the data from other samples. The OCSVM classifier converts instances into a high dimensional attributes space and locates a suitable boundary hyperplane. That approach can detect the intrusions with only limited samples whereas, it has lower accuracy. Muhammad Ashfaq Khan [66] proposed a hybrid convolutional recurrent neural network-based NIDS. That method was estimated on the CSE-CIC-IDS2018 dataset that comprised seven types of attacks. Moreover, the network was mixed with traffic and non-traffic nodes to examine the suggested method. That suggested method was only investigated on the single dataset.

Different NIDS approaches are illustrated in Table VI.

TABLE VI. DIFFERENT APPROACHES FOR NETWORK INTRUSION DETECTION

Author	Method	Performance measures	Advantages	Drawbacks
Luiz Fernando Carvalho et al. [55]	Ant colony optimized digital signature	TPR is 93% for 1% FPR	Suitable for anomaly detection in large scale network	Lower detection accuracy
Yanqing Yang et al. [56]	MDPCA and DBN	A-90.21% DR-96.22% FPR-17.15%	Reduces the complexities in training sub-sets	Cannot detect the R2L and U2L attacks
Wei Liang et al. [57]	Multi-feature data clustering	DA-0.95 for 75 features	Detection accuracy is improved during a high overlap	Only detect the known attacks
Vajiheh Hajisalem and Shahram Babaie [58]	CFS techniques	FPR-0.01% DR-99%	Lower overhead	Need to reduce network complexity
Chaouki Khammassi and Saoussen Krichen [59]	genetic algorithm (GA) and logistic regression based learning algorithm	FAR-99.81% DR-1.105%	Better accuracy in detecting DOS attack	Need to reduce the misclassified results
Jiyeon Kim et al. [60]	CNN	P-1 A-93% R-1 F-1	New attacks are identified through the CSE-	Only detect the attack belongs to the same category

			CIC-IDS2018 dataset	
Guo Pu et al. [61]	SSC-OCSVM	DR-1 @ 0.05 false alarm rate	Detect large fraction of attacks in lower FAR	Lower detection accuracy
Yang Jia et al. [62]	NDNN	A-0.999 F-0.9998 R-0.9997	KDD99 dataset provides the best performance in all kinds of attacks detection	More network simulation experiments are needed
Ahmed Iqbal and Shabib Aftab [63]	FFANN	A-99.8356% MSE-0.0050	KDD CUP 99 examines different attacks	More improvements needed
Arun Nagaraja et al. [64]	UTTAMA	A-99.952%	A new membership function achieves a dimensional reduction	New distance functions are needed to improve performance efficacy.
Ansam Khraisat et al. [65]	OCSVM	A-83.24%	Detect the intrusions with fewer samples	Lower accuracy for detecting different tasks
Muhammad Ashfaq Khan [66]	HCRNNIDS	A-97.75% P-0.9633 R-0.9712 F-0.976 DR-0.97 FAR-2.5	Provides sufficient security against malicious nodes	The proposed method is tested on a single dataset only

5) *Discussion on traditional methods*

- The anomaly-based methods follow some detection rules based on some considerations thus, it is not capable of detecting all faults in the network. Moreover, the rule-defining process is degraded by the protocols, whereas the custom protocols also affect the rule-defining process.
- The clustering-based NIDS methods reduce the computational complexities in the network by grouping large datasets. In contrast, these methods affect detection rates in positive and negative ways. Moreover, the clustering approaches consume more time and can be affected by local minima.
- Classification-based NIDS approaches to improve the detection accuracy of network intrusion. Due to its adaptive nature, more data can be trained and tested using the ANN. On the other hand, the detection performance is improved by adding more layers within the network. Thus resource utilization is increased, resulting in over-fitting issues. Furthermore, that approaches needs relevant information for detecting unknown attacks.
- In evolutionary algorithm based NIDS, the detection accuracy and intrusion detection performance depend

on the algorithm used. The meta-heuristic algorithms adopt the behavior of living organism; thus, it does not require prior information about the network. The evolutionary algorithms do not affect by network noises. At the same time, the evolutionary algorithms are hard to map with network related issues.

- Compared with other methods, hybrid NIDS approaches have better performance but require high resources due to the combination of multiple techniques.

From the above analysis, it was noted that the rule-based approaches are affected by the protocols and clustering approaches increases the complexity due to large datasets and the classification based approaches needs more layers to provide an accurate results.

#### D. Deep Learning (DL) and Machine Learning based NIDS

Several methods are reviewed in the literature for detecting intrusion in the network, but they lack data management and feature learning. Both are considered important issues in IDS. Thus the DL based approaches are developed for detecting security threats in networks. Some of the DL based approaches are listed below.

Quamar Niyaz et al. [67] proposed a DL approach for detecting intrusion in the network in which self-taught learning (STL) was adopted. That proposed STL method comprised two stages wherein the representation of good features was learnt from unbalanced data collection. Then that learn representation was employed for labelled data that was adopted for classification. In that approach, the NSL-KDD dataset was adopted, which was minimized version of the KDD Cup 99 dataset. The sparse auto-encoder and soft-max regression matrix-based IDS were implemented in that paper. Furthermore, the performance of the IDS was enhanced by adding an extension of auto-encoders and stacked auto-encoder.

Hongpo Zhang et al. [68] proposed a denoising auto-encoder (DAE) and a weight loss function to select appropriate features for detecting intrusion by minimizing the feature dimensionality. Then, the chosen features were categorized through the multilayer perceptron (MLP) to identify the intrusion. In that proposed method, one key feature selection adds the weights to several samples' loss functions, which eases the feature selection. In that method, 12 features were chosen among 202 features with a 5.9% selection ratio. In MLP, two hidden layers were used for classification, which yielded an accuracy of 98.80%.

Fahimeh Farahnakian and Jukka Heikkonen [69] proposed a deep auto-encoder (DAE)-based method to detect network attacks caused by several vulnerabilities. That proposed DAE was trained in a greedy layer-wise fashion to evade the over-fitting and local optima. That proposed approach was executed through training and testing phases. During the training process, the system did the adoption of the training dataset and the creation of the DAE model. During the testing phase, a model was used for labelling test data. The input layer denotes 117 features of the dataset, and then the hidden layer chooses

32 features. In that method, the sigmoid function was chosen for hidden layers.

Vinayakumar et al. [70] proposed a deep NN (DNN) for detecting intrusion and classifying cyber-attacks. The Apache Spark cluster computing platform designed the scalable computing architecture in that proposed method. That proposed architecture explores the processing competence of a general purpose graphical processing unit (GPGPU) for rapid network investigation. The proposed architecture of DNN comprises five hidden layers for extracting complex features and pattern recognition ability. That proposed method was executed for different classifiers such as KDDCup 99, NSL-KDD, UNSW NB-15 and WSN-DS. Moreover, the result implies that the dataset of KDDCup99 and NSLKDD offer higher accuracy in the 95% to 99% range. The performance measures for binary classification of the KDDCup99 dataset with five layers of DNN are illustrated in the table.

Faten Louati and Farah Barika [71] proposed a DL based multi-agent system (MAS) for detection by combining the multi-agent features with DL algorithms. In that approach, the agents were generated by three algorithms: MLP, auto-encoder and k-nearest neighbour in which the autoencoder was used for feature reduction. In contrast, MLP and autoencoder were used for classification. In that approach, the MLP was a subset of DNN that was based on the backpropagation (BP) algorithm. Moreover, in autoencoders, the output layer had a similar number of nodes as the input layer. The auto encoders minimize the number of features from 120 to 10. In addition, the MAS enhances the network performance through proactivity and reactivity, which eases intrusion detection. The MAS comprises a pre-processor agent, reducer agent, classifier agent and decision-maker agent.

Soosan Naderi Mighan and Mohsen Kahani [72] proposed a hybrid DL and support vector machine (SVM) for feature extraction and classification. The stacked autoencoder (SAE) was used to reduce feature sets' dimensional reduction. In addition, the SVM was adopted for classification. In the pre-processing stage, symbolic features were converted into numeric values that range from zero to several symbols. The data normalization step was executed to minimize the dimension for all attributes. Then the latent features were extracted in the second phase; after that, the DL approach detected the attack. That suggested model was investigated on the ISCX IDS UNB dataset and it results in faster execution time.

Kasongo and Yanxia Sun [73] proposed feed-forward DNN (FFDNN) along with wrapper based feature selection (WFEU). The proposed method used an extra tree algorithm for optimum feature selection. That proposed method was evaluated under AWID and UNSW-NB15 datasets. The UNSW-NB15 dataset comprised 39 numerical features, three input nominal features had the feature type of binary, float and integer. In the initial phase, the FFDNN was implemented; after that, the WFEU was included. The experimental results demonstrate that the wrapper-based feature extraction was effective for the UNSW-NB15 dataset. In AWID, the

proposed model was implemented with a whole set of features; after that, 26 features were used from 154 attributes.

Sandeep Gurung et al. [74] proposed a DL and sparse auto-encoders for feature learning. That proposed method was trained by the NSL-KDD dataset that yields the output value as 0 (normal user) or 1 (intruder). In a pre-processing step, the numeric parameters were replaced instead of non-numeric parameters then the data was normalized. That proposed method reduced the false alarm rate lower than the signature-based method. Mike Nkongolo et al. [75] proposed a novel dataset, UGRansome1819, to detect unknown network attacks like zero-day threats. That proposed dataset benefited from unknown attacks that were not explored before and could not be observed by known attacks that were more efficient than the KDD99 and NSL-KDD datasets.

By analyzing several DL-based intrusion detection approaches, it has been concluded that deep network models examine all types of intrusion in the network. Furthermore, the deep networks can classify the intrusion type thus, it can be useful for detecting unknown attacks in the network. The node with an Internet protocol (IP) address and Internet produces network traffic that blocks the service to users [76]. However, the ML based methods are applicable in ad-click prognosis systems, and a two-way authentication system provides a secure connection between digital environments [77, 78]. If the attack arises from several distributed hosts, it will cause distributed denial of service attack (DDoS) that is more harmful than normal DoS [79, 80]. Illegitimate users create the DDoS to deny the server provided services [81]. Moreover, the system performance is improved by adding auto-encoders that increase detection accuracy.

The DL-based IDS with its pros and cons are illustrated in Table VII.

TABLE VII. DL BASED METHODS FOR IDS

Author	Method	Datasets	Classifier	Outcome	Advantages	Disadvantages
Quamar Niyaz et al. in 2016 [67]	DL	NSL-KDD dataset	Auto encoder	-	Improved performance by adding NB-tree and random-tree classifiers	The proposed method was not evaluated under real time IDS

1) *Discussion on DL and ML approaches:* As mentioned earlier, the traditional methods have some limitations in intrusion detection; thus, the DL and ML based methods are used to resolve such issues. The insight on DL and ML based approaches are discussed below:

- The ML based methods provide better results in higher detection accuracy, but their performance completely relies on the data training.
- The DL methods efficiently examine enormous data in the network, but optimized layers improve their performance. Thus if the DL is used it must be used with the optimization algorithm to improve the computational efficacy.
- In a supervised learning based ML approach, classification is an important task; however, manual data labelling consumes more time for processing. Thus, the data labeling must be improved to get the benefits in ML approaches.
- The methods reviewed in the above section have used commonly used datasets such as KDD, CUP 99 etc., which do not contains the updated data of new types of attacks. While applying the methods to these datasets, the method's robustness cannot be determined. On the other hand, constructing a new dataset is expensive and needs expert knowledge.
- The better performance of IDS is not guaranteed while using ML with the dataset without real-world samples.

Findings: From these analysis, it is found that the method should be improved in terms of data collection, feature extraction and classification. Moreover, the inclusion of up-to-date dataset is also important factor to examine the unknown attacks. Moreover, these findings are more sufficient for proving efficient solution to improve the IDS against various attacks.

#### E. Limitations of NIDS

Although several methods are available for network intrusion detection, some limitations are listed below.

- Despite the ongoing research on IDS, intrusion detection techniques still have some drawbacks, such as slow detection time and high false detection. Due to the high detection time, it is hard to make working these methodologies for high speed networks.
- It is impossible to run soft-computing techniques on huge data with many features and imbalanced data. For analyzing such huge data, efficient sampling and feature selection techniques must be used.
- Parallely coordinated IDS are needed for large-scale and fast computing networks [82].
- Recently developed approaches perform better in detecting network intrusions but do not detect all types of attacks. Moreover, the available datasets comprised only a few attacks; thus, it is not effective for detecting all types of attacks. The up-to-date datasets may reveal new attacks in the network; thus, most of the recent

IDS cannot detect several types of attacks due to the unavailability of up-to-date datasets.

- The important issue with anomaly-based method is that it can examine the zero-day attack when properly modelled. The improper modelling of anomaly-based methods will raise the false alarm rate.
- The dataset must be integrated with the DL models to identify more attacks in the network to learn many patterns. In these cases, the dataset generation will be expensive.
- Most importantly, the unbalancing dataset may degrade network performance by reducing detection accuracy; thus, a balanced dataset is required for better dataset performance.
- The major challenge in IDS is the execution in the real-world environment, whereas most existing methods are not validated using a public dataset in the lab.
- Several methods suggested in existing works are complex in structure; this may cause extra overhead for the network process.
- To minimize the routing overhead of the network by proper feature selection, the researchers propose optimization algorithms, but the convergence speed of the existing algorithms will affects the feature extraction.
- The ML approach has some limitations, such as handling raw, high dimensional data and unlabeled data. Thus it cannot provide better classification in the presence of large datasets and complex data labelling. Thus the ML approaches are not suitable in the case of multi-classification function.
- The IDS are also adopted in IoT applications thus that deal with several sensor nodes in such methods. Not all kinds of IDS are suitable for this sense; only lightweight IDS is preferred in these applications due to minimum power utilization.
- IDS plays a major role in providing better system security than other systems. However, new malicious attacks are occurring in large amounts, making providing system security within computer networks a tedious task. Therefore, systematically updating available datasets would be the need of the hour.
- The challenges associated with IDS are false alarm rate, low detection rate, unbalanced datasets and response time. Misuse or signature based IDS are usually accompanied by some degree of false-positive alarm rates and are inefficient in detecting unknown or novel attacks. The main challenge of this system is updating the signatures of harmful intrusions. The challenges associated with anomaly based IDS are miscalculation in detection, lack of speed, difficulty in alerting and unbalanced datasheets.

## V. CONCLUSION

The IDS is a sufficient mechanism for securing the network against intrusions; thus, a comprehensive review of this topic is needed. This survey paper aimed to better understand intrusion detection in the network in accordance with different aspects. Different methods reviewed in this paper provide perceptive growth in intrusion detection. A wide range of methods was developed on this topic, each with advantages and drawbacks. A comparative analysis of different methods is given in this paper. Initially, several attacks occur in the networks were analyzed. After that, the NIDS is categorized under the detection technique and monitor platform. Further, the detection techniques are specification-based, anomaly-based and hybrid methods. Similarly, depending on the monitoring platform, the monitoring platform is classified as network-based or host-based. Additionally, classification-based, algorithm-based, clustering-based IDS are reviewed in detail. Tables provided deep insight into these methods and their pros and cons in each section. Different datasets are used in several methods to show the performance efficacy of the suggested method. It is found that most existing approaches detect few attacks only due to the availability of up-to-date datasets. By analyzing different methods, IDS is limited; the signature-based IDS are not effective for detecting the type of attack; thus, efficient IDS are modelled for detecting several kinds of attacks on the network.

The anomaly-based IDS effectively detect different types of attacks in the network, resulting in a higher false alarm rate; hence in future work, the anomaly-based approach will be improved by minimizing the false alarm rate. Even though the anomaly-based approaches can detect the zero-day attack, they cannot provide the desired outcome if it is not properly designed. To provide these issues, the ML and DL approaches are developed. The important task in intrusion detection is feature extraction. In the view of feature extraction, the DL outperforms ML by automatically extracting features. In addition, the survey shows that the classification-based methods had better performance in intrusion detection than all other methods. In addition, DL models are more effective for classification. Thus, it is concluded that DL approaches are more effective for detecting unknown attacks in the network. Most DL-based approaches are validated through different datasets in which the detection accuracy is based on feature selection. For this purpose, optimization algorithms are adopted. But single algorithms are not improving optimum feature selection. Since no methods were developed for unknown attack detection in the network with optimized DL. On the other hand, it is observed that the lack of an up-to-date dataset degrades intrusion detection in the network. This review cannot affirm the best method to detect unknown attacks in the network, but it suggests an effective way to detect unknown attacks. The future research direction of unknown attack detection is deliberated in the next section.

### A. Future Works

The future scope of IDS is listed below.

This review verified that DL approaches are more effective, but their performance can be improved by adding an

efficient algorithm. Hence, hybrid DL approaches are suggested for detecting known and unknown attacks in future work. In order to improve the detection of unknown attacks, it is important to use the up-to-date method. Future work will focus on unknown attack detection in the network; hence, the recently developed UGRansome1819 dataset is suggested. The intrusion detection not only improved by the dataset but also improved by adding an efficient feature section approach. In fact, hybrid pattern search whale optimization algorithm will be effective for optimal feature selection. Pattern search is a non-derivative algorithm that is suitable for updating an optimum weight as well as the whale optimization algorithm (WOA) has a better convergence speed. Hence adopting both these algorithms will improve the feature selection. The important task after feature selection is classification, which provides the final outcome about the attacks in the network. At the same time, the lack of processing speed will reduce the detection accuracy. Furthermore, the hybrid bi-directional long short term memory (Bi-LSTM) with the gated recurrent unit (GRU) has to be implemented to classify unknown attacks in the network. These improved feature extraction and classification approaches will be effective solutions for detecting unknown attacks in the network.

Department of Telecommunication Engineering, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana<sup>3</sup>

**Abstract**—This paper proposes a new population-based global optimization algorithm, Ọdigo Metaheuristic Optimization Algorithm–QMOA, for solving complex bounded-constraint/single objective real-parameter problems found in most engineering and scientific applications. It’s inspired by the human socio-cultural informal discipleship learning pattern inherent in the behavior of the Ndigbo peoples; the subject – primary (Nwa-ahja), in mercantile cycle grows to a secondary (Mazi) owing to the intuitive stratagem (dialect - Igba) embedded in an aged-long cultural model “Igba-ọsọ-ahja” (meaning, strategic marketing skills, and practice). The model mimics the search routine for satisfying a customer’s need in the market, built into exploration and exploitation applied in the mathematical model. About 30 complex classical unconstrained functions are tested, comparing results with that of five similar state-of-the-art algorithms. Also, 29 CEC-2017 single objective real constraint benchmark serious dimensional problems were simulated and compared against the winners of that competition. Validation includes statistical (t-test, p-value) comparison and for 50 Dimension constraint problems as QMOA demonstrated superior performance. TCS (9.18%), WBP (6.3%), PVDP (601%), RGP (319%), RBP (760%), GTCD (202%), HIMMELBLAU (4%), and CDP (88.12%) are the improvements made on 8 CEC-2020 engineering real design problems against the former best performances; QMOA is simple to implement, replicate and applicable across domains. Also, some new, improved optimum was obtained in Shubert and Schaffer 4 function compared to the global optimums.

**Keywords**—Human socio-cultural; nature-inspired; informal-learning; global optimization

## I. INTRODUCTION

Humans and animals face challenges within their time and space of habitation, and they attempt to solve the challenges by making decisions and selecting and combining variables influencing the conditions. The challenges range from simple to difficult-complex ones, but the satisfaction derived from attaining the goal motivates effort for solution pursuant [1]. Engineering has availed very good solutions for small scaled problems using exact methods, but such fails when the problem becomes special and high dimension, become very costly and time consuming [2]. Meanwhile, the study of nature showed complex problems solved by meta-ideas and heuristics. The aesthetics that describes the meta-heuristics provide solutions that are near-optimal yet scalable with problem dimensions [3] despite the difficult procedural

uncertainties [4]; the huge difficulty is associated with the mapping of routines called intelligence from rules or heuristics that describe events of nature which falls in a multidisciplinary field [5, 6]. Research in this direction has yielded several methodologies for solving engineering problems, yet more are anticipated [6]. This work aims to address some multidisciplinary domain concerns; a significant gap in balancing exploitation and exploration in populations of solution search impacts the state-of-art. Also, most recent works have scantily described the critical analogies of the metaphors that reflect the aesthetics of the target nature’s source with the derived mathematical models, while the majority favors hybridization. Also, only a handful of the existing algorithms had human behavior metaphors, which this work proposes. Based on life science, a simple category of existing solutions could be into biological and non-biological (abiotic) hybrids, Bio-Abiotic hybrids, Bio-Bio hybrids, and Abiotic – Abiotic hybrids; however other literature may use alternative categorizations such as Swarm, Evolutionary, and Human intelligence. Genetic algorithms (GA) led the natural biological methods [7]. Particle Swarm Optimization (PSO) is inspired by flocks of birds and schools of fish [8] [9]. A few others due to space constraints are; Artificial Bee Colony from bee foraging [10]; Ant Colony [11]. In literature, numerous applications of the metaheuristics includes scheduling, loading, packaging, design, and control [12], image processing, amongst numerous others. The abiotic category is based on artificial physical experiences, such as Tabu Search, which made use of the creation of a tabu list [13]; Water Evaporation Optimization (WEO), mimicking the evaporation of water [14, 15]; JAYA mimicking the gravitation towards success [15]; Atomic Orbital Search (AOS) [16], etc. Some modified/hybrids are; Grey Wolf and PSO [17] gave (GWO-PSO), MOGSABAT [18] from the multiobjective gravitational search algorithm, and the echolocation ability of the bat algorithm [19]. Many other metaheuristic methods can be found [20, 21]. QMOA is a new strategy proposed by this work; the data is from the human population shown in Section II. The aesthetics are based on informal learning. The mathematical relations are developed in Section III and experiments, results and discussions are also presented in Section III, while Section IV is the conclusion.

The data of this work is gathered from the Ndigbo people’s mercantilism. This ideology is found in major Market setups across the World, where Ndigbo are found in huge populations

[22, 23]. They cooperate and maintain this characteristic ideology they call “igba”; meaning stratagem. [24, 25]. The aesthetics; every male is disciple/given-chance-to-hands-on/learn informally in commerce backed by some form of agreement [26]; a model known to them as “Igba-oso-ahija” which means strategic marketing skills acquisition and practice. Ahija (market) is a solution space and holds all history of exploitations and explorations through Igba-oso-ahija model [27]. There exist huge risks and sacrifices, but the Ndigbo tolerates them [27].

A. QMOA Algorithm Description

In the Ahija environment, the ultimate is to become a Mazi; The initial population is generated randomly as Ahija-size. This is the “initialization mode”; The readiness, practicing, discipline, trading, cooperation, and the reluctance of the agents (known as umu-ahija in Igbo) is adjusted against the new environment each day; [from start-transduction mode to update-matching mode].

II. MODELING DATA AND AESTHETICS

The work started with a collection of data from a local ahija; the data is found at <https://data.mendeley.com/datasets/wt3vt72mph/1>. A few assumptions and facts extracted from data include but are not limited to the following parameters:

- 1) **NORMS:** (i) Every Mazi Own at least one shop. (ii) Every Nwa-ahija is attached to a Mazi, a shop, and an ahija. With an agreement, (iii) Death or risk are inevitable etc.
- 2) **AXUMES:** (i) Every Nwa-ahija must satisfy a certain set percent of discipleship requirements to become a Mazi.
- 3) **FACTS and Probable:** (i) Certain Nwa-ahija may succeed, fail, die, or get impeded. (ii) Certain Mazi may become greedy and unjust. (iii) Certain Umu-ahija had gotten second and third chances to make up, and many ahija exist.

B. Sample Size of Selected Market

Data in Table I shows a snapshot of the collection, and the values represent the sub-total in each case. For example, the column representing “Japan”; “JAPANLINE”; “shops:35”; Parts: [12: “Nissan”, 23: “Toyota Accessories”, NULL:” x”].

C. The Model - Ahija

The visualization of the setup of ahija as a system (inputs, process, and outputs) schematically looks like Fig. 1 (left, right)

Fig. 1(a) shows Ahija [n+9] described in Fig. 1(b) explicitly; the lines show the nonlinear relationships. The inner layers are shops and are associated with entities enlisted. The local Ahija are networked across major cities in Nigeria (Ibadan, Lagos, Onitsha, etc.) which affiliates to extensions in Countries like Japan and Germany. The Ahija primary agent (humans) are umu-ahija, and secondary are ndi-oso-ahija, Mazi, Bankers, customers (Regular and Non-Regular), suppliers, forwarding and clearing and etc. Meanwhile, the number of decision variables in sales, storage, borrowing etc., varies with constraints of environments like the cash flow, religion, and local/global politics etc.; taking shop 9 – GermanyLine Fig. 2; it comprises 1 –Mazi, 5 – Umu-ahija, 1 – Onye-oso-ahija, 12 –

Regular Customers, 100 – Emergency Customers and trading on Benz-Spare Parts as shown.

TABLE I. SAMPLED DATA FROM A MARKET AND SHOP DISTRIBUTIONS

Object	JAPAN	TOYOTA	GERMANY	AB	BAMENDA
Mazi	35	43	101	122	199
Umu-ahija	210	250	591	696	1162
Ndi-oso-ahija	35	43	101	122	199

Fig. 2. Snap off idumota sampling.

In obtaining the adjacency list from the data, assumptions made included (1) (1/0 means connected/not-connected)

respectively; (2) also shop data is deterministic data at capture time, the network of the single shop nine(9) is modeled, and the simulation – Bayes graph is as shown

Fig. 3. The schematic representation of the network traffic.

The complex network of the shop (54500 edges, 364 nodes), on a market day named Orië; Fig. 3 is made. It depicts the intense cognitive field (energy) of nonlinear relationship maps responsible for transduced processes with experience (edges) of umu-ahja (nodes) that Orië day. Daily customer satisfaction time monotonically decreases with increasing edges, even with constraints in cycles. Beyond shop 9, thousands of shops contribute to the ahja data; the computer structural model is shown in Fig. 4.

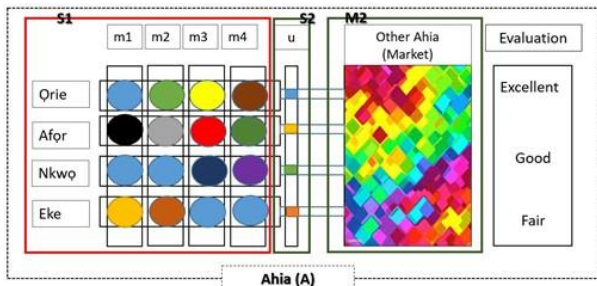

Fig. 4. Ahja environment across many shops.

S1, S2, m1, m2, m3, m4, and M2 represents: shops 1, ndi-oso-ahja, nwa-ahja-1, nwa-ahja-2, nwa-ahja-3, nwa-ahja-4, and many other distance ahja (markets). The updates are processes of the umu-ahja transforming on every market day (Orië, Afor, Nkwò, Eke). The colours is evidence uncertainty.

#### D. Initialization of Population (Market-Size)

OMOA; with the decision variables, Igba-oso-ahja and D-dimensions, the solution vector in the ahja can be represented as (1).

$$Mazi = [x_1, x_2, x_3, \dots, x_D] \quad (1)$$

The fitness value of each Mazi will be computed as a vector of (2);

$$f(Mazi) = f(x_1, x_2, x_3, \dots, x_D) \quad (1)$$

For instance, a new shop with new umu-ahja (ages of 3 and 8 yrs.), some constraints of this age group include (a) Nostalgic energy in early months, inherent childishness (comprises of untargetted and undirected energies): chaotic sleeping patterns, food pattern, and desires for the first few months persist. But discipleship (hands-on, disciplinary

actions, corrections, task handling, rewards) between 1 and 5 years changes their energies to focused excitement; next is integrity and trust test; Each nwa-ahja has a position and cost affected by such constraints and uncertainty in capacity, inductiveness, and reluctance. The population is generated using (3).

$$pop = \Phi(M, D) \quad (3)$$

The  $\Phi$  is a random generator, M is the market population (pop), and D is the dimension. The pseudocode is shown below.

#### Initial parameters

Initialize the structure for the empty individuals

Initialize population array

while (not termination) Do

    generate uniform random population with

        bounded size of market

    evaluate the cost of the individual

    update individual population

end while

return best solution

#### E. Mathematics of Igba-oso-ahja

Fig. 5(a) in 3-dimensional space during the search is shown in 2-Dimension as Fig. 5 (b) as agents move to satisfy customers' scarce demand for "gold" and "leather" as in Fig. 4 to exploit S1 and explore S2.

Fig. 5. Igba-oso-ahja cooperation by to find gold.

They cooperate, meet set thresholds, and satisfy the customer to get his Gold. Initializing a new Mazi, a new shop, and his contribution to the solution space will be given by (4).

$$U_n = f(X_1) \quad (2)$$

Combining equation (1) and (2);

$$U_n \leftarrow \begin{cases} x_i \in \{x_r\} & \text{mazi with new umu-ahja} \\ x_i \in X_1 & \text{1mazi, without umu-ahja} \end{cases} \quad (3)$$

Some of the major constraints (3) as mentioned in Section II. n; the number of generations – the stopping criteria, r indicates x is random. Mazi cost alone in trade without umu-ahja in the cycle of Ahja days (6) resolves to a fitness vector:

$$U_n = X_{n-1} * (P(i,:)) \quad (6)$$

Where  $P(i,:)$  is the cost of Mazi in the population of P,  $i$  cycles of Ahja days, and the transmute of Mazi's energies via the training processes. At the same time, the  $\mu\mu$ -ahja adopt the emitted energies originating from multidiscipline like phycology, social tactics, resilience, experience, transactional techniques, relationship with customers, banks, etc., The differences compared to theirs cut across domains and, by analogy, involve transduction [28]. This process is given by a resemblance of balancing potentials and kinetics.

$$T = rand(1, D) * (P(p,:)) - \frac{1}{2} * Ef * (X_r) \quad (4)$$

Where  $P(p,:)$  in (4) is the cost of the new population at time p,  $Ef$  is the energy factor, while the  $X_r$  random  $\mu\mu$ -ahja cognitive state of five analogous Bayesian energies interacting actively in a shop.

$$X_r = X_{r+i} + 1 / 8 * Ef * (X_{r+i-1}) \quad (5)$$

$$X_{r+i-1} = X_{r+\Delta(i-1)} + 1 / 40 * Ef * X_{r+\Delta(i-1)} \quad (6)$$

$$X_{r+\Delta(i-1)} = 1 / 80 * X_{r+\Delta(i-n)} \quad (7)$$

Equations (5), (6) and (7) are all nonlinear cognitive vectors, and ratios of series [1/8, 1/40, and 1/80] of time divisions (could take any ratio as they are probabilities of random events, recall a state ranges from 0 to 1),  $i, r$  remain the same; visually, a huge network ensues as shown below.

Fig. 6. Cognitive correlations between nwa-ahja (PN) to any.

Fig. 6 clusters N1  $\mu\mu$ -ahja with each other, and N2 and N3 are the clusters with customers. The probabilistic behavior of the interaction (edges) shows the very interesting transition of the  $\mu\mu$ -ahja (nodes) in the network in Fig. 7.

Fig. 7. Progress of cognitive signature on  $\mu\mu$ -ahja character.

Current time  $t$ ; the previous timestamps as the selected node (60). Search in a generation gives (11).

$$X_r = X_{r+i} + 1 / 8 * Ef * (X_{r+\Delta(i-1)} + \dots + 1 / 40 * Ef (1 / 80 * X_{r+\Delta(i-n)})) \quad (8)$$

Where updates at  $r+i$  taken during iteration. The compact dynamics (12); mimics a rhythmic nodding to music and stratagem - igba, which gives.

$$U_n = U_{n-1} + T_{n-1} * X_r \quad (12)$$

Where  $U_n$  is a vector of emergent solutions. The threshold facilitates  $\mu\mu$ -ahja exploration; disciple-Rhythm -  $rD$  known as discipleship compliance, given by (13).

$$U(ij) = \begin{cases} u_m^j & \text{if } m \leq rD \text{ OR } j = \delta \\ x_m^j & \text{if } m > rD \text{ AND } j \neq \delta \end{cases} \quad (9)$$

Where  $m$  is a random number [0,1], delta  $\delta$  has the same dimension and size as the solution but is pseudorandom. This cooperation serves as the bond linking one source to another [23, 29]. Mazi; sometimes sacrifices profit for an improved - customer base and to escape the local optima trap by analogy as Igba-oso-ahja updates; objectives of the fitness bound the strategy as given in Fig. 8.

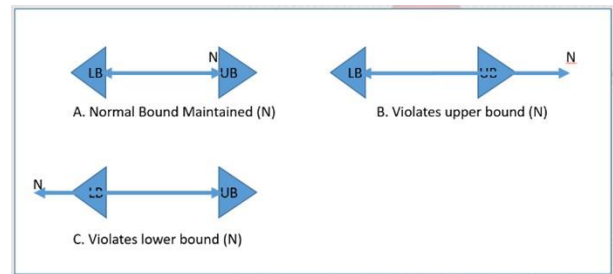

Fig. 8. Boundary strategy.

Constraints are bounded as in A, N collapse to upper-bound (UB) in B, and N collapse to lower-bound (LB) as shown in Fig. 8. Finally, methodic update results to best solutions shown.

$$X_i = \begin{cases} U_i \\ f_i = f_{U_i} \end{cases} \text{ if } f_{U_i} < f_i \quad (10)$$

$X$  and  $f$  remains the same if  $f_{U_i} > f_i$

Where (10);  $f_{U_i}$  is the fitness function from the best cost of the discipleship and adjustments made (error correction), while  $f_i$  is the best solution fitness of the original objective function, which is optimal.

#### F. Graphical Flow of QMOA

The  $\mu\mu$ -ahja can be considered as moving particles [30-32]. Mazi realization comes after generations of successful cycles [33]; rather than unhealthy competition, all  $\mu\mu$ -ahja depends on each other; The main body's pseudocode (2) during iteration is as follows:

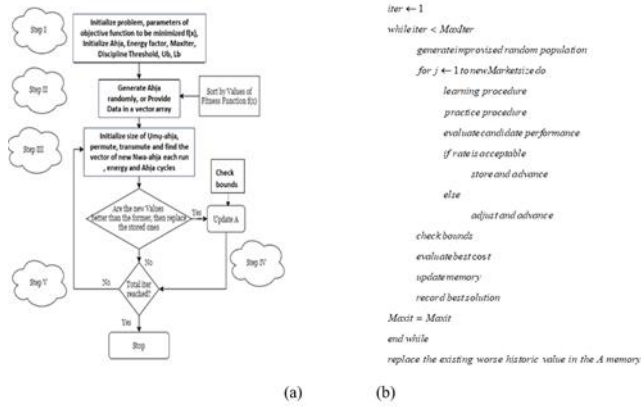

Fig. 9. Qdigbo metaheuristic optimization algorithm - QMOA and pseudocode.

The flow chart of Fig. 9 shows the methodology for applying the QMOA algorithm. The subsequent sections discuss applications.

### III. APPLICATION OF QMOA ON BENCHMARK FUNCTIONS

Most metaheuristic algorithms use Pattern Matrix, and the solutions are identified as those that improved through the number of generations up until the convergence time of the simulation. QMOA inherent energy synergy principles.

- 1) Default parameters are used
- 2) 30 independent runs were used for Unconstrained Benchmark, 50 for constraint functions. The parameters for the engineering designs are as stated in the referenced literature provided
- 3) The total number of cost function evaluations is  $1000 \cdot n \cdot M$ , where  $M = 10$  is the number of iterations. The logarithmic Scale was considered for visualization due to its convenience and compact.
- 4) For the Constraint problems as depicted by the competition, a solution value less than  $10^{-8}$  is treated as zero; several performance indicators for solution values are used: best, worst, mean, and standard deviation (Std). Test for convergence time also provided;

#### A. Experiments and Comparison of Results

QMOA is compared with five of the best similar algorithms as shown in Table II. Their codes are in the open domain/available online. The choice of only five is being mindful also of the limited space constraints to publish results.

TABLE II. ALGORITHMS USED FOR VALIDATION

S/N	Algorithm	Ref	Category
1	Harris Hawks Optimization (HHO)-- 2019	[34]	Novel Idea
2	Moth Search (MS)-- 2018	[35]	Novel Idea
3	Elephant Herd Optimization (EHO)-- 2015	[36]	Novel Idea
4	LSHADE-SPACMA ( A2) - 2017	[37]	Hybrid/Modified
5	EBOwithCMAR ( A3) ---2017	[38]	Hybrid/Modified

The list in Table II is a competitive group; notably, 4 – 5 won the CEC 2017 competition [39, 40].

#### B. Experiment 1: Difficult Unconstrained Benchmark Functions

QMOA is validated on the existing established algorithms listed in Table II with about 30 difficult functions chosen with modality (unimodal to check and confirm exploitation strength, multimodal for diversity or exploratory capability of QMOA), Separability (possible separable and non-separable) and then multi-dimensionality (confirming search and exploratory strength of QMOA). The performance averages are visualized using boxplots. Further, the significance and statistical students test (t-test) was conducted for all algorithms, with a time complexity test. A subset of test benchmark functions with varying degrees of difficulty is used to substantiate that QMOA can exploit and explore the solution space and find the solutions for optimum. In Table III, unconstrained benchmark test functions are categorized in modality, Separability, and Dimensionality ( $N$ ), also:  $M$  is the modality,  $\theta$  – Uni-modal;  $I$  – Multimodal,  $S$  is the Separability,  $\theta$  – Non-Separable;  $I$  – Separable.

C. Benchmark – Unimodal and Separable Functions

To tighten the competitiveness, we identified the algorithms with the highest performances with a t-value above 0.05. QMOA and A3 (all best solutions in BOLD font) lead with equal best performance as shown in Table IV. The MS was next, followed by A1, HHO, and WFS.

QMOA and A3 leading showed good exploration, and exploitation strength, particularly of QMOA obtained the best optimal objective solutions before the completion of generations. Fig. 10 also shows consistent distributions with fewer outliers.

Fig. 10. Boxplot for unimodal and separable functions.

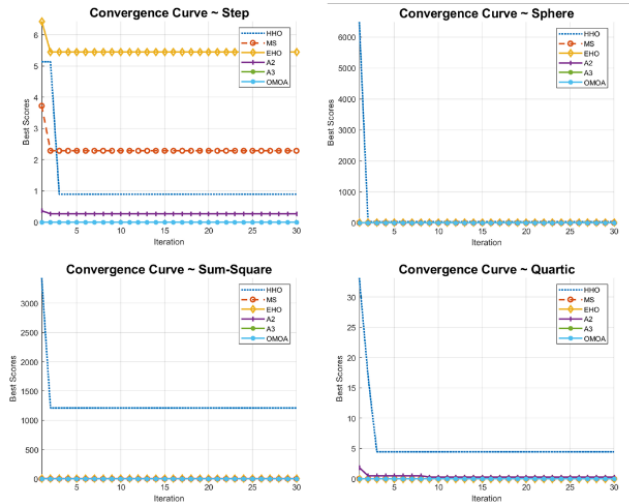

Fig. 11. Comparison of convergence curve for unimodal and separable functions.

Fig. 11 convergence comparison shows that QMOA, A3, A2, and WFS have faster and best convergences to the optimum in these problems while HHO lagged behind most of the time.

D. Unimodal and Non-Separable

The functions in this category include 30-dimensional problems Zakharov to Dixon Price with great complexity. Table V shows QMOA and A3 tops, followed by A2, A1, HHO, MS, and WFS. Besides Beale, which did not yield a better result, QMOA got even Easom, a problem with inherent complex nature.

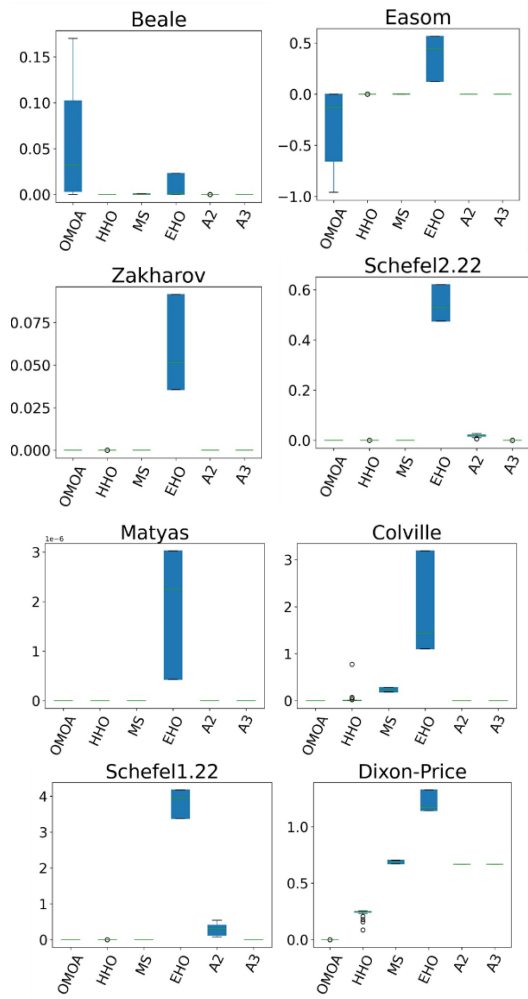

Fig. 12. Boxplot of unimodal and non-separable results.

The boxplot of Fig. 12 shows that the mean solutions distribution of the data of QMOA and A3 are tight, with little outliers equalling minimal deviation.

The convergence comparison of Fig. 13 confirms the summary made at the beginning of the subsection.

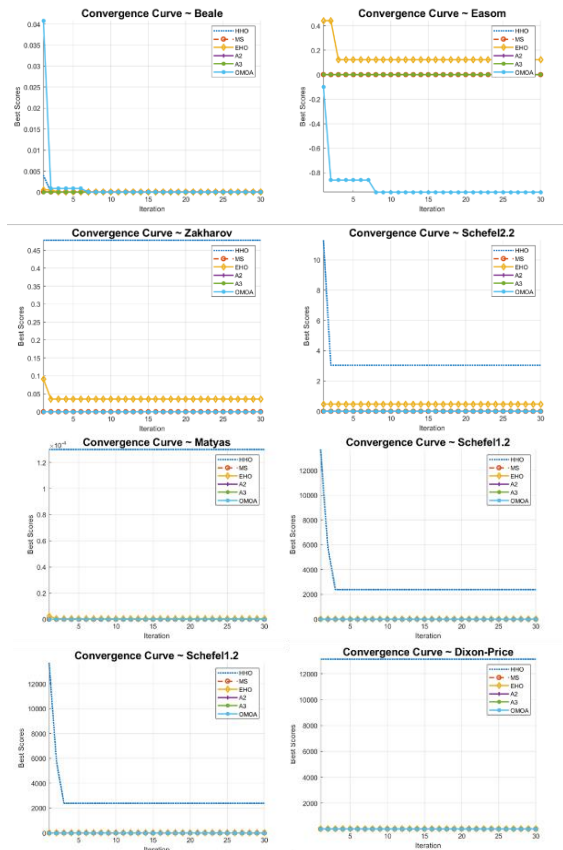

Fig. 13. Comparison of convergence curves for unimodal and non-separable function.

### E. Multimodal and Separable

Complex structures, multiple, unequal hilltops, and valleys-shaped functions are tested as shown in Table VI. Besides the booth function, QMOA had remarkable exploratory abilities for the dimensionalities above  $n = 2$  (i.e.,  $n = 5, 10, 30$ ) of the last three functions while tracking deeper than values provided by the global optima in literature for Holder Table, Michalewicz (2, 5, and 10). Rastrigin ( $n = 30$ ) was also explored optimally by QMOA and HHO.

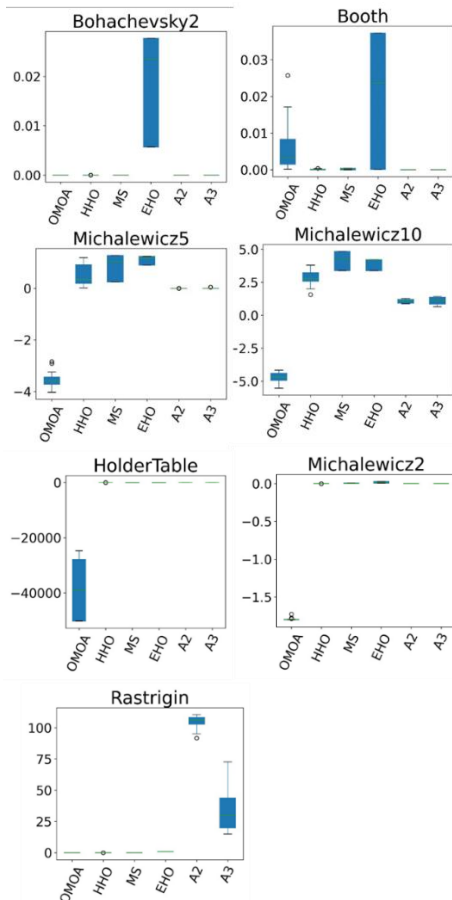

Fig. 14. Multimodal and separable boxplot.

The visuals of the boxplot in Fig. 14 show mean solutions of QMOA adequately located in the region with very few deviations and outliers.

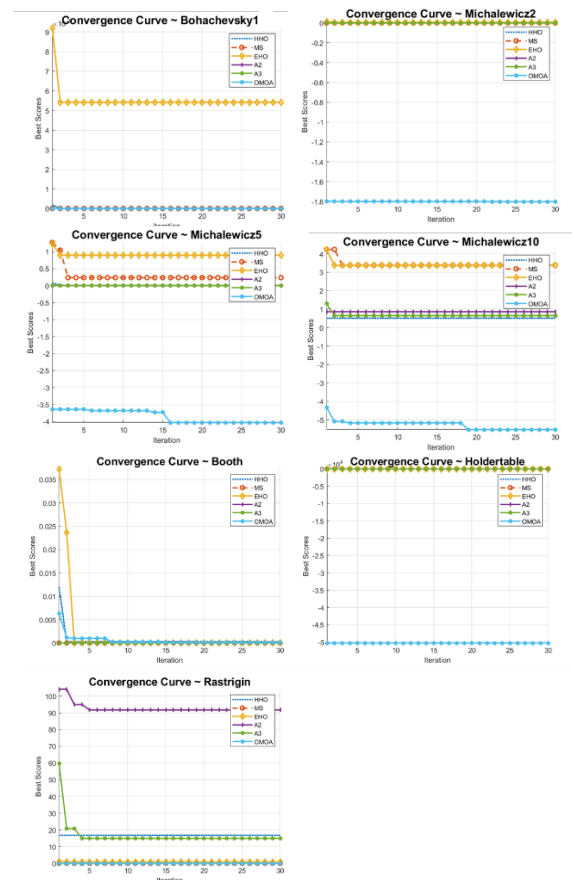

Fig. 15. Convergence curves for multimodal and separable function.

In Fig. 15, QMOA had made extra-advance to explore for solutions far better than all the compared algorithms in these problems. Even some of the solutions were far better optimum that set global values as the Holder Table model.

F. Multimodal and Non-Separable

Table VII shows QMOA led the exploration alongside A3, A2, and HHO though the depth of the troughs in Six-Hump

Camel, Shubert, and Drop Wave seems to have shown that QMOA dived deeper than the others with the peaks of Schaffer 4 also.

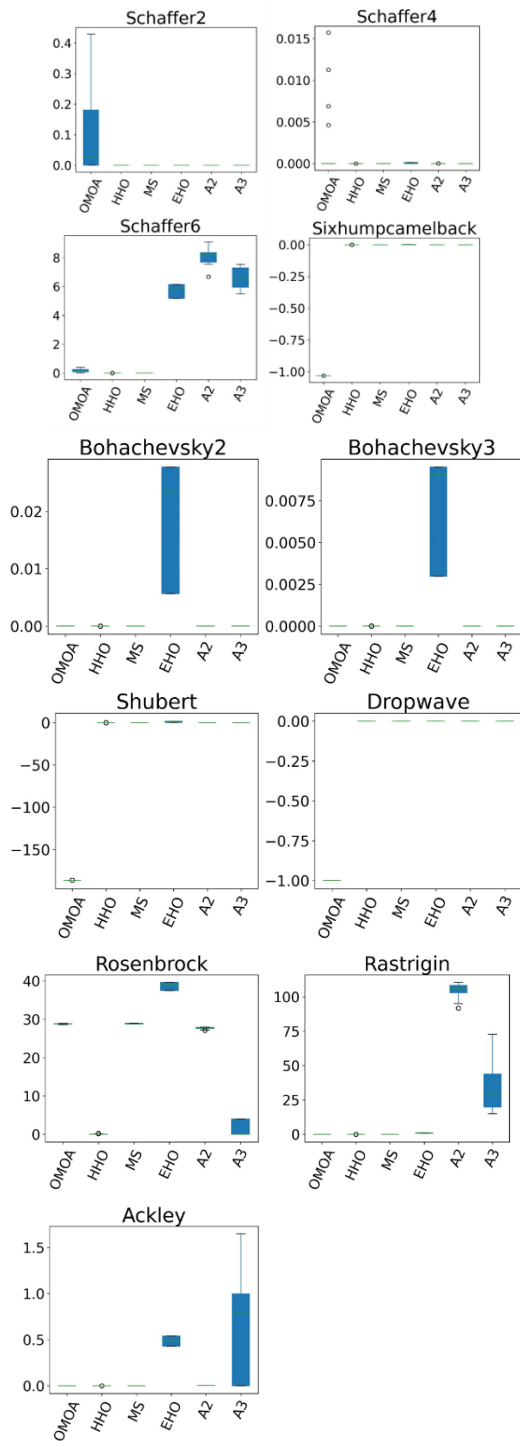

Fig. 16. Multimodal and non-separable boxplot.

The boxplot in Fig. 16 shows the clear visuals, confirms OMOA better. The exploratory ability of the OMOA is evident from mean solutions distribution and standard deviations.

The convergence is a reflection of the ability of the tree depth of the network of markets embedded in the model visualized in Fig. 17.

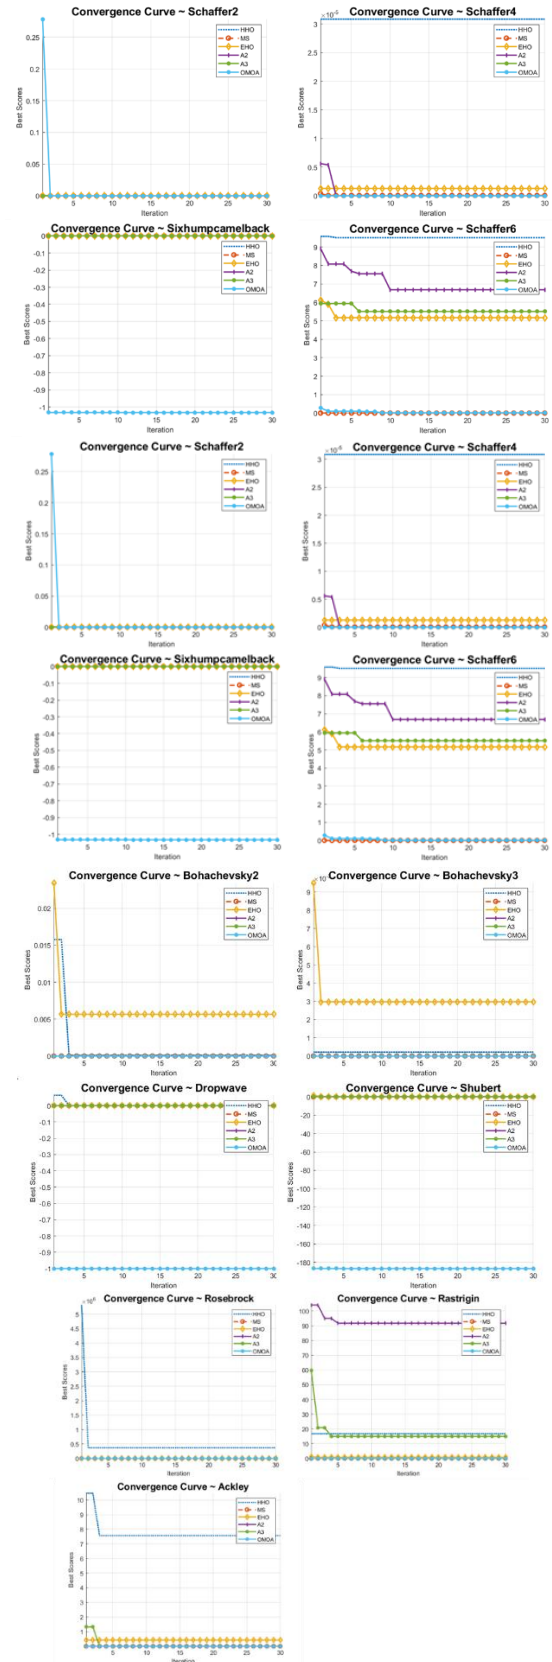

Fig. 17. Convergence curves for multimodal and non-separable function.

G. Statistical Test and Significance

Table VIII presents the entire statistical hypothesis test carried out to confirm the difference in mean and significance validation in the distribution of solutions by the algorithms on the 30 unconstraint benchmark functions.

Table IX is the summary of the test conducted to prove the hypothesis of the performances of the experiment; **1**: means QMOA (in black ink) is more significant, **-1**: gives better significance to the contender (another algorithm), while **0**: depicts no significant difference in performance (contender, equal, QMOA).

Sign (better) ==> Significance (1 = QMOA; -1 = Alternative Algorithm; 0 = no significant difference), nan = not a number, inf = infinite

TABLE IX. SUMMARY OF SIGNIFICANCE AND RANK

(-1,0,1)	HHO	MS	EHO	A2	A3
QMOA	[5, 8, 17]	[4, 5, 21]	[2, 1, 27]	[3, 6, 21]	[4, 13, 13]

The highest equal performance point, 13 is between QMOA and A3, with QMOA leading with 13 optimal solutions, more than A3's other 4 better performances. Next is HHO with 8 equal points, QMOA with 7 better optimal solutions, and HHO making 5 places. MS and A1 shared very close contest with EHO behind. Table X also is the presentation of the mean runtime measure given below.

TABLE X. RUNTIME TEST RESULTS BASED ON RASTRIGIN

QMOA	HHO	MS	EHO	A2	A3
2.493096	45.6716	756.4435	788.1535	202.0933	217.6285

The performance of QMOA in this section was very high on benchmark complex unconstraint problems compared to contending methods.

H. Results and Statistical Testing with CEC 2017

This section reports QMOA on real-parameter single objective optimization challenging problems featured in Computational Evolution Computation - CEC 2017 with a statistical comparison between QMOA and winners of the competition.

I. Result of QMOA with CEC 2017

The values are the differences between the global optima and the ones obtained with QMOA for 10D, 30D, and 100D during every 51 runs, as shown in the Table XI, and competition is presented in Table XII for 50D

1) 10D, 30D, 50D and 100D Performances

- The uni-modal functions EC1, EC2, and EC3 results were least expected within the number of functional evaluations provided, perhaps due to parameter tuning differences from recommended.

- EC7 – EC10 multimodal functions all attained global optima in all dimensions. QMOA also met 10D and 30D optimal values, with a minor difference for 50D and not too good 100D. EC5 solutions are not good in all dimensions; while EC6 10D was globally optimal, the rest dimensions were not impressive and inadequate for some ranges of solutions.
- Hybrid functions optimization; QMOA yielded optimal global solutions for EC11, EC14 – EC17, and EC19 - EC20 leaving out EC12, EC13, and EC18 with not too good in solutions.
- Besides EC21, EC22, and EC27 of the Composition functions with non-optimal solutions, QMOA achieved optimal global solutions for others, i.e., EC23, EC24, EC25, EC26, EC28, and EC29 in all dimensions, respectively.

J. Time Complexity Analysis

The competition provided appropriate information on the modalities to compute the time complexity [39]. The observation and experimentation shown in Table XII of this work is as follows:

- Evaluate a code consisting of basic arithmetic operation for 1,000,000 iterations and recode the time ( $T_0$ ).
- Evaluate the hybrid function EC18 for 200,000 times the four dimensions (10D, 30D, 50D, and 100D) with record ( $T_1$ ).
- For every dimension, find the meantime of computing  $\bar{T}_2$  the hybrid function EC18 five times run with a termination iteration of 200,000.
- Calculate the time complexity of the algorithm using the relation  $(\bar{T}_2 - T_1) / T_0$ .

Table XIII depicts that the complexity of QMOA is not increasing significantly with the increase in the dimension of the functions.

TABLE XI. STATISTICAL RESULTS FOR CEC 2017 SIMULATIONS D10, D30, AND D100

K. Comparison of QMOA with the Winners of CEC2017 (EC1-EC29)

The subsection presents a performance comparison between the 50D problem size for QMOA and other state-of-art high-performing algorithms, especially those that won the CEC2017 competition for real-parameter single objective optimization challenges, as shown in Table XII. The last row represents the values of a Wilcoxon rank-sum test at an alpha value of 0.05. The terms designate the status of the QMOA

against each competing algorithm such that  $w(+.mean..win)/t(=.mean..tie)/l(-.mean..loss)$  For an algorithm making its first entry, the results show very high success [41] shown by Table XII; QMOA had remarkably shown better performance on most of the complex problems considered, as the last row shows. Also, QMOA showed better performances compared with the winners of the competition (competing method, equity, QMOA  $\rightarrow$  w/t/l), e.g., (EBOwithCMAR won 11, equal in 1 and QMOA won 17).

L. Benchmark Design Real Engineering CEC 2020 Single Objective Problems

Eight (8) difficult engineering design-constrained problems that exhibit functional inequality and equality constraints are considered; compared with state-of-the-art algorithms from CEC 2020 real-world optimization issues presented in [42-44]. Among the results presented are the experiments' statistical best, mean, median, worst, and standard deviations. Generally, all models follow a structure as shown in Eq. (15).

$$\min f(x)$$

$$s.t. : g_n(x) \leq 0, n = 1, \dots, m \quad (11)$$

Where  $f$  is the fitness,  $x_s$ ' are the design variables,  $g$  is the constraint with less than equality (often greater than for maximization problems), and  $n$  is the number of constraints. The conversion of the functional constraint from inequality to equality transforms the problem into equation (16).

$$f_p(x) = f(x) + o \sum_{n=1}^m \Phi_n [g_n(x)]^2$$

$$s.t. \quad o > 0 (\text{i.e. penalty factor})$$

$$\Phi_n = \begin{cases} 1 & \text{if } g_n \text{ is violated} \\ 0 & \text{if } g_n \text{ is satisfied} \end{cases} \quad (12)$$

Where  $f_p(x)$  is the penalized objective function. High-performing state-of-the-art algorithms are adopted and compared against the design of certain engineering problems of Fig. 18 (a: Welded beam), (b: Pressure Vessel, and c: Compression Spring). The constraint violations are considered, and the penalty function method is used, which often transforms a constrained problem into an unconstrained continuous counterpart for ease of implementation.

Fig. 18. Engineering design parameter problems.

M. Statistical Comparison of Results for Tension / Compression Spring Design Problem

The design problem in Fig 18 (c) aims at reducing the weight of the tension/compression spring without compromising domain properties like the shear stress, frequency wave, and displacement functionalities [45]. The control variables are wire diameter ( $x_1$ ), mean coil diameter ( $x_2$ ), and the number of coils ( $x_3$ ); the mathematical formulation is detailed in [42]. Upon the experiment, QMOA yielded the most optimal weight compared to the other high-performing algorithms within a minimal number of function evaluations. The result of the compared simulation is shown in Table XIV.

N. Statistical Comparison of the Results for Welded Beam Problem

The welded beam problem Fig. 18 (b) [46] is to minimize the cost of construction. The impacting constraints include shear stress( $\tau$ ); bending stress in the beam ( $\sigma$ ); buckling load

of the bar ( $P_c$ ); end deflection of the beam ( $\delta$ ) and side constraints. The decision variables are (1) the thickness of the weld ( $x_1$ ), the length of the attached part of bar ( $x_2$ ), the height of the bar ( $x_3$ ) and the thickness of the bar ( $x_4$ ). The model formulation is given in [42]. And compared simulated statistical results in Table XV with parametric results in Table XVI.

In less than 60000 functional evaluations of 10 runs, QMOA yielded a mean cost that is the most optimal for the welded beam in comparison while obeying the constraints.

O. Results for Pressure Vessel Design Problem

The Pressure Vessel Design objective in Fig. 18 (b) [47] is to minimize the cost associated with materials, building, and welding of a cylindrical vessel with capped ends and a hemispherical-shaped head. The impacting variables include the shell thickness x(1), the head thickness x(2), the inner radius x(3), and the length of the cylindrical section excluding the head x(4); the model formulation is given in [42].

The yield of QMOA on the Pressure Vessel design problem produced the best optimal mean value and had a far smaller number of function evaluations of Table XVII.

QMOA met all the inequality constraints; best mean fitness as shown, followed by MCEO, WCA, and NM-PSO, respectively. However, contrary to the large number assigned to the penalty using the other algorithms, QMOA found better results with negligible penalty value for problems of spring and welding beam, and even no penalty was applied to vessel design.

P. Robot Gripper Problem

The complexity involved in manipulating the grippers to minimize the difference between the minimum and maximum forces of the robotic action is ongoing research. Seven design variables, geometric properties, with about seven inequality constraints, are targeted. The Mathematical formulations are found here in [48].

Fig. 19. Schematics of robotics gripper system.

Fig. 19 is schematics of the robotic gripper system, and the experimental result is shown in Table XVIII.

The experimental result of QMOA on the gripper problem showcases a new optimum as against the optimum global set value [42]; also better than the competing algorithms in comparison [44].

**Q. Rolling Element Bearing**

Five design variables that affect the optimal design of a rolling bearing with the capacity to carry load efficiently amidst nine inequality constraints are considered in the design. The mathematical derivations are provided by [42], while we show the schematics in Fig. 20.

Fig. 20. Schematics of rolling bearing.

The result of the experiment is shown in Table XIX.

With an optimum global set at (25287.918415), the experimental result of Table XIX shows that QMOA had set a better global optimum as it also performed better than the competing algorithms [44].

**R. Gas Transmission Compressor Design (GTCD)**

Four variables with one inequality constraint are targeted when designing the gas transmission compressor. The work [42] provides the mathematical formulation while we show the schematics in Fig. 21 and the solutions provided by many optimization state-of-the-art to designs.

Fig. 21. Schematic of gas transmission compressor system with design variables.

The results of the comparison for the experiment on GTCD are shown in Table XX.

TABLE XX. RESULTS OF OPTIMIZATION OF GTCD AND STATISTICAL OUTCOMES

Algorithms	x1	x2	x3	x4	Optimum cost

QMOA	50.0000	1.00000	20.1422	60	<b>9.8081911E+05</b>

The experimental results show QMOA had a set a new global optimum than that set by the competition as the global optimum is (2.9648954173E+06) [42], with the other algorithms as presented in [49].

**S. Himmelblau's Function**

This nonlinear function has been used to test many novel metaheuristic algorithms; it has five main design variables and six inequality constraints to be handled, as shown in Himmelblau [50]. In Table XXI, we show the results of the performances of the metaheuristic algorithms used in comparison.

The experimental result shows that QMOA obtained a better minimum compared to the competing algorithms and set a new global optimum compared to the global presented by [42], which is  $-3.066554E+04$ , with the other algorithms as presented in [49].

**T. Multiple Disk Clutch Brake Design Problem**

The design objective is to minimize the mass of the multiple disk clutch brake, five decision variables with nine nonlinear constraints. The mathematical formulation is given in [42].

QMOA performed better than ABC, which was reported as best at the time of competition report, and others in this design problem and further set a much better global optimum than benchmarked in [42]; 0.23524245790; with the other algorithms as presented in [49].

#### IV. CONCLUSION

In this work, QMOA, a new nature-inspired population-based metaphor, was proposed and used in experiments and engineering designs with very great performance. The idea stemmed from the informal learning pattern and discipleship, which is ingrained in the socio-cultural behavior of the indigenous peoples - the Ndigbo of a West African tribe is presented. The learners cope through practice and observation. The experiment conducted considered 30 benchmark unconstrained problems, 29 CEC 2017 (50D) real-parameter single objective constraint optimization, and about 8 engineering design constrained problems from CEC 2020; the results showed that QMOA had balanced exploitation and exploratory capacities with very good convergence time too. Comparison to the performance of other well-established state-of-the-art algorithms depicts the exceptional performance of the automata. The significant test also confirms the relative efficiency of QMOA with t-values and p-values presented in Table VIII and summarized in Table IX. The convergence time test using the Rastrigin function also shows QMOA had better speed than the contender in Table X. The competing algorithms were the most award winners in past competitions from 2017 till date. In all complex engineering problems presented, QMOA had performed remarkably well and had, in some cases, set new minimum attainable best solutions; Of interest are the new values better than the set global optimums in some functions and engineering designs (Clutch Disc, Himmelblau, GTCD, Rolling Bearing, Robotic Gripper).

The future direction is to further validate with the most recent CECs and design optimization problems in other fields. Meanwhile, QMOA shows merit to be considered in the current state-of-the-art.

**Abstract**—Brain disorders are a significant source of economic strain and unfathomable suffering in modern society. Imaging techniques help diagnose, monitor and treat mental health, neurological, and developmental disorders. To aid in the Computer-Aided Diagnosis of brain diseases, deep learning (DL) was used for the analysis of neuroimages from modalities including Positron Emission Tomography (PET), Structural Magnetic Resonance Imaging (SMRI), and functional MRI. In this study, a Whale Optimization Algorithm is used with Deep Learning to analyse MRI scans for signs of neurological disease. WOADL-BDDC may detect and label abnormalities in the brain based on an MRI scan. It uses a two-step pre-processing procedure, first using guided filtering to get rid of background noise and then using U-Net segmentation to get rid of the top of the head. QuickNAT, along with RMSProp, is used to segment the brain. When analysing data, WOADL-BDDC uses radionics to collect information from every layer. When used in a convolutional recurrent neural network model, the Whale Optimization Algorithm may accurately categorize mental illness. WOADL-BDDC is put through its paces using ADNI 3D. Compared to state-of-the-art classification results from Vgg16, Graph CNN, Modified ResNet18, Non-linear SVM, ResNet50-SVM, ResNet50-RF, the suggested technique achieved the greatest accuracy. It was demonstrated that the suggested model is superior to other models for classification from MRI images. In simulations, the proposed approach is shown to be effective in optimizing hyperparameters with an accuracy of 94.38 % on TR set and 94.87% on TS set, Precision of 96.43% on TR set and 97.62% on TS set, and an F1-Score of 89.35 % and 92.10% on TR and TS set, respectively.

**Keywords**—Brain disorder detection; magnetic resonance imaging; deep learning; convolutional recurrent neural network; whale optimization algorithm

## I. INTRODUCTION

The brain is the management center of the central nervous system and is liable for implementing activities all over the human body [1, 2]. As in other medical sectors, there exist innovative neuroimaging technologies comprising positron emission tomography (PET), and MRI was introduced and utilized for identifying Alzheimer's Disease (AD) based molecular and structural biomarkers [3,17]. Rapid progression in neuroimaging techniques makes them challenging to incorporate largescale, higher-dimension multimodal neuroimaging datasets [4]. Thus, computer-aided machine learning (ML) algorithms for integrative analysis have gained considerable interest. To apply this ML approach, Pre-

Processing steps or appropriate architectural design must be defined in advance [5]. Generally, a classification study using the ML method needs four stages: feature selection, feature extraction, feature-based classification algorithm selection, and dimensionality reduction [6]. This process requires multiple optimization steps and professional knowledge that might take considerable time [7]. To conquer this problem, deep learning (DL), an emerging field of ML study that uses raw neuroimaging information to generate features through "on-the-fly" learning, is received significant interest in the Area of large-scale, higher-dimension medical imaging analysis. DL approaches, like convolution neural networks (CNN), have proved to outperform the present ML method [8, 9]. Compared with conventional ML techniques, the DL approach automatically discovers the proper representation without specialized knowledge and permits the non-expert to utilize DL approaches efficiently. Thus, the DL method has rapidly become a method of choice for medical image analysis [10].

This study progresses a Whale Optimization Algorithm with Deep Learning based Brain Disorder Detection and Classification (WOADL-BDDC) on MRI images. The WOADL-BDDC technique initially performs pre-processing in 2 stages: guided filtering (GF) based noise elimination and U-Net segmentation-based skull stripping. Besides, the QuickNAT with RMSProp optimizer is applied to segment the brain parts. For feature extraction, the WOADL-BDDC technique performs a radionics approach that separates features of all aspects. Finally, the WOA with convolutional recurrent neural network (CRNN) model is applied to classify brain disorders. The experimental evaluation of the WOADL-BDDC technique is tested on the ADNI 3D dataset.

The wide range in tumour size, shape, and location poses a significant problem for diagnosing brain tumours. The scientific community can benefit from this review since it provides a thorough literature on brain tumour detection using magnetic resonance imaging. The healthcare sector is unlike any other. Regardless of financial constraints, this is a top priority area that attracts customers expecting only the best service. Given deep learning's track record of success in the real world, it should be no surprise that this promising technique is already playing a crucial role in medical imaging, yielding promising results with high accuracy. The brain is the master organ, regulating the functions of every other body component.

\*Corresponding Author.

Due to the intricacy of size and position variations, automated brain tumour recognition in MRI is challenging. The pictures produced from MRI scans of the brain are processed using proposed statistical, morphological, and thresholding methods to detect tumours. Based on our findings, we can confidently state that conventional algorithms perform admirably for both the number of initial clusters and the locations of their centers. Pixel classification becomes difficult if these groups shift depending on the parameters you use to construct them. As it is, the cluster centroid value is chosen at random in the most common fuzzy cluster mean procedure. Because of this, it will take longer to get the intended result. Radiologists have to spend a lot of time manually segmenting and evaluating MRI brain pictures. The segmentation is performed using machine learning approaches that are less accurate and have a slower calculation speed. Tumor categorization and identification using neural network methods have been attempted extensively but with mixed results. Detection accuracy relies on the segmentation and detection algorithms employed. Thus far, current systems need to provide better picture quality and precision.

A convolutional recurrent neural network (CRNN) will be employed to categorize the tumors in the picture. Increased precision and decreased repetition are the only two benefits of this method.

## II. LITERATURE REVIEW

The authors [11] modeled a deep ensemble learning structure to harness DL techniques to tap the 'wisdom of experts' and compile multisource data. At the voting layer, two sparse AEs were instructed for feature learning to minimize the correlation of features and expand the base classifier eventually. At the stacking layer, a non-linear feature-weighted technique related to a DBN was devised to rank the base classifiers, which disrupt the conditional independence. In [12], the authors intend to formulate an innovative DL technique for detecting or productively predicting AD. The authors devised densely connected CNNs with a connection-wise attention system for learning the multilevel attributes of brain MRI for AD categorization. The authors employed the densely associated NN for deriving multiscale features in pre-processing images. A connection-wise attention system has been implemented for integrating associations among attributes from distinct layers. In [13], the authors employ a DL-related Granger causality estimation of brain connectivity structure. It uses the robustness of LSTM in changing time series processing. The authors employ MRI to examine the cerebral cortex property and exploit rs-fMRI to analyze the function network's graph metric. In [14], the authors establish that it is settled well with the multi-task learning method. In [15] devised a DL technique for every level of feature extracting process and fuzzy hyper-plane related least square twin SVM (FLS-TWSVM) for classifying the derived features for initial analysis of AD through removing sagittal plane slices from 3-D MRI imageries. In [16], an Alzheimer's classification and detection method was provided. The BoVW method was employed to enhance the efficacy of texture-related features, like the histogram of gradient, GLCM, and scale-invariant feature transform, LBP.

Brain tumours are notoriously difficult to diagnose because of the wide range of tumour sizes, forms, and shapes that must be considered during the process [25]. Surgical, radiological, and chemotherapeutic options are all on the table when a brain tumour diagnosis has been made, and prognoses can be formulated based on the tumor's nature and location [26]. Therefore, early diagnosis and identification of brain tumours aid in treatment planning and patient monitoring. It's a vital factor in better treatment and increased survival rates. To learn more about tumours, many medical imaging and diagnostic methods are performed. It is possible to distinguish between usually and abnormally expanding brain cells with the aid of imaging techniques like magnetic resonance imaging (MRI) and computed tomography (CT)[27]. Computed Tomography (CT) scans are utilized for diagnosis through X-ray and computer to produce pictures of the patient's brain in axial slices [28].

According to the systematic literature evaluation, there is space for improvement in brain tumour detection. Because brain tumours can be any size or shape, current segmentation methods need further work before they can be used for tumours. The importance of enhancement and segmentation in tumour identification stems from their role in addressing the shortcomings of current approaches.

The significance of medical data offered along with imaging data can be emphasized by incorporating clinical features, including texture-related features, for generating hybrid feature vectors. Though several computer-aided diagnosis models are existed in the literature to perform the brain tumor classification processes, it is required to improve the classifier results. Due to the repeated extension of the model, the number of parameters of DL models also rises rapidly, which leads to model overfitting. So, the WOA algorithm is used to select CRNN parameters. Personalized image collection based on estimates has been proven to be capable of seeing channels during a CT examination, thanks to the ongoing development of AI. Significant learning, in particular, has demonstrated encouraging outcomes in automated planning. It's so good at processing visual information that we can now employ neural connections to construct meaningful images rather than merely sort them. In particular, CRNN Association is well suited for evaluating images from channels like CT and X-ray. CRNNs are mainly designed to handle photographs better and finish picture groups. In this way, CRNNs can approach radiologists' accuracy when recognizing crucial elements in CT channels or other signature images.

## III. THE PROPOSED WOADL-BDDC MODEL

In this study, we have established a new WOADL-BDDC technique for recognizing brain disorders on MRI images. The WOADL-BDDC approach encompasses GF-based noise removal, U-Net-based skull stripping, QuickNAT with RMSProp-based brain segmentation, radionics feature extraction, CRNN classification, and WOA hyperparameter tuning. Fig. 1 represents the block diagram of the WOADL-BDDC system.

### A. Image Pre-Processing

A GF is an edge-preserving smoothing light filter. It applies edge-preserving smoothing on the image, utilizing the content of the secondary image, named a guidance image, to impact the filtering. The guidance image could be a completely different image or different versions of an image. The bilateral filter might filter out texture or noise when maintaining sharp edges. A Gaussian operator can compute the convolution operator, and a proposal of Gaussian smoothening can be made by convolution. The Gaussian operator can be defined using the following equations:

$$G_{1D}(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\left(\frac{x^2}{2\sigma^2}\right)} \quad (1)$$

The optimum smoothening filter for the image can be localized in the frequency and spatial domains, where the ambiguity relativity can be satisfied as follows [19]:

$$\Delta x \Delta \omega \geq \frac{1}{2}. \quad (2)$$

The Gaussian operator in 2D can be represented by:

$$G_{2D}(x, y) = \frac{1}{2\pi\sigma^2} e^{-\left(\frac{x^2+y^2}{2\sigma^2}\right)} \quad (3)$$

Where  $\sigma$  (sigma) signifies the standard deviation (SD) of Gaussian and  $(x, y)$  represents the Cartesian coordinates of the image. In medical applications, it serves as an initial phase since it identifies path abnormality in the speed, brain, and accuracy of diagnoses. It isolates non-brain tissues such as the scalp and skull from the brain image. Skull stripping removes unwanted components and non-brain anatomy from scanned images. There exist five convolution blocks in the downsampling route. Currently, there are overall of 1024 feature maps. Excepting the last block, max pooling with stride 22 can be performed after the completion of every block for downsampling. The feature map is reduced in size from 240x240 to 1515. Each up-sampling block initiates by a deconvolution layer of stride 22 and filters size 33. Consequently, feature map is becoming increasingly popular. The two convolution layers in the up-sampling block lower the quantity of deconvolution feature map and feature map in the encoding route.

### B. Brain Segmentation

In this work, the QuickNAT carries out the segmentation of brain regions with RMSProp optimizer. QuickNAT is the first method that uses an unlabelled neuroimaging dataset with auxiliary labels for training and a higher testing speed of the FC network for brain segmentation [18]. QuickNAT comprises sagittal, coronal, and axial views monitored by a view aggregation stage to deduce the last segment. Every FCNN is a similar structure and is stimulated by the conventional encoding/decoding-based UNet structure with skip connection improved with an un-pooling layer. Also, the study presents dense links in all the encoding/decoding blocks to promote feature re-usability and to help gradient flow, that is, the small number of training datasets. A multi-class Dice loss and weighted logistic loss can enhance the network.

Fig. 1. Block diagram of WOADL-BDDC system.

In contrast, it compensates for higher-class imbalanced datasets and encourages the accurate assessment of anatomical boundaries using a proper weighting system. The two primary techniques of QuickNAT are the training method with auxiliary labels and the FCNN framework. The trained model and code are presented as extensions of MatConvNet for off-the-shelf usage.

### C. Radiomics Feature Extraction

For the process of extracting features, the presented algorithm will use radiomics features. The abovementioned features are derived by in-house software, utilizing PyRadiomics and python's skit-learn package [19]. Texture, intensity, and shape are the three kinds of features that are calculated. Twenty-six shape-based and intensity-based features can be extracted for all extraction settings (width, filter, bin, and contour). With sixteen distinct stages, which can be permutations of 2 contours (HGG and Gold), bandwidth (2, 4, 8, 16), and two filters (LoG and original) and the entire count of derived radiomics imaging features was 1450.

### D. CRNN-Based Brain Disorder Classification

The CRNN model is applied here to detect and classify brain disorders. The study presents the CRNN utilized for organizing MRI [20]. Initially, CNN is used for learning higher-level feature representation. Next, the CNN-learned feature was fed into the Bi-GRU layer for learning the temporal correlation data. At last, this feature was provided in the FC layer by Softmax function for the outcome of the likelihood distribution of distinct classes. In the presented method, the convolution RNN has encompassed two BiGRU layers ( $l_9 - l_{10}$ ) and eight convolution layers ( $l_1 - l_8$ ). The network parameter and architecture are given below:

$l_1 - l_2$ : The first two stacked convolution layer uses 32 filters with the stride of (1,1) and receptive field of (3,5). Then, max-pooling with the stride of (4,3) decreases the size of feature maps.

$l_3 - l_4$ : The subsequent two convolution layers use 64 filters with a stride of (1,1) and a receptive field of (3,1) and are utilized for learning local patterns alongside the frequency dimension. It can be max-pooling with the stride of (4,1).

$l_5 - l_6$ : The succeeding pairs of convolution layer applied 128 filters with a stride of (1,1) and receptive field of (1,5) and are utilized for learning local patterns along the time dimension. It can subsequently be the max-pooling with the stride of (1,3).

$l_7 - l_8$ : The successive two convolution layer uses 256 filters with a stride of (1,1) and receptive field of (3,3) for learning joint time–frequency features. It can subsequently be the max-pooling of (2,2) stride.

$l_9 - l_{10}$ : 2BiGRU layers with 256 cells were utilized for temporal summarization, and the activation function was used. The dropout with the possibility of 0:5 is applied to every BiGRU layer to prevent over-fitting. Fig. 2 illustrates the framework of CRNN.

#### E. Hyperparameter Tuning

For adjusting the hyperparameters related to the CRNN model, the WOA is utilized in this work. WOA is a population-based heuristic approach that models the hunting strategy of humpback whales [21]. They construct unique maneuvers for paralyzing the prey by swimming nearby them in a spiral or circle-shaped path. This technique is named the bubble-net attack. The hunting behavior can be specified into two stages. The initial stage is the exploration phase, where the whales randomly seek prey. The next stage is the exploitation stage, whereby the whales implement bubble-net hunting. The following equation is utilized for mathematically modeling these behaviors as follows:

$$\vec{D} = |\vec{C} \cdot \vec{X}(t) - \vec{X}(t)| \quad (4)$$

$$\vec{X}(t+1) = \vec{X}(t) - \vec{A} \cdot D \quad (5)$$

Fig. 2. Framework of CRNN.

Whereas  $\vec{X}^*$  represents the best position of the attained solution,  $t$  characterizes the count of iterations, and the constant variables  $\vec{A}$  and  $\vec{C}$  are characterized by:

$$\vec{A} = 2\vec{a} \cdot \vec{r} - \vec{a} \quad (6)$$

$$\vec{C} = 2 \cdot \vec{r} \quad (7)$$

Now,  $\vec{r}$  denotes an arbitrary vector amongst [0, 1], and variable  $\vec{a}$  is an arbitrary vector utilized for controlling the convergence procedure. It can be linearly decreased from two to zero through iteration:

$$\vec{a} = 2 - t \frac{2}{T} \quad (8)$$

In Eq. (5),  $t$  indicates the present iteration, and  $T$  shows the maximal iteration count of the vector  $\vec{A}$  utilized for displaying the transition method amongst the exploratory and exploitative actions.

In WOA, the exploitation stage could be one of 2 models, shrinking surroundings or spiral-shaped methods. During the shrinking surrounding model, it is accomplished by reducing the value. The spiral path model upgrades the distance betwixt the most efficient search agents attained up to this point ( $\vec{X}^*$ ) and searching agents ( $X$ ), then boosts a novel location for the searching agent based on the subsequent as:

$$X(t+1) = D \cdot e^{bl} \cdot \cos(2\pi l) + X^*(t) \quad (9)$$

The probabilities value of 0.5 is set as follows:

$$\vec{X}(t+1) = \begin{cases} D' \cdot e^{bl} \cdot \cos(2\pi l) + X^*(t), & p \geq 0.5 \\ \vec{X}(t) - \vec{A} \cdot D, & p < 0.5 \end{cases} \quad (10)$$

Whereas  $p$  denotes an arbitrary probability value. The pseudocode of the proposed model is shown in Algorithm 1.

IV. RESULTS AND DISCUSSION

The presented WOADL-BDDC system is simulated using a Python tool. The results are examined under the ADNI 3D dataset [22].

Fig. 3. (a) Original, (b) Pre-processed, (c) Segmented.

Fig. 3 visualization of the sample outcomes offered by the WOADL-BDDC system. Fig. 3(a) depicts the original brain MRI and the pre-processed image is provided in Fig. 3(b). Besides, the segmented images by the WOADL-BDDC system are shown in Fig. 3(c).

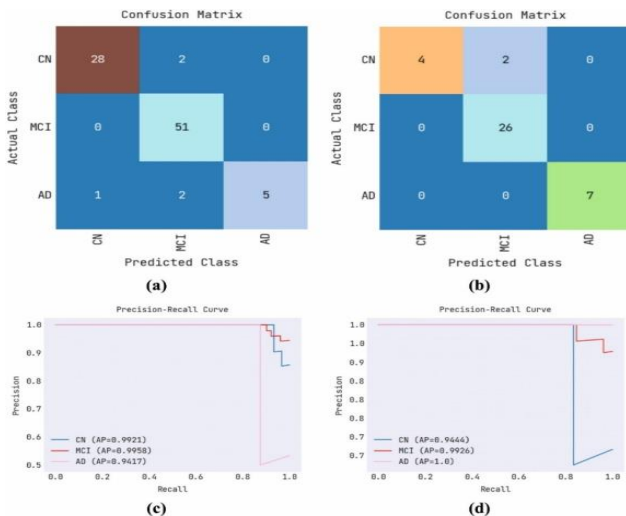

Fig. 4. (a) TR set confusion matrix (b) TS set confusion matrix (c) TR set PR-curve (d) TS set PR-curve.

Fig. 4 determines the classifier results of the WOADL-BDDC system under the training (TR) set and testing (TS) set. Fig. 4(a) represents the confusion matrix offered by the WOADL-BDDC model under the TR set. The figure symbolized that the WOADL-BDDC model had identified 28, 51, and 5 instances under CN, MCI, and AD classes. Also, Fig. 4(b) describes the confusion matrix offered by the WOADL-BDDC methodology under the TS set. The figure exemplified that the WOADL-BDDC algorithm has identified 4, 26, and 7 instances under CN, MCI, and AD classes. Fig. 4(c) and 4(d) validate the precision-recall analysis of the WOADL-BDDC system under training and TS sets. The figures described that the WOADL-BDDC method had acquired maximal precision-recall performance under all varying classes.

Table I reports the overall brain disorder classification outcomes of the WOADL-BDDC model. Fig. 5 represents a brief brain disorder classifier results of the WOADL-BDDC model under the TR set. The results indicated that the WOADL-BDDC model had shown enhanced results under all measures. It is noticed that the WOADL-BDDC model has gained an accuracy of 94.38%, percent of 96.43%, sense of 85.28%, species of 95.93%,  $F1_{score}$  of 89.35%, and FPR of 4.07%.

TABLE I. RESULT ANALYSIS OF THE WOADL-BDDC SYSTEM WITH DISTINCT MEASURES

Metrics	TR set	TS set
Accuracy	94.38	94.87
Precision	96.43	97.62
Sensitivity	85.28	88.89
Specificity	95.93	94.87
F1-Score	89.35	92.10
False Positive Rate	04.07	05.13

Fig. 5. Result in the analysis of the WOADL-BDDC system under the TR set.

Fig. 6. Result in the analysis of the WOADL-BDDC system under the TS set.

Fig. 6 exemplifies a brief brain disorder classifier results of the WOADL-BDDC approach under the TS set. The outcomes referred that the WOADL-BDDC process has shown enhanced results under all measures. It is observed that the WOADL-BDDC system has gained an accuracy of 94.87%, percent of 97.62%, sense of 88.89%, species of 94.87%,  $F1_{score}$  of 92.10%, and FPR of 5.13%.

An obvious ROC analysis of the WOADL-BDDC approach on the TR set is shown in Fig. 7. The outcomes referred to the WOADL-BDDC algorithm have exhibited their ability to categorize distinct classes.

Fig. 7. ROC curve of WOADL-BDDC system under TR set.

Fig. 8. ROC curve of WOADL-BDDC system under TS set.

A detailed ROC analysis of the WOADL-BDDC system on the TS set is displayed in Fig. 8. The outcomes stated the WOADL-BDDC approach had revealed its capability in varying classifier classes.

The training accuracy ( $TR_{acc}$ ) and validation accuracy ( $VL_{acc}$ ) acquired by the WOADL-BDDC system on the test database is depicted in Fig. 9. The simulation value stated that the WOADL-BDDC method had reached increased values of  $TR_{acc}$  and  $VL_{acc}$ . In particular, the  $VL_{acc}$  looked that greater than  $TR_{acc}$ .

The training loss ( $TR_{loss}$ ) and validation loss ( $VL_{loss}$ ) accomplished by the WOADL-BDDC system under the test database are displayed in Fig. 10. The simulation value pointed out that the WOADL-BDDC system has achieved lesser values of  $TR_{loss}$  and  $VL_{loss}$ . In particular, the  $VL_{loss}$  is lesser than  $TR_{loss}$ .

Fig. 9. Result analysis of WOADL-BDDC system in terms of  $TR_{acc}$  and  $VL_{acc}$ .

Fig. 10. Result Analysis of the WOADL-BDDC model in terms of  $TR_{loss}$  and  $VL_{loss}$ .

TABLE II. COMPARATIVE ANALYSIS OF THE WOADL-BDDC SYSTEM WITH RECENT SYSTEMS

Methods	Accuracy (%)	Specificity (%)
WOADL-BDDC	94.38	95.93
Vgg16	90.35	89.50
Graph CNN	94.00	93.02
Modified ResNet18	92.81	94.66
Non-linear SVM	75.58	75.63
ResNet50-SVM	92.49	87.36
ResNet50-RF	86.31	79.57

A comprehensive comparison study of the WOADL-BDDC model on brain disorder classification is shown in Table II [23, 24].

Fig. 11 represents a comparative investigation of the WOADL-BDDC technique with recent approaches in terms of accuracy. The results indicated that the non-linear SVM and ResNet50-RF models had attained the least accuracy values of 75.58% and 86.31%, respectively. Following, the VGG16 has shown a slightly enhanced accuracy of 90.35%. In contrast, the graph CNN, modified ResNet18, and ResNet50-SVM models have reached reasonable accuracy values of 94%, 92.81%, and 92.49%. Finally, the WOADL-BDDC model has obtained promising performance with a higher accuracy of 94.38%.

Fig. 12 signifies a comparative investigation of the WOADL-BDDC system with current methods in terms of species. The outcomes indicated that the non-linear SVM and ResNet50-RF approaches had correspondingly accomplished the least  $spec_y$  values of 75.63% and 79.57%. Next, the VGG16 has demonstrated a somewhat improved  $spec_y$  of 89.50%. In contrast, the graph CNN, modified ResNet18, and ResNet50-SVM models have reached reasonable  $spec_y$  values of 93.02, 94.66%, and 87.36%. Finally, the WOADL-BDDC methodology has attained promising performance with a higher  $spec_y$  of 95.93%.

Fig. 11.  $Accu_y$  analysis of WOADL-BDDC system with recent algorithms.

Fig. 12.  $Spec_y$  analysis of WOADL-BDDC system with recent algorithms.

These results confirmed the automated and accurate brain disorder classification results of the WOADL-BDDC model.

## V. CONCLUSION

In this study, we have established a novel WOADL-BDDC technique for recognizing brain disorders on MRI images. Primarily, the presented WOADL-BDDC technique performs pre-processing in two stages: GF-based noise elimination and U-Net segmentation-based skull stripping. Besides, the QuickNAT with RMSProp optimizer is applied to segment the brain parts. For feature extraction, the WOADL-BDDC technique performs a radiomics approach that separates features of all aspects. Finally, WOA with CRNN model is applied for brain disorder classification. The experimental evaluation of the WOADL-BDDC technique is tested on ADNI 3D dataset. The comprehensive comparison study highlighted the adequate performance of the WOADL-BDDC technique in different measures. In the future, an ensemble of DL-based classifiers can be employed to improve the WOADL-BDDC technique's detection performance.

## VI. FUNDING STATEMENT

The authors received no specific funding for this study.

## VII. CONFLICTS OF INTEREST

The authors declare they have no conflicts of interest to report regarding the present study.

# A Study on the Designation Institution for Supercomputer Specialized Centers in Republic of Korea

Hyungwook Shim, Yonghwan Jung, Jaegyoon Hahm\*

National Supercomputer Department, Korea Institute of Science and Technology Information, Daejeon, Republic of Korea

**Abstract**—In Korea, specialized centers are designated for 10 strategic fields for the purpose of jointly utilizing supercomputer resources at the national level. Based on the “National Supercomputing Innovation Strategy,” it plans to select 10 centers in three stages by 2030, and has now completed the designation of the first-stage specialized centers in 2022. With the second designation in 2024 ahead, it is urgent to review and improve the existing designation institution for fairer and more effective selection of specialized centers. Therefore, this paper analyzed the influence of evaluation items and the influence of evaluation items on evaluation results by using logistic regression analysis and network centrality analysis to prepare improvement plans for the existing evaluation model. As a result of the analysis, improvement measures were derived, such as subdividing evaluation items with low impact, expanding the items, and lowering the allotment of evaluation items with low impact.

**Keywords**—Supercomputer; specialized center; evaluation system; logistic regression model; network centrality analysis

## I. INTRODUCTION

Korea's supercomputer governance consists of a national center, a specialized center, and a unit center. The national center secures and operates supercomputing resources, supports policy establishment, and manages joint utilization. The specialized center performs supercomputing resource establishment and operation, basic application research and dissemination of results, etc. The unit center is a resource independently operated by individual private research institutes and companies [1]. Specialized centers maintain their qualifications for five years after designation. Currently, designation of specialized centers in 7 fields has been completed, and by 2028, it will be expanded to 10 fields[2]. Recently, the Ministry of Science and ICT announced that it would establish the “3rd supercomputer development basic plan”(referred to as '3rd Basic Plan'), the top plan for supercomputers, and establish a user support system centered on specialized centers. Therefore, at the beginning of the "3rd Basic Plan", the government should make efforts to improve the special center designation institution to ensure fairness, effectiveness, and sustainability. As a measure to improve the government's evaluation system in the field of science and technology, a statistical method using the influence of each evaluation item on the evaluation result is widely used [3]. Therefore, this paper also presents a plan to improve the specialized center designation institution by using the

evaluation results for the designation of the existing specialized center.

This paper consists of six sections. Sections I and II presented an academic value through a qualitative analysis of the background, meaning, and source research of this paper. Section III introduces the function, role, and protection system of the supercomputer specialized center, and Section IV explains the methodology of this paper. In Section V, a case study for improving the evaluation model is conducted and the results are gradually presented. Finally, in Section VI, the results were summarized and the viewpoint was straightened out, and the final point and pursuit plan of this paper were presented.

## II. LITERATURE REVIEW

Major prior studies are as follows. Hirao (2010) introduced projects for the introduction of peta-class next-generation supercomputing systems [4], and Hsu (2015) analyzed foreign trends for exascale supercomputing development and introduced major projects invested in the United States [5]. Mitsuhsa (2021) introduced Fugaku's flagship project related to Japan's Fugaku supercomputer and presented design details such as Fugaku's scale and performance [6]. Savin (2019) introduced the supercomputing center community system in Russia and mentioned the advantages in terms of energy efficiency and the provision, monitoring, and management of resources through a shared utilization network. In addition, improvement plans were presented through analysis of the current status of the Joint Supercomputer Center [7]. Prior domestic studies are as follows. Huh (2021) conducted research on ways to improve the legal system to vitalize the supercomputing ecosystem in Korea. Regarding the supercomputer-related law, the ‘Supercomputer Act’, problems such as the role of related institutions, project costs, mutual cooperation system, and consistency with higher-level plans were identified, and improvement measures were proposed with a focus on policy consistency and effectiveness enhancement [8]. Shim (2022) conducted a study to improve the evaluation index for selecting a research institute for the national R&D project of the Ministry of Land, Infrastructure and Transport. Using the evaluation score of each evaluator, the evaluation index was determined through an artificial neural network, and a method for improving the score distribution for each evaluation index was derived using logistic regression analysis [9]. Shin (2013) conducted a study to prepare improvement plans for local government

\*Corresponding Author.

performance indicators, classified performance indicators by characteristics, and applied development procedures that considered visions and promotion strategies for each local government and key outcomes by function. In addition, improvement measures were derived considering desirable performance indicator attributes such as relevance, clarity, timeliness, reliability, and comparability [10]. Lee (2018) set the field and elements for improving the educational environment and set the direction of the indicators through a delphi survey by experts for the purpose of developing educational environment improvement indicators. As a result of the analysis, the indicators for improving the educational environment, such as the adequacy of the total floor area of the classroom, the adequacy of general school teaching, whether or not to secure seismic performance, the deterioration of firefighting facilities, and energy consumption, were finally determined [11]. Ji (1999) conducted research for the rational development of informatization indicators that measure the national informatization level. The author first set informatization facility indicators, informatization use indicators, and informatization support indicators, subdivided them into 6 groups, and proposed an informatization measurement indicator system consisting of a total of 28 indicators in consideration of informatization level, reality, and applicability aspects[12]. Kim (2022) conducted a study on how to improve the global cyber security index, which is used to diagnose the level of national cyber security development and strengthen cyber security capabilities. The author established basic principles for the improvement and utilization of the Global Cyber Security Index and suggested development plans through survey-based SWOT analysis[13].

The academic value of this paper is as follows. It is novel because no research has been conducted on the improvement of evaluation system related to the existing domestic supercomputer. Although Huh (2021) conducted a study on institutional improvement measures related to supercomputers, this paper only examines the appropriateness of the evaluation system. Also, research related to the development and improvement of existing evaluation system draws conclusions using a qualitative method of asking and organizing the opinions of experts. However, in this paper, the influence of each index of the existing evaluation model was analyzed using a statistical method using the actual evaluation result data of the evaluation committee, and a comparative analysis was performed with the improved evaluation model. Lastly, a survey was conducted on the appropriateness of the evaluation index targeting the researchers of the specialized center support institution that was evaluated, and the fairness of the improvement model was added by reflecting the opinions of all parties participating in the evaluation.

### III. SUPERCOMPUTER SPECIALIZED CENTER

#### A. Definition of Supercomputer Specialist Center

Supercomputer specialized center defined as an institution that possesses expertise for professional use of supercomputers, provides specialized services based on resources, manpower, and technology specialized in the field, conducts research and development, and promotes the use of supercomputers. The functions and roles of the specialized

centers in Table I include the establishment and operation of supercomputing resources by field, service provision, base application research and dissemination of research results, large-capacity data management and operation support, and human resource training.

#### B. Evaluation Institution for Designation of Supercomputer Specialized Center

The designation of specialized centers is in accordance with the "Operational Guidelines for Designating Supercomputers by Field" (referred to as 'Operational guidelines'). The Operating guidelines are based on Article 9-2 of the "Act on the Promotion and Utilization of Supercomputing" (referred to as the 'Supercomputer Act'), which includes the functions and roles of specialized centers, designation procedures and methods, establishment of operation plans, evaluation of operational performance, composition and operation of evaluation teams, etc. The designation procedure is shown in Fig. 1. First of all, the institutes, universities target organizations that can submit applications are central administrative agencies, national and public research, private companies and organizations with expertise in each field, and meet the requirements such as 4 or more supercomputer experts and supercomputer possession (1.5 million dollars or more). After submitting the application, one institution in each field can be designated as a specialized center through the first written examination, the holding of a briefing session, and the second face-to-face examination. Finally, among institutions with a score of 70 or more, the institution with the highest score is selected.

In the evaluation system, the subject of evaluation is the evaluation team, and it is made up of 3 or more and 10 private experts, including the head. The evaluation team conducts both the first and second evaluation, and the main evaluation items are shown in Table II. The items and indicators were derived through the FGI of experts in the related field, and the evaluation items include the 'Related Performance', 'Validity of operation purpose and plan', 'Suitability of center manpower', etc.

TABLE I. FUNCTIONS AND ROLES OF THE SPECIALIZED CENTERS

	Main Content
Function and Role	<ul style="list-style-type: none"> <li>· Providing supercomputing services in specialized fields</li> <li>· research and development of supercomputing technology and application specialized in specialized fields</li> <li>· xpansion of resource sharing through participation in the joint utilization system</li> </ul>
Service	<ul style="list-style-type: none"> <li>· stablishment, operation and service of specialized resources for each sector centered on 10 strategic fields</li> <li>· tilization support and consulting through field experts</li> <li>· Community development and education by field</li> </ul>

Fig. 1. Specialized center designation procedure.

TABLE II. EVALUATION ITEM AND INDICATOR

Evaluation item	Evaluation indicator	points
Related Performance	Performance of R&D manpower training	10
	Performance of service, data management and research support	10
Validity of operation purpose and plan	Justification and Necessity of Designation	5
	Challenge and specificity of vision and operational goals	10
	Suitability of goals, project contents, research methods, etc.	10
	Excellence of Expected Performance and Utilization Plan	5
	Center fostering and operation support plan	10
Suitability of center manpower	Appropriateness of personnel planning and organizational composition	10
	Researcher's expertise	10
Facility and Equipment Securing Plan	Facility, Equipment Status and Expansion Plan	15
	Facility Status and Expansion Plan	5
Added points	Ratio of joint utilization resources	10

In the specialized center designation institution, the evaluation items and indicators for designation are important factors in selecting a specialized center representing a specific field for the next five years. Regarding the national R&D project evaluation system, Lee (2010) also emphasizes the effects of the need for improvement of evaluation items and indicators, and the preparation of improvement plans using evaluation results [14]. Using the actual evaluation result data, the appropriateness of new discovery of evaluation items, removal of existing items, and adjustment of points allocation was proved. Therefore, in this paper, it is necessary to review the appropriateness of evaluation items based on the evaluation results of the seven specialized centers.

#### IV. THEORETICAL BACKGROUND AND METHODOLOGY

##### A. Research Procedure

In many papers such as Ahn(2022), regression analysis, AHP, and machine learning analysis are mainly used to research measures to improve the evaluation system [15]. The analysis results are effective in discovering individual improvement factors for evaluation items, and can provide intuitive results to researchers. However, evaluation items are grouped into various sub-indicators, and due to the nature of R&D, the range of evaluation items such as research method, content, and research timing is radially intertwined. Therefore, it is more effective to discover improvement factors by considering the correlation between evaluation items, and in this paper, an improvement plan was derived considering the result of network centrality analysis to reflect the correlation between evaluation items. The research procedure of this paper is shown in Fig. 2. First, using logistic regression analysis for the existing evaluation model, the influence on the selection result for each evaluation item and the appropriateness of the points assigned are reviewed. Second, through network centrality analysis, the evaluation model improvement plan is derived by analyzing the structure and centrality that affect evaluation items. Finally, the results are summarized and implications are drawn.

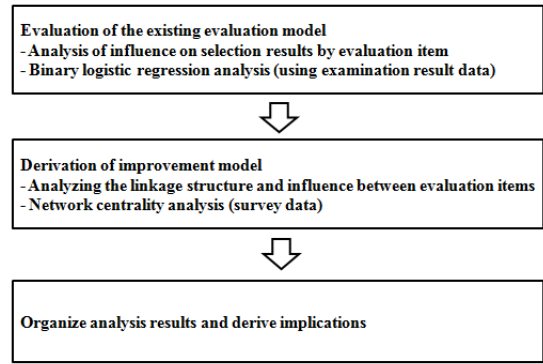

Fig. 2. Specialized center designation procedure.

##### B. Logistic Regression Model Analysis

Binary logistic regression analysis is used to estimate the relationship between a binary dependent variable (categorical) and multiple independent variables to explain the influence of the independent variable on the dependent variable or to predict the value of the dependent variable for the value of the independent variable. It is an analysis technique that regression models can generally be expressed as in Equation (1), and  $\hat{y}$  has values of 0 and 1.

$$\hat{y} = b_0 + b_1X_1 + b_2X_2 \cdots b_kX_k + \epsilon \quad (1)$$

As shown in Fig. 3, the regression model can be divided into total variance SST (Total Sum of Squares), which means the difference between the actual value and the mean, and error variance SSE (Error Sum of Squares), which means the difference between the actual value and the estimated value, and variance by the regression equation SSR (Sum of Squares due to Regression). Through these three fluctuation values, the coefficient of determination, which means the contribution to explain the diversity of the dependent variable, is obtained, and the regression coefficient  $b$  can be estimated as shown in Equation (2) through the least squares method in which the variation in error(SSE) is minimized.

$$b_k = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^n (x_{ij} - \bar{x}_i)^2} \quad (2)$$

In this paper, the selection result was substituted as a dependent variable, and '0' was set as not selected and '1' as selected. Independent variables represent 4 evaluation items excluding added points, and were analyzed by standardizing them to values between 0 and 1.

Fig. 3. Regression model conceptual diagram.

C. Network Centrality Analysis

Network analysis is an analysis method that analyzes the characteristics of relationships that exist between objects (nodes). It can visualize a microscopic network of relationships by deriving characteristics such as connection strength and connection structure between research subjects using nodes and links. Network centrality analysis is an analysis method that utilizes centrality indicators using the number of connections between nodes, distances, and travel routes among various measurement indicators [16]. Connectivity centrality, proximity centrality, betweenness centrality, and eigenvector centrality are typically used as centrality indicators [17]. The eigenvector centrality index used in this paper is a method of analyzing centrality by weighting the centrality of the other node. Characteristically, as shown in Equation (3), the maximum eigenvalue  $\lambda$  of the matrix between nodes is used.

$$C_i = \frac{1}{\lambda} \sum_j \alpha_{i,j} C_j \quad (3)$$

$i, j$ : Node

$C$ : Eigenvector centrality

$\lambda$ : eigenvalue

$\alpha$ : Connection relationship (connected 1, unconnected 0)

Nodes mean evaluation items during analysis, and using the matrix constructed using the survey results, eigenvalues are calculated and eigenvector centrality for evaluation items and indicators is estimated [18].

V. CASE STUDY

A. Data

Data for case studies can be classified into two types. First, the data for the logistic regression analysis use the evaluation result data of the specialized center evaluation team. The evaluation result data uses written evaluation data for 7 fields, and uses the evaluation scores written by the evaluation team for a total of 15 institutions in 7 fields. The dataset is shown in Table III. A, B, C, and D were selected as independent variables and entered as 0~1 scale. The dependent variable was selected as a nominal variable (dummy variable) with two values of 0 and 1 depending on whether or not it was selected.

Next, as data for network centrality analysis, data from an online survey targeting 60 people, including executives and employees belonging to seven specialized centers, are used. The survey items consist of a total of 17 items, including a total of 16 items in the Likert scale method and one item in the matrix method.

B. Logistic Regression Analysis Results

The analysis results of the regression model including all evaluation items are shown in Tables IV and V. Table IV shows the Nagelkerke R2 index, which indicates the explanatory power of the entire model, and the Hosmer-Lemeshow index, which is a goodness-of-fit test of the model. In the Hosmer-Lemeshow test, the chi-square value indicates the degree of agreement between the actual value of the dependent variable and the predicted value by the model and

the smaller the chi-square value, the higher the fitness of the model. The extent to which independent variables explained the dependent variable was about 24%. Since the value of the significance probability  $p$  in the goodness of fit of the model was larger than 0.05, the null hypothesis was not rejected, so the goodness of fit can be considered acceptable.

Table V is the estimation result of the regression coefficient of the model. First, if the sign of the regression coefficient  $\beta$  is positive (+), the greater the value of the corresponding independent variable, the greater the possibility of being classified as a selected group representing the dependent variable '1', and negative (-) means the opposite case. As a result of the analysis, evaluation items A and D are positive (+), and the higher the score of evaluation items A and D, the higher the possibility of being selected. B and C are negative (-), and the higher the score, the higher the possibility of not being selected. The significance probability is less than 0.05 for both evaluation items A and D in the 95% confidence interval, which can be considered significant, and B and C are 0.227 and 0.901, respectively, which are greater than 0.05, so it can be considered insignificant. Wald is a statistic that verifies whether the coefficient value for each covariate is zero.  $\text{Exp}(\beta)$  represents the odds ratio and means the influence on the evaluation result when an evaluation item increases by one unit. It can be interpreted that when the score of evaluation item A increases by one unit, the probability of being selected increases about 20 times.

TABLE III. DATASET

Item	Indicator	Definition	Data coding
Independent variable	A	Related Performance	0~1 (Scale)
	B	Validity of operation purpose and plan	
	C	Suitability of center manpower	
	D	Facility and Equipment Securing Plan	
Dependent variable	Result	-	0, 1 (Dummy)

TABLE IV. ANALYSIS RESULT OF HOSMER-LEMESHOW TEST

	Chi-square	Significance probability	Note
Hosmer-Lemeshowtest	8.120	0.422	Nagelkerke R2 :.240

TABLE V. ESTIMATION RESULT OF THE REGRESSION COEFFICIENT

	B	S.E.	Wald	Significance probability	Exp(B)
A	3.014	1.449	4.328	.037	20.378
B	-.846	.700	1.462	.227	.429
C	-.243	1.958	.015	.901	.785
D	2.698	1.162	5.393	.020	14.849
Constant	-5.741	1.770	10.520	.001	.003

As a result of the statistical analysis of Table VI, it can be confirmed that the evaluation items B and C are not appropriate in the direction and significance probability affecting the evaluation result. In the case of the significance probability, it cannot be a factor that absolutely determines the validity of the independent variable, but in the case of the direction, it can be a factor that can determine the validity of the independent variable in consideration of the evaluation criteria. Therefore, after excluding the two evaluation items with a negative (-) sign, the regression coefficient was re-estimated, and the re-estimation results are shown in Table VII. The regression coefficients of the A and B evaluation items showed positive (+) values, and it was confirmed that they were somewhat reduced compared to the previous ones. The significance probability was statistically significant at the 90% confidence interval, and it was confirmed that the influence of the evaluation result was somewhat lowered according to the odds ratio result. The influence of D on the selection result was about 1.6 times greater than that of A. Through this, it is necessary to improve evaluation items B and C as a method for modifying the model. In order to prepare improvement measures, the network centrality analysis results are additionally conducted and the two analysis results are comprehensively considered.

TABLE VI. RESULT OF THE REGRESSION COEFFICIENT ESTIMATION

	B	S.E.	Wald	Significance Probability	Exp(B)
A	1.638	.918	3.188	.074	5.147
D	2.102	1.080	3.788	.052	8.184
Constant	-6.297	1.780	12.515	.000	.002

### C. Network Centrality Analysis Result

The result of visualizing the network for evaluation items is shown in Fig. 4. Node A represents relevant performance, node B represents the validity of operation purpose and plan, node C represents the suitability of center manpower, node D represents the facility and equipment securing plan, and node E represents the evaluation items for the add points. The size of a node increases as the frequency of the node increases, and the frequency is determined by the number of choices made by the respondent. The link is expressed as a straight line connecting the nodes, and the higher the co-occurrence frequency, the bolder it is.

Fig. 4. Regression model conceptual diagram.

As a result of the analysis, the frequency of nodes was highest in evaluation item B, which means the validity of the operation purpose and plan, followed by D, E, A, and C in order. As for the links, the B-D link that connects the validity of the operation purpose and plan and the add points evaluation

items appeared in the thickest form, followed by B-C and D-E in that order. In other words, it can be analyzed that the strength of the relationship between B-D, B-C, and D-E is relatively strong and the strength of the relationship between the evaluation items C-A and A-E is relatively weak around evaluation item B in the network between evaluation items evaluated by the response group. The strength of the relationship can be interpreted in various ways, but from the perspective of the evaluation system, it can be interpreted in two cases. First, the allocation of evaluation items with high relationship strength should be relatively higher than those with low relationship strength. This is because the higher the relationship strength, the greater the effect on the overall evaluation scores. Second, it is necessary to distinguish between evaluation item groups with high relationship strength and evaluation item groups with low relationship strength. If the impact on the evaluation results is significantly large due to the difference in relationship strength, it may be appropriate to classify or exclude groups of evaluation items. Therefore, in this paper, when considering the improvement of the overall evaluation system, the relationship strength was used as a basis for adjusting the evaluation item. In order to analyze the quantitative influence of each evaluation item in the network, the centrality value is used, and the eigenvector centrality value, which considers the centrality value of other related evaluation items among the centrality values, was estimated. The results of the eigenvector centrality analysis for the evaluation items are shown in Table VII. The evaluation item with the greatest eigenvector centrality is B (0.572), followed by D (0.550), E (0.393), C (0.355), and A (0.300) in that order appears. In the quantitative analysis results, the centrality values of evaluation items B and D were relatively high, and E, C, and A were low.

TABLE VII. EIGENVECTOR CENTRALITY

	A	B	C	D	E
Eigenvector centrality value	0.300	0.572	0.355	0.550	0.393

Based on the analysis results, it can be divided into two groups according to the size of the centrality value. It can be divided into two groups: B, D, E, C, and A. When improving the evaluation system, it is appropriate to increase the score for the group with high relationship strength and to adjust the score for the group with low relationship strength.

The comprehensive improvement plan for the evaluation model, including the result of network centrality analysis, was determined by segmentation of evaluation item B. The reason for this decision is: First, it was derived as the most influential indicator in the model as a result of network centrality analysis, while being an object that needs improvement according to the results of regression analysis. Second, in the case of evaluation items B and D, the centrality value is similar, but the score of B is twice as high, so it is necessary to adjust the score of evaluation item B downward. Third, evaluation item B has the largest number of sub-indicators, so there is a limit to representing all the characteristics of sub-indicators. Fourth, in the case of improvement evaluation item C according to the results of regression analysis, it is appropriate to improve B evaluation item first because it has a low influence on other

evaluation items and is clearly classified as a group with B evaluation item. Therefore, this paper subdivided evaluation item B into two evaluation items. B1 is 'Challenge and specificity of vision and operational goals', 'Excellence of Expected Performance and Utilization Plan', B2 is 'Justification and Necessity of Designation', 'Suitability of goals, project contents, research methods, etc.', 'Center It was grouped under 'fostering and operation support plan'. For the improved model, logistic regression analysis is re-executed to examine the validity of the improvement.

#### D. Improvement Model Evaluation

The analysis results for the improvement model are shown in Tables VIII and IX. Through the Nagelkerke R2 index and the Hosmer-Lemeshow, a goodness-of-fit test of the model, the degree of explanation of the dependent variable by independent variables was about 33.6%, which was about 12% improved. As for the goodness of fit of the model, the value of the significance probability p was greater than 0.05, so the improved model also did not reject the null hypothesis.

TABLE VIII. ANALYSIS RESULT OF HOSMER-LEMESHOWTEST

	Chi square	Significance Probability	Note
Hosmer-LemeshowTest	5.772	0.673	Nagelkerke R2 :.336

Table IX is the estimation result of the regression coefficient of the improvement model. As a result of the analysis, all evaluation items are positive (+), and the higher the score, the higher the possibility of being selected. As for the level of significance, A, C, and D evaluation items were found to be significant at 95% confidence interval. B1 and B2 were found to be insignificant, but it was confirmed that they were greatly improved compared to the existing model. In addition,  $Exp(\beta)$  was similar for all evaluation items within 1.349 to 1.466, and the influence of B1 and B2 also increased by three major levels compared to the value of 0.429 in the existing model.

TABLE IX. ESTIMATION RESULT OF THE REGRESSION COEFFICIENT

	B	S.E.	Wald	Significance Probability	Exp(B)
A	.369	.189	3.814	.050	1.446
B1	.365	.246	2.201	.138	1.440
B2	.359	.195	3.381	.066	1.432
C	.383	.128	8.866	.003	1.466
D	.300	.104	8.234	.004	1.349
Constant	-22.980	6.606	12.102	.001	.000

### VI. CONCLUSION

This paper identified problems in which the initial evaluation items and points assigned in the national supercomputer specialized center designation evaluation institution were consistently applied until the end of the project, and proposed a sustainable evaluation model improvement plan using evaluation result data. The difference from previous studies is that a network centrality analysis was

newly performed to quantitatively analyze the strength of the relationship between evaluation items, and it was reflected in the improvement of evaluation items and indicators. As a result of the analysis, it was confirmed that the improvement plan of regrouping and subdividing the evaluation items using the eigenvector for the evaluation items was appropriate. It is expected that the results of this thesis will be used to continuously improve the designation institution and that excellent specialized centers will be selected.

The limitations of this thesis are that it has not been able to secure a lot of evaluation result data because many specialized centers have not yet been designated, and the effect of the improvement model has been proven only through statistical analysis. Therefore, in the 2023 second specialized center designation stage, plans are being established to apply the improved model in consultation with government agencies and re-verify the effect using the evaluation result data.

#### ACKNOWLEDGMENT

This research was carried out through major project (K-23-L02-C03-S01) support of Korea Institute of Science and Technology Information.

# Time Series Forecasting using LSTM and ARIMA

Khulood Albeladi, Bassam Zafar, Ahmed Mueen

Department of Information Systems-Faculty of Computing & Information Technology, King Abdulaziz University, Jeddah, KSA

**Abstract**—Time series analysis is the process of evaluating sequential data to extract meaningful statistics. In the current era, organizations rely greatly on data analysis to solve and predict possible answers to a specific problem. These predictions help greatly in decision-making. In time series problems, the data is used to train the different machine and deep learning models. The models train on provided data displays particular outcomes. These outcomes anticipate possible solutions. In this paper, the two most effective Python models LSTM (Long Short Term Memory Loss) and ARIMA (Autoregressive integrated moving average) are used. These are the two most recommended models while dealing with Time series forecasting. The selected dataset is from Mulkia Gulf Real Estate available at MarketWatch. The main objective of this research paper is to study and compare the results of the two models used and determine which one is the best-suited model for that particular type of prediction. However, these are widely used models but the focus point of this research is determining the performance variance between these two models. LSTM became famous in 1997 as a training model that can remember patterns based on previous data while ARIMA is famous for forecasting variables of interest using a linear combination of previous values of the variable. The findings state that ARIMA is better for time series forecasting than LSTM based on the mean average of the basic evaluation parameters.

**Keywords**—Stock analysis; machine learning; deep learning; time series; ARIMA; LSTM

## I. INTRODUCTION

Time series is a time-dependent dataset, which means that the values are obtained in specific intervals of time. Usually, the values are taken at regular intervals, but the sampling could be irregular [4]. If a time series has a definite pattern, then any value of the series should be a function of previous values. Time series models differ from others in the way it predicts. With the advancement of information technology, now there are many more ways to collect time series data. A time series model uses a lag value of the target variable and uses it as a predictor variable, whereas traditional models use other variables as predictors. Time series analysis is the process of extracting output from time series data using different techniques. One of the famous types of time series analysis is Time series forecasting. In time series forecasting, the results are the predicted outputs from the trained models. There are many forecasting models available. In this research, LSTM and ARIMA models are used.

A general LSTM model has a cell; each cell has three parts, i.e. Forget gate, Input Gate and Output Gate. The states are affected by both past states and current input with feedback connections. LSTM models are able to learn long-term dependencies with feedback connections. LSTM can be single or multilayered models, the functionality differs for

both. They are preferred because they hold information for a long time by default. ARIMA forecasts temporal dependencies using only historical values. These models help to gain better insights into the data and predict future trends. It works by stationarising the series, means studying the correlation of the values and check its residual diagnosis ACF and PACF plots.

A number of forecasting problems can be solved using LSTM and ARIMA models. Although, the models have been used for prediction in the past (21) 19 18 12, but the goal of this research is to elaborate the differences between the outcomes that these models provides. The key point is understanding how well one model performs than the other when trained on same datasets. The evaluation of these models is done based standard evaluation parameters (MAE, MSE, R recall, etc.). The graphs included will also help in determining which model is best for doing time series for stock price prediction.

## II. REVIEW OF RELATED LITERATURE

The time series is the set of quantitative observations arranged in chronological order. Time series analysis has attracted a lot of attention in the past three decades [1]. In the past, it is generally believed that time can be a continuous or discontinuous variable and no comparison exists between the dependent variables [2]. Time series have always been used in the field of econometrics. Jan Tinbergen (1939) devised the first time series econometric model. He also started the scientific research program on the basis of experienced econometrics. At that time, it was hardly considered that chronologically ordered observations might depend on each other. The dominating assumption was that, according to the classical linear regression model, the surplus of the estimated equations is randomly determined and is independent of each other [3].

The fundamental goal of building a time series model is the same as building a precision model that provides a value nearly equal to the values present in the series. From a statistical point of view, time series are the recordings of aleatory processes which vary over time. The most distinguishing feature of time series is that the distribution of observation at a specific point conditional on the previous value of the series depends on the outcome of those previous observations, simply making the outcomes independent. The recordings can be a continuous pattern or a set of discrete values. There are two main types of time series patterns that exist, stationary and non-stationary. Stationary time series values have statistical properties and moments while non-stationary values are simple recordings with changing statistical properties. Both types of series can be used in time series forecasting models [5] [6].

Time series forecasting model building is done based on the type of dataset used to train models. Stationary datasets are easier to train for prediction than non-stationary datasets. In fact, it is a necessity to convert a non-stationary dataset into a stationary dataset [7]. Models easily understood stationary datasets and extract information more efficiently from them. There are certain methods devised to convert non-stationary datasets into stationary datasets [8]. The popular methods are the Hilbert-Huang transform, Fourier transform, Dicky Fuller, etc. Hilbert Hhuang method is specially developed for analyzing non-linear and non-stationary data [9].

Naturally, people's habit of forecasting and making predictions is immemorial. Simply forecasting is the name of predicting outcomes of a plan, but in python, the forecasting is done using datasets available and training them using in-built functions. Using time series forecasting is the process of finding possible values for anything using a known data set. Time series is a popular technique in the current era to solve all types of problems, predicting directly affects the decisions and escort towards clearer imagination. Time series forecasting can be done using both machine learning and deep learning models. The models are different based on their working specifications [10].

There are numerous models in python that serve the purpose of predicting values. Supervised machine learning models and deep neural networks are used for prognostications. Supervised machine learning empowers systems with the ability to learn automatically from the data and get better outcomes with experience without being explicitly programmed [11]. Similarly, deep networks have applications in many areas of life including prediction, detection, creation, etc. Deep neural networks model provide better forecasts as compared to machine learning models. When dealing with real world's problems shallow neural networks need to be sufficiently expressive to predict the task optimally while deep neural networks (DNNs) have been proposed as a way of producing more predictive models [12]. These models are sequences of layers in which each layer uses a linear transformation function. When the layers are combined, it constructs a deep neural model. As many functions are included, that automatically enhances the models' prediction ability.

These models have complex backgrounds and seem difficult to build. With the passage of time, there came a great evolution and now these models are readily present in python libraries. Python has libraries with inbuilt forecasting models that can be used to do predictions. LSTM and ARIMA are the two most influential and long-established models. Models are used considering the characteristics of the encountered problem. A traditional LSTM is a sub-type of RNN model that saves previous sequential data as temporal pieces of information [13], [14], [15].

A general LSTM model comprises the cell; each cell has three parts, i.e. Forget gate, Input Gate and Output Gate. These states are affected by both past states and current input with feedback connections. A standard recurrent cell consists of Sigma and Tanh cells. Each memory cell in LSTM has recurrently self-connected linear unit LSTM. These linear

units are called CEC (Constant Error Council). The architecture of LSTM permits it to bridge huge time lags between relevant input events of almost 1000 steps and more. This method is used in the processing of time-series data, in prediction, as well as in the classification of data.

LSTM models work efficiently and have been widely used in various kinds of tasks. The activation function in the output layer determines in which direction the training will lead here [16], [17].

ARIMA (autoregressive integrated moving average) is also a sub-type of RNN networks and has proven immensely useful for prediction [18], [19], and [20]. They have been studied thoroughly and remodeling has been done on ARIMA processes. These models were popularized by George Box and Gwilym Jenkins [21]. That's why ARIMA processes are sometimes known as Box-Jenkins models. They effectively put together everything in a comprehensive manner and the relevant information required to understand and use univariate ARIMA processes. ARIMA models have gained popularity because they can very accurately do short-term forecasts. Sometimes there is some information that cannot be extracted through regression, so ARIMA is used to capture this additional information. In these models, autocorrelation and partial autocorrelation functions are used, as basic instruments, to identify the stationarity of time series [22]. Both LSTM and ARIMA models have their own specific functionalities and their own advantages and disadvantages.

The previous studies showcase the use of ARIMA and LSTM models in different industries. The use of these models is common in finance and commerce markets but they cannot be seen used in trading markets. The literature gives insights that use of LSTM and ARIMA models in prediction problems is very limited. The research is done to discuss the results of implementation of these two models and evaluating the performance models when they are trained on same dataset. The results helps estimate which model is more useful for stock exchange prediction.

### III. METHODOLOGY

Time series forecasting is used to deal with a surprisingly vast set of problems. There are different techniques available to implement time series forecasting, each differs slightly but affects greatly. The process consists of five major steps. As in this paper, High Price prediction is being done using two different models (i.e. LSTM and ARIMA). This five-step methodology is used to implement these two models. Although the general working of all five models is identical, it varies greatly according to the technicalities used in each model.

Fig. 1 shows the general methodology steps which are explained, respectively.

Fig. 1. General methodology flowchart.

A. Understand the Problem

As mentioned earlier, time series data is used to deal with lots of problems. Time series forecasting is the type where certain solutions are speculated by training previous data. The solutions are; predicting stock market reach at a certain time, estimating survey results based on previous data, weather prediction at a certain date, etc. it is important to build a model keeping in view the nature of the problem you are dealing with. Explore the models that can be used according to the given problem. In addition to understanding models, thoroughly understand the techniques used to implement these models in order to choose the best according to the problem.

The purpose of this research is to build two different time series forecasting models in order to proclaim which is the best model for predicting high prices. To do so, there are two best-performing models (LSTM & ARIMA) that have been working exceptionally well while dealing with prediction problems.

B. Data Gathering / Pre-processing

After understanding the nature of the problem, the next step is to determine the type of data needed in order to train the models. The data should be the cross-sectional type of data. This type has one dependable variable that confides in numerous independent variables. In such data types, the small-scale or aggregate entity is observed at different points in time. In a nutshell, this is the data of different entities collected at the same time.

In this paper, data from Mulkia Gulf Real Estate from Saudi Exchange datasets are used. The data is extensive to cause models to overfit, so certain sheets (i.e. Fig. 2; sheet 1 & Fig. 3; sheet 7) are chosen to train models. It is a cross-section of data perfectly meeting the criteria of the needed data. The purpose of using this data is because the data possess similarities that are consonant with the prediction problem. After training models on this data the trained model can be used to predict the high price value. This data accurately meets the criteria of needed data to predict the highest price value.

After data has been selected, the next step is to pre-process this data. As mentioned earlier, the data type used is non-stationary and cross-sectional data. The models used can train on stationary data more efficiently, so it is necessary to convert this data into stationary data. There are certain methods available to convert non-stationary data into stationary. ADF (Argumented Dicky Fuller) method is used to transform the data into non-stationary. In python, ADF can be imported from the Stats model library as statsmodels.tsa.stattools.adfullers.

C. Exploratory Analysis

Exploratory analysis is the process of analyzing the relationships between variables that exist in raw data. These initial relationships help to understand the nature of the data and how accurately the desired information will be extracted from it. It's mandatory to do exploratory analysis independent of the type of problem, it's mandatory to explore the data first. It's also called preliminary analysis of data, where you plot the data in its original form to find certain structures. When

preliminary analysis is done, check the validity of measures, and point out any outliers. It also helps in examining the weightage of different variables to evaluate the effectiveness of certain manipulative variables, etc. The major thing that should be implemented while doing preliminary analysis is cleaning disrupted data, checking the data for null values, etc.

Fig. 4 shows that the data has been scaled properly and is ready to train for the prediction models. It also shows the regression patterns of various variables alongside dates.

D. Choosing Libraries and Training Models

In Python, there are thousands of libraries and in-build models available that deal with machine learning and deep learning problems. Python libraries are a set of specific functions put together in a single file. The purpose to make these libraries is to assist coders in doing obvious steps. There is a whole set of libraries available for different domains of artificial intelligence. The problem explained in this research paper is time series forecasting, which is a type of machine learning and deep learning problem. The libraries which come in handy while dealing with such problems are sklearn, tensorflow, numpy, etc.

Fig. 3. Mulkia gulf real estate from Saudi exchange sheet 7.

Fig. 4. Exploratory analysis.

Fig. 5. Basic deep learning neural network.

These libraries are designed according to a specific set of rules that fit their receptive type of problem. For preprocessing of this data; numpy, sklearn, tensorflow, and keras are used. Similarly, there are some in-built forecasting models that are available in python. Use these models suitably for respective problems. The models serve specific purposes; they have been created according to some mathematical ordinances. According to the problem type choose these rules and embed them into deep learning models. A typical deep learning model consists of an input layer, multiple hidden layers (where most of the work is done), and the output layer. Fig. 5 shows the general representation of a deep learning neural network model.

Now keeping in view the nature of the problem, use LSTM and Auto-Regressive models.

### E. Evaluating Models

Evaluation is done by measuring evaluation parameters. The three basic parameters that are used in measuring a neural model's reliability in time series forecasting problems are Accuracy, Precision, and Recall. In addition to these parameters, some auxiliary parameters are available to evaluate regression results. The added parameters are MSE (Mean Square Error), MAE (Mean Absolute error), MAPE (Mean Absolute percentage), and MDAPE (Median Absolute Error Average and Percentage). These metrics collectively help provide an explanation regarding the mistakes made unknowingly.

## IV. IMPLEMENTING TIME SERIES MODELS

In this research paper, the two best time series forecasting models are used that are already available in python. These models will be trained on two datasets from Mulkia Gulf Real Estate from Saudi Exchange. Sheet 1 & Sheet 7 of these datasets will be used to train the models. The aim is to determine which model is the best model for respective targeted industry. The problem is predicting the highest profits values. The trained models will be attested, and finding will be evaluates based on evaluation parameters to get exquisite results. The general methodology explained above will be followed. The models are embedded one by one into the neural networks. After embedding the models, the pre-processed datasets will be provided and will run in the code for the training of models. The general method proposed to train the models is nearly identical. They only differentiate based on the functionality attributes, and the technical

differences, i.e. number of hidden layers used, the evaluation parameters used, and the dataset preparations, the working background. Detailed information on these python models is provided below.

### A. Long Short-Term Memory Loss (LSTM)

As the prediction model should remember long-lasting events from part, LSTM is the first choice to use in this paper. LSTM is an inbuilt python function that can be imported from TensorFlow. LSTM is the branch of recurring neural networks. It was seen that there weren't any RNN structures that can do backpropagation of long intervals, so to solve such difficulties LSTM was proposed. LSTM has two gate unit cells that open and close to the information flow within each memory cell, i.e. Packs of information between time lags [23]. It requires the data used to be in a definite shape. The dimension should be equivalent, and the data should be properly cleaned, integrated, and scaled. The commonly used activation functions for LSTM-based regression problems are Sigmoid and Tanh. Tanh has proven to be very effective in dealing with vanishing gradients.

The functioning of the LSTM model is explained in Fig. 6.

Fig. 6. Flowchart for LSTM working.

As said earlier, LSTM has the ability to remember information for the long term. This is done by remembering the previous output and combining it with the current one. To understand the working of LSTMs better, there is a need to fathom the mathematics behind them.

Divide the working of LSTM neural networks into four stages. In the first stage, the model decides whether to forget or remember information in the previous cell. This value is decided by doing the following calculation:

$$\text{Forgetting value } f_t = \sigma [ W_f (h_{t-1}, X_t) + b_f ]$$

Where  $\sigma$  is the activation used in the input layer,  $W_f$  and  $B_f$  are the weight and bias vectors,  $h_{t-1}$  is the output at time  $t-1$ , and  $X_t$  is the input vector at time  $t$ . If the forgetting value is equal to zero then this means that the previous value has been forgotten.

In the second stage, the model decides which value will get stored in the next cell state. To do so, sigmoid and tanh layers are used. The sigmoid layer chooses the pieces of information which need to be updated, and the layers decide on a second option value. By combing these two values, the models create new values to update the cell state. The formula to calculate sigmoid and tanh values are:

Input gate value  $i_t = \sigma(W_i \cdot [h_{t-1}, X_t] + b_i)$

Updated value  $C_t = \tanh(WC \cdot [h_{t-1}, X_t] + b_C)$

$\sigma$  represents the sigmoid-shaped function, it is the input gate value and  $C$  is the updated value at time  $t$ .

In the third stage, the new cell state  $NC_t$  is obtained using  $f_t$  and its value. The equation below shows how to calculate this  $NC_t$  value,

$$C_t = f_t [C_{t-1} + i_t] e$$

In the final stage of LSTM, it is determined which value will get considers as output. Use the sigmoid equation to determine which cell state will be the output; the value is processed through  $\tanh$  to get a value between 1 and -1.

The inbuilt model present in python work is according to the above-explained structure. The models can be improved further by choosing the correct values of weights and bias values, activation functions, and the number of hidden layers.

### B. Autoregressive Integrated Moving Average (ARIMA)

ARIMA forecasts temporal dependencies using only historical values. The data used for Autoregressive models are prepared differently from LSTM. In addition to necessary preprocessing steps, the AR model's data needs to be stationary. Simply put, data is stationary when its numeric properties do not change over time. From a mathematical perspective, it refers to the data whose Mean and Variance will not depend on time. If the data doesn't meet the properties of the stationary dataset, you can do a series transformation to make it stationary.

ARIMA model is a combination of two models Autoregressive (AR) and Moving Average (MA), integration (I) is applied at least once to make the data set stationary.

In the AR part of the model future values are predicted using the lags from the data values. The general equation AR model is:

$$AR(p): x_t = \alpha + \sum_{i=1}^p \beta_i x_{t-i} + \epsilon$$

The Moving Average is the part of the model where value is forecasted using the forecasting error differences is calculated while making predictions. The general form of MA equations is:

$$x_t = \mu + \sum_{i=1}^q \Phi_i \epsilon_{t-1}$$

Prediction is done by combining all three orders and getting an estimation of how to quickly fit the model. Some standard denotations are used to represent the above three, i.e.  $p$ ,  $d$ , and  $q$ ; " $p$ " is the number of observations included in the model, " $d$ " is the number of times differentiating the raw observations, " $q$ " is the number of moving average size. To find these parameters, first fetch a Correlation and Partial Correlational graph from the dataset.

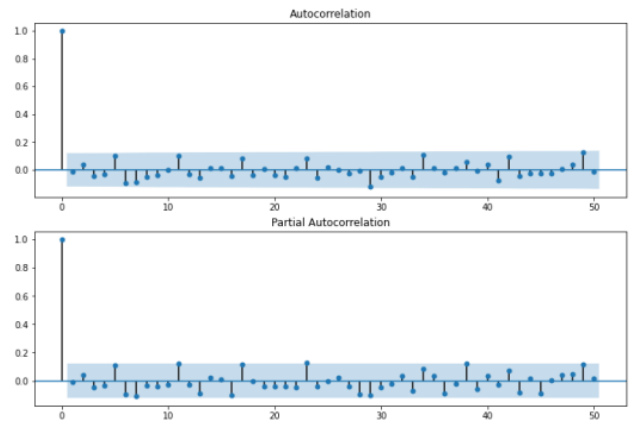

Fig. 7. Autocorrelation graph of sheet 1 data.

Fig. 8. Autocorrelation graph of sheet 7 data.

Fig. 7 and 8 can be used to roughly estimate the value of  $p$ ,  $d$ , and  $q$ . The integer value of  $p$  can be obtained from the cut-off edge points of PAC graphs. Similarly, the value of  $q$  can be obtained using an AC graph. If the graph does not represent steady cut-off points, use in-built PACF and CAF functions.

Fig. 9 shows how the ARIMA works and on which parameters its working can be evaluated.

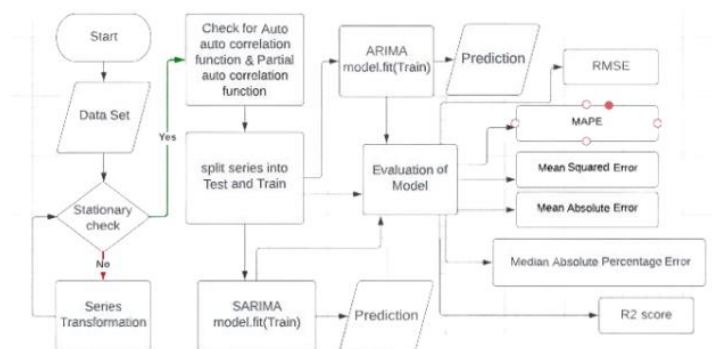

Fig. 9. Flowchart for ARIMA working.

## V. EVALUATION PARAMETERS FOR MODEL'S PERFORMANCE

Taking note of the significance of time series models, it is very important to examine the results of these models. For specific industries, the targeted values of forecasting models are the milestones for making decisions [9]. Artificial intelligence learning models are always trained using real-world data. They are prepared to use for actual problems, so they are usually tested using the same type of data.

Keeping in view the importance of time series models, scientists have devised a number of ways to test the audacity of the models used. In this part, the performance parameters the will be used to evaluate the models will be discussed, and how best model among them will be picked. Following are the parameters used for testing model's prediction validation.

### A. R Square Score - R2 Score

It's a statistical value that is used in a prediction model to find the extent of difference between dependent variables that can be made sense of by the independent factor. In simple words, R2 is how well the testing data fits the trained regression model. The general formula used to calculate the R2 score of the training models is.

$R^2 = 1 - \frac{\text{sum of squares due to regressions}}{\text{total sum of squares}}$

The R2 score can only be calculated for both. The R2 values for both models are displayed in Table I.

TABLE I. R2 VALUES

R2 Score	LSTM	ARIMA
Sheet 1	-0.2142	0.826684
Sheet 7	-0.3214	0.7389812

### B. Mean Square Error - MSE

It is the mean square of differences between the trained model values and tested values. It squares the values of the differences in order to remove the negative sign and increase the weight of the larger values. The formula used to calculate the MSE is

$$MSE = \sum (X_t - X'_t)^2 / n$$

n = Number of items forecasted

t = Time period values

X = actual values of the dependable variable (In the case, actual values of the highest prices)

X' = Prediction values of the dependable Variable

In order to estimate the performance of the model, calculate MSE, the smaller a value is the better the model prediction. The MSE value for the ARIMA model (Sheet 1 & Sheet 2; 0.033151 and 0.015704).

### C. Root Mean Square Error - RMSE

RMSE is obtained by taking the square root of MSE equations. Root square is added in order to return the MSE value to become consistent, not compromising the ability to

penalize error. There are certain models that contain inconsistent but larger errors. To calculate the possibility of occurring such an error, compare RMSE with MAE to see if such errors are present. The RMSE value for LSTM is (Sheet 1 & Sheet 2; 0.088/0.474 and 0.130/0.232).

### D. Mean Absolute Error - MAE

It is the mean of the absolute difference between the observed value, and the real observation value. In other words, it tells how much larger the difference between actual and predicted values which can be expected from the model. The smaller the value of MAE, the better the model will work. If the value is zero, the model can predict future values accurately. Models are compared on the basis of MAE values such as; a model with a smaller MAE will be considered best among all. MAE simply calculates the error; it can't identify the weightage of individual values. The general equation used to measure MAE is:

$$MAE = \sum (X - X') / n$$

The MAE value for ARIMA is (Sheet 1 & Sheet 2; 0.111602 and 0.071160).

### E. Mean Absolute Percentage Error - MAPE

MAPE is obtained by measuring the percentage of MAE to the real values, (In this case it's X - Real values of Prices. Mainly find MAPE, when data is without Zeroes and Extreme values. Read this error the same as MAE which means the lower MAPE value model is the best model. The MAPE value for ARIMA is (Sheet 1 & Sheet 2; 0.011073 and 0.007107).

### F. Median Absolute Percentage Error - MDAPE

A little modification is done in MAPE - Mean Absolute percentage error in order to get MdAPE. The median of the MAE is found by arranging the values from the smallest to the largest; then the middle value only if it's even is picked as MdAPE.

MdAPE is recommended for evaluation when you are dealing with ARIMA models. MDAPE evaluation is done for ARIMA models. MdAE Percentage is interpreted as good when it's between 10% and 20%. The RMSE value for ARIMA is (Sheet 1 & Sheet 2; 0.630533 and 0.333124).

In addition to all the parameters mentioned above, also study the avg\_loss and val\_loss graphs to evaluate models like LSTM. These additional parameters help to evaluate and compare the two models better.

## VI. RESULTS

The purpose of the research is to know which model is the best-performing model for the Highest Price value prediction among the two that have trained using different Python libraries. The results will comprehend using graphs combined with the evaluation parameters explained above.

As mentioned, two sets of Data have been used; Sheet 1 & Sheet 7 from the dataset of Mulkia Gulf Real Estate available at Saudi Exchanges. The first model trained on this data is Long Short Term Memory (LSTM). The evaluation graph shows the regression between actual trained and prediction train values from sheet 1 to sheet 7 as follows:

Fig. 10. Sheet 1 LSTM prediction.

Fig. 11. Sheet 7 LSTM prediction.

Fig. 10 and 11 shows the regression differences present between actual value and predicted values. The LSTM model is evaluated using RMSE, avg\_loss, and val\_loss. The RMSE value for sheet 1 is 0.088 & for sheet 7 is 0.130. The average and validation losses are between 0.08 and 0.17.

The next model trained was the Autoregressive Integrated Moving Average (ARIMA) model made by importing ARIMA from statsmodels.tsa library from python. The graphs indicating the model results for real and predicted values are:

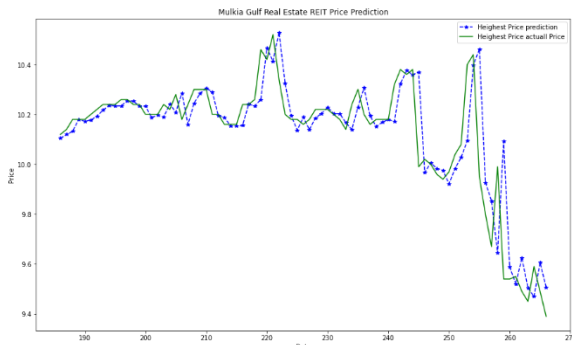

Fig. 12. Sheet 1 ARIMA prediction.

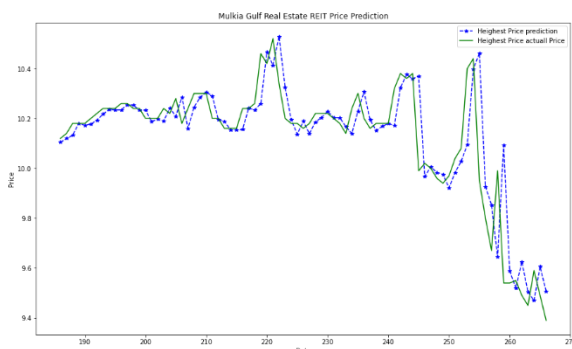

Fig. 13. Sheet 1 ARIMA prediction.

The visualization shows (Fig. 12 & 13) shows very little difference between the actual value and the predicted values from ARIMA.

The mathematical evaluation of ARIMA was done using MAE, MAPE, MdAPE, and MSE. You can read those values from tables. The overall values gave an idea that ARIMA can predict the future highest price more accurately than LSTM.

## VII. CONCLUSIONS

In this paper, the time series forecasting problem is explained. In this paper, the highest price prediction using two python in-built models (i.e. LSTM & ARIMA) is done. The data is trained on the Mulikia Gulf Real State dataset. The dataset is pre-processed and trained on deep-learning models. After training evaluation of models is done using evaluation parameters; MAE, MSE, RMSE, val\_loss, accuracy, R2 score, etc. The values of these parameters collectively determine which model performed the best. These parameters indicate that the ARIMA model can predict the highest price more accurately. When viewed from the graphical point of view, there is very little difference between actual values and predicted values in Fig. 12 and 13, this shows that ARIMA can predict more precisely as compared to LSTMs. Overall, it was concluded that for stock price prediction, ARIMA models can perform better than LSTM Models.

**Abstract**—In the era of cloud computing, the effectiveness of utilizing supervised machine-learning-based intrusion detection models for categorizing and detecting malicious network attacks depends on the preparation, extraction, and selection of the optimal subset of features from the dataset. Therefore, before beginning the training phase of the machine learning classifier models, it is required to remove redundant data, manage missing values, extract statistical features from the dataset, and choose the most valuable and appropriate attributes using the Python Jupyter Notebook. In this study, partitioning-based recursive feature elimination (PRFE) method was suggested to decrease the complexity space and training time for machine learning models while increasing the accuracy rate of detecting malicious attacks. On the information security and object technology cloud intrusion dataset (ISOT-CID), some of the most popular supervised machine learning classification techniques, including support vector machines (SVM) and decision trees (DT), have been assessed using the suggested PRFE technique. In comparison to some of the most popular filter and wrapper-based feature selection strategies, the results of the practical experiments demonstrated an improvement in accuracy, recall, F-score, and precision rate after using the PRFE technique on the ISOT-CID dataset. Additionally, the time required to train the machine-learning models was reduced.

**Keywords**—Machine learning models; big cloud environment; intrusion detection system (IDS); Jupyter Notebook; feature selection; ISOT-CID introduction

## I. INTRODUCTION

In the era of cloud computing and with the steady growth in the volume of transmitted and received data, machine learning models have emerged as one of the most significant contemporary techniques used to recognize and categorize dangerous assaults from network traffic. Preprocessing techniques on the data are therefore necessary in order to increase the precision and effectiveness of these models. A fundamental set of sub processes known as data preparation comprises steps including deleting duplicate data, filling in missing values, and turning some categorical data into numerical data so that machine learning models can interpret it [1], [2]. In a machine-learning process, incoming data is analyzed by computers to create patterns that foretell learning outcomes with a minimum of human input [3]. Based on how

the learning algorithm is implemented, machine learning models can be divided into three groups.

The supervised machine learning (SML) model is used when the data available for the training phase is labelled, which means that some dataset attributes contain the correct answer that will be used at the end of the learning process to evaluate the final outputs. This model can be developed using either classification or regression algorithms [4], [5]. When dealing with a dataset that lacks labelled features, the unsupervised machine learning (UML) model is used and relied on; the model instead relies on trial and error to evaluate the learning process's outcomes. Moreover, this model can be developed using clustering algorithms [6]. While the reinforcement machine learning (RML) model evaluates the outcomes of the learning process based on the existence of an entity that performs a set of actions in a specific environment, a reward is given if the action matches the desired result. This model can be done with value-based, policy-based, and model-based algorithms [7].

One of the key elements influencing how well supervised machine learning models can detect and categorize harmful intrusions is feature engineering [8]. This can be done by selecting the dataset's most significant and connected features to the model outputs, a process known as feature selection, and then creating a new feature from the already accessible ISOT-CID dataset, a process known as feature extraction [9], [10].

In the feature selection phase, duplicated features and features that were not related to the outcomes of the learning process were excluded from the ISOT-CID dataset. The focus is only on the features that are most influential in building the detection model and are related to the results of the learning process, which would reduce the time required in the data training process and improve the quality of the outputs. The methods for selecting features can be divided into three types. In the filtering method, the degree of variance is calculated for each feature in the dataset, and higher or equal features are selected by the user based on a predetermined variance threshold [11]. One disadvantage of this method is that it does not consider the relationship between the selected features and target variables.

The wrapper technique uses a sophisticated search algorithm to analyze every feature combination in the dataset, then uses a machine-learning algorithm to evaluate the learning outcomes and choose the feature set that produces the best output. The high rate of classification accuracy for malicious attacks is one of this method's key benefits in terms of selecting the best features. The exorbitant expense and complexity of this technology are also disadvantages. Forward selection (FS), backward selection (BS), and recursive feature elimination (RFE) are three of the most significant algorithms utilized in this strategy [12]. The filter and wrapper methods' issues are addressed by the hybrid approach. There are two sections to the process. The features of the dataset were first created using a filtering technique. In the subsequent step, wrapper techniques were used to select the best features. Two of the most crucial algorithms used in this method are random forest importance (RFI) and LASSO regularization (LR) [13], [14].

The remainder of this paper is organized as follows: The literature review is summarized in Section II. Section III presents the research methodology and the five steps involved in this investigation. A detailed description of the ISOT-CID datasets is provided, along with information on the proposed partitioning-based recursive feature elimination (PRFE) technique, model flowchart, algorithm, performance metrics, research findings, and building ML classifier models. Section IV describes the discussion of results. The final Section V of this paper presents conclusions and suggestions for future research.

## II. LITERATURE REVIEW

This section consists of two main parts. The first part focuses on reviewing and analyzing some of the previous work on supervised machine learning classifier algorithms, such as support vector machines, decision trees, naive Bayes, and k-nearest neighbor algorithms, and their improvements. In addition, the main limitations of each approach were identified. In the second part, we look back at some of the previous studies on feature selection techniques and analyze them. We explain the main improvements and limitations of each technique.

### A. Machine Learning Classifier Algorithms

Without human interaction, intrusion detection systems can recognize new assaults using machine learning (ML). The IDS is able to modify its execution plan by using ML and taking into account recently acquired data. The two main categories of learning strategies are supervised and unsupervised strategies. In supervised learning, examples with input and output labels provided during training are used to "train" algorithms [15]. The unsupervised learning algorithms are allowed to make their own interpretations of the data because the training dataset is empty of labelled data. Unsupervised learning employs clustering and association algorithms to find patterns and distinctions in the data [16].

Peng et al. suggested using supervised machine-learning methods to categorize harmful attacks in a cloud environment and develop a decision tree-based model for intrusion detection. In order to guarantee the efficacy, excellence, and

accuracy of the proposed models for categorizing hostile assaults, researchers have relied on a variety of preprocessing methods to prepare and clean enormous datasets. The suggested model was found to be more efficient and effective than naive Bayesian and k-nearest neighbor models in laboratory trials using the Knowledge Discovery and Data Mining (KDDCUP99) dataset. The decision tree's training duration is not ideal, though, and this is its biggest drawback. Additionally, only the k-nearest neighbor and naive Bayesian models were contrasted with the decision tree model [17].

Using the Apache Spark machine learning library, Belouch et al. conducted a comparison study to assess the effectiveness and detection accuracy of support vector machines, random forests, decision, and naive Bayes algorithms (MLLIB). The results of the lab tests performed on the UNSW-NB15 dataset demonstrated the random forest algorithm's efficiency and effectiveness in comparison to other models. The greatest issue is that the model takes a long time to create and train because the feature selection technique isn't used [18].

Belavagi and Muniyal offered classification and predictive models for intrusion detection using machine learning classification techniques as logistic regression, support vector machine, naive Bayes, and random forest (RF). The techniques are evaluated using the Network Security Laboratory- Knowledge Discovery in Databases (NSL-KDD) dataset. The testing findings demonstrated that, with a peak value of 99%, the Random Forest classifier outperformed the other techniques in all criteria. However, the use of feature selection strategies to choose the best features from the dataset in order to minimize dimensionality is not examined in this paper [19].

An intrusion detection-based big data model was suggested by Azeroual and Nikiforova using unsupervised machine learning and the K-means clustering technique. The correlation-based filter method is used by the author to select the attributes that have the greatest impact on the results of the learning process. The Synchro Phasor dataset used in the laboratory tests revealed a high degree of classification accuracy for harmful attacks. However, the fundamental issue is that the lack of test support in the Apache Spark framework prevented the authors from comparing the suggested model to other solutions [20].

Souhail et al. suggested a two-stage network-based IDS (NIDS) technique to recognize network threats. The proposed approach combines LR, gradient boost machine (GBM), support vector machine (SVM), recursive feature elimination (RFE), and random forest feature selection methods for the complete UNSW-NB15 dataset. The results showed that the accuracy rate of multi-classifiers using decision trees was about 86.04%. Due to the usage of the recursive feature elimination-based feature selection technique, the key restriction is the amount of time needed to create and train the model [21].

A detection framework using an ML model was proposed by Alshammari and Aldrabi to feed IDS and detect abnormal network traffic in cloud environments. An ISOT-CID dataset containing both malicious and normal traffic is used in this detection method. Six machine-learning models were trained

using this dataset, and they were then tested using split- and cross-validation techniques. Only two of the results were satisfactory, but the other four were accurate enough to be useful. The model's reliance on a large dataset or considerable dataset, which has an impact on how well the system is fitted and evaluated, is the biggest drawback, though [22].

### B. Feature Selection Algorithms

Using evolutionary algorithms and support vector machines, Ashahri et al. suggested an embedding-based feature selection technique to minimize the number of dataset features from 45 to 10. The ten traits that had been chosen were then divided into three groups based on their level of significance in the following stage. Laboratory tests revealed that the suggested hybrid algorithm has a true-positive value of 0.973 and a false-positive value of 0.017 [23].

Based on 70% of the DDOS dataset from NSL-KDD, Mohammed and Gyasi suggested an intrusion detection system for distributed denial-of-service (DDOS). Random forest (RF) and multilayer perceptron (MLP) were utilized for the detection tasks, and recursive feature elimination (RFE) was used to choose the top 10 features. With receiver operating characteristic (ROC) ratings of 91% and 97%, respectively, their binary classification findings were precise. However, the accuracy and ROC score of our suggested binary classification were 99.86% and 99.7%, respectively. Furthermore, all of the assaults in the sample were found using our intrusion detection technology. However, due to the usage of the recursive feature elimination-based feature selection technique, the key restriction is the amount of time required to create and train the model. Additionally, a sizable dataset must be used to assess the proposed model's efficacy [24].

The stratified k-fold cross-validation (SKCV) method was proposed by Prusty et al. to improve classification accuracy by removing redundant and weak features whose deletion had the least impact on the training error while retaining an independent and strong feature to improve the generalization performance of the model and address the overfitting problem (RFE). This method creates a model with the whole set of features before prioritizing them based on relevance. The model was then rebuilt with the lowest priority feature deleted, and the feature importance estimate was revised. However, developing and refining the model using the SKCV method takes a lot of time [25].

For the NIDS methodology, Kasongo and Sun combined the filter-based feature selection technique of the XGBoost algorithm with five classification algorithms: logistic regression (LR), k-nearest neighbors, artificial neural network (ANN), decision tree, and support vector machines. This study uses binary and multiclass classification using the UNSW-NB15 dataset. Multiclass classification performed poorly, with the maximum accuracy being just 82.66%, while binary classification using the k-nearest neighbor classifier did well, with an accuracy of 96.76%. However, a sizable dataset must be used to assess the suggested model's efficacy. The classification model is unaffected by the filter-based strategy of selecting characteristics as well [26].

The intrusion detection model proposed by Thaseen and Kumar uses a multi-class SVM classifier and a rank-based chi-square feature selection technique. The chi-squared test can be used to determine the deviation from the predicted distribution when the feature event is thought to be independent of the class value. A multi-class SVM is used to categorize the various sorts of attacks in the NSL-KDD dataset. Using the proposed model, 31 features were selected from a total of 41. The accuracy rate of the suggested system was 98%, while the false positive rate was 0.13% [27].

### III. PROPOSED METHODOLOGY

The methodology of this experimental study consists of five stages. First, the flow features were extracted using a CIC flow meter tool. In the second stage, dataset preprocessing was performed, and in the third stage, the best subset features were selected using the proposed PRFE technique. In the fourth step, a machine learning detection model is made. Finally, using the proposed PRFE technique and the ISOT-CID dataset, some supervised machine learning techniques are tested. Fig. 1 illustrates the five phases of the experimental study, which will be discussed in the remainder of this research.

Fig. 1. Research methodology phases.

### A. Features Extraction

As shown in Fig. 2, the original ISOT-CID dataset consists of 12 attributes and 6,293,326 records [28]. In this study, a CIC flow meter was used to extract statistical and analytical features from the network flow. The CIC flow meter is a Java open-source tool that can generate and extract row attributes from huge Packet Capture (pcap) files and save the results in the comma-separated value (CSV) file format. Eighty-five network flow attributes were extracted from the ISOT-CID dataset using the CIC Flow Meter tool. The list of extracted features will be reduced to 80 after eliminating the five features that contained more than 90% missing data. Then, the proposed PRFE-based feature selection technique is used to choose the best, most important and most influential features of the learning process output [29]. Fig. 3 illustrates the number of features and records in the ISOT-CID dataset after the feature extraction stage.

### B. Dataset Preprocessing

The dataset used in the actual experiments in this study was ISOT-CID, which is considered the first huge, public, and labelled cloud intrusion detection dataset. The size of the ISOT-CID dataset is greater than 2.5 TB, and it consists of normal and malicious traffic activity collected from different cloud tiers, virtual machine hosts, and hypervisors. ISOT-CID data is collected in two phases and consists of different data formats, such as network traffic, CPU utilization, memory dumps, and event logs. The dataset consists of several types of attacks, including remote to local (R2L), input validation, backdoors, Denial of Service (DOS) and probing.

Fig. 3. ISOT-CID dataset after features extraction.

1) *Eliminate the missing values*: The dataset always needs to be reprocessed to remove duplicate and missing data before being used in the training phase of machine learning models, because relying on this dataset without processing would affect the quality of the learning results. A Python Jupyter Notebook was used to process and eliminate missing values in the ISOT-CID dataset. As shown in Fig. 4, some values in the flag, protocol, and fragment columns are missing.

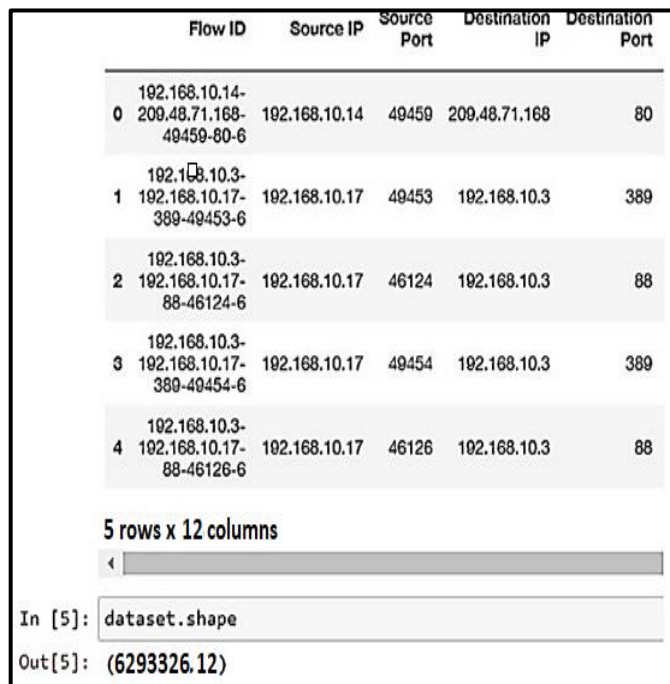

Fig. 2. ISOT-CID dataset before features extraction.

```

Fig. 5. ISOT-CID after handling missing values.

Fig. 5 shows the ISOT-CID dataset after the missing values were taken care of by dropping them using the Python Jupyter Notebook. This improved the machine learning model's ability to classify and find malicious traffic.

2) *Label encoding for categorical data:* Dealing with machine learning algorithms to detect and classify malicious assaults in a big cloud environment requires encoding and converting some of the textual data that exists in the dataset into digital and numeric data to enhance and increase the level of accuracy of the learning results. As shown in Fig. 6, categorical attributes were converted to (0, 1) instead of (benign or malicious) attributes using the label encoding method.

```
In [11]: dummy = pd.get_dummies(dataset['classification'])

Out[12]:
```

	benign	malicious
0	1	0
1	1	0
2	1	0
3	1	0
4	1	0

Fig. 6. Encoding the categorical into numeric data.

3) *Handling the imbalanced-labelled data:* Class imbalance is a machine learning issue where the classes are not evenly represented in the data. This can cause issues while training machine learning models because the models may be biased towards the more prevalent class. The model will be more likely to pick up on and predict the majority class if

there are more samples of one class than the other. As a result, when the model is used to analyze data that is more evenly distributed, it may produce erroneous conclusions. Addressing unbalanced classification difficulties is a challenge in developing models with good performance. Fig. 7 illustrates the number of benign and malicious objects in the classification class before handling the imbalanced labelled data using the oversampling technique.

Synthetic Minority Oversampling Technique (SMOTE) is a method of oversampling, in which artificial samples are produced for the minority class. This method solves the overfitting problem caused by random oversampling. By interpolating nearby positive examples, we focused on the feature space to create new examples. Fig. 8 illustrates the number of benign and malicious objects in the classification class after handling the imbalanced labelled data.

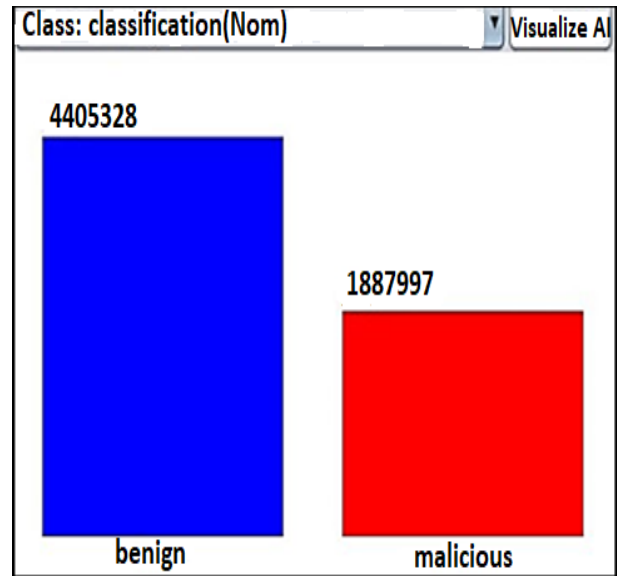

Fig. 7. Classification attribute before using SMOT.

Fig. 8. Classification attribute after using SMOT.

### C. Proposed Features Selection Algorithm (PRFE)

Feature selection is a technique used to improve the accuracy of malicious attack classification by selecting the attributes that are the most important and significant to the outcome of the learning process and eliminating the least informative attributes. In this study, the ISOT-CID dataset was used to find the most useful attributes. To deal with labelled datasets, a supervised-based feature selection method was used [30]. Recursive feature elimination is a wrapper-based feature selection approach that assesses the significance of features using a machine-learning algorithm. All dataset features were used to train and fit the ML classifier model in the initial stages of recursive feature elimination, and the feature importance was calculated for each feature. The recursive feature elimination model is used repeatedly, with the least important features being thrown out and the most important ones being saved for the next round, until the best features are found. The partitioning-based recursive feature elimination (PRFE) technique was proposed in this study to improve the accuracy rate of classifying and detecting malicious attacks while reducing the complexity space and time required training the ML classifier models. Algorithm 1 illustrates the Partitioning-based Recursive Feature Elimination (PRFE) algorithm for selecting optimal features from the ISOT-CID dataset.

---

**Algorithm 1:** Partitioning based Recursive Feature Elimination (PRFE)

---

#Input

F: set of features where  $F = \{f_1, f_2 \dots f_n\}$

N: number of the required features

G: the number of groups where:  $1 < G \leq N$

$i = 1$

#Output

O: ordered ranked features.

R: ordered ranked groups.

Step 1: Train the model using all attributes

Step 2: Compute the model's accuracy

Step 3: Calculate and ranking the feature importance using the RFE-impotence class  $F_i^{\text{rank}}$  where  $i = 1 \dots N$  (N is the number of features).

Step 4: Divided the feature into equal number of groups (G), where numbers of features in each group are equal.

Note:  $G[i]$  contains number of features.

Step 5: Ranking and sorting the groups (G) in ascending order based on their features weight.

Step 6: Eliminating the lowest weighted group.

Step 7: Build ML classifier model and calculate model performance.

Step 8:  $i = i + 1$

Step 9: If  $i \neq G-1$

Repeat step 4 to step 7 until  $i = G-1$

End

---

Fig. 9. Partitioning based Recursive Feature Elimination (PRFE) flowchart.

As shown in Fig. 9, the process of selecting optimal features from the ISOT-CID dataset using the PRFE technique occurs in two stages. In the first stage, the RFE importance class was used to rank and sort the feature subsets individually according to their importance and how strongly they were related to the outcomes of the learning process. In the second stage, the features are partitioned into groups, with an equal number of features in each group. For example, if we have 100 attributes, we can divide them into ten groups, each with ten attributes. Subsequently, the groups are ranked and sorted in ascending order, the lowest weighted group is eliminated in each iteration, and the training procedure for the remaining groups is repeated to obtain the best group of features. So, the number of tests went from 100 to 10, and the space and time needed to train the machine learning models became less complicated.

### D. Building the Machine Learning Classifier Models

For supervised learning, the ISOT-CID dataset was divided into training and testing sets. As a result, 80 % of the data were chosen at random and used to train machine-learning models, whereas the remaining 20% were utilized to evaluate the classifier's performance. Table I illustrates the statistics of the ISOT-CID Dataset used in this study.

TABLE I. STATISTICS OF THE ISOT-CID DATASET

Traffic Type	Total	Training 80%	Testing 20%
benign	3112457	2489965.6	622491.4
malicious	3180869	2544695.2	636173.8
Total	6293326	5034660.8	1258665.2

To evaluate the performance of the machine learning classifier models with different sets of selected features, accuracy, precision, recall, F-score, and error performance measurements were utilized. A confusion matrix was used to calculate the classifier performance indicators. "True positive" (TP) denotes benign instances that are correctly predicted, true negative (TN) denotes malicious instances that are correctly identified, false positive (FP) denotes malicious instances that are incorrectly assumed to be normal, and false negative (FN) denotes malicious instances that are incorrectly detected as normal [28]. Table II illustrates the five metrics that are commonly used to measure and evaluate the effectiveness of machine learning classification models.

TABLE II. PERFORMANCE METRICS FOR ML CLASSIFICATION MODELS

Metric	Formula	Interpretation
Accuracy	$\frac{TP+TN}{TP+TN+FP+FN}$	Overall performance of model
Precision	$\frac{TP}{TP+FP}$	How accurate the positive predictions are
Recall Sensitivity	$\frac{TN}{TN+FP}$	Coverage of actual positive sample
F1 score	$\frac{2TP}{2TP + FP+FN}$	Hybrid metric useful for unbalanced classes
Error Rate	$\frac{FP+FN}{TP+TN+FP+FN}$	the percentage of the classification that is done wrongly

E. Experiment Findings and Analysis

1) *The experiment setup:* Using the HP Z Book G3 workstation with Microsoft Windows 11 64-bit Enterprise edition and an Intel Core i7-6820HQ CPU @ 2.7GHz, 32GB RAM, the novel proposed PRFE approach was created using the Python version 3 code, which was implemented using the Jupyter Notebook platform and Anaconda virtual environment for Windows to execute Scikit-learn, NumPy, and Panda's libraries.

2) *The experiment findings:* Accuracy is one of the most important performance metrics in intrusion detection. The accuracy of the four supervised machine-learning classifiers using the proposed PRFE method outperformed the RFECV and RFE techniques in terms of overall performance. When PRFE-based selected features were used instead of RFECV- and RFE-based selected features, accuracy improved by approximately 0.75% and 2.25%, respectively. As shown in Fig. 10, with PRFE-based selected features, the Support

Vector Machine (SVM) classifier achieved the highest accuracy percentage of 99.25%. The k-nearest neighbor (KNN) classifier performed the worst in this trial. In general, the four machine-learning classifier models were more accurate after they used PRFE-based feature selection.

As shown in Fig. 11, the precision findings, which demonstrate the classifier's percentage of accurately identified instances, which is one of the key markers of excellent models. Classifiers trained with PRFE-based selected features outperformed those trained with RFECV and RFE-based selected features. When compared to other classifiers, the support vector machine (SVM) has the highest precision percentage of 98.80%. In contrast to prior results, the k-nearest neighbor (KNN) classifier has the lowest precision percentage in this trial, with a value of 96.50%. In general, the four machine-learning classifier models were more accurate when they used the PRFE-based feature selection method.

Fig. 10. Accuracy percentage comparison among PRFE, RFECV and RFE algorithm.

Fig. 11. Precision percentage comparison among PRFE, RFECV and RFE algorithm.

Fig. 12 shows the recall and sensitivity rates of the prediction models. Classifiers trained with PRFE-based selected features outperformed those trained with RFECV and RFE-based selected features. When compared to other classifiers, the decision tree classifier had the highest precision

percentage of 99%. In this experiment, naive Bayes exhibited the lowest precision percentage (97%). In general, the recall rate of the four machine learning classifier models got better when they used the PRFE-based feature selection method.

Fig. 12. Recall percentage comparison among PRFE, RFECV and RFE algorithm.

classifiers' f-scores performed better than when RFECV- and RFE-based selected features were used. With PRFE's chosen features, the support vector machine (SVM) classifier achieved the greatest f-score percentage of 99%. The k-nearest neighbor (KNN) classifier performed the worst in this trial with 97.5% (Table III).

Fig. 13. F-Score percentage comparison among PRFE, RFECV and RFE algorithm.

Fig. 13 shows the f-score rate of the predictive models. In general, when PRFE-based selected features were used, the

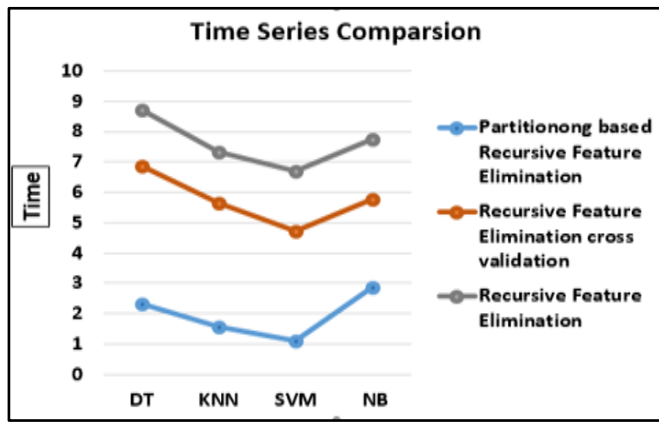

Fig. 14. Time series comparison among PRFE, RFECV and RFE algorithm.

Fig. 14 indicates a decrease in the time required to train the model using the proposed PRFE method compared to RFECV and RFE techniques.

#### IV. DISCUSSION OF RESULTS

The ISOT-CID dataset was used for the evaluation experiments, which were carried out using Python programming and the Jupyter Notebook. In the evaluation experiment, the proposed PRFE was compared with RFE- and RFECV-based feature selection techniques. The comparison with the other approaches is defined in terms of accuracy, precision, recall, F-score, and time series. The evaluation trial demonstrates PRFE's advantages over competitors. Therefore, in this section, we will discuss how it stacks up against more modern research methods.

The traditional methods for selecting the most important features in the previous studies were characterized by simplicity and the low time required training machine learning models, while suffering from a low level of accuracy in identifying and detecting malicious attacks. Modern methods focus on raising the level of accuracy while neglecting the time required training machine learning models. Therefore, the proposed PRFE technique enhances the accuracy rate by combining supervised machine learning classifier models with partitioning-based recursive feature elimination techniques. This led to an increase in the level of accuracy in identifying and detecting malicious attacks to 99.25, while simultaneously reducing the time required to train automated training models to 1.2 minutes. Because this study deals with the cloud-based intrusion detection system (CIDS), the proposed PRFE technique was evaluated using the ISOT-CID dataset, which is considered one of the first public datasets of its kind collected from a production cloud environment. Most previous studies lacked datasets from a real cloud computing environment that were available to the public. This made it hard to make and test realistic detection models.

#### V. CONCLUSION AND FUTURE WORKS

Feature engineering techniques such as data preprocessing, feature extraction, and feature selection should be used to reduce the dimensionality of the input features, improve model performance, and shorten model computational time. Choosing the most relevant and influential characteristics has

traditionally affected the power and predictability of the final classifier model. The most pertinent and effective features were chosen from large datasets using a variety of feature selection techniques, including chi-square, information gain, backward feature elimination, and recursive feature elimination. In this study, a PRFE-based feature selection method was developed to classify and select the optimal feature subset from ISOT-CID, which is considered one of the largest public intrusion detection datasets. The best feature subset was selected by partitioning the features into groups with an equal number of features in each group and eliminating the lowest-weighted group in each iteration. The PRFE method improved accuracy, precision, recall, and F-score rate while cutting training time by ignoring one group instead of removing one feature at each iteration.

In this experimental study, the proposed PRFE-based feature selection technique was first compared with recursive feature elimination (RFE) and recursive feature elimination with cross-validation (RFECV) techniques. The results showed that the proposed PRFE technique improved the accuracy, precision, recall, and F-score percentage with the four common machine learning classifier models compared to the RFE and RFECV techniques. Second, a few popular filter- and wrapper-based feature selection methods, including chi-square, information gain, and backward feature removal, are compared to the proposed PRFE-based feature selection strategy. The results of the experiments show that when the PRFE method is used with four popular machine learning classifier models, the accuracy, precision, recall, and F-score percentage are all higher than when the chi-square, information gain, and backward feature elimination strategies are used. In future work, a new unsupervised deep learning algorithm for detecting zero-day attacks will be proposed. This algorithm will use different neural network topologies, such as fully connected, recurrent, and temporal convolutional models, to reduce the number of false alarms while maintaining the accuracy of detecting and classifying malicious network attacks.

# Parameter Extraction and Performance Analysis of 3D Surface Reconstruction Techniques

Richha Sharma<sup>1</sup>, Pawanesh Abrol<sup>2</sup>  
Dept. of CS & IT, University of Jammu, Jammu, India<sup>1,2</sup>

**Abstract**—Digital image-based 3D surface reconstruction is a streamlined and proper means of studying the features of the object being modelled. The generation of true 3D content is a very crucial step in any 3D system. A methodology to reconstruct a 3D surface of objects from a set of digital images is presented in this paper. It is simple, robust, and can be freely used for the construction of 3D surfaces from images. Digital images are taken as input to generate sparse and dense point clouds in 3D space from the detected and matched features. Poisson Surface, Ball Pivoting, and Alpha shape reconstruction algorithms have been used to reconstruct photo-realistic surfaces. Various parameters of these algorithms that are critical to the quality of reconstruction are identified and the effect of these parameters with varying values is studied. The results presented in this study will give readers an insight into the behaviour of various algorithmic parameters with computation time and fineness of reconstruction.

**Keywords**—3D reconstruction; point cloud; feature detection; feature matching

## I. INTRODUCTION

The 3D reconstruction process can generate the photo-realistic 3D surfaces of objects using their digital images to generate their sparse and dense 3D point clouds. The generated point cloud (PC) data is to be transformed into a substantial digital representation of the scanned objects to enable its use in numerous application fields including Computer-Aided Design, Medical Imaging, Reverse Engineering, Virtual Reality, and Architectural Modeling [1]. Since object surfaces in point clouds are to be reconstructed, various reconstruction approaches have been proposed over years to fast-track the research in this area. Earlier, 3D reconstruction was mainly applied in the field of Industrial and Architectural design, Animation industry, Medical Modeling, Robotics, etc. but with the advent of Machine Learning and 3D vision technology, the application range has widened to other fields like autonomous driving, remote sensing, 3D printing, and even online shopping. The sample points can be generated from the laser scanner, photogrammetry technique, or some mathematical function. In most cases, the sample points will elucidate the shape and topology of the object's surface. Algorithms for surface reconstruction (SR) are applied to the sample points, and to obtain a 3D model of the object [2]. 3D reconstruction can usually be done in three manners 1) Using 3D modeling software like AutoCAD, FreeCAD, 3D MAX, etc. 2) Using 3D scanners to obtain models in real-time. 3) Using digital images with the help of RGB-D cameras. Close-range photogrammetry has been dealing with manual or

programmed picture measurements for accurate 3D modelling. Although many applications utilize 3D scanners as a regular source of data input, image-based modelling is still the most thorough, affordable, portable, adaptable, and widely-used method. It is a low-priced and easy way to obtain depth images. Point cloud obtained from RGB-D data is of middle density with the advantages of being cheap and flexible along with the color information. It is limited to close-range objects with moderate accuracy in applications like Indoor reconstruction, object tracking, human pose recognition; etc. Laser-scanner-based 3D reconstruction of an object is quick and accurate and provides realistic textured 3D surfaces of a scene or object being studied. Because of the high cost and less availability, researchers have been inspired to use photogrammetry to produce realistic 3D surfaces from an object's image. It is used for mapping and modeling common indoor household objects. With the ease of availability of digital cameras and computers in homes and organizations, the processing cost of image-based reconstruction has diminished. The work in this paper evaluates the efficacy of various surface reconstruction techniques. It proposed a framework for reconstructing 3D surfaces that can generate a 3D model of typical indoor objects from their digital photos. Correspondence matching is done over the image sets to obtain a dense set of points that are projected to 3D space. Furthermore, by applying SR techniques to the resulting point cloud, a photo-realistic surface is formed.

The paper is structured as: Section II presents a summary of surface reconstruction algorithms and work related to 3D reconstruction. Section III presents the framework of the used methodology along with a description of the selected algorithms used for reconstruction. Section IV provides a discussion of the experiment with the obtained results. The conclusion and future outline of the work is given in Section V.

## II. RELATED WORK

Reconstructing a 3D surface from an order of digital images comprising a scene/object is a demanding and significant exercise in computer vision. Over the years, authors have employed several SR approaches to create a precise and photorealistic 3D surface from an image or group of images depicting a variety of objects. 3D reconstruction from images (photogrammetry), is a long-standing technique whose potential could only be seen after the development of computers and digital photographs and is widely used in entertainment to create scenarios for games, acquire human expressions, scanning products for commercials, etc.

TABLE I. DESCRIPTION OF SURFACE RECONSTRUCTION ALGORITHMS

Authors	Year	Algorithm	Description
Edelsbrunner and Mucke [3]	1994	Alpha shape algorithm	It is a heuristic approach and performs well in uniform sampling and has the complexity of $O(n^2)$
Bernardini <i>et al</i> [4]	1999	Ball-Pivoting algorithm	Forms a 3D mesh by joining the triangles created by rolling the ball through points. It is data-driven and is sensitive to noise and is not expensive in terms of time and memory and results are of favorable quality.
Amenta <i>et al.</i> [5]	2000	The Crust algorithm	Delaunay Triangulation is estimated employing the Voronoi diagrams over the point cloud forming a smooth surface from unstructured points. It is robust and does not require a hole-filling mechanism. It has the complexity of $O(n \log n)$
Amenta <i>et al.</i> [6]	2001	Power Crust algorithm	It gives approximated polygon surface with the amalgamation of median balls. The algorithm is robust and no hole-filling structure is needed in reconstruction as the factual geometry of the object is captured.
Amenta <i>et al.</i> [7]	2001	Cocone algorithm	Delaunay-based algorithm for surface reconstruction with added post-filtering restrictions. It produces an incomplete surface with a low-density point cloud.
Dey and Goswami [8]	2003	Tight Cocone algorithm	The reconstructed surface uses the 'In' marked computed Cocone tetrahedral triangles. This method is not robust to a noisy and sparse point cloud and has a time complexity of $O(n^2)$ .
Dey and Goswami [9]	2004	Robust Cocone algorithm	It can reconstruct surfaces from noisy points and is also considered a labeling algorithm as it marks cocone triangles as "in" and "out".
Kazhdan <i>et al.</i> [10]	2006	Poisson Surface Reconstruction	The watertight surface is recreated with Marching Cubes (MC) algorithm and stored in an octree. The algorithm is resilient to noise.
Kazhdan <i>et al.</i> [11]	2013	Screened Poisson Surface Reconstruction	It incorporates point constraints in solving the screened Poisson equation to compose the solved indicator function more accurately.

### A. Surface Reconstruction Techniques

From input data, which is classically obtained from 3D scanners or photogrammetry as scattered points in 3D space, the process of SR creates a 3D surface of the object [12]. The surface is then often recreated in the triangulated form (points joined in the form of triangles with sharing edges and/or vertices), depending upon the type of point data employed [13] making a visible, 3D model of a real object. In the field of computer graphics, numerous surface reconstruction techniques have been developed and used. In this paper, a few of the well-known surface reconstruction algorithms are briefly discussed and presented in Table I. A brief description of a few of the algorithms is given in hierarchical order in terms of the year in which they were introduced.

The primary input of the SR process is a digital image set of the object being reconstructed. This is done by detecting features from the image that will help in the process of reconstruction. These feature points are searched for correspondence; projection of the same 3D point of the object across the images [14]. Two feature detection algorithms have been used. SURF (Speeded up Robust Features) focuses on blob-like structures in the image [15]. It is fast, robust, and invariant to rotation and scale which makes it a good feature detection algorithm [16]. Min Eigen Features detect the corners (locations with steep intensity variations in any direction) in an image. Feature matching, generally known as image matching is performed in many computer vision applications like image registration, object identification, and object recognition. It consists of detecting a set of interest points each associated with image descriptors from image data. After the extraction of features from the image set, corresponding feature points are matched. Matching shows that features are from the corresponding locations from completely different images.

There are certain issues and constraints while dealing with point data. The unstructured-ness of data makes it difficult to

implement and reconstruct the surface because of the non-uniformity of input data. Dataset size is another major constraint and can lead to a tradeoff between accuracy and performance. Performance has been always a bottleneck in all computer-based applications in terms of time, memory efficiency accuracy, and completeness.

### III. METHODOLOGY

A digital image sequence of the scene or item being recreated serves as the primary input to the SR process. Fig. 2 demonstrates the process used to recreate an object's 3D surface from a series of digital images. A set of distinguished feature points are found in the image sequence and used for correspondence matching across the photos to begin the 3D reconstruction process. The exhaustive matching of all image points is considerably reduced by feature detection, making it computationally cheap. The robust feature points are also easily recognizable and image transformation-invariant. Consequently, by identifying feature points in the photos, the computation time for correspondence matching is significantly decreased.

The dataset used in the work comprises images of irregular indoor household objects to be reconstructed. It consists of first-hand image data comprising 4 image sets taken from an android phone having a (16+20) MP dual camera placed at a distance of 25 cm from the object. Images were preprocessed to a standard form for further use and Table II shows the parameter values of preprocessed images. Fig. 1 presents the image dataset used as input in this paper for the implementation purpose and the attributes of the images are given in Table II. Image features were detected and extracted from all the images containing the object of interest using the SURF (Speeded Up Robust Features) algorithm. The SURF-identified feature points are readily distinct and invariable to image transformations [17] and hence are then used for correspondence matching.

TABLE II. PARAMETER VALUES OF IMAGES USED FOR IMPLEMENTATION

Parameter	Value
Size of image	1520 x 2048
Min-Quality	0.1
Confidence	99.90
Roi (x, y, width, height)	[30, 30, 2018, 1490]

Fig. 1. The input image dataset.

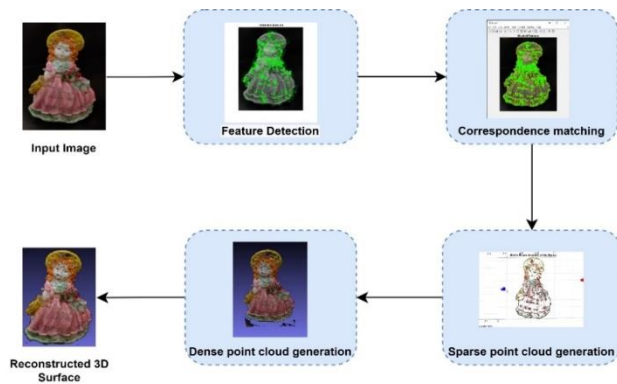

Fig. 2. Methodology of 3D surface reconstruction.

An approximate-nearest-neighbor (ANN) search discovers the matched point pairs. An image pair of the object with enough overlap has been selected for the purpose of matching. The features of the first image were inserted in the k-d tree which acts as queries to the feature points of other images of the pair. The k-d tree has been used for the efficient search of K-nearest neighbors of the feature points. The accuracy of the paired points is then tested using a RANSAC-based estimation. Matches that do not satisfy the basic matrix equation are discarded as non-fits.

SFM has been applied to build sparse point clouds (SPC) from huge image sets. In SFM, correspondence matching finds the matched points from the image set that are triangulated to obtain the 3D location of these points. The obtained point clouds are not dense and do not comprehend the object's geometry or specifics of the scene under reconstruction, hence are inadequate for 3D modelling [18]. Thus, dense correspondence matching must be done to build dense point clouds (DPC) from sparse points of the image sets [19], precisely unfolding the specifics of the scene/object being reconstructed and as shown in Fig. 3.

The pronounced methodology for 3D reconstruction used in this paper is grounded on several well-known algorithms in the fields of correspondence matching, SFM, SR, and so on. Rather than delving into the thorough mathematics of these

techniques, the study focused on the application of existing techniques to create an inexpensive, robust, and simple answer to the problem of 3D reconstruction. Because of its robustness, swiftness, and capability to reconstruct surfaces with irregular geometry, the approach described in this paper is easily applicable to industry. The photogrammetry-based reconstruction method conversed here can efficiently substitute expensive laser scanners as prime 3D reconstruction methods in numerous application areas due to its little workforce requirement and reduced functioning cost. Three surface reconstruction algorithms were tested on a PC generated from digital images. The performance of these reconstruction algorithms is evaluated in terms of time, resource usage, reconstruction quality, and so on. The following section provides brief overviews of these algorithms.

Fig. 3. 3D point cloud of object Image (row1 sparse point cloud, row 2 dense point cloud).

#### A. Poisson Surface Reconstruction (PSR)

PSR intends to create a 3D mesh from a DPC by minimalizing the difference between the surface normal directions of the recreated surface and the 3D points [10] (Fig. 4). The surface normal of each point's surface for the input point cloud is found by computing the eigenvectors over the k-nearest neighbor of each point, and an octree of pre-defined depth is used for storing the reconstructed surface. A 3D indicator function  $x$  is defined as having the value of 1 inside and 0 outside the surface.  $\nabla x$  (grad of the indicator function) is a vector field comprising non-zero values at the points near the surface where  $x$  can be varied.

For the points where  $\nabla x$  is not zero, the value of  $\nabla x$  equates to the surface normal vector of corresponding points and is stated as:

$$\nabla x = V \quad (1)$$

On both sides of the equation, the divergence operator is applied to modify the equation into a standard Poisson problem and can be articulated mathematically as:

$$\Delta x \equiv \nabla \cdot \nabla x = \nabla \cdot V \quad (2)$$

Fig. 4. Flow chart of Poisson surface reconstruction.

The indicator function ( $x$ ) is represented in 3D space for solving the Poisson equation. Octree represents the indicator function and its leaf nodes store  $x$  at various points over the reconstructed surface. The MC algorithm extracts the surface from the indicator function. The algorithm works by marching through the points in a 3D point cloud following the indicator function having a value of 1 close to the surface and 0 afar from the surface. By interpolation of points among the vertices of the cube during the traversal of the octree, a triangulated 3D mesh is generated and stored in the octree. The quality of reconstruction, computation time, etc. of PSR depends upon several parameters like Octree depth ( $D$ ), Samples-per-node ( $S_n$ ), and Surface offsetting ( $S_{off}$ ). An octree with depth  $D$  generates a 3D mesh having resolution ( $2^D \times 2^D \times 2^D$ ) that rises with the rise in  $D$  value and hence, the memory usage also rises severely.  $S_n$  indicates the least number of points that are allocated to individual leaf nodes of octree by the MC algorithm. If the data is noisy, a greater number of points are allocated as the surface is interpolated with the entire data points.  $S_{off}$  specifies a correction value of the threshold for the reconstructed surface.  $S_{off}=1$ , no correction required,  $S_{off} < 1$  signifies internal offsetting, and for external offsetting  $S_{off} > 1$ .

### B. Alpha-shape

It contains points, edges, triangles, and tetrahedrons. A subgroup of the triangles from the Delaunay triangulation is carefully selected to obtain a surface. The initial triangle with the property of minimum area is considered as the 'seed' which is further used to propagate the whole surface [3]. A subset of the 3D Delaunay triangulation of  $P$  is the  $\alpha$ -complex of a set of points ( $P$ ) for a given value of the parameter, with the  $\alpha$ -shape serving as its underlying space. As the value of  $\alpha$  varies, different  $\alpha$ -shapes can be generated. For  $\alpha = 0$  the  $\alpha$ -shape is  $P$  itself and when  $\alpha = \infty$ , the resultant shape is the convex hull of the point set. Changing the value of  $\alpha$  from 0 to  $\infty$ , different  $\alpha$ -shapes can be attained.

### C. Ball Pivoting Algorithm (BPA)

It is an effective surface reconstruction technique in which a ball of the pre-defined radius is rolled across the point cloud [4]. Triangular inter-connected 3D mesh is generated as the ball moves through the cloud, connecting the 3D points. The process is repeated until all the points are linked to a triangle. The algorithm is divided into two steps. The primary step is to find a seed triangle, and the second step is to expand the seed triangle to create a 3D surface, as shown in Fig. 5 and 6. For the input points, the surface normal for all points is computed and a point ( $p$ ) is selected.

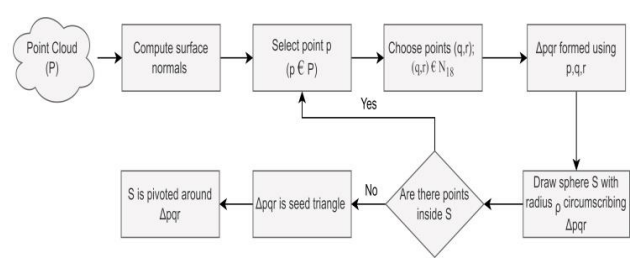

Fig. 5. Flow chart of ball pivoting algorithm (Step I).

Fig. 6. Flow chart of ball pivoting algorithm (Step II).

A triangle is formed by picking two nearest neighbors' triangle if the sphere ( $S$ ) has no point inside it else, a new point is chosen from the point cloud. The seed triangle is extended by rolling the ball that is pivoted to the chosen edge of  $\Delta pqr$  to find an alternative point in the point cloud. Another triangle is formed by joining the new-found point to the pivoting edge. The process is repeated until all the points have been navigated and linked by triangles to form a 3D mesh, as shown in Fig. 7. ( $q,r$ ) of  $p$  such that  $(q,r) \in N18$  resulting in  $\Delta pqr$  and its circumsphere is searched for points.  $\Delta pqr$  is the seed triangle.

BPA is sensitive to variations in ball radius ( $\rho$ ) which acts as a critical parameter in defining the number of reconstructed faces. A small radius causes the model to be vulnerable to input noise while a high value of radius can result in missing details creating holes in the generated surface. Another parameter is the angle threshold which is the maximum permissible angle between the active and the new edge constructed by rolling the ball. The rolling of the ball is stopped for the region where the angle threshold is achieved. An upsurge in threshold angle increases the computation time. The clustering radius is the lowest permitted distance between a recently added point and the active edge point. If there is less space separating two locations than the clustering radius, the two are combined. This is done to prevent processing DPC from consuming too much memory as a result of creating too many little triangular meshes.

The methodology defined and implemented in this study is based on well-known algorithms in the area of correspondence matching, structure-from-motion, surface reconstruction, etc. Instead of delving into the intricate mathematics involved in creating these algorithms, the focus here is on using these techniques to create a practical, reliable, and straightforward solution to the 3D reconstruction task. The photogrammetry-based 3D reconstruction strategy detailed here can successfully replace the pricey laser scanners as the principal

3D mapping method in industries due to its minimal labor demand and nearly zero running cost [20].

#### IV. EXPERIMENTAL RESULTS

The experimental work has been performed on Intel Core (TM) i7 CPU with 20 GB RAM accompanied by NVIDIA GeForce 1050Ti. MATLAB 2021 on windows 10 has been used for implementation. To analyze how well the 3D reconstruction algorithms performed, some point clouds were produced from digital image sets of various objects. To create a realistic 3D surface of the acquired item, PSR, Alpha shape, and BPA algorithms have been applied to the point clouds. The topology surface, the number of faces and the amount of time the algorithm took to compute each 3D surface are all taken into consideration in the analysis. The parameters affecting the reconstruction process were inspected in detail, by altering the control parameters of respective algorithms in terms of the execution time and reconstruction fineness. Fig. 6 shows the graphs of selected algorithmic parameters with respect to time. The primary influencing parameter in PSR is Octree Depth (D), and execution time grows with depth as the resolution of the 3D mesh increases by  $2^D \times 2^D \times 2^D$ . It has been found that an increase in alpha value causes an increase in execution time in the Alpha shape technique, which is a

critical parameter for the quality of the rebuilt surface. The ball radius is an important parameter in BPA, and it has been found that as grows in value, surface reconstruction takes longer to complete. The performance of selected reconstruction algorithms has been evaluated with the same input images and is compared in terms of how fine is the reconstruction. The final triangulated surfaces are investigated to measure the fineness of the surface. The more the number of faces, the finer is the reconstructed surface. The data in Table III shows the number of faces of the reconstructed surface for the corresponding input image for each of the algorithms. A graphical representation is given in Fig. 8. Among the selected algorithms, BPA reconstructs the minimum number of faces as it only creates a small collection of surfaces from point clouds. Alpha shape and PSR algorithms created more surfaces than BPA.

TABLE III. NUMBER OF 3D RECONSTRUCTED FACES OF EACH MODEL BASED ON SELECTED ALGORITHMS

Model	PSR	Alpha Shape	BPA
1	138666	226709	36429
2	224968	208791	51778
3	240180	280285	78132
4	136416	91976	7756

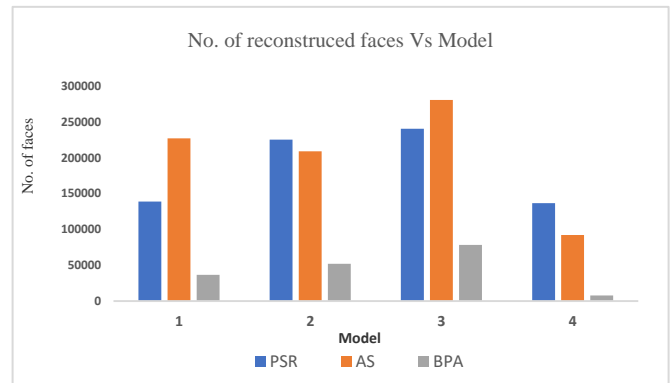

Fig. 8. Number of 3D Reconstructed Faces

#### V. CONCLUSION

A framework for the reconstruction of a 3D surface has been presented in the paper to reconstruct photorealistic 3D surfaces of irregularly formed objects from the set of their digital images to attain 3D point clouds that can be sparse, followed by dense clouds. The topology of the surface generated by these algorithms is based on the density of point clouds. Performance study of algorithms (PSA, Alpha shape, and BPA) has been carried out by observing their behavior with varying values of control parameters (octree depth, alpha value, and ball radius), on the amount of time taken and obtained quality of the reconstruction. Alpha shape and PSR algorithms performed better in creating more faces and hence a finer reconstructed 3D surface. To build a fine, feature-preserved, and accurate surface from the point cloud, several issues and constraints need to be considered. Noisy, sparse, and non-uniform points make the surface reconstruction process challenging. More research reconstructing finer surfaces using image features will be done in the future.

#### ACKNOWLEDGMENT

This research did not receive a specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

# Classifying Weather Images using Deep Neural Networks for Large Scale Datasets

Shweta Mittal, Om Prakash Sangwan

Computer Science and Engineering, Guru Jambheshwar University of Computer Science and Engineering, Hisar, India

**Abstract**—Classifying weather from outdoor images helps prevent road accidents, schedule outdoor activities, and improve the reliability of vehicle assistant driving and outdoor video surveillance systems. Weather classification has applications in various fields such as agriculture, aquaculture, transportation, tourism, etc. Earlier, expensive sensors and huge manpower were used for weather classification making it very tedious and time-consuming. Automating the task of classifying weather conditions from images will save a huge time and resources. In this paper, a framework based on the transfer learning technique has been proposed for classifying the weather images with the features learned from pre-trained deep CNN models in much lesser time. Further, the size of the training data affects the efficiency of the model. The larger amount of high-quality data often leads to more accurate results. Hence, we have implemented the proposed framework using the spark platform making it scalable for big datasets. Extensive experiments have been performed on weather image dataset and the results proved that the proposed framework is reliable. From the results, it can be concluded that weather classification with the InceptionV3 model and Logistic Regression classifier yields the best results with a maximum accuracy of 97.77%.

**Keywords**—Weather classification; big data; transfer learning; deep learning; Sparkll; convolutional networks

## I. INTRODUCTION

Weather classification is a task of classifying weather conditions by looking at the weather data. Accurate weather classification enables users to organize day to day activities for instance deciding what type of clothes to wear, planning outdoor travel or sports activity, solar technologies, etc. [1]. It plays a critical role in various other fields such as in agriculture, it helps farmers to decide which fertilizers or pesticides to use, whether to turn off the sprinklers etc. based on the outdoor weather conditions. Accurate weather classification also helps in improving reliability of vehicle assistant driving and outdoor video surveillance systems [2]. Timely prediction of severe weather conditions helps saving people life and property. It helps to avoid road accidents, train derailment and ship collisions caused due to severe weather conditions like rain, fog, storm and snow [3]. It also assists in predicting natural calamities, thereby helping in saving people's life to a greater extent. Thus, timely and accurate classification of weather images is of utmost important to society and needs to be explored further by the researchers and meteorologists.

Convolutional Neural Network (CNN) is the commonly used deep learning architecture now-a-days to classify image

datasets. It comprises multiple convolutional and pooling layers for better hierarchical representation and a Fully Connected Layer at the end for classification. Numerous variants of CNN such as ResNet, Inception V3, Exception, VGG-16, and VGG-19, etc. have been developed by researchers in past for improving the accuracy of networks. Several features such as sky, shadow, reflection, haze, contrast, etc. are present in images which are used by the CNN for weather classification.

In this paper, a framework based on transfer learning techniques has been implemented for classifying the weather images into its appropriate category with the help of features extracted from pre-trained deep CNN models. Automating the classification will not only save time and resources but also aids in increasing the reliability of the process. Section II highlights the work done by researchers in the field of weather image classification. Limitation and challenges of existing technologies has been presented in Section III. Section IV defines the proposed framework. In Section V, the hardware and software required to implement the proposed framework have been discussed. The experimental results have been described in Section VI and the conclusion and future work has been presented in Section VII of the paper.

## II. RELATED WORK

In the past few years, a significant amount of work has been done by researchers to resolve the issue of weather classification. As the weather dataset is quite huge, researchers have implemented big data technologies such as Hadoop and Spark to process weather datasets. Alam and Ajmad proposed architecture for parallel and distributed processing of big Weather datasets using Hadoop and Map Reduce platforms [4]. Yang et al. used big data technology to implement a regression model for predicting weather conditions with a large amount of weather data [5]. Ismail et al. build a big data framework for predicting weather temperature using Map Reduce technique and the proposed framework had the advantage of improved efficiency and scalability [6].

Dhoot et al. implemented the ARIMA technique and Kalman filter to forecast the weather using a spark framework and it was found that the ARIMA model with spark resulted in a significant reduction of execution time [7]. Spark was also used by Jayanthi and Sumathi to analyze weather datasets using ipython notebook and the proposed framework overcome the drawback of Hadoop in terms of processing speed [8]. Sudmant et al. studied the values and limitations of big data for fair weather prediction and emphasis on the need for technological advances for sustainable development [9].

In past, numerous authors have experimented with different architectures of neural networks to forecast weather conditions and the results were quite promising. Reddy and Babu surveyed various models for weather forecasting and it was found that Feed Forward Neural Networks (FFNN) and Time Delay Recurrent Neural Networks (TDNN) are well suited for short-term and long-term forecasting respectively [10]. Ren et al. too surveyed deep learning-based weather forecasting models and compared their performance with conventional NWP techniques [11].

Tran et al. reviewed neural networks for air temperature forecasting and found that Multi-Layer Perceptron (MLP), FFNN, Ward Style ANN, Radial Basis Function (RBF), Generalized Regression Neural Network (GRNN), etc. were widely used networks whereas few studies also used deep learning networks which provide encouraging results [12]. A comparison has been done between traditional and emerging techniques used in weather forecasting and it was concluded that for classification, CART, Adaboost and XGBoost gave the best results while for prediction, Linear Regression gave better performance [13].

Sharma and Ismail implemented 19 layers deep CNN using Keras and Tensorflow library for classifying the weather images into 4 classes (rain, shine, sunshine, and cloud), and the model provided 94% accuracy [14]. Wang and Li applied the fusion of DenseNet and ResNet CNN for classifying the weather images into nine classes and it was concluded that the output of the proposed integrated model was better than implementing the basic models alone [15]. Xiao et al. build a weather dataset comprising 6877 images of 11 different categories and proposed MeteCNN, a deep CNN model for classification [16]. The proposed model gave 92% accuracy and its performance was found to be superior to VGG19, VGG16, ResNet18, ResNet34, and MobileNet models.

Elhoseiny et al. studied the CNN layer's performance for two pre-trained models i.e. ImageNet-CNN and Weather-Trained CNN to classify weather images and the proposed work outperformed state-of-art methods [2]. Ibrahim et al. proposed a WeatherNet framework that combines both weather and visual conditions and comprises 4 parallel deep CNN models a) NightNet to classify dawn, night, day, and dusk b) GlareNet to classify Glare and No Glare c) PrecipitationNet to detect clear, rain and snow d) FogNet to detect fog and no fog [17]. Xia et al. introduced the ResNet-15 model to classify the "Weather-Dataset 4" dataset consisting of weather images into four classes and it was concluded that the proposed model performed superior to the traditional ResNet50 model [18].

Dhananjaya et al. discussed the application of weather classification for autonomous driving and build a dataset for the classification of weather, light level, and street type into nine classes [19]. An active learning framework has been implemented to reduce redundancy in the dataset and the ResNet50 network has been used for classification. Guerra et al. too build a weather dataset comprising 5500 weather images of five different categories and further implemented CNN for feature extraction using Matlab and Caffe library. The experimental results proved that all the variants of ResNet performed better than VGG and CaffeNet [3]. Matteussi et al.

implemented a Deep Learning algorithm on the BigDL framework using spark and Tensorflow library and the results concluded that ResNet performed better than VGG in terms of speed while LeNet achieved higher accuracy [20].

Zhao et al. too implemented the CNN-RNN approach for multi-label weather recognition to extract co-related visual features [21]. CNN model is extended with the attention model for feature extraction and the RNN model is used to model the dependency among labels. The experimental result proved that the proposed model is better than VGGNet. Li et al. combined CNN features with other features such as haze, contrast, brightness, etc. to construct a high dimensional vector for multi-class weather classification and the proposed model is proved to be effective and inspiring [22].

Zhang and Ma proposed Multiple Kernel Learning (MKL) for multi-class weather image classification and the results proved that the proposed technique gave better results as compared to SVM and AdaBoost [23]. Kang et al. presented a framework for weather image recognition to classify weather images into three categories: hazy, snowy, and rainy. The performance of GoogleNet, Alexnet, and the Multiple Kernel-based Learning approach was compared and it was found that GoogleNet slightly outperformed Alexnet [24].

Chen et al. proposed a weather recognition system using MKL and active learning techniques for automatically labeling the weather images into sunny, cloudy, and overcast categories, and the proposed system achieved better performance [25]. Lu et al. proposed an approach using a collaborative learning strategy to classify a dataset of 10k images into two categories: sunny and cloudy [26]. The proposed approach has been compared with SVM, Adaboost, LLC, and ScSPM techniques and the results proved the efficiency of the proposed approach.

Chu et al. build a large-scale dataset to estimate weather from images and demonstrated the relationship between different visual and weather features [27]. Random Forest has been implemented to classify the images and the results were found to be satisfactory for sunny, cloudy, and snowy classes. For rainy and foggy, the model did not give good results. Li et al. constructed a decision tree-based SVM classifier for extracting features to automatically acquire weather conditions from images using C++ and OpenCV [28].

Wang et al. introduced a new method for multi-class weather classification which builds feature vectors from the combination of real-time weather factors and dark channel feature value derived from images [29]. The proposed model is implemented using the Adaboost classifier on 5k images and the results demonstrated that the model performed better. Transfer learning has been applied by Challa and Vaishnav using the pre-trained ResNet50 and DenseNet161 models to classify the weather images [30].

As per the review of the work done by researchers, it can be concluded that Multiple Kernel Learning and pre-trained Neural Networks such as AlexNet, ResNet, VGG, and GoogleNet have been widely used by researchers for the classification of weather images. Big Data frameworks such as Spark and Hadoop have also been explored to process big datasets.

### III. CHALLENGED AND LIMITATIONS OF EXISTING APPROACHES

Many existing weather classification techniques make use of expensive sensors and huge manpower for classifying weather images. These methods rely on human observations, thus are more prone to errors and are very time-consuming. Numerical Weather Prediction (NWP) models are also being widely used for forecasting the weather conditions, but the techniques are quite expensive and rely on the power of supercomputers for data processing.

Recent work on weather classification includes classification of weather conditions from images. CNN has an advantage of automatically detecting the important features from images without any human intervention. For getting the optimized results, CNN models require huge amount of processing power and large datasets for training. Further, training weather images using CNN models also require tuning number of hyper-parameters such as number of convolutional and max-pooling layers, kernel size, regularization techniques, etc.

To overcome the above mentioned issues, transfer learning techniques are applied to transfer the knowledge learned from pre-trained deep CNN models to our weather image dataset. As transfer learning utilizes the features extracted from pre-trained CNN models, training time is considerably reduced. It too eliminates the need for tuning of number of hyper-parameters. Transfer learning has proved its potential in number of applications such as natural language processing, sentiment classification, text classification, spam email detection, video classification, drug efficacy classification, etc. [31].

Further, the size of weather images generated is also huge. Existing weather classification techniques exploiting the transfer learning techniques do not make use of big data technologies as well as lacks scalability. Thus, there is a need of weather classification framework which can scale on number of machines and can support big weather image datasets.

### IV. PROPOSED METHODOLOGY

To overcome the limitations discussed in previous section, a weather image classification framework has been proposed and implemented using spark platform. Fig. 1 describes the proposed framework which comprises of three steps: image loading, feature learning and multi-class classification. Firstly, weather images are loaded into the spark via the readSchema() method of the ImageSchema library and a dataframe is created. Afterward, image data is given as input to the pre-trained deep CNN model to automatically learn hierarchical feature representation. At this stage, either we can freeze all the layers of the pre-trained models or some of its layers are unfreeze and fine-tuned to learn the desired features [32]. The final step is to use the learned features from the deep CNN models as input to the classifier model which classifies the outdoor weather image into its appropriate category.

In step 2, 5 deep CNN networks i.e. InceptionV3, Xception, ResNet50, VGG16, and VGG19 have been explored for feature learning and experiments have been conducted to determine the model which gave the highest accuracy. VGG16 and

VGG19 is 16 and 19 layered deep neural network whereas ResNet50 is 50 layered deep Convolutional neural networks. Inception V3 is also a very powerful neural network which is 42 layers deep and has an advantage of performing multiple different transformations. Xception is a 71 layers deep neural network and incorporates depth-wise separable convolutions. All the layers from the pre-trained CNN models have been frozen in this case study.

In the last stage of proposed framework, one of the two classifiers i.e. Logistic Regression and Random Forests has been implemented for classification of weather images. Logistic Regression is a supervised ML technique which uses a sigmoid activation function for solving classification problems. To reduce the over-fitting and generalization error, the Logistic Regression classifier is trained with elastic net regularization. Two hyper-parameters for Logistic Regression need to be optimized; alpha ( $\alpha$ ) which is used to assign the weight to both L1 and L2 penalty and lambda ( $\lambda$ ), a regularization parameter that defines the balance between minimizing the training error and model complexity. If  $\alpha$  is 0, the model follows L2 regularization while if  $\alpha$  is 1, the model follows L1 regularization.

Random Forests is another popular supervised machine learning technique based on ensemble learning which combines the results of a large number of weak decision trees to form a robust classifier. As shown in Fig. 2, 10 different combinations of the networks are possible and the same has been implemented using the Sparkdl library. Extensive experiments have been performed to determine the CNN model and classifier which provided the maximum accuracy for weather image classification.

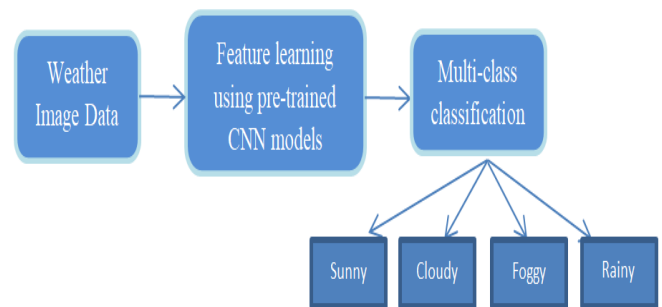

Fig. 1. Proposed framework for weather image classification.

Fig. 2. Proposed architecture for weather classification.

## V. EXPERIMENTAL SETUP

To evaluate the efficiency of the proposed framework, Multi class weather image classification datasets freely available on Kaggle.com has been used [33]. Dataset comprises 1125 images of four different categories i.e. cloudy, rainy, shiny, and sunrise. Sample images from each target class have been shown in Fig. 3. Categorization of target classes for the dataset has been presented in Fig. 4.

Fig. 3. Outdoor weather images (a) shine (b) cloudy (c) rainy (d) sunrise.

For the experimental setup, spark version 2.3.0 has been set up on a local PC (i.e. driver and the executor are set up on the same local machine) with 16GB RAM (12 GB RAM is allocated to spark) and 1 TB hard disk. Python version 3.7 and Java version 1.8 has been installed as shown in Table I. Further, there are more than 150 parameters in Spark which needs to be tuned for any spark application to achieve optimized results. There is no default value of a parameter that fits every application; values of these parameters vary with workload and the type of application.

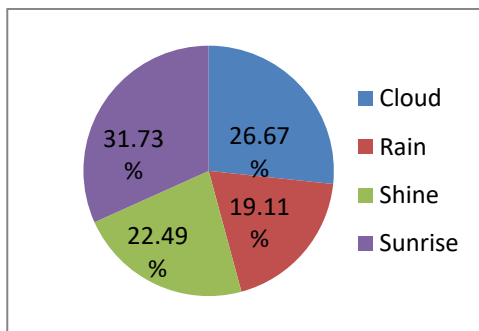

Fig. 4. Categorization of target class.

TABLE I. LOCAL PC CONFIGURATION

Parameter	Value
RAM	16GB
Hard Disk	1TB
OS	64-bit Windows 10
Spark version	2.3.0
Java	1.8
Python	3.7

Optimal tuning of spark parameters i.e. driver memory, driver cores, executor cores, executor memory, number of partitions etc. improves the performance of spark application to the greater extent [34,35,36,37]. As size of data is not very large, 4g memory is sufficient to store the data as well as to run the CNN models with Logistic Regression as classifier. While for Random Forest classifier, minimum 8g driver memory is required. Number of cores allocated to driver/executor too impacts the application's performance. If a cluster has n number of cores, number of partitions for input data should not be less than n as it might lead to under-utilization of resources. Few cores will be left idle and resources would not be utilized efficiently. Thus, number of input partition should either be equal or greater than number of cores. In this research work, number of cores and partitions has been set to 2 and 4, respectively.

To evaluate the efficiency of proposed framework, following metrics have been used:

- 1) Accuracy: It can be classified as the ratio of truly predicted samples to the total number of predictions.
- 2) Precision: It can be defined as the ratio of truly predicted positive values to the total number of positive predictions.
- 3) Recall: It can be defined as the ratio of true positives and total positive samples.
- 4) F1 score: Calculated as the harmonic mean of precision and recall.
- 5) Training Time: Time required for training the model.

## VI. RESULTS AND DISCUSSION

For Logistic Regression classifier, impact of regularization parameter, alpha and lambda on model's accuracy has been studied. Accuracy values for different value of alpha have been observed and results are shown in Table II. It can be interpreted that accuracy of the Logistic Regression model trained using ResNet50 model is maximum when the value of alpha lies between 0 and 0.5.

TABLE II. IMPACT OF ALPHA ON MODEL'S ACCURACY

Alpha	Accuracy
0	97.28
0.1	97.28
0.2	97.28
0.3	96.8
0.4	96.8
0.5	97.28
0.6	96.8
0.7	96.38
0.8	95.92
0.9	95.92
1	96.28

Further, 5 fold Cross-Validation method has been used to determine the optimal lambda value of Logistic Regression.

Numerous values of  $\lambda$  i.e. (0.01, 0.05, 0.1, 0.3, 0.5, 0.7, 1.0) have been examined and the results concluded that the model achieves higher accuracy for  $\lambda$  value of 0.01. Thus, for implementing the Logistic Regression classifier,  $\alpha$  and  $\lambda$  has been set to 0.5 and 0.01, respectively.

For Random Forest classifier, the number of trees in forests impact performance of classifier to a greater extent. Thus, for different values of trees, its impact on the accuracy and run time of an algorithm has been studied and results are shown in Table III. It can be interpreted that till a certain value i.e. 150, the accuracy value of the model increases with an increase in the number of trees in the forests. Afterwards, the accuracy value decreases. Random Forest classifier provided the best accuracy value of 97.73% with 150 trees in the forests. It can also be observed that the increase in the number of trees has no significant impact on the training time of an algorithm.

Train and test data have been divided in the ratio 80:20. Table IV describes the accuracy, F1 score, precision, recall, and training time for 10 different possible architectures specified in Fig. 2. It can be interpreted that with the InceptionV3 pre-trained model and Logistic Regression classifier, the accuracy value is maximum i.e. 97.77%. Factorized convolutions, grid size reduction, asymmetric convolutions and use of auxiliary classifiers are some the significant features of InceptionV3 model resulting in its higher accuracy value. Instead of getting deeper, InceptionV3 extracts features in more depth.

TABLE III. IMPACT OF NUMBER OF TREES ON THE PERFORMANCE OF PROPOSED NETWORK

No. of trees	Accuracy	F1 score	Precision	Recall	Time
10	94.57	94.55	94.68	94.57	14 min 24 sec
50	96.39	96.38	96.4	96.38	16 min 3 sec
100	97.28	97.29	97.41	97.28	14 min 35 sec
125	97.29	97.29	97.32	97.28	13 min 58 sec
150	97.73	97.73	97.82	97.73	13 min 1 sec
200	96.38	96.4	96.49	96.38	14 min 5 sec

TABLE IV. OUTPUT OF PROPOSED FRAMEWORK FOR NUMEROUS PRE-TRAINED DEEP CNN MODELS

	Accuracy	F1 score	Precision	Recall	Time
ResNet50+LR	97.28	97.29	97.33	97.28	7 min 35 sec
VGG16+LR	94.57	94.61	94.83	95.57	10 min 12 sec
VGG19+LR	94.12	94.13	94.31	94.12	6 min 35 sec
InceptionV3+LR	97.77	97.74	97.75	97.74	6 min 42 sec
Xception+LR	95.02	95	95.11	95.02	8 min 2 sec
ResNet50+RF	97.73	97.73	97.82	97.73	13 min 1 sec
VGG16+RF	96.38	96.35	96.46	96.38	28 min 1 sec
VGG19+RF	93.66	93.64	93.62	93.66	26 min 45 sec
InceptionV3+RF	91.4	91.5	91.7	91.4	24 min 14 sec
Xception+RF	90.04	89.98	90.32	90.04	50 min 50 sec

Further, the second highest accuracy value i.e. 97.73% has been achieved with the ResNet50 pre-trained model and Random Forests classifier. ResNet50 pre-trained model with the Logistic Regression classifier too gave promising results. The Xception model trained using the Random Forests classifier provided the least accurate value of 90.04%. It can also be concluded that the time taken by the framework for training the dataset with the Logistic Regression classifier is quite low compared to the Random Forests.

Table V demonstrates the confusion matrix for weather image classification for dataset 1 with Inception V3 pre-trained CNN model and Logistic Regression classifier, where the row represents the actual labels and the column represents the predicted labels. As shown in Table III, the total number of test images is 221. The number of test images for classes cloudy, foggy, rain, shine, and sunshine is 45, 64, 47, and 65, respectively. Out of 221, 216 images are predicted true by the classifier.

TABLE V. CONFUSION MATRIX FOR INCEPTION V3 LOGISTIC REGRESSION MODEL

	Cloudy	Rainy	Shine	Sunrise	Total
Cloudy	44	0	1	0	45
Rainy	1	63	0	0	64
Shine	0	0	45	2	47
Sunrise	0	0	1	64	65
Total	45	63	47	66	221

Fig. 5. Comparison of the proposed framework with the existing techniques.

The performance of proposed framework has been compared with the existing techniques utilizing the same weather image dataset for classification. Fig. 5 shows the comparison of accuracy value of the proposed framework with the four existing approaches. Our proposed framework yields the maximum accuracy value of 97.77% when Inception V3 model and Logistic Regression classifier (InceptionV3+LR) has been used. Models proposed by Oluwafemi and Zenghui (2019), Togacar et al. (2020), and Sharma and Ismail (2022) had lower accuracy values of 86%, 95.85% and 94%

respectively [14,38,39]. Model proposed by Al-Haija et al. (2020) had the accuracy value of 98.22%, thus performed slightly better than the proposed InceptionV3+LR model in terms of accuracy [40]. Further, Model proposed by Al-Haija et al. had precision and sensitivity values of 96.5% and 96.4%, respectively while the proposed InceptionV3+LR model has better precision and sensitivity values i.e. 97.75% and 97.74% respectively. Hence, InceptionV3+LR model has better ability to capture false negatives and true positives than existing techniques. Time taken by the proposed framework for training is also very less i.e. 6 min 42 sec.

## VII. CONCLUSION

Weather Prediction is a very vital activity performed before numerous day-to-day activities. Deep CNN is a deep learning technique widely used to classify image datasets but the techniques require very huge datasets and high computing devices for achieving optimal results. Transfer learning is proven to be effective in scenarios with smaller datasets and the unavailability of high computing devices. It helped in minimizing the learning time by utilizing the features learned from the previously trained deep CNN models.

In this paper, a framework based on transfer learning has been proposed for classifying the weather conditions from outdoor images and the performance of various CNN models has been compared for accuracy, precision, recall, f1 score, and training time. From the results, it can be observed that with the InceptionV3 pre-trained model and Logistic Regression classifier, the accuracy value is maximum i.e. 97.77%. Further, it can be concluded that the time taken by the framework for training the dataset with the Logistic Regression classifier is quite low compared to the Random Forests. The comparison has also been done with the existing techniques and the results proved the efficiency of the proposed framework. Further, the proposed framework is scalable and has support for big datasets. In the future, some layers from pre-trained CNN models can be un-freeze and fine-tuned to learn better hierarchical representation.

# Exploring College Academic Performance of K to12 IT and Non-IT-related Strands to Reduce Academic Deficiencies

Marilou S. Benoza<sup>1</sup>, Thelma Palaoag<sup>2</sup>

Infotech Development Systems Colleges, Inc, Ligao City, Philippines<sup>1</sup>  
University of the Cordilleras, Baguio City, Philippines<sup>2</sup>

**Abstract**—Improving students' academic performance is a significant concern among academics. Despite various strategies to improve academic performance, there are still a significant number of students who fail academically. This study sought to investigate the possible reasons for the academic deficiencies among Infotech Development Systems Colleges, Inc. Information Technology (IT) students in the IT and Non-IT-related strands, if their strand is significant to their academic performance in college, as well as formulate a solution based on the identified reasons and recommendations to reduce the negative academic remarks. The researchers employed survey questionnaires and interviews to conduct exploratory data analysis. Similarly, the Senior High School academic performance and actual grades of the respondents from AY 2018-2019 to First Semester of AY 2021-2022. On the tested hypothesis showed statistical significance ( $p < 0.05$ ) on IT-related strand. The study further reveals that the Non-IT-related strand has more students with academic deficiencies compared to IT-related strand and highlights a variety of reasons cited. Respondents cited misalignment of strand to current program, instructor not speaking clearly, unreliable internet connection, and failure to complete and submit an academic task as reasons for academic deficiencies. The researchers designed a model that can potentially eliminate academic inadequacies. The model takes into account both internal and external factors; for internal variable it includes effective time management, a positive attitude and mindset, prompt and punctual completion of requirements, and good study habits. While for the external factors, competent and student-friendly instructors, a stable, strong, and accessible internet connection, a conducive learning environment, relevant available resources and facilities, adaptation of limited face-to-face or hybrid classes, and alignment of SHS strand to college program of choice are recommended.

**Keywords**—Academic performance; exploratory research; reduce academic deficiencies; thematic analysis

## I. INTRODUCTION

Expanding our worldview through education broadens our perspective. Many nations, like the Philippines, are shaping education to be the most valuable resource a nation may possess. Philippine Basic Education introduced the K-12 Curriculum, which requires students to complete two years of senior high school before being eligible for college. Students who enroll in this program may select their own track or strand based on their preferences or areas of interest, or they may choose to pursue work for the remaining two years of

senior high school. Senior high school students follow a basic core curriculum and can specialize in one of four areas. These tracks are distinct fields of study, akin to college courses. The tracks are Academic, Technical-Vocational and Livelihood (TVL), Sports, and Arts and Design. Some of the most popular strand under Academic and TVL tracks are Science, Technology, Engineering, and Mathematics (STEM); Accountancy, Business, and Management (ABM); Humanities and Social Sciences (HUMSS); General Academic, Information and Communication Technology (ICT) and Home Economics (HE). Magdadaro [1] mentioned that having an ideal strand offer learners a sense of self-assurance and can help students to be passionate about their chosen career.

Academic performance is among the several components of academic success and key feature in education. [2], [3] Academic success and obtaining good grades are among the main goals in all levels of education while having positive outcomes both for the learners and educational systems. [4] The students' performance (academic achievement) plays an important role in producing the best quality graduates who will become great leaders and manpower for the country thus responsible for the country's economic and social development also one of the major factors considered by employers in hiring workers especially for the fresh graduates. Thus, students have to put the greatest effort in their study to obtain good grades and to prepare themselves for future opportunities in their career at the same time to fulfil the employer's demand. [5], [6] Many factors, including socioeconomic status, student temperament and motivation, peer, and parental support influence academic performance. [7] Factors affecting the academic performance of students are numerous and they can vary from nation to nation as well as even from person to person. As such, it would be really inadequate to investigate students' academic performance through a single-factor perspective [8] Students' performance also determines quality of education that will be passing to the students by the potential teachers at primary and secondary school levels. The good academic performance of students at the Senior High School is of paramount importance in every educational system. Meanwhile, numerous factors influence the academic performance of students and have been researched, but many problems persist. [9], [10].

There is a noticeable situation in which students enroll in college courses that are not associated with their track or

strand of senior high school. The mismatch rate is high between the strand of the learners during their senior high school and the course they enrolled in college. [11] Three mismatch characteristics affect students' academic outcomes: (1) a mismatch between expected and real grades, (2) a mismatch between expected and real levels of interest in studying, and (3) a mismatch between expected and real time for extracurricular activities at university. [12] The student's past performance in SHS has a significant effect on the student's self-efficacy in using information and communications technology (ICT)-related technologies in college. Computer self-efficacy also influences the students to achieve their academic goals in college; also, both past performance and computer self-efficacy have a strong influence on technology outcome expectations, however, the technology outcome expectations have a less significant effect on the students' achievement of their academic goals. [13] Low academic performance and adjustment to college are phenomena not new in the global education institutions. In fact, reported 60% of students who cannot adjust to college drop out early in school. The students who cannot establish good relationships with their friends, teachers and school administration, who do not like the school and the subjects have a higher tendency to be absent from school and to drop out of school. Also, that the specific causes of school dropouts include the difficulty of adjusting with the school curriculum. [14], [15], [16], [17] Moreover, mentioned that the problem of low academic achievement of students in the examinations is one of the most challenging problems that faces students as well as teachers. Low or weakness of the student's mark under the normal average in a study subject level as a result of a variety of reasons, including those related to the student himself, or those related to family, social and academic environment. Consequently, this may lead to frequent repetition of failure, despite their abilities that qualify them to get the best marks. [18].

In Infotech Development Systems Colleges, Inc. (IDSCI), it was discovered that a significant number of students in Information Technology programs have incomplete and failed remarks on their final grades, particularly in professional courses, as well as a significant number of dropouts, resulting in a decrease in program enrollment. In addition, students who took the non-IT-related strand in SHS are thought to have more incomplete and failed grades than those who took the IT-related strand.

The purpose of this study is to investigate the factors that contribute to the academic shortcomings of the respondents and to establish whether or not their strands have an impact on their academic performance. In addition to this, the researchers are interested in determining if the curriculum that they have chosen for their college is compatible with and advantageous to them. The researchers intend to carry out this study to serve as a guide to the institution, as well as for the students, particularly those who are enrolled and wishes to enroll in the Information Technology Department. The guidance will be presented in the form of a model with the goal of reducing the detrimental effect that it has on academic achievement. This model was designed using the causes that have been discovered for the academic deficiencies, as well as

the recommendations made by the students, which included the alignment of their SHS strand.

## II. METHODOLOGY

The exploratory research method was used in this study to determine ways to reduce academic deficiencies by examining respondents' college academic performance. This study was conducted among sixty-two (62) Information Technology (IT) students from Infotech Development System Colleges, Inc. and was divided into IT and Non-IT-related Strands based on their chosen strand. In order to gather enough information, the researcher used a survey questionnaire. The questionnaire was issued to eighty (80) target respondents, however only sixty (62) were retrieved. The proponent foregoes the available size with a confidence level of 90% and a margin of error of 5%.

After initiating the strand, the researchers identified the college academic achievement of the target respondents in order to determine the number of students that received INC and failed remarks. The researchers employed a questionnaire in which respondents were asked to assess their level of agreement with the criteria that had been devised to match the SHS Strand to the chosen college program. The questionnaire was distributed to respondents using Google Form, and the categories on the item on SHS strand matching on the college program, as well as if their strand was beneficial to their academic achievement in college, were listed to aid respondents in choosing the right decisions. In addition, weighted mean and standard deviation were utilized in order to identify and analyze the data.

The researcher also utilized the SHS and college academic performance to further determine if the respondent's strand has a significant relation to their academic performance in college. The research used the Pearson R statistical tool for the correlation. See (1). The SHS generated weighted average (GWA) was converted into a numerical value stipulated in the institution's Student Handbook. The numerical value was converted using a 6-point performance equivalent scale (6-Outstanding to 1-Failed).

$$r = \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum (x_i - \bar{x})^2 \sum (y_i - \bar{y})^2}} \quad (1)$$

A separate survey questionnaire was also distributed only to respondents who had Incomplete or Failed remarks in order to determine the reason for their negative remarks. A 5-point Likert scale was used in both instruments. See Table I.

TABLE I. FIVE-POINT LIKERT SCALE FOR THE MATCHING AND BENEFITS OF SHS STRAND

Point Score	Range Interval	Descriptive Rating
		Level of Agreement
1	1.00-1.79	Strongly Disagree
2	1.80-2.59	Disagree
3	2.60-3.39	Neutral
4	3.40-4.19	Agree
5	4.20-5.00	Strongly Agree

Moreover, the researcher used thematic analysis to identify the recommendations by the respondents to reduce the academic deficiencies. Thematic analysis is the process of identifying patterns or themes within qualitative data. The goal of a thematic analysis is to identify themes, i.e. patterns in the data that are important or interesting, and use these themes to address the research or say something about an issue. This is much more than simply summarizing the data; a good thematic analysis interprets and makes sense of it [19].

A structured interview was conducted to collect the possible recommendations to reduce academic deficiencies. There were twenty-four (24) IT students who participated in the interview. These were the students who has failed or incomplete grades. Based on the respondents' recommendation, the analysis produced six (6) themes which included time management, positive attitude and mindset, instructor, requirement completion, study habits, and resumption of classes. The flowchart of the research process is presented on Fig. 1.

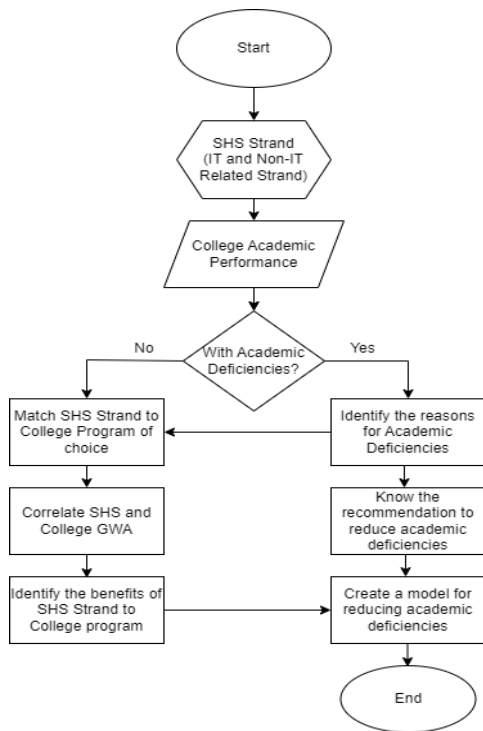

Fig. 1. Flowchart of the research process.

The researcher retrieved the instruments automatically through Google form. The academic performance of the respondents was measured using their actual grades from AY 2018-2019 to First Semester of the AY 2021-2022 taken from the Office of the Registrar with the permission of the IT students. The Student Profile Form was also used to identify the academic strand of the respondents. In this study, the respondents' Senior High School (SHS) strand were identified and categorized into IT Related Strand (ITRS) and Non-IT-Related Strand (NITRS). ITRS includes STEM and ICT while the NITRS includes ABM, HUMSS, GAS, Home Economics, Automotive, Agriculture, Arts and Design, Electrical, Dressmaking and Industry-al Arts. The meaning and

significance of the responses were interpreted through processes that included gathering, synthesizing, tabulating, and interpreting the meaning and significance of the responses. Tables and graphs were created to display the collected data. Data analysis was carried out using Microsoft Excel and Social Science Statistics Calculator. Mean, standard deviation, frequency, percentage, and correlation for descriptive analysis.

### III. RESULTS AND DISCUSSION

In Fig. 2 shows the academic remarks status of the respondents. The results show that 58% got passing remarks but despite the high rate of passing grade there were still 42% respondents who got incomplete or failed academic remarks. Fig. 2 also reveals that 19% belong to IT-related-strand while 23% also belong to non-IT-related strand students.

Fig. 2. Academic remarks status of the respondents.

Academic excellence is not universal among students; there are some students that despite of various strategies to improve academic performance, there are still number of students who fail academically. Failure in small doses is actually crucial in learning. However, when students completely fail academically, this means that they are unable to overcome the small failures over time to learn and grow and eventually succeed [20]. There are many causes of student failure, and these causes could be looked at in various ways. In this study, the researcher also would like to identify the reason of IT and non-IT-related strand for academic deficiencies in the area of subject matter, teacher factor, learning environment, motivation and attitude, and personal issues in order to provide sufficient solution based on the determined reasons for academic deficiencies. And also, to determine if their strand has an effect and beneficial to their college academic performance.

#### A. Reasons for Academic Deficiencies

1) *Subject matter*: Fig. 3 shows the reasons for academic deficiencies in terms of Subject Matter. In the course content was too difficult to understand, ITRS got a mean score of 3.33 with SD of 1.12 interpreted as neutral while NITRS got a mean score of 3.13 with SD of 1.13 interpreted as neutral. Too much course content/information was presented at a time making it difficult to be absorbed, ITRS yielded a mean score of 3.67 with SD of 0.71 interpreted as agree while NITRS gained a mean score of 3.47 with SD of 1.13 interpreted as agree. On the prerequisite competencies were not well developed in the preceding year level, ITRS obtained a mean score of 3.67 with SD of 1.00 interpreted as agree. On the other hand, NITRS obtained a mean score of 3.13 with SD of 1.25 and was

interpreted as neutral. In terms of the SHS strand undergone was not aligned with the present program being taken up, ITRS received a mean score of 2.78 with SD of 1.09 contrary to NITRS which received a mean score of 3.60 with SD of 1.40 interpreted as agree.

Fig. 3. Reasons for academic deficiencies in terms of subject matter.

According to the data, misalignment of the SHS strand to the enrolled program is one of the reasons why non-IT-related strand respondents received incomplete or failed remarks, as opposed to IT-related strand respondents. NITRS respondents mentioned that the topic presented in their current program is too different from the topics and discussion in their SHS strand, and they are finding it difficult to acclimatize. They also said that enrolling in an IT-related strand will make it easier for them to understand the lecture and other class activities. Moreover, the ITRS and NITRS both agreed that a fast-paced discussion was also one of the reasons for academic deficiencies. They have a hard time absorbing information that is delivered at the same time since it does not give them enough time to comprehend and learn the lesson. ITRS further stated that in the previous year's level, the required competences for the next course were not fully developed. Lack of competence causes a lack of confidence and willingness to complete tasks and activities. Students with strand mismatch lag behind others as it is more difficult for them to follow the unfamiliar subjects of their course. Students suffering from strand mismatch are also deprived of interpersonal relationships as forming them is directly related to academic engagement. It also has various indirect effects from these relationships to cognitive and behavioral participation [21].

2) *Teacher factor*: Fig. 4 shows the reasons for academic deficiencies in terms of the teacher factor. On the instructor did not speak clearly, ITRS got a mean score of 2.67 with SD of 1.12 interpreted as neutral while NITRS got a mean score of 3.91 with SD of 1.33 interpreted as agree. The instructor did not provide clear explanations, ITRS yielded a mean score of 2.78 with SD of 1.20 interpreted as neutral; on the other hand, NITRS yielded a mean score of 2.40 with SD of 1.35 interpreted as disagree. On the instructor did not consider extended deadlines, ITRS gained a mean score of 2.78 with SD of 1.09 interpreted as neutral while NITRS got a mean score of 2.67 with SD of 1.40 interpreted as neutral.

According to the research, NITRS respondents have difficulty understanding the lesson since their instructor did not talk in a manner that was appropriate for the situation. Respondents even claimed that some professors speak so quickly and utilize unfamiliar terminologies that they are unable to understand what they are trying to communicate. They also have difficulty understanding some computer words because they come from different strands. The ITRS, on the other hand, does not agree or disagree with the provided rationale; similarly, the instructor failed to present a clear discussion with which the NITRS disagrees. Teachers with poor communication skills may cause poor academic performance of students and lead to unstable professional life after school. Good communication minimizes the potential of unkind feeling during the process of teaching and learning. For a teacher, it is very pertinent to have good communication skills to create good classroom environment for effective teacher-student interaction to promote effective learning by students and acquisition of desired professional goals. Good communication is not only needed for effective teaching and learning, but it is also very important in the effectiveness of every human concern in life [22].

Fig. 4. Reasons for academic deficiencies in terms of teacher factor.

3) *Learning environment*: Fig. 5 shows the reasons for the academic deficiencies in terms of the learning environment. In terms of the internet connection being poor, ITRS obtained a mean score of 3.33 interpreted as neutral on the other hand NITRS received a mean score of 3.67 with SD of 1.54 interpreted as agree. On the learning area was un-comfortable, ITRS got a mean score of 3.33 with SD of 1.22 while NITRS yielded a mean score of 3.40 with SD of 1.24 both interpreted as agree.

Fig. 5. Reasons for academic deficiencies in terms of learning environment.

Because of the unreliable internet connection, NITRS respondents find it difficult to complete a course satisfactorily, according to the data. Students rely heavily on internet connections in the new normal; from online classroom discussion to assignment submission, a poor internet connection prevents them from joining the class and completing duties. They also underline that being in an uncomfortable learning environment does not help them perform well, and that some people feel uncomfortable when they are being observed doing an activity or participating in a class discussion. Though ITRS does not agree or disagree with either of the above reasons, it is one of their group's highest mean scores, indicating that they are thinking about the reasons for their weaknesses. According to Torres-Diaz, students who do not have access to the internet are more likely to perform poorly on their examinations in comparison to students who frequently utilize the online educational resources. People who participate in interactive activities with their classmates and professors, as well as those who use online resources appropriately for their schoolwork, have a tendency to have better academic achievement overall [23].

4) *Motivation and attitude*: Fig. 6 shows the reasons for the academic deficiencies in terms of the learning environment. On lack of motivation, ITRS gained a mean score of 3.11 with SD of 1.17 while NITRS received a mean score of 3.13 with SD of 1.13 both interpreted as neutral. In terms of failure to do tasks and homework, ITRS obtained a mean score of 2.78 with SD of 1.09 interpreted as neutral on the other hand NITRS yielded a mean score of 3.87 with SD of 1.06 interpreted as agree.

The data shows that NITRS respondents, despite the fact that they did not dislike the courses, accept the fact that they failed to complete the academic task as the reason for their negative academic performance. However, ITRS respondents did not agree or disagree. Furthermore, although being neutral, the highest mean of the latter group lacks enthusiasm to perform as expected and continue with their academic responsibilities.

They lose interest in what they are doing because they see no reason to finish what they have started. Sometimes students lack motivation, so they become apathetic [24]. When students are unmotivated, they might feel that academic success doesn't matter or that they will never achieve it. Students who lack motivation might have experienced a good deal of failure early on in their education and feel there is no point in trying any longer. These students need to find a "why" when it comes to academic success, a reason that will motivate them to achieve their goals. A motivation can come from a career goal, a desire for a future accomplishment, the hope to be financially stable, or even the desire to give back to the community or family members.

5) *Personal issues*: Fig. 7 presents the reasons for academic deficiencies in terms of personal issues. On

procrastinating or delayed doing tasks, ITRS got a mean score of 3.11 with SD of 0.93 interpreted as neutral on the other hand NITRS received a mean score of 3.93 with SD of 1.10 interpreted as agree. Lacking confidence in participating in class, ITRS got a mean score of 3.11 with SD of 1.45 interpreted as neutral while NITRS gained a mean score of 2.80 with SD of 1.37 interpreted as neutral.

Fig. 6. Reasons for academic deficiencies in terms of motivation and attitude.

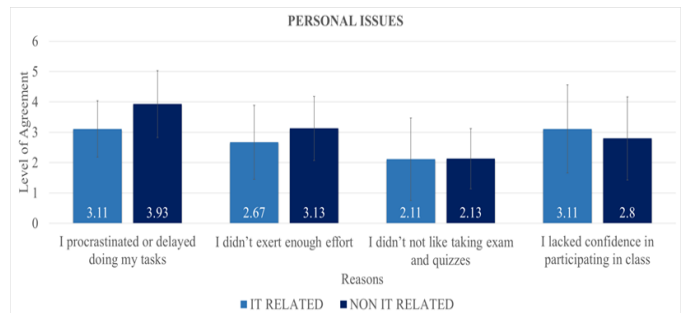

Fig. 7. Reasons for academic deficiencies in terms of personal issues.

According to the research, NITRS respondents have a habit of not completing projects on time. Respondents also admitted to making excuses for not doing their work and deferring chores like schoolwork or preparation for a test by doing anything else instead. ITRS responses do not agree or disagree with the stated personal concerns, but the highest mean in their category agrees with NITRS, and their lack of confidence in engaging in class may be a cause in their academic deficits. Late assignment submission indicates poor quality pupils in terms of performance. Their drop-out percentage (33.33%) is greater than the rate of on-time submissions (5.23%). Their request for an extension on the due date of their tasks is most likely due to poor time management rather than a desire to enhance performance. Students who submit their assignments on time perform better than those who submit their assignments late [25].

### B. Agreement on the Matching of Strand to College Program of Choice as Perceived by the Students

With the above-mentioned reasons, the researcher further investigates if their SHS strand has equipped them with information and skills in preparation for their higher education, and how linked the respondent's strand was to their current program.

TABLE II. THE MATCH OF STRAND TO COLLEGE PROGRAM OF CHOICE AS PERCEIVED BY THE RESPONDENTS

INDICATOR	IT RELATED			NON IT RELATED		
	Mean	SD	INT	Mean	SD	INT
The SHS strand chosen specialization is aligned to the college program of choice.	4.28	0.92	SA	4.00	1.12	A
The specialization subject taken in SHS were related to the courses taken in college	4.21	1.01	SA	4.09	1.01	A
Some knowledge contents needed in college courses are introduced in SHS subjects	4.13	1.06	A	4.09	0.84	A
Some pertinent skills needed in college are taught and developed in SHS	4.24	0.87	SA	4.09	0.98	A
The SHS curriculum meets the college program requirements	4.10	0.94	A	4.09	0.98	A
General Mean and SD	4.19	0.96	A	4.07	0.99	A

Interpretation Legend: SA-Strongly Agree A-Agree N-Neutral D-Disagree SDA-Strongly Disagree

Table II presents the matching of SHS strands based on the perspective of the IT respondents. The result show that in Table I, in terms of the SHS strand chosen specialization is aligned to the college program of choice, ITRS got a mean score of 4.38 with Standard Deviation (SD) of 0.92 and interpreted as strongly agree while the NITRS got a mean score of 4.00 with SD of 1.12 and interpreted as agree. On specialization subjects taken in SHS were related to the course taken in college ITRS got a mean score of 4.21 with SD of 1.01 while the NITRS only agreed with 4.09 mean score with 1.01 SD. Some knowledge content needed in college is taught and developed in SHS and their curriculum meets the college program requirements, ITRS got a mean score of 4.13 and 4.10 with SD of 1.06 and 0.94 while NITRS got a mean score of 4.09 and 0.84 and 0.98 SD, both interpreted as agree. On some pertinent skills needed in college are taught and developed in SHS, ITRS got a mean score of 4.24 with SD of 0.87 and interpreted strongly agree while the NITRS got a mean score of 4.09 with SD of 0.98 interpreted as agree. ITRS on general mean and SD got a mean score of 4.19 and 0.96 while NITRS got a mean score of 4.07 with SD of 0.99 both interpreted as agree.

The data demonstrates that the SHS strand courses, particularly those related to IT; match the courses offered by the IT program. The IT related strand, in contrast to the non-IT-related strand, strongly suggests it is needed in college courses, and the SHS curriculum fits some but not all of the college program standards. College program curriculum is an important factor in a student’s learning development. The structures, standards, and performance indicators of the secondary and tertiary curriculum influence success in college. The usage of a vertically-aligned curriculum is beneficial to the students, although it needs systematic effort. Specialized pre-college courses gear students with advanced knowledge and make them excellent in their chosen fields [26]. During Senior High School, the students will gain the mandatory skills needed for their future professions that will help them do their work in a better way.

C. Correlation between SHS GWA and College GWA

After matching, to further tests the connection between SHS strand to their chosen college program the researcher correlates the SHS GWA to the College GWA to discover if the SHS Strand influences their college academic achievement.

1) Correlation between IT-Related strand and college GWA: Fig. 8 shows the correlation between the SHS GWA of the IT-related strand and their college academic performance.

The data reveals that although technically a positive correlation with  $r = 0.4115$ , the relationship between variables is weak. The p-value is 0.026567. The result is significant at  $p < 0.05$ . By normal standards, the association between the two variables would be considered statistically significant.

2) Correlation between Non-IT related-strand and college GWA: Fig. 9 shows the correlation between the SHS GWA of the Non-IT-related strand and their college academic performance. The data reveals that although technically a negative correlation, the relationship between variables is only weak with  $r = -0.114$ . The P-Value is 0.527587. The result is not significant at  $p < 0.05$ . The association between the two variables would not be considered statistically significant.

Fig. 8. Correlation between IT-Related strand and college GWA.

Fig. 9. Correlation between Non-IT related-strand and college GWA.

According to the research, regardless of the strand that IT students choose, it has no effect on their academic performance; nevertheless, enrolling in a related strand has a significant benefit over enrolling in a non-related strand. ITRS respondents also stated that it is simpler for them to grasp the lesson since they have prior knowledge on specific courses. Because of the information they gained in their SHS strand, they are also confident in their ability to contribute and interact in class. In the study of Alipio [27], academic achievement was affected by SHS strand and academic adjustment. Moderation effects between academic adjustment and SHS strand suggest that STEM strand students performed better than those in other SHS strands.

**D. Agreement on How Beneficial the SHS Strand to Academic Success in College**

The study also determines how beneficial the SHS strand is to the academic performance of the respondents' program of choice. This would determine whether or not the learning from their strand was beneficial to their learning acquisition in college. The study also determines how beneficial the SHS strand is to the academic performance of the respondents' program of choice. This would determine whether or not the learning from their strand was beneficial to their learning acquisition in college.

Table III presents how their SHS strand helps their academic performance in college. ITRS perception on SHS strand helps them accomplish their class activities and projects in college obtained a mean score of 4.38 with SD of 0.68 considered as strongly agree while NITRS perception obtained a mean score of 4.15 with SD of 0.87 understood as agree. On SHS strand helps them get high scores in quizzes in college obtained a mean score of 4.07 with SD of 0.70 defined as agree while NITRS obtained a mean score of 4.15 with SD of 0.94 interpreted as agree. ITRS got a general mean of 4.22 and general SD of 0.70 interpreted as strongly agree while NITRS got a general mean of 4.07 with SD of 1.00 and interpreted as agree.

In comparison to the NITRS, the data shows that respondents in the IT-related strand strongly believe that their chosen stand aided their academic achievement in college, particularly in completing class tasks and projects. Some ITRS

respondents stated that some of the college class activities were already presented in their SHS strand, and that the knowledge and abilities required to complete the work had already been gained. Despite the confidence in easy understanding of the course or lesson and task performances, contrary to NITRS experiences due to the mismatch of strand taken in SHS, ITRS cannot confidently believe that their strand was highly effective in getting good grades and test scores because the technique and modality of delivery in higher education are different. However, when compared to non-related strands, aligned strands provide a significant advantage in academic achievement, particularly in the acquisition of knowledge in IT professional courses. According to Lumboy [28] the level of difficulty experienced by the respondents on their college subjects are highly related to the strand they have taken in senior high school. Those who are graduates of STEM excelled over the other as evident in their college academics.

**E. Recommendation to Reduce Academic Deficiencies**

Fig. 10 presents the recommendation to reduce academic deficiencies as perceived by the respondents. The researcher uses thematic analysis to analyze the result. Based on the respondents' recommendation, the analysis produced six (6) themes which included time management, positive attitude and mindset, instructor, requirement completion, study habits, and resumption of classes. Among the themes, requirement completion got the highest percentage of 38%, followed by positive attitude with 25%, study habits and instructor both received 13% while time management is 8% and resumption of classes with the lowest percentage of 4%.

Fig. 10. Recommendation to reduce academic deficiencies.

TABLE III. AGREEMENT ON HOW BENEFICIAL THE SHS STRAND IS TO ACADEMIC SUCCESS IN COLLEGE

INDICATOR	IT RELATED			NON-IT RELATED		
	Mean	SD	INT	Mean	SD	INT
My SHS strand helps me understand the course/lesson in college easily.	4.31	0.66	SA	3.91	1.13	A
My SHS strand helps me accomplish the class activities and projects in college.	4.38	0.68	SA	4.15	0.87	A
My SHS strand gives me confidence in participating in class discussions in college.	4.31	0.66	SA	4.18	0.85	A
My SHS strand helps me perform the class laboratories.	4.20	0.77	SA	3.91	1.2	A
My SHS strand helps me achieve high grades in college	4.03	0.73	A	4.12	1.02	A
My SHS strand help me get high score in quizzes in college	4.07	0.70	A	4.15	0.94	A
General Mean and SD	4.22	0.70	SA	4.07	1.00	A

Interpretation Legend: SA-Strongly Agree A-Agree N-Neutral D-Disagree SDA-Strongly Disagree

1) *Time management*: The necessity of time management in obtaining academic success was underlined by the NITRS respondents in particular. Respondents admitted to not prioritizing their academics as also shown in Fig. 7 and suggested time management as a solution. Knowing what to prioritize, giving time to difficult topic courses, and efficiently organizing their schedule will all help them overcome their academic deficiencies. Some of the responses under this theme include: “In my situation, I had a lot of obligations. Most of the time I can’t manage my time. I need to work to pay my enrollment fee so most of the time I skip classes. My recommendation is time management to avoid failed/INC”, “Give time to the subjects where I am having difficulty”, and “Plan your time well. Do your assignments early enough”.

2) *Positive attitude and mindset*: The majority of NITRS respondents clearly indicate that having a positive attitude and mindset would be extremely beneficial in overcoming academic difficulties. They go on to say that taking a real interest in the course, learning from mistakes, being open to new learning and setting appropriate goals are all things that will help them succeed in school. Negative thinking, according to the respondents, just causes stress and discourages students from pursuing academic success. Some of the responses under this theme include: “Keep a positive attitude. Find genuine interest in the topic. Think about the class and the workload positively”, “Just don’t think of anything that is not related to the very goal of education or the purpose of having a school, especially if those thoughts are just making us stress”, “We must stop pointing and complaining about our conditions as a student. Instead, make solutions to those problems and not excuses, so that we can move on”, and “Learn from mistakes. First of all, you must practice self-criticism and try to analyze the reasons that have caused the failure.”

3) *Instructor*: Instructors play a significant part in every student's academic career, and the instructor's impact can sometimes determine a student's success or failure. Fig. 4 shows that the NITRS respondents have difficulties understanding the lesson because the instructor does not talk properly, and they propose that they convey the discussion in a clear manner. The respondents also recommend that instructors should demonstrate sympathy, be more considerate of students' situations, especially when it comes to submitting activities, and encourage them to pursue their academic goals. In the same way, double-check every submission. Students are motivated to succeed academically when their instructor has a positive view-point and understands their circumstances. Some of the responses under this theme include: “Help the student whenever possible. Ask how you can help. Encourage them and don’t give up on them”, and “I recommend to all teachers to make sure to double check the records of their students.”

4) *Requirement completion*: To avoid academic deficiencies, the majority of respondents recommend meeting all academic prerequisites. Fig. 6 shows NITRS indicating that the reason for their poor academic performance is that they did not complete the task and homework. The respondents then

recommend that students complete all class activities and deliver all required output. The likelihood of passing the course and program increases with a complete submission. Some of the responses under this theme include: “Do all task/project/take quizzes/exam and always participate in online class”, “Try to meet each subjects needed output”, “For me my recommendation to avoid inc is to comply all the requirements, don’t miss out the activity and study more”.

5) *Study habit*: Respondents advise practicing reviewing prior to attending class and taking exams. Additionally, students should concentrate on their studies in order to reduce academic deficiencies. Proper study habits help to improve academic standing, boost confidence in class participation, and achieve high grades on exams. Some of the responses under this theme include: “Focus on the study”, “Review”, and “Don’t be lazy all the time”.

6) *Resumption of classes*: The pandemic has changed the mode of delivery of classes, and some students have been affected and have not fully recovered from the abrupt change in delivery. There were students who excelled in face-to-face delivery but struggled to deliver successfully in online mode, encountering difficulties in meeting the required output and failing to join the class due to a variety of factors. In lieu of the difficulties encountered, a respondent from ITRS has suggested that the face-to-face mode of delivery be resumed to ensure quality learning and that they could truly understand the discussion and avoid academic deficiencies. A response under this theme: “I recommend f2f classes because I think implementing f2f classes will help students to be motivated and has an energy to do things on time and the communication between the teacher and students will really help a lot in the performance of the students.”

#### F. Model for Reducing Academic Deficiencies

Based on the identified causes of academic deficiencies and the respondents' recommendations to avoid them, the researcher developed a model that could potentially reduce academic deficiencies. The model (see Fig. 11) is made up of two (2) components: internal and external, as well as students at the center who will execute and carry out the given components. Internal factors include effective time management, positive attitude and mindset, prompt/punctual requirement completion, and good study habits. Furthermore, in order for the student to remain motivated to achieve academic success, these external factors should be considered; competent and student-friendly instructors, stable, and strong, and accessible internet connections, conducive learning environment, relevant available resources and facilities, adaptation of limited face-to-face or hybrid classes and lastly alignment of SHS strand to college program of choice.

##### 1) Internal factor

a) *Effective time management*: By carefully managing time through meticulous preparation of every second of every day, the student may regulate their schedule so that their time is spent efficiently and they can finally attain their objective. According to Vences Cyril [29], having these skills gives

students the ability to plan ahead and prioritize upcoming assignments and events. This is an important factor in keeping students organized and avoiding procrastination, and ultimately leads to academic success. Being efficient with time may also lead to the discovery of limitless possibilities to focus on oneself and one's mental health, resulting in a right mentality. Ahmad, Batool, & Hussain Ch [30] also mentioned that time management is important in enhancing learners' performance and accomplishments. It is a talent to manage time, and every student must be familiar with and command of this skill in order to get better outcomes. A student can only survive if he or she has good time management skills.

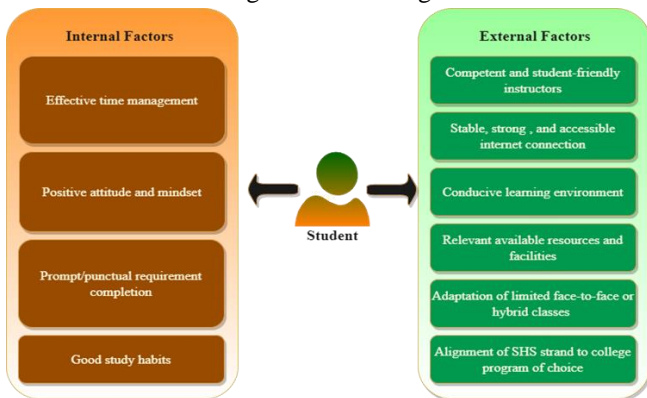

Fig. 11. Model for reducing academic deficiencies.

*b) Positive attitude and mindset:* Having a positive mentality reduces negative thinking, and they will be more focused on studying and executing academic tasks, as well as driven to complete them on time. An article from Overcoming Fear of Academic Failure: Reasons Why Student Fail vs Thrive stated that the ability to learn from failure and keep working toward your goals anyway comes from adopting a resilience mindset. This takes practice, but you can train yourself to understand that failure is part of life and then be willing to keep trying anyway. An important aspect of resilience is the desire to learn from mistakes. Even if you fail, knowing that you can find a solution and work toward your goals in new ways should help you overcome failure [31].

*c) Prompt/punctual requirement completion:* In order to be a successful student, it is essential to complete assignments on time. Meeting time schedule demonstrates that the student can efficiently manage their time and priorities. Numerous activities are evaluated, and timely completion of assignments is essential for receiving excellent scores. By completing assignments on time, students are able to avoid late submission penalties and keep excellent scores in their courses. There are a numerous of benefits associated with doing your assignment in a timely manner. These would include learning how to be more disciplined and independent, improving your ability to manage your time more effectively, which would give you more flexibility to pursue other interests, and increasing the amount of information that you have obtained. By having a great understanding are more likely to achieve a better grade [32].

*d) Good study habits:* There is a substantial association between students' study habits and academic achievement. The study habits of students were used to predict their achievement. The use of study strategies and habits can help students improve their academic performance. Study habits are the reason for the development of academic achievement. [33] [34] [35] Students who have a wide range of self-management skills can deal with long and uncertain deadlines by breaking far-off goals into smaller, closer goals on their own. Students who don't have these skills, on the other hand, would benefit from structures that set sub-goals with deadlines. For example, having students turn in an outline for a paper after the first third of the semester, the first draft after the second third, and the final draft at the end of the semester helps break down a big goal into smaller, more manageable goals. In an ideal world, this scaffolding of self-regulated learning and writing could be used as a model for long-term projects in the future. In general, making goals closer (e.g., with sub-goals) may help the student do better in school and stop putting things off. [36].

## 2) External factor

*a) Competent and student-friendly instructor:* Students' performance is also affected by outside forces that are beyond their control. Because of the diverse worries of the student, having competent and sympathetic instructors will assist the student perform well in class. When the learner thinks that they are being understood, they feel comfortable and motivated to fulfill the work provided. Naz [37] mentioned that for quality education the competent teachers are necessary. Teacher's professional competence includes knowledge and understanding of children and their learning, subject knowledge, curriculum, the education system and the teacher's role. Academic performance has a highly substantial and positively correlated relationship with teachers' levels of expertise, grasp, and clarity on the topics they teach. In addition, aspects of a teacher's demeanor such as engagement, pace, the overall attitude of the instructor, openness, and rapport have a substantial bearing on students' cumulative grade point averages [38] [39].

*b) Stable, strong, and accessible internet connection:* Because of the new normal delivery it is also required to have a solid internet connection in order for the students to join classes, submit requirements and acquire relevant information. Dogniez [40] stated that improved connectivity and the vast learning resources that are available over the Internet can be harnessed to advance access and quality of education. A reliable internet connection offers a lot of convenience and allows us to complete tasks with much less hassle, whether that's downloading a document or making a video call to a work colleague or a loved one. With a good internet connection, we can work, educate ourselves, entertain ourselves and save money.

*c) Conducive learning environment:* A suitable setting is a necessary for learning. Comfortable learning place with minimal destruction helps the student comprehend and grasp the information being taught. In addition, having restricted, substandard and run-down resources and facilities also

hampers student progress, thus it proposes that students should have suitable available learning materials and facilities. This will bring about an enjoyable, exciting and meaningful process, whereby students anticipate attending courses. Students will also feel more at ease learning in a classroom atmosphere and would be able to concentrate more intensively on understanding the subjects at hand. It is supported by Chongui [41] stating conducive environment for learning, such as one with comfortable class-room set-ups, relevant use of teaching materials and interesting classroom activities, will further motivate the students to learn.

*d) Relevant available resources and facilities:* Students' academic success is greatly influenced by the quality of school facilities, and inadequate facilities result in low performance. [42] The availability and proper usage of school physical amenities have a key role in improving students' academic achievement, whereas the lack of such facilities may lead to students' poor academic performance. If physical facilities are accessible and utilized sensibly to fulfill the demands of the students, this would definitely increase students' enthusiasm in studying and lead to superior performance. [43].

*e) Adaptation of limited face-to-face or hybrid classes:* Due to the COVID-19 pandemic, the academic delivery method switched from in-person to online. Some students adapted the new method with ease, but others did not, which affected their academic achievement. There are students that succeed and do better when there is face-to-face interaction, particularly in skills-based courses that need laboratory activities. The researchers chose to incorporate limited face-to-face or hybrid classes in the model in order to meet the demands of students for laboratory activities in light of the ongoing pandemic threat and the contemporary method of instruction.

Adopting hybrid course delivery, which could provide a solution to ensure that Bioscience students receive practical laboratory experience and face-to-face contact to stay motivated and benefit from the on-campus facilities and support, while also giving students some of the flexibility provided by remote study. Student demographics and digital equality must be taken into account in the present competitive higher education market, where student retention is crucial, to ensure that the right strategy is used to serve all students.[44] Kemp [45] also mentioned that with a blended learning strategy, teachers can assign a variety of in-person and online activities to their students. Allowing students to choose how to finish particular task types may be an effective strategy to help more students feel in charge of their own learning and to help them fit learning more readily into their other responsibilities at home and at work.

*f) Alignment of SHS strand to college program of choice:* Students' senior high school track or strand has an impact on their academic success and self-regulated learning. The students' senior high school experience has better prepared them for college, especially in the nursing program. Graduates of senior high school's academic STEM program seem better equipped to enroll in the nursing program, better able to handle the rigors of the program, and more likely to

succeed in nursing school. [46] The model also implies that it would be more advantageous and students would have easier time learning if the strands are connected to the curriculum or perform a bridge program.

Al-Muslimawi and Hamid [47] found external and internal factors that influence students' academic performance in their study. The study found that learning facilities and technology had the greatest impact on students' academic performance, while extracurricular activities can improve academic performance and college life. Competence and aptitude are also excellent indicators of academic success. Family issues might negatively impact students' performance. In addition to socioeconomic position and other factors, work and finances affect students' academic achievement. Social and other issues can slightly affect quality performance, but they are easier to overcome. Moreover, class schedule, size, and atmosphere can negatively impact learning. And, most students' academic performance is affected by text books and test procedures.

In the related studies, significant similarities were discovered, which validates some factors in the researchers' designed model. The researchers, on the other hand, included additional variables that might potentially improve academic performance and fill the gap of the previous studies. Existing studies have identified a number of factors and potential solutions, but the researchers opted to build an approach that concentrated on reducing academic deficiencies. The developed model is a blend of conventional and contemporary solutions that also takes into account the changes in academic mode of delivery caused by the COVID-19 pandemic. And these modifications affected the academic achievement of the students in some way. In addition, because students in this study had an additional year of high school, the researchers investigated whether or not this factored into their academic success in college.

#### IV. CONCLUSION

The researcher discovers that the Non-IT-Related strand, in comparison to the IT-Related strand, has a number of issues in terms of academic performance for a variety of reasons. They emphasize that because of the strand misalignment, they find it difficult to understand the courses in the program chosen. It is also believed that instructors who do not communicate clearly have an impact on students' ability to absorb knowledge, and that students who have an unreliable internet connection have a harder time performing effectively in class. Respondents acknowledged not finishing academic tasks and not submitting them on time, resulting in failed and incomplete remarks. In addition, both the IT-related and non-IT related strands are in agreement that their SHS strands are related to the program that they intend to study in college; however, the IT-Related strand is the one that believes their strand is more beneficial to their academic success in college than the non-IT related strand. The IT-related strand was determined to be statistically significant at a level of  $p < 0.05$ , which indicates that enrolling in the IT-Related strand offers a considerable advantage over the non-IT related strand. As a result, the researchers constructed a model that, with the help of the given reasons and recommendations from the respondents, can potentially eliminate academic inadequacies.

In order to effectively address and give a solution to the problem that has been recognized, the model takes into account both internal and external factors. It is recommended that, with regard to the internal variables, effective time management, a positive attitude and mindset, prompt and punctual completion of requirements, and good study habits be utilized. While for the external factors, the model includes competent and student-friendly instructors, a stable, strong, and accessible internet connection, a conducive learning environment, relevant available resources and facilities, adaptation of limited face-to-face or hybrid classes, and alignment of SHS strand to college program of choice.

The approach that was formulated might be used as a guide by the institution, particularly in the formulation and process of the admission policy to avoid or address misalignment of strand to the college program of choice, evaluation of teaching professionals, and acquisition of education infrastructure. In addition to that, this may also be of use to the Information Technology Department in terms of assessing their curriculum, the approach utilized by teachers, and the monitoring of their students in conjunction with the Guidance Office. Furthermore, this model may be of assistance to the government education sector, particularly CHED and DepEd, in the process of reevaluating the policies and guidelines, particularly as they pertain to the implementation of the K to 12 or Senior High School program and how this program affects academic performance in college.

The investigation was conducted on the IT Department, but the researchers recommend looking into other programs. Additionally, to perform in-depth study on the alignment of the curriculum between senior high schools and higher education institutions, as well as how it contributes to other possible causes of academic inadequacies.

#### ACKNOWLEDGMENT

Above all the authors thank and praise Almighty God for making everything possible. Sincere appreciation to the respondents of the study, to Dr. Thelma Palaoag, Dr. Regina Sarte and Dr. Florivel Villacorta for the humble ideas and support. The panel of experts for the constructive inputs and precious time for the improvement of the study. And lastly, authors' family and colleagues for the motivation and inspiration.

**Abstract**—In recent decades, mobile health (m-health) applications have gained significant attention in the healthcare sector due to their increased support during critical cases like cardiac disease, spinal cord problems, and brain injuries. Also, m-health services are considered more valuable, mainly where facilities are deficient. In addition, it supports wired and advanced wireless technologies for data transmission and communication. In this work, an Artificial Intelligence (AI)-based deep learning model is implemented to predict healthcare data, where the data handling is performed to improve the dynamic prediction performance. It includes the working modules of data collection, normalization, AI-based classification, and decision-making. Here, the m-health data are obtained from the smart devices through the service providers, which comprises the health information related to blood pressure, heart rate, glucose level, etc. The main contribution of this paper is to accurately predict Cardio Vascular Disease (CVD) from the patient dataset stored in cloud using the AI-based m-health system. After obtaining the data, preprocessing can be performed for noise reduction and normalization because prediction performance highly depends on data quality. Consequently, we use the Gorilla Troop Optimization Algorithm (GTOA) to select the most relevant functions for classifier training and testing. Classify his CVD type according to a selected set of features using bidirectional long-term memory (Bi-LSTM). Moreover, the proposed AI-based prediction model's performance is validated and compared using different measures.

**Keywords**—Artificial Intelligence (AI); M-Health System; Data Collection; Cloud Storage; Gorilla Troop Optimization (GTO); Bi-directional Long Short-Term Memory (Bi-LSTM); dynamic prediction

## I. INTRODUCTION

The healthcare industry faces several challenges in diagnosing disease and providing affordable services [1, 2]. Providing patients with the best possible care based on a review of their medical histories, medical decisions, and the variability of their molecular properties is one of the fundamental requirements of any healthcare system. Due to the rapid development of new technologies, these systems have been dealing with several problems with data gathering, information association, data retrieval, and decision-making [3]. Due to logistical constraints caused by mobile phone use in developing nations, many healthcare sectors have significantly transformed. Mobile technology [4] has recently been crucial in several technological domains among

subscribers in practically all countries. The advancement of new technologies and their use in the healthcare industry, known as "m-health" [5, 6] are aided by mobile devices and communications. The general framework of m-health system is shown in Fig. 1. Still, the m-health framework [7, 8] has many challenges and issues, which include the followings:

- Better interpret the data from multiple sources produced by numerous mobile and information sources after 2021.
- Enabling smarter, more personalized behavior change and engaging tools to inspire more meaningful users and patients to improve their health and well-being. The vast amount of health data from 5G mobile health users also needs to be intelligently adapted and transformed. It is essential to accurately estimate the relationship between the genomic data sequence and other medically relevant data.

The interpretation of large medical imaging datasets and other relevant diagnostic/imaging data generated by the latest generation of mobile imaging devices requires reliable, accurate and secure data analysis methods.

For instance, the cardiac arrest is now more likely in the situation where life is currently halted. Patients' health conditions deteriorate when they put off getting medical care because they are worried about contracting a communicable illness. For diagnosis and therapy, accurate predictions are essential. Researchers are constantly creating useful decision assistance systems, but CVD diagnosis is still difficult. Several intelligent tools have been developed based on machine learning and data-driven methodologies to address these issues. These methods have all included connecting many data sources to create a collective understanding for future research and predictive analysis [9, 10]. Several research have demonstrated that the severity of heart diseases may be automatically diagnosed using various machine learning approaches, such as combining numerous classification algorithms and augmentation algorithms to create reliable automated prediction systems. The CVD dataset was utilized in the research to test seven models, including SVM, KNN, LR, DT and various ensemble methods. Moreover, the AI-assisted diagnosis can help doctors make diagnoses more quickly and cheaply, which can help save patients' lives earlier in the process when there is a shortage of medical professionals.

Fig. 1. General framework of M-Health systems.

Furthermore, many prediction-based techniques have been developed for various conditions, including neurological and cardiovascular heart disorders. In m-health systems, patient data is gathered to help with disease tracking, diagnosis, and prompt services, particularly in places where immediate care is complicated. Another online platform with a substantial library of medical content built on multimedia is called E-Medicine. Despite the availability of these new communication channels [11, 12], the technological support for the healthcare industry often needs to meet expectations due to scalability and other technical issues. To make the service more accessible to providers, users, and medical professionals, a more suitable m-health architecture needs to be designed. In addition, all data transmissions must be quick and secure to ensure timely delivery [13]. Security is one of the most crucial elements, particularly in relation to wearable sensors and handheld devices. The major research objectives of this paper are as follows:

- To develop a computationally efficient M-Health framework by using an advanced Artificial Intelligence (AI) mechanism.
- To accurately predict the cardiovascular disease from the obtained patient health information with reduced time and computational complexity.
- To improve the prediction rate of the M-Health systems, a Gorilla Troop Optimization Algorithm (GTOA) mechanism is deployed.
- A bidirectional long-short-term memory (Bi-LSTM) model has been implemented to ensure efficient and accurate disease diagnosis.

A comprehensive analysis was performed using various performance measures to validate and test the results of the proposed GTOA using the Bi-LSTM model.

The following sections make up the remaining parts of this article: The traditional approaches and methods for dynamic disease prediction in m-health systems are reviewed in Section II. In accordance with its primary disease prediction

outcomes, it also analyses the benefits and drawbacks of each technique. The entire description of the proposed approach, including its workflow and extensive illustrations, is provided in Section III. Using a variety of parameters, Section IV compares and validates the results of the proposed and existing disease prediction models. In Section V, the study concluded with its findings, implications, and future scope.

## II. RELATED WORKS

This section gives an exhaustive assessment of the literature on the current AI development approaches. Additionally, it looks at each work's benefits and drawbacks in relation to its performance, core concepts, and processing method.

The most popular machine learning approaches are classification algorithms. Based on their preferred method of learning, machine learning models can be broadly categorized into three categories: reinforcement learning, unsupervised learning, and supervised learning. When a machine learns how to assign labels to each class of data that process is known as classification. Moreover, the ANN, NB, DT, and LR are the most popular machine learning models specifically used in the healthcare applications for disease prediction. To identify patterns and address AI issues, the ANN is constructed using a network of neurons and weighted connections. During training, the random forest generates a number of decision trees and produces the results that receive the most votes. This method is applied to tasks involving classification and regression. NB is a Bayes' rule-based classification system that works under the presumption that all of the features that forecast the ideal value are unbiased. Based on the likelihood that the data belong to a particular class, the Nave Bayes model can determine the class of a given set of data. A straightforward method known as "nearest neighbors" can be used to save all existing cases and categorize new cases based on how similar they are as determined by distance functions.

Istepanian and Anzi [14] utilized a new m-health framework for an intelligent healthcare delivery systems. The purpose of this work was to investigate the relevant big data

issues, and technological innovations for developing an effective m-Health framework. Moreover, we validated different types of data analysis approaches for the M Health system, including descriptive models, diagnostic models, predictive models, and prescriptive models. Based on this research, machine learning and deep learning tools are analyzed to be of great importance and play an important role in the m-Health framework. Mishra et al. [15] pursued a new approach to improve the effectiveness of m-health systems using big data and IoT technologies. This paper targets to construct a new IoT based m-Health framework for disease monitoring and patient empowerment. Also, it intends to minimize the cost and enable an effective utilization of the medical components for proper m-Health management and control. However, the system model of the suggested framework could be difficult to understand, and it failed to demonstrate the efficiency and reliability of this systems. Alotaibi, et al. [16] analyzed the major applications of using AI and big data analytical models for developing a highly proficient m-Health systems. Here, a systematic review is conducted for investigating the different types of AI mechanisms to improve the performance of m-health systems. Moreover, this work used various performance measures to assess the quality of m-health systems that includes interactivity, veracity, usefulness, effectiveness, user satisfaction, and customization. The major drawbacks of this framework are inaccurate system response, various privacy and security problems.

Al-Marridi, et al. [17] employed an AI technique for optimizing the energy efficiency of m-health systems. The purpose of this work is to effectively minimize the latency and jitter by properly providing the resources and services from the cloud data centers. Moreover, it mainly concentrated on the optimal allocation of resources in the m-health systems. For this purpose, the deep learning based neural network algorithm was deployed, which supports to reduce the distortion and maximize the compression ratio of the healthcare framework. The primary advantages of this framework are reduced time consumption, optimized energy consumption, and delay. Elhishi, et al. [18] deployed a mobile health application system for identifying the leukemia cancer, where a straightforward medication management scheme was also used to remind the patients about their schedules. Specifically, it intends to develop a construct a new prototype for identifying the suitable solution with reduced time and cost. In addition, the Convolutional Neural Network (CNN) based deep learning classifier has been utilized to detect the leukemia cancer using the blood film input. Lano, et al. [19] utilized an AI mechanism to assist the m-health application systems. Here, the machine learning model is utilized to analyze the behavior elements of the medical systems. Mendo, et al. [20] provided a thorough analysis of the many machine learning models employed to raise the capability of mobile health systems. We also explored the rise of mobile healthcare devices and applications for reviewing patient health records. Pankaj et al. [21] used a machine learning approach to diagnose diabetes using the M-Health application. Abed et al. [22] introduced an integrated electronic medical system that enables efficient medical monitoring. Here, the machine learning based traffic flow classification model was utilized

for reducing the time delay and traffic during data transmission/communication.

Alhussein, et al. [23] developed a voice pathology detection system with the help of CNN model for mobile health applications. The purpose of this work was to design a smart m-health framework by using the transfer learning mechanism. In addition, various types of features such as mel-frequency cepstral coefficients (MFCC), pitch frequencies, and linear prediction cepstral coefficients (LPCC) are also used. Shaban-Nejad, et al. [24] presented a detailed analysis demonstrating the importance of using AI in personalized healthcare systems. The scope of this paper was to improve the speed, accuracy, and reduce the time in the health systems. Shatte, et al. [25] presented a comprehensive survey for examining various ML methodologies used for developing a computationally proficient healthcare monitoring framework. Moreover, it discussed about the importance of using ML techniques in the field of medical treatment and diagnosis. It includes the mechanisms of active learning, Bayesian network, ensemble learning, regression, KNN, multivariate classification, random forest, linear discriminant analysis, and discriminative dictionary learning. Dargan, et al. [26] presented a comprehensive survey for examining the different types of deep learning mechanisms used in a health application systems. Key factors for using deep learning methodologies are layered or multi-level nonlinear processing and whether learning is guided or unguided. Garcia et al. [27] developed a framework for mental health monitoring systems (MHMS) based on machine learning models. The main consideration of this paper is to ensure the properties of increased privacy, high storage capacity, reliable data transmission, reduced energy consumption, and flexible data labeling. Tian, et al. [28] intended to design a smart healthcare framework with the specific parties of efficiency, convenience, and personalization. This framework includes the major participants of doctors, patients, hospitals and research institutions.

Based on the literature review, the problems associated to the conventional M-Health frameworks are as follows:

- Complex system design.
- Increased error prediction rate.
- Computational burden.
- High time consumption.
- More resource utilization.

Therefore, the proposed work motivates to develop a new M-Health framework for dynamic disease prediction.

### III. PROPOSED METHODOLOGY

This section provides the complete explanation for the proposed m-health systems with the overall workflow and illustrations. The original contribution of this work is to predict the cardiovascular disease according to the patient information collected from the cloud storage by using an advanced AI mechanism. The architectural model of the proposed M-Health framework is shown in Fig. 2. The development of mobile systems, especially for emergency

applications, is usually a product of information and communication technology. Moreover, the emergency applications are highly crucial for the patients who suffered with heart disorders, brain injuries, spinal injuries, and etc. The M-Health services are beneficial, particularly in areas without many medical facilities, where hospitals are dispersed among the population, or where the cost of medical care is high. Also, it is built on new wireless and wired technologies, including cloud computing, Global System for Mobile Communications (GSM), and 4<sup>th</sup> or 5<sup>th</sup> generation technologies. Smart sensors are a feature of M-Health systems, which also have 5G connectivity capabilities linked with Web 2.0, online communities, and cloud - based services. Furthermore, the majority of M-Health-capable sensors and gadgets use low-power Bluetooth and ZigBee technologies to transmit data to other endpoints. The information is then shared to the distant systems or cloud data storage over communication networks for additional processing and decision-making. The modules involved in the proposed M-Health framework are as follows:

- Data collection using smart sensors.
- Data transmission to cloud.
- Deep learning based cardiovascular disease prediction.

Initially, the data collection is performed through smart sensors that are planted inside the human body, which are further connected with the mobile devices or gateways. Then, the smart devices like mobile can be used to enable communication between the patients and healthcare professionals at anywhere. After that the obtained health information is transmitted to the cloud systems for further operations. Furthermore, the deep learning based AI mechanism is applied to accurately predict the cardiovascular disease from the obtained patient health information. As shown in Fig. 3, the proposed AI based disease prediction system comprises the following operations:

- Secure data collection from cloud or data centers.
- Data preprocessing.

- Gorilla Troop Optimization Algorithm (GTOA) for feature selection.
- Bi-directional LSTM based classification.

After obtaining the health data from cloud systems, the data preprocessing is applied to generate the balanced dataset by performing the operations of cleaning, normalization, noise removal and balancing. Since, the raw dataset comprises some un-related attributes or information that may disrupt the accuracy of disease detection. Hence, the data preprocessing is more essential for an accurate disease prediction and diagnosis. After that, an intelligent and computationally efficient GTOA is applied for reducing the dimensionality of the dataset by choosing the most relevant features. It is also helps to improve the disease detection rate and reduce the overall time consumption of the processing system. Finally, the deep learning based AI model, named as, Bi-LSTM has been applied to accurately predict the type of cardiovascular disease according to the set of extracted feature set. The performance of the proposed GTOA using the Bi-LSTM model is validated and tested with various parameters. The primary advantages of the proposed model are as follows: easy to understand, reduced complexity in processing, less time consumption, accurate disease prediction, and computationally proficient.

#### A. Cloud Model

In this framework, the cloud system comprises two layers such as data annotation & analysis, and storage & access layers, in which the storage layer stores the M-Health information obtained from the mobile devices through network service providers. The data is related to the patient's medical information like previous history, glucose level, BMI, heart rate, etc. Typically, the cloud is one of the most suitable and convenient platform for the users to store and retrieve the information. Specifically, the cloud has the major benefits of reduced cost, stability, and efficiency for the M-Health applications. Here, isolation strategies are used to enable secure data storage operations that ensure privacy and confidentiality of patient medical information. The data storage model of the cloud system for the proposed M-Health application system is shown in Fig. 4.

Fig. 2. M-Health framework of the proposed system.

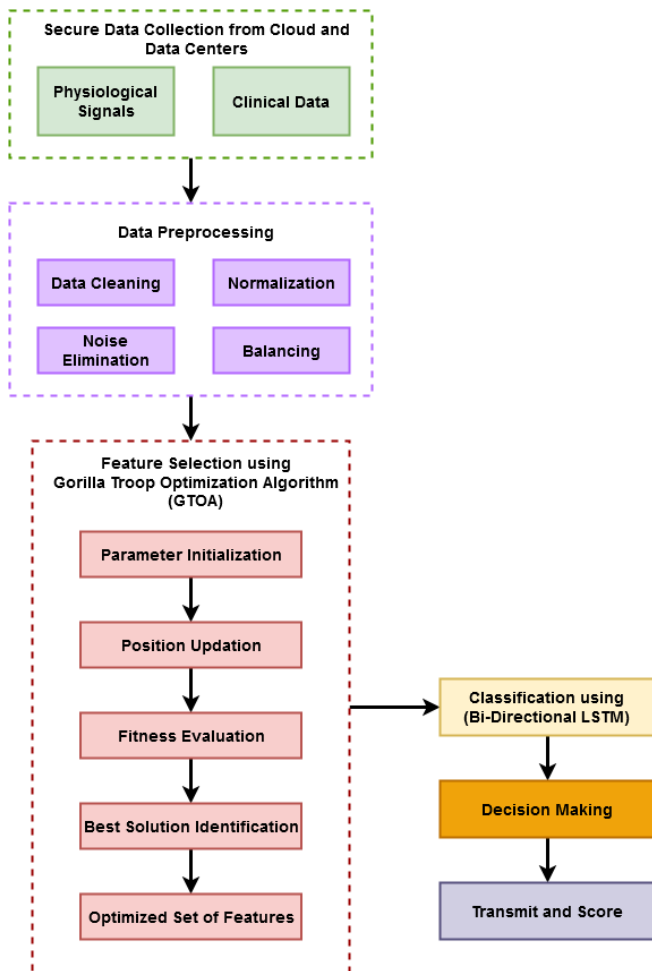

Fig. 3. Flow of the proposed dynamic prediction system.

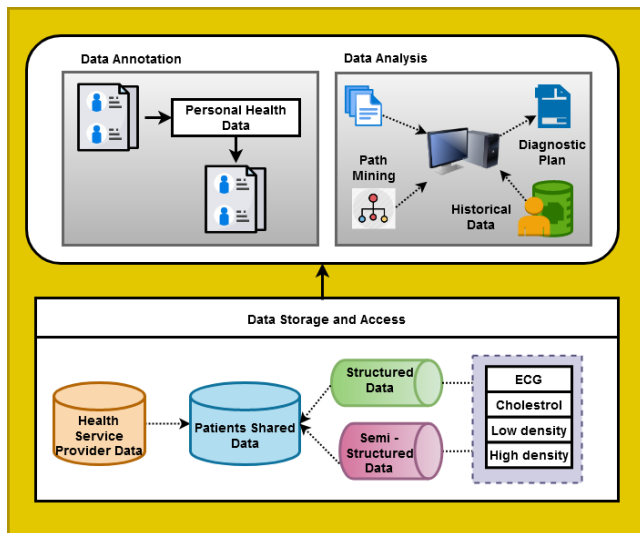

Fig. 4. Cloud data storage model.

### B. Secure Data Collection

The health or medical information about the patients like clinical records, and physiological signals are gathered from the smart sensor devices. Here, the wearable smart devices monitor the patients' data, and transmits the obtained

information to the mobile device. Since, the existing data are gathered from the cloud systems, which comprise the information of patient history, age, BMI, gender, blood pressure, etc. This information is updated by the medical centers, and it can be used to predict that whether the patient is affected by the CVD or not.

### C. Data Preprocessing

After collecting the information, we apply data preprocessing to create a noise-free and balanced dataset for accurate disease prediction and classification. The main goal of this work is to accurately detect CVD disease in order to provide appropriate treatment and recommendations to patients. Data normalization and noise reduction techniques are used to make the data noise-free at this stage. Noise and other environmental influences are present in the raw data that comes from the sensor nodes. Moreover, it includes the preprocessing operations of cleaning, normalization, noise elimination, and data balancing. This technique is used to tune the noisy data into a clean dataset. In other words, anytime data is acquired from various sources, it is done in a primary manner that makes analysis impossible. So that the deep learning model being used can produce better outcomes, data must be presented in the correct format. Pre-processing describes the changes made to our data before the algorithm receives it. The removal of mistakes, inconsistencies, and missing values from the dataset is the focus of the data cleansing/cleansing stage. Various approaches or techniques have been developed to address this issue. The data value missing from the cell in the corresponding column is known as a missing value. In healthcare, missing values may occur due to human error, non-applicability, sensor omission, patient absence from the ventilator due to medical decisions, or patient state unrelated to a particular variable. Moreover, the missing values can be handled by either rejecting them or imputing the missing information. In addition, the data scaling is performed by using the min-max algorithm, which scales the features in the range of [0, 1], and [-1, 1]. It is estimated as follows:

$$D = \frac{d - d_{mn}}{d_{mx} - d_{mn}} \quad (1)$$

Where,  $d_{mn}$  and  $d_{mx}$  are the minimum and maximum values of the dataset. Based on this operation, the balanced and quality improved data is produced as the output, which can be used for an accurate CVD prediction.

### D. Gorilla Troop Optimization Algorithm (GTOA)

After preprocessing, the GTOA is applied to optimally select the features from the balanced dataset for accurately predicting the disease. This technique provides the best solution for setting features to train the classifier. Finding the best viable or desirable solutions to a specific problem that is frequently faced in a variety of fields is referred to as optimization. Multiple factors have contributed to the popularity of meta-heuristics in engineering applications. For instance, they are simple to execute, contain reasonably simple concepts, perform better than local search algorithms, have many different applications, and knowledge of the derivative function is not required. In the existing disease prediction frameworks, various meta-heuristics optimization techniques

are deployed for feature optimization and dataset dimensionality reduction. However, it faces some complications associated with slow convergence, a high number of iterations, complexity in computation, and more time consumption. Hence, the GTOA is utilized in this work, which supports reducing the dimensionality of the preprocessed dataset by selecting the most relevant features used for CVD prediction.

In this technique, the five distinct operators are used to simulate exploration and exploitation optimization procedures based on the behaviors of gorilla, and its phases are shown in Fig. 5. During exploration, three distinct operators have been used such as:

- Migration to unknown place for increasing the capability of exploration.
- Migration to other gorillas for balancing both exploration and exploitation.
- Move in the direction of an identifiable place to increase the capability of GTO.

These operations are mathematically performed as shown in below:

$$AG(h+1) = \begin{cases} (Up_b - Lo_b) \times \alpha + Lo_b & r < d \\ (\beta - K) \times G_r(h) + H \times B & r \geq 0.5 \\ G(i) - K \times (K \times (G(h) - AG_r(h)) + \gamma \times (G(h) - AG_r(h))) & r < 0.5 \end{cases} \quad (2)$$

Where,  $AG(h+1)$  indicates the candidate position vector of gorilla at iteration  $h$ ,  $G(h)$  denotes the current vector of gorilla,  $r, \alpha, \beta, \gamma$  are the random numbers from [0 to 1] that can be updated at each iteration,  $d$  is the parameter that is used before optimization ranging from 0 – 1,  $Up_b$  and  $Lo_b$  are the upper and lower bounds respectively. Moreover, the optimization parameters  $K, H$  and  $B$  are computed by using the following equations:

$$K = U \times \left(1 - \frac{itr}{max_{itr}}\right) \quad (3)$$

$$U = \cos(2 \times \rho) + 1 \quad (4)$$

$$H = K \times a \quad (5)$$

where  $U$  is the function computed using equation (4), iteration denotes the current iteration, and  $\lceil \max \rceil$  iteration denotes the total number of iterations used to perform the optimization,  $\rho$  is the random number from 0 to 1, and  $a$  is the random number from -1 to 1. Consequently, the other optimization parameter  $B$  is estimated by using the following equation:

$$B = w \times G(h) \quad (6)$$

$$w = [-K, K] \quad (7)$$

Where,  $w$  indicates the random value in the range of [-K to k]. Similarly, the other two operators are used in the exploitation stage that supports to increase the performance of searching. During exploitation, the following operations are performed:

$$AG(h+1) = H \times Q \times (G(h) - G_{sb}) + G(h) \quad (8)$$

$$Q = \left( \left| \frac{1}{P} \sum_{i=1}^P AG_i(h) \right|^v \right)^{1/v} \quad (9)$$

$$v = 2^L \quad (10)$$

Where,  $G(h)$  indicates the vector position of gorilla,  $G_{sb}$  is the silverback of gorilla,  $Q$  is the function estimated by using equ (9),  $v$  is the setting parameter, and  $P$  is the number of gorillas. Then, the vector position of each candidate gorilla  $AG(i)$  is updated at iteration  $h$  as shown in below:

$$AG(i) = G_{sb} - (G_{sb} \times I - G(h) \times I) \times CV \quad (11)$$

$$I = 2 \times rand - 1 \quad (12)$$

Where,  $I$  is the impact force, and  $CV$  is the coefficient vector. Finally, the cost of all solutions is estimated, and based on this the best solution is obtained as the optimal solution.

---

*Algorithm 1 – GTO for feature selection*

---

Input: Population size  $P$ , maximum number of iterations  $N$ , parameters  $\delta$  and  $s$ ;  
Output: Location of gorilla and fitness value;  
Step 1: Initialize the random population as  $G_i$ , where  $i = 1, 2 \dots P$ ;  
Step 2: Estimate the fitness value of Gorilla;  
Step 3: While (Until reaching the stopping criterion) do  
    Update the parameter  $K$  by using equation (3);  
    Update the parameter  $H$  by using equation (5);  
    For (each Gorilla  $G_i$ ) do  
        Update the current location of gorilla by using equation (2);  
    End for;  
    Compute the fitness value;  
    If  $AG$  is better  $G$   
        Set  $G_{sb}$  as the best location;  
        For (each Gorilla  $G_i$ ) do  
            If ( $|K| \geq 1$ ) then  
                Update the current location of gorilla using equation (9);  
                Else  
                    Update the current location of gorilla by using equation (11);  
                End if;  
            End for;  
            Estimate the fitness value of gorilla;  
            If (New solution is greater than previous)  
                Update  $G_{sb}$  as the best position;  
            End while;  
Return  $G_{best}, Best_{fit}$ ;

#### E. Bi-Directional LSTM

Finally, the Bi-LSTM algorithm is applied to precisely classify the CVD with high reduced complexity and high accuracy. Typically, the Recurrent Neural Networks (RNNs) are the foundation of the LSTM method [29], Input gates, output gates, and forget gates that form the primary LSTM unit cell. The LSTM creates an internal feedback state due to processing various inputs close to one another, which helps the network comprehend time and the significant variability of the displayed data. Through gate control, the LSTM network incorporates resolving gradient vanishing to a certain level. While an LSTM framework can understand and preserve past data, it cannot accurately include new data to support a final prediction. As a result, a Bi-LSTM with two-way functionality was made using the LSTM network. In sequence prediction modelling, bi-LSTM networks perform better than other RNN and LSTM architectures, especially regarding speech or handwriting recognition and machine translation. Bi-LSTM contains two separate LSTMs that can integrate and aggregate data from both forward and backward directions. It is useful to have access to past and future context when performing sequence labeling tasks. Bi-LSTM proposes to transfer and invert each sequence to her two hidden entities, to produce a result by integrating the two logical states, and to obtain knowledge of the future and the past. Although they have identical sentence embedding, two opposing directions' parameters in the Bi-LSTM framework are different. By using this mechanism, the CVD is properly predicted and categorized with less time consumption.

#### IV. RESULTS AND DISCUSSIONS

In this section, we describe and compare the full results of the proposed disease prediction models. The CVD dataset is used to verify and contrast the outcomes of the suggested prediction mechanism. This data comprises extensive patient information and medical records. Moreover, the different types of parameters used to validate the results, and are computed as shown in below:

$$Precision = \frac{TrP}{TrP+FaP} \quad (13)$$

$$Recall = \frac{TrP}{TrP+FaN} \quad (14)$$

$$F1 - score = 2 \times \frac{(Precision \times Recall)}{(Precision+Recall)} \quad (15)$$

$$Accuracy = \frac{Correct Prediction}{Total Prediction} \quad (16)$$

Where,  $TrP$  is the true positive,  $FaP$  is the false positive, and  $FaN$  is the false negative. The attributes and descriptions of the CVD dataset used in this study are shown in Table I.

Fig. 6 presents a comparative analysis of conventional [30] and proposed AI mechanisms used for CVD prediction and classification. For this analysis, the parameters precision, recall, f-measure and accuracy have been considered. The proposed model offers improved computation capabilities and system efficacy as a result of the best feature processing and selection.

The accuracy of CVD prediction is significantly increased when the proposed optimization and classification model is used; however ordinary machine learning and deep learning methods perform less well due to insufficient feature processing and selection.

TABLE I. CVD DATASET DESCRIPTION

Attributes	Descriptions
Age	In years
Gender	Male or Female
Chest Pain	Type of CP
Blood Pressure	BP level in mm Hg
Serum Cholesterol	In mg/dl
Fasting blood sugar	>120 mg/dl (1 true and 0 false)
Rest ECG	0 – Normal 1 – Abnormal 2 – Maximum heart rate
Max_heart rate	Maximum heart rate
Exercise induced angina	0 – No 1 – Yes
ST depression	Depression induced by exercise
Slope	1- Up 2- Flat 3- Down
No of vessels	Vessels colored by fluoroscopy
Thalassemia	Normal, irreversible, and fixed
Num	No of risk, low risk, high risk, and very high risk

Fig. 6. Performance comparative analysis with machine learning techniques.

Fig. 7. Error analysis.

Fig. 7 compares the Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) rate of the existing [31] and proposed classification methodologies. Absolute error is the term used to describe the size of a measurement error. Estimate using the difference between the measured value and the actual value. Mean Squared Error, or MSE, measures how inaccurate a statistical model is. The mean squared difference between observed and expected values is computed. Additionally, the MSE increases as model error increases and is equal to 0 when a model is error-free. Mean squared error, also called mean squared error, is a commonly used technique to assess the accuracy of predictions. It exemplifies the Euclidean gap between predictions and measured actual values, and is indicated in the results that the MAE.

Table II and Fig. 8 [32] provide an overall comparison of existing and proposed prediction methods used for CVD detection and classification in terms of recall, f1 score, accuracy, precision, and time shows the analysis. Based on our results, we conclude that the proposed BTOA-integrated Bi-LSTM model provides better results than other techniques. The GTOA helps to extract the most relevant and optimal features for classifying the disease. Hence, the training and

testing operations of the classifier are improved, so the overall prediction efficacy of the proposed model is highly improved.

Fig. 9 to Fig. 11 validates the CVD prediction performance of the baseline [33] and proposed mechanisms. Here, the similarity coefficients are also estimated for determining that how accurately the classifier predicts the disease from the dataset. From the overall results, it is determined that the combination of proposed GTOA integrated Bi-LSTM provides a highly improved results over the other techniques.

TABLE II. COMPARATIVE ANALYSIS

Methods	Recall	F1-score	Precision	Accuracy	Time (s)
DT	64.40	63.94	63.42	63.69	0.53

## V. CONCLUSION

CVD is a life-threatening condition brought on by sudden heart problems, high blood pressure, and strokes. Early intervention and remote monitoring devices are the best ways to treat CVD patients. Also, the M-Health systems offer a variety of remote management applications for monitoring, and patients benefit from self-reported outcomes and affordable solutions. Recently, sophisticated and intelligent technologies can provide advanced procedures for healthcare services. Such technologies are also connected with m-Health systems to track, handle, and store patient data. This paper proposes a complete M-Health framework for predicting CVD using an advanced AI mechanism. The information collected by the sensors is sent to local databases and stored in cloud storage services with the latest technology enabling mobile networks. Data will be collected via a cloud computing platform or medical facility for further analysis. The GTOA-integrated Bi-LSTM techniques have been adapted for CVD classification. The suggested deep learning model is an excellent choice for CVD prediction based on examining

patient attributes from a dataset. During analysis, the performance and results of the proposed GTOA-integrated Bi-LSTM technique are validated and compared using various measures. Overall, the estimated results state that the proposed GTOA integrated with Bi-LSTM outperforms other methods with highly improved results.

# Reducing Cheating in Online Exams Through the Proctor Test Model

The Case of Indonesian Learners of Arabic from the Book of Silsilat Al-Lisan

**Abstract**—The World Health Organization (WHO) officially declared coronavirus (COVID-19) a pandemic on March 11, 2020. Educational institutions must change most face-to-face learning activities in class to online. This situation forces academic institutions to change the format of assessing student learning outcomes. Online exam surveillance applications utilizing cameras and other blocking browsers (proctors) are becoming popular. However, the appearance of the proctor model supervised exam system also raises controversy. The main discussion regarding this proctor system is the integrity of assessment and the capacity of students to adapt to this new method of supervision. The main question is whether students feel comfortable using the proctor system in exams and whether this system affects students' scores. To answer this question, we have analyzed the scores obtained from a trial of 152 scores of students learning Arabic at Hasanuddin University Makassar, Indonesia. The experiment involved three exam models: online format from home using the Sikola Learning Management System (Modality 1), online directly using the Proctor System in the Sikola Learning Management System (Modality 2), and a paper exam format in person under the supervision of a lecturer (Modality 3). The results show that students prefer Modality 1 (online at home with the Sikola LMS system). There is a statistical difference between the scores obtained by students from the three modalities analyzed. Student scores with modality 1 are higher than the other two modalities. On the other hand, there was no difference in scores between modalities 2 and 3. The online exam system (modality 2) can be applied to online exams in higher education institutions because it can reduce or even keep students from cheating.

**Keywords**—Reducing cheating; online exam; proctor test models; Indonesian learners of Arabic; Silsilat Al-Lisan

## I. INTRODUCTION

The World Health Organization (WHO) declared the new coronavirus (COVID-19) a pandemic on March 11, 2020 [1] officially. COVID-19 has spread rapidly due to the high transmission capacity of the virus and the routes of transmission (especially via aerosols when coughing and sneezing). In addition, about 30% of patients have various life-threatening symptoms [2]. Higher education institutions must change their learning process activities based on the spread and the symptoms it causes. The face-to-face learning process is suspended. Universities are trying to adapt to this

situation which has become a challenge worldwide. At the study program level, the teaching team must adjust their teaching and assessment systems [3]. On the other hand, lecturers and students have received online learning activities well, both in learning activities and in the assessment system.

An online assessment or exam system with strict monitoring is starting to be widely used. This proctor system has generated significant controversy, especially in science education [4]–[7]. Among the concerns of educators and students are psychological disturbances, privacy, and various environmental factors [5]. Dragan et al. (2020) concluded that online exams with remote supervision proved to be a timely solution, and also, the emotional needs of students who might feel stressed by these rigorous proctor exams should be considered [8].

Two of the most significant challenges in the online exam proctor system are the assessment standards and students' ability to adapt to this new exam modality. Several studies have been carried out to analyze student dishonesty in the online exam proctor system and various ways to prevent it. A study by Guangul et al. (2020) concluded that combining various assessment methods has helped minimize academic dishonesty [4]. Li (2021) developed an anti-collusion approach based on optimizing remote online testing [9]. Recently, Pettit et al. (2021) have analyzed studies conducted so far that provide recommendations for improving student authentication and preventing fraud [7]. Baso [2022] also wrote an online exam model with a reliable proctor system to reduce academic cheating that might occur [10].

The integrity of the evaluation in online exams can be monitored in various ways, including taking the exam in person or using a real-time supervisor system [5]. One of the real-time online monitoring systems is the website Uji.sikoola.com which provides real-time online monitoring services using a webcam and a browser lock [11]. Students are connected to the online exam page sikoola.ujian.com which monitors students during the online exam. Before the exam starts, students must check their internet speed. The sikoola.ujian.com system will analyze the internet speed used by students in real-time and provide good, moderate, or bad status for student internet speed. Furthermore, students must

\*Corresponding Author.

check the webcam device they are using. If the webcam is not working, students cannot enter the online exam waiting room.

The main objective of this study was to compare the attitudes and scores obtained by students in the Arabic study program who took the Arabic language skills exam learned from the *Silsilat al-Lisan* book [12] through the online exam proctor system on the *sikoola.ujian.com* page.

In relation to the purpose of this research, the questions to be answered are:

- What is the students' attitude towards the three modalities of the exam in measuring the Arabic language skills they have learned from the book *Silsilat al-Lisan*?
- Are there differences in the scores obtained by students from the three exam modalities given?

## II. MATERIALS AND METHODS

### A. Population and Sample

The research was conducted in the Arabic study program at Hasanuddin University, in two batches of students, namely the 2022 and 2021 batches (ages between 20-21 years). The 2022 batch consists of 52 students, and the 2021 batch of 46 students. This group of students sequentially took Arabic 1 and Arabic 3 courses. The questions tested were sourced from the book *Silsilat al-Lisan*.

The exam is carried out three times at an interval of two weeks. The score range of each test is 0-100. The model of the three exam questions is the Multiple-Choice Question (MCQ). The first exam was conducted online via <https://sikola.unhas.ac.id>. Students take exams simultaneously where they can access this page from anywhere (modality 1). The second exam is also conducted online on the <https://sikoola.ujian.com> page which has a strict monitoring feature (modality 2). The third exam was conducted in class with supervision from a team of lecturers supporting Arabic 1 and Arabic 2 courses (modality 3).

### B. Study Design

Students must take all three exams (modalities 1, 2, and 3). The reason is that students can feel the difference when taking exams with different modalities. In the modality one exam, they take the exam from anywhere. It's just that the time for carrying out the exam has been determined when it starts to be accessed and when the questions will be closed automatically. In other words, the first modality test is carried out simultaneously at the same time.

Examination with modality two is also carried out simultaneously at the same time. Exam venues may vary. It's just that there are mandatory requirements that must be met, namely, the device used must have a functioning webcam. In addition, the internet speed used is at least 40 Mbps upload. This speed would be considered moderate. If the internet speed test result equals or exceeds 50 Mbps, the system will categorize it as good. However, if the internet speed test results are below 40 Mbps, the *sikoola.ujian.com* system will assess the network used by this student as bad. Bad speed test results will prevent students from accessing exam questions on

the *sikoola.ujian.com* page. If this condition occurs, students must move locations to find an access point with a minimum internet speed test of 40 Mbps.

In addition, in this online exam with modality 2, the exam supervisor can observe the behavior of the examinees. The faces of each examinee will be displayed on the monitor screen on the *sikoola.ujian.com* page. If there are examinees who move a lot by looking left and right, the exam supervisor can send a warning message to these students. In addition, if an examinee opens a new page other than the exam page from the browser used, the *sikoola.ujian.com* application will block it. Thus, the examinee's monitor screen will be locked. Likewise, if the examinee opens another browser, the screen will be locked again. In the same way, if the examinee presses a key on the keyboard, the monitor screen will also be locked. Lockdown time can be set as needed, for example, 20 seconds or 50 seconds, or even an hour.

Examination with modality three is conducted in class. Examinees receive test papers. The exam supervisor will supervise them during the test. After students took the three MCQ tests with three modalities, they filled out a survey that included questions about their attitudes toward the three test modalities.

### C. Statistical Analysis

The research team used the statistical software SPSS 26 to analyze the data. The research team conducted a normality test on standardized residual values to calculate whether the three test score variables were normal or not. If the results are normal, then the repeated measure ANOVA test is used, and vice versa. If it is not normal, the researcher will use the Friedman (non-parametric statistics) test to analyze the data.

The basis for the decision of the normality test used in this study is:

- If the Sig value  $> 0.05$ , then the data is normally distributed.
- If the Sig value  $< 0.05$ , the data are not normally distributed.

The interpretation is as follows:

- The Within-Subjects Factors output table shows three score variables from three exams (modality 1, modality 2, and modality 3).
- The output table of Mauchly's Test of Sphericity is used to see the similarity of the assumption of variance (Sphericity Assumed) of the research data provided that the Sig value is  $< 0.05$ . If these conditions are not met, the researcher will use the Greenhouse-Geisser as a condition for testing the hypothesis.
- The Tests of Within-Subjects Effects output table will be used by researchers to:

- 1) Make a hypothesis formulation.
- 2) Know the basis for decision making.
- 3) Conclusion.

- The formulation of the hypothesis is:
  - H0: there is no difference in the average score of the three test modalities given to students
  - Ha: there is a difference in the average score of the three test modalities given to students.
  - The basis for the decision to be used is:

- 1) If the value of Greenhouse-Geisser Sig > 0.05, then H0 is accepted and Ha is rejected.
- 2) If the Greenhouse-Geisser Sig value < 0.05, then H0 is rejected and Ha is accepted.

### III. RESULTS

A descriptive analysis of this study can be seen in Table I:

TABLE I. DESCRIPTIVE

			Statistic	Std. Error
Standardized Residual for MODALITY1	Mean		0,0000	0,10102
	95% Confidence Interval for Mean	Lower Bound	-0,2005	
		Upper Bound	0,2005	
	5% Trimmed Mean		-0,0022

Minimum	-1,53	
Maximum	1,68	
Range	3,22	
Interquartile Range	1,67	
Skewness	0,196	0,244
Kurtosis	-1,178	0,483

#### A. Research Question One

The data is obtained in the following Table II to answer the first question of this study about students' attitudes towards the results of the MCQ exam scores with three modalities.

TABLE II. ATTITUDES TOWARDS MODALITIES

NUMBER OF STUDENTS	ATTITUDE TOWARDS MODALITIES					
	MODALITY 1		MODALITY 2		MODALITY 3	
	Trust	Untrust	Trust	Untrust	Trust	Untrust
Batch 2021	16	30	46	0	46	0
Batch 2022	33	35	52	0	52	0

#### B. Research Question Two

Table III shows three variables to be tested, namely, MCQ score modality 1, MCQ score modality 2, and MCQ score modality 3, as shown in Table IV.

As for Sphericity, Assumed with the condition that Sig. < 0.05 and then in the following Table V, it is obtained Sig 0.010 > 0.05. Thus, Sphericity Assumed is not fulfilled. Therefore, Greenhouse-Greiser will be used as the basis for testing the hypothesis.

TABLE III. TESTS OF NORMALITY

	Kolmogorov-Smirnov <sup>a</sup>			Shapiro-Wilk		
	Statistic	df	Sig.	Statistic	df	Sig.
Standardized Residual for MODALITY1	0,173	98	0,000	0,934	98	0,000
Standardized Residual for MODALITY2	0,105	98	0,010	0,951	98	0,001
Standardized Residual for MODALITY3	0,092	98	0,039	0,937	98	0,000

a. Lilliefors Significance Correction

TABLE IV. WITHIN-SUBJECTS FACTORS

Measure:	MCQSCORE
MODALITY	Dependent Variable
1	MODALITY1
2	MODALITY2
3	MODALITY3

TABLE V. MAUCHLY'S TEST OF SPHERICITY

Mauchly's Test of Sphericity <sup>a</sup>							
Measure:	MCQSCORE						
Within Subjects Effect	Mauchly's W	Approx. Chi-Square	df	Sig.	Epsilon <sup>b</sup>		
					Greenhouse-Geisser	Huynh-Feldt	Lower-bound
MODALITY	0,908	9,283	2	0,010	0,916	0,932	0,500
Tests the null hypothesis that the error covariance matrix of the orthonormalized transformed dependent variables is proportional to an identity matrix.							
a. Design: Intercept Within Subjects Design: MODALITY							

To get conclusions from this statistical data, it can be seen in Table VI. This output table, known as Tests of Within-Subjects Effects, will display the Greenhouse-Geisser as can be seen in Table V below:

TABLE VI. TESTS OF WITHIN-SUBJECTS EFFECTS

Measure:	MCQSCORE					
Source	Type III Sum of Squares	df	Mean Square	F	Sig.	
MODALITY	Sphericity Assumed	17880,660	2	8940,330	193,272	0,000
	Greenhouse-Geisser	17880,660	1,831	9764,337	193,272	0,000
	Huynh-Feldt	17880,660	1,865	9589,111	193,272	0,000
	Lower-bound	17880,660	1,000	17880,660	193,272	0,000
Error(MODALITY)	Sphericity Assumed	8974,007	194	46,258		
	Greenhouse-Geisser	8974,007	177,628	50,521		
	Huynh-Feldt	8974,007	180,874	49,615		
	Lower-bound	8974,007	97,000	92,516		

Based on the hypothesis with the Greenhouse-Geisser Sig. < 0.05, then 0.000 < 0.05 is obtained, meaning H0 is rejected, and Ha is accepted, or there is a difference in the average score of the three test modalities given to students.

IV. DISCUSSION

The COVID-19 pandemic has forced lecturers and students to change academic activities, including activities to measure student learning outcomes. Several research results show acceptance of the learning achievement measurement method with proctor applications [13]–[15], including in Indonesia [11]. In this study, to answer the first research question, the results obtained can be seen in Table I previously, where it can be seen that students believe in the MCQ exam model modalities 2 and 3. However, in the 2021 and 2022 batches, some students do not believe in modalities 1.

The research team conducted interviews to explore the causes of the distrust of some students towards the MCQ exam

model with modality 1. In general, it can be concluded that the cause of this distrust is the opportunity for students to commit fraud during the exam. Opportunities for students to commit fraud include searching for answers via Google (Googling), asking other friends via mobile (chatting via WhatsApp, Telegram, etc.) during exams, or opening books. Opportunities for fraud are open because there is no direct supervision. However, some students still have a reliable academic attitude by not cheating during exams.

On the other hand, the research team found that the basis for the 100% confidence of the two groups of students in the MCQ modality 2 and 3 exam models was the feelings of students monitored both offline and online. This strict supervision makes students not think of committing fraud. This condition instead makes students focus on answering exam questions.

Table I above (descriptive statistics) shows that the test scores in modality 1 are higher than in modalities 2 and 3. This data can be accepted logically because it is possible that during the exam, some students cheated. They are looking for answers to questions they have difficulty answering via googling or asking other friends by chatting. On the other hand, the test scores on modalities 2 and 3 are lower because, logically, it can also be understood that there are no opportunities for students to commit fraud. Examination modalities 2 and 3 close opportunities for cheating during exams, especially for students who have cheated on exams with modality 1.

The assumptions of the research team are based on Fig. 1:

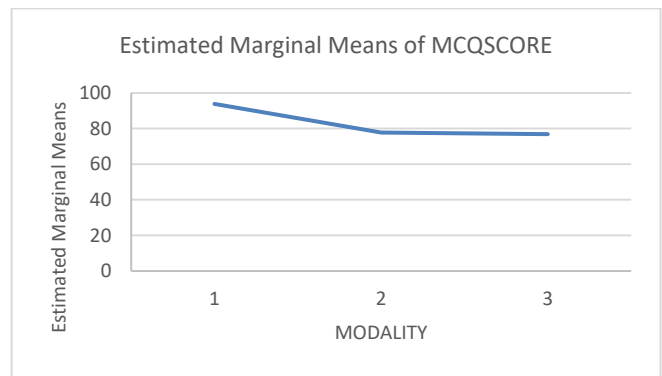

Fig. 1. The test scores with modality.

Fig. 1 shows that the results of the test scores with modality 1 are higher than modalities 2 and 3. However, the results of the test scores for modalities 2 and 3 do not appear to have a significant difference. On the other hand, modality 2 and modality 3 have different test channels; modality 2 is carried out online while modality 3 is carried out offline.

Logically the score results are relatively the same or not significantly different even though the exam channels are different because exam students are under strict supervision. In modality 2, supervision uses the proctor application system. As for modality 3, supervision is carried out directly by F2C in the exam room.

Thus it can be said that modalities 2 and 3 have in common close supervision during the exam. This strict supervision puts the exam atmosphere in a safe condition where students think they have no opportunity to cheat in the exam.

## V. CONCLUSIONS

In this study, it was found that the attitude of students lacked confidence in the score of the exam results with modality 1. The cause of this distrust was caused by the opportunity for students to commit fraud during the exam. In contrast, students believe in the score of the exam results with modalities 2 and 3. Student trust in the score of the exam results with modalities 2 and 3 is due to the strict supervision conditions during the exam even though the channels of modality 2 and 3 are different, where modality 2 is online channel whereas modality 3 is offline channel.

With these results, it can be claimed that measuring learning outcomes through MCQ with modalities 2 and 3 is reliable. If the exam is conducted online, modality 2 can be used as a solution; if offline, modality 3 is used as an alternative.

## ACKNOWLEDGMENTS

We are grateful to the all students of Arabic Study program of Universitas Hasanuddin who involved in this research.

# A Framework of Outcome-based Assessment and Evaluation for Computing Programs

Wasan S. Awad, Khadija A. Almhoson  
College of Information Technology, Ahlia University, Manama, Bahrain

**Abstract**—This paper is to present a framework for student outcome-based assessment and evaluation, including the process and detailed activities leading to continue assessment of the successes of an academic program which is essential to its sustainability. Moreover, this paper provides a survey of the literature that reviews the different means of assessing and evaluating an academic program together with the critical performance metrics which aid in quantifying such evaluation. The presented framework is implemented on the Information Technology program over a course of five years. The paper provides empirical insights about how careful implementation of the presented framework enabled the College of Information Technology in Ahlia University to achieve outstanding results in quality assurance and to be ABET accredited. The results of the implementation prove the effectiveness of the framework in improving the student performance and the program. This paper fulfils an identified need to study how student outcome-based assessment and evaluation model enables an academic institute to foster quality assurance instead of relying on ad hoc practices which might lead them to trial-and-error approach. The presented framework could be followed by other institution aiming for international accreditations.

**Keywords**—Student outcomes; program assessment; program evaluation; program accreditation; ABET accreditation; continuous improvement

## I. INTRODUCTION

The College of Information Technology (IT) of Ahlia University has a clear academic planning framework to fulfill the aims and objectives of its academic programs. The academic planning framework is transformed into an annual college operational plan that is derived from the strategic plan of the University. The academic planning framework for Information Technology Program comprises three perspectives. One is the study plan that has to be carried out in order to execute the program successfully to the students enrolled in the program. The second perspective is the Program review. The purpose of the quality program review plan is to apply measures that ensure the quality of delivery, assessments, and contents of the program. Third is the college operational plan that is aligned with university strategic plan and is meant to conduct activities/tasks that provide continuous support to the successful and smooth execution of the program.

The Information Technology (BSIT) program, as any other academic program, leading to an academic degree, is based on a curriculum constituting of a combination of courses and relevant activities that are organized for the achievement of some learning outcomes defined by the offering institute/university. In this regard, the program shall have well defined

Program Educational Objectives (PEOs) that leads to fulfilling the mission and goals of both college and university. These objectives should:

- be broad statements which express what graduates are expected to attain after few years of graduation [1], [2];
- serve the missions of both college and university;
- satisfy program constituencies needs.

Furthermore, the set of Student Outcomes (SOs) of the program should be defined. These SOs describe what students are expected to know and be able to do by the time of graduation. These relate to the skills, knowledge and behaviors that students acquire as they progress through the program. There are six SOs defined by Accreditation Board for Engineering and Technology (ABET) [1].

At the level of courses of BSIT, students' performance is measured by the achievement of relevant course level outcomes. These course level outcomes are called Course Intended Learning Outcomes (CILOs). The CILOs are measured against the performance indicators set at IT program level. These performance indicators are generated from the student outcomes defined for the program. CILOs are satisfying the standards set by Bahrain National Qualification Framework (NQF) of the level 8. The courses in BSIT program have up to thirteen (13) CILOs that are required to be achieved by the students in each individual course. The achievements of the CILOs in all the courses translate the achievement of student outcomes for the program. These CILOs are related to the Knowledge and Understanding (A1, A2, A3), Subject-Specific Skills (B1, B2, B3), Critical-Thinking Skills (C1, C2, C3), and General and Transferable Skills (D1, D2, D3, D4) that students acquire as they progress through the program.

The program assessment and evaluation process should take place at different levels, including PEOs, SOs and CILOs. This ensures having a comprehensive and effective process in place. Regarding program assessment, it is the practice of identifying, collecting, and preparing the data needed for the evaluation. Regarding evaluation, it could be viewed as the practice of interpreting the data collected through the different assessment means to find the attainment of the SOs [3].

The objective of this paper is to thoroughly present and document a framework based on SOs assessment and evaluation that could be adopted by any academic program for the purpose of continuously assessing its success level. Thus, this paper presents the well-defined procedure and detailed activities comprising the framework developed by the College

of IT of Ahlia University for assessing and evaluating student outcomes of BSIT program- that are derived from ABET SOs- to fulfil the college mission and goals, achieve program objectives as well as achieve the prescribed graduate attributes by attaining the student outcomes. This framework is based on the longitudinal methodology followed while applying SO based assessment and evaluation model on BSIT program over a course of five years. It is intended to remain valid even if ABET redefined it's SOs. The findings will guide other higher education institutions to continuously evaluate and improve their academic programs, achieve outstanding results in quality assurance, and to be ABET accredited.

The remainder of the paper is organized as follows. Section II presents a detailed survey of the literature highlighting different means of assessing and evaluating academic programs together with the performance metrics in use. Section III provides a comprehensive overview of the proposed framework followed by the College of IT in Ahlia University. Section IV discusses the results of implementing the framework over five academic semesters. Section V lists the challenges faced by the college while implementing the framework and the college actions in overcoming these challenges. Last section presents the conclusion.

## II. LITERATURE REVIEW

### A. Survey of the Literature

Literature is rich with studies on the different approaches of program assessment and evaluation. One of the common approaches is curriculum mapping. It explores the links between curriculum content to be delivered and the learning outcomes. This is done by inspecting the relationship between the intended, delivered and received curriculum. The intended curriculum could be examined through the courses' syllabi and materials prepared by faculty members, which contain the learning objectives for each course. The taught curriculum could be examined through interviews with faculty members teaching/ coordinating the courses. The received curriculum could be explored through focus group interviews with students. This approach suggests to use student learning outcome as the base of curriculum development and assessment by treating it as the basis for formative and summative assessments. It considers when, how, and what is taught, as well as the assessment measures in use to gauge achievement of expected student learning outcomes. The strength of this approach is that it aids in identifying whether the intended curriculum and courses' materials has been actually taught and has been actually learnt by students. Moreover, it demonstrates the links between the main components of the curriculum, which are: learning outcomes, learning opportunities, content, and assessment. Furthermore, it studies the curriculum from multiple perspective. On the other hand, this approach has some drawbacks. The main one is being subject to recall bias from faculty members and students. Added to that, it is impossible to determine the extent to which topics were reinforced in the curriculum [4].

Another approach [5] is presented for the ABET-accredited program. Their strategy is based on the assessment and evaluation of their program at both course and program levels. Their process started by defining the vision and mission of

their program that serves the university vision. Then they established PEOs that leads to both university and college mission. That was followed by setting the students outcome based on an ABET accreditation body and American Society of Civil Engineers. These SOs are expected to be gained by the students from the different courses constituting their curriculum, by attaining the prescribed Course Learning Outcomes (CLOs). The assessments and evaluations of PEOs, CLOs and SOs were essential components in the assessment of the whole program which leads to decisions and actions that improve the program. In this regard, they mapped CLOs of each course to the most relevant SOs- taking into consideration that the least number of mapped SOs with CLOs is the better- and documented that in a mapping table. It worth to mention that weighted numbers from 1 to 5 were used in the mapping, where the weights represent the strength of each CLO in fulfilling the SO. Moreover, the course credit hours are also taken into consideration to determine how strong the course contributes in attaining the relevant SOs. That was computed using the following formula:

$$\text{Credit hour assigned for each SO} = \left[ \frac{\text{total weights of each SO}}{\text{Sum of weights}} \right] \times \text{course credit hour} \quad (1)$$

Due to the ever-increasing importance of outcome- based models, proofed by demanding such model by many accreditation bodies such as: ABET, International Engineering Alliance (IEA) and National Commission of Academic Accreditation and Assessment (NCAAA) [6]- many research works were devoted to shed the light on success stories of adapting this model in assessing different academic programs and getting international accreditations. Some other works were focused on the implementation of a particular stage in the model. Following are some examples.

A complete framework has been proposed in 2019 [7], [8] which is built on set of sustainable practices to advance quality assurance on outcome-based education systems and ensure delivering effective academic program by higher education institutions. It is worth to mention that this framework guided their four programs to successful ABET accreditation. The framework consists of four main types of activities which are: strategic planning, educational practices and strategies, assessment and evaluation and continuous improvement. These activities lead to strategically aligning the program outcomes with the market needs, delivering relevant skills through educational practices, evaluating the attainment level of graduating students and defining remedial actions to improve attainment, in case any deviations in performance were observed in the assessment results.

This framework, as recommended by many international bodies such as ABET with respect to student outcome centered approaches, requires setting measurable learning objectives of the academic programs, measuring those objectives with appropriate assessments to assess and evaluate the effectiveness of the academic programs, as well as having a continuous improvement process to identify the weaknesses in the programs and rectify it quickly.

With respect to the assessment and evaluation phase, they try to make the process comprehensive and at the same time lightweight to avoid extra load on faculty. They used a

combination of direct and indirect assessment methods. The direct assessment was through faculty members and the taught courses as well as an exit exam. With respect to courses assessments, SOs were assessed through formative assessments in the entry level courses and summative assessments in the exit level courses. The formative assessments gave warning signs indicating that a problem is there which needs to be resolved to improve the attainment level. Furthermore, faculty are informed at the beginning of the semester whether their course assessments will be used for program assessments to aid in planning their courses assessments. Courses to be covered in program assessments should have standardized rubrics to assess the attainment of the performance indicators. Such rubrics helped faculty in reducing the variations in assessment process. A program quality assurance team collaborates with faculty to assure that assessment questions intended to assess a particular SO are in line with the rubric. With respect to the exit exam, students were required to do an exam at the time of their graduation, where each question was designed for assessing a specific performance indicator. However, the students did not solve the exam seriously as it did not have any academic weightage. Thus, it was decided not to use the exit exam as an assessment tool again. Indirect assessments allowed them to hear the voice of other stakeholders through surveys and meetings with external advisory board.

Jalil in 2019 [9] shared the experience of Energy and Renewable Energy Program in Electromechanical Engineering Department in University of Technology-Iraq in measuring SO attainment while preparing for ABET accreditation. He detailed the process of measuring SO attainment for the four years' work in the program. Although, author frankly stated that attainment of student outcomes is a challenging task for all Iraqi Universities, ABET approved the adopted process as an appropriate way of measuring SO attainment. The Electromechanical Engineering Department started adopting the process of SO assessment in 2014, in which it focused on final exam grades in the assessment and evaluation. After two years, it changed the policy, after consulting ABET experts, and started considering the grades of different course assessments. To achieve that the department put the assessment plans; covering assessments methods, their mapping to CLOs, and the mapping between CLOs and SOs; in the course syllabus at the beginning of the year. Here it is worth mentioning that the department adopted many to many mapping between CLOs and SOs. Faculty members shall prepare the prescribed course assessments with detailed rubrics and performance indicators. Moreover, faculty members shall decide the target to be achieved by the student in order to consider the SO attained for each course, taking into consideration that target shall be above 60% since 50% is the pass degree set by the ministry. After grading course assessments, the average grade of the student is compared with the target and only if it is above the target, the corresponding SO is considered met. In case of an SO not attained, an action plan should be developed to improve the attainment. At the end of the year, the department prepares assessment reports - detailing assessment results, visual graphs, and the summary- and uses these reports in the annual review. The analysis over the year depicted that SO attainment was improved when they relied on different assessments with detailed rubrics rather than

relying on final exam grades only. Moreover, adopting problem-based learning by many faculty members in different courses helped in improving the attainment results. However, it was mentioned that attainment level still needs to be improved in order to qualify the program for ABET accreditation.

In [6], one of the stages of an outcome-based model was spotlighted, which is data preparation. The author presented a coherent vision of a systematic approach of data preparation that aids in collecting the required data (i.e. assessments' data that are mainly used for SOs evaluation as well as program's data that talk about the state of affairs of multiple stakeholders such as students, faculty members, facilities and institute) needed for the accreditation visit by different accreditation agencies. His approach started by identifying the different tasks; which were 23 tasks, to be accomplished in order to satisfy ABET requirements. That was followed by mapping each task to the required resources/ committees, from 7 well defined resources, and defining an interface between the different resources, which define explicit communication between their inputs and outputs. The effectiveness of this approach was illustrated by preparing data- to be used for accreditation- that revealed the real image of the program. Furthermore, it increases awareness, among faculty members, of the importance of such stage in conducting a successful assessment of a program as well as their roles and responsibilities. This led to reducing the load on the program coordinator and smoothed the process of getting the required data from all the faculty members.

Another effort was made in [3] that focused on the design and implementation of performance metrics for successful evaluation of assessments data. This work was made due to the importance of such performance metrics in quantifying the achievement of both program objectives (at program level) and student outcomes (at both program and course levels). The performance metrics were attainment, student achievement and x-th percentile. These metrics with the formulas behind them were tested and their results were analyzed on a sample course. The analysis revealed that getting high values of one metric did not lead to high values of the other metrics and their values depended on the scored marks distribution. They generalize their findings by stating that students' achievement is often less than SOs attainment for mean value which is less than the average marks that is in turn less than the passing threshold for uniformly distributed marks.

## B. Summary and Research GAP

The following Table I summarizes the literature review and provides a critique to each of the research works mentioned above:

The above summary indicates that there is a need for a framework that is not subject to recall bias from its main constituencies. Moreover, it is desired to be based on SOs assessments and evaluation to facilitate the accreditation by many international accreditation bodies. Furthermore, it shall have a systematic approach of aggregating data from different sources. In addition, should provide a comprehensive assessment to the entire program's SOs using a wide range of assessment tools, such as: courses' assessments, surveys, major projects, just to mention a few. Added to that, the framework

shall have a precise mean of computing the attainment level of each SO, to be compared with an absolute metric goal that is decided by the offering college / department based on the

collective experience of multiple faculty members and the market need.

TABLE I. LITERATURE REVIEW SUMMARY

Author , Date	Assessment and Evaluation Model	Main Focus	Results	Our Critique
Plaza et al., n.d., 2007	Curriculum mapping technique	-The intention is to verify that intended, delivered, and received curriculums are the same based on outcomes statements. -Intended curriculum is examined through the courses' syllabi and materials prepared by faculty members, the taught curriculum is examined through interviews with faculty members teaching/ coordinating the courses, and the received curriculum is explored through focus group interviews with students.	Concordance between the intended/ delivered and received curriculums	-This assessment model is not widely adopted since institutes are looking for international accreditations and the majority of the accreditation bodies require student outcome based models to be implemented. -This model is subject to recall bias from program constituencies (i.e. faculty members and students)
Iqbal Khan et al., 2016	Student outcome based model	-It is a comprehensive work detailing the success story of getting the Civil Engineering program accredited by ABET -It has been applied on the whole curriculum, considering the least mapping between SO and CLO. -Weighted mapping between SO and CLO was applied. -Courses were assigned rates regarding their impact in achieving the SO and their credit hours was considered in finding the attainment.	The proposed procedure is applicable for developing a new engineering program or adjusting an existing one to serve both the college and university missions and goals.	This paper provides a precise mathematical formula for computing the attainment level of each SO
Almuhaideb & Saeed, 2020	Student outcome based model	A full framework qualifying 4 computing and engineering programs to be accredited. -Lightweight (to avoid extra load on faculty) and comprehensive process (Applied on all courses as well as exit exam). This was achieved by treating assessments in entry level courses as formative and assessments in the exit level courses as summative one.	The lightweight assessment process was effective in assessing all the program SOs. However, it was noticed that Exit exam was not a reliable assessment tool since there are no academic weightage on it and students do not solve it seriously. Thus, future evaluation process will be limited to courses' assessments.	This work provides a comprehensive but lightweight assessment to all SOs of the program
Jalil, 2019	Student outcome based model	A process followed by Energy and Renewable Energy Program in adopting SO based model to be eligible for ABET accreditation. -In 2014, started adopting SO for evaluation on final exam grades only but in 2016 they started considering the grades of different course assessments. -It adopted many to many mapping between CLOs and SOs. -The metric goal is different from one course to another determined by the instructor (but should be above 60%).	SO attainment was improved when they relied on different assessments with detailed rubrics rather than relying on final exam grades only. Moreover, adopting problem-based learning by many faculty members in different courses helped in improving the attainment results. However, it was mentioned that attainment level still needs to be improved in order to qualify the program for ABET accreditation	-Metric goal should not be determined by an individual (i.e. faculty member) but would be better to be determined by the offering department or college taking into consideration different faculty opinions and experience to reduce the possibilities of human errors.
Rashid, n.d., 2021	Student outcome based model	Focus on one stage of student outcome based model which is data preparation by identifying required tasks and mapping responsible committees or needed resources to them.	Ease in collecting data that revealed the real image of the program from faculty members and reduce the load on the program coordinator	A great effort in coming up with a systematic approach of aggregating the data from different sources smoothly. This general approach could be used by any institute while collecting and preparing the data to be used for accreditation purpose
Ahmed & Bhatti, 2016	Student outcome based model	Design and implementation of performance metrics for evaluating the assessments data. These were attainment, student achievement and x-th percentile. -The proposed passing threshold is the min (70% , avg). -The study was applied on sample courses and not all the courses in the curriculum.	getting high values of one metric did not lead to high values of the other metrics and their values depended on the scored marks distribution. They generalize their findings by stating that students' achievement is often less than SOs attainment for mean value which is less than the average marks that is in turn less than the passing threshold for uniformly distributed marks	Passing threshold should not be relative to the students score. It should be an absolute value determined to ensure that attaining the student outcome will lead to satisfying the market need.

III. PROPOSED FRAMEWORK

A. Development of PEOs and their Mapping to SOs and CILOs

The outcome-based assessment framework proposed started by defining the Program Educational Objectives (PEOs) for the BSIT program, taking into consideration that educational program must be regularly reviewed, assessed, and evaluated [7], [10] for many reasons, including:

- 1) Meeting educational standards and measures of quality: This award the program a recognition of its quality, integrity and performance which lead to receiving confidence from educational community and the public [5].
- 2) Ensuring that PEOs are based on the program stakeholders needs as well as assessing the degree of attaining these PEOs which is an important sign of the level of success achieved [5].
- 3) Improving student learning experience.
- 4) Ensuring the sustainability of the program [11].

The final list of PEOs was discussed and approved by the main program constituencies (i.e. faculty, alumni, external advisory board, and employers); which is:

- 1) Exhibit the relevant skills and knowledge for pursuing the IT career in industry including corporate as well as government sector.
- 2) Pursue life-long learning leading to entrepreneurship, research and development.
- 3) Contribute to the society through their ethical and professional norms by demonstrating them in IT professions.

These PEOs are supposed to be fulfilled through the different courses in the program curriculum. Table II presents the mapping of ABET six SOs to BSIT three PEOs.

Each course has a set of CILOs that should be attained by the students upon completion of the course. Each student outcome is translated to the relevant performance indicators to assess the student outcomes within a program. To assess the student outcomes for the program, each performance indicator is mapped to the relevant CILOs of that particular course. Table III shows the complete view of the BSIT program student outcomes in relation to performance indicators as well as their one-to-many mapping to CILOs, assuming equal weights across all CILOs mapped to a particular SO.

TABLE II. BSIT SOS- PEOs MAPPING

PEOs \ SOs	1	2	3

6	√	√	

TABLE III. STUDENT OUTCOMES AND PERFORMANCE INDICATORS FOR IT PROGRAM

Student Outcomes	Description	Performance Indicators	CILOs
1	Analyse a complex computing problem and to apply principles of computing and other relevant disciplines to identify solutions.	P1.1- Understand computing concepts to solve complex problems	A1
		P1.2- Understand the latest trends and technologies.	A2
		P1.3- Analyse complex computing problems	C1
2	Design, implement, and evaluate a computing-based solution to meet a given set of computing requirements in the context of the program's discipline.	P2.1- Model a computing-based solution	B2
		P2.2- Design a computing-based solution	B2
		P2.3- Create an innovative computing-based solution	C3
		P2.4- Integrate various components to the computing-based solution	C2
		P2.5- Implementing a computing-based solution using appropriate tools	B3
		P2.6- Evaluate a computing-based solution	C1
3	Communicate effectively in a variety of professional contexts.	P3.1- Use of appropriate methods/tools for communication	D1
		P3.2- Explain the ideas effectively in written	D1
		P3.3- Organize information properly in written	D3
		P3.4- Present information effectively and well organized	D3
		P3.5- Present the ideas appropriately in front of variety of audience	D1
4	Recognize professional responsibilities and make informed judgments in computing practice based on legal and ethical principles.	P4.1- Understand professional practices / standards	A3
		P4.2- Understand legal and ethical principles	D4
		P4.3- Make ethical and professional Judgements in computing practices	D4
5	Function effectively as a member or leader of a team engaged in activities appropriate to the program's discipline.	P5.1- Perform individual task to meet team goals	D2
		P5.2- Work effectively with other team members	D2
		P5.3- Act as an effective leader to other team members	D2
		P5.4- Plan the tasks and resources to develop computing-based solutions	D3
6	Apply computer science theory and software development fundamentals to produce computing-based solutions.	P6.1- Understand the problem domain	B1
		P6.2- Identify user needs within the given problem	B1
		P6.3- Apply software development fundamentals in developing computing-based systems	B1

## B. Assessment and Evaluation Process of PEOs, SOs and CILOs

A number of data collection methods as well as assessment tools have been defined to facilitate measuring the achievement of both CILOs and SOs and consequently PEOs. After that comes the stage of utilizing the results and feedback in continuously improving the program with its learning and assessment processes and achieving high quality standards.

The proposed approach has short term (every academic semester) and long term (every three years) processes. It is carried through three main stages, which are:

1) *Data collection and preparation:* Data is gathered from various potential- internal and external- sources that cover all the program stakeholders. The primary sources are:

a) *Faculty developed assessment:* A faculty can use variety of summative and formative assessment to evaluate the student during the semester. The grades of each question in the summative assessments need to be recorded for all the enrolled students in a course. This is done by filling the CILOs Evaluation excel sheet by the faculty member. This CILOs Evaluation excel sheet needs to be submitted as part of the course portfolio to the college by the end of the semester.

b) *Internship feedback:* each student is required to go through industrial training program. During internship, the assessment of the students is done by their industrial – site- and academic supervisors. The site supervisor evaluates the student twice; after the completion of the first month of the internship period and after the completion of the internship period. The evaluation is done by filling the mid-evaluation written questionnaire form and final evaluation written questionnaire form. The mid-evaluation form consists of 10 questions; with 5-points scale; and a section to write comments. The final evaluation form has the same set of ten questions plus a space for the evaluator to comment on the strength / weaknesses of the intern as well as provide recommendations on preparing students for the workplace. In similar way, the academic supervisor evaluates the student after the completion of the internship period by filling a written questionnaire form with 5-points scale. Furthermore, a summary report of all the student undertaking the industrial training will be prepared by the college internship coordinator and submitted to the college by the end of the semester.

c) *Major project examination and exhibition:* Students in their major project course are examined orally after submitting their written reports. The reports and oral exam aids in performance evaluation by the examination committee, which consists of two faculty members and an external examiner from the industry. Ready assessment forms are prepared to help in assessing and evaluating the students. Moreover, an exhibition is arranged to give the students an opportunity to present their developed projects to various businesses. Many people, including experts from IT field, attend the exhibition and spend ample amount of time in examining and evaluating the projects as well as the students' skills. Their evaluations and comments will be collected through a survey prepared by the college.

d) *Written Surveys:* The College collects feedback from variety of stakeholders and makes use of that in assessing and making informed decision. A third party is responsible for conducting the written surveys, collection and collation of multiple stakeholders' feedback that are passed for the colleges for further action. The main written surveys are:

- i) *Alumni survey:* This felicitates graduate's satisfaction with the program and their learning experience.
- ii) *Senior exit survey:* This reveals students' satisfaction level with respect advising, teaching and learning, administrative support and facilities. Moreover, it prompts students to overall rate the program.
- iii) *Employers' satisfaction survey:* This enables the college in receive employers of the graduates' feedback regarding graduates' job performance, thinking skills and character.

2) *Data collection and preparation:* The success of the program is assessed by the level to which it satisfies the university and college missions and goals. Since the PEOs were derived from the college mission which is in line with the university mission, assessing the PEOs leads to assessing the whole program. PEOs are assessed through the SOs and CILOs mapped to them.

This assessment process is carried at both course and program levels via various assessment tools. Some of these tools are directly assessing SOs and CILOS while others are indirectly assessing them. In case of indirect assessments, a mapping should be done to facilitate assessing CILOs and SOs. The level of CILOs/SOs attainment is compared with a metric goal set by the college. If the attainment level is below the metric goal, then it will be considered as not attained.

These assessment tools are:

a) *Faculty developed assessment:* It is a direct assessment tool carried by faculty teaching courses comprised by the curriculum. A Faculty member assesses students' attainment of CILOs, and in turn SOs, through different course assessments. The faculty will be recording the students' grades in CILOs/ SOs evaluation excel sheet for each course. This sheet details the summative assessment methods used in assessing the student outcomes. Because this serves as quantitative analysis, questions are used as the basic units of computation of assessment. That's why, CILOs/ SOs evaluation sheet records all the students' grade for each question in each assessment and provides a clear mapping between each question in the course assessments and CILOs/SOs. Here, it is worth to mention that each question could be mapped to maximum two CILOs/ SOs. In addition, CILOs/ SOs evaluation sheet provides a summary of the results, indicates the level to which each of the CILO/ student outcomes is being attained, and determines whether the CILOs/ student outcomes have been met or not by comparing their average percentages with the predefined metric goal. This leads to absolute student achievement evaluation since the metric goals is fixed to a target value. It is noteworthy that in case of having students from other academic programs in the courses,

separation must be done during the assessment phase to ensure that only IT program's students are considered in the assessment and evaluation.

*b) Internship written questionnaires and forms:* This is a direct assessment tool since the CILOs assessed by each evaluation form / submitted report is clearly written in the internship course syllabus. It worth to mention that 50% of the student final grade is taken from the total score given by the site supervisor in the two evaluations. However, only 10% of the score given by the academic supervisor will be counted. The remaining 40% of the student grade is based on the evaluation of the three reports submitted by the student during his internship period and after the completion of the internship. Furthermore, CILOs/SOs evaluation excel sheet will be prepared for this course to be taken into consideration in the program evaluation process.

*c) Written surveys:* These are indirect assessment methods. In alumni survey, "alumni experience with the program" section was mapped to SOs and thus used in the

assessment. In senior exit survey, "program overall rating" section was mapped to SOs and used in the assessment. In employer satisfaction survey, SOs were clearly listed to seek employers feedback on them. In addition, "employee learning outcomes and skills" section was mapped to SOs to aid in getting comprehensive assessment.

The aforementioned assessment tools are carried out with different frequencies. Every academic semester, all the direct assessments will be carried out in addition to the senior exit survey. Other surveys are conducted every year.

At the end of each academic year, the result of all the assessment methods will be compiled together, as shown in Fig. 1. That is done by giving weight to each of the assessment tool. In this regard, each of the survey was given 10% and by that we assure balance consideration of the stakeholders (students, alumni and employers) and 70% was given to faculty developed assessments which represent the main direct assessment method. This will give us the percentage of attaining SOs in the year.

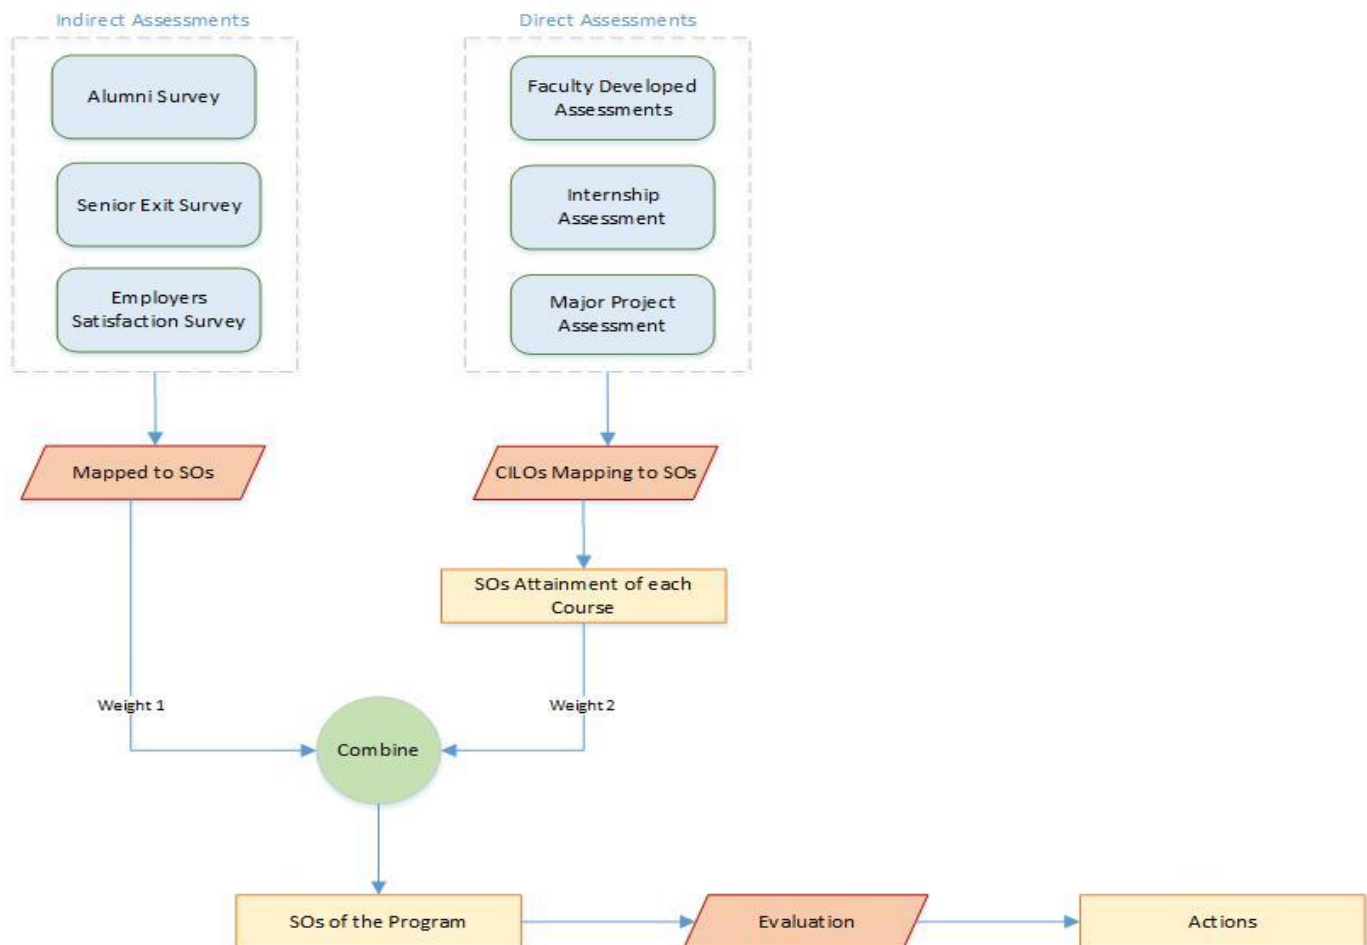

Fig. 1. Outcome based Framework.

3) *Evaluation*: At the end of each academic semester, IT College holds meetings to discuss thoroughly the assessment results, including: SOs achievements and surveys summary reports. With regards to SOs achievements, it gets evaluated on course level as well as on program level. In case of course level evaluation, the attainment of each SO is based on the attainment of CILOs that represent PIs mapped to it. An SO/CILO is considered attained, if the average of the students' grades of questions mapped to SO/CILO is not less than the predefined, absolute, metric goal which is 70%. If any of the SOs is not attained, the course coordinator/ instructor will be requested to provide a reason behind this pitfall and formulate an action plan to be carried on the next semester to improve the SO attainment level and overcome this downfall. On the next semester in which the course is offered, the IT College quality coordinator will follow-up with the faculty member to check the attainment level of those SOs that were not attained earlier. If any SO is still not attained, the reason should be provided as well as another action plan to be placed to be implemented on the following semester. Table IV presents some examples of SOs not attained on the course level and the process of monitoring them by the college. This practice had high impact on improving the teaching methods since faculty members were encouraged to evaluate the effectiveness of their teaching and adopt new techniques that were not used previously in an aim to improve SOs attainment. Moreover, some faculty tried to boost the attainment by revising and adjusting the lesson plan and devoting more time for topics/ concepts that were not comprehended by students. In like manner, assessment methods had been improved because faculty members were motivated to use verity of assessments in assessing each of the SOs. This ensures getting reliable assessment results, because, even if one of the course assessments was not effective in assessing a particular SO, that will be overcome by other course assessments.

The same process is applicable for evaluating SOs on program level; by considering all the courses with CILOs corresponding to its PIs.

Achieving good results demonstrates that the PEOs are based on the needs of the program's various constituencies. In addition, it demonstrates the high competence of the program graduates in their professional career as well as the high level of their employer satisfaction. All the assessments and evaluations results and findings are well documented in the college meeting minutes as well as the annual report produced and maintained by IT College. The report clearly states the pitfalls/ deficiencies, justification of each, areas to be improved, action to be taken in order to improve the program outcomes, meet high quality international standards and ensure its sustainability. This aids in planning how to overcome the existing deficiencies in the near future. Such documentation and reporting reflect the ongoing evaluation in place leading to continuously improve the program effectiveness.

#### IV. RESULTS AND DISCUSSION

The longitudinal methodology opted in this research enabled in assessing SOs achievement and evaluating BSIT program over the last five years. Data was first collected at the outset of the study and then gathered, repeatedly, during the course of the study (i.e. five years). That facilitates observing changes in SOs achievements over time.

Fig. 2 provides empirical insights of the performance of the College of IT after adopting the proposed framework. It summarizes the results of the assessments approach over 5 academic semesters. It illustrates the extent to which each of the SOs is being attained using the weighted combination of direct and indirect assessment methods.

The student outcomes achievements were maintained high over the last five semesters. This comes as a result of the careful implementation of the proposed framework that enabled the College of IT in having a systematic assessment and evaluation process, leading to achieving outstanding results in quality assurance and being ABET accredited. Moreover, there are number of notable routines and practices that did support the presented framework in achieving these satisfying results. Among these practices are advising and counseling that provide customized and personalized advice to individual students guiding them in defining and achieving their academic, career and life goals. That enabled the college in maintaining good student ratio. Furthermore, different workshops are regularly conducted by the college to qualify faculty members with new teaching and assessment methods. Added to that, reviewing the courses' syllabi, routinely, at the beginning of every academic semester and ensuring having up-to-date textbooks brings new advancements in IT into the IT curriculum and confirms that the program is up to date.

The results of the implementation proved the effectiveness of the proposed framework together with other educational practices in improving the student performance and the program.

Fig. 2. Student Outcomes Attainment

TABLE IV. EXAMPLES OF STUDENT OUTCOMES ACHIEVEMENT ANALYSIS

Course	SO	Reported Semester	Current Semester	Instructor	Met/	If Not, Specify the reason	Improvement Plan	Actions Taken	Previous Achievement	Current Semester Achievement
					Not Met					
ITCS 404	1	1st 18-19	1st 19-20	Instructor1	Not Met	More focus was on the solving problems + Poor in critical analysis	The theoretical background is to be discussed more in the class + More exercises and discussion	class discussion + More exercises are given in the class	51.48	77.98
	2									
ITCS 209	1	1st 19/20	2nd 19-20	Instructor2	Not Met	more class discussion was needed + weak math background of the students	More time will be devoted to class discussion + More exercises will be given through Kahoot	More class discussion and exercises were given	61.9	84.45
	6									

Getting such outstanding results does not mean that the IT program does not need continuous improvements. In this regard, the College of IT believes that curriculum development is a dynamic process that ensures having an up-to-date program in line with the rapid advancements in Information Technologies and in compliance with ABET requirements in case ABET changes any of their criteria or requirements.

#### V. CHALLENGES

The College of IT faced number of challenges during the course of implementing the proposed framework. Following is the list of challenges together with how did the college overcome each:

##### A. Balancing between NQF Requirements and ABET Requirements

Bahrain National Qualification Framework has a set of standards and requirements to be satisfied by an academic program in order to endorse its associate qualification and be placed on a specific NQF level (from level 1 for Access1 to level 10 for Doctoral Degree).

BSIT satisfies the standards set by NQF of level 8 [12]. However, in order for BSIT to be accredited by ABET, the program should also satisfy the requirements of ABET. To achieve that, the college came up with a mapping of PEOs, SOs and CILOs, as shown in Table I and Table II.

##### B. Having Students from Different Majors in BSIT Program Courses

Some of BSIT program courses are offered for students from other colleges (such as Engineering College and Business College). However, calculating the attainment of SOs for BSIT program requires considering IT students only. In this regards, the college decided to separate the result of IT students from other students and simply consider IT students' grades in the assessment and evaluation. In case of having few IT students

(i.e. less than four) registered in the course, the results will not be considered in the evaluation of the program.

##### C. Online Course Delivery during COVID-19 Period

Although classes were delivered online during the pandemic, but all the courses content and CILOs were covered and assessed. Even the practical components of the courses were delivered through virtual labs. Thus, the process of assessment and evaluation of SOs were not affected.

##### D. Market Needs and ABET Requirements

Market needs were analyzed and considered while designing BSIT program as well as formulating its goals and objectives. BSIT graduates should be qualified enough to fulfill market needs by having distinguished and desirable skills and knowledge. Fortunately, the proposed framework secured the alignment of program outcomes with market needs by ensuring delivering the desired skills, evaluating the attainment of graduates and taking a remedial action in case any of the SOs was not attained.

##### E. Effect of the Correctness of Mapping of SOs to CILOs on the Reliability of the Evaluation Results

It is well known about SO based model that the quality of its evaluation result depends on the quality of the mapping between CILOs and SOs. Thus, program coordinator (who creates the mapping between CLOs and SO) and instructors (who map assessments' questions to CILOs and SOs) shall be qualified enough to do correct mapping to ensure having reliable results at the end. Due to the highly qualified faculty members in the College of IT in Ahlia University, the obtained results were reliable and trustworthy.

##### F. Overloading Faculty Members during the Data Collection and Assessment Phases

Faculty were overwhelmed with their responsibilities in the data collection and assessment phases. However, it has been

planned to reduce that in the near future and have a lightweight process by selecting some of the courses and their assessments to be considered in the program assessment and evaluation, while other course assessments will be considered as formative one. This should reduce the load on faculty while maintaining good evaluation result that aids in informed decision making and continuous improvement of the program.

## VI. CONCLUSION

The student outcome-based framework presented in this paper has been adopted by College of IT in Ahlia University for the last five years. The vast amount of data collected by the college during this period, boosts the robustness of this framework in extracting continuous improvement requirements. Moreover, number of assessment tools were in use to measure the achievement of CIOs, SOs and in turn PEOs and their results were utilized in making informed decisions regarding continuously improving the program with its learning and assessment processes, achieving high quality standards as well as assuring the sustainability of high quality education.

Although some challenges were faced during the implementation of the proposed framework, this framework helped the college in improving the academic program. Other educational practices supported this framework such as: academic advising and career counselling. The success is reflected by improving the curriculum through adding new courses, removing courses, and modifying the content of some courses based on the market needs, international standards, constituencies feedback and the new trends in IT. Moreover, enhancing current teaching and assessment methods as well as adopting new one is another sign of improving the program that promotes positive assessment results. Furthermore, achieving distinguished and honorable results- such as improving students' performance, attaining high level of graduate attributes, achieving high quality standards, being accredited by ABET and satisfying various stakeholders- are clear indications of the success and improvements in the program.

Despite the fact that the College of IT adopted SOs defined by ABET as SOs for BSIT program, the proposed framework will still be applicable even if ABET re-define their set of SOs. Moreover, it is also applicable to other academic programs.

**Abstract**—The similarity search approach used for image Data Warehouse (DW) can provide better insights into discovering the most similar images compared to the input query. Due to the later innovation improvement, the mixed media complexity is discernibly expanded and modern inquires about regions are opened depending on comparable mixed media substance recovery. Content-Based Image Retrieval (CBIR) algorithms are utilized for the retrieval of images related to the inquiry image from gigantic databases or DW. The queries that are used for DW are complex, take a lot of time to process and many give less accurate results. For these reasons, this paper needs to have an effective technique to improve the similarity search query process that reflects a more positive result. In this paper, show how to extract features from a set of images (color, shape, and texture features) by using CBIR algorithm with Color Edge Detection (CED) method. Once these features are extracted, the proposed method will minimize the distance between these features vectors and the query image one using a Genetic Algorithm (GA). This paper illustrates the extraction of endless strong and imperative features from the database of the images, therefore, the capacity of these features in storing within the frame of features vectors. Accordingly, an imaginative closeness assessment with a metaheuristic algorithm (Genetic Algorithm (GA) with Simulating Annealing (SA)) has been attained between the query image features and those having a place in the database image. This paper introduces a new algorithm CEDF (Color Edge Detection with Gaussian Blur Filter) that applies the Gaussian Blur Filter after using CED method for feature detection of the image. Experimental results show that CEDF method gives better result than the other already-known methods.

**Keywords**—Data Warehouse (DW); Content-Based Image Retrieval (CBIR); Color Edge Detection (CED); Genetic Algorithm (GA); Simulating Annealing (SA); Memetic Algorithm (MA)

## I. INTRODUCTION

A perfect image processing system relies on three vital factors; i.e. acquiring the image, transmitting the acquired image, and stretching security to the image through its transmission. This leads to defective examination of medical images while acquiring an image from the database. Therefore, this paper needs an effective method to remedy this corruption. We present a new method called CEDF. This method added a new value to the image processing process Fig. 1.

Hence, the perfect image processing system consists of three important phases: Image de-noising, image compression and image security.

### A. Image Filtering

Image filtering is considered a very important phase within the image processing system. The image captured by the camera is debased by noise. That is loud image may degenerate more through the transmission process. Such a noisy image may regularly obstruct the operation of the communication system. Subsequently, it is exceptionally basic to have an effective de-noising method to evacuate noise from the image. As per noise pixel dissemination values, motivation noise is composed of two types. These types are irregular and fixed esteem motivation commotion. This commotion is called salt and pepper noise. As the noisy pixel can either have the most elevated or lowest value on grayscale [1].

### B. Image Compression

As with image de-nosing, image compression is additionally an essential stage of the image processing system. The transmission and storage of crude images request huge memory space. A great compression technique with quicker processing and memory-productive compression ability fulfills the requirements of the cutting-edge image processing system. In common, compression leads to the compression of information within the advanced image. The best objective of the compression procedure is to eliminate the repetition of image information. Therefore, the computerized image will be put away more viably. Lossless and Lossy compression techniques are the two essential categories of compression procedures. In the lossless compression strategy, an image sometimes before and after compression is identical to each other. Moreover, each bit of image is put away in the decompression process. While, the lossy compression procedure, there is a contrast between the original and reproduced image. But the reconstructed image is sensibly closer to the initial image [1].

### C. Image Security

The rise of the web causes extraordinary danger to data. These data are stolen through its transmission over the communication channel. Hence, the security of image

information is additionally one of the very crucial perspectives of the image processing system. Cryptography is one of the strategies utilized to supply security to data. In addition, parcel of other methods is developed to supply security to information. Sometimes parcel is not conceivable to keep the message content secured. In such a case, it is basic to keep the presence of the message as a secret. This strategy of giving security to a message is called steganography. Steganography is diverse from cryptography with reality. Cryptography bargains with keeping the message content emitted while steganography bargains with keeping the existence of the message secreta [1].

The bit-flipping mutation is a popular operator, in which a single bit in the string is flipped to form a new offspring string. A variety of other operators has also been developed, but is used less frequently (e.g., inversion, in which a subsequence in the bit string is reversed). A primary distinction that may be made between the various operators is whether they introduce any new information into the population. Crossover, for example, does not while mutation does [2].

All operators are also constrained to manipulate the string in a manner consistent with the structural interpretation of genes. For example, two genes at the same location on two strings may be swapped between parents, but not combined based on their values [3].

In this paper, the extraction of features (color, shape and texture features) will be shown from a set of images. Once these features are extracted, the method will minimize the distance between these features vectors and the query image one using GA. The paper carried out a performance test over an image dataset. Experimental result shows that CEDF results in a recall and precision raised average by 1.4 and 8.05 respectively, which assess and demonstrate the accuracy of the proposed algorithm.

This paper is organized as follows; Section II presents background related to the proposed method, Section III sheds some light on related work, Section IV speaks about the proposed algorithm, section, Section V deals with rating the performance of the proposed method, Section VI measure performance and evaluation, Section VII discusses the experiments and results, and finally, Section VIII is concluding the conclusion.

## II. BACKGROUND

This paper detail the most issues related to similarity search over images in Segment 2.1. Moreover, the proposed work is based on two well-known concepts used to use in all of the research. These concepts are talking about image features and are accessible within the literature. The Omni-technique and the star-join Bitmap index are portrayed in Segments 2.2 and 2.3, separately.

### A. Similarity Search

To be computationally analyzed, images ought to be pre-processed utilizing include extractors. These extractors are capable of generating features vectors that depict the

natural characteristics. This preparation is elaborated as takes after. An image is spoken to as a two-dimensional  $m \times n$  matrix of pixels. Where  $m$  and  $n$  are the image measurements and the pixel has numbers of values that depend on the image sort. For occurrence, the pixel values can be 0 or 1 in parallel images shift between 0 and 255 in grayscale images spoken to by 8 bits and have their values within the run of 0–255 each in RGB color images. A feature descriptor is characterized by: (i) a feature extractor calculation, which tracks down the images. That feature processes their pixels values and produces number of distortions of them, and stores these values in included vectors. (ii) A distance function, which produces a similarity measure. That is utilized to decide at that point the divergence between two images based on their features vectors.

The natural characteristics of images are as a rule depicted by properties with respect to color, texture, and shape. For occurrence, feature extractors may be actualized to calculate Color Histograms [3], the Haralick descriptors [4], and the Zernike moments [3]. Color histograms speak to the conveyance of colors (or levels of gray) in an image by calculating the recurrence. In which the color intensity of each pixel happens. With respect to texture feature extractors, the Haralick descriptors are employment factual approaches. That is to determine co-occurrence networks of images such that each matrix speaks to the connection between the pixel's position and its values.

### B. The Omni Technique

The Omni technique [3] is based on the choice of agent images (i.e. foci) from the DB, which is strategically positioned within the metric space. The number of representative images is given by the inborn dimensionality of the DB whereas the situating is given by the Hull of Foci algorithm. The main thought behind this calculation is to select images near the DB's borders. That can be utilized to progress probability in similarity searches.

### C. The Star-join Bitmap Index

A fundamental Bitmap list [3] built on an attribute comprises of several bit-vectors. One for each esteem an of  $A$ , where the  $i$ -th bit is 1 in case the  $i$ -th push is rise to  $a$ . There is something else; the  $i$ -th bit is 0. In DW, a Bitmap list can be developed to list properties of the dimension tables demonstrating the set of tuples in a fact table. That table holds the corresponding quality values. A Bitmap list with such a plan is called the star-join Bitmap (SJB) index [3].

In this paper, the extraction of features from a set of images (color, shape, and texture features) will be cleared. That is happening by utilizing CBIR algorithms with Color Edge Detection (CED) method. Once these features are extracted, the method will minimize the removal between these features vectors and the query image one employing a genetic algorithm. This paper outlines the extraction of unending solid and basic features from the database of images. Moreover, the capacity of these features is inside the store of features vectors. In like manner, a creative closeness appraisal with a metaheuristic algorithm (GA

with SA) has been achieved between the QI features and those having a put to the database image.

### III. RELATED WORKS

The related work will be divided into three directions of research that is synchronizes with the three phases of de-noising the image. The next sections will conclude the illustration of the following points:

A. Content-Based Image Retrieval, B. Image Similarity-Based Measure and C. Image de-noising.

#### A. Content-Based Image Retrieval

All of the previous research is important and still under research. However, no one mentioned the image as a perfect part of the source of data. Including images is vital as it improves the performance of the DW and broadband the capabilities of DW. That supports more accurate decisions for decision-makers.

A “Trigger” algorithm is used to recognize the lateness in tracking the unusual results in a large national clinical data warehouse of electronic health record (EHR) data [5]. It uses a method that upon the available data in EHR data repository from all departments of veterans’ affairs healthcare facilities. This method analyzes data from seven facilities. The limitations of this research are developing and refining similar algorithms more widely. In addition, that can potentially reduce delays in diagnostic evaluation and improve the quality and safety of patient care.

In addition, there is a research depended on novel identification-based image correction method using a bi-illuminant dichromatic reflection model. That occurs by a previous awareness demonstrated by small patches with close reflection properties, called Spectrum-Shape Elements (SSE) [6]. They introduced a Hausdorff-like metric for the set of spectrum shape elements. The basic properties of these SSEs and their localization methods were proposed. The shortages of this paper are: 1) constructing SSE pairs representing prior knowledge about distortions, 2) distortion-free illumination, 3) adapting the correction technique to other image distortion sources. This technique is showing the sensor noise and pixel sampling.

The author in [7] deals with textual and non-textual features to retrieve similar images by using a novel CBIR algorithm. After that, the algorithm will classify the query image into textual or non-textual categories. In the case of the textual query images, the text is revealed and realized. For the case of visual query, outstanding qualities are detected. Both qualities merged to shape the final feature vector. In addition, through these features, the top-ranked images are retrieved.

Besides this approach is effective for textual and non-textual images, its contribution is as follows: 1) It can deal with three methods of retrievals. 2) It can deal with low-power hardware independent of training efforts. In [8] the paper is about fusing the visual and semantic similarities between the query image and the database image. Then, they use the shortest path algorithm to a weighted graph.

That is for every database image node that has its pairwise similarity measure. This method was conducted on the retrieval of the common CT Imaging of Lung Diseases (CISLs). Furthermore, the results are not only better but also were more efficient. The limitations of this paper are: 1) This method can be only used in a small database but for a large database. In addition, it will consume more runtime and that requires clustering for the images. 2) This method can be only used for single-label data.

The author in [9], is proposed a new idea for the efficient retrieval of top-ranked images. That is done in the available DBs depending on local image features and spatial information in BoW architecture. To detect the performance evaluation of the proposed method, it was performed on seven state-of-the-art detectors and descriptors. After conducting this method over ten different DBs, it showed the accuracy of the proposed method. Additionally, is cleared by high precision and recall percentage record. It also proved that the proposed method exceeds the state-of-the-art detectors. As well as exceeds the descriptors over color, texture, scattered objects and complex DBs. The drawback of that method is never considering the technique scale-invariant and noise-robust.

A new content-based histopathological image retrieval approach has been proposed. This approach proposed a multi-scale and multichannel decoder based on LTP. That is to get special characteristics for every single image histogram representation. It also conducted the VLAD coding on the resultant features. Besides, power-law normalization has been performed to shape the final feature vector. By comparing the state-of-the-art techniques with the proposed approach, it shows the rising retrieval accuracy of the proposed approach. Efficiency and computational complexity are the limitations of the proposed approach [10].

This framework chooses the top-ranked images features. These features are most similar to the query image features for image retrieval. The main goal of any CBIR algorithm is to calculate the two basic descriptors (mathematical features and physical features). The main difficulties that are faced these methods are: 1) minimizing the semantic gap between the results and user expectations, 2) caring about low-level image descriptors [11].

The author in [12], is proposed a new method of Artificial Neural Networks (ANN) that joins Support Vector Machine (SVM) in a symmetric and asymmetric ways. This approach can deal with the classification inhomogeneity between various classifiers. In addition, this approach can deal with the imbalance problems in the CBIR algorithm. This method has been created because the retrieval results in multi-class search environment are so far from the expected. That is for the overlapping semantics between different classes. The experiments carried out on the Corel, Caltech-101 and COIL DBs, and proved the effectiveness of the proposed method compared to the state-of-arts methods.

The usage of the robust and consistent ETL stages in DW was better in achieving high efficiency. That is by

enhancing the preprocessing tasks. As well as, diminishing noise rates and using efficient CBIR that was better for getting top-ranked images. That is by reducing the possibilities of results and that pours into accuracy. Therefore, I will use the “Content-based” that implies the search analysis of the contents of the image. Using this approach instead of the metadata such as keywords, labels, or descriptions related to the image. The term “content” in this setting might allude to colors, shapes, textures, or any other data that can be determined from the image itself. CBIR algorithm is alluring since looks that depend simply on metadata are subordinate to content quality and completeness.

### B. Image Similarity-Based Measures

The author in [3], the Memetic algorithm is conducted to retrieve the top-ranked that is relevant to the entered query. The MA-based similarity measures do many operations. These operations are to extract an effective color, a shape and color texture features from the Corel image database. The ILS (Iterated local search) algorithm assesses the quality of the solution by raising the fitness function number. This method succeeds in increasing the average of precision and recall by 1.4 and 8.05 respectively.

One of the most achieving works is [3] and chose it to be the guide in the research. One of the most well-known metaheuristics in dealing with optimization issues could be GA. GA may be a population-based heuristic approach. GA bargains with a major framework to discover an appropriate arrangement for an uneasy issue. In addition, it has demonstrated its proficiency in producing unused arrangements between trial arrangements and recognizing the finest solutions from a populace. It is a must to have a nearby look to survey GA in finding the arrangement space. That was rather than caring approximately abusing the search space that is for improving the metaheuristic algorithm.

There are inexhaustible computer imaging applications requiring a few kinds of similarity estimation as the portion of their forms. Although the applications are much shifted and the execution subtle elements of each arrangement are special, all share the common string in those features or properties of the image (in each application). These features are measured and after that compared to other features from a database of images. In addition, these features would be compared to a few references show to extricate a few significant conclusions or usefulness approximately the image information on hand. There are a few strategies for measuring image similarity. The strategies are: 1) A pattern recognition approach. 2) Comparison of outlines in a video sequence. 3) Image stabilization employing a homographic transformation. 4) Utilizing image feature focuses to compute similarities and generate an image mosaic. Here, this paper will deal with the fourth strategy of measuring similarity search as the previous research. This paper will use this strategy because it will produce more accurate results regarded to the research of that section.

### C. Image De-noising

The author in [13], Wei Wang examined a filtering method called novel inverse by employing a dictionary approach. The most thought is to combine a learned word reference for the representation of the de-convoluted image. As well as, a reverse channel based on non-negativity and bolster limitations. That is to de-convoluted the watched image with an obscure point spread function. The advantage of this approach is that the objective image can be spoken to with more points of interest by the word reference premise. This paper utilizes the substituting course strategy of multipliers (ADMM) to unravel the coming about optimization issue. The limitations are the inability to recognize the blurring data region and the support region. In this work, an image-preparing model is created, whereas an image-filtering module is created using the median channel with a variable versatile window design. This filtering provides change inters of working recurrence and PSNR. The moment stage includes the advancement of a compression module based on lifting wavelets. This compression module provides improved execution inters of compression proportion and PSNR. In the final stage, image encryption is performed to have a secured image [1]. The drawback does not use different filtering techniques to choose the best results.

Here, in [14] a new strategy presents a gradient-based approach for extracting the notable structures from diverse multimodal medical images. That is for the estimation of combination execution and consequent determination. The benefits of this strategy are showing the leading performance of visual perception joint quantitative metrics and the weakly involved calculations. The only limited point that observed here is the inactive strategy with big data. An unused de-noising approach is proposed for rebuilding the Gaussian (AWGN) noise-contaminated images. In addition, through the suggested developmentally optimized adjust Guided Image Filtering [15]. The short-come of this approach is dealing with only one type of noise (Gaussian noise). This research introduces the infrared and visible image fusion algorithm relayed on the image division of a hybrid curvature filter [16]. The limitations of this algorithm are low performance and low enhancement of the running speed.

In this research, evolving an Image Filtering and Labeling Assistant (IFLA) framework is to assist the foremost time-consuming parcel of this handle [17]. The drawbacks of this research are the inability to automatically label the marked-up ranges of images. Moreover, the inability to meet behavioral patterns and programmed individual symmetry. This paper portrays Gaussian filter and Histogram Equalization methods for de-noising and differentiates the upgrade of MR Brain images separately [18]. The suggested future work for this paper, is removing the other types of noise by using the comparing filter.

Another paper, innovates an unused filter for image boosting. This filter relayed on the combination of a shock channel with a fourth-order dissemination equation [19]. The limited result was noticed while applying this algorithm with images of degraded documents. The new

algorithm combines the versatile median filter algorithm with the conventional nonlocal mean algorithm. To begin with that, you should alter the image window and adaptively choose the comparing pixel weight. Then de-noises the image, which can have a great filtering impact on the blended noise [20]. The drawbacks of this calculation are discovering the calculation for color image processing effect and enhancing the time consumption of de-noising image.

The author in [21], point-by-point comparative investigation of diverse de-noising filtering techniques. This technique implemented leaned on four widely used Image Quality Assessments (IQA) metrics. The drawback of this paper is not diminishing more types of image noise. Lufeng Bai, et al. [22] designed a singular method for Cauchy method removal that illuminates the new demonstration. Then a rotating minimization strategy is utilized, and its merging is demonstrated. The limitation of this method is not calculating the precision and recall values to evaluate the system's efficiency.

The proposed strategy [23] is organized utilizing three modules, to be specific. These strategies are: 1) The DIP-based module for concurrently learning noise diminishment and differentiate upgrade. 2) On the off chance that module for combining images and neutralizing color movement and noise enhancement. 3) The PR module for enhancing edge data. The drawback of this strategy is the inputs of the image fusion module can delay the velocity of the whole model. A novel variational paradigm [24] is presented based on adding up to a variety. As well as IO the gauge for at the same time expelling the tangling noise, assessing the location of lost pixels, and filling in them. The suggested issue for enhancing the quality is using a similarity search algorithm.

All of the previous papers proposed various kinds of de-noising algorithms and strategies. Most of these used Gaussian filter lonely or a hybrid of Gaussian filter with different methods for de-noising and upgrading the performance of the targeted image. In addition, it was notable that the medical image has a dominant hand in that issue. Most of the shortcomings were from the use of one type of filtering technique in addition to low performance and running speed.

The proposed paper will introduce a new algorithm CEDF (Color Edge Detection with Gaussian Blur Filter). CEDF applies the Gaussian Blur Filter after using the CED method for feature detection of the image. Furthermore, to assess the efficiency of the system's result, will figure precision and recall values, and show the results applied to Correl DB. By contribution of the Gaussian Blur filter with the proposed method, the results were applied to Correl DB. Moreover, rising through recall and precision average 1.4 and 8.05 respectively and assess the accuracy of the result.

#### IV. PROPOSED ALGORITHM (CEDF)

Multimedia data play an essential role in the decision process. One of the problems when integrating multimedia

data in a warehouse is the retrieval speed of the information. This information is a direct coefficient with respect to efficiency and dealing with dimensions built on information retrieval [10]. The use of DW is most common for storing/ retrieving complex data in multimedia formats. Where DBMS algorithm is traditional and is not designed to fit in handling complex multimedia data, since relational databases store structured data. That is why enhancing warehouse performance on multimedia data is essential. Because of that, this paper deals with boosting the performance of DW. That is activated by upgrading the efficiency of the algorithm with the help of promoting precision and recall results [3].

The proposed method will show how to extract features from a set of images (color, shape and texture features) by using the CBIR algorithm with Color Edge Detection (CED) method. Once these features are extracted, the method will minimize the distance between these features vectors and the query image one, using a genetic algorithm. This paper illustrates the extraction of endless strong and imperative features from the database of images. Moreover, the capacity of these features is within the store through the frame of features vectors. Accordingly, an imaginative closeness assessment with a metaheuristic algorithm (GA with SA) has been attained. This attainment is between the QI features and those having a place in the database image. Finally, the paper will measure the precision and recall of this method. By contribution of the Gaussian Blur filter with the proposed method, the results applied to Correl DB. As mentioned before that the extraction of the image features depended on three basic phases (color, shape, and texture). The paper will use the second and the third phases as it used in the previous paper [3]. The enhancement of the paper only includes the color phase by using (CED) algorithm that we will enumerate in details in the following section.

##### A. Color Edge Detection

Edge detection is the title for a set of scientific strategies, which target classifying focuses in an image. That is because the image concentrated changes strongly or, has discontinuities. Edge detection alludes to the method of distinguishing and finding sharp discontinuities in an image. Edge detection could be a principal device utilized in most image-preparing applications. That is to get data from the outlines as an antecedent step to feature extraction and object segmentation [25]. One of the elemental errands in image-preparing is edge detection. High-level image handlings, such as object acknowledgment, division, image coding, and robot vision depends on the precision of edge detection. Whereas edges are contain fundamental image data.

Within the conventional color edge detection techniques, the color image is, to begin with, isolated into three distinctive channels. These channels are R, G, and B before handling and after that, the algorithm is connected to the particular channels. Additionally, in conclusion, all channels are combined to deliver the result. The high-level image handling applications such as question acknowledgment, protest following, robot vision, etc. In the

case of color image processing, Color images require more memory space for capacity. Unlike the greyscale, images require the transmission of color data requires a bigger transfer speed. By utilizing an effective edge discovery procedure, the unnecessary subtle elements of a color image can be disposed of. In addition, the valuable data can be put away to assist the preparation. This will successfully diminish the memory space for putting away the color data and lower the transmission bandwidth [26]. The edge discovery methods can be broadly classified as:

- Edge detection in grey-scale images.
- Edge detection in color images.

The basic distinction between a gray-scale image and a color image is the pixel in a gray-scale image may be a scalar esteemed work. While in a color image, a pixel is considered as a vector esteemed work because it comprises three-color components (red, green and blue). Due to this, vector esteemed procedures are favored for edge detection in color images [26].

1) *An outline of a few classic edge detectors:* Many edge detection methods have been proposed for grey-scale images in the image handling literature. These edge detectors are categorized as [26]:

- Edge detection strategies are based on the first-order subordinate.
- Edge discovery strategies are based on the second-order subsidiaries.

#### 2) *The four steps of Edge Detection*

- Filtering- Filter image to move forward execution of the edge detector w.r.t noise error.
- Smoothing- stifle as much noise as conceivable, without wrecking the true edges.
- Enhancement- applies a channel to improve the quality of the edges within the image (sharpening).
- Detection- decides which edge pixels ought to be disposed of as noise and which ought to be held (as a rule, thresholding gives the basis used for detection). Localization- decide the precise location of an edge (sub-pixel resolution may well be required for a few applications. That appraise the area of an edge to better than the dispersing between pixels). Edge diminishing and connecting are as a rule required in this step. Edge discovery could be a principal apparatus utilized in most image-handling applications to get data from the outlines. Furthermore, a forerunner step includes extraction and protest segmentation [25].

#### B. *How Does CEDF Works*

Content-Based Information retrieval (CBIR) algorithm features are extracted through several techniques for the features extraction. Most visual images contain color and shape, with low-level image features and notable focuses [3]. Above all, of that, each image stores its attributes in a partitioned database called database features. A similar

CBIR algorithm is outlined in Fig. 1. Here [3], is the recent paper that talked about CBIR and will reuse some steps and add another step to my new paper. On one hand the steps that will use are: (1) how to extract features from a set of images (color, shape, and texture features). (2) Once these features are extracted. (3) minimize the distance between these features vectors and the query image one using GA.

Finally, will measure the precision and recall of this method and show the results applied to Correl DB. On the other hand, we will add a new filtering technique called Gaussian Blur filtering technique with the old method. This technique concludes (RGB color with neutrosophic clustering calculation, Canny Edge strategy to extricate shape features, YCbCr color with discrete wavelet change, Canny Edge Histogram to extricate color features, and gray-level co-occurrence framework to extricate texture features). This filtering technique will raise the average precision and recall percentage and that reflects positive performance results on the proposed algorithm.

1) *CEDF algorithm steps:* Fig. 1 demonstrates the method suggested. The fundamental steps involved in color feature extraction are shown as follows:

- Select the image query to be processed.
- Image query and DB images will be transformed into YCbCr co; or space from the M\*N input RGB image.
- Before applying the canny edge detector to the Y portion of the image, the portion of YCbCr is separated following the transformation of the image.
- After that, the unobtrusive Cb and Cr are combined with the edge that was obtained in the previous step.
- Pixel editing and the addition of CED with a noise-eliminating filtering method.
- After that, a single RGB image is created from the synthesized image.
- The histogram calculation for each portion of the RGB image is followed by the division of the RGB component into distinct R, G, and B components. From HR, HG, and HB, a total of 256 bins have been obtained.
- In each histogram that is obtained, a distinct wavelet transform is used to improve the performance of the features. to apply DWT level 3 to HG and HB and DWT level 2 to HR. There are 128 bins created when DWT is applied. In particular, 64 bins were obtained from HR, while each HG and HB obtained 32 bins.
- The repository is where each image's feature vector is calculated.
- Similarity search algorithms will elaborate to get the most similar images.
- Get the results.

The following section will illustrate the main features of (CBIR) algorithm features.

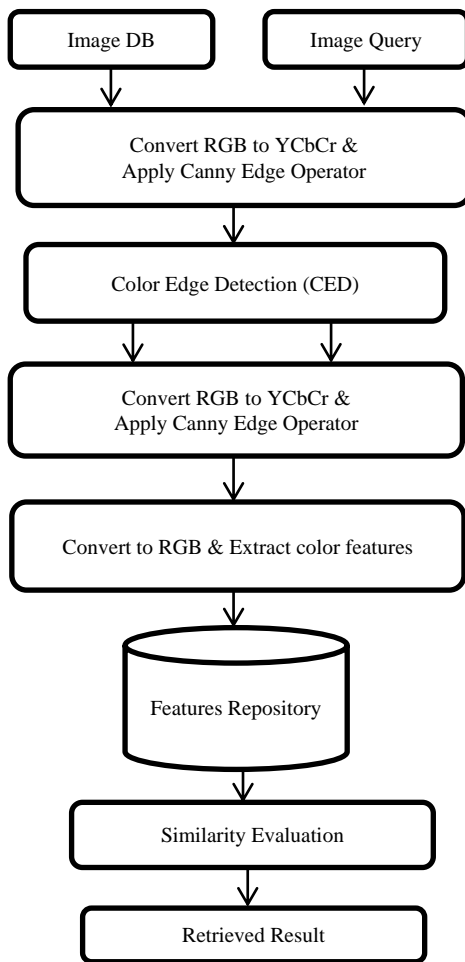

Fig. 1. The proposed method for color feature extraction.

2) *Color features extraction*: In this modern work, the strategy for CBIR algorithm based on the extraction of the color features, are mentioned. This strategy [3] is concluding the conversion of RGB to YCbCr and applies the canny edge detector to the result. Then will use the CED operation that is concluding the proposed filtering technique. The next sections will present the details of how to convert RGB to YCbCr, using the canny edge detector and what are the steps of CED operation.

Color is the foremost broadly utilized visual substance for image recovery. Its three-dimensional values make its separation possibility predominant to the single-dimensional gray values of images. Sometimes recently selecting a suitable color depiction, color space must be decided to begin with. Each pixel of the image can be spoken to as a point in a 3D color space.

a) *Query image conversion and CED*: Commonly utilized color space for image recovery incorporates RGB, Munsell, and CEDF. In the proposed paper case, the method will choose RGB and Y'CbCr spaces. Y'CbCr color spaces are defined by a mathematical coordinate transformation from an associated RGB color space. If the underlying RGB color space is absolute, the Y'CbCr color space is an absolute color

space as well. Conversely, if the RGB space is ill-defined, so is Y'CbCr. The formula that allows converting RGB colors to Y'CbCr is the following:

$$[Y \ Cb \ Cr] = [RGB] \begin{Bmatrix} 0.229 & -0.168935 & 0.499813 \\ 0.587 & -0.331665 & -0.418531 \\ 0.114 & 0.50059 & -0.081282 \end{Bmatrix} \quad (1)$$

After converting the RGB to YCbCr, one should apply the canny edge detector to the result [3]. Edges in any image are helpful in identifying the objects. The new step that is added to the old method is Color Edge Detection (CED). The CED works by following these steps:

- Apply Gaussian Filter to smooth the image to remove the noise.
- Find the intensity gradients of the image.
- Apply non-maximum suppression to get rid of spurious responses to edge detection.
- Apply a double threshold to determine potential edges.
- Track edge by hysteresis: Finalize the detection of edges by suppressing all the other edges that are weak and not connected to strong edges.

b) *Conversion to RGB*: After applying CED, the method reconverts the image to RGB and computes the histogram for every component (R, G and B). The color histogram serves as a viable representation of the color substance of an image in the event. That color design is one of a kind compared with the rest of the DB. The color histogram is simple to compute and successful in characterizing both the worldwide and nearby dispersions of colors in an image. In expansion, it is strong to interpretation and turns almost the seeing pivot. Moreover, the changes as it were gradual with the scale, impediment, and seeing angles.

3) *Shape features*: The shape of an object is an important and basic visual feature that can describe image content. In the context of content-based image retrieval, the word shape is used to refer to the geometry of a region's bounding contour in 2D. Shape feature extraction and representation are the bases of object recognition in an image. It plays an important role in many image-processing applications including content-based image retrieval. The feature extraction stage produces a representation of the content that is useful for shape matching. The easiest way to use geometric information about the objects present in an image is by computing simple scalar descriptors of the regions of interest, such as area, circularity, eccentricity, major axis orientation, dimensions of the minimum bounding rectangle, etc. Usually, the shape representation is kept as compact as possible for the purpose of efficient storage and retrieval, and it integrates perceptual features that allow the human brain to discriminate between shapes.

Finally, here are the steps followed before computing the invariant moments:

- Convert the image 2D matrix to a gray matrix.

- Apply the median blur filter on the gray matrix.
- Apply the Canny Edge detector on the filtered image.
- Generate the moments and then the Invariant moments of the image.
- Store the invariant moments in the features vector.
- Convert the image 2D matrix to a gray matrix.
- Apply the median blur filter on the gray matrix.
- Apply the Canny Edge detector on the filtered image.
- Generate the moments and then the Invariant moments of the image.
- Store the invariant moments in the features vector.

4) *Texture features*: Texture feature is a vital property of the image, which is often characterized as the visual appearance, or material characteristics of the objects within the image. It basically comprises the components of surface primitives (i.e., text components or textual) organized in a few indicated arrange (i.e., text format). The idea of a textual is central to the text. For the most part, it is characterized as a visual primitive that shows certain invariant properties more than once very different positions, distortion, and introduction in a given zone. The text components can be as little as a sand molecule to huge components like bricks in dividers, but they all share the comparative auxiliary and measurable properties inside a gather. The textual properties deliver rise to the seen delicacy, consistency, thickness, harshness, consistency, linearity, recurrence, stage, directionality, coarseness, arbitrariness, fineness, smoothness, granulation, etc., of the text as an entirety.

## V. PERFORMANCE EVALUATION

### A. Database Descriptions

The tests conducted in this consider utilized the Corel DB (A) comprising 1000 differing images and each image within the DB is  $384 * 256$  or  $256 * 384$  size-wise. As such, the results were expressed with the utilization of 10 semantic sets. As well, each set contains one hundred pictures. The Corel DB is of the taking after semantic categories. These categories are Mountains, Africa, Dinosaurs, Buildings, Buses, Nourishment, Elephants, Horses, Beaches, and Flowers. Consequently, with the utilization of the recorded comes about, a clear comparison of comes about can be performed.

Then the proposed paper will measure the precision and recall percentage for every category in the DB by the proposed method (CEDF). After that, the paper will compare the results with some other methods related to the topic of the paper's interest.

For that will appear the adequacy and prevalence of the proposed method in terms of recovery capabilities. Those capabilities will show by the gotten results are too compared with other algorithms in terms of precision and recall rates.

The other comparative frameworks are J. C. Felipe, Z. Mehmood, T. Mahmood, and M. A. Javid [27], N. Ali, K. B. Bajwa, R. Sablatnig, and Z. Mehmood [28], Z. Mehmood, S. M. Anwar, N. Ali, H. A. Habib, and M. Rashid [28]. Zeng, R. Huang, H. Wang, and Z. Kang [29], E. Walia and A. Pal [30], C. Wang, B. Zhang, Z. Qin, and J. Xiong [3], M. K. Alsmadi [3] and the same ten semantic sets (each set contains 100 images of Corel DB) were utilized by these comparative algorithms. Tests of diverse images from 10 semantic sets of the Corel DB appear in Fig. 1.

### B. Precision and Recall Evaluation

To assess the execution and the viability of the proposed CED framework, precision and recall rates are used. Precision could be a degree of the capacity of the CED algorithm to recover. So those images will be compared to the query image. In this respect, the recall rate is the genuine positive rate, and it is utilized to assess the ability of the CED framework. That ability for regarding the number of recovered important images compared to all similar images within the database.

The precision of a CED algorithm is defined as the number of relevant images retrieved as a fraction of the total number of images retrieved [3]:

$$Precision = \frac{\text{number of relevant images retrieved}}{\text{total number of images retrieved}} \quad (2)$$

The value of Precision lies between 0% and 100%.

Another measure to find the effectiveness of a retrieval method is Recall. Recall of a CED algorithm is defined as the number of relevant images retrieved as a fraction of the total number of relevant documents in the database:

$$Recall = \frac{\text{number of relevant images retrieved}}{\text{total number of relevant images in the database}} \quad (3)$$

Recall values have range similar to precision, e.g., between 0% and 100%.

The recall value will be 100% if the entire database is returned as a result set in response to a query. Similarly, the precision value can be kept high by retrieving a small number of images. Therefore, precision and recall should be used together or the number of images retrieved should be specified [3].

The results of the execution of the paper's test were stated by running the proposed CED algorithm simulation five times. In every experiment, 20 inquiry images from each semantic category have been chosen arbitrarily. Then the rates of precision and recall are expressed based on the most elevated 20 images. As can be observed in Fig. 2 the exactness and review rates were calculated for 20 queries in the expansion to their recovered images. As Fig. 2 is illustrating the proposed algorithm contains a great level of effectiveness for the retrieval of images. These images were retrieved by getting higher 5 categories of precision and recall values. As the tests were demonstrating, the increment within the retrieved comparative images will move forward with precision and recall rates. The results on the extracted color, shape, and texture features

combined with the MA component. That poured in demonstrating the exceptionally empowering enhancements of the CBIR algorithm, especially regarding its recall and precision.

Fig. 2. Precision and recall rates of CED [3]

### C. CBIR with Filters CED with /without Filters

To improve the results, should apply some filters to the original image before applying the CED algorithm. Here are the filters descriptions:

- **Blur:** Image blurring is achieved by convolving the image with a low-pass filter kernel. It is useful for removing noise. It removes high-frequency content (e.g. noise, edges) from the image. So, edges are blurred a little bit in this operation (there are also blurring techniques that do not blur the edges).
- **Gaussian Blur:** Blurs an image using a Gaussian filter.
- **Median Blur:** While the “Gaussian” blur filter calculates the mean of the neighboring pixels, the “Median” blur filter calculates the median.
- **Laplacian:** Laplacian filters are derivative filters used to find areas of rapid change (edges) in images. Since derivative filters are very sensitive to noise, it is common to smooth the image (e.g., using a Gaussian filter) before applying the Laplacian. This two-step process is called the Laplacian of Gaussian operation.

The paper used the Corel database for testing purposes. It runs the CED on 20 random query images for each class using the formula proposed in “Precision and Recall” section (Eq. 2, Eq. 3). Those will trial without adding any filtering techniques and with filtering techniques. Without filters, the recall values for the proposed (CED) method are below the average of the proposed (CED) method. That is when the Gaussian filter comparative to the other filters. For that reason, the paper will test some filters that were applied to the query image and the DB before comparing. Fig. 3 shows the recall values for some sets in Corel DB with and without filters. In addition, the results confirm that the Gaussian blur filter has better recall values than using the other different filters or without using any filters.

Fig. 3. Comparisons between using the CED method with and without filters (recall measure).

On one hand, Fig. 3 shows that the Gaussian Blur filter gives better results for all random proposed classes of the DB. On the other hand, the Laplacian filter gives the worst results compared to the others. Consequently, use the Gaussian blur filter with CED method to get better performance and more accurate results.

Without filters, the precision values for the proposed (CED) method are below the average of the proposed (CED) method. That is the case of the Gaussian filter compared to the other filters. For that reason, the paper tested some filters that were applied to the query image and the DB before comparing. Fig. 3 shows the precision values for some sets in Corel DB with and without filters. In addition, the results confirm that the Gaussian blur filter has better precision values than using the other different filters or without using any filters.

On one hand, Fig. 4 shows that the Gaussian Blur filter gives better results for all random proposed classes of the DB. On the other hand, the Laplacian filter gives the worst results compared to the others. Therefore, the paper use the Gaussian blur filter with CED method to get better performance and results that are more accurate.

Fig. 4. Comparisons between using the CED method with and without filters (precision measure).

Fig. 5. Comparisons between the proposed method (CEDF) and other state-of-the-art algorithms (recall measure).

This figure shows that CEDF method gets the highest average over all the other methods. That clears especially on dinosaurs, elephants and flowers. That average is 18.31565% on the recall measure and that proves the effectiveness of the proposed method. That is when the paper compares its results to the results in Fig. 2 that proves the importance of penetrating a new filter (Gaussian filter) to the proposed method CEDF. It will be obvious from these figures (Fig. 3 & 5) that the proposed algorithm has better average recall over different points while using various methods for Corel DB.

Fig. 6 shows that the CEDF method gets the highest average over all the other methods. That average is especially on dinosaurs, elephants and flowers by scoring 100% on the precision measure. In addition, that proves the effectiveness of the proposed method. That is when the paper compares its results to the results in Fig. 2 that run the CED on 20 random query images for each class using the formula proposed in “Precision and Recall” section. This formula is without adding any filtering techniques and that proves the importance of penetrating a new filter (Gaussian filter) to the proposed method CED.

Fig. 6. Comparisons between the proposed method (CEDF) and other state-of-the-art (precision measure).

## VI. EVALUATION AND DISCUSSION

In this section, the paper depicts three experiments dealing with diverse images represented by diverse descriptors. For each context with and without using the filtering technique, took similarity rates to be compared. This comparison will be with each other in the two cases of using the recall and precision values.

Experiment 1: This experiment is based on examining the recall and precision rates when the paper is using different filtering techniques without using any filtering technique. The result of that experiment shows the high rates of recall and precision results. That is when the paper is using the filtering technique with the same DB and that proves the effectiveness of using a filtering technique (Fig. 3 and Fig. 4).

Experiment 2: (recall measure). This experiment depended on comparing the results of the proposed method CEDF. That experiment contains a filtering technique with the other methods of different researchers. Those researchers use the same DB but without using any filtering technique. The results of that experiment show the increasing rate of recall values by 1.4 and that proves the effectiveness of the proposed method CEDF Fig. 5.

Experiment 3: (precision measure). This experiment depended on comparing the results of the proposed method CEDF. That experiment contains a filtering technique with the other methods of different researchers. Those researchers use the same DB but without using any filtering technique. The results of that experiment show the rising rate of precision values by 8.05 and that proves the effectiveness of the proposed method CEDF Fig. 6.

The average precision and recall values of the proposed CEDF method fared better than the other cutting-edge methods, by raising the values by 8.05 and 1.4, respectively.

This is due to the fact that the other developed methods only extract a small number of features from various descriptors including shape, color, and texture. While in this work, measurements of color, shape, and texture were used to extract a large and robust number of characteristics.

Specifically, color characteristics were extracted using YCbCr color with discrete wavelet transform and Canny edge histogram, shape features were extracted using RGB color with neutrosophic clustering algorithm and Canny edge technique, and texture features were extracted using GLCM.

By raising the fitness number, the SA algorithm's combined use with GA increased the solution quality (weight). Because of this, adding the SA algorithm improved the GA's exploitation rather than its exploration of the search space. The experimental findings make it abundantly evident that the MA aids in the retrieval of a significant number of photos that are pertinent to the query image [3].

## VII. CONCLUSION AND FUTURE WORKS

This study is advancement in querying unstructured medical data using a similarity search algorithm. Specifically, the contribution of this work is providing unlimited query support and efficiency in processing unstructured data in the epilepsy field. At the core of the queries are modules, which perform feature extraction from unstructured data. The framework is unlimited by adding CEDF, which has a filtering technique to erase noise and editing pixels. This filtering is done for the query image in the feature extraction phase. The framework is efficient in that it utilizes the distributed computing power of Gaussian filters.

The study shows how to extract features from a set of images (color, shape and texture features). Once these features are extracted, the minimization of the distance between these features vectors and the query image one using a genetic algorithm. Finally, we will measure the precision and recall of this method and show the results applied to Correl DB. By contribution of the Gaussian Blur filter with the proposed method, the results rising through recall and precision average 1.4 and 8.05, respectively and that assesses the accuracy of the result. As a result, such a framework is feasible and useful for medical queries. Although this study is specific to the epilepsy field, however, it is a step forward in data-driven medicine. The data-driven medicine content of the unstructured data is available for unlimited and efficient querying.

After the paper produces a concrete DW infrastructure, the next research will recommend looking into integration and usability issues.

## ACKNOWLEDGMENT

I must first express my gratitude towards Prof. Ahmed Sharaf Eldin for her supervision and for teaching me how to be an independent thinker, she has been an invaluable source of knowledge and ideas and I appreciate her flexibility in allowing me to pursue my own research ideas.

My sincere thanks are dedicated to Dr. Nermin Abdelhakim for his generous assistance and continuous help in addition to providing me with all the facilities required for the success of this work.

# Agro-Food Supply Chain Traceability using Blockchain and IPFS

Subashini Babu, Hemavathi Devarajan

Department of Data Science and Business Systems-School of Computing, SRM Institute of Science and Technology  
Chengalpattu, Kattankulathur, Tamilnadu 603 203, India

**Abstract**—Many blockchain initiatives significantly use the InterPlanetary File System (IPFS) to store user data off-chain. The centralized administration, ambiguous data, unreliable data, and ease of creating information islands are all issues with traditional traceability systems. This study develops a monitoring system using blockchain technology to record and inquire about product information in the supply network of Non-Perishable (NP) agro goods to address the above issues. The transparency and trustworthiness of traceability data were considerably improved by employing blockchain technology's distributed, tamper-proof, and traceable properties. To alleviate the strain on the blockchain and enable efficient information inquiry, a storage structure is built in which both public and private data are stored in the blockchain and the Inter Planetary File System (IPFS) using cryptography. Because of its ability to trace the origin of food, blockchain technology contributes to the development of reliable food supply chains and the establishment of rapport between farmers and their customers. Since it provides a secure location for data to be kept, it can pave the way for implementing data-driven farming techniques. In addition to improving data security, recording farm data in IPFS and storing encrypted file IPFS hashes in smart contracts solves the issue of blockchain storage explosion. And when used in tandem with smart contracts, it enables instantaneous outflows between parties in response to changes in data stored in the blockchain. The paper also offers simulations of the implementation and analysis of the performance. The findings validate that our system improves security for sensitive information, safeguards supply chain data, and meets the needs of real-world applications. Furthermore, it boosts throughput efficiency while reducing latency.

**Keywords**—Blockchain; IPFS; supply chain management; traceability; Ethereum

## I. INTRODUCTION

Everyone is concerned about the nutritional value of the meal they are about to consume. The food supply chain is prevalent, with tedious processes prone to human errors [1]. A blockchain-based supply chain can offer visibility into the movement of commodities by making all transaction records accessible to all network nodes. End-to-end traceability is another feature of the blockchain-enabled food supply chain technology that is helpful in the case of a food investigation or recall. Supply chain management combines actions to transform raw materials into completed goods, increasing customer value and achieving a long-term competitive advantage. The supply chain generally encompasses people, things, initiatives, and organizations involved in transforming raw materials into finished goods, mainly and secondary to

fulfilling customer orders. Although the government has developed national traceability requirements for significant products, fake and subpar interests are still common in the marketplace. Thus, several issues with food security have led to a crisis in consumer confidence, which is also a significant obstacle to national efforts to build a trustworthy society [2].

NP agro-food monitoring program can determine food origin and provide detailed information about food production and distribution. The farm-to-table process includes the production, processing, transportation, and sale of agricultural products. Any fraud in any of the connections above can result in potentially fatal threats to food safety. Therefore, various management solutions have arisen with IoT, automation, and different learnings. These systems can trace the complete procedure autonomously, but they must solve the problem of altered data and food poisoning. The reason for this is that in the conventional data storage procedure, there is always the risk of data being tampered with or lost. Researchers have been experimenting with blockchain technology to store data and protect data security by addressing the issues above [3]. It develops a blockchain-based system for storing agricultural product provenance data. Due to their linkage to IoT devices, agricultural items will automatically transmit whatever data they collect to a network.

Once again, the server will dynamically record the information onto the blockchain following data processing. In this instance, provenance data secure storage is implemented using blockchain technology. As a result, it successfully ensures the authenticity of provenance data. A lot of real-time monitoring data would be produced when many agro items joined the provenance monitoring platform. Blockchain was initially developed for transactions involving digital currencies; the volume of data generated is far less than that of real-time monitoring data. This makes it extremely difficult for the rate of block construction to stay consistent with storing traceability information. Thus, more than a direct application of blockchain technology is needed. We merge the IPFS and blockchain to offer a data storage and query method for a traceability solution for farm products. IPFS is a peer-to-peer decentralized file system with the ambitious goal of connecting all devices that use computers to a single, universal file system. It first suggests a data storage model based on blockchain and IPFS [4]. The submitted video, picture, and sensor data are automatically encapsulated and parsed by this model. The above information is then sent to IPFS, and the blockchain is updated with the associated hash addresses. The blockchain transaction's hash values are then saved in the

database. By requesting the authenticity database hash address of an item in IPFS, customers can access the provenance data using the transaction content from the blockchain.

The article is divided into the following sections: Section II provides a quick review of blockchain technology and terminology, stages, methods, and benefits of traceability. Section III also discusses previous initiatives to incorporate blockchain into provenance systems. Section IV describes a modeling approach that has been presented. Section V goes through the outcomes and performance. Section VI brings the paper to a conclusion.

## II. BLOCKCHAIN FOR TRACEABILITY

Blockchain technology can offer improved tracking of agri-foods from the ranch to your dinner plate. Blockchain technology might greatly minimize the food safety concerns arising from deliberate deception, terrible organization, and being short of guidelines. [5] Blockchain technology will revolutionize how traceability is viewed by overcoming the challenges in Table I.

TABLE I. CHALLENGES IN TRACEABILITY SYSTEM

Challenges
Security and privacy
Credentials and Governing Compliance
Lack of end-to-end visibility
Interoperability
Expiration and Counterfeit Products
Stakeholders Trust management
Conflict of interests
Temperature-controlled Logistics

### A. Functioning of Blockchain

The digital register is a "link" of unique "blocks" information. As new data is added to the network, a new block is created and linked to the chain. To maintain consistency, all nodes (computers) must update their versions of the blockchain ledger. One of the elements that make blockchain so highly secure is the process of adding new blocks [6]. This is due to the requirement that a participating node verifies and validate the validity of new data well before a new node can be recorded to the blockchain. About cryptocurrencies, this can mean proving that brand-new transactions within a block are legitimate and that no coins have been spent more than once.

On the other hand, a single database or worksheet permits revisions to a single version without restriction. Once consensus is reached, the block is added to the ledger, and the underlying records are kept in the distributed ledger [7]. Blocks are safely joined together to form a secure digital chain that extends from the start of the log to the latest addition. Nodes are frequently given fresh amounts of the native currency of the blockchain in appreciation for their work confirming revisions to the linked data.

### B. Merkle Tree

The Merkle binary hash tree of 1987[8] is an essential component of the Blockchain structure. Each node of the

Merkle tree is called a leaf, a separate data item or record. A cryptographic hash function  $H()$ , is used for evaluating a leaf of  $X$  records which in turn has a  $2X - 1$  inner node. A tree with  $X = 2y$  nodes has a complexity of  $y = \log X$ . Also, a single unique root at height  $y = 0$  is the source of the entire hierarchical tree. The claim that the root value  $\hat{R}$  encapsulates the correctness of all the entries in the tree constitutes a statement made to the entirety of the tree. Conforming to each child  $n$  at height  $y'$ ,  $Z$  forms a collection of  $y'$  systems on the whole hierarchy.

$$\hat{R} = HF_t(n, Z) \quad (1)$$

where,  $HF_t$  is a succession of  $y'$  hash function  $H(.)$  calculations. The entire Merkle hash tree is stored by an untrustworthy party to prove, whereas a verifier only stores the root  $\hat{R}$ . The party attempting to verify the authenticity of node  $n$  provides  $Z$  for each node in the tree. Given,

$$\hat{R} = Hf_t(m, Z) \quad (2)$$

Eq. (2) concludes that statement  $n \in \hat{R}$ , where  $n$  is the existing root. Knowing the present  $\hat{R}$ , a steady improvement state occurs from  $\hat{R}$  towards  $R = Hf_t(m', Z_m)$  every time the current node  $m$  reorganized to  $m'$ .

### Hashing

For a continuously increasing value,  $m = \alpha_0, \alpha_1, \alpha_n$ , a hash function  $h(.)$  is applied. This results from a declaration  $\bar{G}$  called Gatherer Hash (GH) to the progression. The process to get  $n$ th hash gatherer  $\bar{G}_n$  is given in eq. (3),

$$\begin{aligned} \bar{G}_0 &= h(\alpha_0), \beta_1 = h(\beta || \alpha_1) \dots \beta_n, \\ &= h(\beta_n - 1 || \alpha_n - 1) \end{aligned} \quad (3)$$

Also, a cryptographic hash function's  $h()$  attribute assures that determining any sequence of numbers other than  $\alpha_0, \alpha_1 \dots \alpha_n$  that yields the current  $GH\beta_n$  is unfeasible.

### C. IPFS

Despite multiple attempts to develop distributed file structures, IPFS has been the initial universal storage structure to achieve high throughput and autonomous delivery on a global scale and on the system level. Peer-to-peer (P2P) networks and blockchain technology allow secure information sharing without a central organization. InterPlanetary File System may replace HTTP (Hyper Text Transfer Protocol). IPFS is a persistent, open-source data storage system. It's used by many to exchange content efficiently. IPFS distributes files throughout the network and uses their cryptographic hashes to identify each item based on its content. IPFS stores file off-chain while referencing blockchain hashes [9]. While IPFS incorporates useful concepts from earlier peer-to-peer systems, its primary contribution is in streamlining, advancing, and integrating tried-and-true methodologies into a single coherent system that is more effective than the sum of its parts [10]. The IPFS constructs an algorithmically authorized data model on top of these, a Merkle Directed Acyclic Graph (DAG) of permanent objects, to aid in effectively disseminating files and file version control. Git13 is a popular system for managing file revisions and distribution. Content addressability, tamper resistance, and

deduplication are all provided by the core IPFS principles [11]. Additionally, the IPFS implements the InterPlanetary Linked Data (IPLD) standards to produce more adaptable, flexible, decentralized data structures that are globally addressable and linkable for many types of data. The Interplanetary Way back is a persistent Web archive that distributes data files into the IPFS network [12]. The CDXJ index is built, and then IPFS is used to disperse the response records' headers and payloads independently. The method has the potential to speed up indexing generally.

### III. RELATED STUDY

To solve the problem of the blockchain's lack of significant data storage, Yang et al. [13] employed Hyperledger as the provenance link that processes the database. Its disadvantages over IPFS data storage include expensive costs, a slow rate of data movement, inadequate privacy, and so on. Additionally, it needs a feedback feature for the customer, preventing retailers from initially accessing the information on product security and other factors. Liao and Xu [14] developed a blockchain monitoring system utilizing intelligent farming and sensor networks to manage tea quality and safety. Using hazard characteristics; they also developed technologies for culinary threat assessment and safety tracing. Xie et al. [15]'s ETH-based traceability of agricultural items used IoT technology to protect data from unauthorized tampering or damage. However, information is saved utilizing blockchain technology at the file storage layer; as a result, network overheads will increase as data volumes do. Bumblauskas et al. [16] integrated IoT and blockchain to track products in real time. Using a Midwestern company's egg supply chain as an example, blockchain technology was implemented from farm to consumer.

A provenance storage solution using blockchain technology would record food progress information in IPFS and analyze such data with the aid of an auxiliary database, claims a study by Hao et al. [17]. Yu and Huang [18] proposed the broiler chicken traceability method by fusing RFID and blockchain technology. The "inverted tooth" design of the chicken claw ring prevents it from being resold. The approach allows intelligent technologies to scan the ring's QR code and access the relevant details and data. Benet [8] advises using the InterPlanetary File System (IPFS) to link all related devices using a single file system. Using a content-addressed strategy, IPFS is a peer-to-peer dispersed file system that provides high-throughput storage space. There are other attempts as well that aim to establish a global file system. The AFS system is installed by Howard et al. [19] and can enhance the capability of cache validation, server process structure, and other things. Additionally, several sizable media file-sharing platforms like Napster, KaZaA, and BitTorrent are developed to hold enormous amounts of data.

### IV. PROPOSED MODELLING

#### A. Non-Perishable (NP) Agro-food Supply Chain Traceability System

Poor server management and maintenance from distributed cloud storage providers or an extremely concentrated variety of cloud providers are the main causes of the present issues

with cloud storage [20]. A backup file's hard disk position might match the original file's hard disk location if the cloud hard drives are centralized, even if both files are kept on the same cloud hard drive. As a result, in the event of a power failure or other issue, the servers malfunction and are unavailable from the outside; the only option is to wait for the servers to recover. Though it is unrestricted, IPFS is a more current Internet technology than the HTTP protocol. It is based on the idea that a file can be divided into numerous bits dispersed throughout the network and obtained from multiple servers consecutively using a P2P network (PPN). If some servers are unavailable, users from outside the network can still connect to the system and access data. Additionally, the network has many backups, even if some nodes' data is completely lost as a result of an error. Data loss, outdated infrastructure, and a lack of user feedback are just a few issues with the conventional centralized public cloud that can be addressed with IPFS's benefits.

High standards for transaction data backup are necessary to ensure the traceability of the supply chains for agricultural products. Since it divides a file into several pieces and disperses them across the network, the IPFS storage system has a more reliable backup capability than cloud storage. The openness of the information kept in IPFS may be ensured by blockchain technology, which is excellent for the supply chain traceability of agricultural products. In this section, we have used the blockchain to track and execute the interactions in the NP agro supply chain products to decrease trust in the central database. We can do this with the help of smart contracts and IPFS transaction records. We can do this by leveraging smart contracts and documenting transactions in IPFS.

#### B. System Model Overview

Numerous parties, including producers, manufacturers, distributors, retailers, logistics, and customers, are involved in the NP agri-food supply chain model. The regulatory framework that governs the traceability system is responsible for distributing both the public and the private keys to each participant.

It is possible to strengthen customers' confidence in the safety of NP agricultural products by providing consumers with complete information on agricultural products via a traceability system. This will allow for increased sales of NP agricultural products. In this article, the relationships between production, manufacture, distribution, retailing, logistics, and sales are disentangled to investigate agricultural goods' transparency. The NP agri-food is planted, transplanted, watered, fertilized, and harvested as part of the production link. Additionally, it requires recording essential data, including details on seedlings, planting techniques, environmental factors, and product transactions. NP commodities are categorized, weighed, packed, priced, and subjected to various operations in the manufacturing unit. It also includes keeping track of data on NP products, production processes, processing parameters, product transactions, and other essential facts. The distribution unit transports the full goods from one place to several others. When handling the delivery of items to the consumer, the shop takes great care. Transportation that is a part of IoT operations is used during production, manufacturing, distribution, and retail operations.

Law enforcement agencies can track down incidents involving how good and safe agricultural products are and identify the principal parties at fault. To certify the integrity and openness of provenance data in farm produce monitoring systems, traceability uses blockchain technology's decentralization, non-tampering, and tracking properties. The production, processing, transportation, and sales of agricultural products may all be monitored with the help of the blockchain-based NP agro products tracking system, which maintains growth data, processing data, logistics details, and sales data. Fig. 1 depicts the structural layout of the blockchain-based monitoring system for NP agro products. The regulator must approve the blockchain traceability scheme, including all parties. The approval follows registration. After registration is complete, the parties involved can transfer individual and NP product traceability data. If you want to check if the data on your chain of custody has been tampered with, you can use the provided a comparison tool to check for validity. Data analysis, a consensus mechanism, key management, smart contracts based on a user's reputation, and key authorization is all part of the system. The most fundamental applications of smart contracts are adding data to blockchains and the subsequent querying of that data. When a request is made, the smart contract immediately begins carrying it out. Businesses may input data in various links, customers can query traceability data, and regulators can keep tabs on it all through the system's platform, which is designed to accommodate a wide range of users. We store the data to IPFS in order to prevent blockchain data explosion. The IPFS hash value is kept in the blockchain once consensus has been reached.

### C. IPFS Encrypted Storage

The blockchain traceability system's current storage option entails immediately writing the traceability data of each system of agricultural goods onto the blockchain. The burden on blockchain's storage grows as there are more nodes, resulting in more transaction data being collected [21]. Due to

the blockchain's unique chain-type topology, users of a single blockchain community can view all the information on the blockchain even when query efficiency is extremely low. To address these issues, this article developed a solution integrating encrypted private data storage and hash storage for public data to enhance the storage style of a blockchain monitoring system for NP agro products. Traceability data for products is just one part of the supply chain's comprehensive dataset, including sensitive information authorized parties may only access. Data confidentiality is a significant concern for rival businesses. Public information may be about the producer, manufacturers, retailers, logistics and their reputation, product details, date of manufacture, price, and provenance. In this work, Algorithm 1 depicts the data entry to the blockchain in protecting traceable information, in which sensitive data is encrypted using a smart contract and then stored on the blockchain alongside the corresponding hash value of public data.

---

#### Algorithm 1: Double Encryption

---

```

Initialize Stakeholders ID, Public_data, Sensitive_info, Keys.
Stakeholders ID → SID
If
    Sensitive_info! = Null then do
        Generate a Random key (KA)
        Sensitive_info → Encry (GCM (Sensitive_info, KA))
        Encry_key → Encry (Key_Encryption_Method
        (KA, PuK))
        (Sensitive_info + Public_data) → IPFS
        Hash (Sensitive_info) + Hash (Public_data) → BC
    End If
If
    Sensitive_info == Null then
        Hash (Public_data) → BC
    End If
End
Result: The hash value stored in the blockchain.
    
```

---

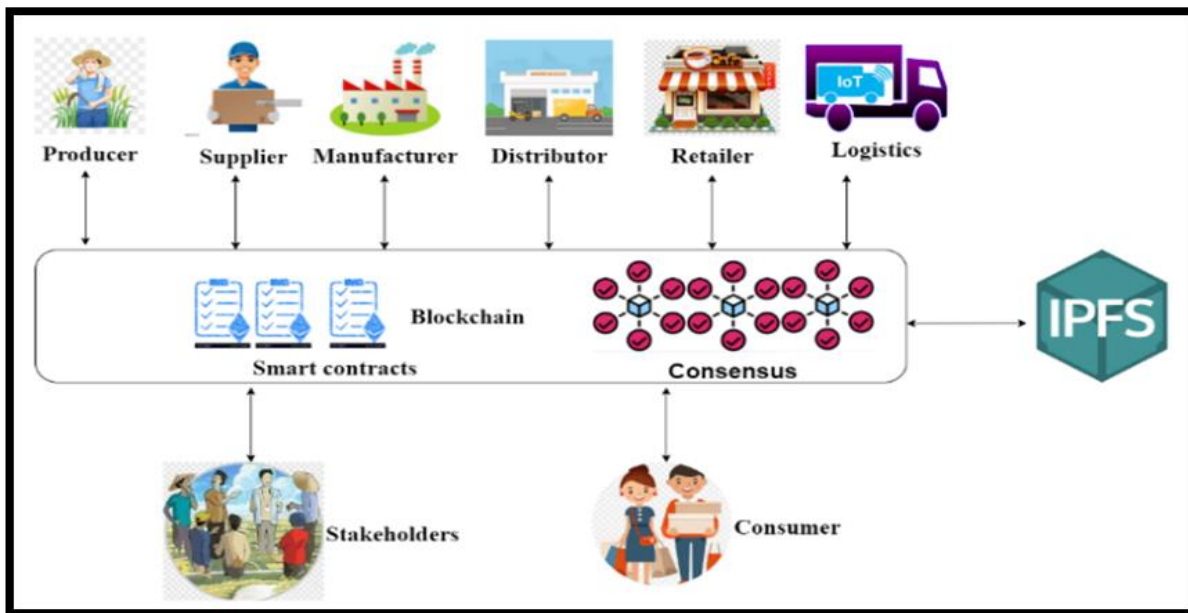

Fig. 1. Blockchain-oriented traceability mode.

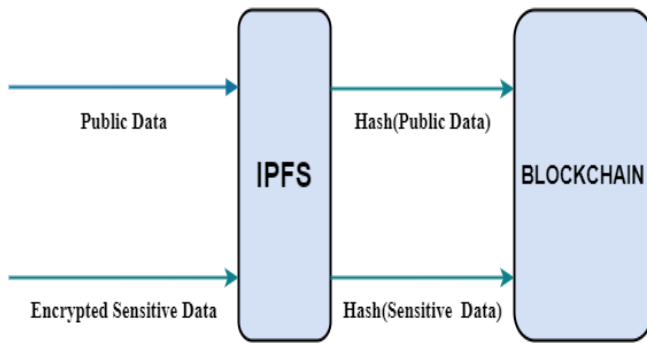

Fig. 2. Storage of public and sensitive data.

The AES encryption technique uses the Galois/Counter Mode (GCM) to encode sensitive data, 'Sensitive\_Info'. The necessary Key, 'K<sub>A</sub>' is chosen at random by a random generator using the smart contract, which also creates as well as uploads encoded substitution cipher to the network. The Key is encrypted using the Key Encryption Method (ECC) to guarantee its security. The viewing node was approved by the encrypted Public Key, 'Pu<sub>K</sub>'. Sensitive data as well as open data are transferred to IPFS. A pair of keys made up of the Encrypted Key and the Public Key of the Trusted Observing Nodes are kept in the current picture of the smart contract and sent to the ledger as IPFS hashes as shown in Fig. 2. The existing node's private key, 'Pi<sub>K</sub>' is used to decipher the blockchain's encoded key in order to acquire the original Key, which is then used to decipher the sensitive data and sight it when the appropriate nodes access the private data.

## V. RESULTS AND DISCUSSIONS

Ethereum is a blockchain open-source platform that is used for simulations. We create and test smart contracts using the Remix Integrated Development Environment (IDE), Ganache, Truffle, and Metamask. The smart contracts are used and tested on the Ethereum Ropsten test networks. The script was created using the Remix IDE and Solidity version 0.8.7. The system requirements include an x64-based processor, Win10 Pro, a 64-bit operating system, an Intel(R) Xeon(R) CPU E5-2630 v4 @ 2.20GHz, and IPFS version 0.8.0. Ganache does nevertheless distribute a certain amount of cryptocurrency to virtual accounts. After each transaction, the cryptocurrency is removed from the contract's designated account. In Ganache, every account has a unique address and private key. The truffle is the framework. Through the Metamask, a bridged browser plugin, Ganache, and the Remix IDE may communicate with one another.

Through IPFS, the file is uploaded to the blockchain. It displays a ledger with a number of records. The key that represents each transaction is used to identify each record. The record is a file's many hashes. Each entry starts with a key, then a record that includes the multi-hash value of the file, the ID of the network node reading the file, and the time stamp. Due to the network's addition of IPFS hash addresses, access to files on blockchains using IPFS is constrained. This restricts access to the IPFS system and its associated hash addresses to legitimate users only. This lowers the number of handlers who have admittance to the files. Also, lessen illegal admittance to

the file as well. Since user activity is not recorded on the IPFS network, users are free to view any files without fear of repercussions. This experiment places a barrier on unwanted access due to the immutable logging of user file access.

### A. Consensus

The consensus mechanism assures blockchain nodes have the latest blocks. Popular ones include Proof of work, Proof of stake, Delegated Proof of Stake, and Practical Byzantine Fault Tolerance [22]. By facilitating competition between dispersed nodes in terms of computational power, POW increases data consistency and integrity, which is helpful in fending off Sybil attacks. The researchers created a POS approach that doesn't require processing resources and a DPOS mechanism to reduce power consumption. PBFT can reach a consensus with a few malicious nodes. Signatures, verification, and hashing prevent tampering, counterfeiting, and message repudiation and made BFT polynomial. PBFT's high consensus cost renders it unsuitable for public chains. Fewer-node consortiums or private chains operate better. The consortium chain is the core network, while PBFT is the consensus method.

### B. Performance and Evaluation

Here, we measure how long it takes to verify a transaction by evaluating all the transaction data from the moment the validator first receives it until the transaction is authenticated. On the Ethereum Ropsten testbed, we assess the latency and throughput of our implementation. The approximate transaction validation time is given for all transaction types, including stakeholders.

Key extraction in ECC encryption is as simple as producing a random integer between two specified values. Any positive integer within the range is valid as an ECC secret key. It is possible to minimize the time spent waiting by taking two different approaches when computing keys throughout decryption and encryption. ECC provides less delay than the alternative by processing keys in two stages. Since the ECC key is shorter, it consumes less computing capacity while still providing secure protocols for authorized mutual authentication.

Some of these are reasonable despite the large additional operations required, such as validating signatures and hash data to and from IPFS, confirming permissions in the control list, and performing several other overheads. Transactions take the longest to complete since the qualifications of both the buyer and the vendor must be confirmed. The effectiveness of the blockchain network is examined in this section regarding various transaction rates. As a result, testing involved using transaction counts of 50, 100, 150, 200, 250, and 300 per second. By changing the number of transactions occurring, the impact of having numerous transactions active in a blockchain was examined.

Standard operations and query transactions were both put to the test in every situation. The number of total transactions has been adjusted to facilitate the development of a more comprehensive understanding of how the amount of all transactions influences the throughput and latency of the blockchain. Each transaction on the blockchain has its

throughput and latency recorded and logged for future reference. This information is stored in a distributed ledger. Fig. 3 and 4 presents the calculations' results on the specifics of the delay and throughput measurements.

Fig. 3. Transaction throughput of the traceability system.

TABLE II. AVERAGE LATENCY AND THROUGHPUT OF THE TRACEABILITY SYSTEM

	Ethereum (Ropsten)
Average Latency	3927.32 MS
Average Throughput	52.21 TPS

Fig. 4. Transaction latency of the traceability system.

Average delay and average throughput are determined from test results on the Ropsten test networks and are shown in Table II. Calculations are done for various transactions, including registration, the record of trace data, approvals, querying of recalls, etc.

### C. IPFS Read Write Latency

While reading files over the network, IPFS reads them more quickly than it writes or adds them. A 0.256 MB file is typically received in around three seconds and written to a remote IPFS gateway in about five seconds. Because it caches the data locally after the initial transmission, IPFS is substantially faster when requesting the same file a second time. We also tested the performance of IPFS on its own to compare the outcomes of the combined systems. Files were

sent between local workstations, and the server latency fluctuated. The impact of delays is more significant on smaller files than on bigger ones. The following is a performance analysis of scaling-out IPFS-attached storage. Table III displays their reading and writing results for different file sizes and latency.

TABLE III. IPFS READ WRITE LATENCY

Read Latency	5MS	10MS	20MS	25MS
25MB	0.395	0.511	0.755	0.841
100MB	1.453	1.505	1.93	1.82
1GB	13.26	13.24	14.14	15.11
Write Latency	5MS	10MS	20MS	25MS
25MB	0.443	0.474	0.741	0.891
100MB	1.597	1.694	1.893	1.99
1GB	14.10	14.73	15.32	15.89

### D. Comparisons

Our system has the following benefits: a better standard of decentralization; better network resilience; more integrity in data communication; and high reliability in data processing, according to the assessment of findings. The time-suggested technique enables more transactions to be added to the chain at the same rate, serving more users and enhancing overall scalability. We are evaluating our solution in comparison to several traceability systems.

TABLE IV. COMPARATIVE RESULTS

Features	Conventional Traceability	Blockchain Traceability
Traceability	Yes	High
Supervision	Medium	High
Credibility	Less	High
Storage Mode	Medium	Medium
Data sharing Scope	Medium	High
Scalability	Less	Medium
Query Rate	High	Medium

Table IV contains comparable outcomes. The performance of the decentralized and blockchain-based traceability systems is lower than that of the proposed method. All designs can track data. The proposed system cannot be altered in any way, making it superior to centralized systems and other approaches. Our method is decentralized, scalable, and protects users' privacy at the same time. This method reduces the amount of data generated compared to conventional blockchain technology.

## VI. CONCLUSIONS

In this study, we developed and assessed a system for tracking agricultural products using blockchain's tracing and anti-tampering features. We also examined the system's architecture for querying and storage. The problems of the blockchain traceability system's enormous data overload

constraint and the lack of private security is addressed, and a suggestion for on-chain and off-chain file storage is made. The public data consumers see in the supply chain is stored in the IPFS, whose hash value is uploaded to the ledger system. For discussing with related firms, the blockchain maintains private data that has been encrypted using an encryption method. The storage approach described in this model integrates the existing scenario, considering the necessity for public scrutiny of supply chain public data and the requirement that private corporate information is encrypted, and minimizes the data burden on the chain. After the consumer scans the Tracking number for public database information, the system validates the information using the relevant block to verify if the product information has been updated. Blockchain technology is expected to develop in the direction of numerous test beds, platforms, and sharding. We will continue looking into the technology tying together diverse platforms and a cutting-edge consensus mechanism suitable for traceability in future studies.

#### ACKNOWLEDGMENT

The authors would like to express their gratitude to everyone who helped them write this article and provided data for this research.

**Abstract**—Disaster management system is developed to monitor flood, tsunami and earthquake, which is effectively preparing for and responding to the disaster. In fact, Malaysia is building the emergency response system for managing the flood disaster since it is highly occurred. However, the current flood emergency response system has limitations, which, has no integration that data entered into spreadsheets and transferred to different storages, and, data analytics that assist in data collection and decision-making. Even though flood emergency response system have been improved, which introducing sirens and loudspeakers to reach flood victims but still difficult to access the basic facilities and receive flood responses. Therefore, this study implements a flood emergency response system with face analytics to assist data acquisition, which analyze flood victim's faces using CCTV infrastructure with HOG algorithm that incorporated with a dashboard. The dashboard categorizes the number of flood occurrence, maximum flood period (days), the number of displaced flood victims and loss assessment. Findings have shown that the dashboard helps the enforcement agencies to implement the real-time information about flood victims. Based on the number flood frequency occurrence in Malaysia from 2017 to 2021, the percentage produced was 27%, 19%, 12%, 19% and 23%. Moreover, the duration of floods has been decreased from 30% to 17% in 5 years that shows the flood emergency response helps the Malaysia government to improve the infrastructure. The significant of this study beneficial to the local enforcement unit and evacuation centers in identifying the flood victims.

**Keywords**—Disaster management system; flood emergency response system; flood emergency response system with face analytics; flood emergency response system with face analytics using HOG algorithm; flood emergency response system dashboard

## I. INTRODUCTION

Malaysia is located in Southeast Asia, bordering Thailand, Brunei and Indonesia, which geographically is located outside the ring of fire and south of major hurricanes. However, Malaysia is often affected by other natural disasters such as floods, landslides, haze, earthquakes, droughts, tsunamis and other man-made disasters. Floods cause the most frequent and severe damage every year, causing loss of life, disease, property, and other damages [1]. In Malaysia, flooding has become a major disaster problem. From July 2012 to January 2019, Malaysia's population was the most highly affected by floods among ASEAN members [2].

As a result, in 2015, the National Disaster Management Authority (NADMA), under the Prime Minister's Office, became the premier disaster management agency for disaster management efforts in the national and international level. The organizational structure of disaster management continues at three levels: federal, state, and county [3].

NADMA provides Flood Early Warning Systems (FEWS) that divided into five classifications as pre-internet, internet of content, internet of services, internet of people and IoT (internet of things) that warn the public about disaster risks going to happen [4], [5]. Due to the unpredictable estimation of flood occurrence, several methods have been proposed to enhance the FEWS.

The first solution is to create a monitoring tool that observes the occurrence of floods and warns victims before trap in the flood area. The importance of this tool is to reduce the number of flood victims in the flood areas, enable rapid evacuation of victims, and prevent loss of life and save more flood victims from flood injuries [6].

The second solution proposes a new dashboard to provide latest information about flood victims, which comes from face images of flood victims that been capture from CCTV. The propose system called as flood emergency response system with face analytics will verify the captured face image from CCTV with the stored face image using HOG algorithm. The face analytics acts as a back end engine for the proposed system.

The rest of the paper is organized as follows: Section II describes the literature review of flood and its causes. Section III explains on methodology used to design the propose system. Section IV explains about the architecture and techniques. Section V explains about the results and discussion. Section VI summaries the implementation of the flood emergency response system with face analytics for better performance in identifying flood victims.

## II. LITERATURE REVIEW OF FLOOD

Flood is a dynamic phenomenon with wide geographical and temporal variation. Furthermore, changes in the flood system, such as levee breaches or the adoption of emergency measures, might alter flow patterns and cause unexpected deviations from pre-planned contingencies. Even though floods

\*Corresponding Author.

may affect human activities and assets in a number of ways, disaster management must be aware of which regions are flooded when and how intensely. In contrast, flood impact assessment is mainly concerned with the greatest flooding extent and maximum inundation depths that occurred during the storm [7].

In Malaysia, flooding is categorized into three types, which are river floods, pluvial floods, and coastal floods.

Fig. 1 depicts a river flood, also known as a fluvial flood, which occurs when the water level in a river, lake, or stream rises and overflows onto the banks, beaches, and neighboring land. Significant rain or snowmelt may have caused the rise in water levels.

Fig. 2 shows a pluvial flood occurs when a heavy rainfall event generates a flood that is not produced by an overflowing water body. A common misconception about floods is that you must be near a body of water to be impacted. Nonetheless, pluvial flooding may occur everywhere, urban or rural, and even in areas where there are no adjacent bodies of water. There are two forms of tributary flooding:

- When an urban drainage system gets overflowing, water rushes onto streets and surrounding structures, resulting in surface water flooding. It happens gradually, giving people time to flee to secure locations, and the water level is usually shallow (rarely more than 1 meter deep). It does not endanger people's lives immediately, but it has the potential to cause significant economic harm.
- Flash floods are categorized as a violent, high-velocity torrent of water generated by heavy rain falling in the region or on surrounding higher terrain in a short period of time. A fast release of water from an upstream levee or dam creates a dangerous and catastrophic situation. This is because of the force of the water produce the hurling debris.

Fig. 3 explains about coastal flooding or named as storm surge, which is the inundation of land near the coast by seawater. Windstorms that coincide with high tide (storm surge) and tsunamis are common causes of coastal flooding. Storm surge occurs when high winds from a windstorm cause water to wash ashore; it is the most prevalent cause of coastal flooding and, in certain cases, the deadliest threat associated with a windstorm. Windstorms during high tide cause damaging storm surge floods; windstorms during low tide cause disastrous storm surge floods. In this type of flood, water overwhelms low-lying regions, resulting in significant loss of life and property. Other factors that influence the strength of a coastal flood include the windstorm's power, magnitude, speed, and direction. Furthermore, the onshore and offshore geographies are another critical factor of coastal flood that bring severe damages. Coastal flood models employ this information, as well as data from previous storms in the region, to determine the likelihood and severity of a storm surge.

Fig. 1. River floods (fluvial floods).

Fig. 2. Pluvial floods (flash floods and surface water).

Fig. 3. Coastal flood (storm surge).

#### A. Causes of Flood in Malaysia

Regardless of the type of flood exist; it is always brought on by the same basic event and the effect typically harmful. Meanwhile different types of floods have different causes, most floods are caused by one of the following events [8] [9]:

1) *Heavy rain*: This is the most common source of floods. When there is too much rain or it falls too rapidly, it literally does not have anywhere to go. This can result in floods, including flash flooding.

2) *River flooding*: River flooding is not necessarily caused by heavy rain. As previously said, river flooding can occur when there is debris in the river or dams that restrict the flow of water.

3) *Broken dams*: Older infrastructure may fail when heavy rains fall and water levels increase. When dams collapse, torrential rains fall on unsuspecting populations.

4) *Storm waves and tsunamis*: Hurricanes and other tropical storms may cause sea levels to rise and bury normally dry coastal areas in many feet of water. Tsunamis, on the other hand, are gigantic waves caused by earthquakes or volcanic eruptions beneath the sea. As these waves approach inland, they acquire height and have the potential to drive a huge volume of water inland in coastal areas.

5) *Channel with cliffs*: When there is fast runoff into lakes, rivers, and other basins, flooding is prevalent. This is frequent in rivers and other bodies of water with steep banks.

6) *Lack of vegetation*: Vegetation can help to slow down runoff and prevent flooding. When there is a lack of vegetation, there is little to prevent water from rushing back and flooding rivers, lakes, and streams.

7) *Moon "Wobble"*: The moon wobble is caused by fluctuations in the moon's elliptical orbit and the related gravitational pull on Earth.

### III. FLOOD MANAGEMENT SYSTEM

Flood management system (FMS) has been used across the world to accomplish the goals of the Framework for Disaster Risk Reduction and the Sustainable Development Goals, which the Disaster Risk Reduction (DRR) strongly recommends. The four fundamental aspects of a comprehensive FMS are risk information, monitoring and forecasting, warning, dissemination, and communication, and reaction capabilities. The complexity of operational FMS varies based on the data given, the technology employed, and the know-how [1].

There are substantial differences in maturity between FMS in developed nations that have the financial resources, technological infrastructure, and human resources, and those in poor countries who have less sophisticated FMS. Fortunately, advances in remote sensing, artificial intelligence (AI), information technology, and social media are creating substantial changes in FMS processes, allowing all FMS to obtain enhanced capabilities. These technologies enable underdeveloped nations to overcome the technological hurdles that FMS have previously encountered. The difficulties that FMS confront, as well as technological improvements and their consequences for flood forecasting and disaster response is explored [4].

Flood risk can be assessed by reviewing the historical record of flooding in a certain location, monitoring the people and property damaged by the flood, and use predictive modelling, expertise, or a combination of the above [16]. It is

also necessary to understand the possibility and repercussions of floods. The availability of extended hydrological data series frequently limits the utility of previous flood data. Understanding risks necessitates costly maps and research, which must be updated as dynamic cities expand. Collecting geographical data sets such as topography, land use, soil, and exposure is the first step in predictive modelling. We also require competent individuals to simulate and evaluate the outcomes. As a result, of these challenges, risk awareness is lacking in the majority of FMS covered locations.

To effectively estimate the development of flood water levels, FMS operators must have a thorough understanding of the present and historical values of important hydraulic parameters in the watershed upstream of the area of interest, as well as their likely future evolution. Water levels, discharges, snowfall, precipitation, and temperatures are all often observed factors. The present and historical values of these parameters are available via a monitoring system, which is typically comprised of a network of ground stations supplemented by occasional field surveys. Ground stations typically measure variables of interest at a single location, providing FMS operators with only limited information on the state of the watershed, especially if the monitoring network has insufficient geographic coverage. Approximately 75% of the flood forecasters polled stated that their river basins lack sufficient gauging stations for rainfall, water level, and streamflow information. Fifty percent of the FCCs who answered disclosed that their measurement equipment, gauges, and data transmission devices are outdated. Another challenge is data transfer from stations to forecasting centers, as a considerable proportion of stations in the developing world rely on human observers, hindering the accuracy and timely transmission of data. As a result, most poor nations struggle to capture the amount, distribution, and change of essential variables like precipitation and streamflow during extremes. Weather radars and remotely sensed rainfall have the potential to improve watershed monitoring by providing geographical, real-time, or near real-time data. However, the data they supply is of lesser quality than observed data, and these approaches are too young to have long enough time series to develop credible hydrological models [17].

The acquired hydrological data should ideally be kept in a database and analyzed in real-time using hydraulic models. Not all nations have a centralized, continually updated database. Data is sometimes stored in spreadsheets for quality assurance before being transferred to a central database a few days or months later. One of the most significant issues confronting operational systems is a shortage of technical competence and human resources. CTFs should have people with considerable flood forecasting training and a large enough forecasting team to successfully deliver timely warnings 74% of flood forecasters, however, admit that their centers lack expertise and personnel capable of integrating data, formulating predictions, and distributing information. This might be owing to a lack of expert specialists in job areas, as well as an increase in the demand for disaster recovery and rescue operations after large floods. The shortage of committed permanent personnel in underdeveloped nations is a key impediment to the efficient operation of FMS. Overall, study results suggest that

forecasters have mostly technical expertise but lack understanding of flood vulnerability assessment, warning communication, and downstream resilience, including evacuation preparations [18].

The rapid change of meteorological variables, particularly precipitation, is a critical input for flood forecasting. Meteorologists employ complex computer models to forecast the weather, in addition to ground and satellite data of the land and atmosphere. Numerical weather predictions (NWP) use current weather measurements and combine them using computer models to estimate the weather's future condition. Understanding the present status of the land, ocean, and atmosphere, which effects modelling initialization at local, regional, and global scales, is a significant problem for quantitative precipitation forecasting. In addition, forecasters in industrialized nations have access to fine resolution modelling using ensemble projections to reflect variability and uncertainty in forecasts. Nationally operated meteorological stations in industrialized nations give worldwide predictions from global NWP systems available in underdeveloped countries, such as the Global Forecasting System. This output, however, has a relatively limited spatial resolution. National authorities should scale these forecasts down to greater geographic resolutions [5].

Some nations, however, are unable to make high-resolution predictions due to a lack of critical skills and resources. Even if the prediction is lowered, residual inaccuracies and a fundamental lack of weather forecasting capabilities may result in the failure to detect approaching severe floods or false positives. Even the weather prediction is intelligent. The quality of the data assimilation technique used to derive the beginning conditions of the hydraulic model influences those forecasts. It is also influenced by the hydraulic model configurations described in the model structure, physical process simplification, and calibration quality, as illustrated in Fig. 4, which shows the impact on the performance of the flood forecasting model. Almost half of study that claim the model utilized to produce early warnings is insufficiently accurate or sophisticated for this purpose. As a result, anticipated hit rates varied among model systems and river basins in various climatic zones [19].

Therefore, the new flood management system contains the cutting-edge technology that can easily discover victims as shown in Fig. 4. Moreover, the method of biometric authenticates the specific victim in order to confirm that victim identity. As a logical consequence, physical papers are increasingly becoming obsolete and being replaced with biometric identification. It may also be claimed that current technology has advanced significantly such as allowing consumers to unlock mobile devices using fingerprints or transfer money using voice commands. In order to develop a victim's identification, a biometric analyze unique biological and physiological traits is used. Fingerprints, face, voice, iris, and palm or finger vein patterns are the most frequent biometric identifiers. Banks, for example, require the biometric data in order to perform their numerous services remotely. People have to go to a branch to create an account or make a loan, but now user access numerous services using the newest technology such as a phone, i-watch, laptop, and so forth.

Fig. 4. Potential of new technologies for flood management system [15].

Fig. 5 states about the physical biometrics, in contrast to behavioral biometrics, which relies on measures of the human body for identification or verification. Face geometry, fingerprints, certain areas of the eye, vein patterns, and other physical characteristics are examples of this. It is simply said that physical biometrics substitutes "things you know" (passwords and PINs) with "things you are". This sort of biometrics employs a hybrid approach of analysis that combines human experience with the power of artificial intelligence to provide findings with a high degree of accuracy. The most prevalent approach for authentic user identification nowadays is static physical biometrics. They are utilized by the vast majority of firms (almost 80% globally) that collect and retain physical biometric data to validate identities for a variety of purposes [10]. Thus, the physical biometric is suitable for flood victim identification.

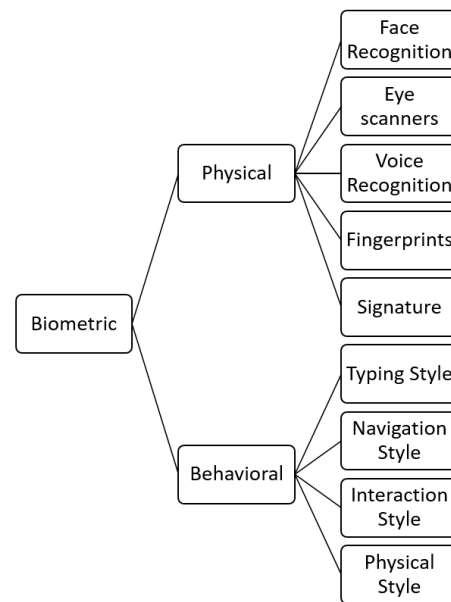

Fig. 5. Types of biometric template.

#### IV. FLOOD EMERGENCY RESPONSE SYSTEM WITH FACE ANALYTICS DASHBOARD (FERSFAD)

The design used for FERSFAD is similar to the laboratory attendance dashboard website based on face recognition system [11] and the technique used for the FERFAD is HOG. CCTV is an idea to overcome problem in contactless criteria that help for a long distance detection [11] [12].

The design of Flood Emergency Response System (FERS), is divided into two parts: facial analytics which is one of the physical biometric and the dashboard that using Power BI. In the facial analytics contains the face analytics components, which are the back end as well as front end of the system of the flood emergency response system dashboard (FERSFAD). The FERSFAD system uses a CCTV camera to send video footage to the computer server that acts as a database for storing image records and calculating face templates using HOG algorithms.

Facial biometrics remains the favored biometric standard due to its ease of deployment and implementation for long distance coverage. In fact, there is no direct contact with the end user and reduces the number of touchpoints on the surface. Furthermore, the face detection and face matching processes is vital for rapid verification or identification, which aids in the search for missing individuals.

In the FERSFAD system, the dashboard creation provides standard requirements of development. Moreover, a huge amount of data from other centers is utilized to give accurate information about the flood. In addition, a quick reference of information about the flood easy to be share among the society and prevent from fake flood information. The propose dashboard has the potential to improve society by boosting safety and security, preventing crimes, and decreasing victim contact.

Therefore, the process starts with capturing the image of the flood victim at the evacuation center. The image of the flood victim is captured using CCTV that has been located at the area of evacuation places [12]. CCTV assists in the data collection phase either the data collection is done during day or night. In the server, the HOG algorithm calculates frames of facial images of the flood victims.

In the enrolment phase, the HOG algorithm involves several steps, which start with Step 1 that is image preparation and color normalization. In the Step 1, the original image is resized to be [8 x 16] metrics and [128 x 64] metrics and the color normalization process transform the resized metrics to be greyscale format. In Step 2, the resized and normalized image metrics are calculated using magnitude and angle of gradients in order to make the image appear closer, which called as face structure. Furthermore, Step 3 implements binning of face structure with gradient calculation using spatial formula that is vital for the matching process. The binning process transforms block normalization into a single-cell normalization that is done in the Step 4. Step 5 involves the HOG feature vector and Scale Invariant and Feature Transform (SIFT) algorithm to search the similar features and save into a database [20].

The HOG algorithm has several methods of detection and matching phase for flood victim faces. The matching technique

involves SIFT process that find the similar features in victims' face captured.

Formula for HOG is magnitude ( $\mu$ ) =  $\sqrt{[(Gx)_2 + (Gy)_2]}$  and angle( $^\circ$ ) =  $\tan^{-1} (Gy / Gx)$ . Benefits of using HOG algorithm in the FERSFAD system is using the SIFT to extract local features, whereas HOG is used to extract global features [13].

To implement the FERSFAD system, the flowchart is designed in estimating overview of the whole process. Fig. 6 illustrates about the flowchart. In the flowchart, it begins with image stored in system database. The image stored in the database is collected from the CCTV that has been collected earlier. The data comes from various units such as evacuation center (indoor) and (outdoor). The CCTV camera detects the victim's face and compare with victim's face image in the database. Once the victim's face match, it proceeds to the recognition process. If the victim's face not matches with the image in the database, person-in-charge of the system needs to add victim's details in system database to update the database. The dashboard displays the detail information about the flood victims.

The programming languages used for the FERSFAD system is Pycharm, which is a Python-specific Integrated Development Environment (IDE) that provides a wide range of necessary tools for Python developers [12]. These tools are tightly integrated to offer a pleasant environment for productive Python, web, and data science development at the back-end of the system. The dashboard connects with phpMyAdmin because it is a web-based utility for managing the MySQL database [12],[13]. Moreover, phpMyAdmin provides an easy-to-use graphical interface for running SQL commands and performing SQL operations. Therefore, at the front-end of the system, the Power BI platform is used to visualize the dashboard for representing the information of the flood victims.

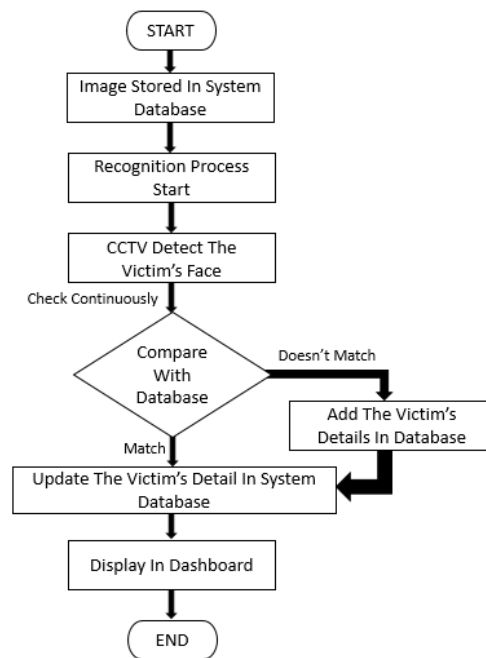

Fig. 6. Flowchart of flood emergency response system with face analytics.

The dashboard website is used to provide analytical data such as the number of people in the shelter, video footage of facial recognition results, and the identities of the people in the evacuation center. This analytical data is used to identify the victims' faces. The dashboard is developed to visualize data [21],[22] for easy to be understand, producing interesting and colorful diagram to distinctive the flood occurrence, maximum flood duration, number of affected flood victims and estimated loss [14].

### V. RESULTS AND DISCUSSION

Based on findings of the FERSFAD system, most researchers and users used for verify or identify the flood victim using their face. The CCTV camera help to capture, analyze and compares pattern based on the victim's facial details [11]. Other than that, the CCTV detects the victim faces to process with other step in detecting and localizes the victims face in images [11], [12]. The process of the capture the victim's face transforms analog into a set of digital information such as database on the victim's facial features. If the victims face match, it verifies the similar faces that belong to the same person. When compare with other biometric technologies such as RFID card, fingerprint scanner and iris templates, the face recognition gives faster detection to verify the flood victim face over an overall victim at the evacuation center [10]. Fig. 7 illustrates the architecture of the FERSFAD system.

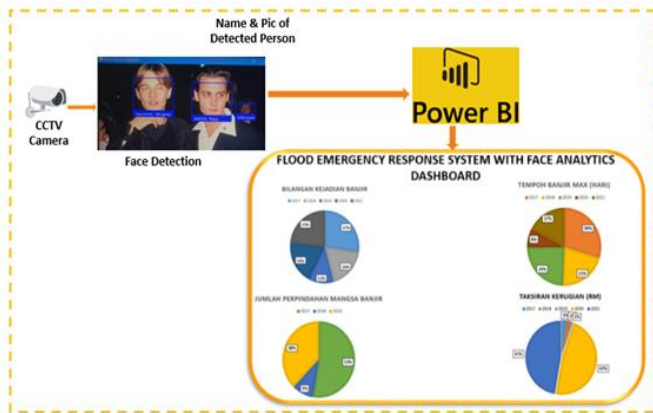

Fig. 7. Flood emergency response system with face analytics architecture.

For instance, there are 230 victims at the evacuation center. Face recognition detects a victim's face using face recognition takes roughly about a second (0.8 second) that is faster compared to fingerprint recognition and took more than two seconds in time (2.3 second). Nonetheless, recognition using an RFID card or fingerprint scanner would take longer time to identify each victim.

The HOG algorithm is included into the system because color data is less important in matching phase for subsequent processing, since the enrolment phase begins by converting the flood victim face image to monochrome in order to detect the victim's face. It evaluates each pixel individually and looks for pixels that are directly connected to (around) the selected pixel. It captures how dark the selected pixel is in comparison to pixels immediately around it. An arrow denotes the magnitude in which the image is darker. The image receives an arrow in

every pixel by repeating this technique for every pixel in the image. These arrows are known as gradients, and they indicate the transition of light to dark throughout the whole image [11-20].

Fig. 8. Dashboard of flood emergency response system with face analytics.

Fig. 8 shows the pie charts in the flood emergency response with face analytics. The pie charts are divided into four parts which are the number of flood occurrence, maximum flood period (Days), the number of displaced flood victims and loss assessment for five years starting from 2017, 2018, 2019, 2020 and 2021. The upper left most section in the pie chart describes about the amount of flood occurrence, which in the highest percentage of the flood occurrence occurred in 2017. Meanwhile, the lowest percentage of the flood occurrence happened in 2019. Thus, in 2017 many flood victims have been affected by the flood disaster.

The upper right most section of the pie charts shows the flood duration in days. To compare data in 2017 and 2019, there are 6% of different between of these two years. The minimum of the flood period (days) in 2020 is with 8%. However, the information about the flood duration has shown a decrement of percentage value due to improving the infrastructure done by the community such as higher dam, enlarging the water channel and making a concrete at the river banks.

The lower left most chart compares for three years of number of affected flood victims which in 2017, 2018 and 2019. In 2017 is the highest percentage of number of affected flood victims, which is 53%. In the second stage in 2019, gives 38 % and the lowest percentage is 9% that is in 2018. The highest number of affected flood victims happened due to no preparation for dealing with flood disaster that the flood victims not aware about the flood disaster.

The lower right most side of the pie charts explains about the estimated loss. Based on the estimated loss information, it is stated that in 2020 and 2021, the amount of loss is 42% and this value is the highest percentage among other values. Even though the duration of floods has been reduced, however, the affected area of flood consists of huge locations in Malaysia since monsoon season, moon's elliptical orbit and the related gravitational pull on Earth. Therefore, many flood victims have been affected tremendously by the flood disaster.

## VI. CONCLUSION

As a conclusion, a flood emergency response system with face analytics has been implemented for flood disaster management system in Malaysia. The flood emergency response system with face analytics has aided evacuation centers in identifying flood victims, strategies to improve the infrastructure and for budget planning. The dashboard displays the actual result of flood victims that gathered from various evacuation centers in Malaysia. The benefit of employing a flood emergency response system with face analytics can aid in data analytics and provides real-time information. Furthermore, the dashboard enables the community to monitor the current situation of flood using their gadgets, phone, tablet, laptop, and other devices. The significant of the dashboard assist victims, police, fire department, and NADMA in preparation for facing the flood disaster. In fact, the flood prediction is estimated and planned to be further investigated in the future.

## ACKNOWLEDGMENT

Thank you to Fakulti Teknologi Maklumat dan Komunikasi, Universiti Teknikal Malaysia Melaka. Authors show appreciation for the funding of this short term grant: PJP/2020/FTMK/PP/S01800 – A Rapid Flood Emergency Response for Prediction Based on Crowd Source Data.

**Abstract**—Rapid advancements in deep learning-based technologies have developed several synthetic video and audio generation methods producing incredibly hyper-realistic deepfakes. These deepfakes can be employed to impersonate the identity of a source person in videos by swapping the source's face with the target one. Deepfakes can also be used to clone the voice of a target person utilizing audio samples. Such deepfakes may pose a threat to societies if they are utilized maliciously. Consequently, distinguishing either one or both deepfake visual video frames and cloned voices from genuine ones has become an urgent issue. This work presents a novel smart deepfake video detection system. The video frames and audio are extracted from given videos. Two feature extraction methods are proposed, one for each modality; visual video frames, and audio. The first method is an upgraded XceptionNet model, which is utilized for extracting spatial features from video frames. It produces feature representation for visual video frames. The second one is a modified InceptionResNetV2 model based on the Constant-Q Transform (CQT) method. It is employed to extract deep time-frequency features from the audio modality. It produces feature representation for the audio. The corresponding extracted features of both modalities are fused at a mid-layer to produce a bimodal information-based feature representation for the whole video. These three representation levels are independently fed into the Gated Recurrent Unit (GRU) based attention mechanism helping to learn and extract deep and important temporal information per level. Then, the system checks whether the forgery is only applied to video frames, audio, or both, and produces the final decision about video authenticity. The newly suggested method has been evaluated on the FakeAVCeleb multimodal videos dataset. The experimental results analysis assures the superiority of the new method over the current-state-of-the-art methods.

**Keywords**—Deepfake; deepfake detection; bimodal; XceptionNet; InceptionResNetV2; constant-Q transform; CQT; Gated Recurrent Unit; GRU; video authenticity; deep learning; multimodal

## I. INTRODUCTION

The rapid development of artificial intelligence techniques: autoencoders, Generative Adversarial Networks (GANs), and variational autoencoders facilitated the generation of hyper-realistic fake videos, images, and audio. A deepfake indicates a synthetic image or video AI-generated by swapping an individual's face with another. Applications such as ZAO [1], and DeepFaceLab [2] enable individuals to rapidly generate forged images and videos easily. Recently, a human's voice can be cloned using advanced AI techniques. AI-based audio manipulation is a category of deepfake that clones a human's voice and shows that human saying things that he never said.

Overdub, iSpeech, and VoiceApp are instances of voice cloning open-access platforms that can generate synthesized deepfake sounds that nearly resemble the target human's speech [3]. The work of [4] is an example of these manipulation methods, which involves the creation of highly realistic deepfake videos with a precise lip-sync using a group of AI technologies; FaceSwap, FaceSwap GAN, DeepFaceLab, SV2TTS [5], and Wav2Lip [6].

The majority of deepfake videos are created by cloning sounds, synchronizing lips, and frame-by-frame synthesizing faces. Nevertheless, they lack natural emotions, pauses, and breathing behaviour. Additionally, they suffer from discontinuity and faces' flickering among frames. Deepfake can be misused to impersonate individuals, configure an opinion towards a public figure, and spread falsified news. Therefore, a deepfake detection method is needed to cope with the progress in the deepfake generation process and to distinguish the fakes in video frames, audio, and the whole video including video frames and audio.

This paper introduces a smart deepfake detection method that captures the manipulation in a video (multimodal by nature) on three levels; video frames, audio, and the whole video. It distinguishes whether a given video is a deepfake or not. Two proposed feature extraction methods are employed to extract features from video frames and audio modalities. The first method applied to the visual video frames modality is the XceptionNet with some newly introduced modifications. The Xception network achieved effective results in distinguishing the manipulated videos [7, 8]. The suggested modifications to the Xception network produce useful spatial information of the video frames and improve the deepfake detection method performance. The second method applied to the audio modality is a modified InceptionResNetV2 model based on the CQT method to produce deep time-frequency information of the audio segments and improve the detection method performance. The CQT is a time-frequency analysis method that produces higher time resolution at high-frequency areas and higher frequency resolution at low-frequency areas [9]. Its efficiency has been proven in music signal processing tasks [10], speaker verification systems [11], acoustic scenes and events detection and classification [12], anti-spoofing [13], synthetic speech detection [14, 15], and speech emotion recognition [9]. The corresponding features extracted from the two modalities are fused at a mid-layer to create a bimodal information-based feature representation for the whole video. Finally, the GRU-based attention mechanism is applied to these three levels of representation independently. This assists to learn instructive temporal information for each level and

\*Corresponding Author.

detect deepfake videos. The GRU performs well in tasks of sequence learning and overcomes the gradient vanishing and explosion problems of the standard recurrent neural network [16]. The proficiency of the attention mechanism has been proven in several areas including machine translations, image captioning, question answering, speech recognition [17], and event detection [18]. A comparative study with recent state-of-the-art deepfake detection methods is conducted in terms of accuracy, Area Under Receiver Operating Characteristic (AUROC) curve metric, precision, recall, F1-score, sensitivity, and specificity.

The rest of this work is organized as follows: Section II presents the literature review for deepfake video detection methods. Section III presents the newly proposed method for deepfake video detection. Section IV is dedicated to the experimental results and analysis. The conclusion and future work are presented in Section V.

## II. LITERATURE REVIEW

The progress of AI-based video and voice generation methods raised the ease of creating natural and highly realistic deepfakes that can never be distinguished. Since deepfakes violate security and pose a real threat to society, several researchers have directed their interest to create methods for detecting deepfakes. However, they concentrate on detecting the deepfakes either in video frames or audio modality.

Some of the existing deepfake visual video detection methods spot the manipulation by targeting specific spatial and temporal artifacts that are generated during the fake creation process. Some other detection methods are data-driven that do not target any specific artifacts and distinguish the manipulation by classification [3]. The deepfake visual video detection methods can be categorized into Convolution Neural Network (CNN)-based methods [19, 20, 21, 22], methods that are based on CNN with a temporal network [23, 24, 25, 26, 27], handcrafted feature-based methods [28], and handcrafted feature-based methods with deep networks [29, 30]. This is illustrated in Fig. 1.

The work of [19] detected the deepfakes by exploiting artifacts left by the generation methods when warping the target image to be consistent with the source video. It used four pre-trained CNN models for detecting fake contents; ResNet101, VGG16, ResNet50, and ResNet152. Since deepfake videos suffer from inconsistency among the inter-frames, Hu et al. [20] introduced two branches that are based on CNNs to capture those local and global inconsistencies and then detect deepfakes. Rana and Sung [21] proposed a deep ensemble learning method for detecting deepfake videos. Their method depended on combining several deep base-learners and then training a CNN on these learners to build an ameliorated classifier. In [22], a fine-tuned InceptionResNetV2 model followed by the XGBoost model was employed to capture discrepancies in the spatial domain of fake videos and then individuate deepfakes. The FakeApp creates forged videos that had intra-frame and temporal inconsistencies between frames.

Such inconsistencies were detected using InceptionV3 CNN and long short-term memory (LSTM) models [23]. As AI-generated fake videos lack normal eye blinking, Li et al. [24] introduced the VGG16-LSTM to capture the temporal regularities in the eye blinking process and then distinguish the deepfakes. Most deepfake videos are created frame-by-frame where each forged face is created independently. This causes incoherence in the temporal domain of the face region; discontinuity and flickering. As a result, Zheng et al. [25] introduced a fully temporal convolution network that aimed to learn the temporal discrepancies while removing spatial ones. Then, a temporal transformer encoder followed by a multi-layer perceptron was employed to learn the long-range inconsistencies along the time dimension, and then distinguish the deepfakes. In [26], a 2D CNN-based Spatio-temporal learning model was introduced to learn and capture spatial and temporal inconsistencies of forged videos. This temporal inconsistency was captured from both vertical and horizontal directions over adjacent frames and helped in detecting the fakes. The work of [27] introduced a fine-tuned EfficientNet-b5 model followed by the bidirectional LSTM model and densely connected layer. It aimed to discover the Spatio-temporal inconsistencies in deepfake videos and then distinguish the authenticity of videos. Deepfakes were created by joining the generated face into the source image. This produced errors in facial landmark locations that were detected by estimating the 3D head poses for real and deepfake videos. Then, the estimated difference of head poses was fed into the Support Vector Machine (SVM) for deepfake detection [28]. Khalil et al. [29] proposed a model that employed the local binary patterns descriptor to analyze the texture of real and fake videos. Additionally, a CNN-based enhanced high-resolution network was used to automatically capture informative multi-resolution representations of these videos. Then, the output of both was fed into the capsule network to individuate deepfakes. Ismail et al. [30] introduced a hybrid method in which two feature extraction methods were employed to learn and extract enrich spatial features from the detected face frames of video. These methods were a CNN that was based on the Histogram of Oriented Gradient (HOG) method and the improved XceptionNet. Their outputs were merged to be fed into GRUs sequence to extract the spatiotemporal features and detect the fake videos.

The deepfake audio detection methods can be categorized into handcrafted feature-based methods [31, 32], methods that are based on low-level features with CNN [14, 33, 34, 35], methods that rely on using low-level features with CNN and temporal network [37, 38], and end-to-end deep networks-based methods [39]. This is presented in Fig. 2.

The work of [31] extracted several low-level-features; Constant-Q Cepstral Coefficients (CQCC), Cepstrum, Mel-Frequency Cepstrum Coefficients (MFCC), inverted MFCC, Linear Predictive Cepstral Coefficients (LPCC), and LPCC-residual features. These features were utilized along with the Gaussian Mixture Model (GMM) to detect the forged audio.

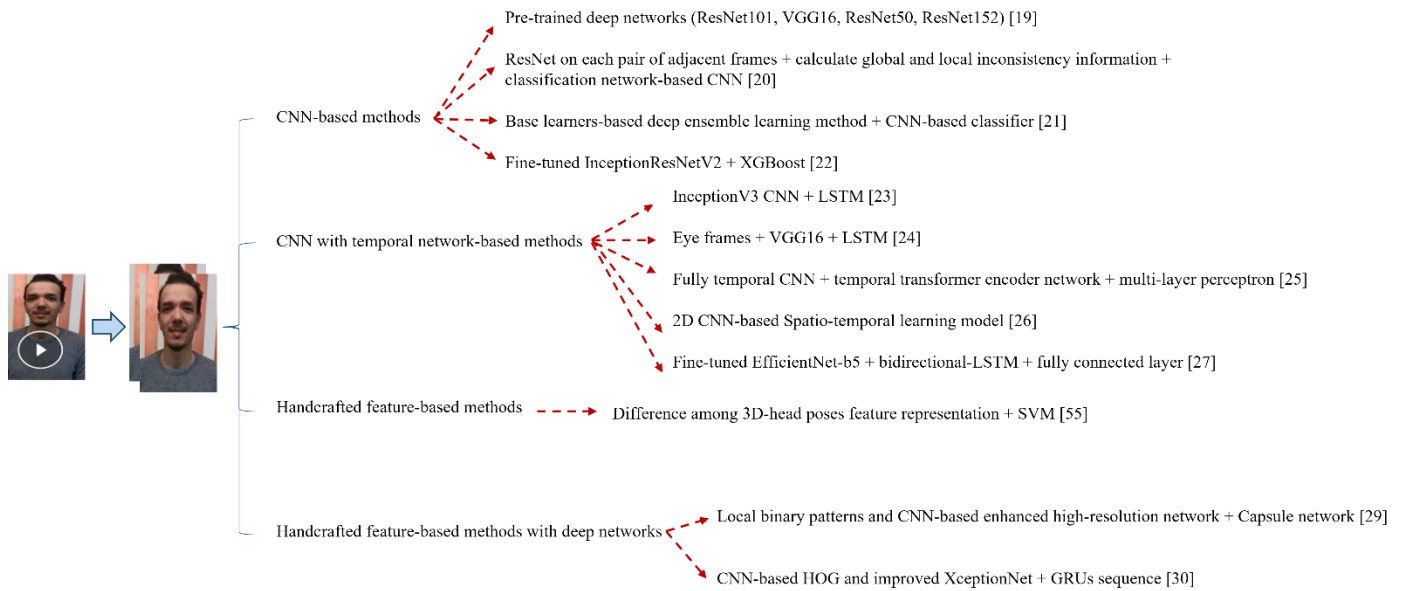

Fig. 1. The deepfake visual video detection methods categorization.

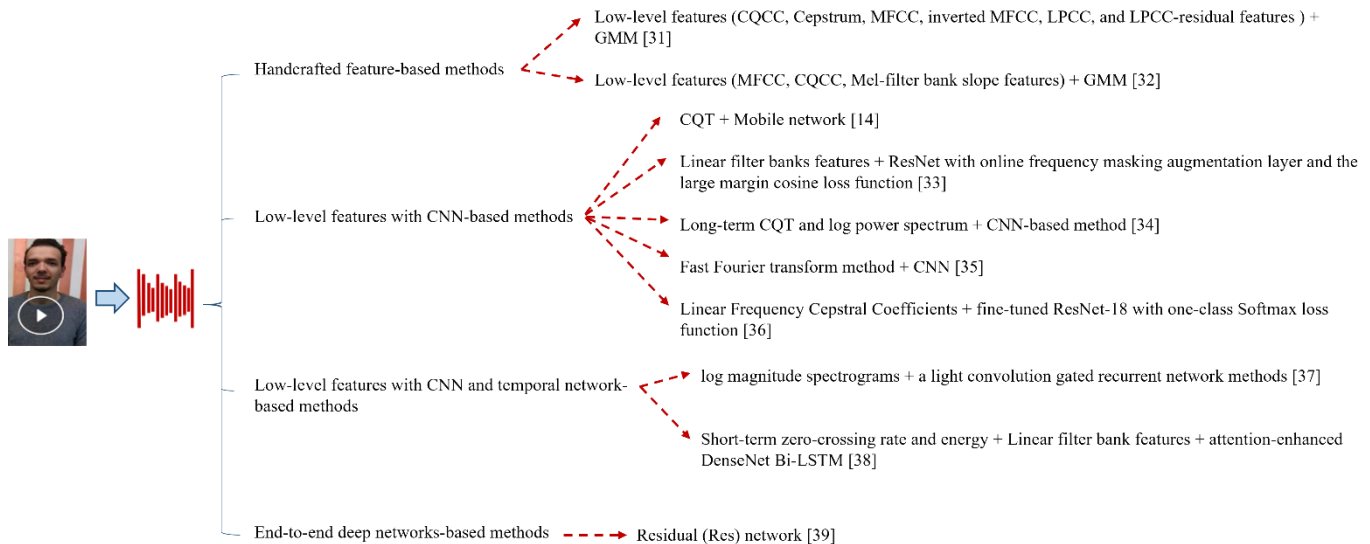

Fig. 2. The deepfake audio detection methods categorization.

In [32], MFCC, CQCC, and Mel-filter bank slope features were employed to train the GMM to capture the vocal tract information and then distinguish the fake audio. Reimao [14] employed the CQT method to convert the audio signals into visual audio representations. These produced representations were fed into the Mobile network model to detect the synthetic speech. The linear filter banks' low-level features were extracted from audios. Then, these features were fed into the ResNet model to produce deep feature representations and detect audio manipulation. In addition, the online frequency masking augmentation layer and the large margin cosine loss function were employed during training the Residual network to learn more robust key feature embeddings [33]. WU et al. [34] employed the long-term CQT and log power spectrum to

extract audios representation. This representation was used as an input to the feature genuinization method. This method learned a transformer with a CNN which was based on genuine speech characteristics. It aimed to maximize the difference between the distribution of genuine and synthetic speeches. Then, the transformed features were utilized with a light CNN model to detect the synthetic speech. In [35], the audio signals were converted into spectrogram images using the Fast Fourier transform method. These images were fed as an input into a CNN to validate audio signal authenticity. The work of [36] utilized Linear Frequency Cepstral Coefficients to convert raw audios into feature vector representations. Then, these representations were fed to a fine-tuned ResNet-18. In addition, a one-class Softmax loss function was proposed to

learn an embedding feature space in which the genuine speech had a compact boundary while the fake data was isolated from the genuine one by a certain margin. In [37], the log magnitude spectrograms were extracted from audio files. Then, a light convolution gated recurrent network was employed on these spectrograms to produce deep features and discriminate the real speech from the spoofed one. The work of [38] employed the short-term zero-crossing rate and energy to select the silent segments from each speech signal. Then, the linear filter bank features were extracted and fed into an attention-enhanced DenseNet Bi-LSTM model to identify audio manipulations. In [39], an end-to-end model which is based on the Residual network was proposed to extract deep features of audio data and then detect the synthetic speech.

Some researchers introduced approaches based on learning from different modalities to detect deepfakes. These approaches, which are often known as deepfake multimodal-video detection methods, can be categorized into CNN-based methods [40, 41, 42, 43], and methods that are based on using CNN and temporal network [44, 45]. This is depicted in Fig. 3.

The work of [40] exploited the perceived emotion cues from speech and face modalities to detect any manipulation in a video. It employed the OpenFace-V1 technique to extract the facial features and the PyAudioAnalysis library to extract the MFCC speech features. Then, the Siamese network-based architecture and the triplet loss were utilized to model the similarity between both modalities within a video and distinguish the fake content. Since any modification of visual video frames or audio modality within a video lead to a loss of lip synchronization, and abnormal lip and facial movements, a multimodal video deepfake detection method was introduced [41]. This method was based on computing the dissimilarity score between visual video and auditory segments. The 3D-Residual network-based architecture was used for extracting visual video features from face segments, and the raw audio segments were converted into MFCC features and then fed into CNN. The contrastive loss was estimated over audio and visual video features for each segment, which forced the real representation of both modalities to be closer than the manipulated one. Additionally, the cross-entropy loss was applied on every single modality to confirm that each one independently learns informative features. The work of [42] presented a multimodal video deepfake detection method based on discovering the defects in manipulated mouth areas via employing genuine audio as a reference. The audios were aligned and clipped into partitions based on phonemes, and Mel-scale spectrograms were extracted and used as audio features. The mouth frames were extracted from videos based on facial landmarks using the `dlib` python library. Then, each mouth frame with a particular phoneme interval was matched to a fixed-length audio partition to produce auditory-visual video pairs. After that a CNN architecture was trained on these pairs to capture the synchronization degree between lip movements and speech by measuring the similarity score of

auditory-visual video pairs. Zhou and Lim [43] employed the asynchrony property between fake visual video, especially mouth movements, and speech to detect any modification within a video. The Multi-Task CNN (MTCNN) was utilized for detecting the face from video frames and the Residual (2+1)D-18 network was applied for extracting visual feature representations of these frames. For audio, a simple 1D convolution network was utilized for extracting 1D waveform signal feature representation. In addition, a sync-stream was built by applying central connections to visual video and audio network feature representations between low-level features; spatial and temporal information, to higher-level semantic representations. At each layer, the representations of visual video and auditory modalities were fused with the current layer of sync-stream. The output of this was utilized as an input to the fusion at the next layer. This helped in modelling the synchronization patterns of both modalities and distinguishing the deepfakes. Based on the observation that machines cannot recreate human emotions naturally in manipulated videos, Gino [44] introduced a deepfake detection method depending on exploiting emotion features from visual video and audio modalities. The low-level descriptors (LLDs) were extracted from raw audio segments using the OpenSmile toolkit and passed to the LSTM architecture to extract emotional features of speech. In addition, the face frames were detected from videos using the BlazeFace tool and then passed into 3D-CNN architecture to extract visual emotional features. After that, two approaches were followed in the final deepfake detection phase. In the first one, the visual and auditory emotional features were combined horizontally. Then, these features were fed either into the LSTM network or into Lazypredict models. In the second, the average between the prediction scores returned by training the LSTM and Lazypredict models on the visual video and auditory modalities separately was computed. The work of [45] detected the fake content in videos by extracting visual video and auditory emotional features and passing them to a deep network. The OpenFace-V2 toolkit was employed for extracting 31 visual features related to the intensity of facial muscle actions, eye gaze, and head position. The `python_speech_features` library was used to extract 13 MFCC features and their respective derivatives; delta MFCC, and delta-delta MFCC, as audio features. The visual video and auditory features were normalized and concatenated to be passed into CNN blocks that were followed by two Bi-LSTM networks and dense layers for deepfake detection.

A few deepfake detection methods are concerned with multimodal videos. However, they do not consider whether a video is manipulated only on the visual video frames level, audio level, or bimodal level which combines visual frames and audio. Consequently, this paper introduces a novel smart deepfake video detection system that can check whether the manipulation is just applied to video frames, audio, or both. It then produces the final decision for detecting the deepfakes on these three levels: visual frames, audio, and the whole video.

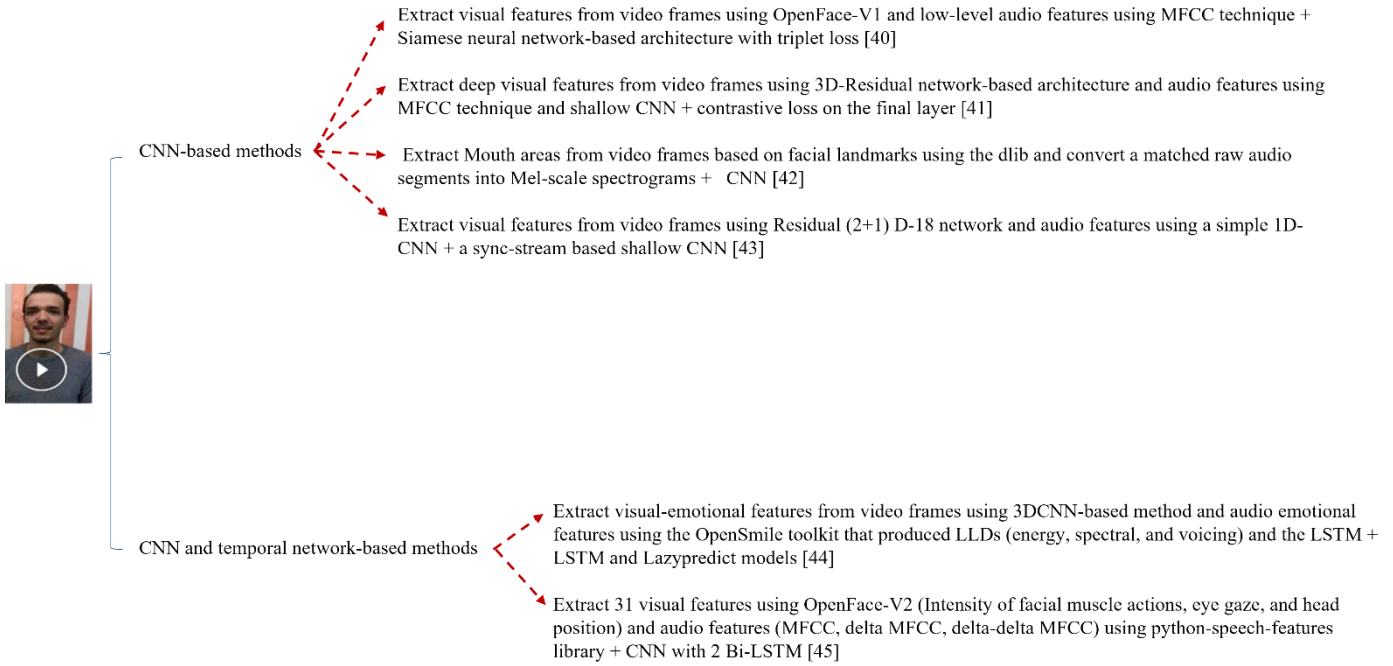

Fig. 3. The deepfake multimodal-video detection methods categorization.

### III. PROPOSED METHOD

The suggested deepfake video detection method consists of three base stages: pre-processing, feature extraction using unimodal and bimodal information, and classification. These stages are shown in Fig. 4 and each one will be described hereafter.

#### A. Pre-processing

The visual video and audio modalities are pre-processed individually. The face frames are extracted from videos and saved separately. They are rescaled to the size  $224 \times 224$ , and their pixel values are normalized into  $[-1,1]$ . These pre-processed face frames will become an input to the next stage for learning and extracting deep visual video features. The raw audio files are extracted from videos and stored separately in a wave format. Then, the audio files are segmented. The CQT method is applied to every audio segment to produce a time-frequency representation of these segments. The CQT method is used for transforming audio signals from the time domain to the time-frequency domain. In CQT, frequency bins are geometrically spaced and ratios between centre frequencies and bandwidths, which are called Q-factors, of all bins are equal [47, 12]. The CQT of a discrete audio signal  $x(n)$  in the time domain is computed by the following formula [10, 46, 47, 48]:

$$X(m, n) = \sum_{k=n-\lfloor N_m/2 \rfloor}^{n+\lfloor N_m/2 \rfloor} x(k) a_m^* \left( k - n + \frac{N_m}{2} \right) \quad (1)$$

where  $m = 1, 2, \dots, M$  represents the  $m^{\text{th}}$  index of frequency bin,  $\lfloor \cdot \rfloor$  denotes the floor function, and  $x(k)$  represents the  $k^{\text{th}}$  sample of a speech time-domain frame. The symbol  $N_m = \frac{f_{sr}}{f_m} Q \in \mathbb{R}$  indicates window lengths,  $f_{sr}$  represents the sampling rate frequency, and  $f_m = f_1 2^{\frac{m-1}{b}}$

indicates the centre frequency of the  $m^{\text{th}}$  bin. The symbol  $f_1$  denotes the centre frequency of the lowest bin,  $b$  refers to the bins number per octave and practically it determines a trade-off between time and frequency resolution. The factor  $Q = \frac{f_m}{f_{m+1} - f_m} = \frac{1}{2^{\frac{1}{b}} - 1}$  produces a constant frequency to resolution ratio for each bin. The term  $a_m^*(n)$  represents the complex conjugate of the complex-valued time-frequency atoms  $a_m(n)$  which is defined as follows:

$$a_m(n) = \frac{1}{C} \omega \left( \frac{n}{N_m} \right) e^{i(2\pi n \frac{f_m}{f_{sr}} + \Phi_m)} \quad (2)$$

where  $\omega(t)$  denotes a window function; Hann (Wang et al. 2019) [49], which is sampled at points specified by  $\frac{n}{N_m}$ . It is zero when  $t$  does not belong to  $[0,1]$ . The  $C = \sum_{l=-\lfloor N_m/2 \rfloor}^{\lfloor N_m/2 \rfloor} \omega \left( \frac{l + N_m/2}{N_m} \right)$  represents a scaling factor, and  $\Phi_m$  represents a phase offset.

The CQT computations are implemented using the librosa python library. The audio files are resampled to 22,050 Hz. A frequency bins number of 84 with 12 bins per octave, a hop length of 128 samples, and a minimum frequency value of approximately 65 Hz are used during the CQT calculations. In addition, the Hann window function is applied. The output of the CQT is then transformed into a log scale; decibels, to cope with the wide range of sound intensity. This produces a decibel-scaled spectrogram that has the shape  $T \times 84$  per audio segment where  $T$  relies on the audio file duration. The duration of audio files adopted here is three seconds and accordingly,  $T$  is equal to 65. The spectrograms are normalized into the range  $[-1,1]$  and then reshaped to  $(65,84,1)$  as three-channel images. They will become an input to the next stage to learn and extract deep auditory features.

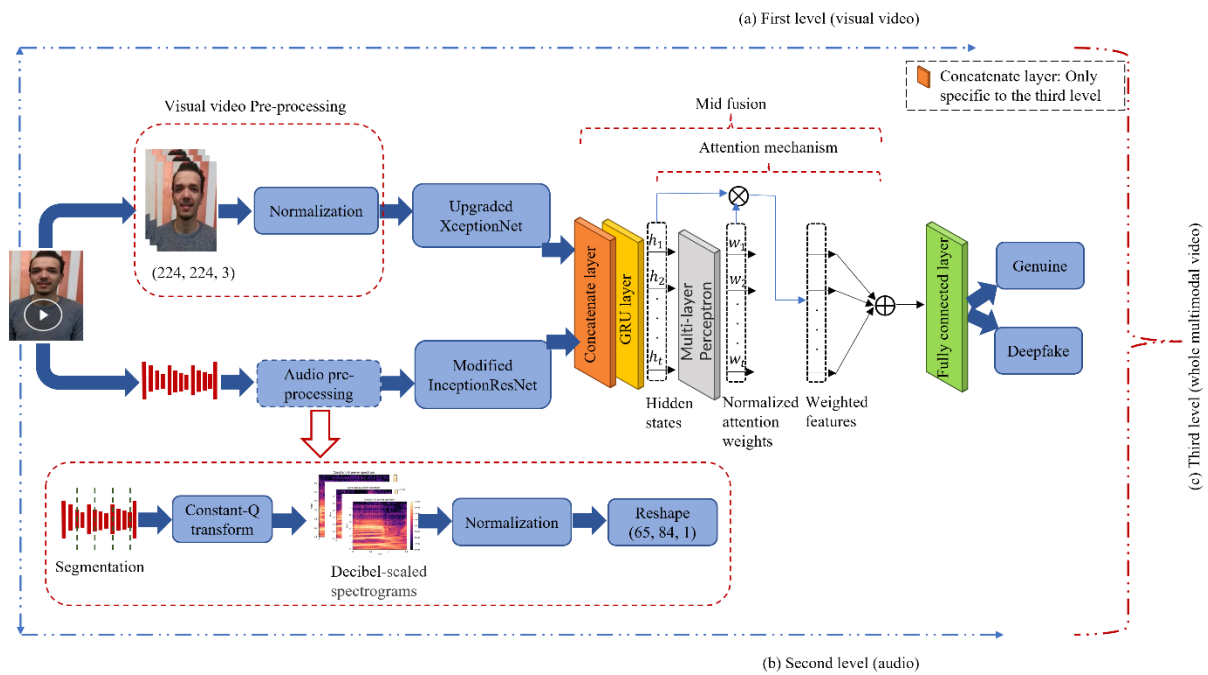

Fig. 4. The proposed smart deepfake video detection system architecture.

### B. Feature Extraction using Unimodal and Bimodal Information

In this stage, the problem of deepfake detection is handled based on proposing two feature extraction methods for visual video and audio modalities. An upgraded XceptionNet is suggested to extract instructive deep spatial features from pre-processed face frames of videos. It outputs a visual feature representation of the unimodality; video frames. A modified InceptionResNetV2 is suggested to apply on the CQT spectrograms representing audio files to extract deep time-frequency features from audios. It produces a feature representation of the unimodality; audio. Then, the corresponding extracted feature representations from these modalities are first fused. This outputs a feature vector representation of the whole video using bimodal information. After that, these various resultant representations are independently passed into the GRU-based attention mechanism. This helps to learn the significant temporal information from the sequential feature representation per video on three levels: visual video frames, audio, or the whole video. Finally, a fully connected layer is applied to produce the final prediction about video authenticity. These components are explained in detail in the following subsections.

1) *Visual video frames features:* The processed face frames of videos with the shape  $(h \times w \times 3)$  are received as an input to the proposed upgraded Xception network where  $h=224$ ,  $w=224$ , and 3 denote the height, width, and RGB channels per frame. The Xception original architecture consists of 36 convolutional layers divided into 14 modules. All modules have shortcut residual connections around them except for the first and last ones. The Xception comprises depth-wise separable convolution layers, which reduce the cost of convolution operation dramatically [50, 51]. The proposed

upgraded Xception network architecture is depicted in Fig. 5. The original XceptionNet is upgraded by first injecting seven layers before the last rectified linear unit (ReLU) activation layer of the last module. These seven layers are convolution with 1536 filters, batch normalization, ReLU activation, convolution with 1024 filters, batch normalization, ReLU activation, convolution with 1024 filters, and batch normalization. The convolution layers produce more informative and exclusive feature maps that help to differentiate between real and fake visual videos. The batch normalization layers, which standardize the input, have the effect of drastically speeding up the training and improving the model's performance by providing a modest regularization. The ReLU activation layers, which give a value of zero for all negative input feature values, add a nonlinear property to the model allowing it to understand and learn complex structures in data. Then, the dropout layer that randomly drops out units with a rate of 0.2 is injected between the last ReLU activation and the global average pooling layers to prevent overfitting and boost the model's generalization. After that two layers are injected after the global average pooling layer; the fully connected layer with 1024 units and ReLU activation function, and the dropout layer with a rate of 0.5. After applying the upgraded XceptionNet to the face frames of videos, the output becomes a vector representation of 1024 features per frame. The suggested modifications to the Xception network attempt to generate an instructive spatial hierarchical representation of frames. This helps to improve the deepfake detection method performance in real-world circumstances; number equations consecutively.

2) *Audio features:* The CQT spectrograms of audio files with the shape  $(65, 84, 1)$  per segment are received as an input

to the proposed modified InceptionResNetV2. The InceptionResNetV2 original architecture is built by joining the inception blocks and the skip connections. Each InceptionResNet block contains convolutions of different-sized filters that are combined by skip connections. These skip connections prevent the degradation problem that occurred via deep structures and reduce the time of training [52].

The proposed modified InceptionResNetV2 architecture is depicted in Fig. 6. The original InceptionResNetV2 is modified first by decreasing the repeating times' number of Inception ResNet blocks; A, B, and C, from 5, 10, and 5 to 4, 7, and 3, respectively. Then, some layers are injected after the last InceptionResNet block C and before the global average pooling layer. These layers are convolution with 512 filters on

a kernel size of  $1 \times 1$ , batch normalization, ReLU activation, a couple of convolutions with 1024 filters on a kernel size of  $1 \times 1$  where each one is followed by batch normalization and ReLU activation, and a dropout with a rate of 0.2. After that a fully connected layer with 1024 units and ReLU activation function is injected between global average pooling and dropout layers. In addition, filter units, kernel size, and stride for some layers are altered as shown in Fig. 6. After applying the modified InceptionResNetV2 to audio files segments, the output becomes a vector representation of 1024 auditory features per segment. The proposed modifications to the InceptionResNetV2 aim to generate an informative deep time-frequency representation of audio segments. This aids to enhance the performance of the proposed deepfake detection method.

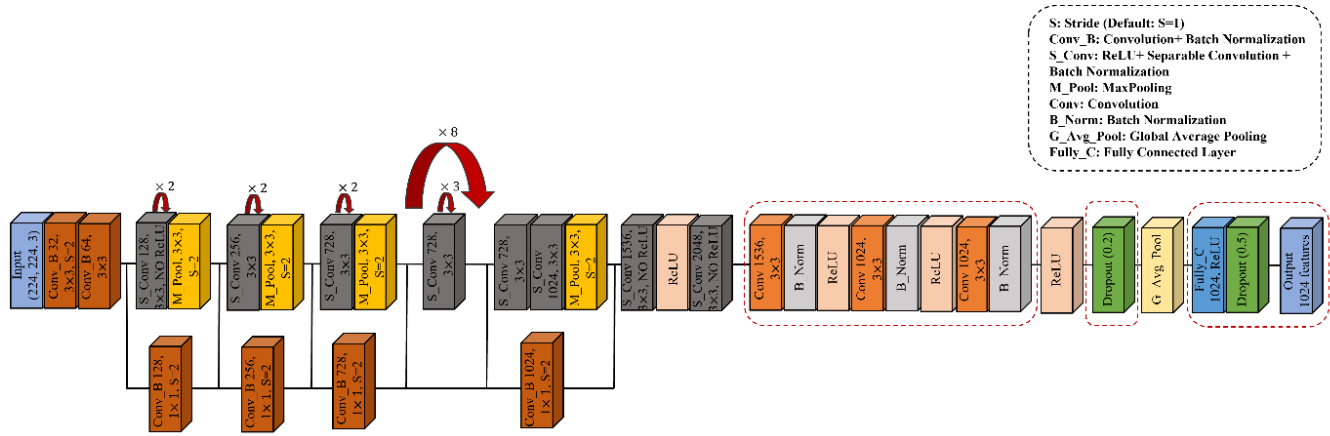

Fig. 5. The proposed upgraded xception network architecture.

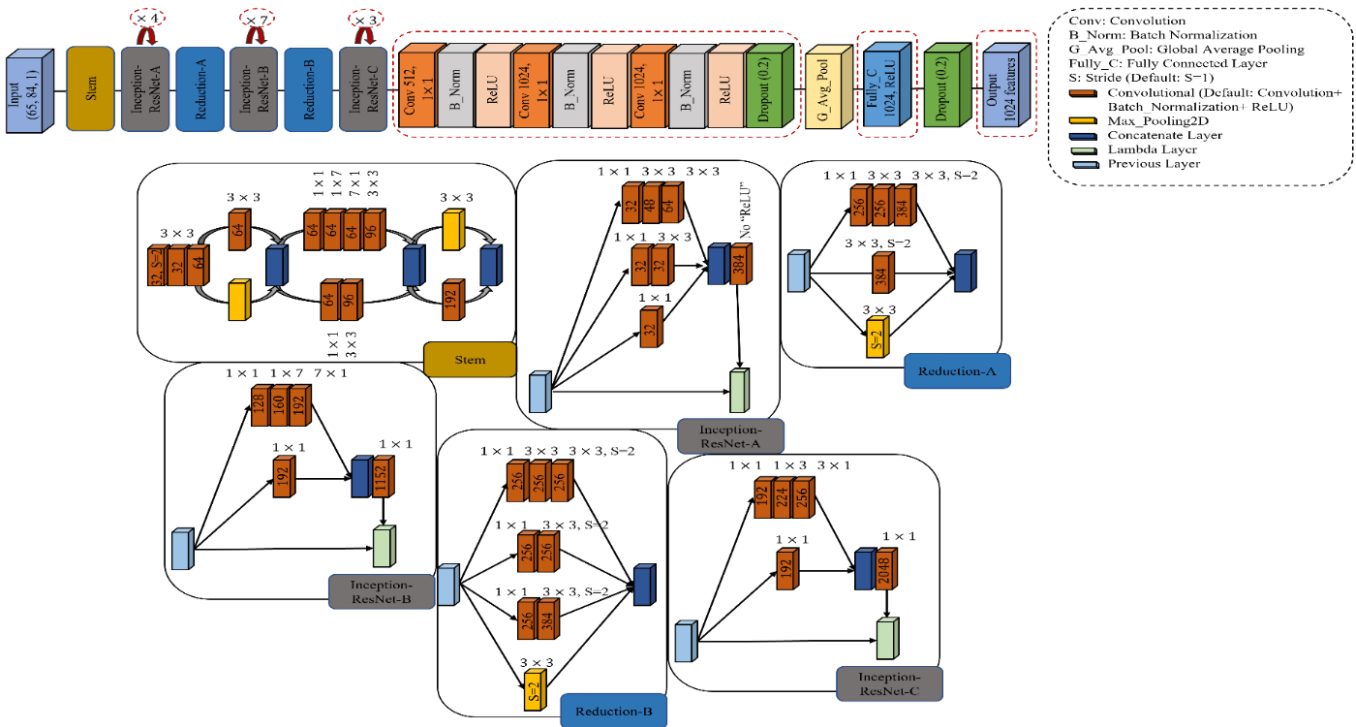

Fig. 6. The proposed modified inceptionResNetV2 architecture.

3) *Bimodal information-based video features*: The deep extracted features from visual video frames and audio modalities using the above-mentioned unimodality-based feature extraction methods are mid-fused at a concatenate layer. This produces a feature vector representation for the whole video, which is based on bimodal information.

4) *Temporal information extraction-based attention mechanism*: Most deepfake videos are generated based on synthesizing faces frame-by-frame, cloning voices, and synchronizing lips. They suffer from flickering and discontinuity of the face frames and lack of normal emotions, breathing, pauses, and the pace at which the target subject speaks among audio segments. As a result, the GRU-based attention mechanism is applied to the three levels of the extracted features independently; visual video frames, audio, and the whole video. This aims to capture the instructive temporal information that helps to differentiate real videos from fake ones.

The GRU architecture is composed of two gates; update (upd) and reset (res), that modulate the information flow from the previous time step to the current step. At each time step  $t$ , the update gate decides the amount of previous information that should be retained, and the reset gate determines the amount of information that needs to be forgotten [53]. The GRU hidden state  $h$  at the time  $t$  is defined by the following formulae [54]:

$$\text{upd}_t = S(W_{\text{upd}}x_t + U_{\text{upd}}h_{t-1}) \quad (3)$$

$$\text{res}_t = S(W_{\text{res}}x_t + U_{\text{res}}h_{t-1}) \quad (4)$$

$$\hat{h}_t = \tanh(W_h x_t + \text{res}_t \circ U_h h_{t-1}) \quad (5)$$

$$h_t = (1 - \text{upd}_t) \circ \hat{h}_t + \text{upd}_t \circ h_{t-1} \quad (6)$$

where  $x$  refers to the input, and  $W$  and  $U$  represent the weight matrices. The symbol  $S(\cdot)$  represents the sigmoid function,  $\tanh(\cdot)$  represents the Hyperbolic Tangent,  $\circ$  denotes the Hadamard product, and  $\hat{h}_t$  denotes the candidate hidden state. As can be seen in Fig. 4, a single GRU is applied to the above-mentioned feature representations on the three levels. It produced a matrix of hidden state vectors at each time step  $t$ , which represents the learned temporal information per visual video, audio, or the whole video. The hidden state vector is defined as follows:

$$H = [h_1, h_2, \dots, h_t] \quad (7)$$

The attention mechanism uses the weights to concentrate on the important features from the input sequence  $H$ . It is defined by the following equations [17, 55]:

$$u_t = \tanh(W_h x_t + b) \quad (8)$$

$$\alpha_t = \text{softmax}(u_t) \quad (9)$$

$$c_t = \alpha_t h_t \quad (10)$$

$$v = \sum_t c_t \quad (11)$$

where  $u_t$  is a result of feeding a hidden vector  $h_t$  into a single-layer Multi-Layer Perceptron (MLP) with the tanh

activation function.  $W$  represents the weight matrix, and  $b$  refers to the bias term. The symbol  $\alpha_t$  represents the normalized attention weights that are produced by applying the softmax layer to  $u_t$ .  $v$  is a video representation that is formed by summing hidden vectors  $h_t$  weighted by attention weights  $\alpha_t$ .

### C. Classification

After the instructive temporal features are produced from the GRU-based attention mechanism, a fully connected layer is used as an output layer with two classes. Softmax function is used to decide deepfake videos from real ones. The Softmax formula is defined as follows:

$$\text{Softmax}(y_i) = \frac{e^{y_i}}{\sum_j e^{y_j}} \quad (12)$$

where  $y_i$  denotes the values resulting from the output layer neurons.

### D. Dataset

The proposed method has been evaluated on the FakeAVCeleb multimodal videos dataset. This dataset consisted of 490 celebrity genuine videos that were selected from the VoxCeleb2 dataset based on various ethnic groups, gender, and age. Its genuine videos are face-centered and cropped. The fake videos of the FakeAVCeleb dataset were generated using DeepFaceLab, Faceswap, and FSGAN, while fake audios were generated using a real-time voice cloning tool (SV2TTS). Additionally, the Wav2Lip was applied to the deepfake videos to re-enact these videos based on the cloned audios. Thus, the FakeAVCeleb dataset had more realistic deepfakes. The FakeAVCeleb was divided into four groups; genuine visual videos with genuine audios, genuine visual videos with deepfake audios, deepfake visual videos with genuine audios, and deepfake visual videos with deepfake audios [4].

To evaluate the proposed method, 1215 genuine and deepfake videos of the FakeAVCeleb dataset are employed. These videos are divided into three subsets: training, validation, and testing.

## IV. EXPERIMENTAL RESULTS AND ANALYSIS

The proposed deepfake video detection method is evaluated by the FakeAVCeleb dataset. Its performance is assessed using the following evaluation metrics [56]:

$$\text{precision} = \frac{\text{True\_Positives}}{\text{True\_Positives} + \text{False\_Positives}} \quad (13)$$

$$\text{sensitivity} = \text{recall} = \frac{\text{True\_Positives}}{\text{True\_Positives} + \text{False\_Negatives}} \quad (14)$$

$$F_1 - \text{score} = \frac{2 \times \text{precision} \times \text{recall}}{\text{precision} + \text{recall}} \quad (15)$$

$$\text{accuracy} = \frac{\text{True\_Positives} + \text{True\_Negatives}}{\text{True\_Positives} + \text{True\_Negatives} + \text{False\_Negatives} + \text{False\_Positives}} \quad (16)$$

$$\text{specificity} = \frac{\text{True\_Negatives}}{\text{True\_Negatives} + \text{False\_Positives}} \quad (17)$$

$$\text{AUROC} = \int_0^1 \text{sensitivity}((1 - \text{Specificity})^{-1}(x)) dx = p(x_2 > x_1) \quad (18)$$

where True\_Positives denotes deepfake samples' number that is correctly predicted. The False\_Positives represents genuine samples' number that is incorrectly predicted. The False\_Negatives denotes deepfake samples' number that is incorrectly predicted. The True\_Negatives refers to genuine samples' number that is correctly predicted. The symbol  $x_2$  represents the predicted deepfake samples and  $x_1$  denotes the predicted genuine samples. The higher the AUROC curve metric, the better the fake video detection method's performance at individuating the deepfake videos from the genuine ones.

The following three experiments are applied to the FakeAVCeleb dataset:

Experiment 1: This experiment represents applying the proposed method to the FakeAVCeleb videos dataset for two levels; visual video frames and audio. The visual video frames and audio modalities are trained end-to-end separately. Thus, a single GRU-based attention mechanism with 1024 units is independently applied to the visual video features that are extracted using the proposed upgraded XceptionNet and the audio features that are extracted using the proposed CQT based modified InceptionResNetV2. This learns the instructive temporal features for each unimodality. The visual video modality is trained for 32 epochs using the stochastic gradient descent (SGD) optimizer [57] with a learning rate of  $2e^{-3}$  which is decayed by  $4e^{-10}$ , and a momentum of 0.9. The audio modality is trained for 27 epochs using the adaptive moment (Adam) optimizer [58] with a learning rate of  $e^{-3}$ . The batch size is 32. Then, the predictions are produced per modality. The performance of visual video and audio on the FakeAVCeleb dataset is shown in Table I and Table II, respectively. The proposed upgraded XceptionNet with a single GRU-based attention mechanism for the visual video modality has achieved 98.51% accuracy and 98.45% AUROC outperforming recent state-of-the-art methods by a large margin. Additionally, the proposed CQT based modified

InceptionResNetV2 with a single GRU-based attention mechanism for the audio modality has achieved 97.52% accuracy and 97.62% AUROC outstanding other state-of-the-art methods by a large margin.

Experiment 2: In this experiment, the prediction results of visual video frames and audio modalities from experiment 1 are employed to produce the prediction for the whole video. Thus, the whole multimodal-video prediction is decided to be genuine if both modalities are predicted as genuine, otherwise, it's deepfake. Experiment 2 performance for multimodal video deepfake detection is recorded in Table III. It has yielded 96.04% accuracy and 95.49% AUROC.

Experiment 3: This experiment represents applying the proposed method to the FakeAVCeleb videos dataset for the third level; whole multimodal video. As the FakeAVCeleb dataset is distributed into four groups: genuine visual videos and audios, genuine visual videos with fake audios, fake visual videos with genuine audios, fake visual videos and audios, the whole video label ( $y_i$ ) is considered genuine if the label of both visual video ( $y_{iv}$ ) and audio ( $y_{ia}$ ) modalities are genuine, otherwise, it's fake. This can be defined as follows:

$$y_i = \begin{cases} 0, & \text{if } y_{iv} = y_{ia} = 0 \\ 1, & \text{otherwise} \end{cases} \quad (19)$$

The single GRU-based attention mechanism with 3572 units is applied to the bimodal information-based video features. This helps to learn the instructive temporal features for the whole multimodal video. The details of GRU-based attention mechanism layers that are applied on top of bimodal information-based video features are described in Table IV. The proposed method is trained for 24 epochs using the SGD optimizer with a learning rate of  $2e^{-3}$  and a decay factor of  $4e^{-10}$ , and a momentum of 0.9. This is employed to update the weight parameters and is aimed to minimize the difference between actual and predicted labels. The batch size is set to 64.

TABLE I. THE PERFORMANCE OF THE UPGRADED XCEPTIONNET METHOD WITH SINGLE GRU-BASED ATTENTION MECHANISM FOR DETECTING THE DEEPFAKE VISUAL VIDEO UNIMODALITY COMPARED TO RECENT STATE-OF-THE-ART METHODS ON THE FAKEAVCELEB DATASET

Model	Unimodality	
	Visual video	
	Accuracy	AUCROC
Experiment 1 (The proposed upgraded XceptionNet with GRU-based attention mechanism for the first level)	98.51%	98.45%
VGG16 [60]	81.03%	81.04%

TABLE IV. THE GRU-BASED ATTENTION MECHANISM LAYERS DETAILS

Layer (type)	Output shape	Parameters number
main_input (Input Layer)	[(None, 8, 4096)]	0
gru (GRU)	(None, 8, 3572)	82191720
attention (attention)	(None, 3572)	3580
Total parameters: 82,195,300 Trainable parameters: 82,202,446 Non-trainable parameters: 0		

The cross-entropy loss (l) function is utilized to measure the efficiency of the suggested deepfake video detection method on three levels: video frames, audio, and the whole video. Its formula [59] is defined as follows:

$$l = -\frac{1}{M} \sum_{k=1}^M (y_k \log(p_k) + (1 - y_k) \log(1 - p_k)) \quad (20)$$

where M refers to the number of visual videos, audios, or whole videos. The  $y_k$  and  $p_k$  denote the actual label and predicted probability corresponding to the  $k^{\text{th}}$  video. It can be seen in Table III that the proposed method, which represents experiment 3, for whole multimodal video deepfake detection has achieved 97.52% accuracy and 97.21% AUROC. Its performance exceeds that of experiment 2 because experiment 2 is unable to learn intercorrelations between different modalities. Additionally, it outperforms recent state-of-the-art methods by an average growth of 34.4% accuracy and 34.2% AUROC as can be seen in Table III.

The experiments are carried out using an OMEN HP laptop with a 16-gigabyte Intel (R) Core (TM) i7-9750H CPU, a 6-gigabyte RTX 2060 GPU, and Windows 11. The proposed method is implemented using the Python programming language. Python libraries such as Keras, OpenCV, Random, Tensorflow, Numpy, OS, and Librosa are used during the implementation.

The accuracy and loss curves of the proposed method on the training and validation subsets of the FakeAVCeleb dataset for the three levels; visual video frames, audio, and whole multimodal videos, are shown in Fig. 7. Additionally, the proposed method confusion matrix for deepfake video detection on the three levels is depicted in Fig. 8. Furthermore, Fig. 9 shows the receiver operating characteristic (ROC) curve

and the AUROC curve of the proposed method performance. As shown in Fig. 9, the ROC curve is extremely close to the top left ensuring the high performance of the proposed method.

Fig. 10 provides a comparison of the proposed method with contemporary state-of-the-art methods using evaluation metrics. As shown in Fig. 10, the proposed method has yielded better performance in comparison to the other methods on the three levels. It has a precision of 96.91%, recall of 100%, F1-score of 98.43%, and specificity of 97.22% for detecting visual videos. Additionally, it has a precision of 100%, recall of 95.10%, F1-score of 97.49%, and specificity of 100% for detecting audios. Further, it has a precision of 98.43%, recall of 97.66%, F1-score of 98.04%, and specificity of 97.30% for detecting whole multimodal videos.

It can be concluded that the proposed upgraded XceptionNet generated a useful spatial hierarchical representation of faces, which contributed to distinguishing between genuine and fake videos. As well, the proposed CQT-based modified InceptionResNetV2 produced a valuable deep time-frequency representation of audio. This assisted to reveal deepfake videos and improved the detection method's effectiveness. Moreover, a concatenate layer that is applied to the features extracted from visual video and audio modalities produced an informative bimodal representation of videos. In addition, the GRU-based attention mechanism, which is applied to the visual video, audio, and bimodal features, assisted in capturing the most important temporal information of videos. This in turn helped to detect the deepfakes. Furthermore, it can be inferred that correlating features from different modalities can improve the chances of achieving accurate deepfake video detection.

## V. CONCLUSION AND FUTURE WORK

A newly smart system for detecting video deepfakes has been presented. Two methods were proposed to extract features from visual video frames and audio modalities, respectively. These methods produced useful spatial information for visual video and valuable time-frequency information for audio, which improved the performance of the deepfake detection

method. In addition, the feature representations of both modalities were passed into a mid-layer to produce an informative bimodal representation per video. It proved that using bimodal information boosts learning during training compared to the method that ignores intercorrelation between modalities. The GRU-based attention mechanism was then applied to the different feature representations to extract the most significant temporal information and detect the

deepfakes. The proposed method has been evaluated on the FakeAVCeleb multimodal videos dataset. It achieved 98.51% accuracy, 98.45% AUROC, 96.91% precision, 100% recall, 98.43% F1-score, and 100% sensitivity on the first level; visual videos. Additionally, it yielded 97.52% accuracy, 97.62% AUROC, 100% precision, 95.10% recall, 97.49% F1-score, and 95.10% sensitivity on the second level; audios. Moreover, it attained 97.52% accuracy, 97.21% AUROC, 98.43% precision, 97.66% recall, 98.04% F1-score, 97.66% sensitivity, and 97.30% specificity on the third level; whole multimodal videos. Consequently, the proposed method outperformed the current state-of-the-art methods by a large margin.
